NOTES OF SOME OBSERVATIONS ON NITRIFICATION.*

BY EDMUND W. DAVY, A.M., M.D., M.R.I.A.
Professor of Forensic Medicine, in the Royal College of Surgeons, Ireland.

A good deal of attention on the part of chemists has of late been given to the subject of nitrification, or the formation of nitrites and nitrates under different circumstances. This has arisen, in a great measure, from the observations of MM. Schlœsing and Müntz,† which were laid before the Academy of France about two years ago. From the researches of those gentlemen, they arrived at the conclusion, that nitrification was due to an organized ferment, and that it was probably the office of some of the low forms of vegetable life, to produce those oxides of nitrogen under different circumstances. And the subsequent investigations of Warrington, Storer and of other chemists, would appear to go far to confirm the correctness of their theory of nitrification, at least, under the conditions in which their experiments were made.

Though there exists, no doubt in many cases, an intimate relation between the formation of nitrites and nitrates, and the development of certain organized germs, still, as far as my observations go, I do not think that there is sufficient proof to show that their development in such instances is the cause of nitrification, and not, rather, one of the circumstances attendant on that process.

My experiments, however, were made not with a view to determine that question, but in reference to the detection of animal impurities in potable waters, and to ascertain the circumstances which were favourable or otherwise, to the formation of nitrites and nitrates in waters which were so polluted, as the presence of such salts is generally regarded as indicating previous sewage contamination; and the drinking of water with such pollution is not only injurious to the health of those who thus employ it, but there exist strong grounds for the opinion which is now very generally entertained, that such water frequently becomes the means of conveying the germs of certain formidable diseases, especially those of typhoid fever and cholera, from its containing the fecal and other emanations of individuals suffering under those maladies, and thus disease and death are often insidiously brought into many homes, when such diseases are prevalent in different localities. Besides, as the formation or production of nitrates is one of great industrial and agricultural importance, any facts which might directly or indirectly enable us to facilitate or hasten that process, would be of much practical value.

As human urine and feculent matters may justly be regarded as the most offensive and dangerous ingredients of sewage in general, my experiments have been confined to those matters, and were principally made on urine, which from its containing different nitrogenous substances readily susceptible of decomposition, is peculiarly suited for the study of the nitrification of animal matters. By mixing this liquid with various proportions of water, and placing the mixtures under different circumstances, I have endeavoured to ascertain those that were favourable or otherwise to their nitrification, and to determine some points connected with that process which required further investigation.

I should here observe, that in detecting the occurrence of nitrification, I have principally used the well known test of Price for nitrites, which consists in adding to the water or mixture, a thin solution of starch containing a little iodide of potassium and acidifying with diluted sulphuric acid, when a blue reaction from the liberated iodine will be immediately produced, should a very minute quantity even, of a nitrite be present. And as there is every reason to suppose that the production of nitrites precedes that of nitrates in the nitrification of organic matters in solution, and the detection of the former is much more easily effected than the latter, at least under the conditions existing in my experiments, I was satisfied in most cases to obtain the evidence of the formation of nitrites by the employment of the test to which I have just referred.

The experiments of Warrington* have led him to conclude, that darkness is an essential condition to the development of those low forms of vegetable life, which are supposed in many instances to give rise to nitrification. This is a question which it is difficult to determine decisively, one way or the other, owing to the impossibility of having with us continuous daylight to operate with. Still I think we may arrive at an approximate conclusion on this point, by making comparative experiments on similar mixtures kept altogether excluded from the light, and on those exposed to its full influence, and then determining the amount of nitrification which had taken place in each after a given time; and if darkness be so essential to that process, we should naturally expect that in the mixtures exposed to its continuous influence, there would be an earlier and a greater development of nitrification, than in those which had been placed under it, for about one-third or one-half

* Read before the Royal Irish Academy, May 12, 1879.
† *Comptes Rendus*, lxxxiv., 301.

* *Journal of the Chemical Society*, January, 1878.

the time each day of twenty-four hours. From the results of several comparative experiments made in this way, I have come to the conclusion, that the conditions of light or darkness exercise but little influence one way or the other in this process, at least under the circumstances existing in my experiments, which consisted in placing different portions of the same mixture in similar bottles, some of which were surrounded with black cloth or velvet to exclude light, whilst others were left uncovered, and all of them were suffered to remain open or uncorked. On examination after a few days, there was but little difference as to the amount* of nitrification that had taken place in each—indeed in some of my experiments, it had progressed to a greater extent in the uncovered than in the covered bottles; and in all made on this subject (except those to determine this point as to the necessity or not of darkness) the mixtures were left exposed to the light, and some to the full influence of strong sunshine, yet still a considerable amount of nitrification took place in each; besides in nature much of the nitrates which occur in the surface soils of different localities, must have been formed under the influence of more or less daylight, all of which facts, I conceive, are more or less opposed to the necessity of darkness in this process.

Another point which has not, I believe, been clearly established, at least as regards nitrification occurring in water containing organic matters, is the necessity of having a certain amount of air or of free oxygen to carry on the process; this I have proved in the following very simple manner:—To water which had been kept boiling for some time to expel its contained air, I added a small quantity of freshly voided urine (the proportion employed being about one part of urine to sixteen parts of water, such a mixture having been found to be very suitable for nitrification), and then repeated the boiling to ensure the removal as far as possible of any dissolved air. Several bottles which had been kept immersed in the boiling mixture, were then filled completely with it, corked and sealed with sealing wax to prevent the access of air. Some, however, of them containing this mixture were left open for comparison. After leaving the bottles for a day or two in the same place, I first examined the open ones for nitrites, and when the test indicated the abundant formation of those salts, I opened one of those sealed, when not a trace of nitrites was discoverable in its contents; the remaining sealed ones were opened at different periods subsequently with the same results. Other comparative experiments were made, where the temperature of the mixtures was artificially kept at a heat very favourable to nitrification, but in every instance where the access of air had been excluded no trace of nitrites could be detected, clearly proving the necessity of more or less air or free oxygen for their formation. But the amount necessary to commence at least, the process is small, for I found that where the mixture had not been boiled previous to the complete filling, corking and sealing of the bottle, that the air dissolved in the liquid was sufficient to cause the production of nitrites to some extent.

The quantity of animal matter which is held in solution in the water, I find exercises a considerable influence over nitrification, for where it occurs in very large proportion, there the process either does not take place at all, or is carried on much slower than in the more dilute solutions. This I have proved by comparative experiments with water mixed with different proportions of the same sample of urine, or of solution of excrementitious matter, where I found that nitrification occurred first in the more dilute mixtures; and that where there was much organic matter present, that the nitrites which might ultimately be formed soon afterwards disappeared again, by their subsequent change or decomposition; whereas those that had been produced in more dilute solutions, have remained unchanged for a considerable time.

But the circumstance which I have found to exercise the greatest influence over nitrification is that of temperature, for I have observed that in cold weather it is very slow in taking place, whilst in warm it is much quicker, and that by the application of artificial heat the process can be greatly accelerated. The correctness of this observation is borne out by the well-known fact, that it is from the soils of different hot climates that we obtain our chief supply of nitrates. As to what may be the most favourable temperature for this process, I have not yet been able to determine, owing to the difficulty, as I am circumstanced, in maintaining continuously the same degree of artificial heat; but I have found that where the mixtures were placed where they were kept at a temperature which varied from about 70° to 80° F., that there the process was carried on very quickly and that nitrites were soon abundantly formed, whereas in similar mixtures maintained at lower degrees of heat or at the ordinary temperature not a trace of those salts could be detected in the same time, and that their presence was not discoverable till after a much longer period.

The foregoing observations have, I conceive, some important bearings as regards the contamination of water with sewage, and the evidence of such derivable from the occurrence in it of nitrites and nitrates. For though the presence of those salts is undoubtedly, in many instances, an indication of previous sewage pollution, still their absence, taken by itself, cannot be relied on as a sure indication of the freedom of the water from such contamination. For the circumstances present may have either been unfavourable to the formation of nitrites and nitrates, or have produced their subsequent rapid disappearance: thus, for instance, the lowness of the temperature of the water may have prevented their formation, or the quantity of organic matter present may have interfered with their development, or have led to their subsequent change and disappearance. Such, amongst other circumstances influencing the presence of those salts in water containing animal matters, it will at once be evident, that their absence, unless accompanied by other indications of purity, cannot be relied on as a proof of the freedom from such contamination.

Before I conclude, I wish to call attention to another fact which I have noticed in connection with this subject, viz., the rapidity with which nitrites are sometimes formed in waters contaminated with sewage impurities. This is a subject of considerable importance in an analytical point of

* In ascertaining the amount of nitrification, the indigo process, as described by Sutton in his 'Volumetric Analysis,' was employed, which served for the determination of the nitrites and nitrates collectively, and though it may not be quite so accurate as some other methods, was sufficiently so for this purpose, as it was only the comparative amount of nitrites and nitrates formed under the different circumstances of the experiments that I wanted to determine.

view, as I shall endeavour briefly to explain. It is well known by those who have analysed potable waters, that the method which chemists now principally employ, to ascertain their purity or otherwise, is to determine the quantity of ammonia a given amount of the water will yield on distillation, both before and after the addition of a strongly alkaline solution of permanganate of potash. The first obtained is termed the free, and the second the albuminoid ammonia. The former is regarded as the representative of the nitrogenous organic matters previously existing in the water, which have undergone more or less decomposition; whilst the latter is produced by the action of the alkaline permanganate or those substances still present in the water. Consequently, the less of each that is furnished by a sample of water when so treated, the purer organically is it regarded, and the safer, other circumstances being similar, would it be for potable purposes.

When lately analysing a sample of water that had been contaminated with sewage, to ascertain the amount of such pollution, which was afterwards the subject of an important legal inquiry, in my first trial, I found that the water yielded a quantity of free ammonia, which was equivalent to 0·970 parts of a grain per gallon, but on repeating the determination a few days afterwards, it was discovered that it had fallen to 0·186 parts of a grain for the same quantity of water, or to less than one-fifth of the former amount; whereas the quantity of albuminoid ammonia yielded had slightly increased. This result as to the great decrease of free ammonia, which at first rather surprised me, I ascertained was due to the formation of nitrites, which had been developed to a large extent, in so short a time, at the expense of the free ammonia.

Such being the case, if the water had not been examined till the date of the second analysis, and if the nitrites had not been taken into account, this water would have been regarded as containing much less free ammonia than it did, and consequently that the previous sewage contamination was less than it really was; this point, is therefore, one of some analytical importance.

It is right for me to observe in connection with this latter fact of the decrease of free ammonia in waters by keeping, that long after I had made that observation, I came across in the *Chemical News* for March 2, 1877, a letter written by Professor Pattison Muir, of Owens College, in which he calls the attention of chemists to some observations his brother had just made in the laboratory of the University at Sydney, in which he had noticed that the amount of free and of albuminoid ammonia, as determined by Wanklyn's process, varied very considerably with the time the sample of water had been kept; but neither of those gentlemen have offered (in the letter referred to) any explanation of the fact further than that Professor P. Muir throws out the suggestion, in the case of the increase by keeping of the albuminoid ammonia, that possibly it might have been owing to the "germs" which have escaped decomposition by the permanganate, undergoing a gradual decomposition in the water, and that ammonia is one of the products of this process. Be this as it may, I have satisfied myself that the loss of free ammonia is often due to the formation of nitrites or nitrates, which are very rapidly formed from it under different circumstances. And as regards albuminoid ammonia, the very slight increase which I observed in my experiment, was, I thought, very easily accounted for by my having in the second determination, carried on the process of distillation somewhat further than in the first trial, and in this way the amount might be very naturally increased.

Finally, my observations that nitrification is greatly promoted by warmth might, I conceive, admit of some practical application in the manufacture of the nitrate of potash in the artificial nitre beds, especially in those of cold countries, and I am not aware that heat has hitherto been anywhere artificially applied to hasten or promote that important manufacture.

NOTES ON SOME JAPANESE DRUGS.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

The Japanese are perhaps the most enterprising and progressive of Eastern nations, and have already made vast strides in the science and education of the West. In Japanese medicine a similar improvement seems to have taken place, for it was remarked at the Centennial Exhibition at Philadelphia, that although 300 specimens representing the advanced materia medica of Japan were exhibited, none of the specimens belonged to the animal kingdom, the various disgusting remedies of that class still used by the Chinese being conspicuous by their absence.

Yet comparatively little is known in English-speaking countries of the drugs used by the Japanese. Beyond an enumeration of thirty well-known drugs used in other countries, no description that I can discover has been published in the English language of the 300 specimens above mentioned.

In *New Remedies* for January, 1877, a short account is given of Japanese medicine,* and the names and uses of a few drugs, and some analyses of a few others have been published in the *American Journal of Pharmacy*, January, 1879, p. 25.

The large quantity of Japanese aconite that has during the last few years been imported into this country, has in some measure drawn attention to the drugs of Japan. Messrs. Wright and Luff have recently obtained from this aconite an alkaloid which they call Japaconitine. Another alkaloid has been discovered in an unnamed Japanese plant by M. A. Petit. These results have led me to examine the collection which was recently presented to the museum, with a view to ascertain whether any of them appeared to merit chemical examination or could be turned to any practical account in this country. Among those which seem most promising may be mentioned the root of *Coptis anemonæfolia*, containing a quantity of berberine; the fruits of *Gardenia radicans* and *G. florida*, in which a colouring matter supposed to be identical with that of saffron has been found; kuhsing root, containing the very bitter alkaloid discovered by M. Petit, and a valerian root, which seems to be more powerful than the English drug.

The thoroughness with which the drugs have been dried, their freedom from admixture and their excellent quality, seem to indicate that it may be possible in the future for drugs from Japan to compete successfully with less carefully prepared products nearer home.

The specimens hereafter described were all met with in the London market, where for some months

* *Pharm. Journ.*, vol. vii., p. 674.

they found no purchaser, nothing being known of their names or uses, all the names being in Japanese characters. In the following notes the drugs have been arranged for convenience of reference under the heads of Roots, Herbs and Leaves, Flowers, Fruits and Seeds, and the Japanese names have been placed in alphabetical order, as being those in which Japanese drugs are most likely to be met with in English commerce on future occasions.

The Japanese names *kung, soh, yoh, kah, she, ning*, which are of frequent occurrence in the following list of drugs mean respectively, root, herb, leaves, flowers, seeds and kernels, and must therefore not be looked upon as part of the name of the plant which yields them.

When presented to the museum of the Pharmaceutical Society by Mr. Christy, the specimens had merely numbers and the names in Japanese characters attached to each parcel; these numbers are here placed in parentheses after each Japanese name, to enable others to whom similar specimens have been distributed to easily identify them by this means.

I have to acknowledge the great assistance kindly afforded me by Mr. K. Takemura, a Japanese gentleman studying in the Society's laboratory, in translating the Japanese labels of the specimens, and also portions of the Sô mokou Zoussetz, a valuable Japanese work recently presented to the North British Branch of the Society. Without Mr. Takemura's assistance the botanical sources of many of the specimens could not probably have been so satisfactorily determined.

The works to which abbreviated reference is made, and from which the synonyms for the various drugs have been taken, are as follows:—

Kœmpfer, 'Amœnitates Exoticæ,' 1712.
Thunberg, 'Flora Japonica,' 1786.
Siebold and Zuccarini, 'Flora Japonica,' 1835.
Smith, Dr. F. Porter, 'Chinese Materia Medica,' 1871.
Miquel, 'Prolusio Floræ Japonicæ,' 1866–7.
Franchet and Savatier, 'Enumeratio Plantarum Japonicarum,' 1875.
Hanbury 'Science Papers,' 1876.

ROOTS.

BAI-MO (30): —*Fritillaria Thunbergii*, Miq. Prol. p. 321; Fr. et Sav. vol. ii. pt. 1, p. 61; Sô mokou Zoussetz, vol. v. fig. 79; *Uvularia cirrhosa*, Thunb. Fl. Jap. p. 136.

Syn. FARU JURI, AMISA JURI, Fr. et Sav.

The drug consists of a white starchy corm varying in size from a hazel nut to a filbert, and consisting of two halves which seem to be respectively the old and young corm, and which enclose between them very young flower buds. They have a bitter taste but no odour, and appear to correspond with the description of the bitter hermodactyle mentioned in the 'Pharmacopœia of India,' p. 246.

This plant is often found cultivated in gardens in Japan, and flowers in June. The corm is the part used in medicine. The corms have some resemblance to those of the hermodactyle formerly used in medicine in this country, and, indeed, closely resemble in appearance the hermodactyle described by Dr. Porter Smith in his work on 'The Materia Medica of China.' The Chinese character is also identical with the Japanese one, but in Chinese is pronounced Pei-mu instead of Bai-mo.

Pei-mu is used in China for rheumatism and aching joints. Whether it is used similarly in Japan I have no certain knowledge.

BIAKOO-BOO KUNG (34):—*Roxburghia sessilifolia* Miq. Prol. p. 143; *Stemone sessilifolia*, Fr. et Sav. vol. ii. pt. 1, p. 92.

Syn. HIYAKUBU, Sô mokou Zoussetz, vol. ii. fig. 55; SHIA-KOU-BOU, Phonzou Zoufou, vol. xxviii. p. 6.

The roots occur in the form of pale shrunken pieces from two to five inches long and internally present a horny appearance. They are tough and flexible. The taste is sweetish at first and afterwards slightly bitter.

In China it is credited with expectorant, antiphlogistic and vulnerary properties.

This liliaceous plant grows in the islant of Kiusiu, and has ovate leaves in whorls of four, flowering in May. It is furnished with numerous tubercular roots, which form the drug used in medicine. The Japanese name is probably given in allusion to the number of these tubercules, *Biakoo* meaning a hundred, *boo*, parts, and *kung*, root. The Japanese character for the name is the same as the Chinese character translated Peh-pu by Dr. Porter Smith in his 'Chinese Materia Medica,' and referred by him to Melanthium (?). The specimen in his collection is also identical in appearance with the Japanese drug.

BIAK-YITZ (12): —*Atractylis ovata*, Thunb. Fl. Jap. p. 306.

Syn. BIYAKU JUTSU, Sô mokou Zoussetz, vol. xv. fig. 49; BIAKOU SITSOU, Phonzou Zoufou, vol. iv. p. 25, 26; IKERA, Fr. et Sav., vol. i. p. 256.

The root of Biak-yitz occurs in pale brown knotty pieces, irregular in shape and slightly bent or twisted, about one inch long and half an inch in diameter. Internally it is whitish and speckled with yellowish brown dots, which under a lens are seen to contain an oily and resinous looking matter, which in another species (*A. lancea*, Thunb.), according to Hanbury ('Science Papers,' p. 255), is not removed by water, alcohol or ether.

According to a writer in *New Remedies*, January 1877, and quoted in the *Pharmaceutical Journal*,* "Biaku juszu" is much used, as well as the root of Sad juzu or So jutsu (*Atractylis lancea*), as an antifebrile remedy in Japan. In China it is used as a tonic, stimulant, diaphoretic and diuretic.

The Japanese name signifies, *biak*, white, *yitz* or *jutsu*, atractylis, and is possibly given in allusion to the pale under-surface of the leaves, since the flowers are red. The plant appears to have somewhat the habit of the *Serratula tinctoria* of this country. It grows in damp places by waysides, and flowers in October. The root is the part used in medicine. The drug mentioned under *Atractylodes alba*, in Dr. Porter Smith's 'Chinese Materia Medica' has the same written character for which Peh-shuh (white shuh) is given as the equivalent sound. His specimens of the root are evidently those of a nearly allied, but different species, being almost globular, and of a more fragrant and slightly different odour. Several species of this genus appear to be used in China under the name of "Shuh."

BOO KUNG (42):—*Eulalia Japonica*, Trin.; TO KIWA, ITO KAJA, KAJA, Miq. Prol. p. 177; OBANNA, SUSSUKI, Thunb. Fl. Jap. p. 42; FUKU, TSIKUSITS, TSIKUBE, SASADSITZ, *Sasa*.

Syn. MEGURI, Kœmpf. Amœn. p. 899, Fr. et Sav. vol. ii. p. 182.

Boo kung consists of very small pieces, much re-

* Vol. vii., [3], p. 675.

sembling in general appearance the *Triticum repens* of English pharmacies, but the pieces rarely exceed a quarter of an inch in length. The taste is slightly sweet; the odour scarcely any.

According to Dr. Porter Smith, Boo kung, or as the Chinese pronounce it Mau-ken—for the written character is the same in both languages—is a generic name for the roots of grasses and sedges. He refers the Chinese drug to *Saccharum spicatum*, which is also known in Japan under the name of Boo and Tsubanna according to Thunberg.

This grass is not unfrequent in damp copses in various parts of Japan, and flowers in August.

BIAK-MONG-DAU (28):—(*Ophiopogon Japonicus*, Ker.).

Syn. JANO-HIGE, Sô mokou Zoussetz, vol. vi. fig. 45, under *Fluggea Japonica*, Kunth., JAMMA SOB, JAWRANG; Thunb. Fl. Jap. p. 139; under *Convallaria Japonica*, L.; MONDO, BIAKFMONDO, RIUNO FIGE, Kœmpf. Amœn. Exot. p. 823 and fig. p. 824; MIH-MUN-TUNG, Hanbury 'Science Papers,' p. 256, with fig. of tubercules; DJIANO-SHIGE, Fr. et Sav. vol. ii. pt. 1, p. 85.

The tubercules which form the drug are about two-thirds of an inch in length and one-eighth of an inch in diameter, of a yellowish-white colour and have a central thread running through them. They evidently consist of dilatations of the cortical portion of the rootlets, the central thread being the meditullium. The taste is sweetish.

In China the drug is considered to be a pectoral and probably answers the same purpose in Japan.

The plant yielding these tubercules is common in uncultivated places in Japan, flowering in October or November. There are several varieties of the plant, var. *genuinus* being small, and vars. *umbrosus* and *Wallichianus* larger plants. Kœmpfer also alludes to another species growing near Satsuma, which has larger roots and is called Temondo. In the Sô mokou Zoussetz, both *Ophiopogon spicatus* and *O. Japonicus*, (*Fluggea Japonica*) are described as "Mong dau" according to Mr. Takemura, but *O. spicatus* is called large and *O. Japonicus* small "Mong-dau." The Chinese character for Men-tung is exactly the same as the Japanese for Mong-dau. The Japanese specimens are, however, smaller than those from China. The name mong-dau means literally *mong*, gate, *dau*, winter, probably on account of the plant flowering at the commencement of winter, and *biak*, white, in allusion to the white flowers.

TSIKU-SETZ NIN-JIN (27):—*Aralia edulis*, Sieb.(?)

Syn. UDO, DO-TOOKI, Sieb. et Zucc. p. 57; DOKU QUATZ, DOSJEN, Kœmpf. Amœn. p. 826; *Aralia cordata*, Thunb. (p. 127) F. et Sav. vol. i. p. 191.

In external appearance and size this drug bears a strong resemblance to the rhizome of *Polygonatum officinale* (Solomon's Seal); the disc-like scars left by the aerial stems are, however, arranged in a somewhat spiral manner, and are rarely more than half an inch apart. The transverse section of the root is of a dirty white colour, horny consistence, and is marked near the circumference with a ring of linear, loosely packed, radiating, vascular bundles. The taste is bitter. The rhizome has no distinctive odour.

The Japanese name, according to Mr. Takemura, means bamboo-knotted-ginseng, *tsiku* meaning bamboo, *setz* a knot or joint, and *nin-jin* ginseng, or in other words a root similar to ginseng, but having scars like those of the bamboo rhizome.

The above identification is given with uncertainty, as I have not been able to obtain either authenticated specimens of the root of *Aralia edulis* or a description of it. It is said to be often cultivated in Japan, and is also found wild, flowering in October. When young it is called sika, when older udo, and when mature dosjen, according to Kœmpfer.

(*To be continued*).

COPAIBIC ACID.*

BY WARREN B. RUSH, PH. G.

In preparing copaibic acid the volatile oil must first be removed, which is usually done by distillation with steam. The oil is, however, much more readily separated on a small scale by one of the following processes: First, by dissolving ten parts of copaiba in ten parts of benzin, adding an equal part of caustic soda solution, sp. gr. 1·30, and agitating well; or, secondly, by mixing ten parts of copaiba, ten parts of alcohol and four parts of soda solution, when the mixture will separate into three layers. A third and most economical way for separating the volatile oil is to shake together three parts of the soda solution with one of the copaiba. After separation, pour off the volatile oil, decant the alkali solution, pass a stream of water over the resin, to wash off adhering particles of alkali, and let it dry. Next, dissolve the resins in benzin, and agitate the solution with very diluted hydrochloric acid until the aqueous liquid remains slightly acid to litmus. Let the mixture rest until the resin and water have separated, decant the water and evaporate the benzin solution to a thick syrupy mass, and let cool. The same resins are thus obtained which are left on the distillation of the volatile oil.

I have observed that if the percentage of oil is below 55 then the oil does not separate, there being sufficient resin to hold the volatile oil combined, and in this condition some of the later is oxidized or altered. It may be separated from the resin by dissolving in benzin or alcohol and treating as above.

The resinous residue left after the separation of the oil contains an acid, a neutral and a soft resin. The following are among the processes for the isolation of the different resins of copaiba: Liquefy the resins by the heat of a water-bath, pour into about twice the weight of petroleum benzin, stir until dissolved, filter, and let evaporate spontaneously. A few particles will remain on the filter, consisting of the usual impurities. Warm the residue left by evaporation over a water-bath and pour it into three times its quantity of alcohol; or heat the alcohol to boiling, mix thoroughly, and while hot filter. The portion left on the filter is the neutral resin. Set the filtrate aside for several days to crystallize. Treat a portion of the neutral resin with hot alcohol, and if it colours the alcohol there is left behind some of the acid resin, and this may be obtained by treatment with hot alcohol and adding the filtrate to the first.

The neutral resin is a yellowish powder, without taste or odour, neutral to test paper; it softens in alcohol and is soluble in ten times its weight of hot chloroform.

After crystals have formed in the alcoholic liquid, filter, and dry on the filter paper under glass. On distilling off the alcohol from the filtrate, the soft resin is left behind. Copaibic acid may also be obtained from the resin by dissolving it in benzin, filtering and evaporating. The residue is heated to 200° F., dissolved in pure naphtha, filtered while warm and set asid to crystallize, after which the crystals are dried under glass.

Of the other processes which have been tried, the following deserve to be briefly mentioned.

Dissolve the oleo-resin in caustic ammonia (sp. gr. 95),

* From the *American Journal of Pharmacy*, June, 1879.

and expose this in a shallow dish at a temperature below 60° F., until hardened; then dissolve in wood naphtha, crystallize and filter. Expose copaiba to the air in shallow dishes until it has become hard and brittle, dissolve it in ammonia water and leave to evaporate in a cool place; then dissolve in hot alcohol, filter and set aside to crystallize. Dissolve the resins left after the distillation of volatile oil in caustic ammonia, let evaporate, disssolve in hot alcohol, filter and set aside to crystallize. The alcohol may be partly recovered in these different processes by distillation.

The crystals cannot be easily obtained without the previous separation of the volatile oil, the acid being soluble in fixed and volatile oils. Doubtless the copaba yielding the largest amount of resins will produce the most acid.

Copaibic acid forms soft prismatic crystals, which are soluble in strong alcohol, ether, fixed and volatile oils. Its alcoholic solution reddens litmus, is not precipitated by potassa or soda, yields with an alcoholic solution of acetate of lead a crystalline precipitate; but, on adding it to an alcoholic solution of nitrate of silver, no precipitate is occasioned until a little ammonia is added. A white crystalline powder falls, which is with difficulty soluble in alcohol but readily soluble in ammonia.

THE ALKALOID OF MIO-MIO (BACCHARIS CORIDIFOLIA).*

BY PEDRO N. ARATA.

The Mio-Mio (*Baccharis coridifolia*, Lam.) is a Composite plant abundant in the Banda Oriental del Uruguay, the Argentine Republic and Brazil. The notoriety which this plant has acquired in these countries is due to the toxic action which it exercises upon the animal organism, it being the cause of considerable losses of sheep and cattle to the farmers, and it is the more dreaded because the animals confound it with the healthy pasture among which it grows. The author reports that he has obtained from this plant an alkaloid in sufficient quantity to allow of the following description.

The dry powdered plant was boiled with distilled water in a porcelain capsule and the water separated by decantation, the operation being repeated until the material was completely exhausted. The united liquors were filtered and evaporated, at first over a fire, and afterwards in a water-bath, to the consistence of an extract, which was mixed with double its weight of a mixture of caustic lime and magnesia and the evaporation was then continued to dryness. The product was pulverized and digested for forty-eight hours with amylic alcohol in a closed vessel with frequent agitation, then thrown on a filter; the filtrate of amylic alcohol upon evaporation left the alkaloid in a crystalline form.

Amylic alcohol is preferable to ether in this operation as it dissolves the alkaloid very readily, especially with heat, and a saturated solution deposits a very voluminous crystalline mass. Under the microscope the crystals appear as long delicate needles, sometimes united and radiating from a common centre so as to form stars.

Water dissolves the alkaloid sparingly; ether and alcohol dissolve it with more facility, but it is not very soluble in them; the best solvent is amylic alcohol.

Dissolved in water the alkaloid gives neither an alkaline nor an acid reaction, it showing no change of colour with vegetable reagents. It dissolves with greater facility in boiling water to which some drops of acetic acid have been added. The acetate that results is fairly soluble in boiling water, but upon cooling the liquid becomes turbid as if concentrated, the turbidity disappearing upon the addition of more water.

The solution of the acetate gave the following reactions:—With sodium phosphomolybdate or phosphomolybdic acid a greenish yellow precipitate, disappearing when heated and reappearing on cooling; with potassium iodohydrargyrate, a yellowish white precipitate; with the double iodide of cadmium and potassium, a light crystalline precipitate; with potassium platinocyanide, a very marked turbidity; with platinum chloride, a light yellow precipitate, disappearing when heated and reappearing on cooling; with gold chloride or picric acid, a yellowish precipitate; with potassium iodoiodide or sodium phosphoantimoniate, a reddish yellow precipitate; with phosphotungstic acid or mercury bichloride, a white precipitate; with potassium ferrocyanide, an abundant white precipitate; with potassium ferricyanide, a dark green coloration when heated; with sodium nitroprussiate, a coloration, and with sodium phosphoantimoniate, potassium sulphocyanide or potassium bichromate, no change. The author considers that the foregoing reactions demonstrate that this substance is an alkaloid and he has named it "baccarina."

Some physiological experiments made upon a sparrow have proved that baccarina exercises a toxic action, and further investigation in this direction has been undertaken by Professor Pirovano. Senor Arato promises to study the elementary composition of the alkaloid and its salts with a fresh quantity of material.

* Abstract of a paper in the 'Annales de la Sociedad Cientifica Argentina,' vol. iv., p. 34.

THE DISCOVERY OF MINERAL WAX, OZOCERITE, IN UTAH.*

BY PROFESSOR J. S. NEWBERRY.

I have obtained some of the recently-discovered ozocerite in Salt Lake City from Professor J. E. Clayton, to whom also I am chiefly indebted for such information as I have in regard to its place and manner of occurrence. He writes me as follows:—"The geographical position of the ozocerite deposits is in the Wahsatch Range, on the head waters of the Spanish Fork, east from the South End of Utah Lake. The material has been found saturating beds of brown and bluish shales, probably of Tertiary age, and in masses of various dimensions, more or less mingled with clay. These shales extend from the San Pete valley in a north-north-east direction for a distance of fifty or sixty miles, and the width of the area or basin which they occupy is at the middle point about twenty miles. The shale beds richest in paraffin vary in thickness from twenty to sixty feet, but there is no considerable accumulation of that substance on the surface, nor would this be possible, as it would be destroyed by the autumnal fires which sweep the country. I examined portions of this region two years ago for coal, and found in the oil shales a few thin seams, and saw the wax-like exudation in several places, but only in small quantity."

Other parties in Salt Lake informed me that the paraffin itself is sometimes twenty feet thick, and that the quantity is enormous; but Professor Clayton says that such statements are not authorized by any facts which have come under his observation.

In the above remarks I have called the earth wax of Utah ozocerite. As it has been stated to be zietrisikite, I may say that on my return from the West, my son and assistant, Spencer B. Newberry, made a series of careful experiments in my laboratory of these hydrocarbons, and with authentic specimens which I have received directly from Gallicia. He found that it had a melting point of 61·5° C., that it was completely soluble in a large volume of boiling ether, and that boiling alcohol extracted from it twenty per cent. of a white wax-like substance. It seems, therefore, to be certainly ozocerite and not zietrisikite, the latter melting at 90° C., and being insoluble in ether.

The Pharmaceutical Journal.

SATURDAY, JULY 5, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE MEETING.

WITHIN a few weeks the British Pharmaceutical Conference—guided as usual by the British Association in the selection of a locality for the annual gathering—will again visit Yorkshire, as our readers will be reminded by the report which appears in the present number of the Journal of the proceedings of the Executive Committee last Wednesday. Those who have experience of the cordial reception the members of the Conference met with in Bradford will not need to be assured an equally hearty welcome probably awaits them in Sheffield, and those who have not had the experience will have heard quite enough of the agreeable nature of the first meeting in Yorkshire to make them anxious to participate in the enjoyment of the one now about to be held.

For these reasons we anticipate that the desire to attend the Conference will be very general, and considering the central situation of Sheffield, as well as the marked prominence of Yorkshire pharmacists in the endeavour to advance the interests of the body to which they belong, we venture to think these combined inducements and the prospect of being able to combine benefit with pleasure, will outweigh even the depressing influence of "bad times" and "bad weather" with such effect as to make the meeting at Sheffield one the most largely attended that has been known since the Conference has been in existence.

There is one circumstance of no small moment to the attendants at such a gathering as the Pharmamaceutical Conference which seemed, up to within the last few days, to furnish ground for apprehension. It is a somewhat exasperating thing to find, after having responded to the kindly invitation of friends to pay a visit to their town, that the local Boniface, in the shape either of an over keen individual, or of an imposing Board of limited liability organization, intervenes between host and guest, holding out his cap with exorbitant demands for the payment of black mail as the sole condition upon which opportunity for friendly intercourse will be allowed. But such things do happen sometimes, and we regret having to remember that a notable instance of the kind was furnished when the Conference last met in Yorkshire. Hotel charges multiplied fourfold to those known to be visitors, and kept at the ordinary rate for chance comers, is a form of purse-cutting that under any conditions would require more than ordinary meekness and pecuniosity to be endured, and that is, we think, especially impolitic at a time when the hotelkeepers have no reason to complain of lack of business.

There was some reason to apprehend that this eminently vicious system of taking undue advantage of a full demand for hotel accommodation would be put in practice at Sheffield and that it would have had the effect of deterring many from going there. But we are glad to learn that arrangements have been made to prevent the rapacity of hotelkeepers being an obstacle to intending visitors. According to a communication just received from Mr. MALEHAM, the local secretary of the Committee for the Sheffield meeting, a reasonable scale of charges has been fixed at one or two of the hotels where a number of rooms have already been secured, and where Mr. MALEHAM offers to secure accommodation for members of the Conference if they will only make early application to him stating what they require.

We think, therefore, this notification holds out the certainty of being able to secure a comfortable *pied à terre* and that we can without any risk urge upon those who are already *habitués* of the Conference gatherings not to omit taking advantage of this opportunity for scientific and social intercourse, while at the same time we recommend those who have not hitherto done so to make the experiment under the favourable auspices now presented and with such fair prospect of realizing the pleasurable as well as profitable results which the President of the Sheffield Pharmaceutical and Chemical Association spoke of at the last annual meeting of that Association as having been experienced by himself on the occasion of his visit to Dublin last year.

Sheffield is a town which is of interest in various ways in a pharmaceutical point of view. It has always taken a prominent position in pharmaceutical as well as in general politics. For some years it sent a member to the Council of the Pharmaceutical Society who, though less aggressive than one of the members of Parliament who represents the borough, on a subsequent occasion led the van of the band of malcontents that came down with a stern front upon the Council to remonstrate against its supposed disregard of trade interests. It cannot, however, be said that even in that position he excited any less kindly feeling towards himself than he did while holding the position of member of the Council. But at the British Pharmaceutical Conference discussion of political questions is not permitted, and whatever may be the individual differences of opinion on such subjects between those who meet at Sheffield, we feel sure they will in no way interfere on that occasion with that friendly intercourse amongst the followers of pharmacy which it is the object of the Conference to promote. On the contrary we anticipate that political war paint of all colours will be washed off for the time and that even timid conservatives and uncompromising Tories will have no occasion to fear being subjected to the vengeance of the peculiar institution for which Sheffield is famous.

Sheffield itself has but little claim to beauty, though occupying a very fine situation upon a natural amphitheatre of hills; but it is surrounded by some of the most lovely scenery in the Kingdom, partly in Derbyshire and partly in Nottinghamshire. The town is the centre of the steel trade, formerly the cutlery ware was the chief article of manufacture; but since the introduction of the Bessemer method of producing steel, this material has been applied for armour plating of ships and other heavy purposes, and the manufacture of these products has been carried out extensively in Sheffield.

In other respects the situation of Sheffield is one calculated to induce every one who can spare the time to spend a few days in visiting the immediate neighbourhood. On the east lies the district of Sherwood Forest formerly the resort

"Of Robin Hood and Little John;
Of Scarlet, George à Green and Much the Miller's Son,
Of Tuck the merry Friar, which many a sermon made
In praise of Robin Hood, his outlaws and their trade."

Here, between Mansfield and Worksop, is the famous "Dukery," including Clumber and Welbeck Abbey, the seats of the Dukes of Newcastle and Portland, where interesting traces of the ancient forest are still preserved. Close by is Newstead Abbey, one of the most beautiful buildings of the kind in the country. On the west, within a few miles of Sheffield, is Chatsworth, "the palace of the Peak," and seat of the Duke of Devonshire, surrounded by scenery which in its way is quite unrivalled. Somewhat further west is Buxton, near the rise of the Derbyshire Wye, with the famous mineral springs that have made it a celebrated watering place, one yielding water having a temperature of 82° F., and the other yielding cold water at a distance of not more than a foot apart.

"Unto St. Anne the fountain sacred is;
With waters hot and cold its sources rise,
And in its sulphur veins there medicine lies.
This cures the palsied members of the old,
And cherishes the nerves grown stiff and cold.
Crutches the lame unto to its brink convey,
Returning, the ingrates fling them away."

This water is in both instances remarkable for its purity, clearness and transparency, and it is used both for drinking and for baths. The use of it for these purposes dates back to a very remote period. Remains of a Roman bath have been discovered, and in the middle ages the chapel of St. Anne was the resort of numerous devotees in search of health. This practice was interfered with at the time of the Reformation, but in the reign of Elizabeth the Buxton waters again came into repute and caused the place to be the resort of great numbers of nobility and gentry, who were crowded into low wooden sheds and regaled with oat cake and a viand which the hosts called mutton, but the guests suspected to be dog. The accommodation for visitors has improved since then, however, and it may be ventured upon without fear of the dog.

Matlock Bath further south has in its neighbourhood some of the most striking scenery in Derbyshire, which was described by Lord Byron as equal to anything in Greece or Switzerland. The limestone caverns and the several tors near Matlock are objects of considerable interest. The mineral springs of Matlock are less celebrated than those of Buxton and the water is chiefly used for bathing; it is highly impregnated with carbonic acid and carbonate of lime, which is deposited when the gas escapes. Owing to this circumstance any object over which the water passes continuously in a thin layer becomes coated or incrusted with the deposited calcareous materials which are locally called petrifactions.

The limestone districts of Derbyshire abound in ferns and fossil remains, as well as minerals, that afford scope for the exercise of botanical and mineralogical skill, and to the geologist the country presents numerous features of interest.

FLOWER FARMING IN SOUTH AUSTRALIA.

In a report on the Botanic Garden and Government Plantations of Adelaide, South Australia, for the year 1878, Dr. Schomburgk speaks favourably of the introduction of flower farming for the purposes of perfumery, but he thinks the further application of the produce in the manufacture of perfumes would be better done elsewhere than in the colony. Dr Schomburgk illustrates the importance of the matter by reference to the quantities of perfume consumed. According to him, British India and Europe consume about 150,000 gallons of handkerchief perfume yearly, and the English revenue from eau de Cologne alone is about £8000 a year, while the total revenue from imported perfumes is estimated at about £40,000 a year. One great perfume distillery at Cannes is said to use annually some 100,000 lbs. of acacia flowers, *Acacia farnesiana*, 140,000 lbs. of rose flower leaves, 32,000 lbs. of jasmine blossoms, 20,000 lbs. of tuberose, besides a great many other sweet herbs. These data will serve to show that the quantity of material used as perfume is immense, and that in the genial climate of South Australia the production of the raw material for extracting the fragrant essential oils is likely to be a successful enterprise.

A MARK OF BARBARISM.

According to a writer in the Chicago *Pharmacist*, the United States Government having recently applied to the German Government for information as to the number of patent medicines and the extent to which they were sold in Germany, a polite reply was sent that as that country was now civilized patent medicines had no existence in it.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, July 2, 1879.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Richardson, Rimmington, Robbins, Savage, Shaw, Symes, Williams and Woolley.

The minutes of the previous meeting were read and confirmed.

Weights and Measures Act.

The President in reference to the Weights and Measures Act, said it had occurred to him whether the half-scruple had not been intended to be recognized under the half-drachm. Looking at the table adopted, it would be found that the words used were $1\frac{1}{2}$ scruple or half-drachm and he thought probably the half-scruple was intended to be authorized.

The Inaugural Address in October.

The President read a letter from Dr. Tilden, agreeing to deliver the Inaugural Address to the students in October next, in accordance with a resolution of Council passed last month.

The name of Mr. Rimmington was added to the Benevolent Fund Committee, having been accidentally omitted.

The Sale of Food and Drugs Bill.

The President drew attention to this Bill now before the House of Lords, where it had been read a first time. He said there was nothing in it specially affecting chemists and druggists, but he found a provision that prosecutions should in all cases be instituted within a reasonable time, in the cases of perishable articles not exceeding twenty-eight days. Who was to be the judge of what was a reasonable time, he did not know.

Mr. Woolley asked if it would not be possible to introduce a clause providing that a reasonable time should be allowed for the return of summonses under this Act. He had known of a case where a summons was served on Saturday and heard in court on the Monday. If assistance had not been at hand, and great efforts used to get evidence, the defendant would probably have been convicted.

The President said if it was considered desirable, an effort might be made to insert some provision of the kind referred to.

Mr. Rimmington said it would be easy in such cases to obtain an adjournment.

Mr. Robbins said it must be the fault of the summoning officer.

Mr. Savage said no doubt in such a case an adjournment would be obtained on asking, but it might entail expense on the defendant.

After some further conversation it was unanimously resolved, on the motion of Mr. Woolley, that an endeavour be made to obtain the insertion of a clause providing that no summons under the Act should be returnable in less than three days.

At a subsequent stage of the proceedings—

The President said he found that the discussion on this point might have been saved if the Bill had been looked at more carefully, for the last line stated that no summons should be returnable in less than seven days.

The New Bye-Laws.

A communication was read from the Privy Council signifying that the Privy Council had approved the new bye-laws recently passed by the Society.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Gibbs, Robert Darton.
Howard, George William.
Hoyle, Richard Ashworth.
Mann, George Frederick.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year were elected "Members" of the Society:—

Gibbs, Robert Darton ....Wednesbury.
Howard, George William ...Tunbridge Wells.
Hoyle, Richard Ashworth ...Rawtenstall.
Mann, George Frederick......Wells, Norfolk.

Chemists and Druggists.

Butterfield, William............Blackburn.
Fox, Alfred Russell ....Sheffield.

ASSOCIATES IN BUSINESS.

The following, having passed the respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Rouse, Frederick William ...Clapham.

Modified.

Evelyn, William Francis......Truro.

ASSOCIATES.

The following, having passed the Minor examination and tendered their subscriptions for the current year, or paid as Apprentices or Students, were elected "Associates" of the Society:—

Bucher, William Henry ......Crediton.
Cherrington, Geo. WiddowsonLondon.
Dobson, George Turner ......Holsworthy.
Gamble, Arthur Gompertz...Grantham.
Gordelier, Frank Heward ...Sittingbourne.
Holmes, William Albert......Kendal.
Hugill, Arthur Major ....London.
Isaac, John Percy ....London.
Jelley, George William ......Coventry.
Jenner, William Edward ...Sandgate.
Kirk, William Peele ....Retford.
Milner, Thomas ....Thirsk.
Richardson, William Henry..Boston Spa.
Scammell, Luther Robert ...Adelaide.
Smith, Frederick Adolphus...Macclesfield.
Thomas, John ....Aberystwith.
Williams, James Edward ...Louth.
Williams, Thomas Henry ...Plymouth.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Barber, William ....Shefford.
Barton, Francis ....Guernsey.
Cooper, William Ecklee ......Upton-on-Severn.
Cox, Frederick John ....Newark.
Harrison, Peter Webster ...St. Helens.
Hope, Arthur Peach ....Uppingham.
Lewis, Jonas Henry ....London.
Mackenzie, Donald ....Dingwall.
Pope, Albert Harry ....Southport.
Robinson, George Duncan R.York.
Taylor, James ....Bayswater.
Watson, William Malcolm...Southport.
Willis, Joseph Danington ...Northampton.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea were restored to the Register of Chemists and Druggists:

William Henry Fisher, 37, Beresford Road, London, N.

Alexander Scott Hill, 68, Devonshire Road, Holloway, London, N.

Charles Edward Mitchell, 31, Cottenham Road, Holloway, London, N.

Charles Wilkinson, 4, Raglan Street, Coventry.

Additions to the Register.

The Secretary reported that

Charles Robert Fenn, 83, Regency Street, London, S.W.

and

Augustus Thomas Isaac, Orange, New South Wales, having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been duly supported by medical practitioners, their names had been placed on the Register.

Payment of Subscriptions.

Mr. Greenish drew attention to the case of a member who had handed his subscription to a traveller in April last, but the latter forgot to tender it to the Secretary until May 1, when the Secretary said he was unable to receive it, as the gentleman's name had been struck off the list of members.

The President said such cases sometimes occurred in the country, where the subscriptions were paid to the local secretaries in time, but were not forwarded to the office. In such cases he apprehended, the local secretaries being representatives of the Society, the members were entitled to be retained on the list.

Mr. Bottle said in the case before the Council the traveller was not its agent and he could not see how the bye-law could be departed from. The only thing that could be done would be to restore the member on payment of the minimum fine.

Mr. Greenish said he believed the traveller through whose forgetfulness the difficulty arose was willing to pay the fine himself, but the member would not allow it.

Mr. Symes suggested that in the case of country members it would be much better that they should forward their subscriptions direct to the office, and be entitled to deduct the cost of the post office order.

Mr. Atkins thought the gentleman in question had a grievance. He had complied in spirit, if not in letter, with the regulations.

Mr. Schacht asked if a post office order received on May 1 would be taken.

The Secretary said if the envelope bore the post mark of April 30, it would be received, being taken as a payment in April. It was stated continually in the Journal that April 30 was the last day on which subscriptions could be received.

Mr. Hampson thought the Secretary had cut the ground from under his own feet. If he received a post office order on May 1, why should not he receive cash, which was better?

Mr. Churchill thought the office was made for the convenience of subscribers, not the subscribers for the convenience of the office. He would move that the gentleman's name be restored without a fine.

The Secretary said he would rather pay the fine himself.

Mr. Robbins thought this case should be dealt with the same as that of a person who sent a post office order.

The Secretary read the resolution under which he had acted for several years past, under which all subscriptions not paid in March were applied for directly by himself, notice thereof being sent to the local secretaries.

Mr. Richardson thought the Council must support the authority of its officers. The line must be drawn somewhere.

Mr. Williams said the officers must act according to the bye-laws.

The Assistant Secretary explained that subscriptions that came to hand after the office was opened on the 1st of May were not received. Remittances found in the letter-box before the office opened on that day were received.

Mr. Frazer said as soon as a post office order was issued, the money became virtually the property of the Society. There was a wide difference between that and paying money to an outsider who might do anything he liked with it.

Mr. Bottle suggested that a half-guinea, which the gentlemen in question had sent at the same time as a subscription to the Benvolent Fund, be received as the fine. The bye-laws did not say to what the fine should be applied.

This recommendation did not meet with any approval.

Mr. Greenish said the gentleman felt he had a grievance, and he himself did think it was a pity that, under the circumstances, the money had not been received.

The Vice-President also thought the rules had been carried out with greater strictness than necessary. He understood that cheques were received and he did not see that the agency of a banker was different to that of any other person.

The President said there was no doubt that this case was clearly within the rules, but he did not think the good of the Society was promoted by over strictness in such a matter. With regard to the question of local secretaries receiving subscriptions he hoped the Council would agree to a resolution proposed by Mr. Greenish:—

"That the regulations regarding the closing of the Registrar's accounts with local secretaries, so far as regards annual subscriptions being paid before the 1st of May, be referred to the Finance Committee for consideration and report."

Mr. Williams suggested that the resolution should be enlarged, and that the Committee should consider the whole question of local secretaries collecting subscriptions at all.

Mr. Rimmington thought it would be a great inconvenience to country members if local secretaries were not empowered to collect subscriptions.

Mr. Savage said he should not object to the scope of the inquiry being enlarged, but he agreed with Mr. Rimmington that it would be a disadvantage to the Society to alter the regulation.

The President said the mover had consented to the addition of the words "and to consider the desirability of relieving local secretaries from the duty of receiving subscriptions."

The motion was carried unanimously.

Reports of Committees.

Finance.

The report of this Committee was received and adopted, and various accounts ordered to be paid.

The Vice-President drew attention to the increase in the gas account as compared with the same quarter last year. The Committee was unable to explain how it occurred, and he should like to know if any experiment had been made with a view to test if any leak existed; for instance, if the state of the meter had been carefully taken at night and in the morning, all burners having been carefully turned out in the meantime.

The Secretary said that Professor Redwood, himself, and the gasfitter were now carefully investigating the matter, and he hoped to be able to place some statistics before the next meeting of the Committee.

Several other suggestions were made with regard to the mode of examining and checking the accounts.

BENEVOLENT FUND.

The report of this Committee included recommendations of the following grants :—

£15 to a member of the Society, in business for fifteen years, but latterly suffering from sickness.

£10 to a member of the Society, aged 69, having failed in business and being unable to obtain a situation.

£5 to a registered chemist and druggist (female), who has had three previous grants of £10 each.

£10 to the widow of a late member. Applicant has had five previous grants.

£15 to the widow of a registered chemist and druggist, having three children dependent on her.

£10 to the widow of a registered chemist and druggist.

£10 to a former associate of the Society suffering from ill-health.

£10 to the orphan boys of a registered chemist and druggist.

£5 to the widow of a registered chemist and druggist.

£5 to the widow of a late member who had £10 in October last.

In two other cases the Committee made no recommendations, in one instance a grant having been made very recently. Another grant had also been recommended, but the Secretary stated that he had that morning received information of the death of applicant.

An application had been received from the managers of the establishment in Belgium, where an orphan child had been placed, for some years past, asking if the annual payment would be renewed, as otherwise the child must be returned to her mother. The Secretary was desired to make further inquiries.

Mr. ROBBINS moved that in the case of the applicant who had died, the amount of the grant should be handed over to the widow.

The PRESIDENT thought the Council should wait and see if application were made. It was not competent to the Council to make a grant to persons on whose behalf no application had been made.

The report and recommendations of the Committee were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee included the usual report from the Librarian, to the following effect :—

Attendance during the day: highest, 29, lowest, 9, average, 21; Evening, highest, 19, lowest, 8, average, 12. Circulation of books: town, 150; country, 66; carriage paid, £1 7*s.* 7½*d.* He had also reported the following donations to the Library :—

Analytical Index to the Records known as the Remembrancia, 1579–1664; London, 1878. From the Corporation of the City of London.

Institute of Chemistry of Great Britain and Ireland, Register of Fellows and Associates, 1879. From the Institute.

Berzelius (I. J.), Traité de Chimie, trad. par A. J. L. Jourdan [et M. Esslinger], 1829–33, 8 vols.

Whitlaw (C.), New Medical Discoveries, with a Defence of the Linnean Doctrine, and a Translation of his Vegetable Materia Medica, 1829, 2 vols.

New London Dispensatory, containing a translation of the Pharmacopœia Londinensis, etc., 2 ed.; also a translation of Magendie's Formulary, by T. Cox and C. W. Gregory, 1835, 2 vols.

Liebig (J. v.), Organic Chemistry in its Applications to Agriculture and Physiology, edited by L. Playfair, 1840.

Journal de Pharmacie, 1835-6, sundry numbers. From the Rev. C. E. Drew.

Muter (J.), Introduction to Pharmaceutical and Medical Chemistry, 2 ed., 1879; Introduction to Analytical Chemistry, 2 ed., 1878. From the Author.

Tommasi (D.), Riduzione del Cloruro di Argento e del Cloruro Ferrico, 1878; Riduzione del Cloralio, 1878; Azione dei Raggi Solari sui Composti Aloidi d'Argento, 1878. From the Author.

Victorian Chemists' Assistants' Association, Sixth Annual Report, Rules, Catalogue of Library and Museum, etc., 1879. From the Association.

Squibb (E. R.), Notes on the Estimation of Urea, and on the Revision of the United States Pharmacopœia in 1880, 1879; Fluid Extracts by Repercolation, 1879; Proposed Legislation on the Adulteration of Food and Medicine, etc., 1879. From the Author.

The Committee recommended that the usual letters of thanks be forwarded.

The Committee recommended the purchase of the following books for the library :—

General Fund :—

Wurtz (Ad.), Dictionnaire de Chimie, latest ed.

Buchoz (P.), Herbier de la Chine, 1788–9.

Hanbury Fund :—

Bentham (G.), Flora Hongkongensis, 1861.

Griesbach (A.), Flora of the British West India Islands, 1864.

The Curator had reported the attendance in the Museum to have been as follows :—During the day, average, 10; evening, average, 6. He had also reported the following donations to the Museum :—

Fresh Specimens of Biennial Henbane, from Mr. A. P. Balkwill.

Specimens of the Seed of *Psoralea corylifolia*, from India, from Messrs. Corbyn, Stacey and Co.

A dried Ostrich Stomach, as used by the South American Indians for indigestion, from Dr. Symes.

Specimens of Queensland Sassafras Bark, Queensland Sandal Wood (*Eremophila Mitchelli*), the Stem of *Piper Novæ-Hollandiæ*, the bark of a species of *Achras*, known as sweet bark from Queensland, and a fine Fruit of the Trinidad Cocoa Tree, from Mr. Thomas Christy.

Three remarkably fine crystals of Codeia, from Messrs. T. and H. Smith and Co.

A new variety of Salep, the root of West Indian Ipecacuanha (*Asclepias Curassavica*), false Sarsaparilla from St. Vincent, and specimens of naturally crystallized Realgar, from Mons. C. Chantre. The last specimen was obtained from a crack in the earth which served as a vent to a burning coal mine called Ricamarie, near St. Etienne.

The Curator had also reported that he had received from Dr. O. Hesse, specimens of the alkaloids to illustrate his recent paper in the *Pharmaceutical Journal*.

The Committee recommended that the usual letters of thanks be forwarded.

The Curator had reported that he had forwarded nine duplicate specimens to the Society's Museum in Edinburgh.

He had also reported that nineteen duplicate specimens had been forwarded to the Leeds Chemists' Association.

Professors Redwood, Bentley and Attfield had reported that the progress of their respective classses was satisfactory.

Professor Bentley had reported that his class had increased 25 per cent. over 1878.

The Committee recommended the purchase of the collection of Malayan specimens of materia medica offered by Mr. Collins.

The report and recommendations of the Committee were received and adopted.

Mr. SHAW said the Association at Liverpool was now re-arranging the museum, and would be very much obliged by the Council granting a set of labels, which he understood were in possession of the Society.

The PRESIDENT said he had no doubt that if Mr. Shaw would specify what was wanted, and send an application to the Committee, which met next week, it would be acceded to.

HOUSE.

This Committee recommended that a memorial be addressed to the Board of Works with a view to getting the roadway in Great Russell Street relaid with wood. Also some other minor matters in connection with the house.

Mr. HILLS asked if any reply had been received to the memorial.

The PRESIDENT said it had been ascertained that it would be useless to make any application of the sort before Michaelmas; but if one were sent in then, there might be a chance of its being acceded to.

The report and recommendations were received and adopted.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor giving information as to the progress of cases which had been placed in his hands. In one case, the defendant, Mr. Mumby, had paid the penalty of £5 and costs. The appeal in the case of the Society *v.* The London and Provincial Supply Association, Limited, was not likely to come on before November.

A communication was read from Mr. James Galloway, Great Horton, authorizing the erasure of his name from the register. In two cases it was recommended that the Solicitor be instructed to commence proceedings, one of the cases having been a long time under consideration, and with regard to which a great deal of correspondence has taken place.

The PRESIDENT moved

"That the Council go into Committee to consider the various items in the report."

Mr. SYMES had no objection, but thought it would be well if some reference were made in the report to the subjects on which the Council went into Committee, so that members might see that the matters referred to were being considered.

After some further conversation on this subject, it was unanimously resolved to go into Committee to consider certain cases of alleged breaches of the Pharmacy Act.

The various cases having been discussed in detail, the Council resumed, and the report and recommendations of the Committee were adopted unanimously.

It was moved by Mr. WILLIAMS, seconded by Mr. GOSTLING, and carried unanimously, that a certain firm of solicitors, who had made inquiry as to the form of appeal from a decision of the Registrar, be informed that any such appeal must be made in writing.

APPOINTMENT OF PROFESSORS AND CURATOR FOR THE ENSUING YEAR.

Professor REDWOOD was reappointed Professor of Chemistry and Pharmacy for the ensuing year.

Professor BENTLEY was reappointed Professor of Botany and Materia Medica for the ensuing year.

Professor ATTFIELD was reappointed Professor of Practical Chemistry for the ensuing year.

Mr. HOLMES was reappointed Curator of the Society's Museum for the ensuing year.

LIST OF LOCAL SECRETARIES, 1879–80.*

The following were proposed as Local Secretaries for the ensuing year:—

Towns eligible.	Names of persons appointed.
Aberdare	Thomas, Watkin Jones.
Aberdeen	Davidson, Charles.
Abergele	Hannah, John.
Aberystwith	Davies, John Hugh.
Abingdon	Smith, William.
Accrington	Sprake, David Lewis.
Altrincham	Hughes, Edward.
Andover	Gould, Robert George.
Arbroath	Shield, George.
Ashbourne	Bradley, Edwin Silvester.
Ashby-de-la-Zouch	Johnson, Edwin Eli.
Ashton-under-Lyne	Bostock, William.
Aylesbury	Turner, John.
Ayr	
Banbury	Ball, George Vincent.
Banff	Ellis, Bartlett.
Bangor	Baker, Henry Villars.
Barnsley	Badger, Alfred.
Barnstaple	Goss, Samuel.
Barrow-in-Furness	Steel, Thomas.
Bath	Commans, Robert Dyer.
Beaumaris	
Bedford	Cuthbert, John M.
Belper	Ashton, John.
Berwick	Carr, William Graham.
Beverley	Hobson, Charles.
Bewdley	
Birkenhead	Nicholson, Henry.
Birmingham	Southall, William.
Bishop Auckland	Leigh, John James.
Blackburn	Pickup, Thomas Hartley.
Blackpool	Harrison, John.
Blandford	Bird, Matthew Mitchell.
Bodmin	Williams, Joel Drew.
Bolton	Dutton, George.
Boston	
Bournemouth	Duncan, Alexander.
Bradford (Yorkshire)	Rimmington, Felix W. E.
Brecon	Meredith, John.
Bridgnorth	Deighton, Thomas Milner
Bridlington	Forge, Christopher.
Bridport	Tucker, Charles.
Brighton	Gwatkin, James Thomas.
Bristol	Stroud, John.
Buckingham	Sirett, George.
Burnley	Thomas, Richard.
Burslem	Blackshaw, Thomas.
Bury	
Bury St. Edmunds	Youngman, Edward.
Buxton	Barnett, Alexander.
Calne	
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Hollway, Alfred Brown.
Cardigan	Jones, John Edward.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, Richard M.
Carnarvon	Lloyd, William.
Chatham	Crofts, Holmes Cheney.
Chelmsford	Baker, Charles Patrick.
Cheltenham	Smith, Nathaniel.
Chester	Baxter, George.
Chesterfield	Greaves, Abraham.
Chichester	Long, William Elliott.
Chippenham	Coles, John Coles.
Christchurch	Green, John.
Cirencester	Mason, Joseph Wright.
Clitheroe	
Cockermouth	Bowerbank, Joseph.
Colchester	Cordley, William Bains.
Congleton	Goode, Charles.
Coventry	Wyley, John.
Crewe	McNeil, James Norton.
Cricklade	
Croydon	Barritt, George.
Darlington	Robinson, James.
Deal	Green, John.
Denbigh	Edwards, William.
Derby	Stevenson, Richard.
Devizes	Evans, John.

* Local Secretaries are appointed in all towns in Great Britain which return a Member or Members to Parliament, and in such other towns as contain not less than three Members of the Society or Associates in Business.

Towns eligible.	Names of persons appointed.
Devonport	Codd, Francis.
Dewsbury	Matterson, Edward H.
Diss	Gostling, Thomas Preston.
Doncaster	Howorth, James.
Dorchester	Evans, Alfred John.
Dorking	Clift, Joseph.
Dover	Bottle, Alexander.
Droitwich	Taylor, Edmund.
Dudley	Gare, Charles Hazard.
Dumfries	Allan, William.
Dundee	Hardie, James.
Dunfermline	Stiell, Gavin.
Durham	Sarsfield, William.
Eastbourne	Gibbs, Joseph.
Edinburgh	Mackay, John.
Elgin	Robertson, William.
Ely	Pate, Henry Thomas.
Evesham	Dingley, Richard Loxley.
Exeter	Delves, George.
Eye	Bishop, Robert.
Falkirk	Murdoch, David.
Falmouth	Newman, Walter Francis.
Fareham	Batchelor, Charles.
Faversham	Underdown, Fredk. W.
Flint	Jones, Michael.
Folkestone	Goodliffe, George.
Forfar	Ranken, James A.
Frome	
Gainsborough	Spouncer, Henry Thomas.
Gateshead	Elliott, Robert.
Glasgow	Kinninmont, Alexander.
Gloucester	Meadows, Henry.
Gosport	Hunter, John.
Grantham	Cox, John.
Gravesend	Clarke, Richard Feaver.
Greenock	Fraser, Charles.
Grimsby, Great	Botterill, George Thomas.
Guernsey	Arnold, Adolphus.
Guildford	Martin, Edward W.
Haddington	Watt, James.
Halifax	Dyer, William.
Harrogate	Davis, R. Hayton.
Hartlepool	Jackson, William G.
Harwich	Bevan, Charles F.
Hastings and St. Leonards	Jameson, William E.
Haverfordwest	Williams, William.
Hawick	
Helensburgh	Harvie, George.
Helston	Troake, Marler H.
Hereford	Jennings, Reginald.
Hertford	Lines, George.
Hexham	Gibson, John Pattison.
Heywood	Beckett, William.
Hitchin	Ransom, William.
Horncastle	Kemp, William.
Horsham	Williams, Philip.
Huddersfield	King, William.
Hull	Bell, Charles Bains.
Huntingdon	Provost, John Pullen.
Huntly	Chalmers, George.
Hyde	Wild, Joseph.
Hythe	Lemmon, Robert Alce.
Inverness	Galloway, George Ross.
Ipswich	Anness, Samuel Richard.
Jersey	Ereaut, John, jun.
Kendal	Severs, Joseph.
Kidderminster	Hewitt, George.
Kilmarnock	Borland, John.
King's Lynn	Palmer, Wm. Jos.
Kingston-on-Thames	Walmsley, Samuel.
Kirkcaldy	Storrar, David.
Knaresborough	Potter, Charles.
Knutsford	Silvester, Henry Thomas.
Lancaster	Bagnall, Wm. Henry.
Launceston	Eyre, Jonathan Symes.

Towns eligible.	Names of persons appointed.
Leamington	Davis, Henry.
Leeds	Reynolds, Richard.
Leek	Johnson, William.
Leicester	Clark, Walter Beales.
Leighton Buzzard	Readman, William.
Leith	Finlayson, Thomas.
Leominster	Davis, David Frederick.
Lewes	Martin, Thomas.
Lichfield	Perkins, John Jaquest.
Lincoln	Maltby, Joseph.
Liskeard	Young, Richard.
Liverpool	Abraham, Thomas Fell.
Llandudno	Williams, Thomas.
Longton	Prince, Arthur G.
Loughborough	Paget, John.
Louth	Hurst, John B.
Lowestoft	Sale, Thomas J.
Ludlow	Woodhouse, George.
Lyme Regis	Thornton, Edward.
Lymington	Allen, Adam U.
Macclesfield	Bates, William Isaac.
Macduff	Henry, James Hay.
Maidenhead	Walton, Ralph.
Maidstone	Rowcroft, Albert Edward.
Maldon	Wallworth, David.
Malmesbury	Brown, Francis James.
Malton	Hardy, George.
Malvern	Metcalfe, Edmund Henry.
Manchester, etc.	Wilkinson, William.
March	Davies, Peter Hughes.
Margate	Candler, Joseph Thomas.
Marlborough	
Marlow	
Merthyr Tydvil	Smyth, Walter.
Middlesborough	Robson, James Crosby.
Midhurst	
Monmouth	Key, Hobson.
Montgomery	
Montrose	Burrell, George.
Morecambe	Birkett, John.
Morpeth	Marshall, George T.
Neath	Hibbert, Walter.
Newark	March, William.
Newbury	Hickman, Frederick.
Newcastle-under-Lyme	Cartwright, William.
Newcastle-on-Tyne	Martin, Nicholas H.
Newport (I. of Wight)	Orchard, Herbert Joseph.
Newport (Mon.)	Seys, James Ancas.
New Radnor	
Newton Abbot	Poulton, John.
Newtown	Owen, Edward.
Northallerton	Warrior, William.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	Fitzhugh, Richard.
Nuneaton	Iliffe, George.
Oldham	Hargraves, H. Lister.
Oswestry	Saunders, George James.
Over Darwen	Hargreaves, Wm. Henry.
Oxford	Prior, George Thomas.
Paisley	Hatrick, William.
Pembroke	
Pembroke Dock	John, David W.
Penrith	Kirkbride, William.
Penzance	Cornish, Henry Robert.
Perth	
Peterborough	Heanley, Marshall.
Petersfield	Edgeler, William B.
Plymouth	Balkwill, Alfred P.
Pontefract	Bratley, William.
Poole	Penney, William.
Portsmouth, etc.	Rastrick, Joseph L.
Preston	Barnes, James.
Ramsgate	Morton, Henry.
Reading	Hayward, Wm. Griffith.

Towns eligible.	Names of persons appointed.
Redditch	Mousley, William.
Retford	Clater, Francis.
Richmond (Yorks)	Thompson, John Thomas.
Ripon	Judson, Thomas.
Rochdale	Taylor, Edward.
Rochester	Harris, Henry William.
Rothesay	Duncan, William.
Runcorn	Whittaker, William.
Rugby	Chamberlain, Arthur G.
Ruthin	Bancroft, John James.
Ryde (Isle of Wight)	Pollard, Henry Hindes.
Rye	Waters, William Allen.
St. Albans	Ekins, Arthur Edward.
St. Andrews	Govan, Alexander.
St. Austell	Hern, William Henry.
St. Ives (Cornwall)	Young, Tonkin.
Salisbury	Atkins, Samuel Ralph.
Sandwich	Baker, Frank.
Scarborough	Whitfield, John.
Seacombe	Walker, John Henry.
Selby	Cutting, Thomas John.
Shaftesbury	Powell, John.
Sheerness	Bray, John.
Sheffield	Ward, William.
Shields, South	Mays, Robert J. J.
Shipley	Dunn, Henry.
Shoreham	
Shrewsbury	Cross, William Gowen.
Slough	Griffith, Richard.
Southampton	Dawson, Oliver R.
Southport	Ashton, William.
Spalding	Shadford, Major.
Stafford	Averill, John.
Stalybridge	Brierley, Richard.
Stamford	
Stirling	Duncanson, William.
Stockport	Kay, Samuel.
Stockton-on-Tees	Brayshay, Thomas.
Stoke-on-Trent	Adams, Jonathan Henry.
Stourbridge	Bland, Thomas Frederick.
Stratford-on-Avon	Hawkes, Richard.
Stroud	Blake, William F.
Sudbury	Harding, James John.
Sunderland	Nicholson, John Joseph.
Sutton-in-Ashfield	Buckland, E.
Swansea	Griffiths, William.
Tamworth	Allkins, Thomas Boulton.
Taunton	Prince, Henry.
Tavistock	Gill, William.
Teignmouth	Cornelius, Joseph.
Tenby	Davies, Moses Prosser.
Tewkesbury	Allis, Francis.
Thirsk	Thompson, John.
Tiverton	Havill, Paul.
Torquay	Smith, Edward.
Totnes	Keen, Benjamin.
Truro	Percy, Thomas Bickle.
Tunbridge Wells	Howard, Richard.
Tynemouth	
Uttoxeter	Johnson, John Borwell.
Wakefield	Wice, Jonathan H.
Wallingford	Payne, Sidney.
Walsall	Elliott, George.
Wareham	Randall, Thomas.
Warrington	Woods, Joseph Henry.
Warwick	Pratt, Henry.
Watford	Chater, Edward Mitchell.
Wednesbury	Gittoes, Samuel James.
Wellington (Somerset)	Langford, John Brown.
Wenlock	
Westbury	Taylor, Stephen.
West Bromwich	
Weston-super-Mare	Gibbons, George.
Weymouth	Groves, Thomas Bennett.
Whitby	Stevenson, John.
Whitehaven	Kitchin, Archibald.
Wick	Miller, Kenneth.
Wigan	Phillips, Jonathan.
Wigton	
Wilton	
Winchester	Hunt, Richard.
Windsor	Russell, Charles J. L.
Wolverhampton	Brevitt, William Yates.
Woodbridge	Betts, John.
Woodstock	Griffits, John Alonza.
Worcester	Virgo, Charles.
Worthing	Cortis, Arthur Brownhill.
Wrexham	Edisbury, James Fisher.
Wycombe	Furmston, Samuel C.
Yarmouth, Great	Poll, Wm. Sheppard.
Yeovil	Maggs, Thomas Charles.
York	Davison, Ralph.

Previous to the vote being taken,

Mr. WILLIAMS said he wished to make a few observations on the appointment of one of these local secretaries, but it being a personal matter, he must ask the Council to go into Committee.

This having been done, and the Council having resumed, the list was put to the vote and adopted unanimously.

SUPERINTENDENTS OF WRITTEN EXAMINATIONS.

It was unanimously resolved that the superintendence of the written examinations be offered to the local secretaries at the centres where those examinations are held.

Mr. CHURCHILL asked how the new plan worked. There had been complaints of the number of centres not being sufficient.

The PRESIDENT said there was a feeling in some quarters to reduce the number still further.

The VICE-PRESIDENT said there was also a feeling in many quarters that the number should be enlarged.

Mr. SHAW asked why Worcester had been continued as a local centre, when the Committee had recommended that it should be omitted?

The PRESIDENT presumed the Council must have ordered it. At any rate that was not the question before the Council then.

Mr. ATKINS said he still believed that individual cases of hardship had occurred from the present scheme of local centres, though on the whole the reduction in number might have been an advantage. He hoped that another year the Committee would take careful account of geographical considerations and railway facilities in deciding on these centres. He also hoped that the Preliminary examinations were still in a transition state. He should not be satisfied until this examination, which was purely a scholastic one, was removed from the Society altogether. Nothing in the world could be easier than to demand a certificate from the College of Preceptors or from a university local examination.

COUNCIL EXAMINATION PRIZES.

Messrs. Southall and Moss were appointed to conduct the examinations in the present month for the Council prizes.

Mr. GREENISH proposed an alteration in the regulations providing that candidates should be required to give five days' notice of their intention to compete for these prizes, instead of ten as at present.

The ASSISTANT SECRETARY explained that five days would be sufficient, and, in fact, more convenient than ten.

The motion was carried unanimously.

Mr. CHURCHILL asked who fixed the dates for the Major examination.

Mr. Williams said the Council fixed the months. The exact days were fixed by the office, according to the number of candidates. He had proposed formerly that the examinations should take place every month instead of every alternate month, a change which, he thought, would have proved more convenient; this suggested alteration, however, did not meet with the approval of the Board of Examiners. This month there were 172 candidates coming up.

Report of Examinations.

June, 1879.

ENGLAND AND WALES.

Preliminary Examination.

Seven certificates were received in lieu of the Society's examination:—

3 College of Preceptors.
4 University of Cambridge.

Sales of Poisons by Co-operative Stores.

Mr. Williams was next called upon by the President to move a resolution of which he had given notice with regard to co-operative societies selling or dispensing poisons.

The President asked if the question should be discussed in Committee.

Mr. Williams said he had no objection to what he had to say being published.

Mr. Shaw thought it was not desirable to show their hand, and on the question being put to the vote it was resolved to go into Committee.

The motion was discussed at considerable length, but on being put to the vote it was not carried.

Sale of Patent Medicines.

Mr. Hampson then moved the following resolution, of which he had given notice:—

"That the General Purposes Committee take into consideration the largely increasing sale of 'patent medicines' containing scheduled poisons, by grocers, general dealers, and other unregistered persons, and report thereon, more especially with regard to the advisability of endeavouring to restrict the sale of such 'patent medicines' to persons registered under the Pharmacy Act of 1868."

He said he was very desirous that this Committee should take this subject into earnest consideration. It was evident to all that the sale of poisons under the cover of the patent medicine stamp was a growing evil. He heard the other day that a grocer's assistant was asked what was the dose of chlorodyne, and replied a tea-spoonful. When the Pharmacy Act of 1868 was obtained, it was to all intents and purposes an Act for regulating the sale of poisons, but if anyone were able to sell poison upon affixing a patent medicine stamp to it, evidently the Act was of little or no use. He was told that in the country wholesale houses sent out two-ounce bottles of laudanum by the gross with a stamp on, and that opium itself was also sold in this way. Tincture of aconite was sold by grocers under a stamp, and in fact if any adventurous quack chose to put up the dilute hydrocyanic acid of the Pharmacopœia, under a stamp, and say that 2 or 3 drops were to be taken in water in case of sickness, it might be done with impunity. The time had come when this matter should be considered, for it was never intended that grocers, tailors and others should become the vendors of poisons. If the spirit of the Act were to be carried out, those who knew something about medicines should alone sell these things. The very fact that a person had to go into a special shop in order to purchase a poison was to a certain extent a safeguard; but if people were able to get it at any ordinary shop, the use of poisons would become so indiscriminate that a parliamentary commisssion or inquiry would be the probable result. He did not ask the Council to come to any decision at present, but simply to refer the matter to the Committee.

Mr. Savage seconded the motion.

Mr. Hills asked if it would not be better to refer the subject to the Committee for considering amendments to the Pharmacy Act.

Mr. Hampson thought not; that was a special Committee for a particular purpose.

Mr. Williams said that Committee had considered that any change of the law in this direction was unnecessary.

The President said the great point of the motion was patent medicines. He did not recognize a bottle of laudanum as a patent medicine simply because it had a stamp affixed to it, and he believed that if a prosecution were instituted in such a case it would be found that the law did not protect it. With regard to patent medicines he did not see that it mattered who sold them. If any one came to him for a bottle of chlorodyne, and asked him what was the nature of it, he said he did not know what it contained. In fact, he never recommended patent medicines at all, but rather discouraged the sale of them.

Mr. Greenish suggested an alteration of the wording of the motion to the effect that the Committee take into consideration the largely increasing sale of scheduled poisons by grocers and others under the guise of patent medicines.

Mr. Frazer said if patent medicines were within the law this motion was not required, and if they were not he did not think it was desirable to bring them within it for reasons which he had frequently stated. It was contrary to his notions of trade, and he did not think it would be wise, because it was very doubtful, if chemists would obtain what they asked, whilst they might most probably lose some of the privileges they at present possessed.

Mr. Rimmington thought Mr. Greenish's suggestion would be an improvement.

The Vice-President, on the contrary, thought Mr. Hampson's original form was better.

Mr. Hampson also said he preferred the original wording. He demurred to the statement of the President that it did not matter who sold a bottle of chlorodyne, because it contained several scheduled poisons, and in the interest of the public as well as in justice to themselves, it was desirable that only registered persons should be allowed to sell patent medicines containing poisons. He equally demurred to Mr. Frazer's view that a change was not necessary or desirable. Putting aside the interest of the public, which was of course paramount, it was the privilege of registered persons to deal in poisons.

The President remarked that Parliament fully considered the question when the Pharmacy Act was passed, and said that nothing in the Act should interfere with the making or selling of patent medicines.

Mr. Frazer said his point was that if patent medicines were included in the Act there was no need of further legislation.

Mr. Hampson said he did not assume that the Council had the power to restrict the sale of patent medicines, he simply asked that the Committee should consider the matter.

Mr. Williams thought the Council was now doing the work of the Committee in discussing the merits of the question. The motion was simply that the Committee consider it and report.

The resolution was then put and carried *nem. con.*

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee.

Wednesday, July 2, 1879.

Present—G. F. Schacht, President, in the chair; Messrs. Greenish, Ellinor, Carteighe, Symes, Williams and Attfield.

The minutes of the previous meeting were read and confirmed.

Professor Attfield, Honorary General Secretary, reported the work done since the previous meeting of Committee, including matters relating to the editing, printing, publishing and delivery to members of the Year-Book; the grants in aid of research; correspondence respecting improper use of the membership of the Conference; correspondence respecting the Bell and Hills Fund books; compilation and distribution of the list of subjects for research; collection of subscriptions; organization of the approaching meeting at Sheffield; correspondence with members likely to work on the Executive Committee in 1879-80; and, arrangements for inviting all registered chemists and druggists not already members to join the Conference.

A letter was read from Mr. Siebold, editor of the Year-Book, reporting that the manuscript of the volume for 1879 would be completed a fortnight before the annual meeting. A meeting of the Committee of Publication was ordered to be convened as soon as the manuscript was received, with power to make all arrangements for the issue of the volume.

Mr. Ellinor, from Sheffield, stated that he was authorized by the Vice-President, Mr. Ward, the Local Secretary, Mr. Maleham, and the members of the Local Committee in Sheffield, to explain that rooms for the general meetings of the Conference on August 19 and 20 had been secured, that a considerable amount of interest and enthusiasm existed locally respecting the meetings, that permission had been obtained for members after the meeting to inspect some of the interesting factories of Sheffield, and that on Thursday, the 21st of August, the local members would invite their visitors to accompany them on a drive through some of the scenery of Derbyshire, visiting "Chatsworth" and "Haddon" *en route.* He ventured to think that their friends would not be disappointed with the welcome they would receive, even although in accordance with annually stated requests, strongly renewed this year, the idea of holding a formal banquet in honour of their guests would not be carried out.

SOCIETY OF ARTS.

The History of Alizarin and Allied Colouring Matters, and their Production from Coal Tar.*

BY W. H. PERKIN, F.R.S.

Lecture I.—Delivered May 8.

In December, 1868, I had the honour of delivering three lectures before this society on the "Aniline or Coal Tar Colours." In these I commenced with mauveine, or the mauve dye, the first discovered of this remarkable series of compounds, and then gave briefly the history of all the other important colouring matters which had been discovered up to that date.

Last year, Mr. Wills, who always arranged the business of this Section so assiduously, wished me to give a further account of these colouring matters, but I was unable to do so then. He, however, asked me again this year, and I was glad to be able to accede to this request, little thinking then, and still less only a few weeks since when I met him full of activity and enthusiasm, that he would so soon be called from our midst, and his career here, so full of promise, ended.

When I promised to bring a paper before you, I thought that I would continue the history of the coal tar colours, from the time I gave the lectures just referred to up to the present time. However, on considering the subject in detail, I found the amount of matter far too large, owing to the great number of discoveries which had been made in this field since then; I therefore thought it best to confine myself to the consideration of the most important of the products which have been obtained, and selected alizarin and allied colouring matters.

In giving you a somewhat brief account of this subject, I think it best first to refer to madder, the dye-stuff which, until 1869, was the only source of alizarin. Up to the date just mentioned madder root was one of the most important dye-stuffs known, the annual value of the imports into the United Kingdom being about £1,000,000 sterling.

* From the *Journal of the Society of Arts.*

The plant that gives this root belongs to the natural order *Rubiaceæ*. It is nearly allied botanically, and in appearance, to the ordinary Galiums, or bedstraws. It is a perennial, with herbaceous stem, which dies down every year, the stalk is square and jointed, and this and the leaves are rough with prickles. The flower is very small, and of a greenish yellow colour. The root is cylindrical and fleshy, and of a reddish yellow colour; this, when dried, constitutes madder. It is one of the oldest known dye-stuffs, and is referred to by Pliny. The principal varieties in cultivation are—*Rubia tinctorum*, *Rubia peregrina*, and *Rubia cardifolia*. It is grown in Holland, South of Germany, France, Italy, Turkey and India. It has been cultivated also in this country, but not with permanent success. It is propagated from suckers, and the time from planting until the roots are drawn is from eighteen to thirty months, and sometimes longer. When dried the roots lose their reddish yellow colour and become of a pale red shade. The process of drying is conducted in the air, or in kilns. When dry the roots are beaten to remove sand, clay and loose skin. They are sent into the market either in this condition or in a ground state. There are also various preparations of madder made, the principal ones being *Fleur de garance*, or flowers of madder, and *garancine*. Their preparation is briefly as follows:—

Fleur de garance is made by soaking ground madder in water, with the addition of a small quantity of sulphuric acid; it is then drained in a filter and well washed. The washings contain a considerable amount of glucose, besides other products, and when fermented yield alcohol, which is suitable for a variety of purposes, but is not fit for drinking unless purified. The washed madder is then pressed and dried, and constitutes *fleur de garance*. On account of the products which have been removed this substance is considerably richer in colouring matter than madder.

Garancine is prepared by first washing ground madder much in the same way as for the preparation of *fleur de garance*, and after being pressed it is mixed with concentrated sulphuric acid, in quantity equal to about half the weight of the madder originally taken. After being thoroughly incorporated with this it is heated with steam for three or four hours, placed on filters, and thoroughly washed, pressed and dried. Tinctorially it is about three and a half times as strong as madder.

Madder will not dye unprepared fabrics; they require to be what is called mordanted. In this case the mordants consist of metallic oxides, those of aluminum and iron being the chief ones. With alumina mordants it produces shades of red and pink, with iron mordants shades of black and purple. These mordants may likewise be mixed, and then produce various kinds of chocolate colour. The value of madder and its preparations is determined by taking weighed quantities and dyeing pieces of mordanted cloth with them, the size of the cloth being always the same; after dyeing the patterns are cleared by treatment with soap, and are then dried; and, of course, according to the depth of the colour, so is the value. Standard specimens are used at the same time for the sake of comparison.

In mordanting cotton goods, the mordants, which are chiefly the acetates of iron and aluminum, are thickened and printed on, either with a machine or blocks. They are "aged," as it is called. This used to be performed by hanging the goods in a moist atmosphere for some days, but now they are passed through properly constructed rooms, kept at the requisite temperature and degree of moisture by steam, and then laid in bundles for a time.

The next process is called "dunging." Its object is to remove the thickening which has been used with the mordants, and also to thoroughly neutralize them, at the same time removing any that has not combined with the fibre. This is accomplished by passing the goods through warm water containing cow dung, but now more commonly containing certain salts, as phosphates, arseniates, etc.; these are called dung substitutes. When this operation has been finished the goods are washed, and are then ready for dyeing.

Dyeing with madder is an operation requiring considerable care, especially as the temperature of the dye-bath must be raised only very slowly, otherwise a loss of colouring matter occurs. This makes the operation take some considerable time, often two hours. If garancin is used the dyeing can be conducted more quickly. In this operation the ground madder, or the garancin, is mixed with the water in the dye-bath. A little chalk is also sometimes added. As the colouring matter of the dye-stuff gradually dissolves in the water, the mordants on the goods take it up. It is important in this process that the mordants should be thoroughly saturated with colouring matter, otherwise they do not resist the after-clearing process so well. When dyed the goods are washed with water and then cleared, as most of the colours are very impure, especially the reds, which have a rusty look. The methods of clearing vary according to the class of goods, madder pinks receiving the greatest amount of treatment and care. In this process soap is largely used, but it will not be necessary to enter into further details, as it would occupy too much time, and I only wish to convey to you a general impression of the application of madder to calico printing.

Before leaving this subject I must refer to another most important application of madder, namely, Turkey red dyeing. This mode of dyeing was introduced into Europe from the East, and is undoubtedly of Indian origin; from India it came to the Levant, and was afterwards introduced into France about 1747. The first Turkey red works in the United Kingdom were established about the end of the last century. Turkey red is remarkable for its brilliancy of colour and permanence, and also for the peculiar nature of the processes employed in its production.

For dyeing Turkey red the cotton is first prepared by treatment with olive oil, which is afterwards oxidized by exposure to the air. The oil is usually employed in the form of an emulsion, made by agitating the oil with a solution of carbonate of soda or potash. The goods are passed through this and then exposed to the air, after which they are treated several times in the same manner. When sufficiently charged with oxidized olive oil they are mordanted with an alumina salt, galls, shumach, or other tannin matter. Cotton thus prepared for dyeing is of a buff or yellowish shade.

In the next operation the dye-bath is charged with madder or garancin, a little shumach, and a quantity of blood. The prepared goods are entered into this bath, and heat gradually applied, until it reaches the boiling point, at which temperature it is kept until the dyeing is complete. The goods are then washed in water, and present a dark, heavy, dull red colour. They are next subjected to the clearing processes, which are two in number. These are performed in large copper boilers, with moveable covers, as the clearing has to be done under pressure. The dyed goods are placed in these, with a mixture of common soda crystals and soap, and boiled under pressure for about six hours. They are then removed, washed in hot water, and again placed in boilers, with a solution of soap, to which chloride of tin (tin crystals) has been added. They are boiled in this, under pressure, for about four hours, and then removed, washed and finished. The first clearing considerably improves the colour, but the last one gives that remarkable brilliancy peculiar to good Turkey red. After all this treatment with soap, we can understand that Turkey red is a very fast colour.

No satisfactory process for printing Turkey red has yet been found. Some time since I made a few experiments on the subject. The cloth prepared ready for dyeing was used, and then printed with the colouring matter; it was then steamed, washed and cleared as above. The colours were very good indeed, but the parts which should be white were still of the yellowish colour of the prepared cloth.

When a Turkey red is wanted in a pattern the cloth is first dyed all over with this colour. If white is required in the pattern, those parts are printed with thickened tartaric acid; if yellow, with tartaric acid and a lead salt; if blue, with tartaric acid and Prussian blue. On passing cloth printed in this manner into a solution of chloride of lime, the parts printed with acid, as they come in contact with this solution, cause chlorine to be evolved and the Turkey red destroyed, thus white is produced. If blue has been printed on with the acid, the red being discharged, blue remains. If a lead salt has been printed on, white is obtained; but when passed through a solution of bichromate of potash, yellow chromate of lead is formed. Of course green can be obtained by combining the last two processes. Black is printed on direct. Most beautiful results are obtained in this manner.

Madder is also employed for woollen goods. It is generally used in combination with other dye-stuffs for the purpose of producing brown, buff, or chocolate colours. But I must pass on, the application of madder being a subject on which books have been written, my remarks are therefore necessarily of only a very general character, though I hope sufficient to give some idea of the processes.

Having seen the importance of madder as a dye-stuff and the methods of applying it to fabrics, it will next be desirable to consider the colouring matters it contains, which render it so valuable.

Scarcely anything was know of these until 1827. At this date, two chemists, Colin and Robiquet, obtained the principal colouring matter in a state of tolerable purity. They extracted ground madder with hot water, and, after treating this extract in various ways, obtained a product which, when heated carefully in a glass tube, gave off a yellowish vapour, condensing into brilliant bright red needles. They named this substance *Alizarin*, from the Levant name of madder, *Alizari*.

But the method they adopted for its preparation, viz., sublimation, rendered it a matter of uncertainty whether alizarin pre-existed in madder or was a product of decomposition of some other body. Dr. Schunck, however, afterwards succeeded in obtaining it without having recourse to sublimation. If further proof were needed it was found in the fact that this colouring matter was capable of dyeing mordanted cloth just in the same way as madder. It exists in madder in only very small quantities, not more than to the extent of one per cent.

Alizarin is nearly insoluble in cold water, and 1000 parts of boiling water dissolve only about three parts of the colouring matter. It is more soluble in alcohol, and from high boiling naphtha it may be crystallized in red needles. When crystallized from alcohol it is obtained in orange-coloured needles.

One of the characteristic properties of alizarin is the beautiful blue violet solution it produces on being dissolved in caustic alkalies. This solution, when viewed by the spectroscope, shows two strong absorption bands, one near to C, and the other at D, and a very faint one near to E. Alizarin also dissolves in ammonia with a purple colour. It forms a red lake with alumina, and a black one with oxide of iron.

Curiously, alizarin is not found in the growing madder root. This is easily seen by expressing some of its juice and treating it with caustic potash. In this way a red-coloured solution is produced, and not a violet one, as would be the case if alizarin were present. This coloration is due to the presence of a substance called *rubianic acid*. This body is a glucoside of alizarin, and when decomposed yields alizarin and glucose. This can be easily effected by boiling it with hydrochloric acid, when alizarin separates as a yellow precipitate. Rubianic acid does not possess dyeing properties.

The decomposition of this glucoside in the madder root occurs partly during the process of drying, but not entirely until it is gently heated with water in the dye-bath. This decomposition is caused by a peculiar ferment called *Erythrozyme*, a product which is destroyed if heated with water to 100° C. This is one reason why the madder dyers have to gently raise the temperature of their dye-bath so that this glucoside may entirely decompose, and all the alizarin be liberated and rendered useful. The importance of this may be easily seen by taking two equal parts of growing madder root, and, after bruising them in a mortar, to throw one into boiling water and the other into cold water. On placing a piece of mordanted cloth in each, keeping the one with boiling water still boiling, and gradually raising the temperature of the other, it will be found that the one in boiling water will have scarcely coloured the mordants, whilst the one in cold water and gently warmed up will have dyed them thoroughly.

There is only one other colouring matter in madder that I need refer to, and that is purpurin. This substance was discovered by Colin and Robiquet, and called by them *Matière colorante rose*. It was afterwards obtained in a somewhat purer state by Debus, and by Wolff and Strecker. This substance is separated from madder by boiling it with a solution of alum; munjeet, however, is its best source. It is precipitated from the alum solution with hydrochloric acid and then further purified. When pure purpurin crystallizes in red or orange-red needles, it differs from alizarin in the way it behaves with alkalies; solutions of these yielding with it beautiful cherry-red colours. It also dissolves in alumina salts with formation of pink solutions, which are fluorescent. The spectrum is also very different from that of alizarin.

It dyes mordanted cloth, forming with alumina mordants a yellowish scarlet. The colours it produces with iron mordants, however, are not at all good. The purpurin colours do not resist soaping well, so that madder prints, in the process of clearing, lose all the purpurin taken on in the dye-bath. It is retained, however, to some extent in the cheaper class, such as garancine styles. From this it will be seen that it is a substance of but little value. It exists in the growing madder-root as a glucoside.

A great deal of controversy has taken place respecting the chemical formula of alizarin. Dr. Schunck proposed $C_{14}H_5O_4$, which, according to the present notation, would be $C_7H_5O_2$, whilst Strecker believed it to be $C_{10}H_6O_3$, and related to chloroxynaphthalic acid, a derivative of naphthalene, so that it has long been supposed that it was possible to obtain alizarin from a coal-tar product, though not from the right one. Still there was a good deal of reason to believe that it was a naphthalene derivative, from the fact that, when oxidized it yields the same acid as naphthalene, namely, phthalic acid. Strecker's formula was the one generally believed in. It is right to mention that Strecker changed his views of this subject afterwards.

The chloroxynaphthalic acid above referred to was supposed to be a chlorine derivative of alizarin, the two bodies being thus related:—

$C_{10}H_6O_3$	$C_{10}H_5Cl\ O_3$
Alizarin.	Chlorinated Alizarin.

And many attempts were made to remove this chlorine and replace it by hydrogen, so as to form alizarin; and eventually Martius and Greiss obtained the substance, $C_{10}H_6O_3$, when investigating some amido derivatives of naphthal, but it was not alizarin. They assumed it, however, to be an isomer of that body.

Some time after the experiments of Martius and Greiss, Graebe commenced some researches on quinone (a body related to benzene). At that time no analogous substance to quinone, related to any other hydrocarbon than benzene, was recognized. However, he was induced to consider chloroxynaphthalic acid as a derivative of a naphthalene quinone, which has since been obtained, and also discovered a chlorinated derivative of a quinone of toluene.

(*To be continued.*)

Obituary.

JOHN THOMPSON.

On Friday, June 20, John Thompson, one of the Founders of the Pharmaceutical Society, and one of its earliest local secretaries, died in the seventy-seventh year of his age.

John Thompson was born at Laversdale, in Cumberland, on January 23, 1803. He was apprenticed to a chemist in Hull—Mr. Foster, of Lowgate—and subsequently engaged as assistant to Mr. Fouracre, of Gloucester. He returned to Hull to the late Mr. Edward Smeeton, with whom, in the capacity of assistant, he removed to Leeds when that gentleman opened his establishment there. By Mr. Smeeton he was very highly esteemed, and at his suggestion, and by his help, he commenced business in Thirsk, in the year 1828, where he greatly prospered. The business then established is now carried on by one of his sons, four of whom are connected with the Pharmaceutical Society. He was interred at Thirsk on Tuesday, the 24th of June, amid signs of universal respect.

Notice has also been received of the death of the following:—

On the 2nd of May, 1879, Mr. Frederick Whiteman, Chemist and Druggist, Vernon Street, Ipswich. Aged 38 years.

On the 2nd of June, 1879, Mr. Richard John Hinsley, Chemist and Druggist, Manchester Road, Bradford. Aged 42 years.

On the 6th of June, 1879, Mr. Benjamin Alfred Eyre, Pharmaceutical Chemist, Tacket Street, Ipswich. Aged 67 years. Mr. Eyre had been a Member ot the Pharmaceutical Society since 1842.

On the 15th of June, 1879, Mr. James Sellick Hicks, Pharmaceutical Chemist, Fore Street, Looe. Aged 40 years. Mr. Hicks had been a Member of the Pharmaceutical Society since 1864.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[315]. Considering the solubility of ammon. chloride in spirit (1 in 50) it would be impossible to obtain a perfect solution from this recipe. The salt should be used in powder, and the insoluble portion shaken up before the "volatile liniment" be applied.

Hastings. D. H.

[316]. A very presentable "jelly" might be made of this, only it should be sent out for convenience in a gallipot with a china or glass spoon. If this did not meet with the intention of the prescriber, it would teach him a lesson on "Incompatibles" and enable him in future to order a mixture that would pour out of a bottle.

Hastings. D. H.

[319]. I should also be glad of a little information about this prescription.

Some time ago the following recipe was brought to be dispensed:—

℞ Litharge . . . . ʒx.
Ol. Olivæ . . . . ℥v.
Ol. Lavand. . . . . ♏ 40.
Ft. ung.

My directions were more vague than A. Y.'s; but as boiling with water was the only way of forming an ointment, except by using wax, the litharge and oil were boiled with water until combination had taken place. The resulting product, though stiff, might still be called an ointment. Shortly after our customer complained of its being darker and harder than what he had got in London. He obtained some more from the same source, which was nearly but not quite white, soft, contained moisture, and had a cooling effect on the skin.

The spirit of emulation being aroused the greater portion of Whit Monday and part of another day were devoted to preparing a fresh lot.

The litharge was found to be contaminated with peroxide, so some fresh, light-yellow protoxide was made by heating carbonate of lead in an iron vessel, from which a much lighter coloured ointment was produced; but still the consistence was too stiff, the colour not quite white enough, and the ointment did not contain sufficient moisture.

The best result was obtained with

Litharge . . . . ʒv.
Ol. Amygd. . . . . ℥iij.
Aq. . . . . ℥iss.

the water being replaced as it evaporated.

I have not had an opportunity of learning whether this retained its appearance and consistence.

The prescription was from the pen of a well-known skin doctor. W.

[321]. This presents a mixture that undergoes chemical decomposition after standing a few hours.

The acid carbonate of soda acting upon the liq. bismuthi displaces ammonia and inevitably precipitates carbonate of bismuth. (This may be proved by filtering the mixture, and washing until it ceases to make lime water turbid. Nitric acid added dissolves the precipitate with effervescence, giving a solution blackened by AmHS.)

Unless the liq. bismuthi had been omitted it would be impossible not to have a deposit.

Hastings. D. H.

[321]. The precipitate was caused by the loss of ammonia. All the bright samples of liq. bismuthi have a slight odour of ammonia. If that was hardly perceptible I should doubt the stability of the compound, particularly if the weather was warm and the customer were to leave the cork out. In such cases I should be disposed to add a few drops of liq. ammon. This addition to the stock bottle, or a mixture, will redissolve the precipitate. The ammonia should be added in small quantities, and the bottle shaken and allowed to stand after each addition. I should tell the customer the cause of the change, and show how the supplying what has been lost restores the mixture. It should be remembered the addition of ammonia only supplies what has escaped from the bottle, and is quite different to adulterating or sophisticating.

H. G. C.

Queries.

[322]. Here is a puzzle to solve; how to make a usable preparation of these ingredients? I had it as an orthodox physician's prescription to prepare.

℞ Tr. Lyttæ . . . . ʒj.
Acid. Sulph: Dil. . . . . ʒij.
Tr. Lavand. Co. . . . . ʒiij.
Vaseline or Prepared Lard . . . ad ℥ij.
M. "for external use."

W. B.

[323]. How should the following be dispensed?—

Sodæ Siccatæ	gtt. 2.
Ex. Nucis V.	gr. $\frac{1}{3}$.
Ex. Gentianæ	q.s.

Ut fiat pilula. Mitte 24.

I enclose a tracing of the prescription from which it will be seen that the gtt. in the first line is very different from the gr. in the second. The prescription is from a well-known and experienced M.D., who could not be consulted at the time. W. S.

[324]. Can any readers of the *Pharmaceutical Journal* throw light on the following?—

℞ Morphiæ (the alkaloid)	gr. 8.
Chloroformi	♏ 60.
Lin. Belladonnæ	ad fl. dr. 4.

Ft. linimentum.

As dispensed by me the greater portion of the morphia, as I expected, remained undissolved, and a "shake the bottle" label was attached. The patient, however, informs me that he has had it before perfectly bright and clear, of a brownish tint (he compared it in colour to tinct. camph. comp.), and about twice as much in bulk as I had sent. I fail to see how this could be done without departing from the formula.

GULIELMUS.

[325]. I should be glad to have the opinion of the readers of the *Pharmaceutical Journal* as to the proper salt of bismuth to use in dispensing the following:—

℞ Bismuthi	ʒij.
Adipis	ʒvj.
Creosoti	♏ v.

M. ft. ung.

I used the subnitrate as being that probably intended, although I must admit that the prescription might as reasonably have been dispensed with either carbonate or oxide. GULIELMUS.

Notes and Queries.

[610]. FURNITURE CREAM.—In reply to A. P. S. the following is an excellent recipe for furniture paste:—

Bees' Wax	$1\frac{1}{2}$ pounds.
Spirit of Turpentine	4 pints.

Dissolve by means of a water-bath in a closed vessel, then add common soap, $\frac{1}{2}$ pound, previously dissolved in 4 pints of water, and stir well together until nearly cold.

A. W. POSTANS.

[610]. FURNITURE CREAM.—I would recommend the following receipt for furniture cream:—

℞ Yellow Wax	℥v.
Turps	Oj.
Castille Soap	℥iss.

Cut the bees' wax in small pieces, and dissolve in the turpentine by a gentle heat; when nearly cool add the soap (first powdered, rubbed up with ℥ij of water), gradually stirring continually until it becomes thick.

FERRI CIT.

[610]. FURNITURE CREAM.—I think A. P. S. will find the following to suit his purpose:—

℞ Ceræ Flav.	$2\frac{1}{2}$ ozs.
Ceræ Alb.	1 oz.
Sapo. Cast.	1 dram.
Ol. Terebinth.	
Aq. Bull.	ana 10 ozs.
Potass. Carb.	1 dram.

Melt the wax and turpentine together, dissolve the soap and potass. carb. in the water and mix while warm, stirring till cold.

Cambridge. G. J. BULL.

[611]. MOORE'S OINTMENT.—I beg to ask through the medium of your Journal, can any of the readers kindly give me a recipe for Moore's or Old Moore's Ointment, much used in Golden Square, West district?

UNGUENTUM.

Correspondence.

LIN. POTASSII IODID. C. SAPONE, B.P.

Sir,—*Apropos* of a new edition of the British Pharmacopœia may I be allowed to suggest that the directions for making the above liniment be made more definite, and also be supplemented by a note as to the appearance it is intended to have when finished.

Ought it to be a solid or a liquid?

Is it meant to be dispensed in a pot or in a bottle?

As it is possible for such questions as these to be asked, I think none can deny that there are grounds for the above suggestion.

The directions say, "mix the two solutions together." Is it intended to add the iodide of potassium solution to the soap solution or *vice versâ*, for the first process results in a solid substance, whilst by adding the soap solution to the iodide of potassium solution a liquid is produced.

There are other difficulties, however, for I have made several experiments, but have had no two results alike, although the same kind of material and the same quantities were used in each case.

There seems to be a difficulty about the soap most advantageous for the purpose; but the experience above recorded would suggest that hard soap is evidently not an "advantageous soap."

I should feel greatly obliged if those who had the framing of the last British Pharmacopœia will come forward and state what this liniment should be like, or rather what they intended it to be like, for, as far as I know the profession, medical men prefer it in liquid form.

However, when lin. potassii iodid. c. sapone, B.P., is prescribed it ought to be dispensed. Here then comes the query. Is it a liquid or a solid or is it both (for it will readily separate into two parts representing each of those conditions), or ought a substance with a jelly-like appearance to be dispensed for it?

An answer that will remove any cause for doubt will be heartily welcomed by W. H. DE B.

"*Quæro.*"—(1) *Trapogon porrifolius*, in flower. (2) Fungus (*Ustilago receptaculorum*) destroying flowers of goat's beard. (See Cooke, 'Microscopic Fungi,' pl. v., fig. 92–94.

Mr. J. R. Thompson is thanked for his communication.

"*Nux.*"—(1) *Eriophorum polystachyon.* (2) *Rhinanthus Crista-Galli.* (3) *Stellaria graminea.* (4) *Crepis setosa.* (5) *Sedum acre.*

G. R. Y.—Several formulæ for syr. ferri lactophosphatis have already been given in the present series of this Journal. Among others, see that sanctioned by the Paris Society, vol. vii., p. 1041.

E. K. C.—We shall be glad to hear the result of the further experiments you propose to make.

W. C. S. (Luton).—The information will be found in the "Students' Numbers" of the medical journals which are issued previous to the opening of the medical schools.

C. J. Bennett.—We know of no better work for the purpose than the one mentioned.

"*Gulielmus.*"—(1). *Trifolium minus.* (2). *Carex vulpinus.* (3). *Arrenatherum elatior.* (4). *Trifolium repens.* (5). *Lychnis Flos-Cuculi.* (6). *Cardamine pratensis.*

"*Orchis.*"—(1). *Orchis maculata.* (2). *Gymnadenia Conopsea.* (3). *Habenaria bifolia.*

R. Roberts.—(1). *Orchis maculata.* (3). Send specimen with leaves. (6). *Ceterach officinarum.* Nos. 2, 4 and 5 are correctly named.

G. Stevens.—Recipes for "Nervine Balsam" will be found in the Journal for March 30, 1878, vol. viii., pp. 773 and 782.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Maleham, Nemo, Strachan, J. B. P., G. R. Y., W. C. S., Hirudo, Quaero.

SWEET SPIRIT OF NITRE.—WHAT IT WAS, IS, AND OUGHT TO BE.

BY W. SMEETON.

Under the above comprehensive title appeared a paper, written by Mr. Rimmington, of Bradford, in the November number of the Journal for 1877. It provoked a discussion and the facts that appeared to come out were that the ethereal liquid which is produced when alcohol and nitric acid are distilled together by the B.P. process is a compound of alcohol, nitrite of ethyl, aldehyde, and perhaps other unknown substances, and that the B.P. process would always yield an article containing the same proportion of the same ingredients. But at the outset, Mr. Rimmington condemned the B.P. process as being unnecessarily complex, and one that probably did not meet with universal adoption. Of course this might be said of any process, and the quantity to be operated upon will also be a modifying agent. Mr. Rimmington's remarks respecting the directions to allow the still to cool before adding more acid were quite to the point; but if, on the other hand, the whole of the acid is added to start with the action is very violent, and if the quantities dealt with are large, it is almost sure to lead to loss of ether. If the acid is added later on without waiting for the cooling, red fumes are apt to come over. In this dilemma we are left, and we should have been under obligation had Mr. Rimmington pointed out a more excellent way. Mr. Umney has also stated that nitre made by the B.P. process was unfavourably received, and I suppose most manufacturers must occasionally have found the result unsatisfactory.

Just before the British Pharmacopœia came out, Professor Redwood read a very exhaustive article on spirit of nitre, explaining the B.P. process, and briefly reviewing other processes. The Edinburgh and Dublin forms of making hyponitrous ether first, were dismissed as not being applicable for large quantities and expensive. There may be something in this, for whatever Professor Redwood states is so well considered that it may always be taken as correct. Still, after trying several processes, I have come to the conclusion that with the quantities with which I deal, none is so satisfactory as the Edinburgh plan. It is as easy and takes less time, but what is of much more moment, it makes a nitre that is very pleasant and uniform in character. I am not sure it is the best plan, but it is the best I know, and I do not find it very difficult to manipulate.

I take twelve pints of alcohol and add to it carefully three pints of nitric acid either at once or in successive portions. This is placed in a still having a capacity of eight gallons, connected with a stone worm and Woulfe's bottles to catch what escapes the first condenser and receiver. Action will sometimes commence without artificial heat; if it does not I turn on steam till it does, but before the temperature reaches 140°, distillation commences, rapidly at first, and requires very careful condensation. The distillate is in appearance and quantity about the same as that obtained by the B.P. process, but I think it is more ethereal and certainly more acid. It is now neutralized with milk of lime and solution of chloride of calcium added. The nearly pure ether separates, floats on the surface, the heavy liquid below contains the alcohol of the distillate, and certainly most if not all the aldehyde and possibly other products. With the hope of utilizing the washings and recovering alcohol or ether, I have redistilled them with lime and filtered through charcoal, but it is bad smelling, ultimately goes yellow, and is certainly best out of good spt. nitre, though not worse than much that is sold. The main difficulty of this process is the volatile character of the ether, rendering the separation by a syphon a somewhat risky process, and giving, if inhaled, a most cadaverous hue to the operator. Great care has also to be taken when the water and lime are added to keep all very cold, as the mixture with the spirituous liquid generates heat enough to make the ether boil. With these precautions the process is not more than ordinarily difficult. One ounce of the ether with a pint of sptirit makes nitre of 5 per cent. strength; two ounces 10 per cent. or B.P. strength, as Mr. Rimmington has pointed out. The 5 per cent. is, I think, strong enough for medicinal purposes, and would generally be preferred.

In conclusion, I beg to say that whether this is the spt. nitre that is to be, or not, it has much to recommend it. It has a beautiful sweet flavour, something like chloroform, and I believe is free from aldehyde and other noxious products.

NOTES ON SOME JAPANESE DRUGS.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

ROOTS.

(*Continued from page* 5.)

DEE-OH (53):—*Rehmannia lutea*, Max.

Syn. TI-HWANG, Porter Smith, p. 184; SAS-HIME, Sô mokou Zoussetz, vol. xi. fig. 62; DZIWÔ, Fr. et Sav. vol. i. p. 328; SAÔ HIME, GOMA TOME SAÔ, Phonzou Zoufou, vol. xvii. fol. 23.

This root occurs in pieces one or two inches long and about one-quarter to one-third of an inch in diameter, soft and flexible, and very much wrinkled externally, internally soft and moist, of a deep brownish-black colour, with a darker line marking the juncture of the bark and meditullium. Taste earthy and slightly sweet. Several species of this Gesneraceous genus are largely used in China as alteratives and tonics, and are supposed to possess cooling and purifying properties.

The Japanese character for this drug is identical with that translated Ti-hwang, under *Rehmannia Chinensis*, in Dr. Porter Smith's 'Chinese Materia Medica,' "dee" or "ti" being the name of the plant and "oh," like the Chinese "hwang," meaning yellow, in allusion to the yellow colour of the flowers.

The plant is cultivated in Japanese gardens and flowers in May, and was in the first place probably brought from China.

GAH-DITZ (23):—*Curcuma Zerumbet*, Roxb.

This root corresponds exactly in shape and taste and odour with specimens of zedoary or zerumbet root in the museum of this Society; most of the pieces are, however, of a rather more horny consistence than the zedoary root seen in commerce. Mixed with this rhizome are a few specimens of cassumunar root (*Curcuma Zedoaria*, Roxb.), which are easily distinguishable by their yellow colour when cut or scraped.

Gah-ditz comprises both the long and short zedoary, or in other words, both the central and lateral rhizomes.

This plant is probably not wild in Japan, as it is not mentioned either in the 'Sô mokou Zoussetz' or in 'Franchet and Savatier's Flora'; it is probably cultivated in Japan like several other medicinal plants belonging to the Scitamineæ.

HAK-TAU-AU (48):—*Anemone cernua*, Th.

Syn. NEKO BANA, Fr. et Sav. vol. i. p. 4; HOKINA G'ZA, Phonzou Zoufou, vol. vi. fol. 23; OKINA GUSA, SHAGUMA SAIKO, Sô mokou Zoussetz, vol. x. fig. 34; OLLINA GUSA, Thunb. Fl. Jap. p. 238; KAWARA SAIKO, Sieb. et Zucc. Fl. Jap. p. 14.

This is an unbranched, cylindrical, hard and brittle root, three to five inches long, or more, about the size of a goose quill, coarsely furrowed longitudinally, and crowned with the silky bases of the leaves. The transverse section is brown and horny, and shows a small central cavity lined with white fibres; this cavity appears to run through nearly the whole length of the root. The taste is sweet and slightly acrid. It probably possesses similar properties to the common *Anemone Pulsatilla*, to which plant it is nearly allied.

The Japanese name literally translated means white-headed old man, and is probably given in allusion to the white silky appearance of the tufts of young leaves. The Chinese name Hak-too-woo, is very similar in pronunciation.

The plant, like *Anemone Pulsatilla*, grows in Japan on dry hilly places at an altitude of 500 to 2000 feet, and flowers in March or April.

It is said to be used as a bitter medicine in China and Japan.

HAN-GE (47):—*Pinellia tuberifera*, Ten.

Syn. KARASUBISHAKU, Sô mokou Zouss. vol. xix. fig. 1; Phonzou Zoufou, vol. xvii. p. 23; SANG-PWAN-HEA, Hanbury 'Science Papers,' p. 262, with fig. of root; MIDSUMMER ROOT, PWAN-HIA, Porter Smith, 'Chinese Materia Medica,' p. 149. TOO HANGE, Fr. et Sav. vol. ii. pl. 1, p. 3; FANKE SO, KRAS NO FISIAKU, Thunb. Fl. Jap. p. 233.

This drug consists of small white starchy corms, varying in size from a pea to that of a small marble. They are usually slightly flattened, and have a small depression on one side surrounded by a number of little pits, which are apparently the scars of the radical fibres. They appear to have but little taste, but a powerful pungency is perceptible after the drug is chewed, as in many other plants of the arum family.

According to Dr. Porter Smith the powdered drug has an action like colchicum and has been used for a long time in the Hankow Mission Hospital as a substitute for the sulphate of potash in Dover's powders. Although containing a quantity of starch this drug is never attacked by insects.

The plant is found in uncultivated places and in fallow fields, flowering in May and June. It probably derives its name from the time of flowering, "han" meaning middle and "ge" summer.

KAI (56):—*Dioscorea quinqueloba*, Thunb.

Syn. KIKUBA-DOKORO, Sô mokou Zouss. vol. xx. fig. 54; KAI, TOKORO, Kœmpf. Amœn. p. 827. KASSUDA FANNA DAKKA, KARASUNO SENI, Thunb. Fl. Jap. p. 150.

This is a sliced tuber, the slices being one inch or more broad, about half an inch thick, or rather less, and two or three inches long. The cortical portion consists of a wrinkled pale brown skin, marked here and there with the scars of rootlets. Internally it is yellowish-white and shows a few scattered vascular bundles. The substance is moderately hard and tough. The taste is slightly but not persistently bitter. It has very little odour.

Of its medicinal properties I have no knowledge. The root is edible, according to Kœmpfer, who describes it as similar in appearance to ginger. Thunberg states that the name "fanna dakka" means nose higher, and is given because children put the winged capsules on their noses to make their noses look larger, while "karasuno seni" means crow-berry.

The plant has much the habit of the black bryony of this country, but the leaves are larger and have five shallow lobes. It flowers from June to September.

KAS-HI-YU (43).

This is a large tuberous root, varying in size from two to four inches long and one to two inches in diameter. Externally it is of a blackish-brown colour, with one or two deep furrows, or in some pieces it exhibits a slightly wrinkled surface, while in others it presents transverse scars or ridges which by friction have become pale. Internally the root presents a nut-brown colour and a shining resinous fracture; the structure appears uniform. The root is extremely hard, requiring a blow from a hammer to fracture it. The taste is slightly astringent and the odour earthy.

I have not been able to identify it.

KESSO:—*Patrinia scabiosæfolia*, Link. (Valerianaceæ.

Syn. OMINA-MESHI, Sô mokou Zoussetz, vol. ii. p. 21; WOMINA MESI, JAMA NJAN KUSOO, URO AMISI, ORO AMI, Fr. et Sav. vol. i. p. 216.

This root was not presented with the others, but was offered in the London market under the name of "kesso" and was imported from Japan; as a product of that country it seems to demand notice here. The root resembles that of *Valeriana officinalis* in general appearance and odour, but differs in the central portion to which the rootlets are attached, being very small and short, rarely exceeding one-third of an inch in diameter; the rootlets form a compact tuft from two to three inches long, are of a dark brown colour, and have a slightly scaly surface, by which and by the colour they are easily distinguished from valerian root. The odour of the root is even more powerful than that of *Valeriana officinalis*. The taste is bitter and aromatic. It grows in stony mountainous places and blossoms in July.

KI-KYÔ (33): — *Platycodon grandiflorum*, A.DC. (Campanulaceæ), So mokou Zoussetz, vol. iii. fig. 3; Phonzou Zoufou, vol. iv. p. 14, 15.

Syn. *Campanula glauca*, Thunb. Fl. Jap. p. 88; KEKKO, KIRJO, KIRAKOO, Kœmpf. Amœn. p. 822.

This root is white, about three or four inches long, strongly but sparingly furrowed longitudinally, tapering from just below the part where the stem arises, simple, or once forked, and giving off from the shoulder or thickened portion near the top of the root one or two short often horizontally-spreading lateral branches. Internally it is tough, white, and slightly spongy, with a yellowish-white horny ring surrounding the meditullium. The taste is at first sweet and mucilaginous, but afterwards faintly bitter. The juice is milky in the fresh root, according to Kœmpfer.

These specimens do not in any way correspond with those described under the name of *Platycodon grandiflorum* by Dr. Porter Smith (p. 173). The Chinese character there translated kih-kang is, however, identical with the Japanese character kikyo. The Japanese root was, however, recognized at sight by Mr. Takemura, who told me the plant yielding it had a large blue flower, and on showing him the figure of the plant in the Sô mokou Zoussetz, he at once identified it as the one yielding the root. Dr. Porter Smith's specimen in the museum of the Pharmaceutical Society is therefore probably incorrect.

According to Kœmpfer, this root is considered only second in medicinal value to the celebrated ginseng, which is not surprising, since it has a stronger resemblance to the outline of a human body than even that famous root.

Kikyo grows commonly on the borders of cultivated fields, and flowers in July and August.

KIN-KEE (55):—*Malva sylvestris*, L., Fr. and Sav. vol. i. p. 62.
Syn. ZENI-AOI, Sô mokou Zoussetz, vol. xii. fig. 54.

This root resembles in every respect that obtainable in England, except that it is whiter and evidently carefully washed and rubbed before drying.

It is probably cultivated in Japan, and not really wild, according to Franchet and Savatier.

KUH-SHING (14).

This drug is very similar in appearance to decorticated marshmallow root, but of a more yellowish tint. It occurs in angular pieces four or six inches long and one-third to three-quarters of an inch in diameter, and is very fibrous; the meditullium occupies the greater portion of the root and is marked where it joins the cortical portion by a ring of faint brown radiating dotted lines. The dotted appearance under a lens is seen to be due to the presence of porous vessels. The taste is intensely bitter. Examined by Mons. A. Petit, of Paris, it was found to contain a new alkaloid, to which its bitterness is due.

Thunberg refers "kusin," a name similar in sound but different in meaning, to *Sophora heptaphylla*, L., but the root of that plant does not appear to be bitter. The Japanese character for "shing" means bitter.

I have not yet been able to identify this drug.

OH-REN (58):—*Coptis anemonæfolia*, Sieb. et Zucc. (Ranunculaceæ); Sô mokou Zouss. vol. x. fig. 36.
Syn. KAKOUMA G'ZA, Fr. et Sav. vol. i. p. 10; Phonzou Zoufou, vol. vii. p. 2.

This drug closely resembles in appearance that of *Coptis Teeta*, Wall., but is more slender and more curved, and has less of the smooth stem which is often attached to the latter. The rhizomes are about one or one and a half inches long and two lines thick, occasionally branched, and always bristly with short, slender, wiry rootlets. Externally it is of a dark brown colour and internally of a golden yellow. The taste is bitter.

The Japanese character ("oh-ren," meaning yellow ren) is exactly the same as the Chinese one for hwang-lien, which is the rhizome of *Coptis Teeta*, Wall., and not a *Justicia*, as stated by Dr. Porter Smith in his 'Chinese Materia Medica,' p. 126, and whose specimens in the museum of the Society are certainly the rhizome of *Coptis Teeta*.

The Japanese drug, like *Coptis Teeta*, probably contains a quantity of berberine. It is not a little singular that *Coptis Teeta*, *Berberis Lycium*, *Hydrastis Canadensis* and *Coscinium fenestratum*, which all contain berberine, have all been found useful in inflammation of the eyes.

Two other species of Coptis are figured in Sô mokou Zoussetz, viz., *C. trifolia*, Salisb. (fig. 38) and *C. quinquefolia*, Miq. (fig. 37), both of which are much smaller species, and other species are described by Franchet and Savatier, but all of these have a more slender rhizome.

(*To be continued.*)

INSECT POWDER.*

BY WILLIAM SAUNDERS.

The insect powders of commerce are the powdered flowers of different species of *Pyrethrum*. Those of *Pyrethrum carneum* and *roseum* were introduced some thirty years ago under the name of Persian insect powder, and subsequently those of *Pyrethrum cinerariæfolium*, a native of Dalmatia, Austria, as Dalmatian insect powder. Both the Persian and Dalmatian powders are good insecticides, but the latter is much the more energetic in its action and hence commands a higher price; indeed, it is so much preferred that it is gradually driving the so-called Persian powder out of the market. The fact of the flowers of *P. roseum* being less active than those of *P. cinerariæfolium*, has been accounted for on the ground that the single flowers are much more powerful than the double ones, and that the double flowers occur in *P. roseum* in much larger proportion than in the other species. The flowers, either whole or powdered, preserve their activity for a long period. A recent European experimenter states that he could not perceive any particular loss of activity in samples which had been kept for six years. The fresh (undried) flowers act very slowly as compared with the same dried and powdered, and the plant itself powdered is quite inactive. It is singular that while there are many other composite plants closely related to the genus *Pyrethrum*, as yet this peculiar property has been found only in plants belonging to this genus, and even within this limit there are several species whose value as insecticides is very slight. A large number of Compositæ indigenous to Austria have been tested and found to be of no value in this respect. The flowers of tansy (*Tanacetum vulgare*) are said to have a slight stupefying effect.

The *Pyrethrums* are hardy plants which bloom abundantly the second year from seed. The powder is prepared from the half-open flowers gathered during dry weather and dried in the shade under cover, but the process of gathering, drying and preparing involves so much time that their culture can only be made profitable where labour is cheap.

Insect powders have not attracted general attention as insecticides until within the last three or four years, during which time they have been introduced in various

* From the *Canadian Entomologist*, March. Reprinted from the *American Journal of Pharmacy*, May, 1879.

forms in packages and boxes, accompanied by suitable blowers or insects guns for the purpose of properly distributing the powder, and recommended for the destruction of flies, cockroaches, fleas, bugs, etc. Sometimes these prepared articles have been artificially coloured so as to disguise their source, but all have owed their activity solely to the presence of the powdered flowers of one or other of these *Pyrethrums*.

House flies are very sensitive to the effects of these powders. A few puffs of the dust from an insect gun, blown into the air of a room with the doors closed, the discharges directed towards those parts where flies are congregated, will stupefy and kill them within a very short time. The powder is somewhat pungent, and to breathe an atmosphere charged with it will frequently cause a slight sneezing, but beyond this the operator need not anticipate any annoyance. Frequently during the past summer, when flies have been troublesome, we have pretty thoroughly charged the air in our dining-room and kitchen at night, closing the doors, and in the morning found all, or nearly all, the flies lying dead on the floor. A few minutes after its use they begin to drop on their backs, and after a short time die; if a room be closed for half an hour after using the powder, few, if any, will escape. By some this energetic action has been attributed to the presence of a volatile oil in the flowers, by other and later investigators to a peculiar crystalline principle believed to be an alkaloid, but this point does not as yet seem to be fully settled.

More recently we have been experimenting with this powder on the green aphis which troubles our green-house plants. The usual plan of smoking with tobacco is an unpleasant remedy, and is also very injurious to many plants of delicate constitution, whereas the insect powder used to any extent is perfectly harmless to plant-life. After freely charging the air of a green-house with the powder, blowing it in fine clouds of dust among the plants, the tiny tormentors who are busily engaged in sucking the life out of the leaves and tender shoots, soon manifest symptoms of uneasiness and begin to drop from the plants to the ground, and in the course of an hour or two the larger portion of the enemy's forces will be found lying sprawling on the earth, in the pots, or on the shelves and floor of the house, where, probably partly from the stupefying effects of the powder and partly from their natural inability to find their way to any given point, they fail to reach the plants again and hence perish. By applying the powder freely in the evening and giving the plants a thorough syringing in the morning, they may in the worst cases be almost freed from aphides by a single application; it is better, however, to repeat its use the next evening, so as to make sure work. The powder does not appear to kill this aphis as it does the flies. For the purpose of testing this point we placed a number of them in an open glass cell of a microscope slide and powdered then thoroughly, and found some of them alive after two days of such severe exposure to its influence. Having recently found a plant literally swarming with the green aphis, so that the sight of it was almost disgusting, we submitted it to the action of this powder one afternoon, having previously spread a large piece of white paper under the plant so that the effect of the powder on the insects might be distinctly seen. Almost immediately they began to fall on the paper, and in less than ten minutes a hundred or more of them were lying on their backs or crawling sluggishly about. In the course of half an hour some four or five hundred had fallen on the paper, and when the plant was examined again the following morning, there remained but very few on it, and most of these were removed by a slight syringing. We have had the powder used in green-houses by some of our friends, who also report its success. The matter is well worthy the attention of all those who indulge in window gardening or who grow plants in small conservatories attached to dwellings, since if this proves an efficient and economical substitute for tobacco smoke, it will save much annoyance and some loss. Success will necessarily depend on the quality of the material used, but after the experiments we have tried, we feel confident that with good Dalmatian powder there need be no failure. It will be interesting to learn as opportunity offers how moths and other insects will be affected by the use of insect powders. If the beautiful specimens which sometimes fly into our rooms at night can be drugged in this way and captured without a struggle, we may add many a perfect specimen to our collections which would otherwise be more or less defaced. There is quite a field for experiment here.

GERANIUM OIL.*

Under the name of geranium oil several essential oil derived from species of *Pelargonium* and *Andropogon* come into commerce, which on account of their rose-like odour are used as cheap substitutes for oil of roses as well as in its adulteration. The German true geranium oil, or oil of rose-leaved geranium, as well as the French geranium or "palma rosæ" oil are obtained from the *Pelargonium Radula*, by distillation of the leaves and flowers with water. It is colourless, sometimes, however, with a greenish, yellowish or even brownish colour, the latter especially being the most esteemed. It boils at 216° to 220° C., and solidifies at 16° C. and rotates a beam of polarized light to the right.

The smell is agreeable and resembles that of the rose. The so-called Algerian rose oil, from the leaves and flowers of the cultivated *Pelargonium roseum*, Willd., and *P. odoratissimum*, is very similar to the French oil, but is lævogyre, and is especially used in the adulteration of rose oil, but is itself adulterated with grass oil from various species of *Andropogon*.

The Turkish geranium oil (rosé or roshé oil, oil of rose geranium, ginger grass oil) is the ethereal oil of *Andropogon Pachnodes*, a grass indigenous in the East Indies, Persia and Arabia. It is a yellowish thin liquid, with an agreeable aromatic odour and does not readily solidify. It comes into commerce principally through Smyrna and Bombay and is alleged to be prepared in Mecca.

The "palma rosæ" oil contains pelargonic acid, $C_9H_{18}O_4$, a colourless oily liquid, solidifying at a low temperature, melting at 10° C., and boiling at 260° C.; it is one of the series of fatty acids. Among the other constituents of geranium oil are geraniol, $C_{10}H_{18}O$, isomeric with borneol, and a colourless liquid having an agreeable rose-like odour which boils at 232° C., and upon heating with zinc chloride yields geranien, $C_{10}H_{16}$, as a colourless liquid, smelling of carrots, and boiling at 163° C.

According to Guibourt, rose oil, geranium oil and andropogon oil may be distinguished by means of iodine, nitric acid and sulphuric acid. Under a bell-glass is placed a capsule containing iodine and around this are placed watch glasses containing one or two drops of each oil. The true rose oil retains its colour, whilst both the other oils turn brown, the geranium taking by far the most intense colour. If instead of iodine copper filings over which nitric acid has been poured are put under the bell-glass, the glass becomes immediately filled with red vapour which is absorbed by the oils, the geranium oil becoming apple-green, and the andropogon oil and rose oil dark yellow, the former most quickly. If one or two drops of each of these three oils are mixed with an equal quantity of concentrated sulphuric acid, the mixtures become brown, but while the mixture with rose oil retains its delicious odour, that with the geranium oil smells strong and repulsive, and the andropogon oil acquires a strong fatty odour.

---

WALNUT LEAVES AND THE EXTRACT OF WALNUT LEAVES.*

BY C. GOVAERTS.

Preparations of the walnut (*Juglans regia*, L.), after having enjoyed in France the popularity often gained by recently introduced medicines, are not much now employed. Experience has demonstrated, however, that the walnut may be classed among the plants most useful in medicine. The author quotes various authorities who speak highly of its antiscrofulous properties.

The Belgian Codex includes an extract of the dry leaves, and the extract enters into the composition of the "Sirop de Vanier," a preparation largely used. The author's experiments have been directed to ascertaining whether this extract represents the maximum of the active principles contained in the leaves and what are the conditions that may influence the quantity of these principles in the leaves and in the extract.

The leaves of the walnut contain principally chlorophyll, tannin, a volatile aromatic principle and an acrid bitter matter (juglandin) found more specially in the green husk and the epiderm of the seed. Distilled in the fresh state the leaves yield a rather aromatic limpid water, neutral to litmus paper.

The fresh juice is green, but upon being heated it abandons its chlorophyll and at the same time becomes sensibly darker in colour.

In drying the leaves lose 50 to 55 per cent. of their weight, but without sensibly altering in colour or taste. The petioles only turn brown.

These leaves cannot be collected according to the general rule,—*i.e.*, at the commencement of the flowering,—for at that time they have scarcely issued from the buds and are far from possessing the desired properties.

If walnut leaves collected at the proper time and recently dried be compared with those met with in commerce the difference in the characters is striking. After some months in fact the dried leaves, exposed to the open air, turn brown and at the same time lose their aromatic odour and bitterness. This physical change, produced under the influence of moisture and air is the index of a chemical transformation that takes place after the drying. The prolonged action of air and moisture gradually converts the juglandin into an insoluble and insipid black substance and the tannin becomes partially insoluble or decomposed.

Experiments were made with preparations from (1) leaves collected in June; (2) leaves collected in October; (3) leaves collected at the proper time, but which had been kept one year. Tannin being one of the most active principles of the leaves, this was estimated as indicative to a certain extent of the value of the respective preparations. The method adopted was that of Löwenthal, based upon the oxidation of the tannin by permanganate of potash in the presence of indigo carmine. A gram of each extract was dissolved in 100 c.c. of distilled water, and 20 c.c. of each solution were submitted to the action of the permanganate.

(*a*). An extract prepared from the juice of leaves collected in June, clarified by heat and evaporated.—Taste: bitter and astringent. Odour: aromatic. Solution: limpid. Tannin in 1 gram of extract: 0·19 gr.

(*b*). Similar leaves were submitted to distillation, and the residue filtered and evaporated to an extract.—Taste: slightly bitter. Odour: very slight. Solution: turbid. Tannin in 1 gram: 0·19 gr.

(*c*). The remainder of the June leaves were dried in the open air and an extract prepared from them according to the Belgian Pharmacopœia.—Taste: bitter and astringent. Odour: aromatic. Solution: limpid. Tannin in 1 gram: 0·20 gr.

(*d*). Leaves collected in October were dried directly and converted into extract.—The product resembled (*c*) in every respect.

(*e*). Extract prepared from leaves one year old.—Taste: slightly astringent and slightly bitter. Odour: none. Solution: very dark. Tannin in 1 gram: 0·10 gr.

(*f*). Extract of commerce.—Similar to (*e*) with the exception of solution being limpid.

It appears therefore that the full grown leaves may be collected at any period during the fine weather, even as late as October, when they can be removed without injuring the tree. The extract of walnut, in order to represent the active principles as completely as possible, should be prepared with such leaves recently dried. The extract prepared from the defecated juice is as rich in tannin, but does not keep so well, whilst that prepared by decoction should be rejected. The leaves falling in autumn should not be used, although there is reason to believe that they are often employed in preparing the extract of commerce.

Walnut leaves of good quality are of a fine green colour on their upper surface and of a darker green underneath, with brown petioles. They have a parchment-like texture, an aromatic odour and a freely bitter and astringent taste. Altered leaves lose the greater part of their odour and bitterness, and turn a dirty green colour, approaching brown. Fallen autumn leaves sometimes have yellow spots on their surface.

* *Répertoire de Pharmacie,* vol. vii., p. 145.

THE GAS QUESTION.*

BY DUNCAN C. DALLAS.

In a former article I endeavoured to show from my own case—

1. That although I had not required more gas, my consumption was over 75 per cent. excess.
2. That this had been going on for about *fifteen months.*
3. That *after* public outcry had been raised, and without any effort on my part to diminish consumption, the amount burnt returned to the normal rate; and,
4. I suggested as a cause of increased consumption, that the gas supplied previously to the outcry had burnt away more quickly than the normal gas.

Now, it is remarkable how coincident in time with the outcry was the reversion to what I have termed the normal gas. As the figures show there was a sudden drop in my consumption equivalent to 75 per cent.

Just previous to the outcry my consumption had been at the rate of 2100 feet per week. In the week May 18th to 25th my consumption was 1200 feet, *i.e.*, just 75 per cent. less than the previous rate. And I believe this would be found to be a general experience. It is remarkable, too, that the increase, ranging over fifteen months previous to the outcry, should be also a little over 75 per cent. This fact, therefore, stands out clear, viz. the gas supplied for at least fifteen months previous to complaint burnt away 75 per cent. more rapidly than the gas supplied not only before the fifteen months, but since complaint became loud and general.

In the *English Mechanic* for June 27th, 1879, much space is given to the gas question, but entirely in the interests of the companies. In the number of same periodical for the week July 4th the subject has been prudently dropped, although the facts in my first article were brought to the notice of the Editor.

In the number for June 27th no attempt is made to touch the *gravamen* of the charge against the companies. An unfortunate "Gas Consumer" is made to stand in the pillory in consequence of some rather wild suggestions as to the cause of the increased consumption. If he be not a "man in buckram," but a real individual, one-tenth the large space devoted to his punishment and demolition of his crude suggestions would have sufficed.

These advocates of the companies prove too much. They argue as if by no possibility could any but the right kind of gas be supplied to the consumer. As they seem so learned in gas matters I humbly think it behoves them

* From the *Brewers' Guardian*, July 8, 1879.

to grapple with the real question. They cannot deny that there has been a great increase in consumption. And I think they will find it hard to deny that since the outcry there has been a great and sudden diminution of consumption, which cannot be accounted for by more economical methods of using. For, as I have shown by my own case, I purposely made no alteration in the conditions, and my rate reverted to that of 1876-7.

Messrs. "Sigma," "Ethylene," and other advocates of the companies, are therefore on one of the horns of this dilemma. Either they know the cause or they do not. If they know the cause and do not confess it they are uncandid and chargeable with what logicians term *ignoratio elenchi*, and this wilfully, in order to throw us off the scent. If they do not know the cause they have no business to write about the matter.

I confess I am not one of those who believe that mixture with atmospheric air will account for the increased consumption. I think there has been a more subtle cause.

The important ingredient in coal gas as an illuminant is olefiant gas. Next in importance are vapours of hydrocarbons. Lastly, there is light carburetted hydrogen, or marsh gas. Now, the specific gravity of marsh gas is a little more than half that of olefiant gas. Therefore a volume of marsh gas will burn away much more quickly than an equal volume of olefiant gas. But the illuminating quality of marsh gas is very feeble compared with olefiant gas. It would not do, therefore, to increase the quality of marsh gas unduly unless means could be found of increasing its illuminating quality. To one who is not in the secrets of the gas companies it is difficult of course to know what particular method has been adopted. But to show that it is possible to improve the illuminating quality of marsh gas in a simple yet scientific manner, and at the same time *increase its volume*, I beg to refer the advocates of the companies to 'Ure's Dictionary,' vol. ii., p. 552, 1875 edition, where they can read:—

"If marsh gas possessing, it will be remembered, a small amount of luminosity be decomposed by its passage through a heated tube or by the electric spark, the carbon it contains will be deposited, while the amount of hydrogen set free *will occupy double the volume of the orginal gas.*" [The italics are mine.] "Yet the flame of this nearly pure hydrogen will be found to possess a greater luminosity than the flame of the original marsh gas, although it has lost nearly the whole of its light-giving material—accounted for by the presence of a very small quantity of acetylene produced during the decomposition."

I came upon this passage *after* I had arrived at a conviction that the increased consumption was due to the supply of a gas that burnt away rapidly. If, therefore, it has been by some such means that the increased consumption has been induced, however much I may admire, as I do admire, the beautiful scientific rationale of the process, and the more beautiful because of its simplicity, especially if by such economical means as the transmission of an electric spark through some huge volume of marsh gas, it can be in a "jiffey" (if I may be allowed the slang) converted into double its volume, not only without loss to its illuminating power, but with positive increase, yet I do object to paying 75 per cent. more when in the result it does me no better service than the original gas, but rather like its crudent parent, "Will o' the Wisp," brings me grief.

On the contrary, the gas ought to be cheaper. Nor would I be greedy. For, if without much increase of cost two volumes of gas are got where previously only one could be obtained, we must hail as a benefactor the clever gas chemist or engineer who effects this. We should not grudge his fortunate company, if, say, they cheapened production 50 per cent. and kept a lion's share for themselves, but kindly gave us—something.

I am glad to see that *The Pharmaceutical Journal* (June 28th, 1879) has devoted a leader referring to the first article on the present subject in last number of *The Brewers' Guardian*, and urging the importance of the suggested Parliamentary inquiry. An excellent recommendation is also made in that leader, viz. that chemists and druggists who are large consumers of gas for heating as well as illumination, "might be of especial service in helping to keep up an examination of the gas supplied to different quarters, and make observations as to its purity, composition, and illuminating power, that would be a useful check upon the results arrived at in other ways."

This would be most valuable. For what satisfaction is it to be told that there is an elaborate system at the works for protecting us, if, when we examine our gas bills, we find that from some cause or another we have not been protected? It is all very well to test milk at the udder of the cow, but it is more than aggravating to see it pour "sky-blue" from the milk-jug on our breakfast-table.

Let them go on protecting us at the works, but let us also be protected at the burners as regards what they deliver. It could be done very easily if Parliament would give just a little attention to the distressed gas consumers.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.*

BY PROFESSOR ABEL, C.B., F.R.S.

Among the many explosive preparations which have during the last thirty years been proposed as substitutes for gunpowder, on account of greater violence and other special merits claimed for them, not one has yet competed with it successfully as a propelling agent, nor even as a safe and sufficiently reliable explosive agent for use in shells; for industrial applications and for very important military or naval uses, dependent upon the destructive effects of explosives, it has had, however, to give place, to a very important extent, and in some instances altogether, to preparations of gun-cotton and nitro-glycerine.

But there appeared little prospect that either gun-cotton or nitro-glycerine, whether used in their most simple condition or in the forms of various preparations, would assume positions of practical importance as explosive agents of reliable, and therefore uniformly efficient, character, until the system of developing their explosive force through the agency of a detonation, instead of through the simple agency of heat, was elaborated.

Before the first step in this important advance in the application of explosive agents was made by Alfred Nobel, about twelve years ago, the very variable behaviour of such substances as gun-cotton and nitro-glycerine, when exposed to the heat necessary for their ignition under comparatively slight modifications of attendant conditions (*e.g.* as regards the completeness and strength of confinement or the position of the source of heat with reference to the main mass of the material to be exploded) rendered them uncertain in their action, and, at any rate, only applicable under circumstances which confined their usefulness within narrow limits. The employment by Nobel of an initiative detonation, produced by the ignition of small quantities of mercuric fulminate or other powerful detonating substances, strongly confined, for developing the violent explosion, or detonation, of nitro-glycerine, opened a new field for the study of explosive substances, and the first practical fruit was the successful application of plastic preparations of nitro-glycerine and of compact forms of compressed gun-cotton, with simplicity and certainty, to the production of destructive effects much more considerable than could be accomplished through the agency of much larger amounts of gunpowder, applied under the most favourable conditions. Whereas very strong confinement has been essential for the complete explosion of these substances, so long as the only known means of bringing about their explosion consisted simply of the application of fire or sufficient heat, no confinement what-

* Lecture delivered at the Royal Institution of Great Britain, Friday, March 21, 1879.

ever is needed for the development, with certainty, of a decidedly more violent explosive action than they are capable of exerting when thus applied, if they are detonated by submitting some small portion of the mass to the blow or concussion developed by a sharp detonation, such as is produced by the ignition of a small quantity of strongly confined mercuric fulminate.

The conditions essential to the development of detonation in masses of nitro-glycerine and gun-cotton, or preparations of them, and the relations to and behaviour towards each other of these and other explosive bodies, in their character or functions as detonating agents, have been made the subject of study by the lecturer during the last ten years, and some of the earlier results published by him in connection with this subject also led to the pursuit of experimental inquiries of analogous character by Champion and Pellet and others.

Some of the chief results attained by Mr. Abel's experiments may be briefly summarized.

It was found that the susceptibility to detonation, as distinguished from explosion, through the agency of an initiative detonation, is not confined to gun-cotton, nitro-glycerine, and preparations containing those substances, but that it is shared, though in very different degrees, by all explosive compounds and mixtures.

It was demonstrated that the detonation of nitro-glycerine and other bodies, through the agency of an initiative detonation, is not ascribable simply to the direct operation of the heat developed by the chemical changes of the charge of detonating material, and that the remarkable property possessed by the sudden explosion of small quantities of certain bodies (the mercuric and silver fulminates) to accomplish the detonation of nitro-glycerine and gun-cotton, is accounted for satisfactorily by the mechanical force thus suddenly brought to bear upon some part of the mass operated upon. Most generally, therefore, the degree of facility with which the detonation of a substance will develop similar change in a neighbouring explosive substance, may be regarded as proportionate to the amount of force developed *within the shortest period of time* by that detonation, the latter being in fact analogous in its operation to that of a blow from a hammer or of the impact of a projectile.

Thus, explosive substances which are inferior to mercuric fulminate in the suddenness, and the consequent momentary violence of their detonation, cannot be relied upon to effect the detonation of gun-cotton, even when used in comparatively considerable quantities. Percussion cap composition, for example, which is a mixture of fulminate with potassium chlorate, and is therefore much less rapid in its action than the pure fulminate, must be used in comparatively large quantities to accomplish the detonation of gun-cotton.

The essential difference between an explosion and what we now distinguish as a detonation lies in the comparative suddenness of the transformation of the solid or liquid explosive substance into gas and vapour.

The gradual nature of the explosion of gunpowder is illustrated, in its extreme, by burning a train of powder in open air; the rapidity and consequent violence of the explosion is increased in proportion to the degree of confinement of the exploding charge, or to the resistance opposed to the escape or expansion of the gases generated upon the first ignition of the confined substance. In proportion as the pressure is increased under which the progressive transformation of the explosive takes place, the rapidity with which its particles are successively subjected to the action of heat is increased.

In the case of a very much more sensitive and rapidly explosive substance than gunpowder, such as mercuric fulminate, the increase in the rapidity of its transformation, by strong confinement, is so great that the explosion assumes the character of a detonation in regard to suddenness and consequent destructive effect. A still more sensitive and rapidly explosive material (such as the silver fulminate and iodide of nitrogen) produces when exploded in open air effects akin to those of detonation; yet even with these bodies, confinement operates in increasing the rapidity of the explosive to suddenness, and consequently in developing a more purely detonative action. Thus, the violence of explosion of silver fulminate is decidedly increased by confining the substance in a stout metal case, and the enclosure of iodide of nitrogen in a shell of plaster of paris has a similar effect. With chloride of nitrogen, the suddenness of detonation, and consequently the violence of action, was found to be very greatly increased even by confining the liquid beneath a thin layer of water.

Detonation, developed in some portion of a mass, is transmitted with a velocity approaching instantaneousness throughout any quantity, and even if the material is laid out in the open air in long trains composed of small masses. The velocity with which detonation travels along trains thirty or forty feet in length, composed of distinct masses of gun-cotton and of dynamite, has been determined by means of Noble's chronoscope, and was found to range from 17,000 to 24,000 feet per second. Even when trains of these explosive agents were laid out with intervening spaces of half an inch between the individual masses composing the trains, detonation was still transmitted along the separated masses with great though diminished velocity.

The suddenness with which detonation takes place has been applied as a very simple means of breaking up shells into small fragments and scattering these with considerable violence, with employment of very small charges of explosive agent. Thus by filling a 16-pr. common shell completely with water and inserting a charge of half an oz. of gun-cotton fitted to a detonating fuze, the shell being thoroughly closed by means of a screw plug, the force developed by the detonation of the small charge of gun-cotton is transmitted instantaneously in all directions by the water, and the shell is thus broken up into a number of fragments averaging fourteen times the number produced by bursting a shell of the same size by means of the full amount of powder which it will contain (13 oz.). Employing one oz. of powder, in place of half an oz. of gun-cotton, in the shell filled with water, the comparatively very gradual explosion of the powder charge is rendered evident by the result; the shell being broken up into less than twenty fragments by the shock produced by the first ignition of the charge, transmitted by the water. In this case the shell is broken up by the minimum amount of force necessary for the purpose, before the explosive force of the powder charge is properly developed. Extensive comparative experiments carried on not long since by the Royal Artillery, at Okehampton, demonstrated that this simple expedient of filling common shells with water and attaching a small charge of gun-cotton with its detonator to the fuze usually employed, allowed of their application as efficient substitutes for the comparatively complicated and costly shrapnel and segment shells.

Another illustration of the sharpness of action developed by detonation as compared with explosion, consequent upon the almost instantaneous character of the metamorphosis which the explosive agent undergoes in the case of detonation, is afforded by a method which the lecturer applied some years since for comparing the violence of action of charges of gun-cotton and of dynamite arranged in different ways. The charges (5 lb.) to be detonated were freely suspended over the centres of plates of very soft steel of the best quality, which rested upon the flat face of a massive block, or anvil, of iron, having a large central circular cavity. The distance between the upper surface of the plate and the charge suspended over it, was four feet. The sharp blow delivered upon the plate by the air suddenly projected against it by the force of the detonation when the charge was fired, forced the metal down into the cavity of the anvil, producing cup-shaped indentations, the dimensions of which afforded means of comparing the violence of the detonation. A much larger charge of powder exploded in actual contact with the plate, would produce no alteration of form in the metal, and the same negative result would be furnished by the explosion over the plate of a heap of loose gun-cotton of the same or greater weight than the charges detonated. The above method of experiment was devised, in the first instance, by Mr. Abel, in July, 1875, for comparing the quality of some specimens of Llandore steel proposed to be used by the Admiralty for shipbuilding purposes, with samples of malleable iron, and it has since been employed by Mr. Adamson in carrying out a very useful series of experiments, recently communicated to the Iron and Steel Institute.

It has been stated that detonation can be transmitted from one mass of gun-cotton or dynamite to another through intervening air-spaces. The extent to which such spaces can be introduced without checking detonation is obviously regulated by the size of the masses of explosive detonated; but the distances of air-space through which the detonation of a moderate quantity of the explosive agent will communicate to similar masses, are very limited, a space of 2 inches being sufficient to prevent the detonation produced by a mass of 8 oz. of gun-cotton, freely exposed, from communicating to contiguous ones. If the dispersion of the force is prevented in part, and direction is given to the gases violently projected from the centre of detonation, the power of transmitting detonation to separated masses of explosive is increased to a remarkable degree. This is readily accomplished through the agency of tubes, the charge first detonated being just inserted into one extremity, while that to which the detonation is to be transmitted is inserted into the other; or separate charges may be placed at different distances inside a long tube, with long intervening spaces, the initiative charge being inserted at one end. A few illustrations of the results thus obtained may be given. The detonation of a 1-oz. disk of gun-cutton in open air will not transmit detonation with *certainty* to other disks placed at a greater distance than half an inch from it; but if it be just inserted into one end of an iron tube 2 feet long and 1·25 inch in diameter, a similar disk, or even a plug of loose gun-cotton inserted into the other extremity of the tube, will invariably be detonated. With employment of 2 oz. of gun-cotton, in a tube of the same material, thickness, and diameter, detonation was transmitted to a distance of 5 feet. In tubes of the same kind, of very considerable length, 2-oz. disks of gun-cotton placed at intervals of 2 feet, were detonated through the initiative detonation of one such disk inserted into one extremity of the tube. In other experiments a long tube of this kind was fitted with branch pipes, 2 feet long, at those parts where the intermediate disks were placed, and charges of gun-cotton were placed at the extremities of these pipes. By the initiative detonation of 1 oz. of gun-cotton all the charges were detonated, the effect on the air being that of one single explosion. The results obtained with equal quantities of gun-cotton varied with the diameter, strength, and nature of the material of the tubes used. Dynamite and mercuric fulminate, applied to their own detonation, furnished results quite analogous to those obtained with gun-cotton; but in applying fulminate to the detonation of gun-cotton through the agency of tubes, some singular and instructive results were obtained, for an account of which the lecturer referred to his memoir on this subject.

Silver fulminate was employed for the purpose of instituting more precise experiments than could be made in operating on a larger scale, with gun-cotton, on the influence of the material composing the tubes, of the condition of their inner surfaces, and of other variable circumstances, upon the transmission of detonation. Half a grain of silver fulminate freely exposed and ignited by a heated body, will transmit detonation to some of the compound placed at a distance of 3 inches from it, but does not do so with certainty through a distance of 4 inches. But when the quantity of the fulminate is just inserted into one end of a stout glass tube 0·5 inch in diameter, and 3 feet long, its detonation is invariably induced by that of a similar quantity of the fulminate placed just inside the other extremity of the tube; this result is uncertain when the length of the tubes of the same thickness and diameter exceeds 3 feet 3 inches. Glass tubes were found to transmit the detonation of silver fulminate much more rapidly than tubes of several other materials of the same diameter and thickness of substance. Thus, with the employment of double the quantity of fulminate required to transmit the detonation with certainty through a glass tube of the kind described, 3 feet in length, it was only possible to obtain a similar result through a pewter tube 31·5 inches long, a brass tube 23·7 inches long, an indiarubber tube 15·8 inches long, and a paper tube 11·8 inches long. The difference in the results obtained was not ascribable to a difference in the escape of force on the instant of detonation, in consequence of the fracture of the tube, nor to the expenditure of force in work done upon the tube at the seat of detonation, since the glass tubes were always destroyed by the first explosion to a much greater distance along their length than any of the others, and the brass tubes, which were in no way injured at the seat of the explosion, did not transmit detonation to so great a distance as the pewter tubes, which were always deeply indented. The transmission of detonation appeared also not to be favoured by the sonorosity or the pitch of the tube employed, as the sonorous brass tube was not found to favour the transmission to the same extent as the pewter tube. Moreover the transmission of detonation by the glass tubes was not found to be at all affected by coating these tubes with several layers of paper, or by encasing them in tightly fitting indiarubber tubes. These differences appeared on further investigation not to be ascribable, to any important extent, if at all, to the difference in the nature of the material composing the tubes, but to be simply, or at any rate almost entirely, due to differences in the condition of the inner surfaces of the tubes. Thus, brass tubes, the inner surfaces of which were highly polished, and paper tubes, when coated inside with highly glazed paper, transmitted the detonation of the silver fulminate to about the same distance as the glass tubes; on the other hand, when the inner surfaces of the latter were slightly roughened by coating them with a film of fine powder, such as French chalk, they no longer transmitted detonation to anything like the distance which they did when the inner surfaces were in the normally smooth condition. Other very slight obstacles to the unimpeded passage of the gas wave through the tubes were found greatly to reduce the facility with which detonation could be transmitted by means of tubes; thus, when a diaphragm of thin bibulous paper was inserted into the glass tube about half-way between the two extremities, detonation was not transmitted, even with the employment of about six times the quantity of fulminate that gave the result with certainty under ordinary conditions; and similarly the transmission of detonation by increased charges of mercuric fulminate and of gun-cotton was prevented by the introduction into the tubes of light tufts of carded cotton wool just sufficient in quantity to shut out the light in looking through the tubes.

Among several other interesting results furnished by an examination into the conditions governing and results attending the transmission of detonation by tubes, a remarkable want of reciprocity was found to exist between mercuric fulminate and gun-cotton. The latter substance is more susceptible to the detonative power of mercuric fulminate than of any other substance, as will presently be further shown. The quantity of fulminate required to detonate gun-cotton is regulated by the degree to which the sharpness of its own detonation is increased by the amount of resistance to rupture offered by the envelope in which the fulminate is confined. From twenty to thirty grains are required if the detonative agent is confined in a thin case of wood, or in several wrappings of paper; but as small a quantity as two grains of the fulminate suffices to effect the detonation of compressed gun-cotton, provided the fulminate be confined in a case of stout metal (sheet tin) and be closely surrounded by being tightly imbedded in the mass of gun-cotton. If there be no close contact between the two, the quantity of fulminate must be very considerably increased to ensure the detonation of the gun-cotton, and, in attempting to transmit detonation from mercuric fulminate to gun-cotton by means of tubes, it was found necessary to employ comparatively very large quantities of fulminate in order to accomplish this, even through short lengths of tubes. But when the quantity of fulminate used reaches certain limits, the detonation may be transmitted from it to gun-cotton through very long lengths of tube. In applying gun-cotton, on the other hand, to accomplish the detonation of mercuric fulminate, it was found that this result could be attained, and through considerable lengths of tube (seven feet and upwards) by means of very much smaller quantities of gun-cotton than is needed of fulminate to induce the detonation of gun-cotton through the corresponding distances.

This want of reciprocity between two detonating agents corresponds to one even more remarkable, which was observed by the lecturer in his earlier investigations on this subject. In the first place, it was found that the detonation of a quarter of an ounce of gun-cotton (the smallest quantity that can be thus applied) induced the simultaneous detonation of nitro-glycerine, enclosed in a vessel of sheet tin and placed at a distance of one inch from the gun-cotton; while with half an ounce of the latter, the same effect was produced with an intervening space of three inches between the two substances. But on attempting to apply nitro-glycerine to the detonation of gun-cotton, the quantity of the former, which was detonated in *close contact* with compressed gun-cotton, was gradually increased in the first instance to three-quarters of an ounce and subsequently even to two ounces without accomplishing the detonation of the latter, which was simply dispersed in a fine state of division, in all instances but one in a large number of experiments.

The force developed by the detonation of nitro-glycerine was found, by careful comparison of the relative destructive effects of corresponding quantities, to be decidedly greater than that of the fulminate, of which from two to five grains suffice for developing the detonation of gun-cotton, when it is in close contact with them. The non-susceptibility of gun-cotton to detonation by nitro-glycerine is therefore, it need scarcely be said, not ascribable to any deficiency in mechanical force suddenly applied when the nitro-glycerine is detonated.

SPERGULIN, A NEW FLUORESCENT BODY.*

BY C. O. HARZ.

Spergulin occurs in the seed coverings of *Spergula vulgaris* and *S. maxima.* It is produced at the time when the seeds blacken and are nearly ripe. Spergulin is very soluble in absolute and aqueous alcohol. Viewed by transmitted light the solution appears nearly colourless, with a shade of olive-green; by reflected light it exhibits an intense dark-blue fluorescence. Spergulin has not been obtained in the form of crystals. It is very soluble in methylic alcohol, less soluble in amylic alcohol, and scarcely soluble in petroleum or in ether. Concentrated sulphuric acid dissolves it, forming a dark-blue liquid. The fluorescence of an alcoholic solution of spergulin is maintained for more than a year if the liquid be kept in darkness; fluorescence is rapidly destroyed by the action of direct sunlight, and more slowly by that of diffused light.

Small quantities of caustic alkalies, or alkaline carbonates added to an alcoholic solution of spergulin, transform it into an emerald-green fluorescent body; basic lead acetate produces a precipitate in an alcoholic solution of spergulin. The new compound contains 61·85 per cent. of carbon, 7·05 of hydrogen, and 31·80 of oxygen, which agrees tolerably with the formula $C_5H_7O_2$. It appears to be related to chlorophyll, and is probably closely allied with phyllocyanin.

An alcoholic (1 : 8) solution of spergulin showed strong absorption, almost entirely in the violet; in this respect it differs considerably from chlorophyll, phyllocyanin, and phylloxanthin. The author is inclined to regard spergulin as a feeble acid, the acid salts of which, as well as the acid itself, exhibit blue fluorescence, the neutral salts exhibit green fluorescence, and the basic salts are without fluorescent properties.

"MERCURIALINE" (METHYLAMINE).*

BY E. SCHMIDT.

E. Reichardt has described (*Jour. f. prakt. Chem.*, 104, 301) a volatile alkaloid "mercurialine," which he obtained from *Mercurialis annua* and *Mercurialis perennis*, as having the same composition as methylamine, but differing from it in being an oily colourless liquid at the ordinary temperature, and in forming an oxalate and sulphate whose crystallizing characters were not in accordance with those given by Wurtz for the corresponding salts of methylamine.

The author has separated a large quantity of the alkaloid which exists in *Mercurialis annua*, and has compared it with pure methylamine prepared from caffeine. The results prove that the two alkaloids and their corresponding salts are in every respect identical, and that Reichardt's "mercurialine" is none other than an aqueous solution of methylamine. It was also found that the oxalate and sulphate of methylamine do not behave in the manner stated by Wurtz (*Annalen*, 76, 324), but that they are readily crystallizable from water; in fact, agreeing with the results obtained by Reichardt with the oxalate and sulphate of "mercurialine."

Trimethylamine in small quantity was also obtained from *Mercurialis annua*, and its presence there, together with a considerable quantity of the primary base induces the supposition that dimethylamine may also be present. In many plants which the author has examined, he has found a small quantity of trimethylamine accompanying ammonium salts, but has met with no species of plants other than those above mentioned, which contain methylamine, although no doubt methylamine is not confined to them.

THE PREPARATION OF ETHYL BROMIDE.†

BY WM. H. GREENE, M.D.

As bromide of ethyl has recently attracted some notice as an apparently safe and agreeable anæsthetic, having all of the advantages of chloroform without producing the nauseating effects which render ether unpleasant, an easy process for its preparation may be acceptable to pharmacists.

Most cheaply prepared by the action of bromine on alcohol in presence of amorphous phosphorus (Personne), ethyl bromide so made possesses a slightly garlicky odour, almost impossible to get rid of; this is possibly due to a trace of ethylphosphine or a phosphinic ether, but however this may be, the product has been objected to on account of the odour.

* (*Liebig's Annalen*, 193, 73—86). From the *Journal of the Chemical Society*, January, 1879.

† From the *American Journal of Pharmacy*, June, 1879

The process recommended by de Vrij, the action of a mixture of strong sulphuric acid and alcohol on potassium bromide, yields a product contaminated with ordinary ether, and as ethyl bromide and ether boil at 40° and 35° respectively, the ether cannot be removed. This contamination is avoided if the sulphuric acid be dilute, and the following process gives satisfactory results in the preparation not only of ethyl bromide but of other alcoholic bromides.

Twelve parts of coarsely powdered potassium bromide and eleven parts of sulphuric acid, diluted with its volume of water, are heated in a retort or flask fitted to a condenser; as soon as hydrobromic acid begins to be disengaged, twelve parts of alcohol are allowed to flow in slowly, as in the preparation of ether. Ethyl bromide distills over with a small quantity of water and some alcohol. The distillate is agitated with water to remove alcohol, the ethyl bromide separated and dried by potassium carbonate, which at the same time neutralizes any free acid. It needs no further purification. About eight parts of ethyl bromide should be obtained. It should be kept in the dark like all other ethereal compounds containing chlorine, iodine or bromine.

A BRIEF REPORT OF THE ACTION THAT HAS BEEN TAKEN IN ROCHDALE, WITH A VIEW TO SEPARATE THE DISPENSING OF MEDICINES FROM MEDICAL PRACTICE.

Last February the Rochdale Chemists' Association appointed a committee to take such steps as might be deemed desirable with a view to an arrangement for the dispensing of medicines to be done by the chemist instead of by the medical man, as at present.

The first thing that was done was to make somewhat extensive inquiries in different parts of the kingdom as to the practice now in use, and as to the effect, so far as the interests of the medical man and the public are concerned. A brief report of the result of these inquiries appeared in the *Pharmaceucical Journal* for May 3, 1879.

After this, the whole of the medical men of the town were invited to meet the committee, on Tuesday evening, May 20, when eleven responded by their presence, being a majority of the medical men of the town. The result was that certain questions were raised by the medical men, and as they involved the chief objections to the plan, it was thought better to give some time for the consideration of these objections, and accordingly the meeting was adjourned to give the committee an opportunity of obtaining further information, and preparing answers to the questions raised.

As a result of further inquiries, valuable information was obtained from Scotland (Edinburgh and Aberdeen, where the practice of dispensing by chemists is almost universal), and after this another meeting with the medical men was arranged, when the following document was submitted:—

Medical Question I.—It is argued by medical men, that if patients are not supplied by them with medicine, they will have to charge a reduced fee, the loss of which will not be covered by the saving in drugs and charges connected with dispensing.

Chemists' Reply.—Taking the figures as given in a typical case put forward by the medical men, in which 7000 visits are supposed to be made annually, if the fee be reduced 6*d.* per visit we have 7000 sixpences £175

But the reduction of the fee would not be made to all the patients, probably 25 per cent. would continue to pay the same fee as before. This estimate would reduce the loss by about . . £44

Added to this the saving in the cost of drugs, estimated at £93

— £137

Probable pecuniary loss where no dispenser is employed £38

This loss would be more than covered by one extra visit per day in each week of six days, or one visit more per day throughout the year would more than cover the loss and pay for the few drugs which would be kept for emergencies.

Question II.—How could medicines be obtained by the public at night, on Sundays and holidays, when shops were closed?

Answer.—Some chemists would have a provision for all contingencies.

Question III.—How would the poor and the very poor pay for their medicines?

Answer.—A standard price being adopted for general use, exceptions would be made as follow:—The prescription might be marked with the letter P (poor) by the medical man, if he thought any case deserving of such a distinction, when the chemist would charge one half or one-third the ordinary sum, and when the patient was very poor, the mark might be V P, when no charge would be made for the medicine then supplied; but this would be followed by the chemist giving a recommendation to the dispensary, or he would refer the case to the charity organization association (if formed), or an arrangement might be made with the guardians to pay one-half or one-third the standard charge; for those in receipt of parochial relief. The chemist would give credit on the recommendation of the prescriber, which might be expressed on the prescription by the letter C, or the chemist would do so on his own responsibility; but when credit had to be given the fully reduced charge could not be made.

Question IV.—What guarantee would the doctor have that the prescription would not be repeated without further instructions from him?

Answer.—The honour of the dispenser, and the return of the prescription to the prescriber within twenty-four hours after being dispensed, except it was ordered to be repeated any given number of times, when it would be returned after being dispensed for the last time.

Question V.—What about counter prescribing?

Answer.—Ever since the incorporation of the Pharmaceutical Society, chemists generally have discouraged prescribing in the hope that they would ultimately have the duty of dispensing the prescriptions of medical men. Where this practice prevails, there is no prescribing done by the chemists, except for such simple ailments as the medical profession do not care to treat, or the public do not think of asking their advice about. The result may be thus briefly summed up. The more dispensing by chemists the less prescribing, the less dispensing the more prescribing.

Question VI.—Could prescribers rely on prescriptions being accurately dispensed with good drugs?

Answer.—The medical profession need be under no anxiety on this point. There are plenty of properly qualified chemists whose honour is a sufficient guarantee that the intentions of the prescriber will be strictly carried out, both as regards accuracy of compounding and purity of drugs. Physicians at present depend almost entirely on chemists to carry out their instructions, which we believe is done quite to their satisfaction, as well as that of their patients.

After the reading of the above, there appeared to be a dead stand at the first difficulty, viz., that of pecuniary loss to the prescriber. But little difficulty, however, seemed to be felt with regard to the other points. Hereupon the conference terminated without securing the result aimed at at present. But the feeling that remained was that one or more of the medical men would cease to dispense for their patients at no distant date. It is hoped that when once a beginning has been made, others may find it to their advantage to follow the example. The committee cannot close their report without expressing their thanks to those gentlemen at a distance who so kindly answered their inquiries, in very many cases with lengthy explanations and valuable suggestions.

The Pharmaceutical Journal.

SATURDAY, JULY 12, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

DISPENSING BY PHARMACISTS AND MEDICAL PRACTITIONERS.

THOUGH the pharmacists of Great Britain would probably not approve, any more than medical practitioners, of being subjected to the very stringent regulations by which the practice of dispensing is made the especial business of continental pharmacists, there is unquestionably great room for improvement in regard to the way this work is now carried out. Lapse of time, which is a remedy for so many evils, must be looked to as one great source of mitigation for the confusion of pharmacy with medicine which has come to the medical practitioners and the pharmacists of to-day as an inheritance from the apothecaries of last century. But that alone would not suffice to bring about a change in the habits of either medical men or pharmacists, and therefore gratitude is due to any individuals or associations that strive by any means to show the desirability of effecting as far as possible a separation of the duties of the dispenser from those of the prescriber.

Some months ago the Chemists' Association of the town and district of Rochdale undertook to make some inquiries throughout the country, in order to ascertain what was the practice in various localities and thus to obtain a groundwork of information upon which to promote arrangements for dispensing to be done by chemists and druggists instead of by medical men as is so often the case at present. A series of questions addressed to the local secretaries of about eighty towns, situated in various parts of the country, had the effect of eliciting the information required as to whether the medical men in the several towns dispensed the medicines for their own patients; whether, in cases where that was not done, the prescriptions were free to be taken to any *bonâ fide* chemist and druggist to be dispensed, and further how, in cases where it was done, that practice affected the medical men on the one hand and the public on the other as regards fees.

Out of the eighty places from which information was sought there were seventy-two from which replies were received. Some of these merely answered the first question without giving any details as to the effects of the practice in force in the particular town, but others gave fuller information and only in one instance was disapproval of the procedure of the Rochdale Association expressed.

It was found that in twenty-eight towns having an average population of about forty to fifty thousand the doctors with some rare exceptions did all the dispensing, or if the dispensing was done by the chemist and druggist, it was done for the medical practitioner rather than for the patient.

In fourteen other towns containing some 1,400,000 inhabitants the practice of medical men dispensing for their patients was largely prevalent, but not universal.

In fifteen other towns, the aggregate population of which amounted to about one million and a half, the practice was more varied, but there were a large number of medical men who did not dispense medicine for their patients.

In fifteen other towns again, with a somewhat larger aggregate population, the practice of medical men dispensing their medicines was either entirely unknown or but very rare.

Among the towns included in the latter class were Liverpool, Birmingham, Edinburgh and several places of resort for invalids, such as Torquay, Cheltenham, etc. The places where dispensing was practised chiefly by the medical men were either situated in manufacturing districts, as Dudley, Wolverhampton, Stoke-upon-Trent, Bradford, etc., or were agricultural centres, such as Norwich, Taunton, Maidstone, Reading, Grantham, etc.

The testimony furnished by those who sent the replies was very generally in favour of medical men ceasing to dispense, as leaving them free from a task somewhat irksome and often interfering with their attendance upon patients. As regards fees it was stated that it made no difference except in the case of very poor patients. There seemed also to be good evidence that where the change had been made, it met with the approval of the public, and of the medical men as well as chemists and druggists, and that each was benefitted in that way which proved in practice to be the greatest boon to all concerned.

We have now received from the Secretary of the Rochdale Association a further report of the action that has been since taken in Rochdale with a view of separating the dispensing of medicines from medical practice. The committee entrusted with the matter invited the medical men in the town to a conference, the result of which was that certain questions were raised by the medical men involving the chief objections to the plan from their point of view. Further information was then obtained in special reference to these questions, and at a subsequent meeting between the committee and the medical men the whole subject was discussed.

The chief question and the difficulty which seems to stand most of all in the way of medical men giving up the supply of medicine themselves has reference to their professional fee, the idea being that they must charge a reduced fee and that the reduction would not be covered by the saving in drugs and expenses connected with dispensing. The answer given to this is that the loss resulting from reduction of fees would be more than covered by the fees received for a larger number of visits.

The other questions do not involve so much difficulty; thus, for instance, in the obtaining of medicine upon Sundays and at night there is little reason to fear chemists and druggists would not be able to satisfy all requirements. As to the security that good drugs and preparations would be supplied by chemists and druggists, it may fairly be taken for granted that, at the present day, medical men need not be under any apprehension. Apart from the influence exercised by the provisions of the Food and Drugs Act, the improved education of the pharmaceutical body may be trusted to as ensuring proper regard to this point and due consideration that the intention of the prescriber should be properly carried out both by the use of pure drugs and accuracy in compounding.

Another question of some importance has reference to the scale upon which the poorer class of patients would be charged for their medicines. It is suggested that to meet this difficulty a standard scale of charges for medicine should be adopted, and that exceptional reductions of charge should be made in accordance with the recommendation of the prescribers, to be made known by marking the prescriptions with the letters P. or V.P., in those cases where the medical man thought the patients entitled to this consideration on the grounds of being poor or very poor. A further provision for such cases is suggested, according to which an arrangement is to be made with the guardians of the poor to pay one half or some proportion of the dispenser's charge.

These suggestions are worthy of consideration by pharmacists generally as being calculated to pave the way towards a very considerable modification of the mode in which the dispensing of medicine is carried out, and as there is no branch of the chemist and druggist's business which is more in need of such a change for the better, we commend to the attention of our readers the work that has been done in this direction by the Rochdale Association. It is eminently desirable that the attempt thus made to provide for the transfer of dispensing to the hands of chemists and druggists should receive general and earnest support from every member of the body, and we are disposed to believe that by such means it may eventually be possible to secure a very much larger share of this business.

The feeling on the part of medical practitioners is in many instances very decidedly in favour of giving up the practice of dispensing, and we would urge upon every member of the trade the importance of taking all possible advantage of this disposition by offering facilities which will remove some of the difficulties attending such a change of procedure, and by giving every assurance to medical men that the dispensing of their prescriptions would be carried out in all respects so as to command the satisfaction of themselves and their patients.

STRANGE CASE OF ARSENICAL POISONING

Another extraordinary case of poisoning with arsenic is reported as having occurred at Huddersfield which recalls to mind the cases of poisoning resulting from the use of "violet powder" containing an admixture of arsenic. A woman who had been in the habit of taking prepared chalk to relieve heart-burn was attacked after taking a dose with sickness and pains, for which a medical man administered a sedative. Two days afterwards the woman died and a *post mortem* examination revealed appearances of arsenical poisoning. It was then found that she had been supplied with powdered "French chalk" by mistake, instead of prepared chalk, and that this "French chalk" contained as much as 40 per cent. of arsenic. It is stated that the French chalk had been supplied by a Manchester firm and the coroner requested the chief constable to communicate with the Manchester police on the subject.

CHEMICAL SOCIETY'S RESEARCH FUND.

According to the *Chemical News* the following grants have just been made from the Research Fund of the Chemical Society:—

£30 to Mr. W. Whiteley Williams, for experiments on an Improved Method of Organic Analysis.

£25 to Mr. M. M. Pattison Muir, of Caius College, Cambridge, for Determining the Physical Constants and Chemical Habitudes of certain Bismuth Compounds.

£15 to Mr. J. M. Thomson, for experiments on the Action of Isomorphous Bodies in Exciting the Crystallization of Supersaturated Solutions.

£50 to Dr. Wright, for continuing his Researches o Chemical Dynamics.

£25 to Mr. F. D. Brown, for continuing his Researches on the Theory of Fractional Distillation.

£30 to Mr. Bolas, for an Investigation of certain Chromium Compounds.

£20 to Mr. F. R. Japp, for an Investigation of the Action of Organo-zinc Compounds on Quinons.

£100 (the De la Rue donation) to Dr. H. E. Armstrong, for the Determination of certain Physical Properties, especially Refraction Indices, of Typical Chemical Compounds.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The Annual Meeting of the above Association will be held on Thursday, the 17th inst., at 8.30 p.m. precisely, when the President, Professor Attfield, will take the chair, and the Annual Report of the Committee will be read.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, July 2, 1879.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President; Dr. Collins, Messrs. Brunker, Goodwin, Hayes, Hodgson, Holmes, Oldham, Pring (Belfast).

The minutes of the meeting held on June 4 were read and signed.

The President announced the death of Mr. James Whitla, licentiate of Apothecaries' Hall, of Monaghan, a member of the Council; and stated that in accordance with clause 11 of the Pharmacy Act it was necessary to fill up the vacancy thus created within ten days after its notification to him.

Proposed by Mr. Pring, seconded by Dr. Collins, and resolved,

"That this Council have heard with extreme regret of the death of Mr. James Whitla, of Monaghan, and desires to offer to his widow and family their condolence and sympathy in their great affliction; and to express to them the Council's appreciation of the late Mr. Whitla's valuable services as a member of this Board."

Mr. Alexander E. Doran, member of the Society, of Goldsmith Terrace, Bray, Co. Wicklow, was proposed by Mr. E. M. Hodgson, and seconded by Mr. J. L. Holmes, for election to the vacant seat on the Council.

The President having put the motion, Mr. Doran was elected unanimously.

William Whitla, M.D., licentiate of Apothecaries' Hall, Dublin, of Victoria Place, Belfast, was registered as a pharmaceutical chemist.

He was also proposed by Mr. R. W. Pring, and seconded by Mr. E. M. Hodgson, as a candidate for membership.

Mr. James Wells, 52, Upper Sackville Street, Dublin, who was proposed by Mr. W. Hayes at the June meeting and seconded by the President, was now elected a member of the Society.

The above business, which did not admit of postponement, having been transacted, it was

Proposed by Mr. Holmes, seconded by Mr. Hayes, and resolved,

"That the Council do now adjourn, in respect to the memory of the late Mr. Whitla, of Monaghan, member of the Council."

The examination for the pharmaceutical chemists' license was held on the same day, but had not concluded when the Council rose. Five candidates presented themselves for the examination.

Provincial Transactions.

SUNDERLAND CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The general meeting of the Sunderland Chemists' Assistants and Apprentices' Association was held at the rooms, corner of William Street, on Monday evening last, the 7th inst. The President, Mr. R. H. Mushens, occupied the chair. The President gave a brief *résumé* of the past session, saying that he had been much pleased by the manner in which every department of the work had been carried out; that the success of the Association, which had just now closed its first session, had exceeded his highest expectations, which he ascribed to the great interest taken in it by every individual member, as shown by their regular attendance at the meetings, etc. He then stated how the Association had first originated, and how the attempt of the assistants and apprentices in this matter had been ably supported by the chemists, who had rendered very great service to it. The programme drawn up at the commencement of the session had been carried out almost in its entirety, several of the papers reflecting great credit upon their authors. A very fair library also had been raised for the use of the members, which, together with the splendid materia medica collection sent by Messrs. Wright, Layman and Umney and Messrs. Burgoyne, Burbidges, Cyriax and Farries, would be of great value to the Association. Besides these donations, Messrs. Clarke, Bleasdale, Bell and Tollington gave £3 3*s*., at the same time promising £2 2*s*. annually; Messrs. Hearon, Squire and Francis, £2 2*s*.; Messrs. Maw, Son and Thompson, £1 1*s*.; Messrs. Sanger and Son, 10*s*.; Messrs. Southall, Brothers and Barclay, one of their cabinets of materia medica; Attfield's 'Chemistry,' had also been received from Professor Attfield; several books from Mr. George S. V. Wills, and others from chemists in the town.

The President then tendered his hearty thanks to the members for their valuable assistance, and also for the harmony and goodwill which had characterized the past session, rendering his position as much a pleasure as a duty, and expressed a wish that this Association might prosper in the future as it had done in the past; that it might prove useful to every individual member in some way or other and become ultimately second to none in the kingdom.

The Secretary (Mr. R. Thompson) then read his report, in which he stated the number of honorary members was 26, of members 27, and that the average attendance had been 15.

The Treasurer (Mr. A. Harding) read the financial statement, showing the income for the session to be £17 19*s*. 3*d*., the expenditure £6 5*s*. 1*d*., leaving a balance of £11 14*s*. 2*d*.

The reports, as read, were unanimously adopted, and a hearty vote of thanks having been accorded to the officers and committee for their services, to the donors to the library and materia medica collection and to the authors of papers, the meeting proceeded to elect the officers for the ensuing session, with the following results:—President, Mr. A. Harding; Vice-Presidents, Messrs. Robert H. Mushens and R. Leithead; Secretary, Mr. R. Thompson; Treasurer, Mr. G. C. W. Wright; Librarian, Mr. J. Johnson; Committee, Messrs. W. Fowler, J. J. Browell, G. Proctor, J. W. Robinson, C. Rankin and A. H. Rhymer.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

The members of this society held their annual dinner in the Huntley Arms Hotel, Aboyne, last week. Among those present were Mr. D. Reid, (in the chair), Dr. Moir, Baillie Sangster, Messrs Coutts, Cruickshank, Giles, Gordon, Gordon, jun., Presslie, Ritchie, Shepherd, Sinclair, Strachan and J. J. Petrie, Aboyne. After dinner the following toast-list was gone over. "The Queen and the Royal Family," and "The Aberdeen Society of Chemists and Druggists," by the Chairman; The Pharmaceutical Society," proposed by Mr. Presslie, and replied to by Baillie Sangster; "The Medical Profession," by Mr. Cruickshank, acknowledged by Dr. Moir; "The Town and Trade of Aberdeen," proposed by Mr. Strachan, responded to by Mr. Sinclair; "The Aberdeen School of Pharmacy," by Mr. D. Ritchie, replied to by Messrs. Strachan and Gordon; "The Ladies," by Mr. Gordon, jun., responded to by Mr. Giles; "Aboyne and District," by Mr. Shepherd, replied to by Mr. J. J. Petrie; and "The Chairman," by Baillie Sangster. The party returned to Aberdeen in the evening, having enjoyed themselves thoroughly.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The History of Alizarin and Allied Colouring Matters, and their Production from Coal Tar.*

BY W. H. PERKIN, F.R.S.

(*Continued from page* 18).

The attention of Graebe, in conjunction with Liebermann, was then turned to alizarin, which they thought probably might belong to the quinone series; but it was important that they should first know to what hydrocarbon it was related. To obtain that information, alizarin prepared from madder was taken and heated with powdered zinc, according to Baeyer's method of reducing aromatic compounds, and in this manner they obtained a crystalline hydrocarbon, having the composition $C_{14}H_{10}$. This was shown to be anthracene, a hydrocarbon contained in coal tar. Reasoning from the information which they had thus obtained, they assumed alizarin to be a dioxyquinone acid of anthracene—

$C_{14}H_{10}$	$C_{14}H_8O_2$	$C_{14}H_6\binom{OH}{OH}O_2$
Anthracene.	Anthraquinone.	Alizarin.

But to prove this to be the case it was necessary to produce alizarin from anthracene.

This hydrocarbon was discovered by Dumas and Laurent in 1832. They obtained it from the product which comes over towards the end of the distillation of coal tar. They gave it the formula $C_{15}H_{12}$, and as this was one and a-half times the molecular weight of naphthalene they called it paranaphthalene. It was further examined by Laurent, who changed its name to anthracene. He also obtained from it a body which he called anthracenuse, by oxidizing it with nitric acid; to this he gave the formula $C_{15}H_8O_4$ and $C_{15}H_7O_5$.

In 1854-55, when studying under Dr. Hofmann, at his suggestion I took up the subject of anthracene for my first investigation. I prepared the hydrocarbon by distilling pitch. Dr. Hofmann afterwards kindly obtained for me, from Messrs. Bethel, several pounds of a product rich in anthracene. On oxidizing anthracene I obtained a product to which I assigned the formula $C_{14}H_{10}O_2$, and not doubting Laurent's formula for the hydrocarbon anthracene, believed this oxygenated product to be derived from it by loss of carbon and hydrogen. These results were not published, and I only mention them here because it was through the experiments I then made that I obtained much information, which afterwards proved to be of great value to me; and, moreover, the products I then made served for the experiments to which I shall have to refer presently.

In 1857, Fritsche examined a hydrocarbon from coal tar, to which he gave the formula $C_{14}H_{10}$, and showed that it had many properties in common with anthracene.

In 1862, Dr. Anderson published an account of his investigations on anthracene. He found it to possess the formula $C_{14}H_{10}$, and to be identical with Fritsche's hydrocarbon. Dr. Anderson also prepared the oxidation product, and found it to contain $C_{14}H_8O_2$. He called it oxanthracene; it is identical with Laurent's anthracenuse, and with the product I obtained.

Graebe and Liebermann at once recognized this as the quinone of anthracene. It, therefore, only remained for them to convert this into the quinone acid by replacing two atoms of hydrogen by hydroxyl, and thus settle the question as to whether alizarin be a quinonic acid of anthracene or not.

The process they adopted has long been used by chemists; it consists in first replacing the hydrogen of the compound with bromine or other halogen, and then treating the resulting body with sodic, potassic or other metallic hydrate, and according as one, two or more atoms of hydrogen have been replaced by bromine, so on its removal by the metal of the hydrate, a compound containing a corresponding number of atoms of hydrogen replaced by hydroxyl is obtained.

Acting upon this principle, Graebe and Liebermann heated anthraquinone in sealed tubes, with bromine, in the proper proportions, to obtain a dibromanthraquinone, $C_{14}H_6Br_2O_2$. And this substance, when fused with caustic potash, yielded alizarin in combination with the alkali, from which it was separated by means of an acid. They also proposed a second method for preparing dibromanthraquinone, viz., by oxidizing tetrabromanthracene—

$$C_{14}H_6Br_4 + O_2 = C_{14}H_6Br_2O_2 + Br_2.$$

The great importance of alizarin, as a dyeing agent, induced Graebe and Liebermann to patent their process, but it was of no commercial value. They had, however, solved the question of its relationship to anthracene and anthraquinone, and also established its formula—

$$C_{14}H_6\binom{OH}{OH}O_2$$

Strecker, in 1866, had given the correct formula for alizarin, but did not publish it in the ordinary way results of research are usually published, but adopted it in his 'Traité de Chimie Organique.' And it was not until he drew my attention to the fact, that I became aware of it. He also states that he instituted experiments in 1855, in conjunction with Staedel, to establish the relationship between alizarin and anthracene. Graebe and Liebermann appear to have had no knowledge of this.

On distilling purpurin, the other colouring matter of madder previously referred to, Graebe and Liebermann also obtained anthracene, and this confirmed the formula Strecker had assigned to this substance, viz., $C_{14}H_8O_5$.

Purpurin is anthraquinone, with three atoms of hydrogen replaced by hydroxyl.

$$C_{14}H_5\left\{\begin{matrix}OH\\OH\\OH\end{matrix}\right\}O_2$$

Graebe and Liebermann's process for the preparation of alizarin being found to be impracticable, it was desirable, if possible, to find a new method which would render their discovery of commercial value.

It has been known for a very long time that sulphuric acid acts upon many organic bodies, producing substances called sulpho-acids. In composition these represent the body acted upon *plus* sulphuric anhydride, the basicity of the product (if derived from a neutral body) increasing with the number of molecules of sulphuric anhydride used in its formation. These so-called sulpho-acids have been found, however, to be nothing more than acid sulphites; thus the acid produced by the combination of benzol with one molecule of sulphuric anhydride is an acid sulphite of phenyl, or phenyl-sulphurous acid:—

$$\underbrace{C_6H_6SO_3}_{\text{Sulphobenzolic acid.}} = \underbrace{C_6H_5SO_3H}_{\text{Phenylsulphurous acid.}}$$

And that obtained by combining naphthalin with two molecules of sulphuric anhydride is an acid disulphite:—

$$\underbrace{C_{10}H_8(SO_3)_2}_{\text{Disulphonaphthalic acid.}} = \underbrace{C_{10}H_6\left\{\begin{matrix}SO_3H\\SO_3H\end{matrix}\right.}_{\text{Naphthylene-sulphurous acid.}}$$

The experiments of Würtz and Kekulé, in 1867, confirmed this view of the constitution of these acids. They found that sulpho-benzolic acid, when heated with caustic potash, produced a phenate and sulphite, thus:—

$$\underbrace{C_6H_5SO_3H}_{\text{Sulpho-benzolic acid.}} + 3\,K\,HO =$$

$$\underbrace{C_6H_5OK}_{\text{Potassic phenate.}} + SO_3K_2 + 2\,OH_2$$

* From the *Journal of the Society of Arts.*

In the same year Dusart also found that disulphonaphthalic acid yielded in the same way a naphthylenate and a sulphite.

$$\underbrace{C_{10}H_6 \left\{ \begin{matrix} SO_3H \\ SO_3H \end{matrix} \right.}_{\text{Disulphonaphthalic acid.}} + 6\,KHO =$$

$$\underbrace{C_{10}H_6 \left\{ \begin{matrix} OK \\ OK \end{matrix} \right.}_{\text{Potassic naphthylenate}} + 2\,SO_3K_2 + 4\,OH_2$$

By the addition of an acid to the products of these reactions they obtained, first from benzol, by means of the sulpho acid, hydrate of phenyl, phenol of carbolic acid, and from naphthylene, the dihydrate of naphthylene.

$$\underbrace{C_6H_6}_{\text{Benzol.}} \qquad \underbrace{C_6H_5OH}_{\text{Hydrate of phenyl.}}$$

$$\underbrace{C_{10}H_8}_{\text{Naphthylene.}} \qquad \underbrace{C_{10}H_6 \left\{ \begin{matrix} OH \\ OH \end{matrix} \right.}_{\text{Dihydrate of naphthylene.}}$$

In this second example it will be seen that we have obtained a body standing to naphthylene as alizarin does to anthraquinone. In other words, two atoms of hydrogen have been replaced by two hydroxyls.

It therefore appeared probable to me that, if a disulpho acid of anthraquinone could be produced, alizarin might possibly be obtained by a similar process.

From my previous knowledge of the remarkable stability of anthraquinone, and that it might be dissolved in strong hot sulphuric acid, and would then crystallize out unchanged on cooling, it did not appear very probable that a sulpho acid could be formed; nevertheless, experiments were made, varying temperatures being employed, when eventually it was found that by heating a mixture of sulphuric acid and anthraquinone very strongly, combination actually took place, the mixture becoming perfectly soluble in water. After removing the excess of sulphuric acid from the new product it was mixed with caustic potash and heated to about 180° C.; it soon became coloured, and then black. When the reaction was considered complete, the black alkaline mass was dissolved in water, and formed a rich purple solution. On acidifying this it became yellow, from the separation of a copious precipitate, which, on examination, proved to be artificial alizarin. This product, when collected on a filter and thoroughly washed, was found to dye madder mordants with the greatest readiness.

The great obstacle to the preparation of alizarin, viz., the use of bromine, was thus removed, and, as the result has proved, a process had been obtained by which this colouring matter could be manufactured in quantity.

I may here mention that, while these experiments were in progress, Caro, Graebe, and Liebermann were investigating the same reaction in Germany.*

A short time after I had discovered this method of making artificial alizarin, I found an entirely new process, in which anthraquinone is not required at all.*

Anthracene forms with chlorine a beautifully crystalline body, called dichloranthracene, having the formula, $C_{14}H_8Cl_2$. This substance combines with Nordhausen sulphuric acid, forming a bright green solution, which consists of a sulpho acid of dichloranthracene. This compound undergoes a remarkable change when heated with sulphuric acid, hydrochloric acid and sulphurous anhydride being evolved, and a sulpho acid of anthraquinone formed. This process has proved to be of great value, as will be seen further on.

When artificial alizarin was first manufactured it was noticed that the colours produced by it differed, to some extent, from those produced with madder or alizarin. The red shades were more brilliant and more scarlet, and the purples bluer; the blacks were also more intense, and some persons went the length of saying that alizarin had not been produced artificially at all. This I refuted in a paper read before the Chemical Society in May, 1870,† when I showed that alizarin could be readily separated from the commercial product, and then possessed all the properties of natural alizarin, both as regards its dyeing power and in its other characteristics. As no doubt now exists on this point, I think I need not further discuss it.

In a foot note‡ in the paper just referred to I stated that "when purifying artificial alizarin by converting it into an alumina lake, I found that, upon digestion with carbonate of potash, this lake gave a red coloured solution, containing a colouring matter dyeing mordants very similarly to alizarin, with the difference that the reds were more scarlet, and the purples bluer or more slaty. I have not obtained this body in a perfectly pure state as yet, but it appears to be crystalline. It gives two faint black bands when examined in alkaline solution with the prism, but these may perhaps be due to the presence of traces of alizarin." Some time after this, I made a complete examination of this substance,§ and my analytical results showed it to have the same composition as natural purpurin, viz:—

$$C_{14}H_5 \left\{ \begin{matrix} OH \\ OH \\ OH \end{matrix} \right\} O_2$$

though it differs from it in properties, in fact, it is an isomeride of that substance. Being a derivative of anthracene, I therefore named it anthrapurpurin. Auerbach,|| in 1872, separated a colouring matter from artificial alizarin. He named it isopurpurin. It is, however, identical with anthrapurpurin. The name isopurpurin is now mostly used for this substance on the Continent.

The importance of anthrapurpurin as a colouring matter can scarcely be overrated. I believe I may truly say it is of as great importance as alizarin itself, and its existence in artificial alizarin has been the cause of its marvellously rapid success, as it gives a brilliancy to the reds which cannot be obtained with madder. Anthrapurpurin differs from alizarin in many particulars. When heated it is mostly decomposed, only a little subliming in orange-red vapours, and condensing as yellowish red leaves. If a mixture of anthrapurpurin and alizarin be sublimed, the

* Graebe and Liebermann, in a paper published in the *Moniteur Scientifique*, April, 1879, p. 399, state that "Caro was the first to observe that anthraquinone, when heated with sulphuric acid above 200°, formed sulphoconjugated acids, which, like the brominated compound, gave alizarin on fusion with potassium hydrate; soon afterwards, or almost at the same time, Perkin made the same observation." Again, at pp. 400—401, they state "The patent of Caro, Graebe, and Liebermann is dated a day before that of Perkin. If any particular importance is attached to dates, the advantages rests without dispute with Caro, for the filing of the patent of the German chemist was delayed through irregularity (*vice de forme*). The signatures had already been given in to the Patent Office, Berlin, on the 15th June." I may remark, in reference to the first statement, that Graebe and Liebermann neither give or adduce any evidence to substantiate their claim to priority. Their remark that I had soon afterwards, or almost at the same time, made the same observation, also goes to show that they have none. And in reference to the statement that their signatures had been given in to the Patent Office, Berlin, on the 15th June, I find that on May 20th I wrote to Mr. Robert Hogg, of Glasgow, enclosing patterns dyed with artificial alizarin, which I had prepared by fusing the sulphoconjugated acids of anthraquinone with potassium hydrate, and my patent might then have been secured, but was delayed. Therefore, their conclusions, from the argument as to dates, should be reversed.

* Patented November, 1869, No. 3318.

† *Journal of the Chemical Society*, 1870, p. 133.

§ *Journal of the Chemical Society*, 1872, p. 659; 1873, p. 425.

|| *Moniteur Scientifique*, 1872, p. 686.

sublimate will consist almost entirely of alizarin, as this substance is not so easily decomposed by heat.

Anthrapurpurin dissolves in caustic alkalies with a more purple colour than alizarin. It also differs in its behaviour with alumina. A solution of anthrapurpurin in sodic carbonate, when mixed with freshly precipitated alumina, is not absorbed by it, whereas alizarin under the same conditions is perfectly absorbed. It crystallizes in orange yellow needles, from alcohol or glacial acetic acid.

By heating it with acetic anhydride I obtained a triacetyl derivative, and by using benzoyl chloride, a tribenzoyl one, thus showing it to contain three replaceable hydrogens. Its alkaline solutions give two faint absorption bands when viewed with the spectroscope, these bands being in the same region of the spectrum as those produced with alkaline solutions of alizarin. When oxidized with nitric acid it does not yield phthalic acid.

On heating anthrapurpurin with ammonia to a temperature of 160°—180°C., in a closed tube, I found it changed into an amidated compound, which has been named anthrapurpuramide. This substance does not dye mordants. Its solution in alcohol is of a clear dark orange-red colour. It dissolves in alkalies with a purple colour. Anthrapurpuramide is isomeric with amido alizarin. Its formula is—

$$C_{14}H_5 \left\{ \begin{array}{l} NH_2 \\ OH \\ OH \end{array} \right\} O_2$$

In my paper on anthrapurpurin it is mentioned that there is a colouring matter in artificial alizarin dyeing alumina mordants of an orange colour.* This was afterwards obtained in a crystalline condition, and was under investigation for some time, but the research was laid aside on account of more pressing subjects. This substance, however, proves to be flavopurpurin, a colouring matter lately described by Schunck and Roemer,† and obtained by them from anthraflavic acid. It has the formula—

$$C_{14}H_5 \left\{ \begin{array}{l} OH \\ OH \\ OH \end{array} \right\} O_2$$

and is therefore isomeric with anthrapurpurin.

The amount of it contained in artificial alizarin is not very large. It is much more freely soluble in alcohol than anthrapurpurin, and crystallizes from that solvent in orange coloured silky needles. Its alcoholic solution, when poured into water, forms a yellow precipitate; this, however, has a satiny aspect, owing to the crystalline character of the precipitate; it dissolves in caustic alkali with a purple colour, redder than that produced with anthrapurpurin, and in ammonia it forms a brownish red colour, anthrapurpurin forming a purple solution.

Flavopurpurin dyes mordants, but the colours on those of alumina are of an orange red colour, the pinks being somewhat of a salmon shade. The purples are more like those of alizarin, but very dull in comparison with them.

In artificial alizarin I believe there is yet another colouring matter not investigated, dyeing alumina mordants a still yellower shade than flavopurpurin. It is apparently present in very small quantities.

We now see that the product at first made and called "artificial alizarin," contained at least three colouring matters, viz., alizarin, anthrapurpurin, and flavopurpurin; as I think it will be convenient to retain this name at present, for simplicity sake, it will be understood that, when I use it, I do not refer to pure alizarin, but to commercial products known by that name.

Before proceeding to speak of some of the products found in artificial alizarin, I wish to draw attention to a soluble intermediate substance which is obtained in its preparation if the process of heating with caustic soda be not carried on sufficiently long. In this case, although the alkaline product dissolved with a strong violet colour, I noticed that, when acidified, no colouring matter, or

* *Journal of the Chemical Society*, 1873, p. 425.

† Deut. Chem. Ges. Ber., 1876, p. 679.

only a small quantity, was precipitated, a strong dark yellow solution being obtained. On isolating this body it was found to be crystalline, forming orange-coloured needles, easily soluble in water, but insoluble in ether. With alkalies it forms a blue violet-coloured solution; it does not dye mordants. When fused with caustic aklali it is converted into anthrapurpurin. From the mode of its formation and from its decomposition with alkalies I gave it the formula:—

$$C_{14}H_6 \left\{ \begin{array}{l} OH \\ SO_3H \end{array} \right\} O_2$$

and named it sulphoxanthraquinonic acid.* Some time afterwards Graebe and Liebermann† further investigated this compound and confirmed this formula. With the alkaline earths it forms two sets of salts—acid and neutral ones—the former being of a yellow colour; the latter violet. These probably could be used as pigments.

The artificial alizarin, as first made, contained not only three colouring matters, but also other products not possessing dyeing powers. These are of considerable interest, as will be seen further on. Amongst these are anthracene, anthraquinone, and hydroanthraquinone, products which are the result of a peculiar reverse action, or process of reduction, which takes place in the preparation of artificial alizarin during the operation of heating with caustic alkali. The first, viz., anthracene, was only formed in the early experiments, and resulted from overheating. But the two other substances are always obtained if caustic alkalies alone are used. Of anthraquinone I have already spoken, but I have not referred to the action of reducing agents upon it. If anthraquinone be mixed with a solution of caustic potash and zinc dust, the liquid quickly becomes red, especially if heated, the anthraquinone dissolving. This liquid may be filtered; but as the oxygen of the air quickly acts upon it, films of anthraquinone are formed; if the air be excluded, a clear red-coloured fluid is obtained, and on the addition of an acid, a yellow precipitate is formed. This substance is hydroanthraquinone, produced from anthraquinone by its union with hydrogen. Its formation may be represented thus:—

$$\underbrace{C_{14}H_8O_2}_{\text{Anthraquinone.}} + H_2 = \underbrace{C_{14}H_{10}O_2}_{\text{Hydroanthraquinone}}$$

The other bodies I have to speak of are not due to any reverse chemical action, but are the products of direct changes, and were regarded as secondary products.

On boiling up artificial alizarin with dilute caustic soda, and adding milk of lime, it was found that the colouring matter was precipitated, leaving a yellow or orange coloured solution. On filtering this off, and adding an acid to the filtrate, a pale yellow precipitate was obtained. A quantity of this was prepared, washed and dried, and from some of it Dr. Schunck‡ succeeded in isolating a beautiful yellow crystalline product. This he called anthraflavic acid, and assigned to it the formula, $C_{15}H_{10}O_4$. Not being satisfied with this formula, I afterwards submitted it to investigation,§ and showed it to have the composition $C_{14}H_8O_4$, which has since been confirmed by others. This formula is the same as that of alizarin, and therefore, anthraflavic acid is an isomeride of that substance. It is prepared from its barium salt, which is somewhat difficultly soluble in water.

Anthraflavic acid is a beautiful substance, crystallizing in bright yellow silky needles, and, when heated, gives a sublimate of golden yellow crystals in the form of leaves or plates, a certain amount being, at the same time, carbonized. It does not dye mordants. It combines with alkalies, forming compounds dissolving in water with an orange red colour. The barium salt, already referred to, crystallizes in needles of a brownish red

* *Journal of the Chemical Society*, 1870, p. 139.

† 'Jahresbericht,' 1871, p. 685.

‡ 'Proc. Lit. and Phil. Soc.,' Manchester, vol. x., p. 133.

§ *Journal of the Chemical Society*, 1871, p. 1109.

colour, and its cold aqueous solution is somewhat similar in appearance to that of potassic bichromate.

Dr. Schunck found that anthraflavic acid when fused with caustic potash was converted into a colouring matter, which he thought to be alizarin. I also believed this to be the case until some time afterwards, when I prepared a sufficient quantity of the colouring matter to dye a pattern with. I then found it produced orange red colours with alumina mordants.*

Schunck and Roemer† have since investigated this reaction, and found that the colouring matter is an isomer of anthrapurpurin; in fact, it is flavopurpurin, which has already been described. Its formation may be expressed thus—

$$\underbrace{C_{14}H_8O_4}_{\text{Anthraflavic acid.}} + 3\,OKH = \underbrace{C_{14}H_5K_3O_5}_{\text{Potassic flavopurpurate.}} + H_2 + 2\,OH_2$$

To effect this change in small experiments, a temperature over 200° C. is necessary.

Dr. Schunck and H. Roemer‡ have published an account of another substance which accompanies anthraflavic acid. They have named it isoanthraflavic acid. I had also succeeded in obtaining this substance, and also in preparing it without the formation of colouring matter, except in small quantities.§ To this I shall refer presently.

Isoanthraflavic acid crystallizes from glacial acetic acid, in which it is difficultly soluble, in yellow needles. These lose their lustre on being dried at 100° C. When strongly heated it sublimes in leaves of a golden or orange colour. This substance has the formula—

$$C_{14}H_6 \left\{ \begin{matrix} OH \\ OH \end{matrix} \right\} O_2$$

and is, therefore, another isomer of alizarin. It differs from anthraflavic acid, in forming a barium derivative, which is easily soluble in cold water with a dark red colour. Heated with acetic anhydride it forms a pale yellow crystalline body, having the formula—

$$\underbrace{C_{14}H_6 \left\{ \begin{matrix} OC_2H_3O \\ OC_2H_3O \end{matrix} \right\} O_2}_{\text{Diacetoisoanthraflavic acid.}}$$

When heated to about 180° C. with caustic potash it undergoes a very interesting change. The mixture gives a black-looking product, which dissolves in water with a beautiful purple colour. On acidifying this with an acid a yellow precipitate is formed, which is found to consist of anthrapurpurin. This change is similar to that which takes place when anthraflavic acid is treated with caustic alkalies, but occurs at a much lower temperature. This reaction is as follows:—

$$\underbrace{C_{14}H_8O_4}_{\text{Isoanthraflavic acid.}} + 3\,OKH = \underbrace{C_{14}H_5K_3O_5}_{\text{Potassic Anthrapurpurate.}} + H_2 + 2\,OH_2$$

Isoanthraflavic acid does not dye mordants.

Another substance was found in artificial alizarin, as a bye-product, by Caro and Glaser. It was first examined in 1871 by Liebermann,‖ who found it to have the formula:—

$$C_{14}H_7\,(OH)\,O_2$$

and named it monoxanthraquinone. It crystallizes from alcohol in fine yellow needles. It does not dye mordants.

Monoxanthraquinone, when fused with alkalies, also undergoes an interesting change. It becomes a nearly black mass, which dissolves in water with a blue-violet colour, and this solution, on being acidified, gives a yellow precipitate, which is nothing but pure alizarin.

$$\underbrace{C_{14}H_7\,(OH)\,O_2}_{\text{Monoxanthraquinone.}} + 2\,OKH =$$

$$\underbrace{C_{14}H_6 \left\{ \begin{matrix} OK \\ OK \end{matrix} \right\} O_2}_{\text{Potassic Alizarate.}} + H_2 + OH_2$$

Now, how can the presence of monoxanthraquinone, anthraflavic, and isoanthraflavic acid in artificial alizarin be accounted for? When sulphuric acid acts upon anthraquinone, two kinds of sulpho acids are formed, namely, a mono and a di.

$$\underbrace{C_{14}H_7\,(SO_3H)\,O_2}_{\text{Monosulphanthraquinonic acid.}} \qquad \underbrace{C_{14}H_6 \left\{ \begin{matrix} SO_3H \\ SO_3H \end{matrix} \right\} O_2}_{\text{Disulphanthraquinonic acid.}}$$

After the manufacture of alizarin had been commenced, Graebe and Liebermann published an account of these bodies.*

They found that monosulphanthraquinonic acid, when heated carefully with alkali, yields monoxanthraquinone.

$$C_{14}H_7\,(SO_3H)\,O_2 + 3\,OKH =$$

$$\underbrace{C_{14}H_7\,(OK)\,O_2}_{\text{Potassic monoxanthraquinonate.}} + SO_3K_2 + 2\,OH_2$$

And this, when further heated, yielded alizarin as previously stated. The disulpho acid, when heated with alkali, they said, formed alizarin.

$$C_{14}H_6 \left\{ \begin{matrix} SO_3H \\ SO_3H \end{matrix} \right\} O_2 + 6KHO =$$

$$C_{14}H_6 \left\{ \begin{matrix} OK \\ OK \end{matrix} \right\} O_2 + 2SO_3K_2 + 4\,OH_2$$

This, as we shall see presently, was a mistake, probably from the fact that the need of a disulpho acid for the preparation of alizarin had never been doubted, the process being supposed to be analogous to that originally described with dibromanthraquinone.

But it was gradually found, when manufacturing artificial alizarin on the large scale, that the smaller the amount of sulphuric acid used to convert the anthraquinone into sulpho acids, the temperature being also kept as low as practicable, that the colouring matter made from such a product yielded with mordants shades of colour more nearly approaching those produced with madder, until eventually the unexpected result was arrived at, that it was necessary to have a monosulpho acid of anthraquinone for the preparation of pure alizarin, and that the disulpho acid does not yield this substance at all, so that, in the preparation of pure alizarin, the following reactions take place, monosulphanthraquinonic acid is first decomposed into monoxanthraquinone; and this, when further heated with alkali, is oxidized into alizarin.

We thus see that this formation of alizarin differs entirely from that originally discovered by Graebe and Liebermann, both as regards the chemicals employed and the chemical changes which take place. We also see that monoxanthraquinone is an intermediate product and not a secondary one.

Disulphanthraquinonic acid, although it does not yield alizarin when heated with alkalies, yields anthrapurpurin. But how is this to be accounted for? It has been shown that the first action of caustic alkali on this acid results in the formation of sulphoxanthraquinonic acid:—

$$C_{14}H_6 \left\{ \begin{matrix} OH \\ SO_3H \end{matrix} \right\} O_2$$

This, when further treated with the same reagent, changes into anthrapurpurin:—

$$C_{14}H_5 \left\{ \begin{matrix} OH \\ OH \\ OH \end{matrix} \right\} O_2$$

* *Journal of the Chemical Society*, 1873, p. 20.
† Deut. Chem. Ges. Ber., 1876, p. 679.
‡ Deut. Chem. Ges. Ber., 1875, p. 1628, and 1876, p. 379.
§ *Journal of the Chemical Society*, 1876, i, 851.
‖ Deut. Chem. Ges. Ber., 1871, p. 108.

* 'Jahresbericht,' 1871, 683-684.

When I became fully acquainted with this fact, I was under the impression that an intermediate body must be formed, standing to anthrapurpurin as monoxanthraquinone does to alizarin, and formed simply by the replacement of the SO_3H group in sulphoxanthraquinonic acid by HO.

Such a substance was found in artificial alizarin, and I have already described it; it is isoanthraflavic acid. In proof of its being always formed previously to anthrapurpurin, I succeeded in obtaining it directly by heating a salt of disulphanthraquinonic acid with a dilute solution of caustic potash. I employed a 5 per cent. solution of this alkali, and only little more than a sufficient amount to effect the decomposition indicated by theory, thus:—

$$\underbrace{C_{14}H_6\left\{\begin{matrix}SO_3H\\SO_3H\end{matrix}\right\}O_2}_{\text{Disulphanthraquinonic acid.}}+6OKH=$$

$$\underbrace{C_{14}H_6\left\{\begin{matrix}OK\\OK\end{matrix}\right\}O_2}_{\text{Potassic Isoanthraflavate.}}+2SO_3K_2+4OH_2$$

The mixture was heated in a closed iron vessel to 180°–190° C. for six or seven hours. In this manner scarcely any anthrapurpurin was formed, and the alkaline solution, when acidified, gave a precipitate consisting chiefly of isoanthraflavic acid. So that in the formation of anthrapurpurin from disulphoanthraquinonic acid we get the following changes:—First, the formation of sulphoxanthraquinonic acid; second, the formation of isoanthraflavic acid; third, the formation of anthrapurpurin; and we see that isoanthraflavic acid is also an intermediate product in the formation of anthrapurpurin, and not a secondary one. The formation of anthraflavic acid has now to be accounted for. When sulphuric acid acts upon anthraquinone, it is found to form two isomeric disulpho acids, one forming an easily soluble sodium salt, the other a less soluble one. The former is known as the β sodic disulphanthraquinonate, the latter as the α. This less soluble, or α salt, when treated with alkalies, undergoes analogous changes to the β salt, but, instead of forming isoanthraflavic acid, yields anthraflavic acid, and this, as previously stated, when heated strongly with alkalies yields flavopurpurin. Anthraflavic acid is, therefore, an intermediate body and not a secondary one.

We see, then, how these various bodies are formed, and as they are proved to be intermediate products, their presence shows imperfection in the process of manufacturing, because, if perfect, these substances should not have been left, but have been converted into colouring matter. There are two other substances whose presence has not as yet been accounted for, and these are anthraquinone and hydroanthraquinone.

Monoxanthraquinone, isoanthraflavic acid, and anthraflavic acid, when being converted into colouring matter by treating with caustic alkali, cause nascent hydrogen to be liberated, as we have seen. This, acting upon other portions of these same substances, reduces them thus:—

$$\underbrace{C_{14}H_8O_3}_{\text{Oxanthraquinone.}}+H_2=C_{14}H_8O_2+OH_2$$

$$\underbrace{C_{14}H_8O_4}_{\text{Isoanthraflavic and anthraflavic acid.}}+H_4=C_{14}H_8O_2+2OH_2$$

And part of the anthraquinone thus formed also unites with hydrogen, forming hydroanthraquinone.

The presence of these two substances, then, represents a certain amount of reverse action, and, consequently, loss to the manufacturer. Fortunately, means have been found of almost entirely preventing their formation, and also of ensuring the intermediate products being converted into colouring matter. I shall have to speak of this further on.

(*To be continued.*)

Parliamentary and Law Proceedings.

The Prosecution under the Apothecaries Act at Birmingham.

Mr. Motteram, Q.C., judge of the Birmingham County Court, gave judgment on Friday, the 4th inst., in the case of the Apothecaries' Company of the city of London against James Harrison, chemist, Stafford Street, Birmingham. The action, which has been several times before the Court, was brought to recover £20 damages, by way of penalty, under 55 Geo. III., cap. 194, sec. 20, against the defendant for prescribing medicine to one Julia Caddick, who was suffering from weakness subsequent to confinement, in November, 1876. The case had been postponed pending the decision of a higher Court in what is known as "Shepperley's case," of Nottingham. The plaintiffs contended that in prescribing medicine for the woman Caddick the defendant infringed the rights of an apothecary. The defendant took refuge under a proviso of the 28th section of the same Act, and counsel on his behalf contended that he had a right to prescribe medicine in a case like that under the notice of the Court. In giving judgment, Mr. Motteram said that if the language of the 28th section were carefully considered, he was afraid it would be found not to have the effect contended for on the part of the defendant. He found from the evidence that the defendant had clearly and unmistakably acted as an apothecary, and the proviso relied upon afforded, in his opinion, no defence in such a case as that. The verdict, therefore, would be for the plaintiffs for £20 damages and costs.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 24th of May, 1879, at Newark, Mr. John Hanson Gibson. Aged 21 years. Mr. Gibson was a Registered Apprentice of the Society.

On the 12th of June, 1879, Mr. James Briggs, Pharmaceutical Chemist, Tipton. Aged 64 years. Mr. Briggs had been a Member of the Pharmaceutical Society since 1842.

On the 28th of June, 1879, Mr. William Henry Moon, Pharmaceutical Chemist, High Street, Ilfracombe. Aged 43 years. Mr. Moon had been a Member of the Pharmaceutical Society since 1863.

On the 1st of July, 1879, Mr. Stephen Cox, Chemist and Druggist, Fore Street, Hatfield. Aged 75 years.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[315]. Sal Ammoniæ.
Spt. Nitre.
Sp. Wine.
Opodeldoc.

In this recipe "sal ammoniæ" means liq. ammon., B.P., and if "A Norfolk Man" tries it he will get a clear solution.

In many districts liq. ammon. is well-known by the name of sal ammoniæ or spirit of sal ammoniæ (just as liq. vol. c.c. is called Hartshorn), and recipes similar to the one in question are so commonly met with that I am surprised there should be any doubt or difficulty in the matter.

Manchester. W. WILKINSON.

---

[319]. I think W. took an entirely mistaken view of the prescription in question. In my opinion, he should simply have triturated the litharge and olive oil in a mortar till a liniment was formed. The late Professor Hamilton, professor of midwifery in Edinburgh, used to prescribe the following as a nipple liniment :—

℞ Plumb. Oxy. Sem. Vit.
Acetum . . . . āā ʒij.
Ol. Olivæ . . . . ʒvj.

Rub together till a flesh colour is obtained.

H. C. B.

---

[322]. What is meant by W. B. in regard to the puzzle to solve, in the admixture of tr. lyttæ, acid. sulph. dil., tr. lavand. co. and vaseline or lard ?

I have made a very nice ointment, almost similar in appearance to pink shaving cream, with the proportions given. I find no difficulty; but I was rather interested in the prescription, owing to the addition of tr. lavand. co., as I have employed a somewhat similar ointment for ringworm. In regard to the compatibility or incompatibility I have nothing to say. It is sometimes very useful as an application.

Northallerton. HENRY BROWN.

---

[323]. The gtt. 2 after sod. siccat. was evidently a slip of the pen ; grs. 2 was clearly meant.

Northallerton. HENRY BROWN.

---

[324]. The prescription of "Gulielmus" is one of those which a pharmacist is often at a loss to understand, and if he be thoroughly orthodox and will adhere to the exact written order of a physician or surgeon, it certainly is sufficient to raise not only discussion but much doubt as to what is meant by morphia when ordered in the proportion of eight grains to half an ounce of a mixture of chloroform and liniment of belladonna.

I observe "Gulielmus" adds after morphia "the alkaloid," so as to italicise, as it were. Now morphia is very sparingly soluble in chloroform ; so also are the acetate and hydrochlorate. Cold alcohol dissolves one in fifty of morphia, the hydrochlorate is soluble in about sixty parts of cold alcohol, the acetate in a little less, and the sulphate in still less.

I have often used the liniment, although not in exactly the same proportions as given by "Gulielmus," in painful neuralgias of the face. The practical point is, How can a complete solution be obtained ? I am sure in "The Month" this question will occupy, as it deserves, some consideration.

As an old compounder, I saw at once the difficulty. The fact was that the person who first dispensed the prescription fully understood the insolubility of morphia in the menstruum ordered. Was a departure of only a slight degree justifiable, so as to have morphia in perfect solution, although that must necessarily be a salt of morphia, under the circumstances ? I at once say it was. In my opinion the medical man intended perfect solution. How, then, is a perfect solution to be obtained ? It cannot be obtained by using hydrochlorate or acetate of morphia. Sulphate, if well prepared, will dissolve, but the easiest mode is to add a small quantity of dilute sulphuric acid, and all trouble vanishes, to either morphia, or hydrochlorate or acetate.

Some one may say this is unjustifiable meddling with a prescription. I say no. The intention is to have morphia in solution, and if the prescriber is unaware of the insolubility of such a large quantity in a given quantity of menstruum, but yet intends a strong solution, surely it is the business of the pharmacist to carry out his intention.

I look upon this question as one of the most important and interesting that has yet been asked. Not one medical man in a hundred, and not one pharmacist in fifty, has any idea of such exact proportions as given by "Gulielmus."

Northallerton. HENRY BROWN.

Queries.

[326]. I shall be glad if any reader can inform me if the following prescription can be dispensed so as to form a mixture of a presentable appearance :—

℞ Tinct. Gelsemin. Semper. . . . . ʒiv.
Ferri et Quiniæ Cit. . . . . ʒiss.
Croton Chloral Hydrat. . . . . ʒj.
Potass. Bromidi . . . . ʒiv.
Potass. Iodid. . . . . ʒss.
Aquæ Chloroformi . . . . . ad ℥viii.
M. Sign. ℥ss 4tis horis ex aqua.

SUB UMBRA FLORESCO.

---

[327]. What is the best method of dispensing the following to obtain a presentable mixture :—

℞ Sodæ Salicylat. . . . . ℈iv.
Croton Chloral . . . . ℈iv.
Quiniæ Sulphat. . . . . ℈j
Aq. . . . . ad ℥viii.
M. Ft. mist. ℥j ter in die sd.

J. H.

---

[328].

℞ Ammon. Bromid. . . . . ʒiv.
Tinct. Hyoscyami,
Tinct. Humuli . . . . āā ʒiv.
Aquæ . . . . ad ℥viij.
M. Ft. mist.

Can any of your readers inform me how the above may be dispensed so that the mixture should be of a clear bright sherry colour—not at all opaque ?

I had the prescription brought by a customer, who assured me it was made up in one of the well known leading city establishments, and it was sent out as thus described.

It was afterwards dispensed by respectable chemists in the country and by myself. All the mixtures obtained in the country corresponded with the one I mixed.

How is it that the London one was an exception, and how can the compound result in a clear bright mixture ?

C. B.

---

[329]. Will you kindly inform me through the Journal how I can make a clear mixture of "dandelion and quinine," on mixing the tr. quiniæ with liq. tarax. ?

Luton. W. C. S.

---

[330]. Will some of your readers kindly inform me how the enclosed prescriptions should be dispensed ?

J. S. NEMO.

Notes and Queries.

[609]. A good ruby colour for bottle lenses is formed by adding a solution of iodine made the same as lin. iodi, B.P. (omitting the camphor), to glycerine slightly diluted. It should be added gradually until the required shade is obtained. Stands well.

CORTEX.

[610]. FURNITURE CREAM.—The following is a good formula:—

Take of—

Yellow Wax	1 lb.
Yellow Soap	2 ozs.
Spirit of Turpentine	2 pints.
Boiling Water	2 „

Melt the wax and soap over a slow fire, add the turpentine, and lastly, stir in the water gently until it is quite cold.

SUB UMBRA FLORESCO.

[611]. MOORE'S OINTMENT. — It is doubtful whether "Unguentum" can obtain an authentic formula for Moore's ointment. Moore was a quack with a cart who treated bad legs, etc., *coram populo.* Leather Lane on Sunday morning was a favourite "pitch." He died a short time ago.

W. J. R.

[612]. SYRUP OF SCAMMONY.—Would some reader kindly oblige me with a good formula for preparing syrup. scammonii, dose ʒj, ad ʒij?

SUB UMBRA FLORESCO.

[613]. DANDELION COFFEE.—Could any reader oblige me with a good form for making dandelion coffee?

FERRI CIT

[614]. "PULV. SALINI EFFERVESC. APERIENTIS."—Information is required respecting the composition of the above, occurring in a prescription signed J. P.

F. C.

[615]. DENTIFRICE WATER.—Could any one oblige me with a recipe for a good dentifrice water.

QUÆRO.

[616]. SILVER PLATING LIQUID.—Will some one kindly furnish me with a formula for a silver plating liquid suitable for coating steel?

VIATOR.

[617]. CHERRY TOOTH PASTE.—D. A. would be greatly obliged for a recipe for cherry tooth paste. He has tried several published in receipt books and journals, but cannot obtain either a good consistency or that bright transparent cherry colour which is so attractive in good tooth paste.

SULPHO-TARTRATE OF QUINIA.—Dr. Prengeber recommends for hypodermic use the following solutions:—

1.	Quinia Sulphate	2·00 gm. or 30 grs.
	Tartaric Acid	0·60 gm. or 9 grs.
	Distilled Water.	6·00 gm. or 100 min.

To be dissolved by gently heating.

2.	Quinia Sulphate	2·00 gm. or 30 grs.
	Morphia (alkaloid).	0·006 gm. or $\frac{1}{10}$ gr.
	Tartaric Acid	0·65 gm. or 10 grs.
	Cherry-laurel Water	6·00 gm. or 100 min.

Both of these injections are very rarely followed by abscess.—*Rép. de Pharm.*, 1879, 99.

CINNABAR-PLASTER. — Dr. Vidal uses with good success, in the treatment of scrofulous ulcerations and of ecthyma, the following plaster, spread upon silk in the usual manner:—

Red Oxide of Lead	2·50 gm. or 40 grs.
Cinnabar	1·50 gm. or 25 grs.
Lead-plaster	26·00 gm. or 400 grs.

Melt the lead-plaster, add the red lead and cinnabar, mix well and spread.—*Rép. de Pharm.*, 1879, 99.

SUMMER DRINKS:—

Milk Lemonade.—Loaf sugar, one and a half pounds, dissolved in a quart of boiling water, with half a pint of lemon juice, and one and a half pints of milk; this makes a capital summer beverage. A half-pint of sherry added is a great improvement.

Still Lemonade.—The juice of three lemons, the peel of one, quarter of a pound of lump sugar, and a quart of cold water. Mix, digest for five hours, and strain.

Lemon Whey.—One pint of boiling milk, half a pint of lemon juice, sugar to taste. Mix and strain.

Lemon Shrub.—The juice of twelve lemons, the thin rind of two, one pound of sugar, the whites of two eggs well whisked, one pint of water, half a pint of rum, and half a pint of brandy. Mix and strain.—*Monthly Magazine of Pharm.*

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

LIN. POTASS. IODID. C. SAPONE, B.P.

Sir,—In answer to W. H. de B.'s inquiry as to the above preparation, we have much pleasure in giving him the information he requires.

The liniment was, we believe, originally introduced to the Medical Council by the late Dr. Rumsey, of Cheltenham, where it was very largely used. It was always intended to be made with white curd soap dissolved in the whole of the glycerine and water, mixed in a water-bath; then, having powdered the iodide of potassium in a large mortar previously warmed, pour the hot solution on the iodide in the mortar, and stir a few minutes until cold; lastly, add the oil of lemon.

You will then have a white solid preparation which does not separate. It was sent out in covered pots as an ointment, although some London houses send it in wide-mouthed bottles.

South Kensington. PLAISTER AND HILLEN.

"*Beta.*"—*Cotyledon Umbilicus.*

R. G. Bumpstead.—The practice of pharmacy in France is limited to persons possessing diplomas as pharmaciens.

Ricini.—We do not consider that an article answering fairly to the name, or that can be sold without danger of prosecution under the Sale of Food and Drugs Act, can be prepared.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. J. H. Dingle, H. Long, Audio, Alpha.

SPIRITUS ÆTHERIS NITROSI:

ITS COMPOSITION AND ANALYSIS.

BY F. M. RIMMINGTON, F.C.S.

The nature, substance and quality of spiritus ætheris nitrosi has long been a problem asking for solution; and as I have given a good deal of attention to it for a long time, and feel myself under a pledge to contribute another paper on the question raised some time ago as to the actual existence of nitrite of ethyl in this compound, I now purpose fulfilling that promise.

Perhaps some discriminating minds will draw a distinction between sweet spirit of nitre and spiritus ætheris nitrosi. I make no such distinction, and all that is said in this paper has reference to a spirit that corresponds with that described in the British Pharmacopœia, in nature, substance and quality.

I think all who have attempted the analytical examination of this preparation, will admit it is surrounded with some difficulty.

There is first, an ethereal fluid, so designated; secondly, an ethereal oil or hydrocarbon; thirdly, aldehyde; fourthly, nitrous acid, uncombined; fifthly, acetic acid uncombined; sixthly, alcohol and water.

The presence of nitrite of ethyl in the spirit of the Pharmacopœia has been denied; and I am willing to admit it may be possibly true, but if true, it is culpably wrong, and is the result of mismanagement. If no nitrite of ethyl be formed, what becomes of the nitric acid used in the operation, and what are the products of the chemical action that takes place? It does not distil over, it does not pass away as gas, but it is nevertheless consumed.

After many attempts to investigate this matter, and trying all the methods that suggested themselves to me, or that I could find described for the estimation of the nitrites, I found none that gave satisfactory results until I adopted the following scheme, by which not only the nitrite of ethyl, but all the other constituents, may be accurately estimated.

The following table, at all events, shows the results in two analyses (out of a great many others) of a typical sample, agreeing with the B.P. tests, etc.:—

	(1).	(2).
Water	7·96	7·93
Aldehyde	1·19	1·19
Alcohol	88·10	88·10
Acetic Acid	·47	·50
Nitrous Acid	·59	·56
Nitrite of Ethyl	1·69	1·72
	100·00	100·00

The method of analysis is as follows:—

The nitrite of ethyl is to be estimated by the conversion of its nitrogen into ammonia, first by decomposing it with pure potash into KNO_2, and distilling this with a zinc and copper couple somewhat after the method recommended by Thorpe, but modified by Dr. Cornelius Fox, and titrating the result with standard acid (process in detail given below).

The amount of nitrous and acetic acids are estimated volumetrically. The two acids are afterwards separately estimated.

Aldehyde is estimated by conversion into acetic acid by peroxide of hydrogen, and titrated.

Water and alcohol by difference.

Estimation of Nitrite of Ethyl.

5 c.c. of the spirit are added to 1 gram of pure potash (free from nitre) dissolved in 40 c.c. of pure water in a 50 c.c. graduated, flask, stoppered and capped with leather, digest in a warm place at a temperature of 150°—200° F. for three hours. Allow the flask to cool and then dilute with water to 50 c.c., shake and then take out with a pipette 10 c.c. of the liquid and run it into a platinum dish, and add to it 40 c.c. of water, evaporate on a water-bath to 20 c.c. to get rid of the alcohol, etc. This residue is now to be washed into a flask of 16 ounces (or 450 c.c.) capacity, containing 10 grams of zinc foil coated with copper, and the volume of liquid made up to about 350 c.c. with water, and connected with a condenser; heat is now to be applied and the distillation carried on as usual. Most of the ammonia comes over in the first 100 c.c. of distillate, but it is necessary to distil another 50 c.c. to ensure perfect exhaustion. The ammonia thus obtained is now to be estimated with a standard sulphuric acid, 1 c.c. equal to ·001 gram ammonia.

The amount of NH_3 found is to be multiplied by $100 \times \cdot 824$ which will equal the total nitrogen in the spirit; and this, minus the nitrogen present in the free nitrous acid, when multiplied by 5·357 will give the nitrite of ethyl contained in the spirit.

Estimation of Nitrous and Acetic Acids.

The amounts of these two acids are necessary to be known in order to judge of the quality of the preparation, and for correctly estimating the nitrite of ethyl. 10 c.c. are to be measured with a pipette and run into a platinum dish, and diluted with an equal volume of pure water, and ·5 gram carbonate of potash added, and stirred until dissolved; the solution is then evaporated on a water-bath to dryness. This saline residue is now to be treated with 5 c.c. of pure alcohol for the separation of the potassium acetate, from the potassium nitrite, and again repeated, and the mixed solutions filtered through a very small Swedish filter; this filtrate evaporated in a tared capsule to dryness, and rapidly weighed. The weight minus ·021 gram (the weight of KNO_2 which is dissolved by 10 c.c. of alcohol) and the amount multiplied by ·6122 gives the quantity of acetic acid present in the spirit.

The amount of acetic acid thus found, multiplied by ·7666 gives the equivalent of NO_2 to which it is equal, and this product deducted from the total acidity, (previously determined alkalimetrically,) leaves the nett amount of NO_2 present.

Estimation of the Aldehyde.

Into a 25 or 50 c.c. flask run 10 c.c. of the spirit, and add 10 c.c. of peroxide of hydrogen, and let it stand two or three hours; by this time the aldehyde will have become converted into acetic acid, and may be estimated by decinormal alkali; the amount thus determined, less the number of c.c. required by the free acids previously determined, multiplied by ·0044 will give the amount of aldehyde.

Estimation of Alcohol and Water.

The alcohol is estimated by the specific gravity, and the water by difference.

The foregoing scheme of analysis probably may look formidable in the eyes of very practical people. It certainly involves some nicety of selection of materials, as to purity, but otherwise it is not difficult.

I append the statement of analysis of four samples of spirit of nitrous ether, obtained from different sources and represented as the "best."

	No. 1	No. 2.	No. 3.	No. 4.
Water	10·55	14·12	16·17	15·49
Aldehyde . . .	·75	·21	·26	·00
Alcohol	87·5	85·2	82·60	83·6
Acetic Acid . . .	·16	·03	·18	·16
Nitrous Acid . .	·29	·27	·69	·68
Nitrite of Ethyl .	·75	·17	·10	·07
	100·00	100·00	100·00	100·00

The nice gradation of quality here exhibited, without any design, is very remarkable.

THE BOTANICAL SOURCE OF ARAROBA.

In a former note on Goa powder, which appeared in this Journal,* it was suggested by Mr. E. M. Holmes that this drug might perhaps be derived from a species of *Cæsalpinia* nearly allied to *C. Sappan*, L. This opinion was founded partly on a microscopical examination of the structure of fragments of wood found in the araroba of commerce, and partly on the appearance of a single leaf of the araroba plant, which was found to bear a considerable resemblance in habit to those of *C. Sappan*. This leaf, kindly supplied from the Royal Botanical Gardens at Edinburgh, was obtained from a slip of the plant brought home from Bahia by Dr. J. L. Paterson. Those who are well acquainted with the plants of the Leguminosæ will readily acknowledge the difficulty of judging of the genus from a leaf alone, without flowers and fruit. These have at length been procured, and the true source of the araroba may now be considered to be definitely settled, and the mystery which has so long attended the natural history of the drug to be satisfactorily cleared up. This information is supplied by Dr. J. M. de Aguiar, who has just published at Bahia† a pamphlet containing a very full and detailed description of the plant, with illustrations of the leaves and flowers, a copy of which has recently been placed at our disposal by Mr. T. Christy.

According to Dr. de Aguiar the flowers and fruit which have been obtained show that the araroba plant is more nearly allied to *Centrolobium* than to *Cæsalpinia*, having truly papilionaceous flowers, and that it belongs to the genus *Andira* of the subtribe Geoffræeæ, which is characterized by having a hard drupaceous one-seeded fruit, sweet-smelling violet or purplish flowers arranged in panicles, a calyx with short teeth, and five distinct petals. From *Centrolobium* it is distinguished by the fruit, which in that genus resembles a samara and is furnished with prickles at its base.

The araroba plant is therefore nearly allied to *Andira inermis*, the bark of which was formerly a well known remedy in this country for intestinal parasites, under the name of cabbage-tree bark or worm bark.‡

The following description is a *précis* made from the information contained in Dr. J. M. de Aguiar's pamphlet:—

The plant from which araroba is extracted is one of the larger intertropical trees which are met with between 13° and 15° of latitude, south of Bahia, especially in the forests of Camamu, Igrapiuna, Santorem, Taperoa and Valencia, and rivals in height the tree commonly known under the name of Oleo (*Myrocarpus fastigiatus* or *Myrospermum erythroxylum**), and sometimes attains even greater dimensions. The ordinary height of the tree is 80 to 100 feet; the trunk is straight, cylindrical, and in the two specimens which were measured in the thickest part one was 31 and the other 48 centimetres in diameter. The tree commences to branch at more than a third of its whole height, and forms a not very leafy head, having the form of a segment of a spheroid. The bark of the tree is not very thick and appears to contain scarcely any of the active principle of the plant. The wood has a yellow colour, and is very porous, having numerous longitudinal canals visible to the naked eye, although these are more distinctly seen under a lens. The trunk in a transverse or tangential section presents lacunæ, more or less large according to the age of the tree, and in these a pulverulent substance (araroba) is found, which in trees recently cut down and before being dried is of a light or pale tint, clearer than that of the wood. The medullary centre exhibits a canal different in appearance from the lacunæ, having a diameter much more considerable. The young branches are entirely fistulose.

So far these particulars seem to correspond exactly with the statement of Dr. Rameiro A. Monteiro, published in the *Journal de Thérapeutique*, vol. vi., p. 248.†

The following details, however, have not, so far as is known, been before published in this country.

The leaves are alternate, compound and paripinnate. The petiole in two specimens which were measured was in the one 32 and in the other 44 centimetres in length, having a variable number of pairs of stalked leaflets, in one specimen 20, and in another, 24. The leaflets are alternate and articulated, oblong, obtuse, entire, and emarginate at the apex, measuring from $2\frac{1}{2}$ to $4\frac{1}{2}$ centimetres in length, and from 1 to $1\frac{1}{2}$ centimetres in width. The distance between the points of insertion of the leaflets is about 2 centimetres, so that the leaflets only slightly overlap each other.

The common petiole or rachis is slender, convex on the under surface, and hollowed above into a small very smooth furrow; the secondary petioles which measure about half a centimetre in length are accompanied for a small distance by the rudiments of stipels. The leaflets are feather-veined, of a green colour on the upper surface and of an ashy hue beneath. The inflorescence is centripetal, consisting of a panicle with a variable number of racemes, each of which consists, in the more luxuriant specimens, of about eight flowers or flower buds. The flowers are shortly stalked, alternately arranged, and are each furnished with a bract, which does not develop at the same rate as the flower, and hence the lower bracts appear smaller than the upper ones. The common peduncle is bare of flowers at the base for about a third of its length. The flowers are purple, papilionaceous, measuring $2\frac{1}{2}$ to 3 centimetres without the claw, which is about $\frac{1}{2}$ centimetre long. The *calyx* is gamosepalous, 2 centimetres long, covered with rusty-coloured hairs, a little flattened on three faces, like

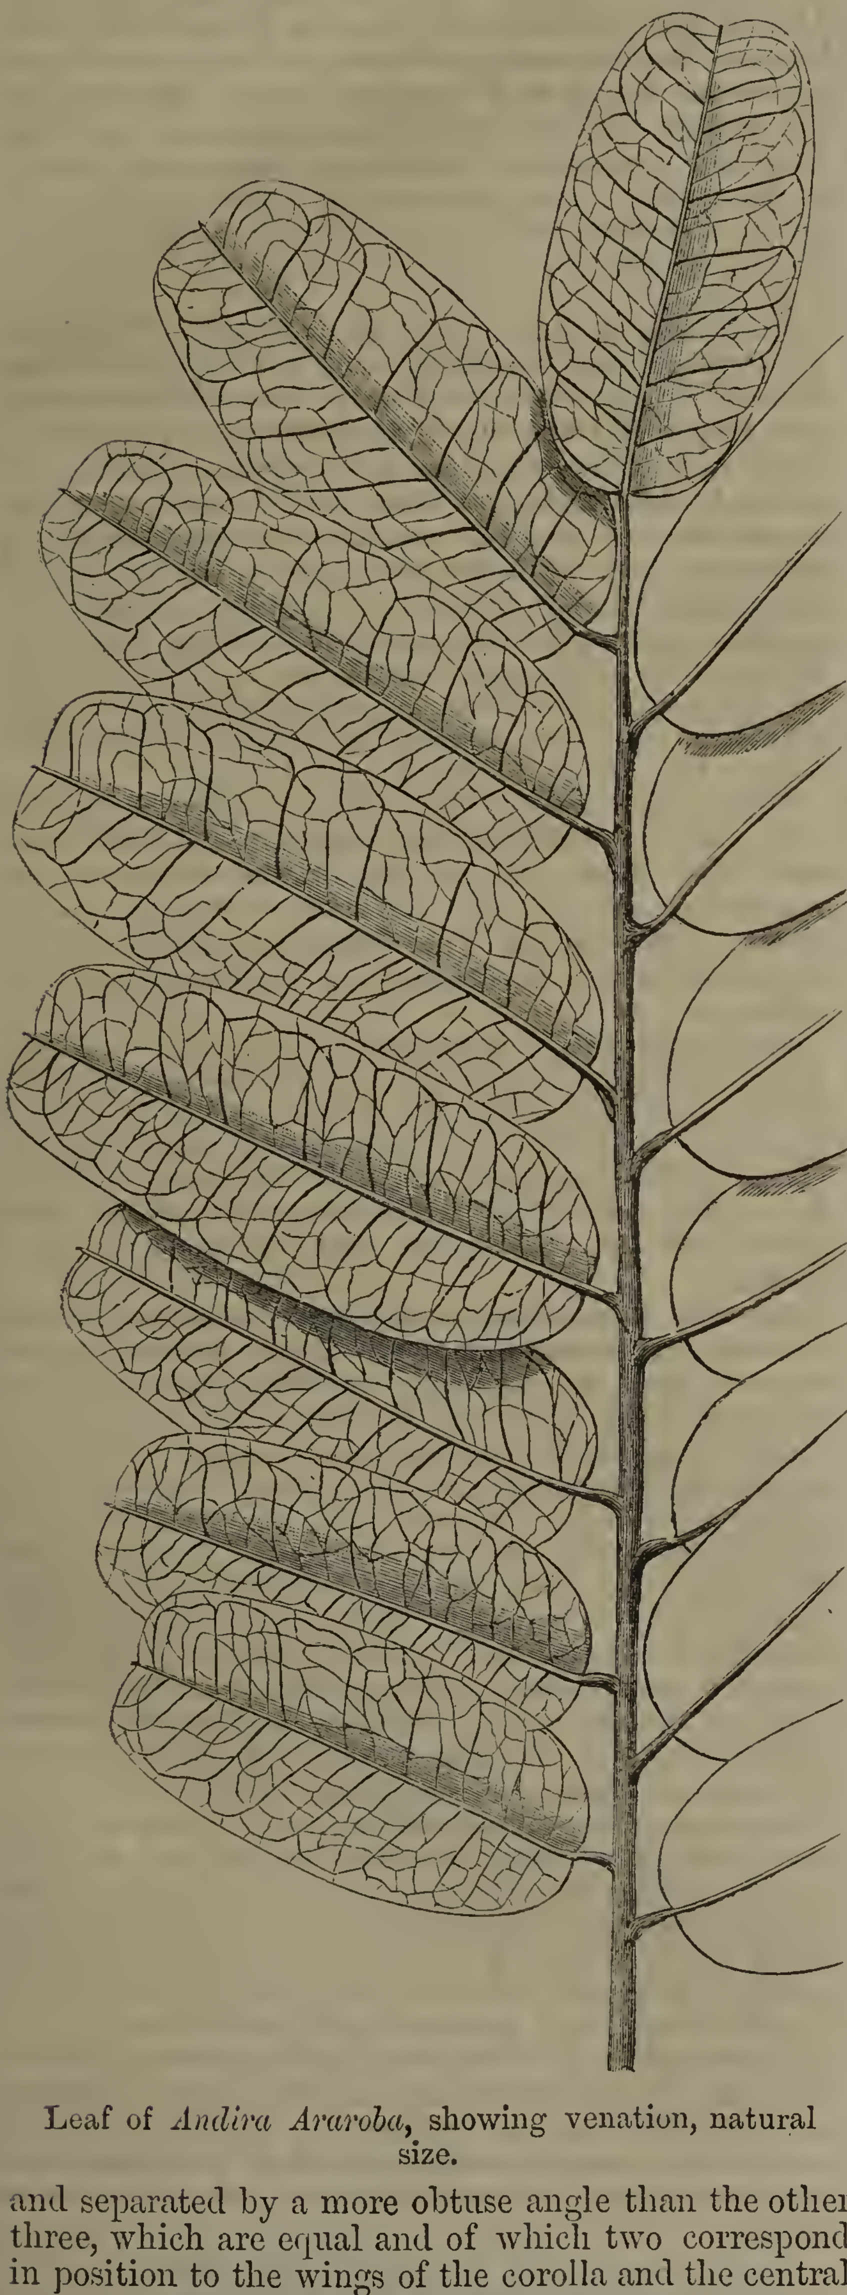
† *Pharm. Journ.* [3], vol. viii., p. 1048.

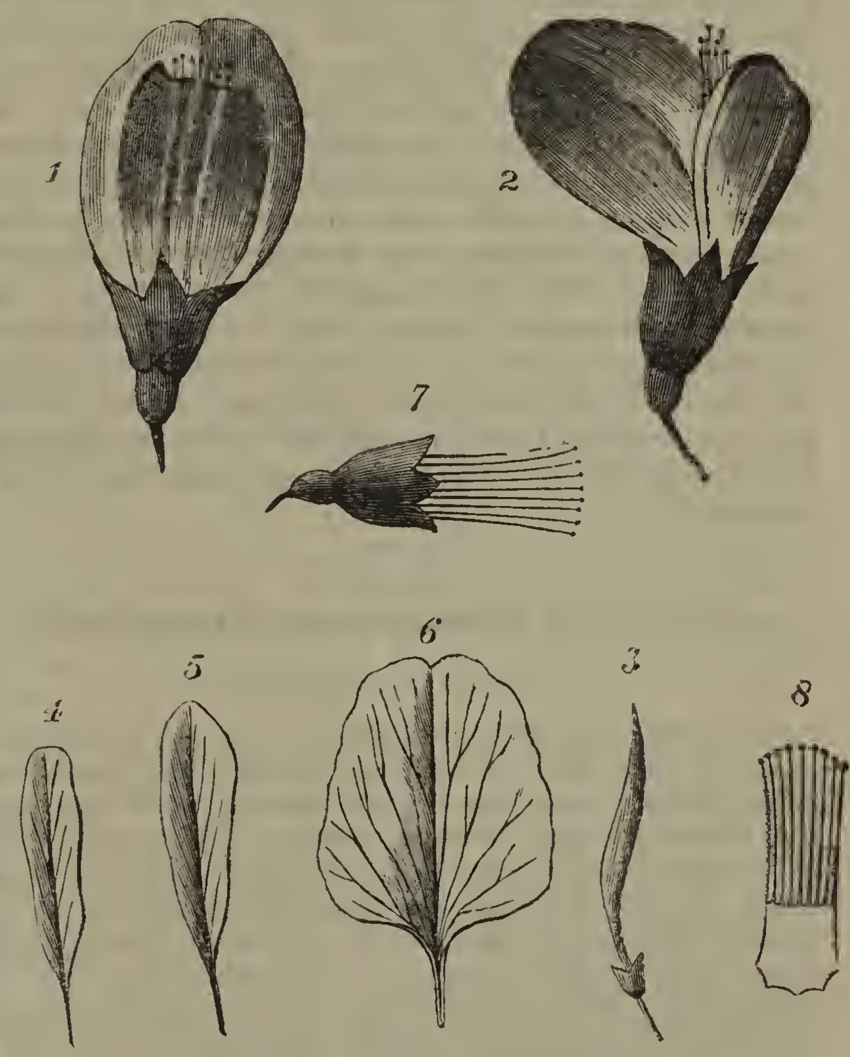
a triangular prism with rounded angles, the dorsal angle being the more prominent and corresponding to the middle of the standard. The calyx is five-toothed, the two upper teeth being larger and longer



Leaf of *Andira Araroba*, showing venation, natural size.

and separated by a more obtuse angle than the other three, which are equal and of which two correspond in position to the wings of the corolla and the central one to the keel.

The *corolla* consists of five clawed petals, the standard being entire, orbicular, about 2 centimetres in diameter, slightly emarginate at the apex, and furnished with a claw about ½ centimetre long, and consisting in great part of the thickened middle vein of the standard. The alæ or wings are obovate, elongated, about 16 millimetres long by 6 broad, curved towards the base, and forming a longitudinal and oblique sinus* (gotteira) near the top of the claw on the side opposite to the standard, the claw being about 7 millimetres long. The two petals forming the keel are similarly formed, but less curved, and 4 or 5 millimetres broad. The *stamens,* nine in number, are monadelphous and perigynous, about 2 centimetres long, and adherent for about a third of their length, but having a slit opposite to the middle of the vexillum. The anthers are ovoid with a longitudinal furrow on their inferior surface, in the middle of which the filament is inserted. The upper surface is convex and smooth. The *pistil* consists of a single carpel, and exceeds the stamens in length by 1 or 2 millimetres. The ovary, which has a stalk about 4 millimetres long, is flattened at the sides, and presents two salient lines or rudimentary wings. The ovary and style (the latter for two-thirds of its length only) are covered with rusty hairs. The ovary is convex on the side opposite to the slit in the androphore, and concave on the side nearest to the two lateral wings.



Flower of *Andira Araroba*.

1. Showing three lower teeth of calyx; 2. Corolla, lateral view; 3. Pistil; 4. Petal of keel; 5. Petal of wing; 6. Standard; 7. Stamens in situ, after removal of corolla; 8. Monadelphous stamens, separated from calyx.

The ovary is one-celled and one-seeded. The embryo is curved, and the seed exalbuminous. The arillus is short and tortuous.

From the above description it will be seen that the araroba plant belongs to the Leguminosæ, and to the tribe of Dalbergieæ. It much resembles in some characters *Dalbergia miscolobium*, Benth., and

* This is not well shown in the original wood-cut.

Andira fraxinifolia, Benth. Neither of these two plants, nor the *Andira inermis*, has the obtuse emarginate leaflets which characterize the araroba tree.

The author believes the plant to have been hitherto undescribed, and proposes the name of *Andira Araroba*, Aguiar, for it, since the drupaceous fruit, panicled inflorescence, purple flowers and the other characters above mentioned clearly point to its being an *Andira*. This opinion is further strengthened by the fact that some other Andiras possess parasiticidal properties, and that the natives, who call the *A. anthelmintica* "Angelim de folha grande," the *Andira Fraxinifolia* "Angelim doce," and the *A. stipulacea* "Angelim Coco," also call the *A. Araroba* "Angelim amargoso," thus recognizing a close alliance in the plants.

With regard to the production of the araroba, the author gives it as his opinion that it is formed by the oxidation of the resin which exists in great abundance in the tree, the oxidation being facilitated by the canals made by insects. He explains the presence of the larger cavities in the tree by the corrosive action of the araroba on the wood. He has not, however, as yet confirmed his theory by experiment. The araroba is collected throughout the year, the older trees being selected because the powder occurs in them in greater abundance. The trunk is cut into sections transversely and these are then split longitudinally. The portions containing powder are then chipped or scraped off with an axe, which is done the more easily as the wood in these parts offers but little resistance. The colour when freshly collected varies from that of the flower of the cotton plant (pale primrose colour), becoming by the action of the air darker, to that of rhubarb, and finally dark purple. The commerce of this article is now chiefly developed in Camamu and Taperoa, although the tree exists in abundance in all the southern part of the Province of Bahia and, according to Drs. Bomfim and Agnello Leite, also in the forest of Sergipe. The tree is not cultivated, but propagates itself spontaneously.

LACTUCARIUM FROM LACTUCA CANADENSIS.*

BY HILAND FLOWERS, PH.G.

The milk-juice, which exudes almost at the commencement of the plant's career, is perfectly inert, though a large quantity is produced. As collected up to July 20, the exudation has a strong narcotic odour, while the palate perceives no bitterness, but simply a flat sweetish taste. Up to this time the plant has borne its reproductive organs, but failed in giving the requisite bitterness. A change, however, occurs about the 25th of July, when we find that the laticiferous vessels are yielding a large supply of juice with a slightly bitter taste and a stronger and more lasting odour. As the season advances, both the bitter principle and the narcotic odour increase.

The milk-juice collected during the latter part of the season dried in irregular masses, crumbling into minute fragments when rubbed between the fingers, and was of a blackish-brown colour, a strong odour and very bitter taste. If kept in a closely-corked bottle it remains soft and is capable of being moulded into cakes. The odour is slightly stronger in the fresh state, and the colour of a greyish-brown.

Aubergier, in 1843, experimented upon this plant, while investigating the subject to ascertain from which lactucarium might be most advantageously obtained; he stated that the milk-juice of *Lactuca canadensis*, or *elongata*, had a flat, sweetish taste and contained mannit, etc., but *no* bitter principle.

In September, 1867, Professor Maisch commenced a series of experiments upon the plant, and upon the personal observation then made, as well as the reports of Doctors DaCosta and Muller, of this city, rested convinced that the plant did contain a bitter principle and did possess decidedly medicinal properties, and that Aubergier had perhaps improperly conducted his experiments, possibly using the expressed juice of the plant, which, according to Professor Maisch (*vide American Journal of Pharmacy*, 1869, p. 145), has a flat, sweetish taste.

Four drachms of the milk-juice collected in September and October were exhausted upon a filter with boiling alcohol. Eight ounces of filtrate were obtained, passed through animal charcoal and concentrated by spontaneous evaporation, when inodorous and tasteless needles were obtained, which melted at about 175° F. and on cooling congealed to a granular mass. They were evidently *lactucerin*. On still further evaporating the mother liquor and adding to it water, a whitish precipitate was produced, from which the aqueous liquor was thoroughly drained. On dissolving the precipitate in boiling alcohol and evaporating the solution spontaneously, more of the tasteless needles were obtained, and pale-brownish bitter scales, which were evidently impure *lactucin*.

The aqueous mother liquor was precipitated by basic acetate of lead, and both the precipitate and the filtrate were freed from lead by sulphuretted hydrogen. On evaporating the solutions, brownish amorphous masses, having a bitter taste, were left, corresponding to the *lactucic acid* and *lactucopicrin* of the European lactucarium.

Lactucerin is in colourless needle-shaped crystals, either united in stellate groups or crossing and overlapping each other; tasteless, soluble in boiling alcohol, petroleum benzin, ether, chloroform, and slightly soluble in cold alcohol; insoluble in water. If heated to above its melting point (175° F.), it volatilizes slowly. Sulphuric acid chars it; nitric acid has no effect unless heated.

Lactucin is insoluble, or nearly so, in water; soluble in alcohol and acetic acid. When pure and not exposed to much heat, the lactucin is in scales of a dull-white cast; under the microscope it presents a rugged surface, slightly tinged with a reddish-brown colour. From my experience, I am inclined to think that if the scales are heated in solution for some time, they will not form again very readily, and are deprived of some of their bitterness. Ammonia will not precipitate it, but rather tends to alter the taste. It is, however, precipitated from alcohol by water, and may thus be purified by repeated precipitation and crystallization. Nitric acid will not dissolve it, nor will the addition of alcohol facilitate this end. The characteristics given by Kromayer, Ludwig and Walz are in accordance with these results.

Lactucic acid is precipitated by basic acetate of lead, care being taken that an excess is not used, for it is soluble in that salt when in excess. It changes blue litmus paper to red, proving its acidity; has an acrid, bitter taste; is soluble in alcohol, both hot and cold, insoluble in petroleum benzin, bisulphide of carbon, ether and chloroform, and has a brownish-green colour.

Lactucopicrin is a brown amorphous mass, and may be purified by repeated treatment with ether, chloroform or alcohol, filtering and evaporating. It has a strong and purely bitter taste, is soluble in alcohol, chloroform, ether and water, and is not precipitated by lead salts from its solution.

The residue of the lactucarium, left after the above principles had been removed by hot alcohol, was treated with bisulphide of carbon, which dissolved a large amount of caoutchouc (*gum elastic*), but there yet remained a

* From th *American Journal of Pharmacy*, July, 1879.

residue, which was treated with ether, removing a pale-yellowish granular powder; with chloroform, removing the remaining caoutchouc and some of the colouring matter, and with alcohol, which yielded, on evaporation, a brownish, bitter, amorphous mass resembling lactucopicrin. Water extracted a large amount of colouring matter. The residue which was now left defied the solvent powers of carbon bisulphide, ether, chloroform, alcohol, water and acetic acid.

The yellowish powder obtained on the evaporation of ether in the above treatment closely resembles lactucerin; but the identity of the two was not proven. When heated it will melt, and volatilize if the temperature is increased. On cooling it forms a resinous mass. It is soluble in hot alcohol, petroleum benzin and chloroform, insoluble in hot or cold water. Sulphuric acid dissolves it, but does not char it. Nitric acid has little or no effect. Muriatic acid dissolves it slightly. Acetic acid and ammonia have no effect. It is precipitated from the alcoholic solution by water.

The statement of Aubergier regarding the worthlessness of this plant is undoubtedly wrong, as there exist, beyond question, several bitter principles with decided physiological action. It is very likely that he collected the juice before the plants were sufficiently matured and the bitter principles developed.

GLYCYRRHIZIN.*

BY J. HABERMANN.

In a previous communication the author had stated that by the treatment of commercial glycyrrhizin with glacial acetic acid he had obtained a considerable quantity of an almost colourless crystalline body. Since then he has pursued the subject as opportunity offered and now presents the result of his further investigation, first giving a *résumé* of the history of the subject.

Our knowledge of the nature of glycyrrhizin is principally based upon the work of A. Vogel, jun.,† T. Lade,‡ Gorup-Besanez,§ and, more recently, Z. Roussin.||

Vogel prepared glycyrrhizin by precipitating an aqueous extract of liquorice root with lead acetate, carefully washing the precipitate, suspending it in water and decomposing it with sulphuretted hydrogen; it was only after repeatedly boiling the mass that he was able to separate the lead sulphide by filtration. Vogel purified the glycyrrhizin by dissolving it several times in absolute alcohol, and he describes it as a light yellow mass, showing no trace of crystallization when considerably magnified, soluble in water, especially when boiling, readily soluble to a large extent in alcohol, and melting at 200° C. to a transparent dark brown mass. He described also the precipitate obtained with neutral lead acetate, as well as a compound with sulphuric acid, and attributed to glycyrrhizin the formula $C_{16}H_{24}O_6$.

Lade obtained his glycyrrhizin by extracting liquorice root with cold water, concentrating upon a water-bath, filtering, precipitating with dilute acid, and purification of the viscous pitchy black precipitate by continued kneading in acidulated and pure water, repeatedly dissolving it in absolute alcohol and evaporating the solution on a water-bath. Lade describes his product as a shining translucent, brown mass, forming upon trituration a brownish-yellow powder, slightly soluble in cold water, especially when containing a little acid, but dissolving more readily in boiling water and giving off then a peculiar odour, recalling that of fusel alcohol. A solution saturated when hot is said to be gelatinous at the ordinary temperature or when perfectly cool to thicken to a clear brown jelly. The taste was extremely sweet, but it was accompanied by a peculiar bitter, and was unpleasant. In absolute alcohol the substance was readily soluble. The yellow colour appeared to Lade to be characteristic of glycyrrhizin. The solutions had an acid reaction upon litmus paper, and small quantities of alkalies made the glycyrrhizin much more soluble in water and coloured the solution deep yellow-brown. Lade also described two lead compounds and attributed to glycyrrhizin the formula $C_{18}H_{24}O_7$. He appears to have been of opinion (1) that glycyrrhizin exists in the root combined with an organic base like ammonia; (2) that he did not succeed in obtaining glycyrrhizin free from nitrogen, although the quantity present amounted to only 0·03 to 0·06 per cent.; (3) that the body was a hydrate, represented by the rational formula— $C_{18}H_{22}O_6 + H_2O$.

Gorup-Besanez modified Lade's method by decomposing the alcoholic solution with small quantities of ether, by which a brown resinous mass was separated, whilst a light wine-yellow solution resulted; this upon evaporation left a light yellow varnish-like residue that yielded a faintly yellowish powder when triturated. Gorup-Besanez expressly states that the product obtained in this way corresponded in properties and composition with the glycyrrhizin of A. Vogel, and differed in analytical results and especially in containing no nitrogen from that of Lade. He describes the preparation and properties of a lead and a lime compound, the former containing six the latter three equivalents of base. Lastly, he describes the decomposition of glycyrrhizin by dilute acids into glycyrretin and sugar according to the equation—

$$C_{24}H_{36}O_9 + H_2O = C_{18}H_{26}O_4 + C_6H_{12}O_6$$

According to this glycyrrhizin would be a non-nitrogenous glucoside, but Gorup-Besanez does not appear to have effected the decomposition by emulsin or any other ferment. The glycyrretin he describes as a brown-yellow resin, with a taste at first scarcely but afterwards strongly bitter, insoluble in water, freely soluble in alcohol, somewhat less so in ether, and precipitated from its alcoholic solution by water. When decolorized by animal charcoal it formed a nearly white powder that he did not succeed in obtaining in a crystalline form. The sugar was obtained as a brownish coloured only faintly sweetish tasted syrup, which reduced alkaline cupric solution in the cold, blackened oxide of bismuth in the presence of carbonate of soda, took a brown colour with potash, showed Pettenkofer's reaction with galls and sulphuric acid, and lastly, upon the addition of yeast, quickly passed into fermentation.

Roussin, like Lade, looks upon glycyrrhizin as an acid, which he calls glycyrrhizic acid, contained in the liquorice root as an ammonia compound. He states that it forms with ammonia two different compounds, of which one, with an excess of ammonia, forms a dark yellow solution, the other, with half the quantity of base, forms an amber solution. According to Roussin, glycyrrhizin plays in both compounds the part of an actual acid, and the compounds are actually salts, capable of undergoing double decomposition not only with all metallic salts, but also with salts of the alkaloids. Roussin considers glycyrrhizic acid to be intermediate in its principal characters between tannic and pectic acids. Of the above-mentioned ammonia compounds the first is a basic glycyrrhizate of ammonia, the second and more important, since it represents the actual sweet principle of liquorice, is glycyrrhizate of ammonia, or ammoniacal glycyrrhizin. In its preparation and purification Roussin followed the method of Gorup-Besanez at first, and then precipitated the ethereal-alcoholic solution with a strong alcoholic solution of ammonia, and washed the precipitate with alcohol. Roussin gives no analytical data.

The starting point of the present author, Herr Habermann, was the glycyrrhizin of commerce, described in the current price lists as "ammoniacal glycyrrhizin," and occurring in more or less deep brown coloured shining amorphous scales. From this substance he finds that a

* Abstract of a paper read before the Vienna Academy of Sciences (*Liebig's Annalen d. Chemie*, vol. cxcvii., p. 105.
† *Journ. f. prakt. Chemie*, xxviii., 1.
‡ *Annalen*, lix., 224.
§ *Annalen*, cxviii., 236.
|| *Pharm. Journal* [3], vi., 53.

crystalline body may be obtained as follows:—Some of it is placed in a good sized retort with glacial acetic acid and heated, while carefully swinging the retort, to boiling. Upon the addition of the acetic acid the substance forms at first a black viscous syrup, which becomes thinner as the temperature rises. The syrup is maintained in full ebullition for a few moments and when solution is complete is filtered through paper as rapidly as possible, preferably by means of a water-bath funnel into a glass or porcelain dish. If sufficient glacial acetic acid has been used solution is not difficult; but if too small a quantity be used there is a separation of crystalline matter in the retort and on the filter, and the filtration becomes prolonged and troublesome. Nevertheless too much solvent is a greater disadvantage than too little, the yield of crystals being smaller. The crystalline mass is separated from the deep brownish black syrupy mother-liquor, pressed, and washed with glacial acetic acid and with absolute alcohol. It still remains contaminated with the dark coloured mother-liquor, and to obtain it perfectly pure and free from ash it requires to be again boiled with glacial acetic acid, filtered rapidly, and the crystalline mass that forms upon cooling recrystallized two or three times from boiling alcohol.

The purified substance forms slightly yellowish bright shining crystalline scales, which under the microscope appear to be homogeneous, perfectly transparent and colourless, and which are better formed in proportion as the separation from the alcoholic solution takes place slowly. In water at the ordinary temperature it is really but little soluble, it forming a transparent faintly wine-yellow coloured jelly, in which isolated hard particles remain suspended in the form of small lumps even after some days. Upon mixing 1 gram with 100 c.c. of water the mass acquires after standing several hours a consistence that will allow an open vessel to be reversed without it falling out. When the jelly is heated it becomes liquefied, and is quite thin when the water boils. In boiling water the compound is very readily soluble. Sufficiently dilute aqueous solutions are at the ordinary temperature gum-like, viscous and frothy. The compound is insoluble in ether, slightly soluble in absolute alcohol even when boiling, slightly soluble at the ordinary temperature in alcohol above 90 per cent., but more soluble therein when boiling. The solubility in alcohol increases rapidly with the amount of water it contains. From weak alcoholic and aqueous solutions it cannot be obtained crystalline; an aqueous solution when evaporated spontaneously or upon a water-bath only yields an amorphous brittle gum-like slightly coloured mass which when dried is not unlike white of egg. Upon treating the aqueous jelly with a little dilute sulphuric or hydrochloric acid it becomes turbid and of greater consistence. Small quantities of ammonia and caustic alkalies added increase the solubility of glycyrrhizin to an extraordinary extent, the solution so obtained being, if the material is pure, almost colourless, but if not pure it is more or less perceptibly coloured. In aqueous solutions sugar of lead and other salts of the heavy metals produce voluminous precipitates; the silver precipitate is cheesy, runs together in globules on being heated, and dissolves readily in ammonia. Similar but more compact precipitates are formed in the alcoholic solution by alcoholic solution of sugar of lead, caustic baryta, etc.; whilst alcoholic solutions of ammonia and caustic potash produce in a strong alcoholic solution precipitates which after standing deposit on the bottom of the vessel as a resinous mass. Fehling's cupric liquor is reduced by it after prolonged heating. Nitric acid dissolves the substance at the ordinary temperature with considerable production of heat to an almost colourless liquid, from which nothing separates upon dilution with water. Upon heating the hydrochloric acid solution over a spirit lamp a brief but tolerably brisk evolution of gas takes place, the liquid becomes turbid through the separation of resinous flocks, and upon dilution with water there is a much more copious separation of colourless flocks. In concentrated sulphuric acid the substance dissolves to an orange-red liquid, from which colourless flocks are precipitated by water.

The substance possesses an intensely sweet taste with an after-flavour faintly resembling liquorice. This after-taste appears to be weaker in proportion with the increasing purity of the product, but in no case in the author's experience was it quite absent. The substance bears a temperature of 100° C. without change, but turns brown at 110° C. and melts at a higher temperature, decomposing to a black pitchy mass and diffusing an odour scarcely resembling that of sugar; finally it inflames and burns with a very sooty flame, and leaves a greyish-black coke-like residue.

Analysis of the crystalline substance was attended at first with considerable difficulty in consequence of adherent acetic acid, which could not be got rid of in the ordinary drying apparatus without discoloration; especially was this the case when the recrystallization from alcohol had not been repeated several times. The difficulty was overcome by drying in a vacuum. Analysis was made of specimens of ash-free substance obtained from different preparations of glycyrrhizin, dried at 100°. As the simplest expression of the mean of the analytical data obtained, the author gives the formula $C_{22}H_{33}NO_9$, but he does not look upon this as the true representation of the molecular weight.

	Mean of results obtained.	Required for $C_{22}H_{33}NO_9$.

N	3·07	3·05

Upon treating a solution in strong alcohol with an alcoholic solution of platinic chloride, a crystalline formation of the platino-ammonium salt was obtained. A further investigation, however, led the author to the conclusion that only a portion of the nitrogen is present in this body in the form of ammonia, whilst the other part is combined in another way. The result corresponded with the composition of an acid ammonium salt of a nitrogenous acid represented by the formula $C_{44}H_{62}NO_{18}$ (NH_4), and for this acid the author adopts the name proposed by Roussin, of "glycyrrhizic acid."

Some other compounds of this acid are also described by the author as follows, the analyses being made after drying at 100°:—

Neutral Glycyrrhizate of Ammonium.—$C_{44}H_{60}NO_{18}$ $(NH_4)_3$.—Obtained upon treating an alcoholic solution of the acid salt with excess of ammonia and evaporating to perfect dryness in a vacuum over sulphuric acid. It formed an amorphous, brittle, light yellow-brown, transparent mass, resembling gum arabic. It was extremely soluble in water and alcohol, but insoluble in absolute alcohol; its solutions were precipitated by various metallic salts. It possessed a nauseous sweet taste. It was rather hygroscopic and when heated readily underwent change, apparently giving up part of its ammonia

Neutral Glycyrrhizate of Potassium.— $C_{44}H_{60}NO_{18}K_3$.—Aqueous solution of potash was added in slight excess to a concentrated solution of the acid ammonium salt in weak alcohol. The smell of ammonia was perceptible at the ordinary temperature. The solution was heated for some time, then left to cool, and absolute alcohol added as long as any precipitate was produced. It was then allowed to stand twenty-four hours under a bell glass, at the end of which time the flocculent precipitate had collected into a resinous mass adhering closely to the sides of the vessel. This, after the clear liquor had been poured off, was washed repeatedly and carefully with absolute alcohol and dried at the ordinary temperature over sulphuric acid. It then appeared as a yellowish-white, light, friable mass, very soluble in water and dilute alcohol, but almost insoluble in absolute alcohol and ether.

Acid Glycyrrhizate of Potassium.—$C_{44}H_{62}NO_{18}K$.—If the previous compound be treated in the dry condition with a moderate quantity of acetic acid and heated it dissolves to a clear slightly coloured liquid. From this solution, filtered whilst boiling, the acid compound quickly separates on cooling in colourless microscopically small granular crystals. It has a very persistent intensely sweet taste, exceeding in this respect levulose, cane sugar, and even the acid ammonium salt. The compound swells up in cold water to a jelly, but it is soluble in hot water to a considerable extent, such solution gelatinizing as it cools. It is soluble in aqueous alcohol, especially when heated, very slightly soluble in alcohol above 90 per cent., soluble in glacial acetic acid when heated, and scarcely soluble in ether. All the solutions are colourless. The salt can be dried at 100° C., but upon heating it further it swells and eventually burns with a smoky flame giving off a peculiar odour.

Neutral Glycyrrhizate of Barium, $(C_{44}H_{60}NO_{18})_2$ Ba_3, is obtained as a yellowish-white amorphous body by adding baryta water in slight excess to a hot alcoholic solution of acid glycyrrhizate of ammonium.

Neutral Glycyrrhizate of Lead.—$(C_{44}H_{60}NO_{18})_2$ Pb_3.—Upon treating a solution of acid glycyrrhizate of ammonium with solution of sugar of lead there is produced a very voluminous white transparent mucilaginous precipitate; when alcoholic solutions are used the precipitate is more compact and more convenient for filtering and washing. Dried in a vacuum over sulphuric acid it forms a yellow-brown, transparent, brittle and friable gum-like mass, having a sweet taste. It is soluble in glacial acetic acid, slightly soluble in water, insoluble in alcohol and ether. Upon heating to 100° C. it is perceptibly coloured brown.

Glycyrrhizic Acid.—$C_{44}H_{63}NO_{18}$.—The lead compound is the most suitable material for the separation of the free acid. The precipitate after being well purified by washing and pressing is rubbed up with a little water to a fine mucilage, placed in a beaker in a water-bath and decomposed by a current of sulphuretted hydrogen continued several hours, the mixture being diligently stirred. The finely suspended lead sulphide is removed by boiling and adding to the liquid in small quantities at a time the white of egg beaten to a froth, and when the precipitate appears in large flocks in the colourless liquid filtering while still boiling through coarse paper. The filtrate thickens on cooling to a somewhat turbid jelly, which upon heating in an open dish on a water-bath shrivels up in a remarkable manner, leaving a brown residue resembling dried egg-white. It has a persistent pure, but not excessively sweet taste. The acid reddens blue litmus paper and decomposes the carbonates of the alkaline earths gradually by boiling. It swells up in water at the ordinary temperature to a jelly, without actually dissolving, and with boiling water forms a thin viscous solution. It dissolves tolerably freely in weak alcohol, especially when heated, also in boiling glacial acetic acid, and only slightly in absolute alcohol and ether. It turns brown at 100° C., and puffs up and burns upon further heating to a black coal. Glycyrrhizic acid reduces Fehling's solution upon heating almost as quickly as grape sugar.

The results of this investigation may be thus summed up:—(1) In liquorice root there is contained a peculiar nitrogenous acid in the form of salts; (2) The acid is tribasic and forms neutral and acid salts; (3) Among these salts the acid potassium and ammonium salts are, from their crystallizability and intensely sweet tastes, especially important; (4) It is probably to the ammonium salts of glycyrrhizic acid that liquorice root owes its peculiar sweet taste.

The author is continuing his investigations upon various decomposition products of glycyrrhizic acid and a second constituent of liquorice root.

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.*

BY PROFESSOR ABEL, C.B. F.R.S.

(*Continued from page* 29).

That the power possessed by different very highly explosive substances, of inducing the detonation of such bodies as gun-cotton and nitro-glycerine, is not solely ascribable to the operation of mechanical force very suddenly developed, is indicated not only by the singular inertness of gun-cotton to the influence of nitro-glycerine as a detonating agent, but also by a comparison of the behaviour of other detonating substances with that of the mercuric fulminate, when applied to the detonation of gun-cotton. Thus the detonation of silver fulminate is very decidedly sharper than that of the mercury compound, yet it is in no way superior to the latter in its power as an initiative detonating agent; indeed, a somewhat larger amount of it appeared to be required than of the mercury salt to induce detonation of gun-cotton with certainty. Again, the iodide and chloride of nitrogen are far more susceptible of sudden detonation than the silver fulminate; yet while five grains of the latter, confined in a stout metal envelope, suffice to detonate gun-cotton, fifty grains of chloride of nitrogen confined by water appeared to be the minimum amount with which the detonation of gun-cotton could be accomplished with certainty, while no success attended the employment of confined iodide of nitrogen in quantities ranging up to 100 grains.

The incompatibility of these results with the general conclusion, based upon numerous and greatly varied experiments, that the facility with which the detonation of gun-cotton and nitro-glycerine, and bodies of a similar character as explosives, is induced by an initiative detonation, is proportionate to the mechanical force aided by the heat developed by the latter, led the lecturer to the conclusion that a synchronism or similarity in character or quality of the vibrations developed by the detonation of particular substances, operates in favouring the detonation of one such substance by the initiative detonation of a small quantity of another, while in the absence of such synchronism, a much more powerful detonation, or the application of much greater force, would be needed to effect the detonation of the material operated upon. This view has received considerable support from results since obtained by other experimenters, especially by MM. Champion and Pellet; but the subject is one which still needs further experimental elucidation.

The physical character of explosive substances, as also the mechanical condition of a mass of the particular explosive substance operated on, are of great influence in determining its behaviour when submitted to the action of an initiative detonation. The liquid nitro-glycerine is far more sensitive to detonation than gun-cotton; one grain of mercuric fulminate, confined in a metal case, suffices to detonate nitro-glycerine when surrounded by it: but, in order to attain this result with any degree of certainty, it is necessary so to confine the nitro-glycerine as to prevent its yielding to the blow developed by the initiative detonation, and thus to some extent escaping from the operation of the sudden concussion to which the particles contiguous to the fulminate charge are submitted.

If nitro-glycerine be mixed with solid substances in a fine state of division, plastic mixtures may be obtained, and the liquid may thus be presented in something like a solid form to the detonating agent; if the particles of absorbent material be moreover of porous nature, as is the case with the infusorial earth called Kieselguhr used in the production of dynamite, a solid nitro-glycerine preparation may be obtained which contains a very large proportion of the liquid (75 per cent. by weight). In this condition nitro-glycerine may be detonated without any difficulty when freely exposed to air; and although it is

* Lecture delivered at the Royal Institution of Great Britain, Friday, March 21, 1879.

diluted with a considerable proportion of absolutely inert material, its sensitiveness to detonation is not in the least diminished. Each particle of the diluent is enveloped in the liquid, so that no portion of the latter becomes isolated from the remainder by the admixture of inert solid matter; hence, when the initiative detonator is surrounded by such a mass, it is in contact at all points with some portion of the nitro-glycerine, and the latter is in continuous connection throughout, though no longer in a mobile condition; detonation is consequently as readily established and transmitted through the mass as though it consisted entirely of nitro-glycerine. Indeed, while the liquid in its undiluted state, if freely exposed to air in a long layer, transmits detonation with difficulty, and very slowly as compared with compressed gun-cotton (the observed rate of progression being, in several experiments, below 6000 feet per second), detonation is transmitted with ease and certainty through very long trains of a solid preparation of nitro-glycerine, such as dynamite, and the rate of transmission is decidedly more rapid than it is with compressed gun-cotton, a result which is in harmony with the greater sensitiveness to detonation and the greater violence of action of nitro-glycerine.

It has already been stated that gun-cotton may be detonated if a confined charge of not less than 2 grains of mercuric fulminate be detonated when closely surrounded by the substance. But in order to attain this result, the cellulose-product must be presented to the detonating agent in a mechanical condition favourable to its action.

Gun-cotton in a loose flocculent condition, or even if in the more compact form of a spun yarn or thread, cannot be detonated through the agency of a large charge of fulminate buried in the material. The light and loose gun-cotton is simply scattered with violence; portions are sometimes inflamed by the heat developed where the fulminate is detonated, a result which is obtained with greater certainty the less violent the detonation produced by the fulminate-charge. If, however, the gun-cotton be converted into a compact form, either by ramming the wool or thread very tightly into a case, or better still, by reducing the gun-cotton fibre to a very fine state of division, and compressing it, when in that condition, into compact masses, it becomes susceptible of detonation by the initiative action of mercuric fulminate, and the quantity of the latter required to bring about detonation is small (down to the limit which has been named above) in proportion as the compactness or density of the compressed material is increased.

Detonation, when established in compressed gun-cotton, is transmitted with great velocity throughout the mass, as already stated, or from one to another of contiguous masses, laid out in long rows, and even, though at a reduced rate, if small spaces exist between the individual masses. But if a small mass of compressed gun-cotton freely exposed to air be detonated when in immediate contact with gun-cotton wool or loosely twisted yarn, the detonation will not be transmitted to these, but they will merely be scattered and perhaps inflamed.

The difference in the behaviour of nitro-glycerine and of gun-cotton when presented to the action of a so-called initiative detonation under the different conditions spoken of above, admits of ready explanation.

It was established, in the first instance, that the action of an initiative detonation is not ascribable to the heat developed within the detonating material itself, in undergoing chemical metamorphosis. If it were so, the detonating mixture known as percussion cap composition and other explosive mixtures, the detonation of which is attended by much greater development of heat than is obtained by the action of pure mercuric fulminate, should detonate gun-cotton more readily than the latter does, whereas very much larger quantities of such materials are required to attain that result; moreover, the readiness with which gun-cotton is detonated should be solely proportionate to the *amount* of fulminate used, which has been shown not to be the case; and gun-cotton should be more readily detonated when in the loose and open condition than in the highly compressed or compact form, because the latter presents it in the condition least favourable, and the former in that most favourable, to ready and rapid transformation by heat. Again, the actual temperature required for the explosion of nitro-glycerine is very considerably above the exploding temperature of gun-cotton, yet a very much smaller charge is required for the detonation of nitro-glycerine than is needed for the detonation of gun-cotton. On the other hand, a quantity of confined percussion cap composition which, if it were pure mercuric fulminate, would be altogether inadequate for the detonation of gun-cotton, suffices for the detonation of nitro-glycerine.

The action of an initiative detonation has already been compared to that of a blow from a hammer or falling weight. The readiness and certainty with which gunpowder, gun-cotton, and other explosive agents are detonated by the latter agency are regulated by several circumstances; they are in direct proportion to the weight of the falling body, to the height of its fall, and to the force with which it is impelled downwards; to the velocity of its motion; to the mass and rigidity or hardness of the support upon which the substance to be detonated rests; lastly, to the quantity and mechanical condition of the explosive agent struck, and to its sensitiveness.

Gunpowder is much more readily detonated by a sharp blow from a small hammer, than by the simple fall of a heavy hammer, or by a comparatively weak blow from the latter. It is very difficult by repeated blows, applied at very brief intervals, to detonate gun-cotton if placed upon a support of wood or lead, both of which materials yield to a blow, the force applied by that blow being transferred through the explosive agent and absorbed in work done upon the material composing the support. But if the latter be of iron, which does not yield permanently to the blow of the hammer, the detonation of those substances is easily accomplished. If the quantity of the explosive agent employed be so considerable as to form a thick layer between the hammer and support, the force applied is to so great an extent expended in imparting motion to the particles of the compressible mass, that there remains little or none by which its detonation can be accomplished, and if the material be in a loose or porous condition (as in the case of a powder or of loose wool), much work has to be accomplished in moving particles of the mass through a comparatively considerable space, in the operation of compressing them, so that a second or even a third blow is required for their detonation; whereas if, by blows or pressure previously applied, the explosive material will be presented in the form of a compact mass, the particles of which have little tendency to motion when force is applied to them, detonation will be much more readily developed. It appears therefore that the detonation of an explosive substance by means of a blow is the result of the development of heat sufficient to bring about most energetic chemical action, or change, by expenditure of force in the compression of the material, or by establishing violent friction between its particles, consequent upon the motion momentarily imparted to them, and that it is brought about with a readiness proportionate to the resistance which they oppose to their motion by the degree of their contiguity to each other.

The exceedingly violent motion of particles resulting from the sudden or extremely rapid transformation of a solid or liquid explosive body into highly heated gas or vapour (which is the effect of a detonation), must obviously exert force which operates upon a body opposed to it in a manner precisely similar to the force applied by opposing a body in the path of a solid mass which is set into very rapid motion. In other words, a detonation exerts a mechanical effect upon resisting bodies precisely similar to that of a blow from a hammer or from a projectile propelled from a gun. Just as the force of a sufficiently sudden or powerful blow from a hammer is transformed into heat by the resistance to the motion of the hammer which the particles of an opposing body offer, and by the consequent friction established between them, so the force or concussive action exerted by the matter set in motion when a solid or liquid is converted into gas or vapour, will also be transformed into heat, the development of which in an opposing body will be proportionate to the resistance to motion which its particles offer, and to the suddenness and violence of the concussion to which it is subjected. The power of accomplishing the detonation of nitro-glycerine, gun-cotton, or other highly explosive substances, freely exposed to the air, through the agency of detonation produced in their vicinity or in close contact with them, appears therefore correctly ascribable to the heat suddenly developed in some portion of the mass by the mechanical effect, or blow exerted by that detonation, and is regulated by the violence and suddenness (either singly or combined) of the detonation, by the extent to which the particles composing the mass of the explosive material are in a condition to oppose resistance to the force, and by the degree of sensitiveness of the substance to detonation, or to sudden metamorphosis, under the influence of heat thus developed.

It will now be evident why the readily yielding nature of the particles of liquid nitro-glycerine tends to counteract its great sensitiveness to detonation, and why, when the motion of the liquid particles is impeded by their admixture with solid matter, and when they are consequently placed in a position to resist mechanical motion by the force applied through the agency of detonation, its natural sensitiveness to detonation, and the rapidity with which it can be transmitted from particle to particle became fully developed.

Again, the reduction of gun-cotton fibre to a fine state of division, which renders the material readily convertible into very compact and dense masses, places the particles in the condition most favourable to resist mechanical motion upon the application of a blow, or of the concussion resulting from a detonation; hence, compressed guncotton is readily susceptible of detonation in proportion to the extent of compression, or to its density and compactness, while loose gun-cotton wool, or the lightly twisted or compressed material cannot be readily detonated, because the force applied is expended in imparting motion to the readily yielding particles of the mass. If the force applied through the agency of a detonator to a mass of explosive material just borders upon that required for the development of the detonation, or if the condition of the mass is such as hardly to present the requisite resistance to mechanical motion essential for its detonation, then, results intermediate between the mechanical dispersion of the mass and its violent chemical dispersion or disintegration, *i.e.*, detonation, are obtained. Thus, frequent instances have been observed, especially in the experiments in the transmission of detonation through tubes, in which the initiative detonation has brought about an explosion attended with little, if any, destructive effect, portions of the mass being at the same time dispersed and occasionally inflamed. Not only have such results often been obtained with gun-cotton and dynamite, but even mercuric fulminate, exposed to the concussion of a distant detonation transmitted through a tube, has frequently been exploded in a manner quite distinct from the violent detonation developed in other instances. Silver fulminate, which under ordinary conditions detonates violently, even when only a particle of the mass is subjected to a sufficient disturbing influence, has been exploded without the usual demonstrations of force, by the transmitted effect of a detonation of mercuric fulminate. In these instances the violence of the concussion produced by the initiative detonation was only just bordering on that required for the development of detonation, and it appears probable that only some small portion of the mass operated upon was in a condition or position favourable to the action of the initiative blow. The remainder of the mass would then be dispersed by the gases developed from the detonated portion; in some instances the particles would be inflamed at the moment of their dispersion, in others, they would even escape ignition. The latter appears to be always the case when gun-cotton is exploded by a blow from a hammer or falling weight. However carefully the arrangements are adjusted with a view to distribute such a blow uniformly over the entire mass struck, the concentration of a preponderance of the force applied upon some portion or portions of the entire mass appears almost inevitable; hence, only a small portion is actually detonated, the remainder being instantaneously dispersed by the gases suddenly generated while the weight is still resting upon the support.

Some experiments made in firing at masses of compressed gun-cotton, differently arranged and of different thicknesses, with a Martini-Henry rifle, at short ranges, afforded interesting confirmation of the correctness of the explanation given of the operation of a blow upon masses of explosive material under different conditions. Disks of gun-cotton of the same density and diameter, but differing in thickness, were fired at; they were freely suspended, and their distance from the marksman was in all instances 100 yards. The thinnest disks were simply perforated by the bullets, not a particle of the gun-cotton being ignited. Somewhat thicker disks were inflamed by the impact of the bullet, while still thicker disks, fired at under the same conditions, were exploded, portions being in some instances dispersed in a burning state. No instance of detonation was, however, obtained. These differences in effect, obtained with masses of different thickness and weight, are due to the difference in their power to resist mechanical motion when struck by the bullet, and in the different amount of resistance to penetration presented by the thin and the thicker disks.

It has been explained that nitro-glycerine may be largely diluted with inert solid matters without its sensitiveness to detonation being reduced, while its detonation in open air becomes very much facilitated, because the mobility of the particles, and their consequent tendency to yield to the force of a blow or detonation is very greatly diminished. But if a *solid* explosive agent is diluted with inert *solid* matter the case is different; for in such a mixture of the finely divided solid with non-explosive solid particles, there must be a partial and sometimes a complete separation of the particles of the explosive by the interposed inert particles with which it is diluted; hence the sensitiveness to detonation is reduced, and its transmission by the particles is retarded or altogether impeded, by a diminution of the extent of contact between the substance to be detonated and the initiative detonation, and by the barrier which the interposed non-explosive particles oppose to the transmission of detonation. Thus a mixture of mercuric fulminate with more than one-fifth its weight of French chalk could not be detonated by means of one grain of pure fulminate enclosed in a copper capsule, which was inserted into the mixture; that quantity, similarly confined, sufficed to detonate undiluted fulminate through a tube 8 inches long and 0·5 inch in diameter. In experiments made in this direction with finely divided gun-cotton, it was found that although dilution with an inert solid, applied in the *solid form*, reduced the sensitiveness of the material to detonation, this was not the case when it was incorporated with a salt soluble in water, the mixture being then compressed while in the wet state. The compressed masses thus obtained were, when dried, in a condition of greater rigidity than could be attained by submitting undiluted gun-cotton to considerably more powerful pressure, because the crystallization of the soluble salt used as the diluent upon evaporation of the water, cemented the particles composing the mass more rigidly together. The gun-cotton was therefore presented in a form more capable of resisting the mechanical action of a small charge of fulminate than a more highly compressed undiluted gun-cotton, and hence the reduction in sensitiveness due to the detonation of the explosive compound is nearly counterbalanced by the greater rigidity imparted to the mass. If a soluble oxidizing agent (a nitrate or chlorate) be employed as the diluting material, the predisposition to chemical reaction between it and the gun-cotton (which is susceptible of some additional oxidation), appears to operate in conjunction with the effect of the salt in imparting rigidity to the mixture, thus rendering the latter quite as sensitive to the detonating action of the minimum fulminate charge as undiluted gun-cotton. Moreover, the interesting fact has been conclusively established, that these compressed mixtures of gun-cotton with a nitrate or a chlorate are much less indifferent to the influence of detonating nitro-glycerine than gun-cotton in its pure state. Chlorated and nitrated gun-cotton are detonated with certainty by means of half-ounce of nitro-glycerine, whereas the detonation of 2 oz. of the latter accomplished the detonation of ordinary compressed gun cotton only once in a large number of experiments.

(*To be continued.*)

QUEBRACHO, A PALLIATIVE REMEDY IN DYSPNŒA.*

Dr. F. Penzoldt, of Erlangen (*Berl. Klin. Wochenschrift*, No. 19, 1879), narrates some experiments both on man and animals with a new drug, the bark of *Aspidosperma quebracho* (*Apocynaceæ*), sent from Brazil, where it is reputed to have antipyretic properties. The form of preparation used throughout was a watery solution of an alcoholic extract of the bark, ten parts of the latter being percolated with one hundred of alcohol for several days, and the liquid filtered, evaporated, dissolved in water, again evaporated to dryness, and the residue dissolved in twenty parts water.

The main results obtained in frogs were complete motor paralysis of central origin, respiratory paralysis, and diminished frequency of the pulse, independent of irritation of the vagus. In rabbits and dogs, motor paralysis and dyspnœa, increasing with the dose administered, were noticed. The dyspnœa in the rabbit, however, appeared to depend on retardation and deepening of the inspirations; while in the dog the inspirations were accelerated. In the latter, also, there was salivation.

Experiments on animals with artificial fever, produced by injecting putrid fluids, showed no decided reduction of the temperature, and hence quebracho is probably not, as was supposed, an antipyretic. It should be added that it is not an antiseptic, but only temporarily retards putrefaction. The results obtained in actual cases of fever in men were also negative, but Dr. Penzoldt thinks that, considering the close chemical relationship between the alkaloid "aspidodermine" which Baeyer has extracted from quebracho-bark, and quinine, the subject requires further working out in this direction.

By the accidental observation of a patient with pleurisy and emphysema, on whom the antifebrile effect of quebracho was being tried, Dr. Penzoldt was led to try the bark in various forms of dyspnœa, depending on emphysema, bronchitis, phthisis, pleurisy, etc., and obtained remarkably good results. A teaspoonful of the above-mentioned solution was given two or three times a day. The most marked objective phenomenon after its exhibition was a reddening of the previously cyanosed or livid tint of the lips and face. In a case of emphysema where the patient was blessed with a nose the seat of acne hypertrophica, the ordinary violet-blue colour of the organ became fiery red, and excited the surprise of the other patients in the ward. The respirations generally became deeper and less frequent, and the patients expressed themselves subjectively much relieved. The first feeling after taking the drug was one of warmth in the head; many said that they had less desire to cough, and that they found expectoration easier. Occasionally sweating occurred, and in some cases abundant salivation. No bad effects were noticed with the dose mentioned.

Dr. Penzoldt finds that the addition of quebracho solution to blood, in the presence of oxygen, makes it assume a bright red colour, and he is inclined to think that possibly the blood is rendered capable of taking up more oxygen than usual, and carrying it to the tissues. This is, however, merely a provisional hypothesis, and at present there is no satisfactory explanation of the fact that, while moderate doses of the extract alleviate dyspnœa in man, large doses cause dyspnœa in the lower animals.

As yet, quebracho bark is not a commercial product, but the *wood* is imported in large quantities for tanning purposes. The action of an extract of the wood is similar to that of the bark, but weaker. The alkaloid aspidodermine affects the frog, on the whole, just as the extract of the bark does.

ANALYSIS OF EUPATORIUM PERFOLIATUM.*

BY PETER COLLIER.

The author reports the following result of the examination of "Boneset," *Eupatorium perfoliatum*, Lin. This plant has long had the reputation in domestic medicine of being a good tonic, especially valuable in the spring. Physicians have also attributed to it virtues as a diaphoretic, expectorant, emetic and anti-intermittent. Whether all claimed for it is true must be settled by the physician, but the present chemical examination has been undertaken with the hope of throwing some light upon the proximate principles to which are due the medicinal effects of the herb. Partial analyses have been made by W. Peterson (*Amer. Jour. Pharm.*, 1851, xxiii., p. 206), and by M. H. Bickley (*Amer. Jour. Pharm.*, 1854, xxvi., p. 459).

Probably the bitter principle is the only one of medicinal importance. It is a brown uncrystallizable substance, soluble in water and alcohol, insoluble in ether. It was impossible to purify this substance well.

Upon evaporation of an alcoholic extract of the drug a few white prismatic crystals were deposited. These crystals were difficultly soluble in hot alcohol and insoluble in ether, water, dilute acids and dilute alkalies. They seem, therefore, to be neither acid nor alkaloid, but rather of an indifferent character.

The drug appears to contain very little volatile oil, although its odour may be accounted for by this small amount present.

Starch is not abundant. The tannic acid found gave the usual reactions, except that it failed to precipitate tartar emetic from its aqueous solution. The albuminoids were calculated from total nitrogen, multiplied by 6·25.

It is impossible to say whether sugar was present in the substance, since the bitter principle would probably give similar reactions.

The following analysis is regarded as an approximation only, but care has been taken to eliminate all preventable errors:—

Analysis of "Boneset," Eupatorium Perfoliatum.

THE PROSECUTION UNDER THE APOTHECARIES ACT AT BIRMINGHAM.

AFTER a delay of about two years, judgment has been given in the case of prosecution for breach of the Apothecaries Act at Birmingham, and as reported in the Journal last week, that judgment is adverse to the defendant. When the case was tried in the Birmingham County Court in July, 1877, it was believed and expected that the appeal then being made against the decision given in the SHEPPERLEY case would result in causing some light to be thrown upon the questions involved in this prosecution as between medical practitioners and chemists and druggists. Upon that ground the County Court Judge resolved to defer judgment until after a decision had been given in the appeal so as to avoid putting the defendant to the trouble and expense of taking a second case to be decided by a higher tribunal.

At the time the Judge expressed himself as being in some perplexity as to the proper intrepretation of the law relating to the case, and as to what might and might not be regarded as coming within the legitimate functions of the chemist and druggist as a vendor of drugs. Having regard to the opinion expressed by Baron BRAMWELL shortly before, he considered that the recommendation and supply of any medicine or drug for the purpose of relieving some bodily ailment might be technically construed as infringing the terms of the Apothecaries Act, inasmuch as that would be doing what the apothecary had a right to do in the exercise of his calling and under the licence of the Society of Apothecaries.

Whilst recognizing this strict reading of the law as correct from a legal point of view, however, the County Court Judge also concurred with Baron BRAMWELL in thinking that it would be very unreasonable for the Society of Apothecaries to interfere in a case so simple as that of a person asking for and receiving a simple remedy for such an ailment as a headache or any similar ordinary complaint. But he also stated that in his own mind he was not prepared to adopt in its entirety the view of Baron BRAMWELL that in every instance a chemist and druggist furnishing medicine to relieve bodily ailments would be stepping beyond his province and—by infringing upon that of the medical practitioner—be committing a breach of the Apothecaries Act.

The opinion expressed at the time by the Judge was that the Society of Apothecaries never intended to interfere with chemists and druggists supplying remedies in trifling cases. He therefore considered that such an interpretation of the law as Baron BRAMWELL had adopted was too strict, and he appears to have been led to this opinion by recognizing the possibility of a distinction being drawn between mere advice or recommendation as to the kind of medicine and its use for certain purposes, as forming part of the business of vending, and the prescribing of medicine as a result of the examination of a patient by the ordinary means of ascertaining symptoms, and with the object of treating disease.

From a common sense point of view there is much reason for recognizing this distinction, but unfortunately the Apothecaries Act does not either define what is meant by acting as an apothecary or specify whether the rights specially reserved to chemists and druggists by the 28th section comprised the right to do as they and apothecaries also had previously done in giving advice as to the use of simple remedies. As a matter of law, therefore, it was difficult, if not impossible, to decide whether or not the recommendation of medicine or advice as to its use in connection with the vending of it was to be understood in the meaning of the Act as "practising as an apothecary." If this were held to be the case it was equally difficult to decide whether or not the right of giving such recommendation and advice was reserved to chemists and druggists in virtue of usage prior to the Act of 1815.

For the sake of gaining from the decision of the SHEPPERLEY appeal some information and guidance on these points the Birmingham County Court Judge adjourned the case heard by him in 1877. That appeal has now been disposed of, but the assistance it was expected to furnish towards the settlement of the important questions above mentioned has not been obtained. It is still an open question what is meant by acting as an apothecary within the meaning of the Act of 1815. It is still a question where the line is to be drawn between the recommendation and advice properly appertaining to the vending of drugs and medicines, as forming part of the chemist and druggist's business, and the application of remedies to the treatment and cure of disease, which is the function of the medical practitioner holding himself out to the public as specially qualified for that work.

It was upon this view that the decision just given by the Birmingham County Court Judge was based. He takes the evidence of Mr. PARSONS as showing undoubtedly that before the year 1815 chemists and druggists did something beyond merely selling medicines; but he points out that even if they were then in the habit of advising patients or prescribing medicine it does not follow that they ever had the legal right to do so, or that at the present day chemists and druggists are protected by the 28th section of the Act in case they do so. The legal right to practise medicine or surgery and to treat disease is given by the registration of the practitioner who holds himself out, in virtue of the special qualification by which he has secured registration, as the proper person for performing those duties.

In the case that has now been decided at Birmingham the defendant had not the legal right to practise medicine, and as the case for which he prescribed was considered to require medical knowledge and skill, he is held to have "acted as an apothecary" and thus to have come within the provisions of the Apothecaries Act. That this is a just decision of the case we may gather from the resolve of the Executive Committee of the Chemists and Druggists' Trade Association not to appeal against it.

In connection with this matter it will be interesting to learn that the President of the Nottingham Medical Defence Association also expresses regret that the SHEPPERLEY case has not led to a decision of the question as to the legality of counter practice, although affording opportunity for an authoritative exposition of the law. In speaking of the general weakness of the case which has called forth so much comment, he seeks to explain this by stating that it was never intended DEATH'S evidence should be relied upon, and that even in the original county court proceedings he was not to be put into the box. There were—he goes on to say—other witnesses, who, judging from the statements they made to the solicitors of the Medical Defence Association, were prepared to prove a strong case against the defendant. Those witnesses entirely failed to support the objects of the prosecutors, who, Mr. STANGER informs us, would have accepted their defeat if the Judge had not unfortunately given a decision in their favour, partly on the evidence of DEATH, but chiefly on the admissions made by the defendant.

It is seldom that litigation is productive of so much satisfaction all round as is claimed to have been the result of the SHEPPERLEY case, and though we are inclined to think that the most substantial satisfaction fell to the share of the lawyers, we are not at all disposed to interfere with the happiness of those who find reason to be pleased.

A NEW PHARMACY ACT IN THE STATES.

THE "People of the State of New York, represented in Senate and Assembly," have just enacted a law "governing the sale of drugs and poisons in the County of Kings" in that state. For convenience of reference and to illustrate the position which pharmacy is taking in the United States a short abstract will be useful.

In accordance with its title this Act makes it illegal for any one not registered under its provisions, after the first day of October next, to open or conduct any pharmacy or store for retailing or compounding medicines or poisons in the county of Kings; but it also goes further and makes it illegal for any but a registered pharmacist to prepare physicians' prescriptions except under the supervision of a registered pharmacist.

The Act is not wanting in stringency in other directions, for in order to procure the registration necessary a person must (1) be a graduate in pharmacy or in medicine, who has had at least four years' experience in stores where prescriptions of medical practitioners have been compounded and hold a diploma from a legally constituted college; or (2) have had at the time of the passing of the Act ten years' practical experience in the preparation of physicians' prescriptions; or (3) have had four years' similar experience and pass an examination by a Board appointed under the terms of the Act, consisting of three pharmacists and two medical men; or some other recognized Board of Pharmacy.

There are two schedules of poisons. Schedule A corresponds to Part 1 of our schedule in containing the poisons that are not to be sold without registration. Among these are to be found several that are in Part 2 of the British schedule, such as the white and red precipitates, essential oil of bitter almonds, and opium and its preparations, except paregoric and other preparations of opium containing less than two grains to the ounce. On the other hand aconite, savin, ergot and cantharides are remitted to the second schedule, which also includes henbane, digitalis, croton oil, creosote, sulphate of zinc, mineral acids and carbolic acid. The registers used for recording the sale of poisons in Schedule A are to be preserved for five years and to be open for inspection by the proper authorities, and none of the poisons in either schedule are to be sold without labelling the bottle or other containing vessel, as well as the outside wrapper, with the name and address of the seller and the word "poison," or without ascertaining that the buyers are aware of their poisonous nature.

Another feature of the Bill is an adulteration section, which provides that the pharmacist shall be held responsible for the quality of his goods, except in the case of original packages and patent medicines. A conviction for fraudulent adulteration is to be punishable by a fine of one hundred dollars and erasure of the offender's name from the register. The duty of prosecuting for offences under the Act is thrown upon the district attorney upon information laid by the Board of Pharmacy.

THE Sale of Food and Drugs Act (1875) Amendment Bill was read a third time in the House of Lords on Wednesday last.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London, on Wednesday, July 16, 1879, the report of the College of Preceptors on the examination held on July 1 was received.

Three hundred and sixty-five candidates had presented themselves for examination, of whom *one hundred and eighty-one* had failed. The following *one hundred and eighty-four* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically).

Allen, Ernest Edward ....Winchester.
Allen, Richard ....Ramsey.

Hull	5	1	4				

The questions for examination were as follows:—

FIRST OR PRELIMINARY EXAMINATION.

1st *July* 1879.

Time allowed: Three Hours for the three subjects.

1. Translate the following passages into English:—

A. Eo concilio dimisso, iidem principes civitatum, qui ante fuerant ad Cæsarem, reverterunt, petieruntque, uti sibi secreto de sua omniumque salute cum eo agere liceret. Ea re impetrata, sese omnes flentes Cæsari ad pedes projecerunt: "Non minus se id contendere et laborare, ne ea, quæ dixissent, enunciarentur, quam uti ea, quæ vellent, impetrarent; propterea quod, si enunciatum esset, summum in cruciatum se venturos viderent."

B. Cæsar loquendi finem fecit, seque ad suos recepit; suisque imperavit ne quod omnino telum in hostes rejicerent. Nam, etsi sine ullo periculo legionis delectæ cum equitatu prælium fore videbat, tamen committendum non putabat, ut, pulsis hostibus, dici posset, eos ab se per fidem in colloquio circumventos.

2. Decline throughout *principes*, *re*, *finem*, *equitatu*, *colloquio*.

3. Explain the construction known as the "Ablative Absolute," by the aid of the examples of it in the above passages.

4. Name the prepositions which occur above, arranging them in a table, according to the case which each takes after it.

5. Translate into Latin:—Cæsar did not wish the conference to be broken off. They appointed a day for the conference. The Helvetii were defeated by Cæsar. The forces of Ariovistus were distant four and twenty miles from our men.

II. ARITHMETIC.

(The working of these examples, as well as the answers must be written out in full.)

6. Find the value of 1 cwt. 3 qrs. 12 lbs. at £1 2*s.* 6*d.* per cwt.

7. Calculate the equivalent, on the metric system, of 10 oz. 5 dr. 2 scr.

8. Divide $(\frac{3}{8}+\frac{5}{16})$ by $(\frac{1}{4}+\frac{1}{5})$.

9. Express as decimals $\frac{1}{4}$, $\frac{1}{5}$, $\frac{3}{8}$, $\frac{5}{16}$.

10. What is the income corresponding to an Income Tax of £13 2*s.* 6*d.*, at the rate of 7*d.* in the £?

11. Compare the measurement of weight in the metric system with the various English standards. Why is the metric system easier to work?

III. ENGLISH.

12. What parts of speech may an adverb qualify?

13. Explain, by the help of examples, the correct use of *shall* and *will*.

14. In what respects does the Relative agree with its Antecedent? How far is it independent of its Antecedent?

15. Parse:—

"If the pilot slumber at the helm,
The very wind that wafts us towards the port
May dash us on the shelves."

16. Write a short essay on one of the following subjects:—The Electric Light, the Phonograph, the Telephone, the War in Zululand, Recreation, Co-operative Stores.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

MEETING OF THE EXECUTIVE COMMITTEE.

A meeting of the Executive Committee of this Association was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on July 8, 1879, at 1 p.m., Mr. Thomas Barclay (Birmingham), President, in the chair. Mr. Robert Hampson (London), Vice-President.

Present—Messrs. Andrews (London), Arblaster (Birmingham), Bell (Hull), Churchill (Birmingham), Cross (Shrewsbury), Davison (Glasgow), Holdsworth (Birmingham), Jones (Leamington), Maltby (Lincoln), Reynolds (Leeds), Southall (Birmingham), Symes (Liverpool), Walker (Coventry), and the Solicitor of the Association.

The minutes of the previous meeting of the Executive were read and approved, the appointment of committees and officials for the ensuing year was proceeded with.

In reply to a question, the Secretary said the taxed costs of the defendant in the case of the Apothecaries' Company *v.* Shepperley, amounting to £165 15*s.* 8*d.*, had a few days previously been paid to the Association.

Mr. Jones directed the attention of the committee to the medical bills before Parliament.

The President said he thought it would be undesirable for the Association to take any steps in regard to these bills until the Select Committee which had been appointed by the House of Commons had issued their report.

Mr. Hampson said it appeared evident that the medical profession were not disposed to allow the question of counter practice to rest. The Apothecaries' Company had just sustained a case in that town and gentlemen reading the medical journals would find their tendency was to support all the demands of the medical men. If the Select Committee were going into the whole question of medical legislation the question naturally arose as to the desirability of the Association moving in the matter.

Mr. Davison said he thought the fact of so many medical men keeping open shops, in very many instances managed by unqualified persons, should be brought under the notice of the chairman of the Select Committee. In Glasgow alone there were about a hundred and twenty such shops.

Mr. Symes said the Select Committee would scarcely be likely to accept any dicta from the Association. If the Association attempted to in any way regulate the practice of medical men it would be stepping out of its province.

Mr. Reynolds said the Duke of Richmond's Bill was the only medical bill which stood any chance of passing during the present session of Parliament.

It was moved by Mr. Hampson, seconded by Mr. Reynolds, and unanimously resolved :—"That the Law and Parliamentary Committee be directed to watch the proceedings of the Select Committee sitting to consider the medical bills in the House of Commons, and to take such action as they may deem necessary."

The President said the gentlemen present would be aware that the Birmingham County Court judge had given his decision a few days previously in the case of the Apothecaries' Company *v.* Harrison, tried in the Birmingham County Court so far back as July 2, 1877, the judgment being withheld pending the decision in the case of the Apothecaries' Company *v.* Shepperley. The decision of the judge was in favour of the plaintiffs, and the defendant had been fined £20 and costs. The Secretary would read the judgment.

The following judgment was then read :—

"This is an action brought by the plaintiffs against the defendant to recover the sum of £20 by way of penalty under the 20th section of the 55 Geo. III. c. 194, for practising as an apothecary without having first obtained the necessary certificate. It was heard before me as far back as July 2, 1877, and was adjourned in consequence of the pending of an appeal to the High Court of Justice against the decision of the county court judge at Nottingham, in a case similar to the present and under the same Act of Parliament. That appeal has now been disposed of, and I am sorry not to be able to derive the assistance from it I anticipated. So far as concerns the question of what is meant by 'acting as an apothecary' within the meaning of the Act, or the still more important question whether in virtue of usage prior to the Act in 1815, the right continued for chemists to act as apothecaries in the treatment of simple ailments and the administration of simple remedies for their relief, the law is left very much in the same state of doubt as it was before. The facts of the case are really these. The defendant is a chemist and druggist carrying on business at Birmingham, and a young woman named Julia Caddick being unwell was advised to go to the defendant's shop for medicine. In her evidence she states that she went to the defendant's shop on November 27, 1876, and saw the defendant and asked him if he would make up some medicine to relieve her from a weakness she was suffering from. She says, 'she told him it was a weakness left on her from her last confinement, and that her womb came down.' She says further, 'that the defendant felt her pulse, looked at her tongue and asked her to describe her feeling, when she told him she suffered much from pains in the back.' After this, according to her evidence, the defendant gave her a bottle of medicine which he said would do her good, and told her to take it according to the instructions on the bottle. She says, 'she gave the defendant one shilling for the medicine and took some of it at once in the shop.' A bottle half full of medicine was produced in court at the trial by the witness and she stated that it was the same she obtained from the defendant at his shop on November 27. The witness was cross-examined at length, but her evidence was not shaken in any respect. The above is all the evidence on the part of the plaintiffs I consider necessary to state at length except that of the medical man, Dr. Suffield, who, in his examination stated, 'that he had heard the evidence given by the woman, and from her description of her suffering, and from what she stated she had told the defendant, he should imagine she was suffering from anæmia, which was a constitutional complaint of a dangerous character, frequently leading to death, if the patient was not properly treated.' In diagnosing a complaint of the nature described, Dr. Suffield observed, 'that one would go a little deeper into particulars than seemed to have been done in this case by the defendant.' On cross-examination Dr. Suffield said, 'he did not think feeling the pulse was a sufficient diagnosis of the disease.' Upon being requested by defendant's counsel, he examined the medicine in the bottle and said he thought it was a preparation of iron and would be a proper medicine for the case. In opposition to this, defendant himself was called as a witness and the material parts of his evidence were to the effect 'that he remembered Julia Caddick visiting his shop in November in the afternoon. She came and asked him to supply her with a bottle of strengthening medicine for a weakness after lying in.' He denies that he examined her at all and states it was not necessary. He says, 'he did not feel her pulse, and she did not tell him anything about the womb coming down.' He admitted, however, 'that he did ask her if the weakness had anything to do with her confinement, stating that he did so because he saw she had been recently confined, and had a baby in in her arms which she said was hers.' The witness then stated, 'I said to her, do you mean general weakness of the constitution; when she said, yes.' The witness then added, 'I mixed her up some stuff which I put into a bottle and put a label upon it. The label on the bottle which had been produced the witness admitted was his label.' He said, 'that the mixture in the bottle was not what the woman had from his shop, that he would swear.' This, with the exception of the evidence of an aged chemist called by the defendant, to whose evidence he should refer hereafter, is the whole of the evidence on the one side and the other, so far as the real question to be determined in the case is concerned. By the 20th section of the 56 Geo. III., c. 194, under which this action is brought, it is enacted, 'that if any person shall after the 1st August, 1815, act or practise as an apothecary in any part of England or Wales without having obtained a certificate as mentioned in the preceding section of the Act he shall be liable to forfeit and pay the sum of £20.' The 28th section of the same Act, the one on which defendant grounds his defence, enacts by way of proviso 'nothing in this Act contained shall extend or be construed to extend to prejudice, or in any way to affect the trade or business of a chemist and druggist in the buying, preparing, compounding, dispensing or vending drugs, medicines or medicinable compounds, wholesale and retail, but all persons using or exercising the said trade or business, or who shall, or may hereafter, use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner and as fully and amply to all intents and purposes as the same trade or business was used, exercised or carried on by chemists and druggists before the passing of this Act.' The first point in this case to be considered is, has the defendant in the instance proved by this evidence acted as an apothecary? if he has, and is not protected by the proviso (it being admitted he has not obtained a certificate from the Society of Apothecaries), he is undoubtedly liable to pay the penalty sued for and the verdict must be for the plaintiffs. The defendant, however, raises two questions by way of defence. First, he says in what he did he did not act as an apothecary, and second, that if in strictness it should be held that he did, inasmuch as he was only carrying on his business of a chemist as chemists carried on their business before the passing of the Act in 1815, he is protected by the proviso referred to, which he contends permits chemists and druggists to carry on their business in the same manner as they did before the passing of the Act, and that chemists, so he says, the evidence proves were in the habit of advising patients in trifling cases as well as supplying them with medicines, and he argues that the present is a case of that character which a chemist would have treated before the passing of the Act, as the defendant has done since. Now with reference to the question raised by the first part of the defence, whether in what the defendant did he acted as an apothecary, the case of the Apothecaries' Company *v.* Lotinga, 2 M. and R., p. 500, decided in 1843, goes perhaps more fully into the question than any other, and in that case, Mr. Justice Cresswell told the jury that, 'an apothecary is a person who professes to judge of internal disease by its symptoms and applies himself to cure that disease by medicine,' and in the same case he tells them that 'a chemist is one who sells medicines which are asked for,' and in effect states, 'that if a chemist himself selected the medicines and determined on what he ought to give, he is stepping out of his lawful province as a chemist and entering upon that of an apothecary.' The definition of a chemist as given by Mr. Justice Cresswell in Lotinga's case would appear not to be large enough, because the 28th section of the Apothecaries Act referred to clearly shows that the trade of a chemist was not confined to selling medicines which were asked for merely, but extended to the preparing, compounding and dispensing them. His lordship's definition of an apothecary is, however, doubtless perfectly correct, for as recently observed by Mr. Baron Pollock, in Shepperley's case, it is to be presumed that Mr. Justice Cresswell did not mean internal as opposed to external disease, in the sense of a man having an eruption produced by some diseased condition of the body which the learned Baron observed would not be any less an internal disease, and if anyone proceeded to judge of it by the symptoms and apply medicine for its cure the law would equally apply to him as it would to the man who attempted to cure a persistent difficulty of indigestion, a diseased condition of the lungs or any of the other evils to which flesh is heir and which affect mankind internally. There is another case, The Apothecaries' Company *v.* Nottingham (34 L. T. N. S. 76), tried before Lord Justice (then Baron) Bramwell in 1876. In that case it was proved 'that the defendant, who was a certified chemist, but not an apothecary, had been in partnership with a duly qualified medical practitioner, but it was also shown that this medical man was not always on the spot. It also appeared in evidence that the defendant had on various occasions been applied to for advice and medicine, both of which he gave to the applicants, but did so as an ordinary shopkeeper from behind the counter. It did not appear that he ever went from his shop to attend on patients, and he was proved in cases of serious illness always to have referred the patients to the doctor with whom he was in partnership,' and the learned Judge in addressing the jury said, 'I feel some little difficulty in putting the case to you, for on the defendant's own admission he says he prescribed and that if a person brought a child to him suffering from diarrhœa and asked what was good for it, he gave a medicine; if, however, the case was serious he sent it to the doctor. Surely,' said the learned Baron, 'that is acting and practising as an apothecary within the meaning of the Act.' There is also a third case, known as 'Wiggins's case,' tried before Mr. Justice Field, on the 23rd and 24th May, 1878, in the Bail Court at Westminster (but not reported, so far as I know, in any of the recognized legal reports), in which his Lordship approves and adopts the definition of Mr. Justice Cresswell in Lotinga's case with the qualification mentioned by Baron Pollock. Upon these authorities, and there are several others of earlier date, I am bound to find and must hold upon the evidence, which is clear and decisive, that the defendant, in what he did, acted as an apothecary in contravention of the Act of Parliament and has incurred the penalty prescribed by it, for it is distinctly proved by the plaintiffs' evidence, and that of the defendant cannot be relied on to alter it in any material degree, that the defendant in performing the acts mentioned in the evidence to enable him to form an opinion on the case proceeded, in the language of Mr. Justice Cresswell, to judge (or pretend to judge) of the internal disease from which the young woman was suffering by the symptoms ascertained by his acts, and applied himself to cure it by medicine. If this is not acting as an apothecary, it is really, I believe, impossible to define what acting as an apothecary is. Upon the second part of the defence the defendant called a witness, named Thomas Parsons, who said 'he was eighty-four years old, and had been apprenticed to a chemist and druggist in 1809.' He said he was apprenticed to Messrs. Blews and Company of Worcester, where one of the partners was an apothecary; and that he (the witness), in the shop, over the counter, and as I understand him, others in the same shop supposed to be competent, though not apothecaries, were in the habit of giving advice as well as medicine in trifling cases, but that if the case were a serious one it would be attended to by the principal, meaning, I suppose, the partner who was an apothecary. This evidence undoubtedly shows that chemists in carrying on their business before the year 1815 did something (lawful or otherwise) beyond selling medicines merely, as stated by Mr. Justice Cresswell, and if the present instead of being a case of a serious character, as I find it from Dr. Suffield's evidence to have been, had been of the trivial nature of those referred to in the evidence of Mr. Parsons, the second part of the defence would have arisen and would deserve serious consideration; but the evidence of Mr. Parsons convinces me that though chemists before 1815 might have advised in trivial cases, they were not in the habit of advising and prescribing as the defendant has done in a case of the serious nature of the present, but would have sent such a case to the apothecary. If, however, it be correct, as Mr. Parsons in his evidence states, that before 1815 some chemists were in the habit, in trifling cases, of advising as well as supplying persons with medicines, it does not at least follow that they ever had the legal right to so advise and supply the medicine or are protected by the 28th section of the Act in case they do. If I were at liberty to speculate, I think it is very probable that some chemists, before 1815, did act as Mr. Parsons says they did, and as is well known some do now, but if they did, I believe they had no legal right to do so and were usurping the rights of those who had, just as the surgeon, as shown by Lotinga's case, usurped and contended for the right to advise and supply medicine as an apothecary, or indeed as the apothecary did when, as is known, he sometimes exercised, though illegally, the right of the physician to attend and prescribe for patients, before he possessed the legal right to do so, which at the present time he undoubtedly possesses. If the language of the 28th section is carefully considered I am afraid it will be found not to have the effect contended for by Mr. Herbert on the part of the defendant. He says that the business of chemists before 1815 extended to, or was carried on by them, 'in advising or prescribing in the shop, over the counter as it were, in cases of a trifling nature and supplying the persons with medicines for the cure of them, and secondly are protected in what they do now, provided they do no more than they did then; but the section with regard to the business of a chemist does not say a word about advising or prescribing.' On the contrary it would seem, from the language used, rather to ignore the fact that to do so formed, at the time of the passing of the Act, any part of the chemist's business. The words of the section are 'that nothing in the Act contained shall extend' or be construed to extend, to prejudice, or in any way to affect the trade or business of a chemist or druggist in—be it observed, not the advising or prescribing as stated by Mr. Herbert was the chemist's business in small matters, but only in 'the buying, preparing, compounding, dispensing, and vending drugs, medicines and medicinable compounds wholesale and retail.' The section then proceeds to provide that all persons using or exercising the said trade or business, or who shall or who may thereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business, in such manner and as fully and amply to all intents and purposes as the same trade or business was used, exercised or carried on by chemists and druggists before the passing of the Act. What business, therefore, the section provides is not to be affected by the Act, and what might be carried on notwithstanding the Act, would appear to be not that trade of a chemist as carried on by him according to Mr. Parsons's evidence in the 'advising and selling medicines,' but only as he carried it on in the buying, preparing, compounding, dispensing and vending his drugs. So it is this trade or business of a chemist so described, not the enlarged or extended one as contended for by Mr. Herbert, that the Act permits him to carry on (and protects him in doing) as fully as he might have done before the passing of the Act. The Legislature would appear not to have known (if indeed it existed) of this extended business of a chemist as now contended for, or if it did, it appears to have ignored it as no part of the legitimate business of the chemist, and declined to protect him in the exercise of it after the passing of the Act. The words 'advising and prescribing' are, as already remarked, not mentioned in the proviso, and there is no word so used in it that could by any ingenuity be construed as including these words unless it be the word 'dispensing,' and that word in my opinion does not, for the true meaning of the word dispensing (in pharmacy), according to Bailey's Dictionary, is, when simples of a composition are set in order lest any of the ingredients should be forgotten; and according to Rees's Encyclopædia, title 'Dispense' (in pharmacy) means 'To dispose and arrange several medicines, either simple or compound, by weight in their proper doses or quantities in order to be employed in the making of the composition.' I have made these few observations for the consideration of the defendant and those associated with him; they form no part of my judgment, which is in no way founded upon them, for, as I have already said, I find the present case was of a serious if not a dangerous nature, and in that view of it I do not understand that even the defendant's counsel would contend his client had the right to treat it as he has done. The defendant, I find from the evidence, has clearly and unmistakeably 'acted as an apothecary,' and the proviso relied upon, in my opinion, affords him no defence in such a case as this, even though I were to admit it is possible that he might in those trifling cases contended for by Mr. Herbert, which for the reasons given, however, I very much doubt. The verdict, therefore, will be for the plaintiffs."

Verdict for the plaintiffs, £20, and costs.

In reply to a question from the President, the solicitor said there were three courses open, provided the Association desired to carry the case further, namely, application for a new trial, appeal by case or appeal by motion. An application for a new trial would have to be supported by one of three grounds, either that the Judge refused evidence that was proposed, that he admitted evidence wrongfully, or that the verdict was against the weight of evidence. Taking the last first, as the Judge acted in the capacity of Judge and jury, he would no doubt say the verdict was not against the weight of evidence, and would refuse a new trial if it were applied for. As regarded the admission of evidence wrongfully, if any such course was taken, according to the Judge's view it was in admitting the testimony of the defendant's aged witness, as to the mode of conducting a chemist's business prior to 1815, and in no other respect had evidence been improperly admitted. Then lastly, as to the refusal of evidence, no evidence which was tendered at the trial was refused. An appeal might be had by case or motion; of these the former was to be preferred as the facts were in such a case stated by the Judge and the matter was brought under review much more easily than was the case where upon motion the Judge's notes taken at the trial were produced in court. After consultation with counsel and taking into consideration that the Judge had found as a fact that the defendant had treated a dangerous case, and that this must be admitted in any subsequent appeal, and since the judgment of one County Court would not govern a case in any other court, he (the solicitor) could not advise the Association to proceed further in that action.

The Executive then went into committee to consider the question of an appeal and after a long and careful discussion on all the points of the case, it was moved by Mr. Churchill, seconded by Mr. Jones, and unanimously resolved:—"That the finding of the County Court Judge in the case of the Apothecaries' Company *v.* Harrison, being as follows: 'I find the present case was of a serious if not a dangerous nature,' this Committee is of opinion that no further steps should be taken by the Association in this action."

Some considerable discussion took place on the advisability of steps being taken by the Association to amend the Pharmacy Act, 1868, when it was moved by Mr. Arblaster, seconded by Mr. Symes, and unanimously resolved:—"That the Law and Parliamentary Committee be directed to take any steps which they may deem desirable to obtain information to enable them to bring about modifications in the Pharmacy Act, 1868, to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists, and to report to the next meeting of the Executive."

The President said the next question on the agenda paper was the consideration of the advisability of steps being taken by the Association to endeavour to obtain the exemption of all registered chemists and druggists from jury service. He continued to say that he was frequently receiving letters from chemists and druggists, relative to the extreme hardship which they suffered from being compelled to attend on juries, and he would move:—"That the Law and Parliamentary Committee be and are hereby empowered to take such steps as they deem advisable to obtain the exemption of all registered chemists and druggists from jury service."

The resolution was seconded by Mr. Andrews, supported by Mr. Arblaster, and carried unanimously.

Several letters were read from members of the Association complaining of cases of infringements of the Pharmacy

Act, when it was moved by Mr. Andrews, seconded by Mr. Symes, and unanimously resolved:—"That the secretary be instructed to collect evidence of infringements of the Pharmacy Act, 1868, and forward particulars of same to the Secretary and Registrar of the Pharmaceutical Society."

The case of a member of the Association against whom an action had been brought by the Excise authorities for the sale of methylated spirit without a licence was considered. It was moved by Mr. Davison, seconded by Mr. Hampson, and unanimously resolved:—"That the secretary be instructed to investigate the case of a member against whom legal proceedings have been taken by the Excise authorities for the sale of methylated spirit without a licence, and that the solicitor be instructed to defend the action if the case on investigation be found satisfactory."

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held on June 26, Mr. C. H. Hutchinson, F.C.S., in the chair.

After the reading of the minutes, Mr. R. H. Parker read a paper on "Myrrh." This paper will be printed in a future number of the Journal.

After a short discussion,

Mr. J. G. Sangster read his report on "Pharmacy," in which he gave an account of the following preparations:—Vaseline, oleate of mercury, oleate of zinc and guaiacate or lithia.

Oleate of Mercury is made by triturating together for some hours oleic acid and freshly precipitated mercuric oxide till combination is effected. In this process heat must be avoided. The ordinary strengths used are 5 per cent., 10 per cent. and 20 per cent. The first and second are thick liquids, the third having the consistence of a soft ointment.

Oleate of Zinc is usually prepared by mixing together hot solutions of soft soap and sulphate of zinc. The precipitated oleate is washed and dried by hydraulic pressure. It is of the consistence of suet, and possesses a pearly-white colour. To mix it with other fats it must be first melted.

Guaiacate of Lithia, introduced by Dr. Garrod, is in the form of dark brown scales. It is prepared by digesting pure guaiacum resin with a saturated solution of lithium hydrate, decanting the clear solution, evaporating and scaling. It is usually ordered in the form of pills, for which spirit is the best excipient.

Mr. Sangster then noticed the following mixture which he had dispensed:—

℞ Ferri Am. Cit.	. . . .	℥ss.
Quin. Sulph.	. . . .	gr. 12.
Acid. Citric.	. . . .	ℨj.
Sp. Chlorof.	. . . .	ℨj.
Aquæ	. . . .	ad ℥vj.

The quinine was dissolved with the citric acid in a small quantity of water and the scale compound in another portion of water. On mixing the two solutions a reddish-brown precipitate occurred, which in a few days dissolved in the supernatant liquid, giving a clear green solution. It seemed to him probable therefore that a compound resembling the citrate of iron and quinine of the Pharmacopœia was formed.

After a short discussion the meeting adjourned.

SOCIETY OF ARTS.

The History of Alizarin and Allied Colouring Matters, and their Production from Coal Tar.*

BY W. H. PERKIN, F.R.S.

(*Continued from page 38*).

I will now refer to the process of making artificial alizarin by means of dichloranthracene in place of anthraquinone.

Sulphuric acid forms two sulpho acids with dichloranthracene, a mono and a di.

To obtain the former, pure dichloranthracene is intimately mixed with concentrated sulphuric acid, warmed up to about 50° C., the mixture being well stirred; this process is continued for about twenty-four hours. It is then diluted, boiled, and filtered from any undissolved dichloranthracene. This filtrate gelatinizes on cooling, and consists chiefly of monosulphodichloranthracenic acid; it is formed thus:—

$$C_{14}H_8Cl_2 + SO_4H_2 = \underbrace{C_{14}H_7\,(SO_3H)\,Cl_2}_{\text{Monosulphodichloranthracenic acid.}} + OH_2.$$

On boiling this with an oxidizing agent, it yields monosulphanthraquinonic acid.

$$C_{14}H_7\,(SO_3H)\,Cl_2 + O_2 = C_{14}H_7\,(SO_3H)\,O_2 + Cl_2.$$

And this, when fused with caustic alkali, behaves in the same manner as the acid prepared from anthraquinone, yielding finally, pure alizarin.

If the dichloranthracene be heated more strongly with sulphuric acid, it is converted into the disulphodichloranthracenic acid* thus:—

$$C_{14}H_8Cl_2 + 2\,SO_4H_2 =$$
$$\underbrace{C_{14}H_6 \left\{ \begin{matrix} SO_3H \\ SO_3H \end{matrix} \right\} Cl_2}_{\text{Disulphodichloranthracenic acid.}} + 2\,OH_2$$

An acid remarkable for the fluorescence of its solutions and salts. If the heating with sulphuric acid be increased after the acid is formed, a very remarkable change takes place, sulphurous anhydride and hydrochloric acid being evolved in abundance, disulphanthraquinonic acid being at the same time formed:—

$$C_{14}H_6 \left\{ \begin{matrix} SO_3H \\ SO_3H \end{matrix} \right\} Cl_2 + SO_4H_2 =$$
$$C_{14}H_6 \left\{ \begin{matrix} SO_3H \\ SO_3H \end{matrix} \right\} O_2 + SO_2 + 2\,HCl$$

This, of course, when fused with alkali, eventually forms anthrapurpurin; and, as some of the disulphanthraquinonate is also formed, a little flavopurpurin is likewise produced.

There is also another reaction which takes place. As dichloranthracene combines with sulphuric acid, water is liberated, so that this acid becomes somewhat diluted. This does not readily form a sulpho acid with the dichloranthracene which has not dissolved, but when heated with it, converts it into anthraquinone.

$$\underbrace{C_{14}H_8Cl_2}_{\text{Dichloranthracene.}} + SO_4H_2 = \underbrace{C_{14}H_8O_2}_{\text{Anthraquinone.}} + 2\,HCl + SO_2$$

As the temperature rises, the acid becomes concentrated, and then combines with it, forming chiefly monosulphanthraquinonic acid.

The process of making monosulphanthraquinonic acid from the monosulphodichloranthracenic acid has not been carried out successfully on the large scale, partly owing to the processes of filtration being very difficult to perform. But the preparation of artificial alizarin from the sulpho acids prepared by heating dichloranthracene strongly with sulphuric acid, is a process of very great importance.

As pure alizarin can now be obtained in any quantity, attention has been turned to the preparation of its derivatives. In 1874, I studied the action of bromine upon it, and obtained monobrom alizarin, having the formula $C_{14}H_7BrO_4$.† This compound dyes mordants somewhat similiarly to alizarin, the colours being a little redder in shade, but not sufficiently different to make it of technical interest. In 1875, I also obtained a nitroderivative of alizarin by acting on diaceto alizarin with fuming nitric

* From the *Journal of the Society of Arts*.

* *Journal of the Chemical Society*, 1871, p. 15.

† *Journal of the Chemical Society*, 1874 p. 401.

acid.* This substance crystallizes in beautiful orange needles, and has the formula, $C_{14}H_7(NO_2)O_4$. It produces with mordants colours very different from alizarin, giving with alumina brilliant orange, and with iron mordants reddish purple colours. It would be a valuable deying agent if it could be produced by a more easy process.

When treated with reducing agents, such as sodium amalgam, or metallic tin and potash, its blue alkaline solution changes to a clear bright red colour, containing another new derivative, namely amidoalizarin, $C_{14}H_7(NH_2)O_4$. This also dyes mordants, the alumina ones of a purple and the iron ones of a bluish or steel-like colour.

A second, or β nitroalizarin, isomeric with that I produced, has been obtained by Rosenstiehl,† and, apparently about the same time, by Caro,‡ by submitting dry alizarin to the action of nitrous acid vapours. It is now manufactured in some quantities, and is known as alizarin orange. Like the nitroalizarin previously described, it gives orange colours with alumina mordants. They are, however, much yellower, and not so fine. This nitroalizarin dissolves in dilute alkalies with a purplish crimson colour; but strong alkaline solutions precipitate it, especially caustic soda, and this property affords a means of purifying it. When boiled with metallic tin and caustic potash, it is reduced, becoming blue and then yellowish green; but, on exposure to the air, this solution changes back to bluish green. Schunck and Roemer§ have just published an account of this reduction product; it is an amidoalizarin isomeric with that just described. It crystallizes in deep yellow prismatic needles, and dissolves in potash with a blue colour. It dyes alumina mordants a dull red, and iron mordants a dull grey colour.

A very peculiar result has been obtained by M. Prud' homme‖ by heating a mixture of glycerine, β nitroalizarin, and concentrated sulphuric acid. By this means a colouring matter is obtained which dyes alumina, and especially iron mordants, an indigo blue shade. It crystallizes in needles of an almost black colour, but having a coppery reflection. The formula is $C_{17}H_9NO_4$. It is manufactured commercially, but as its colours are fugitive it has not met with much favour.

F. de Lalande¶ has made the interesting discovery that purpurin, identical with that found in madder, can be obtained by the oxidation of alizarin. He takes a solution of one part of alizarin in eight or ten parts of sulphuric acid, and adds to it one part of arsenic acid or peroxide of manganese, and heats this mixture to a temperature of 150° to 160° C., until a drop of the fluid mixed with an alkali gives a red coloration. The product is then thrown into water, and the purpurin which precipitates is collected on a filter and well washed.

In this paper I have purposely confined my remarks to the colouring matters and other substances obtained in the manufacture of artificial alizarin, and also to some of the more important derivatives of alizarin; a considerable number of products have, however, been obtained, which are related to anthracene, although this hydrocarbon has not been used in their preparation, such, for example, as anthraflavone from oxybenzoic acid, etc. And, although I do not propose to give an account of these bodies, I wish briefly to refer to some very interesting results which have been obtained by Baeyer and Caro.

These chemists have observed that, when phenol is heated with phthalic acid or anhydride and an excess of sulphuric acid, that two monoxanthraquinones are produced, one identical with that already described, the other being an isomeride of that body. Both of these, however, when fused with caustic alkali, yield alizarin.

* *Journal of the Chemical Society*, 1876, vol. ii., p. 578, and *Deut. Chem. Ges. Ber.*, 1875, p. 780.
† *Deut. Chem. Ges. Ber.*, 1876, 1063.
‡ Patent No. 1, 229, March 22, 1876.
§ *Deut. Chem. Ges. Ber.*, 1879, 558.
‖ *Bull. Soc. Chem.* (2), xxviii, 62—64.
¶ 'Jahresbericht,' 1874, p. 486.

By substituting pyrocatechin for phenol in the above process, they succeeded in obtaining alizarin at once. These results, although at present of no practical value, are of considerable scientific interest, and also show us that anthracene is not the only artificial source of alizarin.

From what I have already said it will be seen to what an advanced state the chemistry of my subject has arrived (and yet there is much to be done), and only those who have been interested in the progress of the manufacture can rightly appreciate the great value of all this research in forwarding the successful and enconomical production of these colouring matters.

As I have already shown, both of the important colouring matters of madder have now been obtained from anthracene, and not only so, but new products allied to these have also been produced, the most important one being that valuable colouring matter anthrapurpurin; we have also flavopurpurin and the derivatives of alizarin. So that, with these colouring matters, dyers and calico printers are not only able to produce all the various madder styles, but to introduce colours of greater beauty and variety than when employing the natural dye-stuff madder.

(To be continued.)

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[315]. In my reply to this question in last week's Journal, I am made, by a printer's error, to say, "sal ammoniæ" in three instances. It ought in each case to be "sal ammoniac." W. WILKINSON.

[322]. Will Mr. Brown kindly detail the method of making a stable preparation of this formula? I can, like him, get a pink creamy ointment; but I fail to induce the components to remain in the combination any sufficient time for the daily use of the patient, and obviously that is the intention of the prescriber.—ANON.

[324]. Permit me to correct what I gather from the remarks of Mr. Henry Brown is a misunderstanding relative to this prescription. Mr. Brown, to whom I am greatly indebted for his clear and lucid arguments, says:—"I observe 'Gulielmus' adds after morphia, 'the alkaloid,' so as to italicize as it were." The words however were not my addition, but formed part of the prescription, and this being so forced me to the conclusion that the prescriber meant what he had written. I cannot think that the pharmacist under those circumstances would be justified in adding anything to convert the morphia into a salt, but having explained my position in relation to this point shall be glad with further expressions of opinion thereon.
GULIELMUS.

[324]. In Mr. H. Brown's very practical answer to No. 324, he does not explain how the preparation which was first obtained by the patient was (according to the statement by "Gulielmus") about twice as much in bulk.

The addition of a small quantity of acid. sulph. dil. could not cause such a difference.
G. H. WRIGHT.

[326]. The mixture containing tr. gelsemin., fer. et quinæ cit., butyl chloral hyd., potass. bromid., potass. iodid.

and aq. chloroform., may be made perfectly transparent, and therefore "presentable," by adding a little magnesia, and filtering through fine filtering paper. The question is, How far is a dispenser justified in thus turning out a slightly opaque mixture as bright and as clear as dark sherry wine? In this case, and in many other instances (328, *infra*), a perfectly bright mixture may be obtained by the simple act of filtration through magnesia, bismuth or orris root, as the case may be. I hold, however, whilst a strong advocate for elegant dispensing, that a mixture like the above, which is only slightly opaque, should not be sent out clear. By filtration, as suggested, I have convinced myself that no change in constitution occurs; but, there is a manifest injustice done to other compounders and other houses, by having resort to the process indicated.

I am aware some houses make it a study to send all mixtures out transparent, if such is possible without undue interference. If therefore, a prescription similar to that given by "Sub Umbra Floresco" or C. B., 328, is filtered, and sent out bright by the first house at which it is compounded, and then the patient has it dispensed at another pharmacist's, will he not naturally wonder why in the one case it was transparent, but in the other opaque? And will he not think that in the first instance it was properly compounded, and look upon the first pharmacist as superior in his art to the second, because from the same ingredients he is able to turn out a bright and pleasing mixture, whilst the second is only able to form a muddy looking compound? I see a great injustice to members of the pharmaceutical body by such procedures. If the patient is whimsical, or if the medical man's wish is understood in such instances, I think in all fairness a note might and ought to be written, such as, "Filter through magnesia," by the medical man or pharmacist who first dispenses the mixture. If such is not done, there is manifest unfairness in thus treating any such prescription.

By what means is a pharmacist, even in the same town, to know exactly how a mixture was at first compounded and its subsequent treatment, if a note be not appended indicative of the mode in which it was dispensed, *i. e.*, provided such a mixture was sent out perfectly transparent?

Northallerton. HY. BROWN.

---

[327]. I am afraid J. H. cannot, without materially altering the prescription, send out a mixture of sodæ salicyl., croton. butyl. and quinæ sulph., so as to have the quinine in perfect solution. If the quinine is dissolved by the aid of an acid it is at once precipitated on the addition of the salicylate and, in the form of a resinoid mass, adheres to the sides of the bottle. The best mode is just to powder the quinine very fine and add "shake the bottle." The mixture is not unsightly and the quinine will remain long enough in suspension to enable a correct dose to be measured.

HY. BROWN.

---

[328]. Is sufficiently answered in my note, *vide supra*, 326. When filtered the mixture is a beautiful light sherry colour and has its original taste unaltered. The small quantity of the resin of the hop only removed.

HY. BROWN.

---

[330]. No. 1 is another example somewhat akin to No. 327. In this case the only way I see out of a difficulty is to omit the acid. sulph. dil., dissolve the sodæ salicyl. and rub up the quinine. The same remarks apply, in the main, as in No. 327, *supra*.

No. 2. "J. S. Nemo" should use solid perchloride of iron and add the acid. hydrochlor. after solution. The HCl is added to obviate oxidation.

HY. BROWN.

THE SUPPLY OF GAS.

Sir,—No doubt I only express the sentiments of hundreds of your readers when I express my thanks that you have taken up the gas question.

I have had my attention drawn to a discussion now going on in *The English Mechanic*, and to the evident partiality "and unfairness of that journal to any but one side of the discussion," and have come to the conclusion that the *Mechanic*, like a good many other journals connected with trade interests, is probably influenced in favour of the gas companies and the great body of gas engineers up and down the country. This last year, as witnessed by newspapers in every part of the country, has given rise to complaints from every class, but instead of trying to help and trace the cause—and most assuredly there is one—the effort seems to be to try and intimidate and "burke" any inquiry.

I trust you will exercise patience and give scope in your columns for free ventilation of the subject, and if the approaching Conference would add "Gas Deterioration" to the list of subjects requiring elucidation, it would be a very legitimate inquiry. Gas engineers and gas officials certainly have not the ability, even if they had the willingness to clear up the present difficulty.

The reference to the production of "marsh gas" by gas companies in place of olifiant gas, as explained in the letter of your last number, to my mind goes a long way to explain matters and I should like to ask my brother chemists if they can bring any evidence to prove that consumers near the works are more often complaining than those at a greater distance away? My theory is that ordinary coal gas is a "wonderful" compound of various gases, and that the lighter and least luminous find their way to the nearest outlets, and those streets nearest the works are the worst lighted.

Any evidence *pro* or *con.* would tend to clear up a difficult problem. MORE LIGHT.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Bermingham, Davidson, Roberts, Sawyer, C. H. F. Student.

"THE MONTH."

After the continuous rain of May and June, it might have been expected that St. Swithin would waive his claim to his accustomed sway of forty days, but since such has not been the case, it is only natural that the long continued rainy weather should give rise to grumbling in agricultural districts; still there is perhaps some reason to be thankful that the weather has been wet rather than fine. Owing most likely to the heat of last summer and to other conditions, as yet not well understood, the number of insects would probably have amounted to a plague this year, had not the wet weather to a certain extent limited their numbers. In *Nature** accounts are given of a swarm of butterflies (apparently *Vanessa Cardui*), being observed on the continent, which obscured the light of day and took two hours to pass, proceeding in a north-westerly direction. This or a similar swarm appears to have passed through Turin on June 2nd, through Switzerland from the 2nd to the 9th, Alsace, France and Spain from the 5th to the 10th, and through Wurtemberg from the 11th to the 21st. The majority of specimens examined by Professor Eimer, of Tubingen, proved to be females, apparently seeking a place to deposit their eggs, of which they were full. This insect is very common this year in the south of England.

Another instance of the abundance of insects this year occurred at Elizabethpol, in Armenia, where the vegetation has been devasted by grasshoppers and locusts. At this place the locusts were so numerous and settled so thickly on the Russian soldiers' faces, uniforms and muskets, that the major ordered firing at them for half an hour, to drive them off, but as this produced no effect a march back was ordered.

Some results of an interesting series of experiments as to the proportion of carbonic anhydride present in the atmosphere and the extent to which it is affected by various causes are reported by M. Reiset in the current number of the *Répertoire de Pharmacie* (vol. viii., p. 308). At a station in the open country a few miles outside Dieppe, having the sea on its west and north-east horizon, and at an elevation of 320 feet, which was taken as a standard for comparison, the mean of ninety-two observations gave equal to 2·942 parts, by volume, of CO_2 to 10,000 of air. The observations at this station were very concordant, the difference between the maximum and minimum proportion of carbonic anhydride observed not exceeding 3 parts in 100,000. Air taken in a leafy wood gave an average of 2·917 parts of CO_2 per 10,000, the average in the air taken at the standard station at the same time being 2·902; air taken in a fine crop of red clover gave 2·898 parts CO_2 per 10,000 against 2 915 at the standard station; air taken in a field of barley and lucerne grass in July gave 2·829 parts of CO_2 per 10,000 against 2·933 at the standard station. These results demonstrate how instantaneously the diffusion of gases takes place. On the other hand the presence of a flock of three hundred sheep at pasture, on a calm day, in the neighbourhood of the apparatus, raised the proportion of carbonic anhydride to 3·178 parts in 10,000 of air. In Paris, in the month of May, observations extending over three years gave an average of 3·027 parts by volume in 10,000 of air.

Comparatively few fresh plants are out in flower this month in the Botanical Gardens. At Regent's Park, in the Economic House, the pimento is in blossom, and in the Herbaceous Ground at Kew, *Actæa spicata*, *Delphinium Staphisagria*, *Nigella sativa*, *Pyrethrum roseum* and *P. Parthenium*, valerian, coriander, rue, black and white mustard, lavender, alkanet, borage and motherwort are in flower.

Of rarer British plants now in blossom at Kew may be mentioned *Liparis Loeselii*, *Stachys germanica*, *Verbascum Lychnitis* and *V. pulverulentum*, *Echium violaceum* and a variety of *Linnæa borealis*.

In the country the elder may now be seen covered with blossom, and the red poppy and the white mustard already deck the railway embankments and chalky cornfields with their lively hues, while the pretty pink-flowered cent ury, always retiring when a cloud overcasts the sun, scarcely opens its blossoms for more than an hour or two now and then.

The digitalis, one of our handsomest wild flowers, is now in perfection. In London it seems coming into fashion again as a garden ornament, cartloads of plants in full blossom being hawked about the streets. A correspondent in the *Gardeners' Chronicle* calls attention to the absence of this plant from the Cotswold Hills and attributes it to the fact that it loves a sandy soil, but does not flourish on the silurian limestones and shales. The Cotswold Hills are almost entirely composed of the cream coloured limestones of the inferior oolite, and to this he attributes its absence. The writer has, however, seen magnificent specimens of the foxglove on the chalk hills of Kent, and it is probably rather the porous character of the soil that it prefers, than its chemical composition, although digitalis can scarcely be called a plant of the chalk.

The flowers of this plant are said to be exclusively fertilized by humble bees, which alone are large enough to fill the corolla, and thus deposit pollen on the stigma. The flowers are proterandrous and appears to be capable of self-fertilization if not visited in time by insects. The anthers at first occupy a transverse position but as they ripen become longitudinal.*

Another plant belonging to the Scrophulariaceæ deserves notice from having been used in former times for the disease known as "burnt holes" in children. A formula for the ointment of *Scrophularia* may still be found in Cooley's 'Cyclopædia' This is the *Scrophularia nodosa*, a common plant in damp ditches by roadsides, etc. From the other British species it is easily distinguished by its acutely pointed, smooth leaves and tuberous knobby root; *S. aquatica*, which grows in similar situations, having obtuse leaves. The flower is interesting on account of the presence of the rudiment of a fifth stamen (staminode) at the base of the upper lip of the flower. This staminode differs slightly in shape in the different species, and in some cases it bears pollen In the genus *Pentstemon*, which is not uncommon. in gardens, the fifth stamen is furnished with a long filament, but the anther is abortive, and the filament is bent in a curious manner from the upper towards the lower lip of the flower, from which it appears to spring, so as to be out of the way of the pistil. *Scrophularia nodosa* is proterogynous; both this species and *S. aquatica* are fertilized by wasps, and as the

* June 26, p. 197.

* Lubbock, 'British Wild Flowers in Relation to Insects,' p. 138.

pistil is bent downwards from the mouth of the corolla it strikes the pollen-dusted breast of the wasps when they visit the flower. It is rather singular that irregular flowers are hardly ever wind-fertilized.*

The leaves of *S. nodosa* are said to possess emetic and purgative properties and are sometimes used externally as an application to burns and swellings, being simply bruised before being applied. In olden times this plant was considered an excellent remedy for the scrofula or king's evil, whence its name. A decoction of the root is sometimes used by farmers for the scab in swine. The juice of the leaves of the water betony, *Scrophularia aquatica*, formerly had a reputation as a cosmetic for the face, "to take away the redness and deformity of it." This plant must not be confounded with the wood betony (*Betonica officinalis*), which is quite a different plant, belonging to the Labiatæ.

Another little plant, common in heathy places and woods, *Veronica officinalis*, is now in blossom. As its name indicates it was formerly used in medicine. It was at one time official in the Edinburgh Pharmacopœia, under the name of *Veronica mas* or *Betonica pauli*. At the present day it is sometimes used by homœopaths. It possesses bitter and astringent properties, although probably in a less degree than the Koromiko (*Veronica salicifolia*), which a short time ago was so highly spoken of as a New Zealand remedy for diarrhœa. When the Linnean system of botany was in vogue the plant was comparatively easy to determine, but at the present day the tyro in botany finds it somewhat difficult to assign a place to the plants of this genus, since the ovary when young is difficult to examine, and the plants differ from the majority of the order to which they belong in having only two stamens in the flower, as well as in the corolla being not very obviously irregular, at least to an unpractised observer. The present species is easily distinguished by its small flowers and *obovate stalked* leaves from *V. Chamædrys*, the most beautiful and consequently the most commonly recognized species, which has sessile leaves, and from *V. montana* which has *ovate* stalked leaves.

The arrangements for fertilization differ considerably in the different species of this genus. In *V. Chamædrys* the anthers and stigmas ripen at the same time, but the stamens turn outwards, while the stigma projects straight forward, so that self-fertilization is impossible. In *V. Beccabunga* (whose curious name is supposed to be derived from the German *bachbunge*) the flowers are proterogynous, and in *V. hederæfolia* the flowers are minute and fertilize themselves.

The Scotch fir (*Pinus Sylvestris*) seems to have produced an unusual abundance of male flowers this year, and the paths and roads in plantations are now everywhere strown with the fallen catkins.

In a letter to the *Times* a few weeks ago, a correspondent wrote, "After a heavy rain a thin film of sulphur has been observed at Windsor, Slough, and in the neighbourhood generally, to settle upon the surface of rain water caught in butts and cisterns." According to a letter on the same subject in *Nature*, by Mr. P. H. Carpenter, "it was first observed on the afternoon of Sunday, June 8, after a remarkably heavy shower, and much disturbed the inhabitants of some of the villages around Eton, who fancied that it smelt 'awful like brimstone,' of which its yellow colour was somewhat suggestive. In some places it gave rise to such a feeling of fright that the people were afraid to go to bed, thinking that the judgment day was at hand." On investigation the sulphur proved, as might have been supposed, to be pine pollen (probably from *Pinus sylvestris*) blown from Windsor Forest. A local chemist and druggist is said to have supported the sulphur theory—a statement which it may be hoped is mistaken. The pollen of Coniferæ is so different in appearance from sulphur, under the microscope, and is so characteristic, that such a mistake could hardly have occurred to any one familiar with the use of a microscope.

† Darwin, 'Forms of Flowers,' p. 147.

The compound pollen of the Gymnosperms has long been known, but it is only lately that F. Elfiring, of Helsingfors, has proved in Strasburger's laboratory, at Jena, that the pollen cell of wind-fertilized or self-fertilized angiosperms is also compound, or in other words that each pollen grain becomes divided into two cells, the one of which plays the part of a vegetative cell merely, and the other takes upon itself the growth and functions of the pollen tube. Of these cells the vegetative one is the smaller and is only separated from the larger by a wall of "cortical plasm," which in particular instances can become transformed into a firmer membrane. The pollen grain may thus be likened to the microspore of a lycopod. This observer does not, however, appear yet to have examined the pollen of cleistogamous flowers, which, as suggested by Dr. E. P. Wright in *Nature*,* might reveal some interesting facts.

The little pine tortrix moth, *Ortholæna turionana*, may now be seen hovering around the fir trees and depositing its eggs on the buds. Later on in October, little turpentine drops may be seen on the buds, underneath which the grub may be found.

It is a singular fact that the flowers of the dahlia have a narcotic effect upon the bees which visit them, so much so that the cultivation of the dahlia has been pronounced to be incompatible with the success of bee-keeping. The honey of the oleander is also avoided by bees and is known to be fatal to flies. The dahlia is such a common flower in gardens that its insecticidal properties might easily be investigated with regard to other insects.

Most persons who live in the country are familiar with the singular botanical monstrosity known as the "hen and chicken" daisy, in which a number of small stalked capitula arise from the primary one. Such a growth in the water-lily family is, however, a great rarity. An instance of this kind is figured in the *Garden*, for July 12th, in which secondary stalked flowers are produced from the primary flower, and in another specimen leaves as well as flowers arise from the primary flower.†

The extent to which a medicinal preparation may be affected by the soil upon which the plant it is prepared from has grown is illustrated by an experience of M. Gérardin, a pharmacien in the Marne department. Having prepared some extract of belladonna from a defecated juice, he found it after some weeks full of granulations. These were removed by dissolving the extract in distilled water and decanting. After washing and drying at 100° C., they proved to consist of a mixture of silicate and chloride of potassium equal in weight to 6·8 per cent. of the original extract. It was then remembered that the

* June 19, p. 183.

† See *Journ. Bot.*, 1877, p. 59.

belladonna plants used had been collected from a spot which had long been frequented by charcoal burners for their operations and the remainder of the explanation was to be found in the pronounced taste of solanaceous plants for silica and potash.

Some time ago an attempt was made in Mozambique to cultivate the opium poppy. The yield of opium from the first crop only amounted to a few pounds, which upon examination proved to be only of moderate quality; it had the appearance of a soft extract of a clay-brown colour and contained 4 per cent. of morphia, 4·3 per cent. of narcotine and 40·9 per cent. of moisture. A specimen of this Mozambique opium was recently presented to the Society's Museum by Messrs. T. and H. Smith; another is included in the case sent by them to the Sydney International Exhibition, and it is noticeable that it has been described by two journals at least, when referring to this case, as the first opium grown in Africa, a statement that would hardly pass muster in the Board schools, notwithstanding the extent to which Egypt has become Europeanized. Messrs. Smith's case appears to rival in interest and value that sent to Paris by the same firm and described in this Journal last year. Perhaps the most striking objects would be some splendid crystallizations of caffein, aloin, muriate of thebaia, codeia and muriate of papaverine, the demand for the latter alkaloid on the continent being said to be in excess of the supply. There is also the cryptopia from 10,000 lbs. of opium, as well as specimens of the new bodies gnoscopine and meconoisine. Among the salts of morphia are the muriate in crystalline cubes, the sulphate in woolly needles resembling sulphate of quinine and the tartrate which has been recently recommended by Dr. Erskine Stuart as the best preparation of morphia for hypodermic injection. There are also specimens, several ounces in weight, of muriate of apomorphia in large steel grey crystals and of cantharidin in fine four-sided prisms.

M. Carles recently called the attention of the Bordeaux Pharmaceutical Society to the presence in commerce of quinine containing an exaggerated quantity of water. A sample examined lost 17 per cent. of water when dried at 100° C., or 5 per cent. in excess of the normal quantity. The same sample was found to contain a quantity of quinidine. M. Dambier said that he had recognized the same fact several times in sulphate of quinine obtained from good houses.

Japanese wax has been the subject of an investigation by Dr. E. Buri, of the University of Strasburg. From the results obtained (*Archiv d. Pharm.*, xiv. 403) he has come to the conclusion that this substance, like other fats, is a mixture of several glycerides, the mixture of fatty acids yielded upon saponification consisting principally of palmitic acid. The palmitic acid is accompanied by one or more acids having a higher melting point, the presence of one having been ascertained which has a melting point considerably higher than that of stearic acid. There is also a small quantity of oleic acid.

According to the *Pharmaceutische Zeitung* a German house is bringing into the market a number of so-called "extra strong essential oils," obtained by the fractional distillation of the finest and most aromatic parts of the respective oils from the less characteristic and more or less indifferent portions. They have, as a rule, a higher boiling-point, and a higher specific gravity than the unseparated oils, and some of them are more soluble in spirit, but this is not always the case. It is claimed, however, that all these oils are essentially improved in aroma.

According to MM. E. Duvillier, and A. Buisine, in the *Comptes Rendus*, the trimethylamine of French commerce, which is chiefly obtained, as indicated by M. Vincent, by the calcination in a close vessel of the residue after the distillation of spirit from beetroot mash, is far from being a pure product, it containing only about 5—10 per cent. of trimethylamine, while dimethylamine is present to the extent of 50 per cent., besides which there are present in the remainder monomethylamine, monopropylamine and monoisobutylamine in about equal proportions.

A new antiseptic agent is reported to have been recently discovered accidentally, during experiments on separating the crystalline sugar from molasses. It is, according to the *Scientific American*, now sold at twenty-five cents the pound, and is made in large quantities by dissolving in water equal parts of chloride of potassium, nitrate of sodium and boracic acid, filtering and evaporating to dryness. It is easily soluble in water and is deliquescent. It passes under the unscientific name of double borate of potassium and sodium, and its action as an antiseptic is said to be prompt and to continue undiminished for a long time.

Messrs. Paterno and Oglialoro, in the *Gazetta Chimica Italiana*, state that the limonine of Schmidt, extracted from the seeds of oranges and lemons, is not identical, as that writer supposed, with the calumbin of Wittstock, derived from calumba root. Limonin is obtained in magnificent colourless shining laminæ, fusible at 275°, while calumbin crystallizes in colourless prisms, fusible at 182°. Its formula is $C_{21}H_{22}O_7$, while that of limonin is $C_{26}H_{30}O_8$.

In the *Practitioner*, Dr. T. N. Dolan reports that he has found chloride of barium successful in certain forms of aneurism, and recommends a trial of it in some cases in which the administration of iodide of potassium is inadmissible. The dose given appears to have been one-fifth to two-fifths of a grain.

Dr. Rutherford in a communication to the *British Medical Journal*, referring to the variation in the dose of euonymin required to produce the desired effect, remarks that "allowing for individual peculiarities, I cannot but suspect that the substance found in the market is not always of the same strength." It is highly desirable either that a definite process for the manufacture of this substance or that tests for discriminating its quality should be sought for and published by those who have introduced these remedies into medicinal use in this country, so that dispensers may know what particular preparation to use.

An interesting account of the dugong, the oil of which is used as a substitute for cod liver oil, is given in *New Remedies* for July. One merchant engaged in the fishery is said to capture as many as six in a day. Unless some protection be afforded it, this interesting cetacean will probably become an extinct animal in the course of years, especially since its flesh makes an excellent substitute for bacon, dugong rashers being easily mistaken for those of pork.

The possibility of poisoning by the absorption of aniline through the skin deserves to be known. A chemist in Poland was experimenting with aniline, when the bottle burst and part of the contents saturated some of his clothing. A few hours afterwards weakness in the muscles set in, his speech became affected, he forgot a number of words and became comatose. By the use of stimulants he recovered, but the muscular weakness remained during the following day. The fact of the symptoms not appearing until a few hours afterwards, although a quantity of the aniline had evaporated in the room, seem to show that the aniline acted as a poison by entering the circulation through the skin.

M. Battandier, in the *Journal de Pharmacie*, points out the danger of using glass wool in analysis. He has found certain samples to contain a quantity of lead, which is easily dissolved out by alkaline or acid liquids.

In *Comptes Rendus* for July 7, it is stated Dr. Tellef Dahll has found a new metal in the arseniuret of nickel and nickel-glance at Oterö, a little island situated some kilometres from the town of Krage. It is obtained by roasting the ore to drive off sulphur and arsenic, dissolving the product in acids and precipitating by sulphuretted hydrogen; the precipitate washed free from nickel and again roasted is the crude oxide of the metal. To the new metal the author has given the name of Norvegium with the symbol Ng. The metal is white, malleable to a certain extent; sp. gr. 9·66. It is soluble easily in nitric acid, but only with difficulty in hydrochloric acid. It is also soluble in sulphuric acid. The solution of the oxide in nitric acid is blue, becoming green on dilution with water. The new metal is characterized especially by the green precipitates formed in solution of its salts by caustic potash, ammonia, and carbonate of soda, the precipitate being soluble in excess, giving blue solutions, and by the insoluble brown precipitate which is produced even in acid solutions by sulphide of ammonium. In the oxidizing flame of the blowpipe, with borax, it gives a yellowish green glass, which turns blue on cooling, the blue colour being clearer in the reducing flame. Microcosmic salt gives a yellow glass, turning emerald green, then violet and blue on cooling. With carbonate of soda upon charcoal the oxide is easily reduced, as also in a current of hydrogen gas.

At the recent drug sales there have been noticed Botany Bay kino, hog tragacanth, salep, jaborandi, patchouli and coca leaves, and Australian gum arabic. Goa powder, which has lately been scarce, has been offered in quantity and of good quality; but the Calabar beans which have been noticed have occurred only in small quantity and present an immature appearance.

From Manchester, offered as cinchona bark, we have seen the bark of *Stenostomum acutatum* in long smooth cylindrical quills. In the London market a new kind of cinchona bark has recently been offered, having the quilled appearance of *C. lancifolia* with the hard character of *C. cordifolia*, and possessing a fracture scarcely at all fibrous; it contains 1·75 per cent. of quinine.

It must often have been observed by those engaged in the compounding of prescriptions, that of the many formulæ which puzzle dispensers, not a few are for external applications in some one form or other of skin disease. The intractable character of these affections may oblige that part of the medical profession who make these diseases their special study to seek for remedies beyond the precincts of the Pharmacopœia. To that course there would be little or no objection, indeed it may be considered an ultimate advantage to medical science, were it not for the fact that these remedies are too often pitchforked together in defiance of chemical laws, or in relative proportions utterly at variance with their physical properties, and this too when a trifling alteration would in many instances result in an efficient, and, perhaps, elegant preparation. A member of the medical profession may be excused his ignorance of pharmacy, the study of disease is of itself sufficient to absorb his leisure time, but he may with advantage to himself and his patients recollect that there exists a pharmaceutical body trained to the art of compounding medicines, and ready to assist him with the pharmacy of any new remedial agent, or the judicious combination of the older ones, either for his formulæ in private practice or for the compilation of a hospital pharmacopœia.

In considering the prescriptions *seriatim*, the first that requires notice is that of No. 322, where "vaseline or prepared lard" is directed as a base for the other ingredients of the formula. Vaseline is ill adapted to retain, without separation, the quantity of fluid contained in this prescription; but an elegant preparation may be made by using the lard, and for the present purpose it should be melted in a water-bath, and, the other ingredients being added, kept well stirred until set or nearly cold, when the whole of the fluid will be taken up, a pink ointment resulting without any appreciable separation and of a suitable consistence for external application. Ointments are usually directed to be made on a slab, or by trituration in a good sized mortar; but it should at the same time be borne in mind that a more satisfactory preparation can sometimes be made by melting the base, such as lard, and after the addition of any other ingredient continuing the stirring until the ointment by gradual cooling has become of a suitable consistence.

The dispenser may reasonably conclude that the "gtt 2" after sodæ siccatæ, in No. 323, is an error due to a slip of the pen on the part of the writer, and that he intended it to be two grains. The combination of soda siccat. with ext. gentian. is quite usual, and the proportion just that which would be expected to form a pill with the extract of gentian.

It must be accepted that the writer of the prescription No. 324 intended pure morphia to be used from his having written "the alkaloid" after morphia, the dispenser therefore has no alternative but to use morphia, and as it is not soluble in the chloroform or in the rectified spirit of the liniment, or both combined, his next best course is to diffuse the alkaloid through the fluid. This may be facilitated by rubbing it in a mortar with a few drops of glycerine, and then adding the chloroform and liniment of belladonna. The morphia will by this means be thoroughly diffused through the fluid. It is difficult to understand why an alkaloid, incapable of solution in the menstruum, should by the writer be preferred to a dissolved salt of that alkaloid, in the same relative proportions. He may have had an end in view when he ordered the alkaloid, or he may not have been aware of its comparative insolubility in chloroform or rectified spirit. "Gulielmus" observes that the patient had previously obtained the liniment from the same prescription of a high colour—a brownish tint, and about twice as much in bulk. Accurately prepared the bulk should not exceed four fluid drachms, and if the liniment was sent out in the usual blue fluted poison bottle, the morphia, though only diffused, may have escaped the patient's observation.

No. 325. Bismuth is very frequently ordered in a prescription without its being indicated what preparation of bismuth the writer intends; but it is usual to use the subnitrate. It should be borne in mind for the dispenser's guidance that the subnitrate, as a salt of bismuth, stood alone in some Pharmacopœias prior to the issue of the B.P. It was the only preparation of bismuth in the London Pharmacopœia, and was the "bismuthum album" of the Edinburgh. Many of the profession, so long accustomed to one Pharmacopœia preparation of bismuth, still continue to write "bismuth," regardless of the carbonate which has been more recently introduced. The subnitrate is very valuable as an external application in many forms of skin disease. It may often advantageously supersede the oxide of zinc when there exists a very irritable condition of the surface of the skin, and in the case of children the subnitrate is especially soothing.

The prescription, No. 326, must be dispensed as others previously discussed containing ferri et quinæ citrat. with potass. iodid. The ferri et quinæ cit. should be dissolved in about ℥j of the aq. chlorof. and the other ingredients in the remainder, with which a little mucilage has been previously mixed; to this should be added the solution of the ferri et quinæ cit. There must necessarily result a decomposition with the formation of a precipitate which may be easily shaken up; the combination does not result in an elegant mixture, but in appearance is not very objectionable.

In the mixture, No. 327, the quinine is not directed to be dissolved, and if it were to be made into a solution, directly on the addition of the salicylate of soda, the quinine would separate as a resinous substance more or less adhering subsequently to the sides of the bottle. If the following method be adopted a satisfactory mixture will result. The salicylate of soda and chloral hydrate should be dissolved separately and then mixed together, and the quinine rubbed in a mortar to a fine powder should be suspended by the aid of about ʒiv of mucilage, and then added to the other ingredients previously in a state of solution; the quinine will be well suspended in the milky mixture. Care should be taken to have the quinine in a state of minute division, and this may be assisted by the addition of about an equal weight of sugar of milk to the quinine whilst being triturated in a mortar previous to the addition of the mucilage.

The prescription, No. 328, cannot be dispensed "so that the mixture should be of a clear bright sherry colour and not at all opaque." If the tincture of hop be of the proper strength there will be a deposit of organic matter with resin of the hop. The flocculent deposition is determined by the bromide of ammonium; without this ingredient neither of the tinctures deposit, but with this salt there is a precipitate from the hop only and not from the henbane. It is scarcely necessary to discuss the question how it was that a London house sent the mixture out bright, and besides it is quite immaterial in presence of the fact that if correctly dispensed there will be a flocculent separation which ultimately deposits leaving the supernatant fluid bright and of a pale yellow colour.

In No. 329, W. C. S. asks, "how a clear mixture can be made of dandelion and quinine, on mixing tr. quinæ with liq. taraxaci?" In the B. P. there is a suc. tarax., a recognized preparation made according to a prescribed formula, but many wholesale houses send out another preparation as liquor tarax.; it is therefore difficult to answer this question without being made aware of the mode of preparation of the liq. tarax. used. There is a turbidity in the mixture of tr. quinæ and suc. tarax., B. P., and it will be followed by a precipitate due to the mixture of tr. quinine with a preparation of a weaker spirituous strength, as the precipitate disappears on the addition of a little rectified spirit.

The mixture, No. 1 of No. 330, must be treated in principle as the prescription previously referred to, No. 327, but in this there is acid. sulph. dil. to dissolve the quinine, which will necessarily make a little difference in the manipulation. The salicylate of soda dissolved in a part of the pimento water should have a little mucilage mixed with it, and the quinine dissolved by the acid and diluted with another portion of the pimento water should be gradually and with shaking added to the salicylate of soda; the result here will also be milky, and closely resembling in appearance the one previously commented on. There is no essential difference with regard to manipulation in these two mixtures of salicylate of soda and quinine. In the former one the quinine is not dissolved, but rubbed to a fine powder and suspended by the aid of mucilage; in the latter the quinine is dissolved in dilute acid, but that acid is neutralized immediately on its coming into contact with the soda, and the quinine, thrown out of solution by the loss of the acid is retained in suspension by the mucilage.

With No. 2 of No. 330 the difficulty is not apparent. The prescription should be dispensed exactly as written, with solid perchloride of iron, adding the acid during solution. This method is adopted in making the tinct. ferri chlorati, 'German Pharmacopœia,' using solid perchloride, dilute spirit and hydrochloric acid.

An emphatic protest must be entered here against the doctrine that medicines dispensed with pharmacopœial preparations and in accordance with the prescription must necessarily be sent out bright. All pharmacopœial preparations should be of the B. P. standard, and if the result of mixing any of these in varying proportions in accordance with the prescription of a medical practitioner should be a turbid mixture, or one with a flocculent deposit, however unsightly this may be, the dispenser is not justified in removing, by filtration or otherwise, for the sake of an elegant result, any of that separated matter without the special sanction of the writer of the prescription; the result would often be a removal of the most active constituents of the medicine prescribed.

PHARMACEUTICAL PREPARATIONS OF COCA.*

BY GEO. W. KENNEDY, PH.G.

Although coca leaf is, comparatively speaking, a new remedial agent in many localities, yet in other places it is extensively known and largely used both in families and prescribed by physicians. In taking a retrospective view of the literature of the drug, I was agreeably surprised to find that so much had been written and so many experiments made with the object of isolating the

* From the 'Proceedings of the American Pharmaceutical Association,' 1878.

active constituents of the leaves, as well as to determine their therapeutic action.

In the last issue of the 'Proceedings,' for the year 1877, page 188, a very correct drawing of the plant will be found, made from a plant growing in the Royal Botanic Gardens, Regent's Park, London, to which I call your attention. The leaves of several species of Erythroxylon have been known from time immemorial, and were used especially among the Indians for chewing, mixed with lime and wood-ashes. Numerous and somewhat fabulous accounts are given of their physiological action: a moderate use is said to produce excitement of the functions, to relieve or prevent muscular fatigue, and to some extent to take the place of food; while an immoderate chewing of the leaf, like that of opium, frequently becomes an habitual vice, producing all the deleterious symptoms and consequences of narcotics, such as a state of half intoxication, stupor, with visionary dreams, premature decay, complete apathy and idiocy. These peculiar symptoms rendered the presence of a narcotic principle probable and induced experimentalists to undertake the investigation of the drug.

Neumann made approximate analyses of the leaf and discovered and described the alkaloid named *cocaina*. Stanislas Martin made a hasty examination, from which it appears that he discovered a bitter principle and a substance analogous to theina. Maisch subsequently was led to think that the plant contained also a volatile alkaloid. This supposition was afterwards confirmed by Lossen and Woehler, who separated the new alkaloid and named it *Hygrina*. They also discovered that when cocaina is heated with muriatic acid it is decomposed, benzoic acid and a new base, *Ecgonia*, being formed. Dr. S. R. Percy, of New York, also claims to have been the first to separate the active principle, to which he proposed the name *Erythroxylin*, inasmuch as the name cocaina might be confounded with other substances of a similar name.

So far, then, we have the following interesting and important active constituents of the drug:—Cocaina (or *Erythroxylin*), hygrina, besides the essential oil, to which I have not yet alluded and to which the odour of the plant is due, and of these the first-named alkaloid is undoubtedly the principle to which attention should be given in making galenical preparations. I find from the condensed reports of investigators that it is soluble in 704 parts of water, more soluble in cold alcohol, and quite soluble in hot alcohol and ether. From all the information I have been able to obtain appertaining to this subject, I would recommend a fluid extract and an elixir, and would propose the following formulæ, which I have found to furnish very satisfactory preparations:—

Extractum Cocæ Fluidum.

Coca leaves, in moderately fine powder	16 troy ounces.
Alcohol (95) per cent.	12 fluid ,,
Water	4 ,, ,,

Moisten the powdered leaves with the above menstruum, pack it carefully into a conical percolator, cover the surface of the powder with a disk of paper and add the remainder of the menstruum; when the liquid begins to drop from the percolator close the lower orifice with a cork, cover the percolator closely so as to prevent evaporation and allow it to remain in this condition forty-eight hours. The cork is then to be removed and percolation allowed to proceed, dropping not faster than at the rate of forty drops per minute, as quick percolation will not furnish good results and should be discountenanced, more especially in the manufacture of concentrated preparations. When the drug to be operated upon is small and the menstruum large, as in most of the tinctures, percolation can be allowed to proceed at the rate of sixty drops per minute with excellent results. The first twelve ounces of the percolate should be reserved and percolation continued with the same menstruum until the drug is thoroughly exhausted; evaporate the last portion at a temperature not higher than 130° F., until reduced to four fluid ounces and mix this with the reserved portion. The fluid extract prepared in accordance with this formula will be found of a dark greenish-brown colour and to contain in the highest degree the odour and taste characteristic of the drug,

Elixir Cocæ.

Coca leaves in moderately fine powder	℥iv.
Alcohol and water, of each a sufficient quantity.	
Oil of orange	gtt. vj.
Oil of cinnamon	gtt. ij.
Syrup	℥iv.

Mix three measures of alcohol with one of water, moisten the powder with two fluid ounces of the mixture, pack it firmly in a conical percolator and gradually pour on a sufficient quantity of the menstruum until eleven and a half fluid ounces of percolate are obtained. Dissolve the oils in a half ounce of alcohol, add to the percolate and finally the syrup. This will furnish a very elegant elixir, and each fluid drachm will represent the active constituents of fifteen grains of the drug when carefully prepared.

THE VALUATION OF TINCTURE OF OPIUM.*

BY PROFESSOR ALB. B. PRESCOTT, M.D.

Twelve samples were obtained, each from a different drug store in Michigan; three in Ann Arbor; three in Detroit; three in East Saginaw, and three in Grand Rapids, the best tincture being asked for in each case.

Each sample was worked by Hager's process (as given in Dragendorff's *Werthbestimmung einiger starkwirkender Droguen*, p. 91) and by Staples' process as used by Procter (*Pro. Amer. Phar. Asso.*, 1870, p. 131; *Am. Jour. Phar.*, 1871, p. 65). I also would refer to the report of L. M. Rice, *Pro. Amer. Phar. Asso.*, 1871, p. 447, and to that of D. C. Dott, *Phar. Jour. Trans.*, 1876, September 16, p. 239. All the operations here reported were done by Mr. Henry Heim, to whom this report is indebted for faithful work and careful study.

The process of Hager, modified for the tincture and in other details, was conducted as follows: The specific gravity of the tincture was taken, and a weighed quantity (from 25 to 30 grams) evaporated nearly to dryness on the water-bath; 1 gram of freshly slaked lime was added, with trituration, then 24 c.c. of distilled water added, and the mixture heated on the water-bath for one hour. The whole was then transferred to a small filter previously wetted, and the residue of the filtration washed with warm water until the filtrate dropped nearly colourless, and the filtrate evaporated on the water-bath to about 25 grams. The liquid was transferred, with rinsings, to a small wide-mouthed bottle, and while it was still warm 1 c.c. of ether and 3 drops of benzole were added with shaking, then 1·1 gram of ammonium chloride added and dissolved and the mixture set aside twenty-four hours. The liquid was then agitated, the crystals detached from the interior of the bottle, the whole brought upon a small filter, previously dried and weighed, the crystalline residue washed with about 8 c.c. of distilled water, dried at about 50° C. (120° F.) and weighed. Hager directed to leave the mixture three hours for separation of morphia. He has also advised to deduct one-tenth for impurities in the crude morphia of the process (the crystals not being washed with ether or chloroform). But the filtrate, about 25 grams, if holding only one-thousandth of its weight of morphia in solu-

* Paper read at the twenty-sixth annual meeting of the American Pharmaceutical Association. From the 'Proceedings.'

tion,* would carry about 0·025 of the alkaloid, fully as much as the one-tenth for foreign substances weighed with the morphia. Now when twenty-four hours are given for crystallization of morphia, there can scarcely be less than 1 part of morphia remaining in 1000 parts of the filtrate. It is not likely, however, that one-tenth the weight of the crystals (not ether-washed) is as much as the impurities. It will be seen from the results given with Staples' process that the ether-washing alone removes a variable quantity, averaging not far from one-tenth the weight of the crystals, and ether-washing certainly does not leave absolute morphia. I should advise ether-washing of the crude morphia in this Hager's process for the tincture and then leave remaining impurities to balance the morphia remaining in the filtrate. The process after Staples was conducted as follows:—

Morphiometric Work with Tincture of Opium. With Hager's Process.

The tincture (about 25 grams, of ascertained specific gravity) was evaporated to one-half its bulk on the water-bath, then set aside twenty-four hours for the tarry matters (soluble in alcohol but not in water) to subside, and decanted upon a filter, the filtrate being received in a small wide-mouth bottle. The tarry residue was washed with 4 c.c. (about 1 fluid drachm) of water and the washings filtered into the previously obtained filtrate. To the clear liquid in bottle was added an equal bulk of alcohol of specific gravity 0·835 and then a mixture of 1·3 c.c. (20 minims) of water of ammonia (specific gravity 0·96) with 1·7 c.c. (25 minims) of alcohol. After agitation, the bottle was closed with a stopper and set aside for four days. The liquid was then agitated, the crystals detached from the side of the bottle, and the whole filtered upon a small filter previously dried and weighed. The last portion of crystals was rinsed from the bottle upon the filter with a little of the filtrate. The crystals were then washed with 4 c.c. (1 fluid drachm) of diluted alcohol, then with the same measure of distilled water, then dried at about 50° C. (120° F.) and weighed. The dried crystals were then washed with 8 c.c. (2 fluid drachms) of washed ether, dried at 50° C. and again weighed.

The directions in Staples' process are to leave twenty-four hours for crystallization of the morphia and to add the ammonia in two portions, in both which particulars the process was departed from.

The process of Hager, it will be seen, takes less time than that of Staples, but the time depends greatly on the period given for formation of morphia crystals. By long standing a slightly greater yield is obtained.*

I have for some time been of the belief that Staples' process was the best for tincture of opium, but as Mr. Heim's results somewhat strengthened the comparative usefulness of Hager's process, I must hold it as nearly or quite as good as the other. Staples' process yields the best crystals of morphia.

* See report of volumetric estimation of total alkaloids as morphia in the filtrates of this work with Hager's process in the writer's paper on Morphiometric Processes for Opium, read at the Atlanta Meeting and to be published hereafter.

* The filtrates of Mr. Heim's work were extracted with amyl alcohol (preceded by benzole-washing in case of Staples' process), and the extracted alcohol, after evaporation of the amyl alcohol, was estimated in acid solution by Mayer's solution. The details and results are given (from Mr. Stecher's work) in the writer's report on Morphiometric Processes for Opium.

INDIGO-BLUE.†

BY E. SCHUNCK.

In the first part of this paper reference is made to previous papers containing accounts of indigo-blue obtained from *Isatis tinctoria*, in which it exists in the form of a glucoside, indican: this when treated with acids, splits up into indigo-blue and indiglucin. It is also decomposed by the action of caustic alkalies, a substance being formed which yields indigo-red, indifulvin, and leucine, when treated with acids. In some more recent experiments on indican from woad leaves, tyrosine has been found amongst the products of decomposition. The indican used consisted of a crude alcoholic extract of the leaves; it is therefore difficult to say whether the tyrosine existed ready formed in the leaves, or was the result of the decomposition of the indican; the latter is more probable, since tyrosine is almost insoluble in alcohol, and therefore would not be contained in the alcoholic extract in quantity. That there is some connection between indigo-blue and tyrosine is seen from the fact that tyrosine, $C_9H_{11}NO_3$, is indigo-blue, C_8H_5NO+2 molecules of water, in which one atom of hydrogen is replaced by CH_3. Its formation may be explained by supposing indican to split up into tyrosine indiglucin, acetic acid, and carbonic anhydride, $C_{26}H_{32}NO_{18}+3H_2O=C_9H_{11}NO_3+2(C_6H_{10}O_6)+2C_2H_4O_2+CO_2$.

In order to ascertain whether other indigo-yielding plants contain indigo-blue in the form of a glucoside as in *Isatis tinctoria*, or in the free state, the following experiments were carried out:—

Polygonum tinctorium.—The leaves of this plant which, are large, oval, and glossy, and of a lively green colour, contain a large quantity of the colour-yielding substance. On cutting them to pieces and rubbing with water to a thin

† From the *Chemical News*, 39, 119—120, 129—130, 143—144. Reprinted from the *Journal of the Chemical Society*, July, 1879.

paste, filtering through calico, and separting the chlorophyll, albumin, etc., from the filtrate by precipitating with lead acetate, a liquid is obtained which yields indigo-blue on the addition of sulphuric or hydrochloric acid and allowing the mixture to stand for several hours. The isolation of the colour-yielding substance is effected by the method formerly employed to extract indican from *Isatis tinctoria*, or by the following, which is preferable:—The leaves are dried in a stove, and while still warm, ground to a powder, and exhausted with alcohol in a percolator. The alcoholic extract is evaporated at the ordinary temperature, and the residue freed from chlorophyll and other impurities by precipitation with lead acetate. On adding basic lead acetate to the filtrate, a primrose-yellow precipitate is thrown down; this is washed with water and with alcohol, and finally suspended in absolute alcohol, and carbonic anhydride is passed through the mixture until the liquid assumes a yellow colour. On evaporating the filtrate at the ordinary temperature and adding water, a portion remains insoluble. This is separated by filtration, and the lead in the filtrate precipitated with sulphuretted hydrogen. The clear solution, evaporated at the ordinary temperature by means of a current of air, leaves a syrupy residue, from which the colour-yielding substance is obtained as a yellow syrup on treatment with absolute ether and evaporation. It shows no signs of crystallization, is soluble in water, alcohol, and ether, the aqueous solution possessing a more or less acid reaction. It assumes a deep yellow colour when treated with caustic alkalies, and gives a light yellow precipitate with lead acetate. When it is mixed with sulphuric or hydrochloric acid, indigo-blue separates out, and the filtered solution gives the characteristic test for glucose with Fehling's solution. If, however, the aqueous solution is allowed to stand or is boiled, or mixed with caustic alkali and allowed to stand, no indigo-blue is deposited on addition of acid. In all probability the substance analogous to indican undergoes a molecular change, resulting in the formation of a body which yields indirubin and resinous matters on treatment with acids.

By allowing a large quantity of the aqueous solution to stand in contact with acids, indirubin and indifulvin are deposited, besides indigo-blue, showing that a portion of the substance undergoes some change, which in all probability may also take place in the cells of the leaf: for from leaves gathered late in the season a substance is obtained which, when treated with acids, yields far less indigo-blue and more indirubin and other products than the substance obtained from the younger leaves.

From these experiments it is inferred that the leaves of *Polygonum tinctorium* contain a substance identical with the indican from *Isatis tinctoria*, and also that no colouring matter exists ready formed in the healthy living plant.

If the leaves of *Polygonum tinctorium* be crushed, and after a short time plunged into boiling alcohol, the bruised portion assumes an intense blue colour, whilst the other portion becomes white.

If the leaves be immersed in water and the water frozen, the portion of the leaves which have been frozen appears of a dark colour after complete thawing, and after steeping in boiling alcohol they assume a dark-blue colour, whilst the unfrozen portions become white. The fresh leaves, after being plunged in cold alcohol or ether, and extraction of the chlorophyll, appear blue; this was supposed to prove the pre-existence of the free colouring matter in the leaves; but by plunging them in boiling instead of cold alcohol, the colour-yielding substance is dissolved before it can decompose, and the leaves become of a pale yellow colour. Moreover, the alcoholic extract on evaporation does not deposit a trace of indigo-blue. The explanation offered for these phenomena is as follows:—The molecules of the glucoside, indican, are in a state of unstable equilibrium, and are enabled to preserve that equilibrium so long as they are contained in the cells of the living plant. As soon as that vitality ceases the indican begins to decompose, and the molecules arrange themselves as their chemical affinities predispose them; the result is, indigo-blue and indiglucin. This reaction takes place so rapidly that in some cases it would appear as if indigo-blue pre-existed in the living plant. By immersing freshly cut sprigs of *Polygonum tinctorium* in dilute hydrochloric acid for some days, and exposing them to the air, the acid is rapidly absorbed by the stalk, passing first to the lower leaves and then to the upper. The absorption of the acid is attended with a change of colour from dark green to dirty yellow, and after some time to dark blue, commencing at the base of the leaf, and gradually extending to the apex, which is reached only in the case of the lower leaves. When the change of colour begins to appear in the upper leaves, they are immersed in hot alcohol, whereby the chlorophyll is dissolved, leaving those parts which have changed colour, blue, and the other portions white.

All these experiments were performed when the plants were in a state of vigorous growth.

The leaves of the *Polygonum tinctorium*, after developing the blue colour, present certain characteristic appearances.

(1). The colouring matter is confined to the parenchyma of the leaves; the stem and ramifications in the coloured leaf may be traced as white veins on a coloured ground.

(2). The younger leaves show more intense coloration, although probably all the leaves contain the same amount of colouring matter; but in the lower leaves it is more widely spread.

(3). The colouring matter, when developed, is contained in the cells of the parenchyma in dots and parcels of various sizes, and in the amorphous state, the intensity of colour being determined by the crowding of the blue particles in the cells.

Bletia Tankervillæ.—Similar experiments, made with the leaves of the *Bletia Tankervillæ*, were attended with similar results, leading to the conclusion that these leaves contained a glucoside, similar to indican, which, on treatment with acids, yields a glucose and indigo-blue.

Indigofera tinctoria.—From want of material it was impossible to conduct experiments on this, the most important of all indigo-yielding plants; but according to P. Micheà, a glucoside exists in the indigoferas of India, similar and in all probability identical with the indican from *Isatis tinctoria*.

From the following plants, supposed to yield indigo-blue, all attempts to obtain a body resembling indican have failed, and they show no indication of the presence of a colouring matter like indigo-blue. They are:—

Galega officinalis,
Hedysarum Onobrychis (sainfoin),
Polygonum Fagopyrum (buckwheat),
Polygonum Persicaria,
Rhinanthus Crista Galli,
Sophora japonica,
Spelanthes oleracea.

THE PAPAW TREE.

The following letter from Mr. S. P. Oliver on the subject of the papaw tree appears in *Nature* for the 10th inst.:—

"In *Nature*, vol. xix., p. 447, is a paragraph relative to the singular qualities of the *Carica papaya*. I cannot but think that some of the properties attributed to this vegetable in British Guiana by the natives of that colony are exaggerated somewhat, *e.g.*, the tempering of steel by its sap, etc.

"Sir Wyville Thomson, in the first volume of 'The Voyage of the *Challenger*,' gives a capital representation of a group of these papaw-trees in the garden of the admiral commanding on the North American station at Clarence Hill, Bermudas, where they seem to abound; I do not know if these diœcious plants are indigenous to these islands or introduced from the West Indies and tropical America. From the cut above mentioned can be seen the quaint growth of these paradoxical trees, which must have been esteemed by the early voyagers, as they have been introduced into all parts of the tropics. The singular-looking straight stems (not unlike the gigantesque tree cabbage stalks of the Channel Islands) are crowned with a tuft of digitate leaves, somewhat at a distance resembling those of the *Aralia papyrifera*, under which the clusters of black purple fruit protrude. In the islands of Bourbon and Mauritius they make a passable *compôte* of these fruits, which are pulpy and full of black seeds when ripe, and the Creole children eat them raw, with what effect on their insides I know not; the birds, however, will not touch them, and as they fall they rot on the ground beneath. In Mauritius, where we lived principally on ration beef cut from the tough flesh of Malagasy oxen, we were in the habit of hanging the ration under the leaves itself, and if we were in a hurry for a very tender piece of *filet*, our cook would wrap up the undercut of the sirloin in the leaves, when the newly-killed meat would be as tender as if it had been hung for a considerable time. Whence are these deleterious effects causing rapid decomposition of animal fibre? and are there any other trees which possess similar properties?

"The Malabars, who were introduced into Mauritius as Coolies, would not sleep under tamarind trees, on account of their supposed noxious effects; but it is possible that superstition has something to do with their objection."

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.*

BY PROFESSOR ABEL, C.B. F.R.S.

(*Continued from page* 50).

If compressed gun-cotton is diluted by impregnating the mass with a *liquid*, or with a solid which is introduced into the mass in a fused state, its susceptibility of detonation is reduced to a very much greater extent than by a corresponding quantity of a solid inert body, incorporated as such with the gun-cotton, the cause being the converse of that which operates in preventing a reduction of the sensitiveness to detonation of nitro-glycerine by its dilution with an inert solid. In this case, the explosive liquid envelops the solid diluent, and remains continuous throughout, occupying the spaces which exist between the solid particles; hence detonation is readily established and transmitted. But in the case of the solid explosive, the diluent, which is liquid, or at any rate is introduced into the mass in the liquid state, envelops each particle of the solid, so that a film of inert material surrounds each, isolating it from its neighbours, and thus opposing resistance to the transmission of detonation, which is proportionate to the original porosity or absorbent power of the mass.

While compressed gun-cotton, in the air-dry state, is detonated by 2 grains of mercuric fulminate imbedded in the material, its detonation by 15 grains, applied in the same manner, becomes doubtful when it contains 3 per cent. of water, over and above the 2 per cent. which exists normally in the air-dry substance. Specimens which had been impregnated with oil or soaked in melted fat and allowed to cool, could not be detonated by means of 15 grains of fulminate. These diluted samples of gun-cotton could only be detonated by adding very considerably to the power of the initiative detonation; 100 grains of confined fulminate generally failed to detonate gun-cotton containing from 10 to 12 per cent. of water, and if the amount reached 17 per cent., 200 grains of fulminate were needed to ensure its detonation.

But moist or wet compressed gun-cotton is decidedly more susceptible of detonation by (dry) compressed gun-cotton itself than by mercuric fulminate.

Thus 100 grains of dry gun-cotton, detonated through the agency of the ordinary fulminate fuze, suffice to detonate wet gun-cotton containing 17 per cent. of water, though this result is somewhat uncertain. If the diluting agent amounts to 20 per cent., detonation is not certain with less than 1 oz. of dry gun-cotton, and if the compressed material be completely saturated with water (*i.e.*, containing 30 to 35 per cent.), 4 oz. of the air-dry substance, applied in close contact, are needed to ensure its detonation.

Detonation is transmitted through tubes from dry compressed gun-cotton to a moist disk of the material with the same facility as to the dry substance; and this is also the case with regard to the propagation of detonation from one mass of moist gun-cotton to another, in open air, all the pieces being ranged in a row, in contact with each other, provided that the piece first detonated does not contain less water than the others to which detonation is transmitted. Some curious results, obtained in experiments on the transmission of detonation, with gun-cotton containing different proportions of water, appeared to indicate that the character or quality of detonation developed by gun-cotton is subject to modification by the proportion of water which the latter contains.

Gun-cotton containing 12 to 14 per cent. of water is ignited with much difficulty on applying a highly heated body. As it leaves the hydraulic press upon being converted from the pulped state to masses having about the density of water, it contains about 15 per cent. of water; in this condition it may be thrown on to a fire or held in a flame without exhibiting any tendency to burn; the masses may be perforated by means of a red-hot iron or with a drilling tool, and they may with perfect safety be cut into slices by means of saws revolving with great rapidity. If placed upon a fire and allowed to remain there, a feeble and transparent flame flickers over the surface of the wet gun-cotton from time to time as the exterior becomes sufficiently dry to inflame; and in this way a piece of compressed gun-cotton will burn away very gradually indeed. A pile of boxes containing in all 6 cwt. of gun-cotton, impregnated with about 20 per cent. of water, when surrounded by burning wood and shavings in a wooden building, was very gradually consumed, the gun-cotton burning as already described when the surfaces of the masses became partially dried. In two other experiments quantities of wet gun-cotton of 20 cwt. each, packed in one instance in a large, strong wooden case, and, in the other, in a number of strong packing cases, were placed in small magazines, very substantially constructed of concrete and brickwork. Large fires were kindled around the packages in each building, the doors being just left ajar. The entire contents of both buildings had burned away, without anything approaching explosive action, in less than two hours. This comparatively great safety of wet gun-cotton, coupled with the fact that its detonation in that condition may be readily accomplished through the agency of a small quantity of dry gun-cotton, which, through the medium of a fulminate fuze or detonator, is made to act as the initiative detonating agent, gives to gun-cotton important advantages over other violent explosive agents for purposes which involve the employment of more or less considerable quantities at one time, on account of the comparative safety attending its storage and the necessary manipulation of it. Moreover, it has been well established by experiments of many kinds carried out on a considerable scale, as well as by accurate scientific observations, that the detonation of wet gun-cotton is decidedly sharper or more violent than that of the dry material; a circumstance which affords an interesting illustration of the influence exerted by the physical condition of the mass upon the facility with which detonation is transmitted from particle to particle. In the determinations made by means of the Noble chronoscope, of the velocity with which detonation is transmitted along layers or trains of gun-cotton and nitro-glycerine,

* Lecture delivered at the Royal Institution of Great Britain, Friday, March 21, 1879.

the lecturer has included experiments with gun-cotton containing different proportions of water. When the material contained 15 per cent. of the liquid, some indications were obtained that the rate of transmission of detonation was a little higher than with dry gun-cotton; the difference was very decidedly in favour of wet gun-cotton, when the latter was thoroughly *saturated* with water. (With air-dry gun-cotton the mean rate of transmission ranged in several experiments between 17,000 and 18,900 feet per second; with gun-cotton containing about 30 per cent. of water, the mean rate of transmisson ranged between 19,300 and 19,950 feet per second.) The air in the masses of compressed gun-cotton being replaced entirely by the comparatively incompressible body, water, the particles of explosive are in a much more favourable condition to resist displacement by the force of the detonation, and hence they are more readily suceptible of sudden chemical disintegration. Moreover, the variations in the rate of travel of detonation in dry gun-cotton, resulting from differences in the compactness or rigidity of different masses of the material, are very greatly reduced, if not entirely eliminated, by saturating the disks with water and thus equalizing their power of resisting motion by a sudden blow.

Another striking illustration of the influence which the physical character of an explosive substance exercises over its susceptibility to detonation and the degree of facility with which its full explosive force is developed, is furnished by one of the most recently devised, and one of the most interesting of existing, explosive agents.

Twelve years ago, soon after the process of producing compressed and granulated gun-cotton had been elaborated by the lecturer, it occurred to him to employ these forms of gun-cotton as vehicles for the application of nitro-glycerine. A considerable proportion of the liquid was absorbed by the porous masses of gun-cotton, and a nitro-glycerine preparation analogous in character to dynamite was thus obtained. The absorbent was in this case a violently explosive body instead of an inert solid as in dynamite, but the quantity of nitro-glycerine in a given weight of the preparation (to which the name of *Glyoxilin* was given), was considerably less than in the Kieselguhr preparation; hence the latter was nearly on a point of equality with it, in regard to power, as an explosive agent.

Nobel has observed that if, instead of making use of the most explosive form of gun-cotton, or trinitrocellulose, a lower product of nitration of cellulose (the so-called soluble or collodion gun-cotton) is added to nitro-glycerine, the liquid exerts a peculiar solvent action upon it, the fibrous material becoming gelatinized while the nitro-glycerine becomes at the same time fixed, the two substances furnishing a product having almost the characters of a compound. By macerating only from 7 to 10 per cent. of soluble gun-cotton with 90 to 93 per cent. of nitro-glycerine, the whole becomes converted into an adhesive plastic material, more gummy than gelatinous in character, from which, if it be prepared with sufficient care, no nitro-glycerine will separate even by its exposure to heat in contact with bibulous paper, or by its prolonged immersion in water, the components being not easily susceptible of separation even through the agency of a solvent of both. As the nitro-glycerine is only diluted with a small proportion of a solidfying agent which is itself an explosive (though a somewhat feeble one), this *blasting gelatine*, as Nobel has called it, is more powerful not only than dynamite but also than the mixture of a smaller quantity of nitro-glycerine with the most explosive gun-cotton, as the liquid substance is decidedly the most violent explosive of the two. Moreover, as nitro-glycerine contains a small amount of oxygen in excess of that required for the *perfect* oxidation of its carbon and hydrogen constituents, while the soluble gun-cotton is deficient in the requisite oxygen for its complete transformation into thoroughly oxidized products, the result of an incorporation of the latter in small proportion with nitro-glycerine is the production of an explosive agent which contains the proportion of oxygen requisite for the development of the maximum of chemical energy by the complete burning of the carbon and hydrogen, and hence this blasting gelatine should, theoretically, be even slightly more powerful as an explosive agent than pure nitro-glycerine.

That such is the case has been well established by numerous experiments, but although this blasting gelatine may be detonated like dynamite by means of small quantities of confined detonating composition, when it is employed in strongly tamped blast-holes, or under conditions very favourable to the development of great initial pressure, it behaves very differently from that material, or other solid though plastic preparations of nitro-glycerine, if the attempt is made to detonate it when freely exposed to the air or only partially confined. It not only needs a much more considerable amount of strongly confined detonating composition than dynamite and similar preparations do, to bring about a detonation with it under those conditions; but when as much as 15 or 20 grains of confined fulminate are detonated in direct contact with it, although a sharp explosion occurs, little or no destructive action results, and a considerable portion of the charge operated upon is dispersed in a finely-divided condition. This dispersion appears to take place to some slight extent with dynamite also, when a small charge is detonated in open air, in consequence of its want of rigidity, though the amount of explosive which thus escapes detonation is very small as compared with the gelatine. (*To be continued.*)

RESIN OF PODOPHYLLUM.*

BY J. U. LLOYD.

Resin of podophyllum is found upon the market in colour ranging from light brown to deep yellow. Can these various shades be obtained from may-apple root without the use of foreign substances?

At first resin of podophyllum was prepared by distilling all the alcohol from an alcoholic tincture of the root and pouring the residue into cold water. It settled into a lump of dark brown colour; when pounded it was a little lighter.

In the present U. S. officinal process there is enough alcohol to cause the resin to separate in a finely divided form if the water be cold. Such an article has either a yellowish or slightly brown cast. The first portions of the percolate furnish the darkest shade. If it be dissolved in its weight of cold alcohol, filtered and precipitated in sixteen parts ice-cold water, it will be much lighter in colour, as impurities are thus separated which were mechanically carried down by the first precipitate. An article thus produced is a shade darker than powdered ipecac, usually of a faint yellowish shade. As a rule, the nearer resin of podophyllum approaches white the better.

If instead of water, or water acidulated with muriatic acid, we use an aqueous solution of alum for the precipitant, the colour before mentioned quickly changes, acquiring in a few hours a rich greenish yellow. The supernatant liquid also turns yellow; this shade cannot be obtained with water or water acidulated according to the Pharmacopœia. It results from a change in the resin, instead of the addition of another substance from the tincture.

Alum-water will scarcely produce an additional precipitate from the liquid after making officinal resin of podophyllum, but will change the powdered resin to greenish yellow, which shade, so frequently found in the market and so often demanded of manufacturers, I have never been able to obtain without the use of foreign substances. Almost any of the colours, excepting that just named, from deep yellowish brown to nearly white, can be produced with pure water for the precipitant, as the variations result generally from impurities carried down by the precipitate or from resins of different densities.

THE CO-OPERATIVE CRAZE.

THE reports of the evidence given before the Select Committee on Co-operative Stores, as they appear in the daily papers, afford but small reason for anticipating that the result of this inquiry will be much to the advantage of the retail traders who are damaged by the competition of these large trading organizations. On the contrary, we fear that the chief effect of the entire proceeding will be to give greater prominence to the stores, in fact to advertise them to the disadvantage of shopkeepers, and to induce imitation of their mode of doing business by large firms. That, we think, will be at least the more immediate consequence, and it is for this reason that we have always maintained that the less there was said about the stores the better. Co-operation is the whim of the day and "going to the stores," one of the most popular amusements of the leisurely and the idle; but like spelling bees, skating rinks, fat claimants, fancy bazaars, and even worship of Miss SARAH BERNHARDT, and many other popular whims which those classes bring into notoriety, the "store" craze cannot be expected to have any greater vitality than any other nine days' wonder which may acquire an inflated notoriety by being run after by the herd of sensation seekers.

But there is a further reason for believing the present craze after co-operative association will subside and perhaps die away altogether. Regarding this system as a means of obtaining ordinary necessaries without allowing the retail trader to perform for the general public the service of distribution, and as the purveyor of such commodities deriving from the performance of that service a remuneration which makes it worth his while to devote his time and energies entirely to that work, the extensive carrying out of the system involves such a disregard of the division of labour and such a violation of the principle of live and let live that it is scarcely possible to imagine its continuance for any long period without being productive of evils that will materially affect the classes which are for the time being benefited by doing for themselves the work of the retail trader and taking the bread out of his mouth.

We do not seek to question the right of a few individuals associating together to economize their means by purchasing a chest of tea and dividing it among themselves; they would be, we think, equally free to make their own coats and trousers or shoes, just as much as they would be entitled to dispense with the use of a carriage and pair, or the services of a footman in plush. If this kind of self-help by association were at all widely carried out, no doubt tailors, shoemakers and carriage builders, as well as other retail traders, would suffer to some extent by loss of business; but, on the one hand, they would not have any real reason to complain of being unfairly used, and, on the other hand, it is not probable that the advantages of such a system would be sufficient to make it so universal as to seriously damage retail traders.

The case is, however, very different when the individuals who have associated themselves together in this way for their own benefit proceed to make their organization a source of profit to themselves by inviting the general public to obtain their supplies of ordinary commodities through the same channel, and thus enter into competition with the retail tradesmen. The unfairness of such competition is in itself sufficient to condemn it, and the probable effect of it upon the trading community is a further reason for regarding it as a thoroughly ill-founded proceeding.

The evidence given last Wednesday affords some indication of what is expected to be the result of co-operative store trading. Mr. CHARLES J. COX, one of the principal clerks in the Admiralty, was asked what was to become of the small traders if stores were to go on increasing at the same rate that they have done in the past, and his answer was that some of them must go. He did not think the shopkeepers would soon become a relic of the past and could hardly give an idea of the time it would take to bring this about; but he was clearly possessed with the idea that some of them would have to go, and that this result would be to the advantage of themselves as well as of the public. In reference to the business of the chemist and druggist especially, he had not the least idea what people would do if they wanted to get medicine on Sundays when the druggists' shops were all swept away by the stores, but had no doubt some method of meeting the wants of the public would be found. It might have been worth while to ascertain from Mr. Cox what was his opinion as to the probable destination of those tradesmen who, to use his language, "would have to go;" also, whether their having to go would have any influence in augmenting the Queen's taxes or the parish rates; but perhaps the members of the Committee had their own views on this subject, and will be able in their report to indicate what may be naturally expected to result from a system of trading by which shares originally worth only £2 are now worth from £75 to £100. This is not a result of the commendable economy of Civil Service clerks, but it is one achieved by unfairly enabling the outside public to dispense with the services of the retail trader, who in the faith of being employed as heretofore has invested his capital in some one or other branch of the business of purveying.

But we do not believe the influence of the "stores" will extend so far as to bring about Mr. Cox's predictions. Considerable hardship and loss will, no doubt, be experienced by tradesmen while the stores remain in favour and while some of them are as prosperous as the one referred to above. That, however, is a precedent that is not likely to be imitated: "Stores" are already entering into competition with stores: the *exploitation de l'homme par l'homme*, under the ægis of limited liability, is being commenced upon the basis of "store" popularity, and we shall not be surprised to see before long some of the numerous schemes for providing every one with commodities for less than they are worth turn out to have their philanthropy limited to the promoters and others concerned in their inception. We have already seen the collapse of some of these literally speaking "too promising" concerns and we think it only requires some degree of patience and fortitude to arrive at a time when the seeds of weakness inherent in this co-operative store craze shall become thoroughly clear to all. That there is foundation for these opinions may be gathered from the evidence furnished by one of our contemporaries devoted especially to the interests of the Civil Service. Testimony from such an unexpected source against the mode in which "store" trading has been carried on is especially significant, and the treatment of the subject in a recent number of the *Civil Service Gazette* is so thoroughly to the point, so much more rational than most of the articles which have appeared in the daily papers—simply echoing the popular cry—that we think it desirable to publish the article *in extenso* as one of the best commentaries on the subject.

"We have often ventured to advise members of Her Majesty's Civil Service to be cautious in their chase after that wild sprite, the treacherous will o' the wisp, named co-operation; and warned them that, unless extremely careful, they would be led by it into a quagmire. Our admonitions were not, as the event has proved, unnecessary, for the mischance we apprehended has come to pass. By running heedlessly after this '*ignis fatuus' the servants of the Crown have got plunged into a bog*, extrication from which will not be easy. Had they strictly confined themselves to co-operation pure and simple, to the purchase at wholesale prices and distribution among themselves of articles of first necessity for their own use and that of their families, in classes or departments, there would have been no valid objection in principle to their economic combinations; but when they constituted themselves genuine traders and storekeepers for the sale of all kinds of commodities to the public at large, which they virtually did—*the ticket limitations being in practice a transparent sham*—they transgressed the limits of legitimate club or class co-operation, and laid their commercial adventures open to reasonable opposition from the regular trading community. To embark openly in trade and enter into competition with those who derived their living, supported their families, and contributed to the national taxation from the business of buying and selling, was not merely foolish but impolitic. The permanent and certain interests of the whole body of public servants were jeopardized for the temporary and uncertain advantage of a few members, *and a feeling of hostility was excited against the Service throughout the country among an active and influential class* previously disposed to be friendly towards it. Great Britain is truly, as it has been designated, a nation of shopkeepers, and to provoke the constituents of such a nation to vindictive antogonism was certainly unwise. Beyond requiring the habit of paying cash for whatever was wanted and inducing the reduction of credit prices by tradesmen to ready money rates, we do not see any present compensating advantages the great majority of Civil Servants have obtained; *but we foresee much injury looming in the future from the warfare which has been stirred up between them and a numerous body of the Queen's subjects.* For a season co-operation is a word to conjure with, and co-operative stores are *à la mode*; but the charm and the novelty will, we may safely predict, soon wear away, and the natural order of things will be restored. *Indeed, already the most fashionable stores are fast getting into disrepute, losing their character in more ways than one.* Scandalous tongues are busy denouncing them as places of assignation, flirtation, intrigue, pastime for the gay and idle, and broadly insinuating that the mob of carriage-people, of wonderfully-got-up girls, nice young men, elderly dandies, and frisky dames who flock thither to promenade, to chat to lunch, etc., are quite as much in search of pleasurable excitement as of cheap groceries and articles of domestic use at wholesale prices. However that may be, *it is to be regretted that servants of the Crown, Civil or Military, should have provoked the enmity of any considerable body of Her Majesty's subjects engaged in fighting the hard battle of life by entering into competition with them in trade, disguised or undisguised*; and we hope that some means may be found for removing the cause of anger and restoring the good-will and fraternal feeling which should subsist between all orders of hard-working men."

So far as Civil Service co-operation is concerned, the light here thrown upon it from a source that is not likely to be antagonistic, gives prospect of some mitigation at least of the injuries that have been inflicted upon retail traders, and as regards "stores" carried on or projected as limited liability companies we do not think there is much to fear.

POSTHUMOUS HONOURS TO A FRENCH PHARMACIST.

By a recent decree the mayor of Saint Omer has changed the name of a street in that town to "Rue Caventou," in honour of the celebrated pharmacist whose native place it was. Among the reasons for thus commemorating Caventou it is specially stated in the decree that he was the discoverer of sulphate of quinine, "by which he could have realized an immense fortune, but that in his love for science and humanity, he did not hesitate to publish his discovery."

EXAMINATIONS IN LONDON.

July 9, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

MAJOR EXAMINATION.

Eight candidates were examined. *Four* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Alcock, Frank Harris ....Burslem.
Allan, James Henry...............Stockton.
Betts, George ....Norwich.
Bird, Henry ....London.

MINOR EXAMINATION.

Eighteen candidates were examined. *Eight* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Atkins, Ernest ....Southampton.
Ballard, Frank English ....Aylesbury.
Beard, James Hogg...............Manchester.
Bennett, Frank William.........London.
Bourne, Chas. Matthew Kemsey...Wolverhampton.
Bown, John Quinton ....Nottingham.
Bridge, George Edward ....Maidstone.
Brook, Joe..........................Lofthouse.
Cambridge, John Underwood...Hartlepool.
Carter, Francis....................London.

MODIFIED EXAMINATION.

Four candidates were examined. *One* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bemrose, Weightman ....London.
Capon, Charles William .. ..London.
Still, David Usborne ....Staplehurst.

July 10, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

MAJOR EXAMINATION.

Eight candidates were examined. *Six* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Dutton, Hugh Odard ....Rock Ferry.
Grimble, Albert ....Boston.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Twelve* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cheers, Robert Salmon ....Northwich.
Clerke, William Burdett.........Leamington.
Crow, William ....Berwick.
Crowther, Arthur..................Tickhill.
Davies, Thomas ....Bridgend.
De Peare, John Thomas ....Spalding.
Dixon, William.....................Stratford-on-Avon.
Drew, Henry William............Southwark.
Feaver, William ....Truro.

July 11, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Nineteen* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Gibson, James Edward ....Sheffield.
Green, William James..........Yeovil.
Harburn, Alfred ....London.
Holland, Tom ....Lincoln.
Hope, Arthur Peach..............Uppingham.
Howell, Edmund ....Oxford.
Humphreys, Griffith ....Corwen.
James, Charles Frederick ......Highworth.

July 16, 1879.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Eleven candidates were examined. *Five* failed. The following *six* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Horton, Thomas ....Peterborough.
Lapthorn, George..................Taunton.
Mayger, William John ....Northampton.
Nowell, Barnes.....................London.
Pisani, Orestes Victoriano ......London.
Ratcliffe, Henry Norman ......Torquay.

MINOR EXAMINATION.

Eighteen candidates were examined. *Eight* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Llewellyn, David ....Cilcerin.
Lodge, Arthur William ....Merthyr.
Lupton, George Frederick ......York.
Macaulay, William Henry ......Rotherham.
Manning, Alfred ....Strood.
Morgan, John Daniel ....Swansea.
Morris, David ....Cardigan.
Olden, Loathan.....................Romsey.
Oldfield, Arthur ....Grantham.
Parkin, George Anthony.........Ripon.

July 17, 1879.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Ten candidates were examined. *Four* failed. The following *six* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Lomax, Alban Edward ....Liverpool.
Porter, Thomas.....................Fleetwood.
Remfry, Samuel Alfred ....London.
Shirley, Stephen Shillito.........London
Smithson, Thomas Henry ......Bradford.
Villar, Arthur ....Staplegrove.

MINOR EXAMINATION.

Seventeen candidates were examined. *Five* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Peck, Frederick William ......Cambridge.
Pickles, Walter.....................London.
Plattin, Henry Ramm...........Fakenham.
Powell, William ....Swansea.
Ratcliffe, George ....London.
Reddish, Augustus Frederick...Patricroft.
Rossiter, Thomas Edward ......Tiverton.
Roughton, William ....Loughborough.
Sagar, Hartley ....Nelson-in-Marsden.
Selleck, William Robert.........Bovey Tracey.
Shadford, Major ....Spalding.
Shrivell, Frederick Wm. Edwd.Hadlow.

July 18, 1879.

Present—Mr. Sandford, President; Messrs. Alkchin, Barnes, Benger, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

MINOR EXAMINATION.

Twenty-six candidates were examined. *Ten* failed. the following *sixteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Smith, John Thomas ....Donington.
Stableforth, John William ......London.
Stedman, Walter ....West Malling.
Stevenson, David Archibald ...Chertsey.
Taylor, James Bennett ....Bedford.
Taylor, Philip Neville............Tipton.
Thompson, Arthur Stevens......Barking.
Topliss, Walter George ....Wainfleet.
Watson, Edward Arthur.........Cheltenham.
Wild, George Frederick ....Hyde.
Willis, Henry James ....London.
Willis, Joseph Darrington ......Northampton.
Wimshurst, Frederick ....Southborough.
Wise, Joseph Norman............Carlisle.
Wood, Robert ....Loughborough.
Wyatt, Charles Frederick ......Old Brompton.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the College of Preceptors.

Laffere, John Athanasius ......Hatherleigh.
Nicholls, Reginald E. ....Lee.

Certificates of the University of Cambridge.

Roberts, William ....Chester.
Wilson, John ....Wolverhampton.

Certificates of the University of Oxford.

Maillard, William Job............Brecon.
Patey, William James............Banbury.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting was held at 32A, George Street, Hanover Square, on Wednesday evening, July 9th, Mr. Branson in the chair, when Mr. Naylor read a paper on "Explosions."

The author divided his subject into two great classes, those in which the explosion was the sole result of purely mechanical action and those in which the force exerted is the product of chemical decomposition. To the latter class more especial reference was made. An explosion was shown to differ from expansion merely in that the one takes place slowly, while the other is instantaneous. Boiler explosions were next considered and referred to one of two causes: either to furring or defects of repair. The manner in which these deposits act in producing an explosion was fully explained, accompanied by a reference to those substances which are used as "anti-foulers." The explosions resulting from the mixture of various gases with air, notably marsh gas and coal gas with air, received a large share of attention.

The Davy lamp was exhibited and the principles of its construction explained and illustrated by experiment.

Reference was next made to those explosions which have occurred during the manufacture of oxygen gas on the large scale from $KClO_3$ and MnO_2. These were said to owe their origin, with but few exceptions, to the admixture of small quantities of soot or sulphide of antimony with the MnO_2 used. Simple methods of detecting these contaminations were described and shown practically. Following this was a somewhat detailed account of the manufacture of gunpowder.

A number of beautiful specimens were exhibited in illustration of the different grain powders, including the various kinds of sporting powder, rifle powder, and blasting powders, and cubes of the kind used by Her Majesty's Government for loading the 100 ton gun.

Brief references were also made to the manufacture, uses, etc., of gun cotton and nitro-glycerine. Specimens of Abel's compressed gun cotton, lithofracteur and dynamite were handed round for inspection. A few remarks upon Abel's fuses and Robinson's universal fuse brought this very interesting paper to a close.

A discussion then followed in which several members took part, and a hearty vote of thanks was awarded to Mr. Naylor, on the proposition of Messrs. E. Cardwell and Robinson.

The president announced donations and subscriptions to the amount of £3 13*s.* 0*d.*

SOCIETY OF ARTS.

THE HISTORY OF ALIZARIN AND ALLIED COLOURING MATTERS, AND THEIR PRODUCTION FROM COAL TAR.*

BY W. H. PERKIN, F.R.S.

(*Continued from page* 59.)

LECTURE II.—DELIVERED MAY 22.

In the previous lecture I gave a brief account of the dye-stuff, "madder," and also of the chemical history of its colouring matters, alizarin and purpurin, their artificial production from anthracene, and of the new dyes which are allied to them, etc. I treated the matter, to some extent, from a purely scientific point of view, as I felt it necessary to do so before proceeding to give an account of the practical operations involved in the manufacture of these substauces.

I now propose bringing before you the history of the technical part of my subject; but before entering into this, I wish to mention that I had the good fortune of being associated with my brother, Mr. T. D. Perkin, in carrying out this manufacture, and to his business habits and skill in devising and erecting new plant, the rapid development and success of this new industry was to a great extent due.† Our works were at Greenford Green, near Harrow, and on the Grand Junction Canal. They were erected in 1857 for the manufacture of the the mauve dye, and afterwards also used for the production of various other coal tar colours. I mention this because we were able to employ some of our plant which had fallen into disuse for our preliminary operations, and thus a considerable amount of time was saved. Our manufacturing experiments for the production of artificial alizarin were commenced about the middle of 1869, and the first question which naturally came before us was that of the production of the raw material, "anthracene." At this period anthracene was unknown to the tar distillers, and, consequently, was not a commercial product. Experiments had, therefore, to be made upon its preparation, not only to obtain it, but also to get some rough idea of the amount that could be produced from coal tar, because, unless it were practicable to get it in quantity, artificial alizarin could not successfully compete with madder.

For the purpose of preparing anthracene for my experiments in 1855 I had employed coal-tar pitch, and distilled it in iron pots. I, therefore, naturally selected pitch as the scource of anthracene, and having a number of iron retorts ready for use, many tons were distilled. From the amount of anthracene we obtained in this manner, we felt assured there was no reason to fear there would be any lack of raw material.

When distilling pitch, we found it generally best not to allow the very last portions of the distillate to mix with the earlier ones, as they are sticky, and contain little, if any, anthracene. Sometimes we re-distilled the distillate; this improved it considerably. (Distillation of pitch in

* From the *Journal of the Society of Arts.*

† Our firm was known as Perkin and Sons.

pitch ovens destroys most of the anthracene.) The oily distillate, on being allowed to stand for some days, deposits the anthracene; this we separated, by draining the products in canvas bags, and then pressing out as much of the remaining oil as possible with a screw press. In July, we set up our first hydraulic press for this purpose. The crude anthracene was then washed with coal-tar naphtha, and afterwards distilled. The apparatus for distilling consisted of two retorts, set side by side, connected to each other by a large bent iron pipe, one retort being used as a still, the other acting as a receiver. The connecting-pipe was kept hot, to prevent the anthracene from blocking it by condensing. The distilled anthracene was partly in the form of a hard, yellow, crystalline mass, and partly in the form of a crystalline powder.

We obtained by this means about ¾ to 1 per cent. of pure anthracene from the pitch we employed. During the time we were carrying on these experiments we asked some large tar distillers, Messrs. Blott, of Poplar, London, to collect the last runnings of their tar stills, and set them aside to cool. These deposited considerable quantities of anthracene, which were collected in canvas bags, and it was soon found that by this means large quantities of anthracene could be obtained. Messrs. Blott then commenced to prepare this substance in quantity,* and to supply us with it. Other tar distilleries were then communicated with, in fact, nearly all the tar distillers in the United Kingdom were either visited or written to on the subject, and the result was that in a short time such quantities of anthracene came in that it was unnecessary for us to continue to distil pitch.

The anthracene obtained from the tar distillers was sent out in casks, and was in a thick pasty condition. It was pressed in hydraulic presses between thick linen sheets, in the same manner as paraffin is pressed when being purified, and was thus obtained in solid cakes, weighing about one-fourth of the unpressed product. Most of the tar distillers now press their anthracene before sending it into the market. The anthracene supplied at first was usually of a very good quality, much better than afterwards, when it was found to be an important product, because the distillers then endeavoured to extract all they could from their tar, and thus many other products were separated with it.

The pressed anthracene was at first purified, as above, with coal-tar naphtha, and then distilled, but it was found to be still far from pure; this was a great drawback, because, when converting it into anthraquinone, by oxidation with potassic bichromate and sulphuric acid, in the way we then conducted the process, a large quantity of the oxidizing mixture was used upon the worthless impurities as well as on the anthracene, thus adding greatly to the expense of the anthraquinone, and not only so, but rendering the purification of that substance more troublesome.

After making a number of experiments with different solvents, which were only partially successful in removing the impurities of the anthracene, I thought that, by distilling it with a caustic alkali, some good might be effected, as all substances of a phenolic character would be removed, and some of the high boiling and less stable products might be charred. In this I was not disappointed. A quantity of anthracene which had been purified with naphtha and distilled was re-distilled in a glass retort with solid caustic potash. The distillate was considerably less in weight than the anthracene taken, and in the retort there was a large quantity of a black carbonaceous residue. Although still not pure, the anthracene was immensely improved in quality, and, with but little treatment with solvents, yielded a chemically pure product, crystallizing in a most beautiful manner, superior to anything I had ever seen before.

The process was next tried on the large scale, caustic soda being employed in place of caustic potash, but I was surprised to find that no purification of any consequence was effected; on repeating it, however, with caustic potash, the same result was obtained as that in the laboratory.

After experimentally proving that anthracene is not destroyed when distilled with potash, this process was adopted on the large scale.

In purifying anthracene with coal-tar naphtha, a loss of anthracene was found to take place, on account of its solubility in that fluid. We found, however, that, by using petroleum spirit, this loss was, to a great extent, avoided; therefore, the use of naphtha was discarded.

After many experiments, the purification of crude anthracene was conducted in the following manner, the first operation, viz., the treatment with petroleum spirit, being conducted in a large, separate building. The crude anthracene was first thoroughly ground under edge-runners, which made most of the ordinary qualities of pressed anthracene into a very stiff, pasty mass. The ground anthracene was then put into boxes, and hoisted to the top floor of the building by means of a windlass. It was then introduced into the large iron cylindrical vessels, which had been previously half-filled with petroleum spirit, and the agitator also set in motion. About 1500 to 1830 lbs. of crude anthracene and about 300 gallons of petroleum were used in each operation, the proportion of petroleum, however, being varied according to the quality of the anthracene.

Steam was then turned on to the steam jacket, with which the cylinder is provided until the petroleum nearly boiled, the manhole being kept loosely covered, to avoid evaporation. The stirring was continued for an hour or two, after which the product was run into cooling tanks. These were not very large, and kept apart, so that the air might freely circulate around them. The principal object of the cooling was to allow any anthracene which had dissolved in the petroleum spirit to crystallize out. When cold, the wooden plugs which close the outlets of these tanks were removed and their contents run out into the filter tank. The filter consists of a perforated wooden floor, covered with coarse canvas. As the petroleum charged with impurities drained away, it was received in a large tank sunk in the ground. The anthracene on the filter was afterwards washed by pouring over it a little clean petroleum spirit.

When thoroughly drained, the anthracene was removed to a tank, provided with a still head, connected to a worm tub; some water was then added, and steam blown through the mixture, to volatilize the petroleum, which afterwards condensed in the worm, and ran into the tank.

In the bottom of the tank, there was a large tap connected with a pipe. When the operation was finished, this was opened to allow the water to flow out, and as this usually carried anthracene with it, it was passed through canvas bags. The front manhole was then opened, and the anthracene removed and placed in dry casks to further drain. In this operation, average qualities of anthracene usually lost about 30 per cent of impurities.

The dirty petroleum in the tank, was pumped into the still, and distilled by blowing steam through it; it then flowed into the tanks, and after the water which had condensed with it was run off sufficiently by the taps near the bottom of the tanks, so that only petroleum flowed from the two little taps placed higher up, it was pumped into the cylinders, and used for a fresh operation, and thus it was used over and over again.

The residue in the still was a dirty, thick, oily product mixed with water; it was run out into tanks, and on cooling became a semi-solid mass. This product was used as fuel under evaporating pans. For this purpose it was kept fluid, by being warmed in a boiler, it was then run through a pipe into a special jet supplied with steam, which converted it into spray. This was kept ignited under the pans by means of a small coke fire.

* July, 1869.

The next operation consisted in distilling the anthracene, thus far purified with caustic potash. For this purpose ordinary Montreal potash was used. This was usually found to contain considerable quantities of caustic potash, and answered the purpose perfectly. We found it necessary to use some caustic lime with it, otherwise the residue left in the retorts caked so hard that it was only with great difficulty that it could be removed.

The proportions used were usually in the ratio of 100 parts of washed anthracene, 30 parts potash, and 6 parts ground lime. These substances were thoroughly ground under edge runners, and introduced into iron retorts and distilled.

When we first distilled the anthracene with potash, we employed retorts with the outlets at the back bolted on, but we found it impossible to get joints to stand the constantly repeated heatings and coolings of the apparatus. We, therefore, had the necks cast on the retorts. It was also found necessary to keep the mouths of the retorts well over the dead plates, otherwise anthracene condensed on the retort door.

For some time we used large iron tanks as condensers, two or three retorts distilling into each, but as considerable quantities of hydrogen gas were given off, the operation of cleaning them out was dangerous, because, as the air mixed with the hydrogen, it became an explosive mixture, and if any part of the retorts had not cooled down sufficiently, this would be ignited; in fact, it was owing to an accident of this kind, that we first noticed the evolution of hydrogen. Afterwards we made experiments to see how small a receptacle could be used, and at last obtained reservoirs of a shape and construction that answered perfectly. They consisted of iron troughs fitted to the retort neck. The further end of the receiver was closed with a loosely-fitting piece of wood. The top consisted of loose iron lids, hinged on one side of the trough, and provided with long iron handles, so that they could be easily opened or closed.

Before the distillation was commenced, these lids were luted down, but this was scarcely necessary, as the sublimed anthracene soon stopped up the crevices. The hydrogen escaped at the back end of the trough. The retorts were set on fire lumps, to prevent their burning out. The distillation was commenced in the morning, after the previous day's residues had been cleaned out from the retorts, and they had been recharged.

Before the receivers were emptied, the lids were opened from below, so that any permanent gas might escape, and then the anthracene removed. This was found to be partly in the form of very pale primrose yellow crystalline cakes and partly as a light sublimate. As it contained some water locked up in its interstices, it was ground under edge runners and then dried. The black carbonaceous residue left in the retorts, when heaped together, easily catches fire and continues to burn for a very long time. The potash was recovered from this residue, causticized and again used.

When commencing the manufacture of artificial alizarin, we employed the process described in my first patent, in which anthraquinone is used. By this method we prepared large quantities of colouring matter. My second process, however, was found, especially at that date, to possess considerable advantages over the first. In this, it will be remembered, dichloranthracene is used, and therefore, as soon as the technical difficulties were mastered, we employed it in preference to the first, though sometimes we manufactured by both.

As most of the colouring matter manufactured by us was prepared by the dichloranthracene process, I have thought it best to describe it first, afterwards returning to our experiences with the anthraquinone method.

A large number of experiments were made upon the preparation of dichloranthracene, such as passing chlorine over anthracene suspended in solvents; or over anthracene which had been purified with petroleum spirit or bisulphide of carbon and then distilled; or anthracene which had been distilled with caustic potash.

The result of these experiments was, that it was found that the best process consisted in passing chlorine over anthracene which had been purified by distillation with potash, as, by this means, a beautiful product was obtained, which could be easily purified; whereas, anthracene which had not been distilled with potash usually gave a confusedly crystallized, sticky mass, very difficult to deal with.

As it was very important to produce colouring matter with the least possible delay, the manufacture of chlorine for the preparation of dichloranthracene was a matter requiring a good deal of consideration; because, if plant had to be erected to prepare it in the ordinary method from black oxide of manganese, a great deal of time would have been lost. We, therefore, thought that, until the ordinary plant could be erected, we might make it expeditiously by decomposing chloride of lime with hydrochloric acid; and we found this to answer our purpose. The apparatus we used was of a very simple nature. It consisted of a large well pitched wooden cask in which a hole was made near the bottom, and fitted with a plug, so that it could be easily emptied. In the top a square hole was cut, from which an earthenware jar was suspended by means of leaden straps. The square hole was closed with a perforated piece of wood, through which a leaden pipe was placed, reaching to the bottom of the earthen jar, the bottom of the pipe was partly cut away, so that liquid could run freely through it. A funnel was also fitted to the top of the pipe. Through another perforation in the top of the cask, a bent leaden pipe was fitted to serve as a delivery tube. This passed to a stoneware Woulfe's bottle. In using this apparatus, hydrochloric acid was poured into the cask. The necessary amount of chloride of lime was then mixed with water in a tub, so as to form a creamy fluid. This was then passed through the funnel into the hydrochloric acid by degrees, and, according as the chlorine was wanted in a rapid or slow current, the chloride of lime was added quickly or slowly. This process does not work well if the chloride of lime is placed in the cask, and the hydrochloric acid added, on account of the greater density of the chloride of lime. One advantage of this method of generating chlorine is that the amount can be easily regulated by the chloride of lime used. Of course, this is an expensive method of preparing chlorine, and we always intended putting down proper plant, with Weldon's arrangement for recovering the manganese; but our attention was then so taken up with other matters, that we kept putting it off, and continued to use chloride of lime until we gave up manufacturing. I should imagine this was the first instance of chlorine being prepared in large quantities in wooden tubs, and I have described it, as it might be useful to others who want a supply of this gas without loss of time.

For treating the anthracene with chlorine, leaden chambers were used, technically called "chlorine ovens." They were about 10ft. long, 4ft. 6in. wide, and 1ft. 6in. deep in the centre. The bottoms are flat until within about 1ft. 6in. of the end. They then gradually slope up about 6in., to the manholes at the ends. The doors of these manholes are slabs of wood covered with lead and held in their place by means of a cross-bar and screw. The lugs are connected with an iron frame, over which the lead is beaten. In the centre of the top are other openings for charging the ovens. They are provided with lids, made air-tight by means of hydraulic joints. The channels in these joints, however, were not filled with water, but by an impurity obtained in the manufacture, called "chlorine oils." At each end of these ovens, two lead pipes are inserted, one for the inlet of chlorine, and the other for the escape of hydrochloric acid and unused chlorine. These pipes are made to project into the ovens, to prevent the action of any "drip," which might otherwise injure the top of the oven. The top is strengthened by cross pieces of timber, fastened with leaden straps. The ovens were usually made of 20-lb. lead. The luting for the end manholes was made of china clay and chlorine oils.

When first made, these ovens were supported on solid brickwork, and it was found that by passing a good current of chlorine over the anthracene, sufficient heat was, by the chemical action, evolved to complete the process; if, however, the temperature was allowed to fall from an interrupted or slow supply of chlorine, the product partially crystallized, and the temperature could not be got up again sufficiently. The anthracene was, therefore, imperfectly chlorinated. To avoid this, a steam chamber was formed in the brickwork and covered by an iron plate, on which the oven rested, and in this way the temperature was always sufficiently maintained.

The hydrochloric acid gas which was formed in this operation, was condensed in coke towers, and the acid used again. The reaction may be written thus:—

$$\underbrace{C_{14}H_{10}}_{\text{Anthracene.}} + 4\,Cl = \underbrace{C_{14}H_8Cl_2}_{\text{Dichloranthracene.}} + 2\,H\,Cl.$$

It is, however, probably much more complicated. Chlorine when acting upon anthracene first forms a dichloride:—

$$C_{14}H_{10} + Cl_2 = C_{14}H_{10},\ Cl_2.$$

This substance is extremely unstable, and unless the temperature be kept near 0° C., decomposes as quickly as it forms, yielding monochloranthracene:—

$$C_{14}H_{10}Cl_2 = \underbrace{C_{14}H_9Cl}_{\text{Monochloranthracene.}} + HCl.$$

This substance, when meeting with fresh chlorine, is believed to combine directly, and form a dichloride of monochloranthracene:—

$$C_{14}H_9Cl + Cl_2 = \underbrace{C_{14}H_9Cl\ Cl_2}_{\text{Dichloride of monochloranthracene.}}$$

and, lastly, this, on decomposing, to yield dichloranthracene:—

$$C_{14}H_9Cl,\ Cl_2 = \underbrace{C_{14}H_8Cl_2}_{\text{Dichloranthracene.}} + H\,Cl.$$

Towards the end of the operation of chlorinating anthracene the chlorine is not all absorbed, and escapes into the air from the coke towers. This was not only a nuisance but also a loss. To avoid this the ovens were put up in pairs, and connected with a leaden pipe; both were charged with anthracene, but only one chlorinated. Any unused chlorine passing away with the hydrochloric acid over the anthracene in the second oven was thus absorbed. The next day the anthracene in the second oven was chlorinated, and the gases passed over the other one, which had been re-charged with anthracene.

The charge for each oven was usually about 400 lbs. of anthracene which had been distilled with potash, and of between 45 and 50 per cent. quality. On passing the chlorine gas into the charged ovens, the anthracene gets dark in colour and fuses,* hydrochloric acid being evolved in abundance. After a time, this fluid product begins to deposit crystals, and soon becomes a semi-solid mass. The operation occupies about five or six hours. When finished, the top manholes were removed, and a light wooden flue placed over them, and connected with the opening into the chimney shaft, the end manholes were then opened, and in a short time the excess of hydrochloric acid and chlorine in the ovens was drawn out. The crude dichloranthracene, which covers the bottom of the oven as a crystalline cake, was loosened by a wooden tool, and then drawn out with a wooden hoe into some convenient vessel. When broken up, the pieces of dichloranthracene appear as a mass of beautiful bright yellow interlaced needles.

* This is due to the chlorination of the impurities, the dichloranthracene being formed afterwards.

This product was next broken up with a wooden beater in tubs containing dilute caustic soda (it must not be ground, however), to remove adhering hydrochloric acid. It was then separated from the alkaline solution, and pressed between linen cloths in the hydraulic press, when a dark, thick, oily product separated out. This consists principally of chlorinated phenanthrene, holding in solution a little dichloranthracene and anthracene, and was called "chlorine oils." I shall have occasion to refer to these again presently.

After pressure, the dichloranthracene was obtained in hard yellow crystalline cakes, but not sufficiently pure for use. It was again broken, and allowed to soak in coal-tar naphtha* for some time, and pressed; this operation was again repeated. The adhering naphtha was then recovered by blowing steam through the product.

The dichloranthracene thus purified was afterwards placed on trays, and dried in a drying-room, and was then ready for the next process. It contains about 84 per cent. pure dichloranthracene.

The chlorine oils, and also the residue left after distilling the naphtha used for washing the dichloranthracene contains a certain amount of dichloranthracene and anthracene. This separates out to a considerable extent if the oils be cooled with ice, but the product is then so thick that it cannot be filtered or pressed.†

Experiments were made on distilling them alone, but owing to the copious evolution of hydrochloric acid, and the frothing of the product, it was not found practicable to treat them in this manner; but by previously mixing an excess of ground lime, and then distilling in iron retorts, a considerable amount of solid product came over containing about 25 per cent. anthracene, which only required to be treated with petroleum spirit to fit it for use. It is believed that the anthracene represents that which had not been chlorinated, the dichloranthracene being decomposed by distillation with lime.

The next process consists in converting the dichloranthracene into the sulpho acids of anthraquinone by treating it with ordinary concentrated sulphuric acid, and the ease with which this is effected was originally one of the advantages of the use of dichloranthracene over anthraquinone.

For this process iron pots were used, as they were found to answer nearly as well as glass, and, of course, were more manageable. As hydrochloric and sulphurous acids are evolved in quantity in the operation, special arrangements had to be made for conducting these away and condensing them. The apparatus used consists of a row of cast iron pots, capable of holding about 30 gallons. These are cast with half-covers, in which there is an opening for the escape of the acid vapours. Earthenware pipes are luted into these openings and connected with a large main, which leads to arrangements filled with coke and supplied with water for the condensation of the hydrochloric and sulphurous acids.

The pots are set in brickwork, and heated by a fire, the upper part being also surrounded by brickwork to prevent loss of heat, the open part of the pot is covered with a lid made of 20-lb. lead, which can be removed when they are emptied. In the centre of this lid an oblong hole, about 6 in. by 8 in., is cut, for the introduction of the dichloranthracene. This is covered by a piece of lead. There are also two small round holes in the lid; one for the introduction of a thermometer, the other as a testing-hole, and fitted with a wooden plug.

These pots were charged with 350 lbs. of sulphuric acid. This was then heated up to about 140° to 160°, and the dichloranthracene gradually added in small shovelfulls at a time, hydrochloric and sulphurous acid being evolved after each addition, causing frothing,

* Petroleum spirit does not answer well for this purpose.

† Perhaps a filter press might be used for this purpose successfully.

especially if the dichloranthracene be of a low quality or damp. The charge used was usually 70 lbs.

After all the dichloranthracene had been added, the temperature was gradually raised until it reached about 260° C., and then continued at this until a sample, taken out by a glass rod and diluted with water, formed a nearly clear solution, devoid of fluorescence. The fire was then drawn, and the product left to cool down until the next morning. It was then found to be still warm, of a brown colour, and the consistency of treacle. The lids being lifted off, it was ladled into copper pails, and carried away to be neutralized with lime.

In this process the following reactions take place:—First, disulphodichloranthracenic acid is formed by the union of the sulphuric acid with the dichloranthracene; and, secondly, this product is oxidized by the excess of sulphuric acid forming disulphanthraquinonic acid. These, however, are not the only changes. Anthraquinone is also formed, which becomes converted chiefly into monosulphanthraquinonic acid; some of it also sublimes, and then condenses in the earthenware main, through which the acid vapours pass.

When fuming sulphuric acid is used in place of the ordinary, no anthraquinone or monosulphanthraquinonic acids are formed.

Pure dichloranthracene, when treated with Nordhausen sulphuric acid, gives the theoretical yield of disulphanthraquinonic acid.

(To be continued.)

Parliamentary and Law Proceedings.

Alleged Death by Opium (?) Poisoning through eating Lettuces.

On Friday, July 19, Mr. C. Aspinall, Liverpool borough coroner, held an inquest on the body of John M'George, sixty-nine years of age. The deceased, who was said to have been a strong and healthy man, was seized with what appeared to be a bilious attack on Monday morning and died about two o'clock the same afternoon. On Sunday evening, at tea, the deceased partook of lettuce, of which the other members of the family had a share. After being taken ill on Monday morning he had some breakfast, but was found apparently in a fit at nine o'clock and was unable to speak afterwards. Dr. Fisher, Walton Road, Kirkdale, was called to the deceased on Monday morning, about half-past ten, and found him in a comatose state. The pupils of the eyes were much contracted, the face livid, the body cold, the mouth wide open, the limbs relaxed and the breathing difficult, all of which were symptoms of narcotic poisoning. The stomach pump was used and remedies prescribed, but without the desired result. Dr. Fisher said he had made a *post-mortem* examination of the body and found traces of opium in the stomach and enough of digested lettuce to account for the symptoms of opium poisoning. He was quite certain that the deceased had died from the effects of opium. In reply to a juror, Dr. Fisher said that the stomach would hold much more lettuce than would be sufficient to account for the traces of opium found. Dr. Anderson, who assisted the last witness in the *post-mortem* examination, said that in his opinion the deceased died from apoplexy, induced by narcotic poisoning. He thought it reasonable to attribute the presence of an opiate in the system to the lettuce deceased had eaten overnight. A very small dose of narcotic would affect an elderly person.

The jury returned a verdict that they were of opinion deceased had died from the effects of poison, but there was not sufficient evidence to show that it was attributable to eating lettuce.—*Liverpool Daily Post.*

Review.

Proceedings of the American Pharmaceutical Association at the Twenty-Sixth Annual Meeting, held in Atlanta, Ga., November, 1878. Also the Constitution, By-Laws, and Roll of Members. Philadelphia: Sherman and Co. 1879.

At an unusually late date the annual volume of the Proceedings of the American Pharmaceutical Association has come to hand. A partial explanation of its retardation is to be found in the postponement of the last annual meeting until November, in consequence of the prevalence of yellow fever in the Southern States last summer. The volume is very bulky, as it contains just one thousand pages, upwards of six hundred being occupied by the Report on Pharmacy, by Mr. Louis Diehl, which corresponds with the Year-Book of the British volume. This report is very copious. It is preceded by an Introduction and is divided into sections of "Pharmacy" (with subsections of "Apparatus and Manipulations," which is usefully illustrated, and "Preparations"), "Materia Medica," "Inorganic Chemistry" and "Organic Chemistry." The reporter has evidently spared no trouble to make his *résumé* of the history of pharmacy as complete as possible; in fact he has almost exceeded proper limits, for some of the authorities, which are carefully placed at the end of each quotation, date as far back as 1876.

The Reports of Standing Committees appointed by the Association to deal with special subjects always form an interesting feature of these volumes, and in the present one there are reports on the Drug Market, Legislation and the Revision of the Pharmacopœia. The last-named lays down the general principles which the Committee thinks should be followed in constructing the Pharmacopœia, and on a future occasion it is proposed to refer to them in this Journal in greater detail; it also contains a scheme for co-operative experiments on the fluid extracts.

The latter part of the volume is taken up with the papers read at the meeting, the discussions on them and the general business. The papers are many of them of much practical interest. As to the business, we regret that some embarrassment exists in the ways and means, due apparently to the commutation for life membership having been fixed at too low a rate at a time when the volume of proceedings, a copy of which is supplied free to each member, was not nearly so large and expensive as now. Several propositions were made, such as a kind of sliding scale of life subscriptions and a *per capita* tax, but after discussion the attempt to find a remedy was postponed until the next meeting, which is to commence in the city of Indianapolis, Ind., on the 9th of September.

Obituary.

Notice has been received of the death of the following:—

On the 4th of June, 1879, Mr. George Masson, Pharmaceutical Chemist, Grenada House, Torquay. Aged 30 years. Mr. Masson had been a Member of the Pharmaceutical Society since 1871, and on several occasions contributed papers to this Journal.

On the 8th of July, 1879, Mr. William Glencross, Chemist and Druggist, Kidwelly, Carmarthenshire. Aged 47 years.

On the 14th of July, 1879, Mr. William Powell, Chemist and Druggist, Bridgend, Glamorganshire. Aged 40 years.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[322]. "Anon" asks how I am able to make a "stable preparation" of tr. lyttæ, acid. sulph. dil., tr. lavand. co., and vaseline or prepared lard, as given in the formula by W. B., July 5? I enclose you two specimens of the ointment prepared with vaseline and lard. I need hardly say the mixture is mechanical, and the simplest way is to rub the tinctures, acid, and vaseline or lard together on a slab, using an ebonite spatula. The rubbing should be in one direction, as in making "Cold Cream." I have experienced no difficulty.

Northallerton. HY. BROWN.

[324]. In further elucidation of the question asked by "Gulielmus," and in reply to Mr. G. H. Wright, permit me to say I think the pharmacist is justified in dissolving such an alkaloid as morphine. It must be observed eight grains are ordered with one drachm of chloroform and three drachms of liniment of belladonna. Practically morphine is insoluble in chloroform, and cold alcohol dissolves only one in fifty. Now, Mr. Wright calls attention to the statement that the person who compounded the prescription first sent "twice the bulk." I observed that, but I had nothing to do with the fact. My object was to show that eight grains of morphine can be dissolved in three drachms of liniment of belladonna. I purposely leave out the chloroform at present. Sulphate of morphine is a very soluble salt, indeed the most soluble of the morphia series. Its solubility in boiling water is one in two. I must not enter into the molecular weight question, as it might be considered foreign; but I may observe that in my opinion it is more scientific to use a soluble salt of morphia than to apply morphine to the skin in the form of a fine powder, trusting to the acids of the sweat—formic, butyric, propionic, or sudoric—to combine with it so as to form an absorbable compound. Of course I cannot tell whether or not the prescriber knew the exact solubility of morphine. He evidently intended a strong solution, and one equal to eight grains of the alkaloid in four drachms of menstruum. I have shown how this can be accomplished without in any way interfering with the activity of the liniment, but rather increasing its curative properties.

If spirit, or water, or double the quantity of liniment of belladonna was added, so as to accomplish solution, by the first compounder, it is manifest the liniment would only be half the strength intended. I may inform Mr. Wright I did not overlook this point, but I had nothing to say upon it except that it was obviously wrong, and I therefore confined my remarks to "Gulielmus's" query.

HY. BROWN.

Queries.

[331]. Would some of your readers kindly tell me what should be the colour of the following when correctly dispensed?—

℞ Liq. Hydrarg. Perchlor., B.P. . . . ℥ij.
Liq. Arsenici et Hydrarg. Hydriod., (Donovan). . . . . ♏clx.
Infusi Gentian. . . . . ℥ij.
Aquæ . . . . ad ℥viij.
M.

W. R. ROBERTS.

[332].
℞ Acid. Tannic. . . . . gr. xx.
Gelatine . . . . gr. iv.
Aq. q. s.,
Glycerin . . . . ♏xvi.
M. ft. pess.

Will some of your readers kindly inform me if it is at all possible to make up the above as written; if not, how it should be dispensed?

It was written by a well-known London doctor, and has been presented at one of the co-operative stores to be made up. They refused to do it.

B. SAWYER.

Correspondence.

THE CONFUSION OF MEDICINE WITH PHARMACY.

Sir,—"The confusion of pharmacy with medicine which has come to the medical practitioners and the pharmacists of to-day is an inheritance from the apothecaries of last century. . . . . Therefore gratitude is due to any individuals or association that strive by any means to show the desirability of effecting, as far as possible, a separation of the duties of the dispenser from those of the prescriber."

The above quotation from your temperate and sensible "leader" in the Journal, July 12, cannot fail to arrest the attention of every one who sincerely desires to see the long vexed question set at rest, viz., shall chemists continue to be perpetually dragged into County Courts for an infringement of the Apothecaries Act of 1815?

The genus "homo," species "John Bull," is notoriously a physic-loving mammal. He has always preferred, and ever will prefer, to call at a "doctor's shop," no matter to him whether that establishment is under the jurisdiction of a L.A.S. of Blackfriars, or a M.P.S. of Bloomsbury Square, London, for help, advice and medicine in every little *malaise* that may befall him. No one can blame the man, and no sober minded person can find fault with the chemist who listens to a tale of suffering, proposes this or that dose, then makes it up and receives the money for his goods. If this is prescribing and violating the Apothecaries Act of 1815, the sooner such a condemnatory power is expunged from the statute book the better, for it is violated every hour of the year. A more unjust clause affecting the lower millions of our population could not exist.

As a veteran apothecary let me claim your gratitude if I point out briefly a ready method by which this frequent collision between the authorities at Blackfriars and the respectable chemists can be fully prevented in future.

The great increase in non-dispensing general practitioners throughout England, as shown by the Rochdale report of May 3, has tended to enable the lower classes to recognize only a "doctor's shop," by the presence of show bottles and nostrums displayed in the windows of our druggists, which were formerly the "sign posts" to the apothecary who dwelt within. Let the chemists seek to be legally permitted to prescribe behind the counter under the following restrictions—the xvii. and xviii. clauses of the Apothecaries Act will certainly aid them in the attempt.

After the Minor examination is over let the apprentice to the chemist devote two years of study, 1st to elementary anatomy and physiology with dissections; 2nd, to attendance on the out-patient practice of a recognized hospital, infirmary or dispensary throughout the country.

When such course is completed, let him present himself for the "assistant's licence" at the Apothecaries' Hall, where in addition to the present examination, his knowledge in visceral anatomy and the elementary principles of medicine shall be tested.

A short Bill in 1874 amended the Apothecaries Act (37 and 38 Vict. c. 34) and removed the apothecaries' apprenticeship. Let the pharmacist seek for a brief Act to acquire this privilege at the hands of the Executive at Blackfriars and all would be finally and amicably arranged.

The dental fee for special lectures and hospital practice required for L.D.S. is £31 10s. The chemist's outlay would not exceed £21.

The present law restricting the dispenser to work only in the premises would still remain untouched.

With these brief suggestions for the consideration of the large body of pharmacists and chemists in England, I would conclude by adding a quotation from clause xviii. of the Act of 1815:—

"Five apothecaries in any county or counties respectively throughout England and Wales, except within the said City of London, the liberties or suburbs thereof, or within 30 miles of the same . . . . shall have full power and authority and are hereby authorized and empowered to examine all assistants to apothecaries throughout the county or counties, in regard of which such apothecaries shall have been so appointed as aforesaid. . . . . The meetings shall take place monthly in some one of the county towns."

The whole wording of this clause xviii. sets forth the purpose of the Act to be one for the benefit of the public and of the dispenser also. AN APOTHECARY.

Sir,—In my humble opinion the time is fast approaching when pharmacists as a body should endeavour all in their power to wrest the dispensing of medicine entirely from medical practitioners, but it must be accomplished so that no loss shall be sustained by either side. In cases where doctors receive large fees for their advice, they are satisfied and do not require also the profit accruing from the sale of the medicine. In districts where they could only get small fees they would prefer not to give a prescription at all, but to vend their medicine and advice for one charge, as they do at present. I would suggest the following arrangement as regards the latter class of prescribing, viz., that the medical man should write his prescription and place a certain mark on it which would signify that when it had been dispensed it was to be returned to the writer of it or else destroyed, that in no case, unless otherwise specified, should the prescription be given back to the patient. By this means I do not think anyone would be at a disadvantage. The chemist would necessarily have to dispense these prescriptions at a very moderate rate, but he would gain by reason of the quantity. C. H. F.

GAS SUPPLY.

Sir,—I think we are all much indebted to Professor Redwood for taking up the very difficult subject of gas supply, inasmuch as we have found our gas account to increase a good deal without sufficient cause to show, and on a recent occasion I took the liberty of questioning the right of this increase. The result was that we disconnected our meter and sent it down to Westminster to be examined, the cost of which was only one shilling, and the meter was condemned for registering too fast.

I gather from this that it is quite within the province of any consumer to have his meter thus examined and tested, when, as in my case, the company would no doubt refund the difference and supply a new one.

I think, however, that there should be some more secure method, presenting less difficulty to the consumer, for correctly estimating the quantity of gas burnt, and thus in a simple manner to check the reading of the company's inspector at each quarterly visit. A. W. POSTANS.

MYRRH: ITS COMPOSITION AND IMPURITIES.*

BY R. H. PARKER.

The first market at which myrrh appears is Berbera—a small seaport town in Eastern Africa, nearly opposite Aden—where it is brought by the natives from the district about Hurrar and Somaliland. Here it is purchased by Aden agents (English and Indian goods being given in exchange) and shipped to Bombay. When sorted at the latter port, it is found to consist of all qualities of myrrh, together with opaque bdellium, foreign resins, such as juniper, and various other impurities (bark, stone, etc.).† The best selections are sent to Europe, the commoner to China, where it is probably used as incense.‡ Bales of bdellium also appear at Berbera, consisting the opaque and perfumed kinds (bissa bôl).

Since myrrh is collected by uncontrolled natives, who probably know very little and care less about the quality of the gums taken to Berbera, it is not surprising that spurious gum resins and foreign substances find their way into English markets.

The sorting at Bombay is by no means carefully conducted and leaves a great deal to be picked out by London wholesale houses and dealers. Here it is of course most efficiently done and the best parcels of "Picked Turkey Myrrh" contain but a very small proportion of impurity.

Myrrh is first sifted in order to remove the small fragments and is then sorted by hand; still, however, pieces of spurious gums will occasionally find their way into the best parcels. I will, therefore, first describe myrrh and afterwards individually the various substances which occur in bales of the drug as imported, viz.:—

1. Opaque bdellium.
2. African bdellium.
3. Bissa bôl (perfumed bdellium).
4. Indian bdellium.
5. Perfumed amyridaceous (?) gum resin.
6. Odourless amyridaceous (?) gum resin.
7. Opaque tasteless gum.
8. Bitter gum.
9. Transparent gum.

The relative preponderance of these varies considerably. Mr. E. M. Holmes found, in 1876, opaque bdellium in largest quantity, next, Indian bdellium, and third, bissa bôl. At the present time in one bale of unpicked myrrh I found African bdellium chiefly, next, opaque bdellium. Of the "spurious gums" picked out from another bale, opaque bdellium constituted about one-third, the remainder being opaque tasteless gum, transparent gums and odourless amyridaceous (?) gum resin. Very little bissa bôl or Indian bdellium occurred in any of the bales I examined.

The substances thus rejected are commercially valueless.

Myrrh and its impurities are readily distinguished by observing—

(1) The characters of the fracture,
(2) The odour, and
(3) The taste.

African Myrrh "Heera Bôl," the "Turkey Myrrh" of commerce.

Botanical source, *Balsamodendron Myrrha.** This may be divided into "soft or oily myrrh" and "dry or gummy myrrh."

"Soft myrrh" occurs in irregularly roundish masses, varying in size from small grains to pieces as large as a hen's egg and occasionally much larger; it has a dull waxy fracture, is readily impressed by the nail, and gives at the same time an oily exudation. The fracture frequently exhibits whitish markings, which in the more globular pieces appear in narrow curved streaks arranged concentrically to the side which was attached to the tree. They are often broad but do not then exhibit the straight interstices or cracks filled with transparent resin characteristic of bissa bôl. The fragrant odour of myrrh is too well known to need description and differs entirely from that of any of the impurities. The taste resembles the odour, it is aromatic and slightly bitter. The colour varies from deep reddish brown to light yellowish brown, some pieces are almost colourless. The paler kinds are to be preferred. Minute transparent resinous tears sometimes appear on the usually powdery surface, due to the exudation of oil which has resinified. Soft myrrh cannot be reduced to a fine powder; indeed if beaten in a mortar for some time it gives a greasy paste.

"Dry myrrh" occurs in masses having a very irregular surface, it is rarely rounded or globular. The fracture is conchoidal, shiny, resists the nail and gives no oily exudation. In odour and taste it agrees precisely with "soft myrrh," but the white markings usually present in the latter are absent. It contains a large percentage of gum (75 per cent.). From the description in 'Pharmacographia,' p. 129, this would appear to be identical with Arabian myrrh, but examination of the specimen in the Hanbury collection proves the latter to differ; it is in small grains or tears, dark coloured, with an almost glassy surface, the larger pieces being formed by agglomeration of the smaller ones. It also is wanting in odour and the powdery exterior of African myrrh.

The "meetiga" of the Bombay market, called Arabian myrrh by Dymock,† differs entirely from either "dry myrrh" or Hanbury's "Arabian myrrh." ‡

The "soft" and "dry" myrrhs, as above described, are very distinct and would almost suggest their being produced by different varieties of *Balsamodendron myrrha*; but since (1) the chemical characters of both resins and gums agree (as shown subsequently), (2) the odour and taste are identical, and (3) the relative percentage of gum is by no means constant, it seems more probable that they are products of the same variety, but from plants either of different ages, or existing under dissimilar climatic conditions.

It is possible that the same tree may, at different seasons of the year, give exudations as unlike as "soft" and "dry" myrrh.

That "soft myrrh" is not converted into "dry myrrh" by long exposure to air is proved as follows:—

(1) The "drying" consists in oxidation of the oil, which would give increased weight § and therefore a relative increment of *resinous* percentage. Now,

† *Pharm. Journ.* [3], vol. vi., p. 661.

‡ See 'Museum Catalogue,' 139c and 139f.

§ 3·325 grams of soft myrrh in thin shavings exposed to the air for three weeks weighed 3·506; an increase equal to 5·4 per cent.

"dry myrrh" has a very much higher *gum* percentage (*vide* subsequent table). The loss of water, if such take place, must be so small that the difference would in no way be explained by it.

(2). In a non-porous body like myrrh, oxidation would be confined to the surface. I have never found a piece of "dry myrrh" with a "soft" interior; on the other hand, a very small *tear* of "soft myrrh," not more than one-eighth of an inch in thickness, which must have been exposed to the atmosphere ever since its exudation, proved on fracture to be very soft and oily *close beneath the surface.*

"Spurious Gums" found in Myrrh as imported.

1. *Opaque Bdellium* (*Balsamodendron Playfairii?*).—Identical with the bdellium opaque, of Guibourt.* Dymock's specimen, however, of opaque bdellium, is *a very brittle* opaque gum, which agrees chemically with the "gum hotai" of Vaughan, but is rather darker coloured, Vaughan's specimen being white. The latter is identified in the Hanbury collection as the gum resin of *B. Playfairii.*

Opaque bdellium may be at once recognized by its *opaque*, yellow-ochre coloured, conchoidal fracture; it resists the nail. It is very hard and difficult to fracture (difference from "gum hotai"), almost odourless, and its taste bitter without acidity. Occurs frequently in large elliptical tears with a coarsely granular surface.

2. *African Bdellium* (*Balsamodendron Africanum*) is met with in large tears like opaque bdellium, but the granulation is less coarse and the surface is traversed by deep cracks. It is very hard; the conchoidal fracture appears slightly opaque, of a dull bluish stony hue, with a characteristic resinous margin; it is reddish and *translucent* in thin layers, almost odourless, and its taste feebly bitter.

3. *Bissa bôl* (*Balsamodendron Kafal ?*), is identical with the perfumed bdellium or "hăbăk hādee" mentioned by Dymock; the "hebbakhade" of the Somalis, and the *Myrrha Indica*, of Martiny. Bales of "bissa bôl" are shipped from Berbera to Bombay; probably a large proportion of it goes to China,† where it is used as incense and, according to Dymock, is mixed with the food of milch cows and buffaloes for the purpose of increasing the quantity and improving the quality of the milk.

"Bissa bôl" resembles myrrh much more closely than either of the bdelliums previously described. In external appearance it is very similar, the fracture is waxy, yields to the nail, giving an oily exudation like "soft myrrh;" yellowish white markings also appear, which, however, differ essentially from those of myrrh in being traversed by angular interstices filled with transparent reddish brown resin (or gum resin). It may be readily distinguished by its powerful aromatic odour, totally unlike myrrh, difficult to describe (perhaps because nothing resembles it), but easily recognized after one introduction to the olfactory nerve. It has been likened by Mr. Holmes to the taste of the spring mushroom (*Agaricus gambosus*), by Dymock to the odour of "lemon lollipop;" when diffused by evaporating the tincture on blotting paper, it is somewhat apple-like. The taste is aromatic and slightly bitter.

4. *Indian Bdellium* (*Balsamodendron Mukul* and *B. pubescens*), or "Googul," collected in Deccan.

* 'Histoire des Drogues,' tome iii., 515.

† A specimen of bissa bôl appears in Hanbury's collection of Chinese drugs.

Occurs in large irregular masses of a dark reddish brown colour. The fracture resists the nail and is covered with characteristic minute shiny points of resin, which also appear on the outer surface. The odour is feeble and cedar like; it appears to be developed on keeping. The taste is slightly acrid and devoid of bitterness.

5. *Perfumed Amyridaceous* (?) *Gum Resin.*—This substance does not appear to have been previously described,* but I have found a few pieces of it in parcels of myrrh obtained from different sources. In external characters it somewhat resembles olibanum or tacamahac, the colour varies from light yellowish brown to light yellow, more translucent than myrrh, some pieces being transparent in mass. It has a waxy fracture, and from the presence of minute cavities filled with oleo-resin of treacly consistence, numerous silky strings join the fractured portions as they are pulled asunder. It is cheesy to the nail, softens in the hand and is very sticky. The odour is powerful, resembling some samples of elemi, but is more pleasantly aromatic. The taste is slightly aromatic without bitterness or acridity. When crushed in a mortar it gives a very adhesive paste. It is not entirely soluble in ether, alcohol, turpentine or chloroform.

6. *Odourless Amyridaceous* (?) *Gum Resin.*—This I have found in considerable quantity; it has a bright yellow powdery exterior similar to the last mentioned gum resin, is very brittle, resinous and mostly transparent. It lacks, however, the cheesy character, the stringy fracture, and is odourless and almost tasteless.

7. *Opaque Tasteless Gum* occurs in irregular tears. It is very hard, fracture dull, somewhat opaque, nearly colourless, odourless and devoid of taste.

8. *Bitter Gum.*—This is more transparent than the last; the colour varies from reddish brown to almost colourless; its very bitter and acrid taste recalls ammoniacum.

9. *Transparent Gum.*—Very variable in appearance, but seems closely to resemble the inferior kinds of acacia gum in colour, taste and glassy fracture. Some pieces of white acacia gum frequently occur.

Composition of Myrrh.

The proximate constituents are—

(1). Resin (two according to Brandes).

(2). Two gums (one precipitable by both lead solutions, the other thrown out by subacetate only).

(3). Essential oil.

The very variable relative proportion in which these occur is best seen by reference to different authors.†

* The nearest approach to this substance is the *Tacamaque jaune huileuse*, of Guibourt, ('Drogues Simples,' 1870, tome iii., 483), the Luban Meyeti of the 'Pharmacographia,' p. 135; but this author says it contains no gum. Now, 42 per cent. of perfumed amyridaceous gum resin is insoluble in cold or hot S.V.R., and dissolves to a large extent in water; the latter solution, however, is scarcely precipitated by acetate or subacetate of lead.

† Planchon, 'Drogues Simples,' tome ii., 156.

Gum.—I have estimated the percentage of gum in different samples of myrrh, the results I have tabulated:—

	1. Myrrh.		2. "Soft Myrrh."		3. "Dry Myrrh."		4. Bissa bôl.		5. Amyridaceous perfumed gum resin.	
Filter and gum	6·73	6·95	5·45	5·54	9·15	9·11	6·13	6·01	6·05	6·03
Filter	2·09	2·33	1·50	1·55	1·65	1·60	1·80	1·72	1·82	1·77
	4·64	4·62	3 95	3·99	7·50	7·51	4·33	4·29	4·23	4·26
Gum, mean per cent	46·3		39·7		75·0		43·1		42·4	

Ten grams of the gum resin were powdered, exhausted with cold rectified spirit, the insoluble gum collected on a weighed filter and dried in a hot air chamber till the weight became constant.

In each case the figures were checked by duplicated experiments.

1. *Myrrh.*—A representative sample of a large parcel of myrrh, powdered and well mixed.

2. "*Soft Myrrh.*"—Very oily pieces selected, the outer portions rejected; was almost pasty when powdered.

3. "*Dry Myrrh.*"—Characteristic specimen with bright glossy hard fracture, easily reduced to a light yellow powder.

4. "*Bissa Bôl*" obtained from a parcel of myrrh, outer portion *not* removed, powder very yellow and oily.

5. *Perfumed Amyridaceous Gum Resin.*—Specimen picked from parcel of myrrh, formed a very sticky paste when crushed.

Equal weights of the dried gums from "soft" and "dry" myrrh were separately dissolved in equal volumes of water; the filtered solutions were precipitated by neutral acetate of lead, again filtered and solution of subacetate of lead added; the amount of precipitates in the parallel experiments were approximately identical.

Resin.—Brandes distinguishes two resins, (1) a soft resin, odorous, and (2) a hard resin (myrrhic acid), inodorous, both soluble in rectified spirit and insoluble in ether.

Unverdorben regards the soft odorous resin as a mixture of the hard resin with volatile oil.

Volatile Oil, sp. gr. ·988, b.p. 266° C.—Flückiger and Hanbury in working on 25 lb. of myrrh obtained only $\frac{2}{3}$ per cent. ('Pharmacographia,' p. 128); Bley and Diesel produced 3·4 per cent.

If the liquid which exudes on pressing "soft myrrh" with the nail be volatile oil, a much larger proportion than 3 per cent. must be present.

The following experiments were tried with the object of obtaining a greater percentage:—

(1). A sample of soft myrrh was made into a thin paste with water and distilled in a current of hydrogen. The result was similar to that obtained by distillation with water in atmospheric air, viz., a very small quantity of nearly colourless oil, lighter than water, together with white flocks of a substance of butyraceous consistence, also lighter than water, but becoming heavier than it by prolonged contact.

(2). Some soft myrrh was macerated in a small quantity of chloroform and the filtered solution distilled; the chloroform came over rapidly and the residue soon acquired an empyreumatic odour.

(3). Soft myrrh was treated with a small quantity of benzole and the filtrate allowed to evaporate spontaneously. The residue, however, soon became very viscid, proving that the solvent did not separate the oil from the resin.

(4). About twelve ounces of "soft myrrh" were selected, reduced in a mortar to a pasty consistence, and subjected to powerful hydraulic pressure; a reddish yellow liquid, of thin treacly consistence, heavier than water was expressed; it is probably volatile oil holding resin in solution, if so, the quantity obtained (about an ounce and three-quarters by weight) would indicate at least 10 per cent. of oil in the sample. I obtained a similar liquid some twelve months since in making an emulsion of myrrh:—One ounce of myrrh was powdered (the odour indicated contamination with bissa bôl) and rubbed with ʒij of water, the gum at once assumed a doughy consistence, from which ʒiij of liquid was readily expressed by the pestle. This mixture (of oil and resin) was reddish brown, heavier than water and very slowly distillable therewith; the distilled oil was lighter than water, but on prolonged contact became a heavier solid. Removed from the water and allowed to dry it formed a transparent brittle resin.

I have several times endeavoured to repeat this experiment with myrrh *free from bissa bôl*, but could in no case get any exudation.

The expressed liquid is possibly that mentioned by Pfaff* as being "heavier than water and not distillable therewith." Brandes describes a volatile oil also heavier than water and distillable therewith, but not with alcohol.

The specimen of oil of myrrh in the Society's museum, prepared at Plough Court (1873), is a light yellow mobile liquid.

Formic acid is said to be produced during distillation.

From the above it appears probable that a large quantity of volatile oil exists in myrrh, only a small proportion of which has, as yet, been isolated, on account of its high boiling point (266° C.) and the readiness with which it is decomposed or resinified by contact with air and moisture at a high temperature.

Probably distillation *in vacuo per se*, or distillation under reduced pressure in an atmosphere from which oxygen would be excluded might prove the correctness of this assumption. *The colouring matter of myrrh* is probably due to the presence of a small proportion of a deep reddish brown resin, which is almost absent from the paler specimens.

The action of nitric acid at once distinguishes true myrrh from any of the "spurious gums" that have been mentioned. It is best observed by saturating white filter paper with the freshly prepared tincture (1 of gum resin and 6 of sp. rectif.), and when the alcohol is almost entirely dissipated, drawing across the paper a glass rod previously dipped in nitric acid (sp. gr. 1·42). True myrrh gives an *immediate* deep yellowish-brown colour, rapidly becoming almost black. The margin soon acquires a red tint, passing through bright crimson to dull purple, which is permanent.

The presence of alcohol of course modifies the action of the acid; the latter should be applied when the alcohol has evaporated, and yet avoiding undue exposure of the dried resin to air, *i.e.*, when the paper begins to recover its stiffness.

The resins from bissa bôl and African bdellium

---

* 'Gmelin,' xiv., 413.

are much less powerfully acted upon; those from the remaining impurities give scarcely any colour at all.

A few drops of the tincture evaporated on glass also give distinctive features. The residues from perfumed amyridaceous gum resin, opaque and African bdelliums, are *opaque;* those from myrrh and bissa bôl are *transparent.*

I cannot conclude without expressing my obligation to Mr. E. M. Holmes for much of the information given in this paper and a great deal of valuable assistance with reference to the history of authentic specimens of the gum resins in the Society's museum.

PHARMACEUTICAL EXTRACTS.*

CRITICAL CONSIDERATIONS UPON THEIR PREPARATION, CLASSIFICATION, GENERAL CHARACTERS, USES, ETC.

BY E. SCHMITT,

Professor of Medicine and Pharmacy at Lille.

The extracts are very important preparations, nevertheless but little is generally known concerning their *raison d'être,* their different modifications, the very diverse modes of their preparation, and their general or specific characters. I shall attempt in this paper to make a study of them under all these aspects, and in order to do so logically I shall proceed as follows: first, define an extract, then describe the origin and advantages of extracts, give the general rules of preparation, indicate the classification of the extracts and finish by giving their general characters.

I. An extract is the product of the evaporation of a natural or artificial juice to the consistence known as "the consistence of an extract," *i.e.,* a paste that is soft, but nevertheless sufficiently firm not to run like a liquid or adhere to the well dried fingers. This primitive definition can in the present day no longer be applied; the consistence of the extract is more variable; thus, the Codex indicates three different types, when it says, "The extract is the product of the evaporation to a soft, firm or dry consistence, of a solution obtained by treating a vegetable substance with a vaporizable menstruum, such as water, alcohol or ether."

Some operators define the extract in a manner more simple still: to them it is the product of the evaporation of aqueous, alcoholic, ethereal or acetic liquids to a pasty consistence. Whatever may be the definition adopted, the extract may be characterized by two essential conditions: the concentration of a medicinal liquid (a natural or artificial juice) and a special consistence to which I shall refer further on.

All the juices, and the juices of indigenous plants especially, contain within themselves germs of fermentation and destruction; they are besides exposed to a second alteration, due to external agents of decomposition. In concentrating the juices, their volume is diminished, the causes of internal decomposition are modified or destroyed and less access is permitted to external agents of fermentation; the causes of disorganization of the juice are thus diminished. Preservation is the primary object of the preparation of an extract; but it is not the only one, for the syrups, wines and tinctures answer to the same want. In concentrating the juice the pharmacist also, by successive operations, effects the removal from the liquid of useless and inactive matters, the albumenoid, pectic and amylaceous principles, for example. Lastly, the extract offers to the medical man a preparation that is active in a small volume, capable of reproducing immediately in a mixture or a syrup, the original juice with all its active elements and also lending itself with a marvellous facility to other pharmaceutical preparations, such as pills, pastes, pomades, etc.

To recapitulate, the extracts supply in a small volume the medicinal principles of plants and animals, and they include all the soluble elements of the plant or animal to the exclusion of inert principles. The active principles are moreover modified in such a manner that they can be better borne, and in higher doses, as has been demonstrated with the squill and digitalis. Further the extract is a good active preparation accommodating itself to all pharmaceutical forms. One single shadow there is to this picture: the preparation of an extract is a delicate operation and its preservation for any length of time is difficult.

II. We are thus led to study in a general way the preparation of extracts. Some among them,—the commercial extracts, aloes, catechu, kino, etc.,—are supplied by the druggists, all the others ought to be prepared in the laboratory of the pharmacist.

When operating with a natural juice it may be concentrated immediately or after clarification: we have thus two kinds of juice extracts, the extract from defecated juices and the feculent or non-defecated extracts, called also Storck's extracts. Sometimes there is incorporated with the fresh juice as much powder of the plant as there is real dry extract in the juice and evaporation is carried on to dryness at from 40° to 50° C., extracts being thus obtained under the form of grumous dark-green powders. In this way are prepared the narcotic extracts of the Belgian Pharmacopœia (aconite, belladonna, conium, lactuca, etc.). These extracts are very active, but are difficult to preserve, so that the pharmacist ought to renew them every year. The name of "rob" is given to the product of the evaporation of the juice of fruits; for instance the robs of buckthorn, juniper and elder.

The natural juices are rather rare: the questions of locality, collection and time interfering with their preparation. In order to obviate this inconvenience the pharmacist prepares artificial juices by treating the dry products with menstrua capable of dissolving their active principles. When the menstruum is vapourizable the artificial juice can be concentrated, and we have then a new series of extracts, the aqueous, alcoholic and ethereal. To these may be added the acetic extracts, of which at present there are but two representatives,—the acetic extract of colchicum and Lalouette's acetic extract of opium,—notwithstanding the efforts of Ferrari to extol the extracts prepared with vinegar. Finally there are the mixed extracts, in the preparation of which ether and alcohol and water and alcohol have been employed as menstrua successsively, as is done with the cubebine of Labélonye and the ergotine of Bonjean.

In all the extracts it is necessary to commence with the study of the juice, then its concentration. Let us commence with the aqueous extracts, which ought always to be supplied when the medical man does not specially indicate the alcoholic or ethereal extract.

Whatever may be the menstruum the substance ought always to be well divided, either by cutting or by coarse pulverization; it is necessary to eliminate carefully the fine powder which would interfere further on with the decantations and filtrations. Thus prepared, the primary substance is exhausted by maceration or digestion, infusion or displacement with distilled water, when that is ordered, or at any rate with water very poor in carbonate of lime. Maceration is effected between 10° and 20° C., for opium and gentian, for example; digestion between 35° and 40° C., for cinchona. Infusion is made with water at 70° C., for digitalis, the extracto-aromatic plants, and valerian root; but these extracts ought to be replaced by alcoholic extracts, which are very superior to them. Displacement is recommended for extract of liquorice, and with me it has succeeded very well for extracts of guaiacum and couch-grass. Decoction I reject, because it determines the coagulation of albumenoid matters in the substance itself, and prevents the solution of some prin-

* *Répertoire de Pharmacie,* vol. vii., p. 249.

ciples which, like astringent principles, form with vegetable albumen and starch insoluble compounds.

The product of these operations is thrown upon a cloth or hair sieve, and the liquid thus separated is reduced to one-third by evaporation; the evaporation can be conducted over the bare fire, ebullition being avoided and the liquid stirred continually. When reduced to one-third the liquid is removed to another vessel and placed in a cellar or some other cool place where it is left to stand two or three days, after which it is decanted or filtered if necessary. The juice is then ready for further concentration.

The alcoholic and ethereal extracts are prepared by maceration or displacement with 60° to 90° alcohol, ether, or ether containing alcohol. The clear tincture is introduced into a distillatory apparatus to collect the greater part of the alcohol or ether, and concentration is effected generally as with the aqueous extracts. The evaporation of all these liquids is carried on in a water-bath; the temperature ought not to exceed 80° C. for alcoholic extracts and 50° C. for ethereal extracts. It is advisable to operate in flat vessels having a large surface but of small capacity; to add the liquid in portions and in proportion as evaporation goes on, and to agitate constantly to favour the disengagement of vapour and to prevent the adherence of the extract to the bottom of the vessel. The action of heat is continued until the attainment of the proper consistence, which it is proposed to define more closely than in the Codex.

Formerly, only the "consistence of an extract" was known: the Codex only specified that the paste should be soft, firm, or dry. The following scale of consistence for extracts is now proposed:—

(1) "Soft or semi-fluid extract," the *mellago* of the Germans, of the consistence of fresh honey.

Examples: The ethereal extracts of male fern, mezereon, semen contra and cantharides; the alcoholic extract of thapsia and the "robs."

(2) "Firm extract," *extractum spissum*, of the true consistence of an extract, not capable of running, like the preceding, when cooled, but allowing threads to be drawn from it by the spatula. Examples: the extracts of cinchona, valerian and gentian.

(3) "Pilular extract," *extractum spissius*, much firmer than the preceding, no longer yielding threads and capable of being used in the manufacture of pills without the incorporation of powder.

(4) "Dry extract," *extractum siccum*, capable of being pulverized. Examples: the extracts of rhatany, monesia and cinchona (Lagaraye's "sel essentiel"). To these may be added the resinous extracts or resins (jalap and scammony), which are in fact alcoholic or mixed extracts, and should not be placed in the same category as Burgundy pitch, tar and the gum resins.

To bring the extract to the dry consistence it is evaporated to the point when the mass becomes friable upon cooling; it adheres no longer then to sized paper, and it may be spread while hot with the spatula upon sheets of paper having the edges turned up. The drying is finished in a stove at between 40° and 50° C. The product is then coarsely powdered and introduced into previously heated glass flasks, the mouths of which are closed with good corks.

The soft, firm and pilular extracts are also placed in flasks, or tall porcelain pots having narrow openings.

All extracts should be kept in a dry and cool place.

These general rules having been laid down some modifications of the *modus operandi* will be described.

Extract of opium is re-dissolved in water and again filtered. This fresh aqueous solution has for its object the elimination of fatty or aqueous matters, wax or substances analogous to caoutchouc, which have been taken up in the first treatment, partly on account of their abundance and partly through the presence of other principles, such as sugar, gum and extractive matter, which favour their solution.

The operator often desires to retain these resinous or resinified matters in the extract, but at the end of the operation they separate from the extractive (the total of the parts soluble in water) and the result is an extract of bad consistence and without homogeneity; the defect is corrected by incorporating in the mass, at the last moment, a little alcohol, as recommended in the Codex for extract of guaiacum, and in the Belgian Pharmacopœia for the dry extract of cinchona.

Dry extracts less alterable and more easy to preserve may be obtained by incorporating in the mass, while still hot, vegetable powders or dextrin and finishing the drying in a stove at between 40° and 50° C. Extracts containing dextrin are prepared principally in Germany from the narcotic juices and the quantity of excipient added equals in weight the amount of real extract. It is only necessary then in making up prescriptions to use of these extracts double the quantity prescribed by the physician.

A few words more upon mixed extracts requiring the employment successively of several menstrua. The cubebine of Labélonye and the ergotine of Wiggers are prepared by treating with alcohol the ethereal extracts of cubebs and ergot; the extracts are thus freed from waxy and fatty matters which are inert or even dangerous. Bonjean's ergotine is obtained by treating the aqueous solution of ergot with 90° alcohol, which precipitates gummy and albuminous matters and the salts insoluble in alcohol; the preparation is twice as active as the ordinary aqueous extract. Dausse has proposed the successive treatment with ether, alcohol and water for the exhaustion of the extracto-aromatic plants. Mohr also recommends this mixed treatment for the preparation of the narcotic extracts. According to this learned operator the purified juice ought to be evaporated to the consistence of a syrup, then treated with anhydrous alcohol, which precipitates the gums and insoluble salts; the alcoholic liquid should then be evaporated to the consistence of an extract. Mohr's extracts are very active and are easily preserved. The resins of jalap and scammony may also be included in the category of mixed extracts.

In the laboratory of the pharmacist the concentration of the juices is effected by the action of heat: to accelerate the preparation of the extract and prevent prolonged contact with the air it has been suggested to operate in a vacuum. The preparation of extracts, in consequence of the apparatus this would require, would then necessarily become industrial, which ought not to be encouraged. Extracts should be prepared by the pharmacist; they are very active medicinal agents upon which the medical man ought to be able to depend, and notwithstanding the authority of such names as Grandval, Berjot, Dausse and others, I always prefer the extract prepared in a pharmacy, for the following reasons:—The dry extracts prepared in a vacuum are very hygrometric; after a very short time and by simple contact with the atmosphere they form a mass more or less elastic and difficult to manipulate. Also, it is very easy for an isolated pharmacist to collect the two or three kilograms of the substance which he requires for the preparation of his extract, but would it be possible to find the hundreds and thousands of kilograms required for an industrial manufacture in good condition and of certain origin? The analysis of extracts is very little understood; the adulteration of commercial products is therefore too easy to execute and impossible to detect. Lastly, it has not been proved, so far as I know, that the extracts prepared in a vacuum have a therapeutic value superior to that of the extracts prepared by the ordinary method.

The following process appears to me to be preferable:—Quite recently an attempt has been made to substitute the action of cold for that of heat in the concentration of juices, and extracts have been prepared by congelation. This congelation may be effected by the cold of winter or by means of well-known apparatus, such as Carré's. It is advisable not to purify the juices of plants or fruits before proceeding to congelation, for the coagulation of the vegetable albumen takes up much of the active principle, which is then wanting in the extract. The juice is submitted to two or three successive congelations, the frozen juice is broken up, put into a linen or hair bag, and then strongly pressed. The concentration is such that the evaporation of the juice may be finished by putting it on plates in a stove heated to 30° C. The alteration of the juice is much less than by the ordinary processes, and extracts of rhatany, catechu and aloes are obtained which are perfectly soluble.

This process, employed by myself in the preparation of medicinal diastase, has given excellent results in respect of the yield as well as the quality of the product. Some milk after three congelations had lost 57 per cent. of its original volume; its density had increased from 1032 to 1108, and by exposure on a plate to the sun this milk gave a very fine dry extract.

The question of yield ought also to occupy the attention of the pharmacist; this is treated of in the Codex, p. 433, in a table very well drawn up. I would only wish to add to this table a column in which the figures 1, 2, 3, 4, should indicate to the operator the degrees of consistence, from the semi-fluid to the dry extract. The consistence is moreover strictly correlative to the yield, without which it has no practical value.

I should like to see the preparation and employment of dry extracts more extended. Whether prepared by immediate desiccation, or by incorporation of vegetable powders or of dextrine, these extracts are better for preservation and they are more certain from a posological point of view. The German Pharmacopœia orders several extracts to be dry which in French pharmacies are kept soft. For example, take the extract of opium: in Germany it is the powder of opium which should contain 10 per cent. of morphia, and the dry extract 20 per cent. These requirements are certainly very reasonable; in the Codex it is absolutely indispensable to indicate the amount of water which opium and its extract may contain. The same remark applies to all the extracts of soft or firm consistence. In Germany, besides opium, the dry extracts are those of aloes, colocynth (simple and compound), campechy, calumba, myrrh, nux vomica (aqueous and alcoholic), rhatany, compound rhubarb and senega. The narcotic extracts dry and containing dextrine are often demanded; they are besides necessary for the preparation of the compound powders.

I have intentionally omitted to speak of the fluid extracts, the use of which has spread so rapidly in England and America. I think, and I hope to prove subsequently, that the fluid extracts ought to be excluded from medicinal use.

It now remains to treat of the general constitution of the extracts, their classification, and their general characters.

(*To be continued.*)

RECENT CONTRIBUTIONS TO THE HISTORY OF DETONATING AGENTS.*

BY PROFESSOR ABEL, C.B., F.R.S.

(*Concluded from page 70.*)

In comparing the effects of these nitro-glycerine preparations with each other and with compressed gun-cotton and preparations of it, by detonating equal quantities quite unconfined upon iron plates, the results appear to establish great superiority, in point of violence of action or destructive effect, of the more rigid explosive agents (the gun-cotton preparations). Thus, employing iron plates 1 inch thick (supported upon an anvil with a central cavity), and 4 oz. of each material unconfined, the charges being all about the same diameter, exploded by detonators of equal strength, and simply resting upon the upper surface of the plate, compressed gun-cotton produced a considerable indentation of the upper surface of the plate, and long cracks in the lower surface; a species of nitrated gun-cotton, called tonite, produced a much shallower indentation, though still a very marked one, but did not crack the lower surface. Dynamite produced only a very slight impression upon the plate, and none could be detected by the eye on the plate upon which the blasting gelatine was exploded. The difficulties, brought out by past experience, which attend the contrivance of really comparative tests of the explosive power of such substances as those under discussion, is well exemplified by the foregoing results, which were influenced to the maximum extent by the physical characters of the several substances when applied, as they were upon these iron plates, in a perfectly unconfined condition, so that the particles were free to yield to the force of the initiative detonation in proportion to their mobility. But, for this very reason, these experiments afford excellent illustration of the extent to which the development of detonation and the sharpness of its transmission through the mass is influenced, not only by the inherent sensitiveness of the substance to detonation (or by its chemical instability) but also by the degree of proneness of their particles to yield mechanically to the force of a blow as applied by an initiative detonation. Thus, although in comparing two substances of similar physical characters, compressed gun-cotton and compressed nitrated gun-cotton or tonite, the superiority of the pure compound over the mixture, in point of sharpness and violence of action, is well illustrated, a comparison of the result furnished by the weakest of the four explosive agents tried, viz., tonite, with that of the substance which should be superior to all the others in explosive force (*i.e.*, the blasting gelatine) demonstrates the important influence which the comparatively great rigidity of the mass in the one case exerts in favouring the completeness and sharpness of its detonation in open air, and the great disadvantage under which the other explosive is applied, arising out of the plastic and therefore readily yielding nature of the material. But if, by exposure to a moderate degree of cold, this plastic nitro-glycerine preparation is made to freeze (for it partakes of the property of the liquid itself of freezing at a temperature above the freezing point of water, and becomes thereby converted into at least as rigid a substance as the two descriptions of gun-cotton) its detonation upon an iron plate produces an indentation, as well as a destructive effect upon the lower surface of the plate, very decidedly greater than those furnished by the corresponding amount of pure compressed gun-cotton. Similarly, the effect produced by the detonation of dynamite upon a plate of the kind used, is but little inferior to that of gun-cotton, and decidedly greater than that of tonite, if it is employed in the frozen condition.

A series of experiments has been made with cylinders of lead having a central perforation 1·3 inch in diameter extending to a depth of 7 inches, and leaving solid metal beneath of a thickness ranging from 3·5 to 5·5 inches, according to the size of the cylinders used. These furnished results of considerable interest as illustrating the action of these several detonating agents. Charges of 1·25 oz. of each explosive substance were used throughout the experiments, and were placed at the bottoms of the holes. By the detonation of the charges the cylindrical holes in the lead were enlarged into cavities of a pear shape (and sometimes approaching the spherical form), of various diameters; in some instances the metal was besides partially torn open in a line from the bottom of the charge-hole to the circumference of the lower face of the cylinder; and in the case of some of the gun-cotton charges, the fissure in the metal in this direction was complete, the base of the block being separated from the remainder, in the form of a cone. In the first place the portions of the holes above the charges were simply left open; in the subsequent experiments they were filled up to a level with the upper surface, with dry, fine, loose

* Lecture delivered at the Royal Institution of Great Britain, Friday, March 21, 1879.

sand, or with water. The dimensions of the cylinders were increased in successive experiments until, in the case of every one of the explosives used, the mass of metal was sufficiently great to resist actual fracture at the base of the cylinder. Under the conditions of these experiments, more or less considerable resistance being opposed to the mechanical dispersion of the plastic explosive substances, their detonation was greatly facilitated, though even then, the holes in the lead blocks being left open to the air, some amount of the blasting gelatine evidently escaped detonation; the widening of the upper part of the charge-hole, in experiments of this nature made with the gelatine, indicated that detonation was transmitted to small portions dispersed in the first instance and in the act of escaping from the block. In all the experiments, whether the holes were left open or filled with sand or water, the effect produced upon the base of the block by the detonation of compressed gun-cotton was considerably more violent than with the other explosive agents, indicating a sharpness of action which was only shared by the blasting gelatine when used *in a frozen state* in one of these experiments. The dimensions of the cavities produced by the gelatine were, at the largest part, considerably greater than those produced by the dynamite and nitrated gun-cotton (tonite), and slightly greater than those of the gun-cotton charges; but in the latter, the fracture of the base of the cylinder gave rise in most of the experiments to an escape of force, so that in these cases the effects of the detonation could not be well compared by measurements of the cavities. When the gelatine was converted by freezing into a rigid mass its superiority in explosive force even over compressed gun-cotton was well illustrated; the base of the lead block was all but blown out, the cavity produced was considerably the largest, and the suddenness and violence with which motion was imparted to the water tamping caused the top of the block also to be blown off in the form of a cone. An excellent illustration was obtained, by comparing this result with those furnished by the gelatine in its normal plastic state, of the influence exercised by the physical condition of an explosive substance upon the rapidity and completeness with which detonation is transmitted through its mass.

The difficulties attending the application of blasting gelatine, in some directions in which explosive agents are applied, on account of the uncertainty attending the development of its explosive force, even with the use of a comparatively powerful detonator, unless it be very strongly confined, has led to attempts to reduce its non-sensitiveness to detonation by mixing it with materials intended to operate either by virtue of their comparatively great sensitiveness, or of their property, as solids, of reducing the very yielding character of the substance, or in both ways.

Some of these attempts have been attended with considerable success. Thus the incorporation of about 10 per cent. of the most explosive form of gun-cotton or trinitrocellulose, in a very finely divided state, with the gelatine, renders it so much more sensitive that it can be detonated with certainty in the open air by means of the strongest detonating cap now used for exploding dynamite. This effect appears to be less due to the comparative sensitiveness of gun-cotton to detonation than to the modification effected in the consistency of the material, which, though still plastic, offers decidedly greater resistance to a blow than the original gummy substance. The particles of hollow fibre of the gun-cotton appear also to have the effect of absorbing small quantities of nitro-glycerine which are less perfectly united with the soluble gun-cotton than the remainder, and which, existing as they do in somewhat variable proportions in the gelatine, have occasionally an objectionable tendency to exudation, if the incorporation of the ingredients has been less perfect than usual. The substance, when modified as described, has no longer that great adhesiveness which is exhibited by it in the original state, and which renders it less easy to manipulate.

Lastly, its explosive force appears to be in no way diminished by this modification of its composition; on the contrary, its superiority in this respect to compressed gun-cotton becomes more manifest, as demonstrated by some of the experiments with lead blocks, while its action partakes of that sharpness peculiar to the detonation of the rigid gun-cotton, as indicated by the fissure of that part of the metal situated beneath the charge. Finely divided cotton fibre has a similar effect to trinitrocellulose in modifying the physical character and increasing the sensitiveness to detonation of the blasting gelatine, but its explosive force is, of course, proportionately reduced with its dilution with an inert substance.

Nobel has made the interesting observation, that an addition to the blasting gelatine of small proportions of certain substances rich in carbon and hydrogen, which are soluble in nitro-glycerine, such as benzol and nitro-benzol, increases to a remarkable extent the non-sensitiveness to detonation of the original material; and this observation has led to experiments being conducted by engineer officers in Austria, with a view of endeavouring to convert the blasting gelatine into a material which should compete, as regards some special advantages in point of safety, with wet gun-cotton in its application to military and naval purposes, and especially as regards non-liability to detonation or explosion by the impact of rifle bullets. If boxes containing dry compressed gun-cotton are fired into from small arms even at a short range, the gun-cotton is generally inflamed, but has never been known to explode; the sharpness of the blow essential to the latter result, which the bullet might otherwise give, being diminished by its penetration through the side of the box before reaching the explosive. It is scarcely necessary to state that wet gun-cotton, containing even as little as 15 per cent. of water, is never inflamed under these conditions. On the other hand, dynamite is invariably detonated when struck by a bullet on passing through the side of the box, and blasting gelatine, though so much less sensitive than dynamite, behaves in the same way in its ordinary as well as in the frozen condition. The Austrian experiments indicated that the gelatine when intimately mixed with only 1 per cent. of *camphor*, generally, though not invariably, escaped explosion by the impact of a bullet, but that when the proportion of camphor amounted to 4 per cent. the material was neither exploded nor inflamed, though, in the frozen state, it was still liable to occasional explosion. These results were considered indicative of a degree of safety in regard to service exigencies, approaching that of wet compressed gun-cotton. The camphoretted gelatine still labours, however, under the disadvantage of being readily inflammable, and of burning fiercely, and consequently, of giving rise, like dynamite and dry gun-cotton, to violent explosion, or detonation, if burned in considerable bulk; a result which was explained by the lecturer in his discourse delivered at the Royal Institution in 1872. Moreover, the camphoretted blasting gelatine is so difficult of detonation by the means ordinarily applied that a large initiative charge of a very violent detonating mixture consisting of pure specially prepared trinitrocellulose and nitro-glycerine is prescribed, by the Austrian experimenters, as being indispensable to its proper detonation.

The action of camphor and of other substances rich in carbon and hydrogen in reducing greatly the sensitiveness to detonation of the preparation of soluble gun-cotton and nitro-glycerine, is not to be traced to any physical modification of that material produced by the addition of such substances, and no satisfactory theory can at present be advanced to account for it on chemical grounds.

The camphoretted gelatine, like Nobel's original gelatine itself, may be kept immersed in water for a considerable time without any important change; the surface of the mass thus immersed becomes white and opaque, apparently in consequence of some small absorption of water, but no nitro-glycerine is separated, and on re-exposure to the air the material gradually assumes once more its original aspect. It has consequently been proposed to render the storage of blasting gelatine comparatively safe by keeping it immersed in water till required for use, but the test of time is still needed to establish the unalterableness of the material under this condition.

There can be little question that this interesting nitroglycerine preparation, either in its most simple form, or modified in various ways, by the addition of other ingredients, promises, by virtue of its great peculiarities as a detonating agent, to present means for importantly extending the application of nitro-glycerine to industrial purposes; and it is not improbable that, through its agency, this most violent of all explosive agents at present producible upon a large scale may also come to acquire special value for important war-purposes.

It has been pointed out that the complete solidification, by freezing, of plastic preparations containing nitroglycerine, such as dynamite and the blasting gelatine, has the effect of facilitating the transmission of detonation throughout the mass, and of thus developing or increasing the violence of their action, under certain conditions of their applications, *i.e.*, when they are either freely exposed to air or not very closely or rigidly confined. But while, under circumstances favourable to the detonation of these substances, when in the frozen state, their full explosive force is thus much more readily applied than when they are in their normal (thawed) condition, the frozen substances are less sensitive to detonation by a blow or an initiative detonation. On the other hand, if subjected to the rapid application of great heat (as for example by the burning of portions of a mass of the explosive substance itself), a detonation is much more readily brought about with the frozen material than if it be in its normal condition. Thus a package containing 50 lbs. of cartridges of plastic dynamite, when surrounded by fire, burned away without any indication of explosive action; on submitting 10 lbs. of frozen dynamite to the same treatment, that quantity also burned without explosion, though at one time the combustion was so fierce as to indicate an approach to explosive action; but when the experiment was repeated on the same occasion, with 15 lbs. of frozen dynamite a very violent detonation took place after the material had been burning for a short time, a deep crater being produced in the ground beneath.

The following is offered as the most probable explanation of this result. When a mass of dynamite, as in these cartridges, is exposed to sufficient cold to cause the nitroglycerine to freeze, it does not become uniformly hardened throughout, partly because of slight variations in the proportion of nitro-glycerine in different portions of the mixture composing the cartridge, and partly because unless the exposure to cold be very prolonged the external portions of the cartridges will be frozen harder or more thoroughly than the interior. It may thus arise that portions of only partially frozen or still unfrozen dynamite may be more or less completely enclosed in hard crusts, or strong envelopes, of perfectly frozen and comparatively very cold dynamite. On exposure of such cartridges to a fierce heat very rapidly applied, as would result from the burning of a considerable quantity of the material, some portion of one or other of the cartridges would be likely to be much more readily raised to the igniting or exploding point than the remaining more perfectly frozen part in which it is partly or completely imbedded. If the ignition of this portion be brought about (which it will be with a rapidity proportionate to the intensity of heat to which the cartridge is exposed), the envelope of hard frozen dynamite by which it is still more or less completely surrounded and strongly confined, will operate like the metal envelope of a detonator, in developing the initial pressure essential for the sudden raising of the more readily inflammable portion of the dynamite to the temperature necessary for the sudden transformation of the nitro-glycerine into gas, and will thus bring about the detonation of a portion of the cartridge, which will act as the initiative detonator to the remainder of the dynamite. On igniting separately, at one of their extremities, some dynamite cartridges which had been buried in snow for a considerable period, the lecturer has observed that, as the frozen material gradually burned away, very slight but sharp explosions (like the snapping of a small percussion cap on a gun nipple) occurred from time to time, portions of the frozen dynamite being scattered with some violence. He did not succeed in obtaining actual detonation by thus burning frozen cartridges surrounded by others in a similar condition, but he has been informed by Mr. McRoberts, of the Ardeer Dynamite Works, that he has more than once detonated a small heap of hard-frozen cartridges weighing altogether one pound, by igniting one cartridge which was surrounded by the remainder. These facts appear to substantiate the correctness of the foregoing explanation. They point to the danger of assuming that, because dynamite in the frozen state is less sensitive to the effects of a blow or initiative detonation than the thawed material, it may therefore be submitted without special care to the action of heat, for the purpose of thawing it. Instances of the detonation, with disastrous results, of even single cartridges of frozen dynamite, through the incautious application of considerable heat (as for example by placing them in an oven, or close to a fire), have been, and are still, of not unfrequent occurrence, even though Mr. Nobel has insisted upon the application of heat through the agency only of warm water, as the sole reliable method of safely thawing dynamite cartridges.

While the sensitiveness to detonation of air-dry gun-cotton remains unaffected by great reduction in temperature of the mass, and while in this respect it presents advantages over nitro-glycerine preparations, wet gun-cotton becomes very decidedly more susceptible to detonation when frozen. Thus the detonation of gun-cotton containing an addition of from 10 to 12 per cent. of water is somewhat uncertain with the employment of 100 grains of strongly confined fulminate, and 200 grains are required for the detonation of the substance when containing 15 to 17 per cent. of water; but the latter in a frozen state can be detonated by means of 30 grains of fulminate, and 15 grains are just upon the margin of the amount requisite for detonating, with certainty, frozen gun-cotton containing 10 to 12 per cent. of water. The deadening effect of solid water upon the sensitiveness of gun-cotton to detonation is, in fact, intermediate between those of a liquid and of inert solid substances.

The effects produced and products formed by the explosion of gun-cotton in perfectly closed spaces, both in the loose, and the compressed form, and by its detonation in the dry and wet state, have been made the subject of study by Captain Noble and Mr. Abel, the method of research pursued being the same as that followed in their published researches on fired gunpowder; results of considerable interest in regard to the heat of explosion, the pressures developed, and the products of explosion of dry and wet gun-cotton have been obtained, which are about to be communicated to the Royal Society.

In may briefly be stated that the temperature of explosion of gun-cotton is more than double that of gunpowder (being about 4400° C.); that the tension of the products of explosion, assuming the material to fill entirely the space in which it is fired, is considerably more than double that of the powder-products under the same conditions; that the products obtained by the explosion of dry gun-cotton are comparatively simple and very uniform under different conditions as regards pressure; that the products of *detonation* of *dry* gun-cotton do not differ materially from those of its explosion in a confined space, but that those furnished by the detonation of *wet* gun-cotton present some interesting points of difference. Messrs. Noble and Abel are extending their investigations to the nitro-glycerine preparations.

The great advance which has been made within the last twelve years in our knowledge of the conditions which determine the character of the metamorphosis that explosive substances undergo, and which develop or control the violence of their action, finds its parallel in the progress which has been made in the production, perfection, and application of the two most prominent of modern explosive agents, nitro-glycerine and gun-cotton. Discovered at nearly the same time, less than forty years ago, the one speedily attained great prominence, on account of the apparent ease with which it could be prepared and put to practical use; a prominence short-lived, however, because the first, and somewhat rash, attempts to utilize it preceded the acquisition of sound and sufficient knowledge of its nature and properties. Even many years afterwards, when the difficulties attending its employment appeared to have been surmounted, the confidence of its most indefatigable partisans and staunchest friends received a rude shock from which it needed the support of much faith and some fortitude to recover.

Meanwhile, the other substance, which now shares with it the honours of important victories won over gunpowder, continued to be generally regarded as a dangerous chemical curiosity, even for some time after its present position as one of the most important industrial products and useful explosive agents was being gradually but firmly secured for it, step by step, by the talent and untiring energy of a single individual.

Almost from the day of its discovery, the fortunes of gun-cotton continued to fluctuate, and much adversity marked its career, until at last its properties became well understood, and its position as a most formidable explosive agent, applicable on a large scale, with ease, great simplicity, and with a degree of safety far greater than that as yet possessed by any other substance of this class, has now become thoroughly established. Since the lecturer last discoursed on the properties of gun-cotton, seven years ago, this material has attained a firm footing as one of the most formidable agents of defence and offence. For all military engineering operations, and for employment in submarine mines and torpedoes, compressed gun-cotton, stored and used in the wet condition, has become the accepted explosive agent in Great Britain; within the last five years upwards of 550 tons have been manufactured for this purpose, and are distributed over our chief naval stations at home and abroad. Germany some years since copied our system of manufacture and use of gun-cotton; France has provided itself with a large supply for the same purposes, and Austria, where the acquisition of bitter experience of the uncertainty of gun-cotton in the earlier stages of history, naturally gave rise to a persistent scepticism regarding its present trustworthiness, appears now also about to adopt wet gun-cotton for military and naval uses.

But while the usefulness and great value of compressed gun-cotton in these important directions has been established, its technical application has made but slow progress as compared with that of the simple nitro-glycerine preparation known as dynamite, which, in point of cost of production and convenience for general blasting purposes, can claim superiority over compressed gun-cotton. Already in 1867 a number of dynamite factories, working under Nobel's supervision, existed in different countries; in that year the total quantity manufactured amounted to eleven tons; in another year the produce had risen to seventy-eight tons; in 1872 it had attained to 1350 tons. Two years afterwards the total production of dynamite was nearly trebled, and in 1878 it amounted to 6140 tons.

There are as many as fifteen factories in different parts of the world (including a very extensive one in Scotland) working under the supervision of Mr. Nobel, the originator of the nitro-glycerine industry, and some six or seven other establishments exist where dynamite or preparations of very similar character are also manufactured.

How far the rate of production of dynamite will be affected by the further development of the value of Nobel's new preparation, the blasting gelatine, it is difficult to foresee, but there appears great prospect of an important future for this very peculiar and interesting detonating agent.

It is hoped that the subjects dealt with in this discourse afford interesting illustration of the intimate connection of scientific research with important practical achievements.

TINCTURE OF KINO.*

BY R. ROTHER.

The tendency which many tinctures, fluid extracts, and other solutions have to deposit a bulky sediment; of ointments to rancidify, and even of syrups to ferment and otherwise change, cannot compare in point of annoyance with the disposition of tincture of kino to gelatinize. It would be idle to relate the numerous inefficient devices that have been resorted to in order to circumvent this change. The writer once entertained the theory that the cause of the transformation resides in a septic movement transmitted by a soluble septase originally present in the gum, or imparted to it by some extraneous organism. To exclude this or nullify its action, the writer proposed the application of the strongest alcohol, and also by increasing the material strength of the tincture. Owing to the fact that the different varieties of kino do not possess the instability in a like degree, the writer for a time believed he had found the true remedy. But on a later occasion, a concentrated tincture (1 in 4) solidified with surprising rapidity, and thereby demonstrated that neither strong alcohol nor a high degree of concentration can obviate the change. The writer then thought that to light might, perhaps, be ascribed the cause of the phenomenon, especially since a dark bottle partially filled with officinal tincture, whilst remaining in a closet protected from light, had for a long time retained its contents intact, but on being removed to another receptacle and exposed to diffused daylight, the tincture speedily gelatinized. It was, however, proposed to test this thoroughly, and in order to ascertain what possible influence the atmosphere might also exert, the writer on the 12th day of January, 1878, prepared eight fluid ounces of U.S. officinal tincture of kino, by maceration and filtration through starch. Four fluid ounces of this was poured into a pint bottle, and set away, exposed to diffused light, this was marked No. 1. No. 2 was a half-ounce phial filled with the tincture and tightly corked. No. 3 was a two-ounce phial, loosely corked, containing one fluid ounce of the tincture. No. 4 was the same as No. 3, with the addition of one grain of benzoic acid. No. 5 was a two-ounce phial containing half a fluid ounce of the tincture and half a fluid ounce of water. No. 6 was a duplicate of No. 3, kept in a dark closet, preserved from light. Nos. 2, 3, 4 and 5 were so situated that, during part of every day when the sun was shining, they were exposed to the direct rays.

On the 23rd of May, 1878, the contents of No. 1, which had in the meantime been occasionally shaken and given fresh air, showed signs of becoming viscid. To find what effect ammonia would have on it at this stage, half a fluid ounce was mixed with three drops of aqua ammoniæ. It gelatinized instantly. The remaining tincture of No. 1 now gradually thickened, and by the end of July had set to a firm jelly.

At the 10th of April, 1879, no change had yet occurred in No. 2. No. 3 was barely fluid. No. 4 was a thick jelly. No. 5 was quite fluid, showing a slight tendency to viscidness. No. 6 was a thick jelly.

In the course of observing these indications, it was decided, on the 5th of February, 1879, to make a second experiment, and to this end eight fluid ounces of tincture of kino was prepared by maceration; double the officinal strength in kino, but with a menstruum composed of one part by measure of strong alcohol and three parts water.

* From *New Remedies*, July, 1879.

One-half of this, marked No. 7, was placed into a twelve-ounce wide-mouthed bottle, loosely stopped, and so disposed of as to stand, at intervals, in direct sunlight. The other half, marked No. 8, was diluted with an equal measure of its menstruum, and stored away in a pint bottle under similar conditions to No. 7.

Both No. 7 and 8 were frequently shaken and exposed to fresh air by removing the stoppers of the bottles. At the 18th of May, 1879, No. 7, which had for some time back been thickening by imperceptible degrees, became firmly gelatinous. But No. 8, at the present writing, shows no signs of viscid tendency. No. 2 has also remained *in statu quo*. No. 5 has now became quite syrupy, and all the others have become more firmly solid.

Now, on reviewing these results, it appears that No. 2, although having been freely submitted to the action of light, but securely shielded from the access of air, has remained in prime condition. Nos. 1, 3, 4, 6 and 7 prove that the contact of air has caused their alteration. No. 4 indicates that benzoic acid hastens the change. No. 6 gives evidence that air without light is as active as with it, and, in conjunction with No. 2, confirms the non-intervention of light. Nos. 5 and 8 plainly point out that a tincture weak both in kino and alcohol is the most permanent in the presence of air. No. 7, together with the strong tincture first cited (1 in 4), demonstrate that a concentrated tincture of kino, especially when prepared with a strongly alcoholic menstruum, is the most unstable form.

It appears, therefore, that the gelatinous condition is due to an oxidation product. The ramifying propensity of this insoluble substance causes it to pervade the liquid with invisible filaments and thus produce the impression of homogeneity. On the appearance, however, of the slightest trace of viscidity, the addition of water precipitates the gelatinous body in purplish flakes, which rapidly subside, leaving a red supernatant solution.

The abundant supply of air in the large bottles has promoted the transformation at a higher rate, as will be seen from the experiments, the tinctures in the smaller phials requiring a proportionately longer time to undergo decomposition. When the tincture is yet homogeneous, the liquid adhering to the walls of the vessels, after agitation, all runs down again, but after the alteration has begun, much of the liquid permanently adheres, the insoluble matter, owing to its uneven contraction, giving the residue after drying a peculiar veined appearance. The partially gelatinized tinctures cannot be filtered, the viscid body retaining the liquid portion. The semi-congealed fluid, however, on drying, yields a compact residue, from which alcohol or water readily removes the soluble parts. In fact, it seems as though much of the kino of the market is the residue of a partially gelatinized juice, and it is probable that the instability of some tinctures is partly chargeable to this altered gum. The success that is claimed to attend the U.S. officinal method of preparing the tincture, that is, the percolation through sand, may be accounted for by the fact that this very faulty operation sacrifices a large proportion of the gum by agglutination amidst the sand, and thus yielding a weak percolate, such a solution having, according to the writer's experiments, elements of more stability. A trial of oxidation with potassium permanganate was made, but since this agent in contact with organic matter always gives a precipitate of manganese dioxide, its effect in this instance was not easily judged. Still a weak solution of permanganate acidulated with acetic acid poured into the tincture produced a precipitate which, although it may have been contaminated with dioxide, yet had great resemblance to the curdy, flesh-coloured mass thrown down by water from the tincture in an advanced state of change. In conclusion, the expression for the sum of the foregoing results is, that tincture of kino is best prepared by maceration with a weak alcohol and then preserved in small phials, well filled and securely stopped, so as to exclude the action of the air.

ASPHALTUM AND AMBER FROM VINCENTOWN, NEW JERSEY.*

Mr. E. Goldsmith reports that he had received from Col. T. M. Bryan a specimen of asphaltum, a mass of which, weighing about 100 pounds, had been found in the ash marl, a layer above the green sand proper, about 16 feet from the surface, in the neighbourhood of Vincentown. It seems that this peculiar hydrocarbon had not been observed in the State of New Jersey before; at least no mention of it is made in the geological reports up to 1868. The specimen presented to the Academy had attached on one side a layer of the marl in which it was found.

As the material in question is properly considered a mixture of various hydrocarbons, it seems to be obvious that the properties vary according to the predominance of one or the other substance contained therein. This kind is very brittle, black, with a resinous lustre. Its fracture is uneven, inclined to conchoidal; the streak and powder appear brown. It melts easily in the flame, like wax, and burns with a yellow smoky flame, leaving, after burning, a voluminous coal and but little ashes. In water, alcohol and solution of caustic potassa, it is not soluble. It dissolves in chloroform and in oil of turpentine. In ether it dissolves with difficulty, forming a yellowish-brown solution by transmitted and a dirty greenish solution by reflected light. Oil of vitriol dissolves it into a black liquor, which, when poured into water, shows that a part of the substance is retained in solution, whilst another subsides as a dark-coloured powder. Nitric acid reacts on the substance at an elevated temperature, forming therewith soluble products of oxidation.

Not far from the pit from which the asphaltum had been obtained a specimen of yellow mineral resin was found. It occurs frequently in the marl of the cretaceous formation, but not regularly; sometimes hundreds of tons may be looked over without finding a single piece; at other times enough has been found to fill a barrel within a day. It is usually known under the name of amber or succinite.

It differed in several particulars from the typical amber found at the bottom and on the coast of the Baltic Sea. Our specimen is lighter than water, whilst the amber from the Baltic is specifically heavier. The latter fuses into a thick sluggish fluid, the Vincentown amber into a very fluid mobile liquid; the cohesion of the Baltic product is stronger than in the specimen in question. These differences indicate its analogy to the variety of succinite called Krantzite by C. Bergeman, who reported its occurrence near Neuberg, Germany.

It melts on heated platium foil into a brown liquid, which runs like water. It takes fire easily, and burns with a yellowish, strongly-smoking flame, leaving but little coal, which rapidly burns away and leaves a small quantity of dark-coloured ashes as a residue. Heated in a closed tube it melts and vaporizes into a grey cloud, which condenses easily into an oily liquid and some small crystals, which are probably succinic acid. The odour of the fumes is strongly penetrating, like acrolein. In water, alcohol or ether it seems to be but sparingly soluble. In chloroform, bisulphide of carbon and in oil of turpentine it dissolves freely. Oil of vitriol makes with it a red solution. Cold nitric acid seems not to affect it much. On warming, the yellowish powder becomes orange-red. It is partly dissolved by caustic potassa. In this yellowish-brown Krantzite Mr. Goldsmith noticed on a fresh fracture a row of white crystals, arranged in radiating groups. The crystals were too small for mechanical separation, but the opinion was expressed that they were succinellite.

MEDICAL LEGISLATION AND ITS RELATION TO PHARMACY.

To those who have followed the proceedings of the Select Committee on the Medical Acts Amendment Bill it will probably be no surprise that this inquiry is still without any definite result. It is true the Committee has concluded its proceedings and has agreed to its report, but at the same time it has decided that, taking into consideration the conflict of evidence and the impossibility of completing the investigation of the subject during the present session of Parliament, much yet remains to be done. Consequently, the Committee has determined to report on the evidence taken up to the present time without comment and to recommend that the inquiry be renewed in the next session of Parliament.

So long as the settlement of the questions raised by the Medical Bills now before Parliament remains unachieved, chemists and druggists will naturally feel some considerable interest in the progress of the measure by which it is sought to ameliorate the position of medical practitioners. It would be unwise for them to ignore the fact that certain members of the medical profession are desirous of imposing restrictions upon the chemist and druggist which could not be enforced in regard to other members of the community, and therefore any expression of opinion upon the relations between the two classes is deserving of careful consideration.

The recent decision of the Birmingham County Court Judge, in the case of the Society of Apothecaries *v.* HARRISON, has furnished the *Medical Press and Circular* with an opportunity of reverting to the subject of counter prescribing and medical dispensing, and in the main the conclusions arrived at are far from being such as to justify dissatisfaction on the part of the chemist and druggist. The view expressed at the outset of the article that chemists and druggists had been transported into a fool's paradise by the result of the SHEPPERLEY case is, however, one we cannot concur with, and we regard it rather as the indication of a habit of mind than as having any more important significance. The representation of the decision in the SHEPPERLEY case as being "half favourable" to the right of chemists and druggists to prescribe across the counter is at best unsupported by any foundation of fact. If it was a decision having reference to the question whether chemists and druggists possess such a right, it was unquestionably a decision in their favour altogether. But we have always looked upon this unhappy case as being one that could not possibly decide anything. The unquestionable fact that the complaint for which the pretended patient in that case sought prescription from the chemist and druggist was a "bogus" complaint entirely destroyed any value the case might have had as a test case, and the evidence of Mr. SHEPPERLEY as to his impression respecting DEATH's ailment sufficiently shows that he suspected being trifled with.

It seems, therefore, absurd to say, as the writer in the *Medical Press and Circular* does, that by the decision given in the SHEPPERLEY case, chemists and druggists were lulled into a "gratifying sense of security" as regards counter prescribing. Allowance may fairly be made for the representations of those more immediately connected with the conduct of the defence, and all things considered they may well be excused for indulging in a blast of trumpets, and the proclamation of a great victory. All this may be tolerated as akin to the loud voiced laudation with which a showman proclaims the wonders of the objects to be seen within his booth. But after all this had been got over, it was still obvious that in any case of prosecution under the Apothecaries Act the real question would be first, whether the individual prosecuted had acted as an apothecary, and second, whether in so acting he had kept within the privileges secured to chemists and druggists by the 28th section of the Act.

As regards the first question it appears that juries no less than judges are disposed to be guided in their decision by their estimate of the nature of the case treated. If that was of a "trivial" nature the decision would be in favour of the defendant. In SHEPPERLEY's case the decision was in this direction, because no disease was treated. If, on the other hand, the nature of the case treated was serious, or what is still more important if the ultimate issue of it was fatal, the tendency of jury and of judge has been to regard its treatment as coming within the terms "acting as an apothecary," and on that ground to give a decision against the defendant.

And then in considering the further question whether the particular instance of "acting as an apothecary" was within the privilege of chemists and druggists according to the 28th section, the vagueness of the terms of that section and the uncertainty what was to be comprised in the exemption it gave would be in most cases likely to result unfavourably to the defendant.

The decision in the Birmingham case is distinctly of this latter kind; it does not in reality touch the question whether a chemist and druggist or any other man has or has not a right to administer or recommend to others medicine for the relief of their ailments; but it simply decides that the case treated was of a serious if not dangerous nature, and that consequently the defendant was infringing the Apothecaries Act by acting as an apothecary.

It seems therefore mere idle assertion to state that by this decision "the gratifying sense of security" created by the decision given in the SHEPPERLEY case "has been rudely broken." No sense of security was ever called into existence by the decision of the SHEPPERLEY case and the decision in the Birmingham case does not in any way differ in its effect from the views expressed as to the Apothecaries Act by the judges upon other occasions.

But in the *Medical Press and Circular* the decision of the Birmingham County Court Judge is represented as being conclusive as to the chemist and druggist never having had any legal right to advise or prescribe, and satisfaction is expressed in the same unfounded way that the decision in the SHEPPERLEY case was held by the opposite party to be a victory. The true foundation of the County Court Judge's decision is, however, too apparent to be overlooked, and consequently the satisfaction to be derived from its assumed significance is considerably less than it might have been if the assumption were correct.

The limitation of illegality to such instances of prescribing as relate to serious cases, is so obviously and clearly the ruling principle of the decision given by the Birmingham County Court Judge that even the writer in the *Medical Press and Circular* cannot avoid saying the decision affords reason for inferring that a chemist and druggist may legally advise and prescribe for any patient who at the time is not "seriously" ill. The possibility of such an inference may be "altogether unsatisfactory" to some medical men who hold the views of the writer in the *Medical Press and Circular*, but all the judicial dicta concerning the Apothecaries Act agree in furnishing ground for the same inference. According to their views it is only the "serious" nature of the ailment treated, and to some extent also the mode of procedure for its treatment, that determines whether the treatment comes within the term "acting as an apothecary," and whether it is to be dealt with as a breach of the law.

We cannot therefore agree with our contemporary that the decision of the Birmingham County Court Judge is a *reductio ad absurdum* because it was based upon a consideration whether the case prescribed for was "serious" or of a "trivial" nature. On the contrary, that is the very essence of the distinction between what may and may not be done. The line of demarcation may not be very definite, but that is one of the difficulties of the matter that is to be faced and dealt with by the exercise of individual discretion, no less on the part of those who seek to prevent improper exercise of medical functions, than by the chemist and druggist who is called upon in the ordinary exercise of his business to be useful in recommending his wares for the relief of his customers' ailments.

We are glad, however, to find our medical contemporary looks hopefully forward to the entire severance of pharmacy and medicine as the best remedy for the discord and ill feeling that have prevailed between medical practitioners and chemists and druggists as to counter practice. Speaking of the recent proceedings of the Rochdale Chemists' Association they are characterized as constituting a decided advance in that direction, and with the view of giving some strength to the movement it is pointed out that the complete separation of pharmacy and medicine is working with perfect success in Ireland. There it is stated very few practitioners in the large towns ever think of dispensing their own medicines, and even in country places no one does so who can possibly supply his patients with their medicines in any other way.

The result is that the time and freedom of mind gained by the practitioner by tabooing personal connection with dispensing more than compensates in earning power for the profits he would derive from making up mixtures, lotions and pills, while at the same time he enjoys the advantage of getting his fees paid in cash at once and avoids the keeping of books, the furnishing of bills at Christmas or Easter.

We entirely join our contemporary in hoping that in this country also the medical practitioner will eventually devote his energies to the use of the tools which the pharmacist places in his hands, and that the pharmacist may be able to content himself with producing medicines of the best attainable quality so as to render the republic of medicine a co-operative compact for the mutual benefit of the parties who have been injuring themselves and each other by an unmeaning contention.

SALE OF POISONS IN INDIA.

WE learn from the *Delhi Gazette* that an attempt is being made to obtain legislation to regulate the sale of poisons in India. The movement has been originated by Mr. BILNEY, chemist to a firm of druggists in India, who proposes the establishment of a Pharmaceutical Society, one of the rules of which should be that no medicine shall be dispensed or poison sold by other than legally qualified men, who shall have been examined by a Board appointed by Government. The *Delhi Gazette* in wishing Mr. BILNEY success in his enterprise expresses an opinion that some law of this description is certainly needed.

BRITISH ASSOCIATION.

THE meeting at Sheffield will commence on the 20th inst., and as we learn from a circular issued by the local secretaries, arrangements are being made for a number of attractive excursions to places of historical and scientific interest. Facilities will also be afforded to visitors attending the meeting for seeing various interesting manufacturing operations, such as the rolling of armour plates, BESSEMER steel making and electroplating. In this respect the present meeting will have especial interest.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

July 22, 23 *and* 24, 1879.

Present on each day—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was present on the 22nd on behalf of the Privy Council.

MAJOR EXAMINATION.

July 22.

Three candidates were examined. *Two* failed. The undermentioned passed, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Russell, James Lawson ....Edinburgh.

MINOR EXAMINATION.

July 22.

Thirteen candidates were examined. *Seven* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bain, John..........................Edinburgh.
Bottomley, Albert Frederic ...Halifax.
Burrell, Thomas ....Montrose.
Clark, Adam Douglas ....Kelso.
Greig, James........................Glasgow.
Jones, John ....Liverpool.

July 23.

Thirteen candidates were examined. *Eight* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jones, James Lewis..............Bangor.
Kelly, Hugh ....Kilmarnock.
Macdonald, Robert ....Edinburgh.
Palmer, Edwin Thomas ....Hammersmith.
Pigott, Samuel ....Manchester.

July 24.

Twelve candidates were examined. *Five* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Ramsay, David Robertson ......Dundee.
Robson, William Stubbs.........Scarborough.
Scott, John ....Newcastle-on-Tyne.
Simpson, Robert George.........Stowmarket.
Thomas, Thomas Gratton ......Bagillt.
Tidswell, Frederick ....Bradford.
Wilks, Charles Frederick ......York.

MODIFIED EXAMINATION.

July 24.

Three candidates were examined. *All* passed, and were declared qualified to be registered as Chemists and Druggists:—

Carter, John ....London.
Greenwood, Samuel ....Bradford.
Manners, John ....Newcastle-on-Tyne.

Proceedings of Scientific Societies.

SOCIETY OF PUBLIC ANALYSTS.

At a general meeting of this Society held at Burlington House, Piccadilly, on Wednesday, June 4th, the following papers, among others, were read:—

Note on the Examination of Spiritus Ætheris Nitrosi.*

BY A. DUPRÉ, PH.D., F.R.S.

Having at various times been asked for explanations as to the method I use for estimating the amount of nitrous ether contained in a sample of spiritus ætheris nitrosi, I take this opportunity of describing the method once for all. The principle of the method will be found in Duflos' 'Apothekerbuch,' edition 1867, p. 251, and I have simply worked out the details a little more fully. For the present I confine myself to the analytical method, and must leave many points of interest connected with the subject to some future time.

Spiritus ætheris nitrosi, as is well known, is directed to be prepared ('Brit. Pharm.') by distilling a mixture of spirit, nitric and sulphuric acids and copper, and mixing the distillate obtained with a certain proportion of spirit. If all the nitric acid employed were used up in the formation of nitrous ether, the proportion of such contained in the finished product, if two pints of spirit are added to the 15 ounces of distillate, would amount to about 6·5 per cent. In practice this result is, however, never obtained; and, according to my experience, we may consider a product containing 3 per cent. of nitrous ether as fairly representing the B.P. preparation.

In judging of the purity, or otherwise, of any given sample of spiritus ætheris nitrosi, B.P., the particular method of manufacture adopted in the preparation of the sample is, of course, perfectly immaterial; as long as it fairly corresponds in strength to the B.P. standard it must be considered as of the nature, substance and quality demanded, however produced.

Characters. B.P. Transparent, very slight tinge of yellow. Specific gravity, 0·845. Effervesces feebly, or not at all, when shaken with a little bicarbonate of soda. When agitated with a solution of sulphate of iron and a few drops of sulphuric acid it becomes olive brown or black. If it be agitated with twice its volume of saturated solution of chloride of calcium in a closed tube, 2 per cent. of its original volume separates in the form of nitrous ether, and rises to the surface of the mixture.

Further Tests of Purity. Should give no precipitate with nitrate of silver; absence of hydrocyanic and formic acids. A small quantity poured on a little water, and ignited, should leave an aqueous solution, which gives no precipitate with nitrate of silver; absence of hydrochloric ether, chloride of ethylene, etc.

The chloride of calcium test is not of much value. Firstly, because only those samples respond to it which are nearly of the proper strength, and no information is gained as to the composition of those samples, from which nothing separates, except of course that they are below the proper strength. Secondly, because the substance separating though chiefly, is not by any means only, nitrous ether. The iron test may be used as a rough quantitative test by using a sample of known strength for comparison, and it offers a very ready means, before a magistrate for example, to show the character of any impugned sample.

Estimation of Nitrous Ether. Ten cubic centimetres of the ether are introduced into a small flask already containing about 1·5 gram of solid potash hydrate. The flask is closed with a well-fitting cork, gently agitated from time to time to promote solution of the potash, and left standing over night. Next day the contents of the flask, more or less yellow according to the amount of aldehyde present, are washed into an evaporating basin with 50 c.c. of water, and the mixture evaporated on a water-bath to about half or one-third. The remainder is allowed to cool, filtered through a little glass wool into a beaker, made up to 300 c.c. with water, 50 c.c. of diluted sulphuric acid (1 in 4) are added, and the nitrous acid present determined by a standard solution of permanganate. This standard solution is prepared by dissolving 8·475 grams of pure permanganate of potassium (or its equivalent) in one litre water; 1 c.c. of this solution is equivalent to 0·01 gram of nitrous ether, and therefore indicates 0·1 per cent. of nitrous ether, if 10 c.c. of ether have been taken. The decoloration of the permanganate is rapid at first, gradually becoming slower. As soon as this is perceived not more than 0·5 c.c. are added at a time, and the process must be considered as at an end if the solution

* Reprinted From *The Analyst.*

still shows a distinct pink or red coloration two minutes after such addition. For every cubic centimetre of permanganate solution then used, the spiritus ætheris nitrosi contains, at a maximum, 0·1 per cent. of nitrous ether. The solution still continues to decolorize permanganate, though but slowly, and much more will have to be added before the coloration becomes permanent. I have however convinced myself, by many experiments, that all nitrous acid present is oxidized when the above indicated point is reached. No doubt other substances are oxidized as well, and the process indicates more nitrous ether than is actually present; but as the error is on the side of leniency, it is perhaps an advantage rather than otherwise. By following out strictly the directions here given, it will be found that duplicate analyses of a sample rarely differ more than 0·1 per cent. from each other; while, with poor samples, the agreement is even more perfect. Should a sample require much permanganate, and the solution, instead of becoming colourless, remains brown or yellow, more sulphuric acid must be added.

If, instead of evaporating and filtering the alcoholic solution, it is at once diluted, acidified, and permanganate added, more of the latter will be required than in the former case. In good samples the difference is sometimes great, but in most poor samples it is but slight, and in such case this more rapid process may be adopted. I have also tried the process of adding at once an excess of permanganate, letting stand five minutes and estimating the excess remaining, but the results given are decidedly too high. Various other methods have been proposed for the estimation of the nitrous ether, but I do not propose to enter into such, as the process given fulfils, I believe, all necessary conditions.

It is stated in most works on the subject that nitrous ether is rapidly decomposed and becomes acid. The latter statement is correct, as far at least as ordinary spiritus ætheris nitrosi is concerned, but the former is not in accordance with my experience. Spiritus ætheris nitrosi becomes acid mainly on account of the oxidation of the aldehyde it contains, while the nitrous ether present suffers but slow decomposition, at least when dissolved in spirit of sufficient strength. The following analyses will illustrate this. Sample I. was prepared by myself on February 21st, 1872, and has been kept ever since in a glass stoppered bottle (white glass) of one litre capacity, which it filled about half at first. About one half of the neck of the bottle was broken off early in 1872, so that the stopper does not fit very tightly since. The bottle stood on a shelf in the laboratory exposed to ordinary diffused daylight, but never to direct sunlight. On the bench below, and near to where the bottle stands, a Bunsen gas burner is frequently in use. Sample II. was bought as a sample of spiritus ætheris nitrosi ('Brit. Pharm.') from a well known wholesale house on December 2nd, 1873. It was contained in the ordinary pint bottle of green glass, and stood ever since in a cupboard of the laboratory, or in other words chiefly in the dark. Both bottles were frequently opened, and small portions of ether taken out in the intervals between the analyses given:—

No. of sample.	Date of examination.	Specific gravity.	Corresponding alcoholic strength.	Total acid free as acetic acid.	Real nitrous ether.
			Per cent. b. w.		
I.	Feb. 21, 1872	·836	84·8	0·10	2·00
I.	Nov. 15, 1873	·839	83·6	0·90	1·98
I.	April 23, 1879	·844	81·7	0·85	0·89
II.	Dec. 2, 1873	·824	89·5	1·19	1·35
II.	April 15, 1879	·847	80·5	1·38	0·96

We see, therefore, that even under somewhat unfavourable conditions the decomposition of the nitrous ether proceeds but slowly, and the plea sometimes advanced by chemists that the sample of spiritus ætheris nitrosi obtained at their shops, and found wanting, had been kept for some time and had decomposed, may safely be set aside as untrue.

In conclusion, I give the analyses of a number of samples, every one of which was bought as spiritus ætheris nitrosi ('Brit. Pharm.'), and should therefore have had a sp. gr. of 0·845, and contained about 3 per cent. of nitrous ether. All, except the last, were, however, bought before the present Sale of Food and Drugs Act came into operation. The last sample was supplied to the Westminster Hospital early in April, 1879. The bottle containing it, a Winchester quart, was labelled "Spiritus Ætheris Nitrosi, Brit. Pharm., sp. gr. 0·845." The bottle was quite full, and had not been opened at the Hospital, the stopper being still tied over with bladder when I took the sample on April 23rd, 1879.

Specific gravity.	Corresponding alcoholic strength. per cent. b. w.	Total free acid as acetic acid. per cent.	Real nitrous ether. per cent.
0·908	54·05	0·42	0·23

0·936	41·8	0·41	0·10
0·851	79·	1·14	1·30
0·928	45·6	0·33	0·25
0·852	78·5	0·28	0·07
0·848	80·	1·28	1·40
0·849	79·7	0·96	0·52

Mr. Hehner suggested that the direct addition of iodide of potassium would give a much fairer measure of the quantity of nitre present. He would add acetic acid and iodide of potassium, which both Dr. Muter and Mr. Wigner said they thought was a very good idea.

The Estimation of Ethyl Nitrite in Spiritus Ætheris Nitrosi B.P.

BY JOHN MUTER, PH.D., F.C.S.

I have been in the habit of using a saponification process for this spirit, but I work in a manner somewhat different from that used by Dr. Dupré, which I think possesses several advantages. The solutions I use are:—

(1). Decinormal solution of hyposulphite of soda (sodium thiosulphate), made exactly according to the directions of the British Pharmacopœia, each c.c. of which =·0127 free iodine.

(2). Solution of potassium permanganate, containing 3·175 grams per litre, and checked to balance the "hypo." solution, by adding excess of saturated solution of potassium iodide to 100 c.c., and then seeing that the iodine set free exactly requires 100 c.c. of "hypo." for complete decolorization, starch paste being added as an indicator towards the end of the process.

I first take the specific gravity of the sample at 60° Fahr., and I then measure out 10 c.c. of the spirit for analysis. This I digest with sufficient potassium hydrate in a small strong glass flask, closed by a cork, through which passes a bent delivery tube, dipping under a column of mercury in a test tube, of such a height as will enable me to heat gently on a water-bath under pressure without bursting the flask. This point is ascertained by a blank experiment, during which the flask is wrapped in a cover to prevent accident; and once arrived at, the same flask and mercury column are always employed. After digestion under pressure with frequent agitation for some time (an hour being usually ample), water is added, and the contents of the flask evaporated in a basin until no smell of spirit is perceptible. The residual liquid having been rendered *just neutral* with sulphuric acid, is filtered into a flask containing 75 c.c. of permanganate solution, previously diluted to 200 c.c. with water and acidulated with 20 c.c. dilute sulphuric acid (1 in 3), and the flask having been corked is left for half an hour. At the end of that time excess of saturated solution of potassium iodide is added (which should produce a clear deep orange solution), and the whole brought under a burette containing the hyposulphite solution and titrated. The number of c.c. of "hypo." used is deducted from the number of c.c. of permanganate put in, and the difference multiplied by ·00375 gives the amount of ethyl nitrite in the 10 c.c. taken for analysis, and if this be multiplied by 100 and divided by 10 times the specific gravity of the original spirit, the answer will be the percentage of ethyl nitrite by weight. In working with spirits of unknown strength it is advisable to put only 20 c.c. of permanganate into the flask at first, diluted and acidulated as directed, and then if all the colour disappears under five minutes, to add 5 c.c. more at a time, until a permanent colour is obtained, lasting five minutes, when the addition of another 5 c.c. will suffice before setting aside for the half hour. In a good spirit it is sufficient to take 5 c.c. for analysis, and to use 35 to 38 c.c. permanganate.

I am the more inclined to believe in the accuracy of this method, because I have found, by experiment, that the action of potassium nitrite on permanganate is not thoroughly trustworthy under half an hour. Ethyl nitrite is, however, much more rapidly affected, and I am at present engaged on a process whereby saponification is entirely avoided, and the whole thing does not occupy more than ten minutes. Until I publish this, I reserve my results on the actual constitution of the spirit, and the loss it undergoes by keeping. I am not at all clear that we should depend entirely on the ethyl nitrite alone for the real value of this medicine, and my other method depends on the estimation of the aldehyd and other bodies present in the article when properly made according to the official process.

The following are some analyses of pure spirits (specially made for me by Mr. Phillips—of Messrs. Knowles and Phillips—strictly by the B.P. process, and answering the gravity and separation tests of that authority), which were recently performed by one of my advanced students, Mr. Luther Scammell:—

Sample	No. 1	contained	3·05	ethyl	nitrite
"	" 2	"	2·91	"	"

I always prefer to do a blank experiment, using 20 c.c. pure rectified spirit, and the same weight of potassium hydrate as I use to the ether, and check it side by side with the sample experiment. In practice I use about two grams KHO and add 10 c.c. of rectified spirit, which aids its solution and helps saponification of the ethyl nitrite. I have also often used for the saponification a small flask fitted to a well cooled upright condenser, and worked at the boiling point; but I find the simple arrangement above stated does just as well.

SOCIETY OF ARTS.

The History of Alizarin and Allied Colouring Matters, and their Production from Coal Tar.*

BY W. H. PERKIN, F.R.S.

(*Continued from page 78.*)

We see, then, that when ordinary sulphuric acid acts upon dichloranthracene, that we get a mixture of the mono and disulpho acids of anthraquinone; the latter, however, greatly preponderates. The product also contains a considerable quantity of free sulphuric acid, which it is necessary to remove; this is done by means of slacked lime, with which it forms a nearly insoluble sulphate, and at the same time neutralizes the sulpho acids, forming soluble lime salts. We conducted this operation in the following manner:—

The crude sulpho acids from the iron pots were diluted in a large wooden tank, and boiled by blowing steam into it. Slacked lime in a wet state was then added by degrees, with constant stirring, until the product was neutralized. Wooden tubs, with mechanical stirrers, were afterwards substituted for the tanks, but by using Korting's steam jet air injectors all stirring arrangements may be dispensed with.

The neutral product was then run into the vacuum filters, to separate the sulphate of lime, the clear filtrate passing into the exhausted receivers. The filters consisted of large shallow wooden tanks, on the bottom of which bricks were laid about three inches apart, so as to form channels, and on the top of these some more bricks, placed side by side so as to form a floor. A layer of about three inches of small pebbles was spread upon this, and then about three inches of washed sand. This filtering medium was protected by a coarse canvas, kept in its place by a wooden framing.

Two iron reservoirs, in which a vacuum could be produced by means of an air pump, were connected with these filters, and so arranged with stopcocks that the filtrate might be passed either into the one or the other. One receiver was kept for the first, and, therefore, the strong filtrate and the first washings of the sulphate of lime. These were made with weak liquors from a previous operation. The further washings were made with boiling water, and were drawn into the second receiver. To get all the useful product out of the sulphate of lime, it was necessary to remove it after it had been well washed, boil it with water and again pour it into the filter. It should always be tested before it is thrown away. A great number of these filters were arranged side by side.

The strong lime salts of the sulpho acids in the first receiver thus obtained were concentrated in iron pans, heated either over a fire or by steam, until they contained about 15 per cent. of lime salts. Soda crystals (sodic carbonate) were then added in sufficient quantity to precipitate all the lime as carbonate, and thus to produce sodic salts of the sulpho acids. These were syphoned off from the carbonate of lime, and concentrated until they contained about 30 per cent. of sodic salts.

This product, which is technically called "soda salt," consists of at least three compounds, by far the principal one being the β disulphanthraquinonate, which yields anthrapurpurin. On standing, the α disulphanthraquinonate separates out with some of the β. The third salt is the sodic salt of monosulphanthraquinonic acid; but, curiously, this salt, which, when pure, is difficultly soluble in water, remains in solution. There is undoubtedly a small quantity of other salts present, some of which are probably derived from sulpho acids of the impurities of the dichloranthracene, but are of no interest to the colour maker. The three salts just mentioned are also formed when anthraquinone is used instead of dichloranthracene. They are sometimes separated, so that the different colouring matters they produce may be obtained in a more or less pure state.

The next operation consists in the conversion of the product just described, and called "soda salt," into colouring matter. This, it will be remembered, is effected by heating it strongly with caustic alkali. This operation we found difficult to perform on the large scale. First of all, it was necessary to keep the heating within certain limits. If too high a temperature were employed, the product was destroyed; if too low, the colouring matter was not formed, or only partially, and, consequently, a small yield resulted.

In the laboratory the experiments on this subject were performed in an air-bath, the products being heated in metallic dishes, a mixture of "soda salt" in a dry state with a saturated solution of the alkali being taken, caustic potash, caustic soda and mixtures of these alkalies being used, and it was considered that caustic potash gave, on the small scale, the best yield of colouring matter.

* From the *Journal of the Society of Arts.*

A mixture of caustic alkali and "soda salt," when heated to about 180° C., soon changes in colour, becoming blue, violet and then appearing as a black mass. As the water evaporates it also becomes pasty. On testing this, it is found to have decomposed so far as to form sulphoxyanthraquinonic acid. To complete the reaction the heating has to be continued for a considerable time.

To carry this process out very many experiments were made, and often with only partial success. One method we tried consisted in employing a long chamber, heated with flues to the requisite temperature, and arranged on the same principle as the ovens used for the continuous baking of fancy biscuits. It was hoped that by introducing shallow iron trays, with the mixture of soda salt and alkali in thin layers, and gradually working them forward to the other end of the oven, that by the time they had arrived there the decomposition would be complete, and thus a continuous method might be established.

This succeeded in a measure, but the time required to keep the mixture in the oven was too long to make it work continuously; moreover, it was found difficult to keep the temperature sufficiently uniform, and local overheating at times occurred, destroying the product.

Another apparatus we tried consisted of a large wrought iron cylinder, which was made to revolve inside a second, but fixed, cylinder of thick cast iron, sufficiently large to allow of an air space of several inches between it and the interior cylinder. This was heated so as to form a hot air chamber, the temperature being carefully regulated and observed with a thermometer. The axis of the revolving cylinder was hollow and perforated with small holes, so that the steam, evolved from the mixture of caustic alkali and soda salt with which it was charged, could freely escape. In this arrangement the heating was very satisfactory, but the operation took a considerable time, especially if the charge were large. Iron cannon balls were afterwards introduced, to keep the mass well mixed; but, curiously, they did not answer the desired purpose, as they became coated to such an extent with the alkaline mixture that when the operation was over they were found to be three or four times as large as when put in. Anthraquinone was found to sublime from this apparatus, and in a smaller one, which was overheated, anthracene was obtained.

This apparatus, although a considerable improvement, was not perfect, a good deal of sulphoxyanthraquinonic acid being often found in the product. However, some considerable quantity of colouring manner was manufactured in it.

Experiments were then made in closed iron tubes, with the products mixed with water. It was assumed that if an excess of alkali were used and a sufficiently high temperature that the presence of water would not interfere with the result. Curiously, this was found not to be true, or only partially so, and it was found that if the caustic alkali and soda salt were in a considerably diluted condition very little colouring matter was formed; the mixture, instead of becoming violet, was of a brown, or chocolate colour, and contained, as we now know, chiefly intermediate products, such as isoanthraflavic acid. On using less water, however, so that the mixture would contain about 25 per cent., or more, of caustic alkali, colouring matter was readily formed.

After experimenting for some time in closed iron tubes, capable of holding ten or fifteen gallons, some larger apparatus was set up. As it was necessary that this should bear a very considerable pressure, we selected sections of Howard's patent safety boilers, which were made of 10-inch drawn iron tubes. At the end of the horizontal tube of this arrangement there is a hole, about four inches in diameter, fitted with a cap, fastened on with screws, and made tight with a vulcanized washer. This hole was used for cleaning out the apparatus. At the other end there is a smaller hole, into which a pipe was screwed and connected with the necessary stop valves and pipes. It was charged and discharged through this aperture. At the top it is provided with a pressure gauge, safety valve and steam cock.

To heat these "pressure tubes," as they were technically termed, we employed a hot air chamber, in which flues passed underneath and at the sides. A thermometer was suspended through a hole in this chamber, and, in case of the temperature rising too high, iron doors in the side were provided, which could be opened so as to quickly admit cold air.

The pressure tubes were charged by gravitation from the floor above, and when the operation was completed their contents were forced up, by the pressure of steam in them, into iron tanks on the top floor of the building, so that all succeeding operations could be performed by gravitation.

The product thus obtained is an intense purple fluid, becoming thick on cooling. It consists chiefly of colouring matter, in combination with soda, of sodic sulphite, and a large quantity of caustic soda. To separate the colouring matter from this purple solution it is first diluted and then acidified.

We performed this operation in large wooden tanks, lined with lead, and called "precipitating tanks;" these were provided with steam pipes; three cocks were also inserted into the front sides of them. A quantity of sulphuric acid being first diluted in these tanks, the purple solution, when gradually run in, becomes orange in colour, owing to the separation of the artificial alizarin as a yellow precipitate; it also froths up, from the evolution of sulphurous acid, which was carried into the atmosphere by means of wooden funnels. If too little acid had been put into the tank some more was afterwards added.

When the operation is thus far completed, the steam should be turned on and the product in the tanks well boiled for about an hour, the object being to make the colouring matter more granular than it is when freshly precipitated, so that the next operation may be facilitated.

After being allowed to cool and settle during the night, the yellow supernatant liquor* can be run off from one of the side cocks. For these liquors we provided large tanks on the ground floor; some water was then run into the precipitating tanks, and then their contents were allowed to flow out on to the filters on the first floor.

These "colour filters," as they were termed, were fitted up in a similar manner to those employed in filtering the lime salt of the sulpho acids of anthraquinone, and were also provided with an exhausted receiver, so that the colouring matter could be washed rapidly. As the first drainings always passed quickly through the filters, they were run into the tanks on the ground floor.

The object of these tanks was that any colouring matter which might have run away mechanically, or separated out on the further cooling of the liquors, would be saved. These tanks were emptied when necessary to within about a foot of the bottom, the colouring matter being removed from time to time, when sufficient hasaccumulated to make it worth the trouble. But to return to the colouring matter on the filters. To fit it for the market, it must be repeatedly washed until nearly perfectly free from saline matter, and neutral to test paper. It is then allowed to drain for some time and afterwards removed to the stock tub.

As we collected the artificial alizarin from the filters, we used to transfer it to a truck, capable of holding several hundredweight of this product, and running on rails. It was weighed before being filled, and again afterwards. It was then wheeled over the large stock tub,

* Herr Glaser has separated from these an acid which has been examined by Graebe and found to consist of a sulpho acid of alizarin.—*Deut. Chem. Ges. Ber.*, 1879, p. 571.

capable of holding several tons, and emptied into it by withdrawing a plug. It was then again re-weighed, filled, weighed and emptied, and this process continued until the stock tub was suffiiciently full. The sum of the weight of the colouring matter from the truck gave the amount s tocked.

The colouring matter then requires to be thoroughly mixed, either by hand or other agitators, and, when perfectly homogeneous, a sample is taken out and tested. As the artificial alizarin is always put into the stock tubs in a concentrated state, when its strength is known, water is added, to reduce it to the proper standard. As a precaution it is then re-examined, and if found of the proper strength, is drawn off into casks and sent to the consumer. There are always several stock tubs, the number greatly increasing where many shades of artificial alizarin are produced.

Instead of the "colour filters," for washing and draining the colouring matter above described, filter presses are now very frequently employed, as they act much quicker. In these the artificial alizarin can be concentrated, until it contains thirty or forty per cent. of dry colouring matter; but this is not necessary, as it is usually sent into the market with about ten or eleven per cent., these being convenient strengths for the dyer. The value of the colouring matter may be determined by evaporating a weighed quantity in a dish, and when dry, again weighing. As it usually contains a little inorganic matter, the ash should be determined and weighed, but the more reliable method is to dye pieces of mordanted cloth, as in madder testing.

It will now be necessary to go back again a little to the formation of the colouring matter from the soda salt.

I have mentioned the various changes through which the monosulpho and disulpho compounds of anthraquinone go when being converted into colouring matter. In the case of monosulphoanthraquinone, it will be remembered that monoxyanthraquinone is first produced; and in the case of disulpho acids, anthraflavic and isoanthraflavic acids are produced before the colouring matters.

As I have already shown, these substances, when converted into colouring matter by heating with caustic alkali, cause nascent hydrogen to form, which reacts upon other portions of them, reducing them to anthraquinone and hydroanthraquinone. The presence of this latter substance in the purple alkaline product from the pressure tubes is easily seen by exposing some of it to the air, when a film of anthraquinone will rapidly form.

As I mentioned before, this formation of anthraquinone and hydroanthraquinone represents loss of valuable products, which should have been converted into colouring matter, and it was, therefore, an important problem to solve as to whether it could be avoided. Success attended the experiments in this direction, and all that was found necessary was to introduce a quantity of potassic chlorate, containing enough oxygen to unite with the nascent hydrogen. The sodic monosulphoanthraquinonate theoretically requires 13·2 per cent; the sodic disulphoanthraquinonates, 10 per cent. In practice, three or four per cent. more is usually employed, but any large excess must be avoided. This improvement was discovered by J. J. Koch.*

By employing chlorate of potash in this operation, the yield of colouring matter is very materially increased, as would be expected from the foregoing experiments. From experiments I have made, it is doubtful whether it acts upon the sodic sulphite at all. The conversion of monoxyanthraquinone, isoanthraflavic acid, and anthraflavic acid, or their sodic derivatives, into colouring matter, may by this modification be represented thus—

$$\underbrace{C_{14}H_7(ONa)O_2}+NaOH+O=$$

Sodic monoxyanthraquinonate.

$$\underbrace{C_{14}H_6\left\{\begin{matrix}ONa\\ONa\end{matrix}\right\}O_2}+OH_2$$

Sodic alizarate.

$$\underbrace{C_{14}H_6\left\{\begin{matrix}ONa\\ONa\end{matrix}\right\}O_2}+NaOH+O=$$

Sodic isoanthraflavate or anthraflavate.

$$\underbrace{C_{14}H^5\left\{\begin{matrix}ONa\\ONa\\ONa\end{matrix}\right\}O_2}+OH_2$$

Sodic anthrapurpurate or flavopurpurate.

It is also found to be an advantage to use less water and more caustic soda. As this makes a very thick mixture, the pressure tubes previously described are not suitable for the operation, and instead of them very strong double rivetted boilers are used, about 11 or 12 feet long and 4 feet 6 inches wide. These are fitted with a stirrer, which is kept moving during the operation, and are fitted up practically in the same manner as the pressure tubes. They are, however, charged through the top manhole. The mixture with which they are charged is about as follows, the amount, of course, being in proportion to the size of the boiler.

A quantity of the soda salt previously described, and representing 100 parts of dry salt, is mixed with about 400 parts of caustic soda, dissolved in as little water as possible, and 15 parts of potassic chlorate. The mixture is best made in the boiler, the stirrer being kept moving all the time, to render it homogeneous.

If sodic monosulphanthraquinonate be used instead of the above soda salt, a little more potassic chlorate may be used, and somewhat less caustic soda, as a smaller amount of the latter substance is used up in the chemical reaction. The preparation of sodic monosulphanthraquinonate will be described further on.

The temperature used is about 170° to 180°, some manufacturers using somewhat lower and others higher temperatures. When the charge contains chiefly sodic disulphanthraquinonate, the operation is carried on for several days and nights, not unfrequently a week; but if it contains sodic monosulphanthraquinonate, two or three days will be found sufficient.

I have often noticed, on heating a mixture of the mono and disulpho compound with caustic alkali, that by stopping the action early, only alizarin is produced, the decomposition of the disulpho acid, and consequent formation of anthrapurpurin, requiring considerably more time.

The products formed in these boilers are treated just in the same way as those from the pressure tubes previously described, *i.e.*, they are blown into iron tanks, diluted, acidified, and the precipitated coloured matter well washed.

I wish now to draw your attention to the first process we used for the preparation of artificial alizarin, viz., the process in which anthraquinone is employed. The anthracene we first used for this purpose was obtained from pitch. We then employed that from the tar distillers. In our earlier operations it was purified simply by treatment with naphtha and subsequent distillation, but afterwards by distillation with potash.

The purified anthracene was ground very thoroughly with water under edge-runners. It was then placed in a lead lined tank, with twice its weight of powdered potassic bichromate dissolved in water. About 3 parts of sulphuric acid, previously diluted, were then added. After well stirring, a very energetic reaction set in, the mixture boiling up to near the top of the tank. When this had been moderated, steam was turned on, and the mixture well boiled for an hour or two. The yellow granular crude anthraquinone was then separated from the chrome alum solution, well washed, and after it

* *Moniteur Scientifique*, April, 1879; p. 419.

had drained, though still wet, was purified by sublimation. At first we used two iron retorts, with openings at the top, and connected with a wide bent iron tube for this purpose, the one acting as a sublimer, the other as a receiver. Afterwards we employed retorts, with an outlet from the end connected with a large sheet-iron cylinder, having one end closed with canvas only.

The wet crude anthraquinone, when heated, gave off a considerable amount of steam, this helped to carry the vapour of the anthraquinone forward, which condensed as an impalpable powder. As the sublimation proceeded, and less steam was given off, small crystals of anthraquinone deposited. On opening the retorts after the operation, magnificent hard yellow crystals were often found suspended from the roofs of them.

The sublimed anthraquinone was then dried, and finally purified by crystallization from high-boiling coal-tar naphtha. The crystallized product was collected on canvas bags, drained, washed with a little clean naphtha, pressed, and then dried.

The amount of pure anthraquinone we obtained from pitch anthracene was, speaking from memory, about 20 to 25 per cent. The yield from ordinary anthracene from the tar distillers, was, of course, much greater. The use of potash in the distillation of anthracene we did not adopt until after we had ceased using the anthracene from pitch, otherwise better results would have been obtained with this product.

Since these early operations were made, a great deal of attention has been and is still being given to the preparation of anthraquinone. A number of experiments were made in my laboratory on the use of peroxide of manganese as the oxidizing agent, but I never succeeded in obtaining such a satisfactory yield as when potassic bichromate was employed. Anthraquinone is now usually prepared in the following manner:—The crude anthracene is first washed with coal-tar naphtha. In employing this as the purifying agent, it is used cold, and well agitated with the anthracene, until every particle has been brought in contact with it. If the crude anthracene contains 20 or 30 per cent. of pure anthracene, it is treated with its own weight of naphtha.

The naphtha is then well drained off from the anthracene, which is afterwards pressed as dry as possible by means of a hydraulic press. If the quality is lower than 20 per cent., it is first treated with about one-fourth its weight of naphtha, and afterwards as if of a quality over 20 or 30 per cent. The adhering naphtha, which is generally about one-tenth the weight of the pressed anthracene, is then removed by steaming, and thus recovered, or it is allowed to evaporate away.

The naphtha which has been used is purified by distillation, and thus rendered fit for a fresh operation. An arrangement of apparatus, such as that described for treating anthracene with petroleum spirit, answers equally when naphtha is used, omitting the cooling tanks. Horizontal stirring machines are now preferred to the vertical ones, as in the latter, the anthracene and solvent, after a short time, move round together with the stirrer, and therefore do not get well mixed. This, however, can be avoided by fixing a few blades to the sides of the machine.

(*To be continued.*)

Parliamentary and Law Proceedings.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

Prosecution of a Chemist by the Excise Authorities.

At the Sunderland Police Court on Wednesday, July 23, 1879, before Mr. Alderman Potts, and Andrew Common, Esq., Mr. John W. Gillies, chemist and druggist, High Street, Sunderland, was charged at the instance of the Excise authorities, "That on May 17, 1879, at Sunderland, he not being a distiller or rectifier of spirits or other person duly authorized or specially licensed by the Commissioners of the Inland Revenue to mix and make methylated spirit, sold a certain quantity, to wit, one gill, of methylated spirit without having in force a licence on that behalf, granted under the authority of the Act, contrary to the terms of the statute in that case made and provided."

Mr. W. A. Young, district supervisor of Excise, conducted the prosecution, and Mr. Henry Glaisyer, of Birmingham, solicitor to the Chemists and Druggists' Trade Association of Great Britain, appeared for the defendant.

Mr. Young said the information was laid under the 5th section of the 24th and 25th Victoria, c. 91, which enacted that every person not being a distiller or rectifier of spirits or other person duly authorized or specially licensed by the Commissioners of Inland Revenue to mix and make methylated spirits, who shall sell any such spirits in any quantity without having in force a licence on that behalf, granted under the authority of this Act, shall forfeit the sum of £50 over and above all other penalties to which he may be liable under any other Act or Acts in force. The authorities, he said, had had complaints made to them that Mr. Gillies was selling methylated spirits, and an officer of the Inland Revenue visited his shop on May 17 last. He asked for a gill of methylated spirits, with which he was supplied; Mr. Gillies stating at the time that he had no licence to sell it and must put something in it. There was an article sold under the regulations of the Board without a licence called "finish," which was methylated spirit, to every gallon of which had been added three ounces of gum resin or shellac. Part of the sample purchased from Mr. Gillies was sent to the laboratory at Somerset House for analysis. It did not contain sufficient gum resin to constitute what was called "finish" by the Board's regulations.

E. Lewthwaite, an officer of Inland Revenue, stated that acting on instructions he visited the defendant's shop on May 17 last, and asked for a gill of methylated spirit. Mr. Gillies supplied him. He said there had been a great deal of bother about that sort of thing and he must put a little of something in it before he could sell it as he had no licence. Fivepence was paid for it. Witness took the spirit home and kept it till he gave it to Mr. Young the supervisor.

Cross-examined by Mr. Glaisyer: When I went into the shop I asked for a gill of methylated spirit, and the defendant replied that he had no licence to sell it and must put something in it before he could sell it. Defendant did not say that he did not sell it. I did not suggest that he had it in stock. Defendant did not say that he kept it only for making his preparations. Defendant did not ask me what I wanted it for. I did not say my son was making experiments and I wanted it for burning. I did not say anything about burning it or making experiments. Defendant did not say he was making "finish." He said he would do something to it. I did not ask whether that would destroy its burning power. I did not see what he put in it. I did not see him put anything in it. I have not seen much methylated spirit; what I bought had a yellowish tinge. I did not see him put any resin into it. I did not shake it up. I kept it a few days and then handed it to the supervisor. It was put in my own bottle.

By the Bench: The defendant went into the back shop to fill the bottle and handed it to me over the counter. He told me before going into the back shop that he would have to put this stuff into it.

William Anthony Young, supervisor, said: I received this sample of methylated spirit from Lewthwaite. It looked about the same as it does now. The bottle contained a gill. I sent about half of it to the laboratory at Somerset House for analysis. I secured the sample myself in the box (produced), addressed it, and sealed it with the Revenue seal. It was addressed, "The Principal, Laboratory, Inland Revenue, Somerset House." It was sent off on June 11. I could not be positive when Lewthwaite gave me the spirit. He got it on May 17, and it was two or three days after I packed it up and sent it to London on June 11. I shook it up when I received it from Lewthwaite, and at the time I divided it I shook it thoroughly.

Henry James Helen said: I am one of the analysts to the Board of Inland Revenue at Somerset House. I remember receiving a parcel from Sunderland on June 12. The box produced is the one in which the bottle was enclosed. The seal was perfect, I analysed it and found it to be methylated spirit containing 429·8 grains or rather less than one ounce of gum resin to the gallon. Methylated spirit to be what the Board of Inland Revenue call "finish" must have dissolved in it three ounces of gum resin.

By Mr. Glaisyer: There was an earlier regulation of the Board which required less. On April 23, 1837, the Board issued an order allowing it to be sold with one ounce of gum resin. If the resin was not thoroughly dissolved, the liquid taken from the top of the bottle would contain less resin than that at the bottom.

This was all the evidence produced.

Mr. Glaisyer (addressing the Bench) said: The charge against the defendant is for selling methylated spirit without a licence. The answer I am instructed to make is that he sold the article known as "finish." If this is proved to your satisfaction the summons must be dismissed. I think I am entitled to go further and say, that in construing this very penal statute, most ample proof is required on the part of the prosecution before the defendant can be convicted, and if there exists a doubt in your minds, the defendant is entitled to the benefit of that doubt, and the charge against him should be dismissed. There is no doubt that the sale of methylated spirit as "finish" is allowed without a licence, and there are the two general orders of the Board of Inland Revenue on that subject which have been mentioned to you to-day. Perhaps I may be allowed in passing to call the attention of the Bench in a few words to the law which sanctions the manufacture and regulates the sale of methylated spirit. In the first place I may tell you that methylated spirit is not spirits of wine. The sale of spirits of wine has been for many years regulated by statute and prohibited except under a wine licence. But for the purposes of art and manufacture it has become requisite that a preparation of spirits of wine should be sold much more generally than is allowed by this provision; and therefore, in the year 1855, an Act was passed by which a mixture of spirits of wine with wood naphtha or methylic alcohol was permitted to be sold under another licence, and that mixture is called methylated spirit. It cannot be sold in its pure state except by persons who have taken out a licence; and the penalty for selling it without a licence is £50, the amount claimed in the present proceedings. Under an Act passed in the reign of Geo. IV. the magistrates have power to diminish that penalty to £12 10s., or one-fourth of the amount; though they cannot make a greater reduction they have power to recommend the Commissioners of Inland Revenue to further remit the penalty, and these recommendations I am glad to say receive the very careful consideration of that Board. Spirits of wine as methylated spirits can therefore be sold with a licence, but the use of methylated spirit as medicine or an ingredient in medicine is most strictly prohibited, and it is chiefly needed in the manufacture of furniture polish and varnish in making various liniments and for burning in spirit lamps. The use of methylated spirit in art and manufacture has constantly called for modifications in the restrictions in its sale, and in consequence the general orders, to which allusion has been before made, have been published by the Inland Revenue Board, and the article known as "finish" is the outcome of these modifications in the law. "Finish" is made by the addition to a gallon of methylated spirit of three ounces of gum resin; thus whilst preserving its utility in art and manufacture it is rendered so nauseous and unpalatable that no one will drink it, and that is really the object with which the resin is added, for nauseous as methylated spirit is, people have been found who had such a craving for spirits that they had actually drunk it. No other alteration is allowed in the constitution of "finish," except the addition of more gum resin or a little colouring matter, and any alteration in other respects incurs a liability to a very heavy penalty—£200 if I recollect correctly. The defence is that the defendant has really sold the article "finish." He would tell you if his mouth were not closed that when this informer came into his premises he told him he did not sell methylated spirit, and had no licence for the purpose. The informer asked if he did not keep it in stock. He said he did, and the informer said he might let him have a gill, and the defendant again replied that he could not sell him methylated spirit, but he could sell him "finish," and proposed to sell him that article, and asked him for what purpose he wanted it. The informer replied that his son was making experiments, and required it for burning, and also inquired if the "finish" which the defendant proposed to sell would burn in a lamp. The defendant said he believed it would, and on those terms he sold him the article "finish." As he measured it out he added to the half pint of spirit at least half an ounce of gum resin, or more than was actually required by the general order. The general order authorized him to sell "finish," and he was under the impression that he had sold it. He would further tell you that he never keeps more than half a gallon of methylated spirit on his premises at one time, that quantity being quite sufficient for the requirements of his business for four months, his sole use for it being the manufacture of certain liniments. He is never asked for methylated spirit, and therefore takes out no licence for its sale. For twelve years he has been carrying on the business of a chemist and druggist in High Street, and this is the only charge that has ever been made against him. On this occasion he says he had sold "finish," and had therefore not infringed the law. I hope you will take that view of the case and discharge the summons.

After some remarks from Mr. Young, the Bench retired to consider the case, and on their return shortly afterwards,

The Chairman (Mr. Alderman Potts) said: The Bench find that the law has been clearly violated, and we cannot do otherwise than convict. We impose the minimum penalty £12 10s. and recommend a reduction to £5. This is the first case, so far as we know, that has arisen in this town, and the defendant, we think, may not have been aware of the order of 1867.

Mr. Young: I will forward the recommendation.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Reply.

[328]. In reply to this query I think C. B. obtained the correct result. Probably the tinc. hyoscyami used by the London firm was made from leaves of the annual plant instead of biennial.

VOLO SEMPER JUVARE.

Queries.

[333]. How is extract. bela. liquid usually dispensed, as a clear dark-brown liquid or as an opaque syrupy liquid with an abundant precipitate? In the directions for its preparation in the B.P. no notice is given as to it being filtered after the addition of the spirit.

Norwich. W. W. WILL.

Can any reader of the Journal inform me the best mode of dispensing the above?

AN APPRENTICE.

[335]. A prescription was presented to me the other day ordering "Emp. Iodinii." I shall be glad of the opinion of your readers as to what I ought to have used, there being no preparation of that name in the B.P. The prescription was written at Birmingham and had been previously dispensed seventeen times in the south of England, but the patient remarked that he could not get "the right stuff" in the north, and on my asking him what had been the colour of the previous plasters he instantly took the prescription out of my hand and left the shop remarking that I did not know my business. NIHIL.

[336]. Can any one inform me what is the use of the following?—

Take of—

Extract of Bark	15 grains.
Extract of Rhatany	8 grains.
Extract of Burdock	2 drams.
Fixed Oil of Nutmegs . . .	2 drams.
Camphor	15 grains.
Beef Marrow	2 ounces.
Olive Oil	1 ounce.
Citron Juice	½ dram.
Bergamot	10 drops.
Otto Rose	2 drops.

Mix and make into a pomade.

EDWARD PRATT.

[337]. Can any of your readers inform me how to dispense the following prescription without separating?—

SPIRITUS ÆTHERIS NITROSI.

Sir,—The subject of the above compound has lately been one of deep interest to me as it no doubt has to many others.

I am persuaded that it is very gratifying to many that spiritus ætheris nitrosi is again occupying the attention of chemists, and trust that something more definite and satisfactory will be arrived at respecting this very remarkable compound.

I have read Mr. Rimmington's paper in your issue of the 19th ult. with much care and attention. There are, however, one or two peculiarities in the results obtained by him that are somewhat difficult to comprehend.

He remarks at the outset that all that is said in this paper "has reference to a spirit that corresponds with that described in the British Pharmacopœia in nature, substance and quality." That I understand to mean, that the sample tested, on being agitated with twice its volume of the saturated solution of calcic chloride, 2 per cent. of nitrite of ethyl will float on the surface; and yet in the analysis of his best sample the per cent. given is 1·72 as being the total amount it contains.

Another peculiarity in Mr. Rimmington's results is that the amount of nitric peroxide obtained is only a little more than one-third of the amount contained in the quantity of nitric acid used. What has become of the other?

I am sure this subject needs further investigation and probably if the contents of the retort were carefully examined after the operation of nitre making is concluded, some further information would be obtained.

NOTES ON SOME JAPANESE DRUGS.

BY E. M. HOLMES, F.L.S.,
Curator of the Museum of the Pharmaceutical Society.

ROOTS.

(*Continued from page* 23.)

BOTAN (59) :—*Pœonia Moutan*, Dec.

Syn. MAU-TAN, Porter Smith, Chinese Mat. Med. p. 169, Phonzou Zoufou, vol. ix. p. 14.

This drug consists of the root bark, which occurs in half quills, from one to three inches long. Externally the pieces are of a dark lilac-brown colour and moderately smooth; internally, pinkish-white and starchy, but hard, or in some pieces horny and darker coloured. The taste is aromatic and pungent and the odour is very similar to that of *Hemidesmus indicus*, but more powerful.

In China this bark is largely used for congestion, hæmorrhages and menstrual disorders, and, according to Dr. Martin, is often prescribed by the Japanese physicians. It is forbidden to be used by pregnant women, being considered abortive. Analysed by Iago* at the pharmaceutical laboratory, at Tokio, it yielded an aromatic crystalline substance, which was apparently a fatty acid allied to caprinic acid, but had a higher melting point. The crystals are very soluble in alcohol and ether, and are precipitated from the alcoholic solution by a large quantity of water. They melt at 45° C. and sublime at a higher temperature. This plant is quite a favourite with florists in Japan and China, who make more than thirty varieties of it. A large number of varieties were exhibited at the last Paris Exhibition, some of them having the delicate perfume as well as the blush tint of the cabbage rose.

REW-TANG SOH (20) :—*Gentiana Buergen*, Miq.

Syn. RINDO, Sô mokou Zouss. vol. iv. fig. 47; SASA RINDO, Fr. et Sav. vol. i. p. 323; Phonzou Zoufou, vol. viii. p. 5.

This drug consists of a short rhizome, giving off a number of brown roots about the thickness of a crow quill, and three or four inches long; these are strongly furrowed longitudinally. The transverse section of the rhizome is pale and spongy, the taste is bitter and resembles that of gentian in character. It corresponds well with the specimens of "Gentian" (Lung-tan-ts'au) in the collection of Chinese drugs presented to the Society by Dr. Porter Smith, but does not answer to his description of the drug. He refers it to *Gentiana asclepiadea*, and other species. *G. Buergeri* was, however, identified from the Japanese description in the Sô moukou Zoussetz by Mr. Takemura as being identical with Rew-tang sau. *Gentiana Buergeri* is found in damp grassy places in Japan, and flowers in September and November.

The name both in Chinese and Japanese has the same meaning, viz., Dragon's-gall-herb, and is given by the Chinese, according to Dr. Porter Smith, to any intensely bitter plant.

SANG-YAK (41) :—*Dioscorea japonica*, Th., Fl. Jap. p. 151.

Syn. YAMA-NO-IMO, JIJENJO; Sô mokou Zoussetz, vol. xx. fig. 56; DSOJO, IAMMA IMO, Kœmpf. Amœn. p. 828.

Sang-yak occurs in white cylindrical tapering pieces, varying from one-half to one inch or more in diameter, and four or five inches long. The outer surface owes its whiteness to being decorticated; the transverse section is also white and presents a uniform appearance. It has no taste or smell. It is probably used, like the Hwai-san-yoh of the Chinese, in diarrhœa. Kœmpfer states that the root is edible.

The word Yak means "medicinal" in Japanese, so that it may be inferred from the name of the drug that it is also used as a medicine, probably in the same way that arrowroot is used in this country. The plant is frequent in shrubberies in Japan, and flowers in September. The leaves much resemble those of the black bryony in shape, but the fruit is capsular.

SEKI-SHO KUNG (3) :—*Acorus gramineus*, Ait. Sô mokou Zoussetz, vol. vii. fig. 10; Phonzou Zoufou, vol. xxxiii., p. 17; Fr. et Sav. vol. ii. pt. 1, p. 10.

This drug consists of a slender rhizome, two to four inches long, and about a quarter of an inch in diameter, sparingly branched and marked with numerous leaf scars like that of *Acorus Calamus*, to which it bears a strong general resemblance, but differs in taste, which in *Acorus gramineus* is pungent and faintly bitter, and in the absence of aroma. The rhizome has been compared with that of specimens of the plant in the British Musenm, and corresponds well with it.

The drug described under this name in Dr. Porter Smith's 'Materia Medica' is not that of *A. gramineus*.

According to Mr. Takemura, the article on this plant in Sô mokou Zoussetz, states that *A. gramineus* is more used in China than in Japan. The name Sekisko appears to be derived from *seki*, meaning a stone (it is the same character as the Chinese Shih), and *sho*, acorus, probably in allusion to the plant growing in damp stony places instead of in the water. It flowers in April.

SENG-KIU (7) :—Sô mokou Zoussetz, vol. v. fig. 1; *Conioselinum univittatum*, Turcz, Fr. et Sav. vol. ii. p. 375.

Sen-kiu is a hard, somewhat rounded, very knotty rhizome, one or two inches in circumference, and apparently formed at first by swellings of the internodes, which are distant about half an inch from each other. These swellings seem to be formed into a rounded mass in the course of development of the rhizome. This mode of growth appears evident from the portions of the cylindrical stem which may be found attached to some of the specimens, and which have smaller knobs at the nodes. The rhizome is greyish-brown externally, and greyish and horny, and slightly marbled with white internally, and has an aromatic taste, recalling that of fenugreek or lovage seeds. Seng-kiu grows in shady places in mountainous woods, and flowers in July.

SENG-KOOTZ (11) :—*Nuphar japonicum*, D. C. (Nymphæaceæ).

Syn. Nymphœa lutea, L.; Thunb. Fl. Jap. p. 223. KAWAHONE, Sô mokou Zoussetz, vol. x. fig. 10; FEISO, KAWAHONE, Kœmpf. Amœn. p. 880.

This drug occurs in flattish pieces, three to six inches long or more, and about one inch broad, and half an inch in thickness, consisting of the rhizome cut in half longitudinally. On the outside the pieces are of

* *Archiv der Pharmacie*, October, 1878, p. 334.

brown colour, marked with round blackish scars where the leaves were attached, and present a swelling beneath each scar where the rootlets have been given off. The cut side and indeed the whole inner surface is of a yellowish or dirty white tint, and very starchy. The substance is soft and tough, and under a lens is seen to be as full of minute holes as a piece of coral. The taste is insipid, and the odour resembles that of marshmallow root.

The name *seng* signifies a river, and *kootz* a bone, possibly in allusion to the colour and porosity of the root.

SEE-YOH-BEI (29):—*Geum japonicum*, Th. (Rosaceæ).
Syn. DAIKONSO, Sô mokou Zoussetz, vol. ix. fig. 41; Thunb. Fl. Jap. p. 220; Fr. et Sav. vol. i. p. 128.

This root consists of a short central woody portion, about half-inch long and one-third of an inch in diameter, almost concealed by a dense tuft of slender slightly furrowed rootlets, which are two or three inches long, and about the thickness of ordinary twine.

The root is pale brown internally, with a darker horny centre (not purple as in *Geum urbanum*). The taste is astringent and has the same peculiar clove-like character as that of *Geum urbanum*. The odour also faintly resembles cloves. It was this characteristic that led to its identification, which was confirmed by a comparison of the Japanese characters with those in the Sô mokou Zoussetz, by Mr. Takemura.

The properties, judging from the taste, must be aromatic and astringent. See-yoh-bei grows by roadsides and margins of fields, and flowers from August to October.

SHAU-BOOKUNG (37):—*Acorus spurius*, Schott, Ann. Mus. Lugd. Batav. 1 p. 284; Araceæ.
Syn. SHOBU, Sô mokou Zoussetz, vol. vii. fig. 9; Phonzou Zoufou, vol. xxxiii. p. 17; KAWA SOB, KAWA SOBU, Kœmpf. Amœn. p. 912.

This drug, except in being split longitudinally into two halves, and in its smaller size, differs in nothing from the *Calamus aromaticus* rhizome obtainable in this country.

As a species it is chiefly distinguished by the shortness of the spathe, which near the apex is only about four lines broad, the spadix being three or four lines thick. Judging from the taste alone, it appears to be only a small variety of *A. Calamus*, L.

TENG-MA (38):—*Urtica tuberosa*, Roxb.(?); Porter Smith, Chinese Mat. Med. p. 225, *Pouzolzia tuberosa*, Wight, Icon. Pl. Ind., vol. ii. t. 697.

This drug consists of flattened shrivelled tubercules about two inches long, one inch broad and one-fourth to one-third of an inch in thickness. Externally they are of a greyish-brown colour and internally present a blackish-brown shining fracture. The tubercules appear to have been hollow inside. The taste is sweet and mucilaginous. The odour is somewhat smoky. In China, according to Dr. Porter Smith, the plant is prescribed in rheumatism, neuralgia, palsy and lumbago.

The Japanese drug closely resembles both in appearance and taste the Chinese specimens presented to the Society by Dr. Porter Smith.

The Chinese name T'ien-ma, or Teng-ma as it is pronounced in Japanese, means *teng*, heaven, *ma*, nettle. Heaven, being the idea of excellence, seems almost an equivalent for good; so that the name seems to imply a nettle possessing unusually good qualities. The root is edible.

TAK-SHA (2):—*Alisma Plantago*, L. (Alismaceæ).
Syn. SAJI-OMODAKA, Sô mokou Zoussetz, vol. vii. fig. 33; TOKUSA, SASI-OMODAKA, Thunb. Fl. Jap. p. 153.

This drug consists of the dried corms. They are somewhat conical in shape, the wide upper end presenting traces of the stem, while the lower tapering portion is covered with the bristly remains of rootlets. The transverse section presents a yellowish-white uniform appearance, sparkling by reflected light, with bright points. The taste is sweetish and the odour aromatic and slightly ammoniacal. It is used in China for dropsy and similar complaints.

Thunberg states that Sasi-omodaka means spoon-like, and that this name is probably given from the shape of the leaves.

TENG-MONG-DAU (26):—*Asparagus lucidus*, Lindl. (Liliaceæ).
Syn. KUSASUGIKADZURA, Sô mokou Zoussetz, vol. vii. fig. 6; Phonzou Zoufou, vol. xxviii. p. 3; TEEN-MUN-TUNG, Hanbury 'Science Papers,' p. 257; KE MUNDO, TEN MONDO, Thunberg, Fl. Jap. p. 257; T'IEN-MEN-TUNG, Dr. Porter Smith, Chinese Mat. Med. p. 145, Tomo-roki, Ten mada, Fr. et Sav. vol. ii. p. 1, p. 59.

This drug consists of spindle-shaped brownish horny looking tubercules, showing traces of a pale thin longitudinally furrowed skin which has evidently been eaten away by insects; the tubercules vary in thickness from one-fourth to one-third or even half-an-inch in diameter in the centre. The taste is sweet and mucilaginous at first with a distinct but somewhat sickly flavour and afterwards a bitter taste. They do not possess a marked odour. The horny portion of the tubercules is not attacked by insects. The tubercules of *Melanthium cochinchinense* in the collection presented to this Society by Dr. Porter Smith agree exactly in taste and appearance with the Japanese drug, and the written character for the Japanese and Chinese drug is identical, although pronounced differently.

The above identification is given on the authority of Sô mokou Zoussetz, but not without some hesitation on my part, since the asparagus flowers in July and the Japanese native name *mong dau* means gate of winter, implying a plant flowering (or fruiting?) late in autumn. Hanbury and Porter Smith both refer it to *Melanthium cochinchinense*, but several other writers to asparagus.

TAU-HOONG-SO (16):—*Veratrum album* (?)
Syn. BAI-KAI-SO, Fr. et Sav. vol. ii. pl. 1. p. 91.

This root presents all the appearance of the *Veratrum album* of commerce, and gives the same orange-red tint when the root is touched with strong sulphuric acid. It consists of a central portion, about two-thirds of an inch in diameter and about one inch or more long, crowned with the membranous bases of leaves and furnished with numerous brown rootlets about a line in thickness and two or three inches long. These rootlets have the numerous transverse wrinkles so characteristic of the roots of *Veratrum album* and *viride*. The taste is bitter at first, but afterwards a burning sensation is produced. The Japanese name does not, however, correspond to that of either *Veratrum nigrum* or *V. viride*, which are figured and described in the Sô mokou Zoussetz, vol. xx. fig. 62, 63. The central axis of the root shows the same crenated ridge where it joins the root bark, which Professor Bentley has shown to be characteristic of the *Veratrum album* of commerce. *V. album* is is, however, a native of Japan, although not described in the Sô mokou Zoussetz.

TO-KEE (8):—*Ligusticum acutilobum*, Sieb. et Zucc. *Syn.* TOKI, Sô mokou Zoussetz, vol. v. fig. 4; Fr. et Sav. vol i. p. 186.

To-kee root bears a strong external resemblance to angelica root, both in size and shape, but the rootlets are less furrowed. It consists of a tap root about one inch in diameter near the top, tapering down to a quarter of an inch, and surrounded by a number of stout rootlets from one-fourth to one-third of an inch thick. The side roots are marked with numerous transverse slightly warty scars; internally the roots present a dark brown colour, with a darker ring around the meditullium and a soft waxy section with very few and small oil vesicles. The taste is sweet and mucilaginous and very faintly pungent. The odour has a faint resemblance to fenugreek.

TO-SAI-SHIN (1):—*Asarum Sieboldii*, Miq. *fol. coriaceis* (Aristolochiaceæ), Sô mokou Zouss. vol. ix. fig 5; Phonzou.Zoufou, vol. viii. p. 8.

The rhizome of this plant is very similar in appearance to serpentary root, consisting of a slender rhizome crowned with numerous crowded discs marking the base of the leafy stems; from this rhizome the rootlets depend in a dense tuft three or four inches long. The roots are of a pale brown colour, cylindrical, quite smooth and unbranched. The transverse section is white and starchy with a slender yellow woody thread in the centre. The taste is aromatic, at first somewhat resembling that of nutmeg or sassafras, then powerfully pungent and causing a flow of saliva like pellitory. The odour is slightly aromatic, but not at all camphoraceous like serpentary.

This variety of *Asarum Sieboldii* is found in copses and woods on the sides of hills, and flowers in April and May. It is not often cultivated in Japan.

(*To be continued.*)

RESEARCHES ON ALBUMIN.*

BY SCHÜTZENBERGER.

It having been observed that albuminoid substances when submitted to the action of baryta under suitable conditions appear to be transformed entirely into crystallizable or into definite principles, it seemed reasonable to suppose that a carefully conducted and complete study of this reaction would be likely to materially contribute to a knowledge of the proximate composition of these bodies, if it did not ultimately solve the question respecting their constitution.

With this end in view, the author instituted and has carried out an extended series of experiments upon the action of baryta solution at high temperatures on coagulated egg-albumin and other nitrogenous principles, the results of which investigation form the subject of the present memoir.

The albuminoid under experiment was placed with the alkaline solution in an iron silver-lined autoclave, and heated to a definite temperature for some hours. After cooling, the contents of the cylinder, consisting of an amber-coloured liquid and a solid deposit, were transferred to a large flask, and the ammonia (1) distilled off into hydrochloric acid and estimated; the residue (2) in the flask was brought upon a weighed filter, washed with boiling water until the baryta was removed, then dried and weighed. The filtrate from the latter was precipitated by a current of carbonic anhydride, the barium carbonate removed, and the baryta remaining in the liquor exactly precipitated by sulphuric acid and its weight ascertained. The acid thus set free, which proved to be acetic acid (3) with traces of formic acid, was distilled off in a vacuum and again determined. The residue remaining from the distillation of the acetic acid, which the author terms *fixed residue* (4), is of a clear yellow colour, friable and easily removable from the vessel; it contains all the fixed principles, such as leucine, tyrosine, etc., which are formed at the expense of the organic substance, in the proportions in which they are produced.

Determination of the Ammonia.—Having proved that coagulated albumin, washed with ether and dried at 140°, contained 16·5 per cent. of nitrogen, the effect of boiling it with three times its weight of baryta under ordinary pressure was ascertained. 1·2 per cent. of nitrogen was evolved in the form of ammonia within the first half hour, the disengagement proceeding slowly, until after one hundred and twenty hours' boiling 2·2 per cent. had been eliminated: this number was never exceeded. At 120° in the autoclave, 2·2 per cent. of nitrogen was evolved by digestion during six or eight hours; at 150°, with only twice its weight of baryta, 3·1 per cent. was obtained; whilst between 150° and 180°, with three parts of baryta for twenty-four hours, 3·95 per cent. was disengaged, and the limit of 4·0 per cent. was not exceeded even by heating with six parts of baryta for six or eight days. These three limits indicate clearly three successive and different stages of decomposition.

Insoluble Barium Salts.—The quantity of this deposit, like the ammonia, varies with the temperature and with the proportion of baryta used: in composition as well as in weight it undoubtedly bears a direct relation to the quantity of ammoniacal nitrogen disengaged. It consists mainly of barium carbonate and oxalate, with a certain amount of barium phosphate and sulphate; the proportions of the two former, the only important elements in the mixture, were as follows: From 100 grams of albumin—

		N.	$BaCO_3$.	BaC_2O_4.
With 200 grams of BaH_2O_2	at 100°	2·1	3·6	3·4
,, ,, ,,	at 120	2·3	4·7	4·3
,, ,, ,,	at 150	3·1	10·5	5·0
,, 300 grams ,,	at 180	4·0	10·8	8·0
,, ,, ,,	at 200	3·95	11·0	8·6
,, 600 grams ,,	at 180	3·79	11·2	18·2
,, ,, ,,	at 250	4·41	12·5	24·2

Acetic Acid.—The proportion of this acid is always relatively small, it varies with the temperature and the proportion of the baryta, as in the previous instances, the smallest quantity obtained being 2·7 per cent., and the greatest 5·4 per cent.

Fixed Residue.—The total weight of this residue, obtained as before mentioned (including 6·53 per cent. of organic matter carried down by the barium carbonate), amounted in one experiment to 95·83 per cent., and in another to 96·5 per cent. of the albumin used; it is evident therefore that the decomposition under the influence of baryta is accompanied by a fixation of the elements of water, inasmuch as the separate weights of the components being added together, there is always an excess varying from 10 to 14 per cent. The ultimate analysis

* From the *Ann. Chim. Phys.* [5], 16, 289—419. Reprinted from the *Journal of the Chemical Society*, July, 1879.

of the fixed residue gave very constant numbers, which did not vary greatly even under different formative conditions, the mean numbers being $C=48{\cdot}16$; $H=8{\cdot}2$; $N=11{\cdot}03$; $O=30{\cdot}75$ per cent.

Volatile Oil.—There is formed, during the decomposition of albumin in the manner under discussion, a very small quantity of a volatile oil, about 1 or 2 per cent., which could not be obtained in sufficient quantity for analysis under ordinary conditions. An operation on the large scale with 10 kilograms of albumin enabled about 50 or 60 grams of the oil to be collected and an examination to be made. It had no fixed boiling point; on account of the small quantity at disposal it was not possible to separate its constituents by fractional distillation: it was therefore divided into four portions boiling from 113° to 120°; 120° to 140°; 140° to 180°; and above 180°, and an analysis of each portion made. From the results of these analyses the author is of opinion that the oil is a mixture of two substances, one, the more volatile, containing oxygen but not nitrogen; the other, nitrogen but not oxygen. The presence of pyrrol in the oil was clearly established by means of its well-marked reactions. The formula, $C_{16}H_{23}NO_3$, calculates very nearly to the percentage obtained, from which if the formula of pyrrol be deducted (C_4H_5N) there remains 3 (C_4H_6O), which may be considered to represent approximately the composition of the remainder. A small quantity of a sulphuretted body is also contained in the oil. The quantity of this albuminol obtainable is so small that it is impossible to assign to it any important part in the constitution, or in the reactions representing the decomposition of albumin.

The proximate analysis of the fixed residue was a work of very great difficulty, and every method that could be devised was tried with only partial success. It was eventually found that the best method was to treat the residue with neutral solvents, and to separate the constituents as far as possible by means of fractional crystallization. The identification of the various principles was afterwards effected by means of ultimate analysis, which, in the absence of any well characterized reactions, was found to be the only sure or practicable means of arriving at satisfactory results. More than 500 combustions were thus made.

The two terms which were the easiest to isolate from the fixed residue, on account of their slight solubility, were *tyrosine* and *leucine*, the former, which is produced to an extent varying from 2·3 to 3·5 per cent., was recognized by its crystalline form, and by its well-known colour reaction with mercurous nitrate; the latter was also obtained in a well-crystallized condition, and gave results on analysis agreeing accurately with the formula $C_6H_{13}NO_2$.

The successive crystalline deposits, obtained by progressively concentrating the solutions from which the leucine, etc., had been partially separated, were composed of amido-valeric and amido-butyric acids, together with two new, definite, crystallizable products, *tyroleucine* $C_7H_{11}NO_2(C_nH_{2n-3}NO_2)$ and a body corresponding with the formula $C_6H_{11}NO_2(C_nH_{2n-1}NO_2)$: the quantity of tyroleucine obtained was about 60 or 70 grams from 10 kilograms of albumin. Tyroleucine presents itself as a white crystalline deposit of chalky aspect, possessing scarcely any taste, but soluble in about 20 parts of water at 15°. It melts and decomposes at 240°, breaking up into a white sublimate and a volatile oily base having an odour of radish; it leaves behind an abundant yellow vitreous residue. The analysis of the chloroplatinate of the base gives it the formula of collidine, $C_8H_{11}N$, and of the vitreous residue the formula $C_{14}H_{18}N_2O_2$; the decomposition of tyroleucine may therefore be taken as proceeding thus—

$$2(C_7H_{11}NO_2)=C_{14}H_{18}N_2O_2+2H_2O$$
$$2(C_7H_{11}NO_2)=CO_2+\underbrace{C_8H_{11}N}_{\text{Collidine.}}+\underbrace{C_5H_{11}NO_2}_{\text{Amido-valeric acid.}}$$

from which one is led to suppose tyroleucine to be a compound of amido-valeric acid with a body of the formula $C_9H_{11}NO_2$, the latter differing from tyrosine only by an atom of oxygen. This is rendered more probable by the fact that tyrosine, when heated under similar conditions, breaks up into CO_2 and a base, $C_8H_{11}NO$, which differs from collidine only by an atom of oxygen.

Among the homologues of leucine, amido-valeric and amido-butyric acids were met with in quantity, but amido-propionic acid in very small proportion only; its presence, however, was clearly and distinctly made out.

To the compounds of the formula $C_nH_{2n}+_2NO_2$, the author gives the generic name *leucines*, and to those of the formula $C_nH_{2n-1}NO_2$ the names *leuceïnes* ($n=6$). Both seem to be frequently produced by the splitting up on crystallization of bodies of the formula $C_mH_{2m}N_2O_4$ ($m=10$ or 12); however by repeated fractional crystallization the compound $C_{12}H_{24}N_2O_4$ gave always the same analytical numbers, from which it is fair to suppose that it has an independent existence. The supposition is moreover strengthened by the fact that similar results were obtained with the lower homologues containing 11, 10, 9, and even 7 atoms of carbon.

For these latter bodies, the name *glucoproteins* has been adopted, on account of their sweet taste; they crystallize less easily than the leucines, especially the lower terms; they are very soluble in water, but almost insoluble in cold absolute alcohol; hot alcohol of 90 per cent. however dissolves them with ease.

Another substance resulting from the decomposition of albumin, which is produced in important quantity, is a yellow viscous body obtained by precipitating certain mother-liquors from which leucines have been crystallized by ether. Dried at 120°, it is converted into a transparent amorphous mass, which on analysis gives numbers comprised between the formulæ $C_5H_9NO_2$ and $C_4H_7NO_2$, very often sensibly approximating to the formula $C_9H_{16}N_2O_4$; it appears in fact to be constituted in great part of butyric leucine with an admixture of some superior homologue.

The longer the action of baryta on albumin is continued, and the more concentrated the solution, the greater is the proportion of leucines and of leuceïnes formed, whilst under the contrary conditions, the intermediate bodies, or glucoproteins, constitute the bulk of the fixed residue, representing the initial terms of the hydration of albumin; under all circumstances caproic leucine and tyrosine appear to be the ultimate terms of the decomposition.

The mechanism of the reaction would therefore appear to admit of the following explanation. The albuminoid molecule losing ammonia and carbon as carbonic, oxalic, and acetic acids, and assimilating water, is converted into a comparatively simple mixture of glucoproteins, $C_nH_{2n}N_2O_4$, containing as its principle term $C_9H_{18}N_2O_4$: by the prolonged action of baryta and a high temperature, these glucoproteins split up partly into leucines and leuceïnes, and partly into double compounds formed by the union of glucoproteins and leuceïnes with the leucines.

The leuceïnes may perhaps be regarded as amido-acids of the acrylic, or of an isomeric series. They reduce ammoniacal silver nitrate on warming, and are attacked by bromine in the cold with formation of HBr and an acid of formula $C_nH_{2n-1}NO_3$. In the analysis of the fixed residue, the ratio of nitrogen to oxygen is never rigorously 1 : 2, but there is always a slight excess of oxygen, so that the ratio is nearer 1 : 2·1 or 1 : 2·3; this difference indicating the presence of small quantities of non-nitrogenous compounds, or of bodies in which the atomic relation of nitrogen to oxygen is greater than 1 : 2. A careful examination for such bodies among the crystalline deposits resulted in the detection of a few grams of an acid from 1 kilogram of albumin, offering a composition very close to that of *glutamic acid*, $C_5H_9NO_4$, and a smaller quantity of a second, whose composition was that of glutamic acid minus water, $C_5H_7NO_3$, which has been called *glutimic acid*. Judging from their amount, these acids play but a secondary part in the constitution of the mixture resulting from the decomposition of albumin: the acids, on the other hand, which are capable of being extracted in reasonable quantity from the insoluble barium salts, do not exhibit a constant composition; they appear to be residues of a progressive decomposition, and to be susceptible of being resolved by the continued action of baryta into a mixture of leucines and oxalic acid.

Without following all the steps by which the author succeeded in tracing the presence of the various bodies which are met with in small proportions as constituents of the fixed residue, and modify slightly the ratio between the nitrogen and oxygen, we may sum them up as follows:—1. Traces of succinic and lactic acids. 2. Tyrosine. 3. Amido-acids of the type $C_nH_{2n-1}NO_3$ glutamic and aspartic acids. 4. Amido-acids of the type $C_nH_{2n-3}NO_3$ glutimic acid. 5. Amido-acids of the types $C_mH_{2m-4}N_2O_6$ and $C_nH_{2n-1}NO_3$. 6. Intermediate compounds of the type $C_mH_{2m}N_2O_5$.

The principle, which is the most constant among the products of the decomposition, and whose proportion is the most easy to determine on account of its sparing solubility, is tyrosine. The maximum quantity obtained of this body was 3·5 per cent.; if, therefore, one molecule of albumin reacts in the formation of one molecule of tyrosine, it points to the approximate molecular weight 5500 for the former, since $\frac{181}{5500} = 3·3$. An expression of the form $C_{240}H_{387}N_{65}O_{75}S_3$ corresponds with a molecular weight equal to 5473, which satisfies the conditions involved in the determination of the sulphur and tyrosine, as well as the results of elementary analysis, thus—

	C.	H.	N.	O.	S.	Mol. weight.
Experiment	52·57	7·16	16·6	21·8	1·8	—
Theory . .	52·62	7·07	16·62	21·94	1·75	5473

Again, taking as the basis of calculation the experiments made with 5 or 6 parts of baryta at 180°, the centesimal proportions of the products were—

N as NH_3.	$BaCO_3$.	BaC_2O_4.	$H_4C_2O_2$.
4·03	17·6	11·0	4·6

which corresponds very fairly for 5473 parts of albumin with—

NH_3.	$H_2C_2O_4$.	CO_2.	$H_4C_2O_2$.
16 mols.	4 mols.	3 mols.	4 mols.

From these numbers the following equation may be written, which moreover would give a fixed residue of 99·6 per cent.:—

$$C_{240}H_{387}N_{65}O_{75}S_3 + 60H_2O = 16NH_3 + 4C_2H_2O_4 + 3CO_2 + 4C_2H_4O_2 + C_{221}H_{435}N_{49}O_{105} + S_3.$$

Deducting a molecule of tyrosine from the formula of the fixed residue, we have $C_{212}H_{424}N_{48}O_{102}$, which approximates very closely to an expression of the form $C_nH_{2n}NO_2$, differing from it only by a slight excess of oxygen.

By taking in this manner the series of experiments made with different proportions of baryta and at different temperatures, a number of equations may be written, in all of which the theoretical composition of the fixed residue corresponds very closely with that obtained experimentally.

There can be no doubt that, during the hydration of albumin, as many molecules of water are assimilated as there are molecules of ammonia liberated; if then from the proposed formula for albumin we deduct the ammonia, carbonic, oxalic, and acetic acids in the proportion furnished by experiment, less a number of molecules of water equal to the number of molecules of ammonia (adding as many molecules of water as there are molecules of carbonic anhydride produced, since the latter probably results from the decomposition of urea) we shall have—

$$[16NH_3 + 4C_2H_2O_4 + 3CO_2 + 4C_2H_4O_2 - 16N_2O + 3H_2O],$$

which leaves $C_{221}H_{341}N_{49}O_{581}$, an expression which corresponds with the type $C_nH_{2n-2}NO$ quite as nearly as that of the fixed residue with the type $C_nH_{2n}NO_2$, the difference on both sides being a slight excess of oxygen. The molecule of albumin therefore resembles that of a body whose formula is $x(C_mH_{2m-4}N_2O_4)$, where $m = 2n$, and undergoes hydration in two distinct steps. At 100°, with a limited proportion of baryta, the grouping fixes a number of molecules of water equal to one-half the number of atoms of nitrogen which it contains, and becomes $x(C_mH_{2m-2}N_2O_3)$. The latter, at a higher temperature, can in its turn fix a number of molecules of water equal to the number of atoms of nitrogen which it contains, changing itself to the formula $x(C_mH_{2m}N_2O_4)$, the final result being the assimilation of as many molecules of water as the albumin contains atoms of nitrogen. *Albumin is then probably an imido-derivative, which by hydration changes into a mixture of amido-derivatives.*

To return to the observed relation between the ammoniacal nitrogen evolved, and the carbonic and oxalic acids produced, it is noticeable that two molecules of ammonia are disengaged for each molecule of acid generated; the simplest reaction which could account for such a phenomenon would be to suppose that the ammonia results from the hydration of urea or cyanamide and oxamide, a supposition which acquires a much greater degree of probability when it is shown that a very large majority of animal nitrogenous principles, when similarly decomposed, yield a quantity of ammonia which is precisely the amount that should be furnished by the carbonic and oxalic acids produced at the same time, supposing the whole to result from the reaction above mentioned. The author has examined wool, hair, osseïn, isinglass, gelatin, goat's hair, silk, fibrin, and chondrin, in all of which the above relations held good.

Summary.—It has been shown: 1. That the mixture of fixed principles derived from albumin by hydration contains only amido-derivatives. 2. That these derivatives can be divided into two unequal portions, one, the weight of which is about 16 to 18 per cent., containing the substances in which the ratio of nitrogen is 1 : 3, or 1 : 4, or 2 : 5; the most important fraction of this portion consists of acids of the formula $C_nH_{2n-1}NO_4$, $C_nH_{2n-3}NO_3C_{2n}H_{4n-4}N_2O_6$, and $C_nH_{2n-1}NO_3$, the intermediate term being only a molecular combination of the terms $C_nH_{2n-3}NO_3$ and $C_nH_{2n-1}NO_3$. The second portion, which constitutes ⅘ths of the residue, may be represented by the formula $x(C_nH_{2n}N_2O_4)$ with a value for n a little less than 9. According as the limit of hydration is attained, the products formed belonging to the type $C_mH_{2m}N_2O_4$ (where m is a multiple of n) are progressively resolved into simple bodies belonging to the same apparent type; these again are resolved into bodies of the type $C_nH_{2n}N_2O_4$, which in their turn are resolved into leucines, $C_nH_{2n+1}NO_2$, and leuceïnes, $C_nH_{2n-1}NO_2$. This interpretation is not affected by the presence of more highly oxygenated acids in the fixed residue, since they may be considered as derived from any of these bodies by substitution of O for H_2.

To the memoir is added an appendix, in which are given the results of some analyses made of fixed residues obtained from different sources. Albumin purified by Wurtz's method was substituted for crude albumin; the baryta was precipitated in one instance by carbonic anhydride, in another by carbonic anhydride and sulphuric acid, and in a third by carbonic anhydride, ammonia, and ammonium carbonate, but no important differences were observable in the products of decomposition. It was also found to be a matter of indifference whether the hydration of the albumin was begun by the action of other agents less energetic than baryta, such as dilute sulphuric acid; on completing the action by the intervention of baryta as usual, the same result was obtained as in the previous instances. A fixed residue obtained by the action of baryta was subsequently boiled for twenty-four hours with a 20 per cent. sulphuric acid, but its composition was not found to be sensibly affected.

In a final operation, conducted with the usual reagents, the action of baryta upon albumin was carried to its extreme limit. The fixed residue was carefully examined to see whether any substance was produced under such condition, which had not been found, or had been overlooked in previous experiments: nothing, however, was met with but the usual mixture of leucines and leuceïnes.

The molecular weight of the various glucoproteins still remains to be determined.

THE REMOVAL OF FIXED OIL FROM COLCHICUM SEED.*

BY EMIL L. BŒRNER.

With the view of determining upon a suitable solvent for the fixed oil contained in colchicum seed, one which, while removing all of this for the preparation of the fluid extract objectionable constituent, would yet dissolve out none of the active principles of the drug, the following course was pursued, viz.:—Separate portions of the drug, in powder No. 60, were treated by percolation, the one with gasolin, a second with petroleum benzin, and a third with stronger ether, U. S. P.; the several percolates resulting were carefully evaporated until entirely free from the odour of their respective solvents.

The fixed oil thus obtained was of a density not unlike that of castor oil at a summer temperature, of a fatty odour, a pale olive colour, and very slightly bitterish taste in the case of the gasolin and petroleum benzin residues, while that exhausted with ether was of a somewhat darker colour and more decidedly bitter.

To ascertain whether the oil, as removed from the powdered seed by the process described, contained any colchicia, portions of each of the three residues were severally agitated with distilled water acidulated with hydrochloric acid, the liquids filtered and the filtrates treated for colchicia, as follows:—

That from the ethereal preparation gave, with concentrated nitric acid, concentrated sulphuric acid, hydrochloric acid and carbonate of potassium, a lemon yellow coloration; a slight white flocculent precipitate with tannic acid; a denser, nearly white, flocculent precipitate with iodo-hydrargyrate of potassium; a heavy, kermes coloured, flocculent precipitate with iodine and a turbidity with chlorine water—the solution becoming yellow upon the subsequent addition of water of ammonia—while the filtrates from the gasolin and petroleum benzin residues, when treated in exactly the same manner, gave no precipitates with any of the reagents mentioned, only a slight yellow coloration being produced by concentrated sulphuric acid.

Upon subjecting a portion of fixed oil separated from a fluid extract prepared by the process of the U. S. P. of 1870 to the same treatment as was pursued in the foregoing experiments, a slight yellow coloration was produced with each of muriatic, nitric and sulphuric acids.

Ether, because of its solvent action upon colchicia, as well as on account of its greater cost, as compared with the other solvents used, was considered objectionable, and was accordingly abandoned for any further experiments. Gasolin and petroleum benzin having, apparently, about equal solvent powers, the former of these was preferred as being more readily expelled from the drug after percolation with it, and before subjecting to the usual treatment for the preparation of the fluid extract. Upon treating a larger quantity of the powdered seed with gasolin, in the manner above described, an oil answering to the description of that first mentioned was obtained to the amount of 9·05 per cent. and having a specific gravity of ·922 at 60° F.

A portion of this oil, tested for the presence of colchicia, in the same manner as that obtained by a previous experiment, gave exactly the same results.

A suitable solvent having thus been found for the fixed oil contained in colchicum seed, its removal from the drug, before treatment in the usual manner for the fluid extract, would seem practicable, as the product obtained, unlike that of the officinal process, which separates the oil upon standing and necessitates its removal, is a perfectly clear preparation.

The advantages resulting from such a removal of the oil would seem to be quite evident, inasmuch as the fluid extract would not then be loaded with it, and would present a much more elegant appearance than does the officinal preparation. This extract being miscible with water, might perhaps even be used hypodermically by evaporating off the alcohol and diluting with water. The more evident may seem these advantages when it is remembered that nothing is sacrificed medicinally and only a slight expense incurred for gasolin, the quantity necessary for exhaustion being scarcely twice the weight of the powder to be treated with it.

Aware of the difficulty of powdering colchicum seed, the writer sought to remove the oil by maceration before grinding, but was unsuccessful, as only a part can be extracted in this way.

Though having no direct bearing upon the query here attempted to answer, the writer would state that, in availing himself of the suggestions offered in Mr. J. U. Lloyd's papers, published on pages 408 and 409 of last year's 'Proceedings,' by omitting the use of glycerin and finishing the preparation with a mixture of three parts alcohol and one part water, a more satisfactory preparation was obtained than when the Pharmacopœia formula was strictly followed.

* From the 'Proceedings of the American Pharmaceutical Association,' 1878.

ACETOUS PERFUMES.*

1. *Concentrated Aromatic Vinegar.*

Concentrated Acetic or Glacial Acetic Acid	8 ounces.
Oil of Lavender (English)	2 drachms.
Oil of Rosemary	1 drachm.
Oil of Cloves	½ ,,
Gum Camphor	1 ounce.

2. *Hygienic Vinegar.*

Strong Brown Vinegar	2 pints.
Gum Benzoin	1 ounce.
Oil of Marjoram	½ drachm.
Brandy	1 pint.
Oil of Cloves	1 drachm.
Oil of Lavender (English)	1 ,,

3. *Toilet Vinegar* (*à la Violet*).

White Wine Vinegar	2 pints.
Extract of Cassie	½ pint.
Extract of Orris	¼ ,,
Extract of Rose (triple)	¼ ,,

4. *Toilet Vinegar* (*à la Rose*).

Extract of Rose (triple)	½ pint.
Dried Rose Leaves	4 ounces.
White Wine Vinegar	2 pints.

5. *Vinaigre de Cologne.*

Eau de Cologne	1 pint.
Glacial Acetic Acid	1 ounce.

6. *Cosmetic Vinegar* (*Piesse and Lubin's*).

Concentrated Vinegar	1 ounce.
Gum Benzoin	3 ounces.
Alcohol, Pure	1 quart.
Balsam of Peru	1 ounce.
Oil of Neroli	1 drachm.
Oil of Nutmegs	½ ,,

7. *Vinaigre à la Rose.*

Glacial Acetic Acid	1 ounce.
Oil of Rose	½ drachm.

8. *White Wine Vinegar.*

Filter best ordinary brown vinegar through animal charcoal till perfectly white.

The Pharmaceutical Journal.

SATURDAY, AUGUST 9, 1879.

A MEDICAL TITUS OATES (?).

When a ready writer is at a loss to find a subject on which to exercise his skill his pen is a weapon especially liable to be engaged in the mischief which a nursery poet tells us is the inevitable consequence of idleness. At the present day, when the possession of a free press offers such abundant scope for literary talent, it is scarcely surprising that we should now and then meet with cases of this kind, referable partly to the inexorable necessity of filling a certain number of columns and partly to the exigencies of the young lions of the press.

But besides the lack of subjects to write about there are other circumstances which tend to bring about the same mischievous exercise of literary skill, and chief among these is the love of sensation which prevails with so large a portion of the public. People demand highly spiced literary food for their daily entertainment, and if divorce cases or breaches of privilege do not afford the requisite *pabulum* the young lions must draw upon their inventive faculties, and manufacture something which will for the moment appease the desire for excitement.

We have recently been made acquainted with a flagrant instance of this kind through the kindness of a friend who has forwarded to us some pages of the *Philadelphia Medical Times*, of June 7. The managers of that journal appear to be impressed with the idea that correspondence between different parts of the civilized world is desirable in order to make the manners and customs of one country known in other countries for mutual benefit, and with that object, as we presume, they publish in the number we now refer to a "London letter." The writer of that letter is an English medical man resident in London, and it might reasonably have been expected that he would have something to say in his letter that would be useful or instructive, and in that sense worth being read by his American colleagues.

The first glance, however, at the London letter of the *Philadelphia Medical Times* serves to dispel such an idea, and it becomes evident that the London correspondent has either been in a state of literary destitution, without any suitable subject to write upon, or he has perversely devoted himself to the production of a sensational story no more fit to appear in the pages of a scientific journal than the ghost stories which school boys delight to find in our illustrated papers at Christmas time.

The article we refer to commences with the statement that amidst the varied relations of the professions there is none more curious than that of consultants and chemists, and especially chemists' assistants. Then it is remarked that any possibility of collusion between the two is not at first sight very apparent, and that of course it is natural for assistants in chemists and druggists' shops to recommend any consultant who is either known to them by repute or in the habit of sending his patients to the shops in which they serve. It is also admitted that chemists and druggists' assistants have some opportunity in common with other folk of seeing whose names most commonly occur in medical journals in connection with certain specialties, and it is further admitted that any reply upon such grounds to the inquiry, "Who is the man to consult for so and so?" would be quite unobjectionable.

So far then chemists and druggists or their assistants may be grateful to the London correspondent of the *Philadelphia Medical Times* for the liberty he is pleased to accord them. But, as he says, "the matter does not stop here;" he has penetrated deeper below the surface; and then he proceeds to lay before his American readers a description of what he pretends to have discovered. No one will deny that many persons who do not know anything about consultants, but yet wish to consult some one for an ailment or disease, think the readiest and surest plan is to drop into some well-known chemist's shop and ask who is the best man to see for such a complaint. What could be more natural than for the person whose daily avocations make him familiar with the repute of certain medical practitioners to be asked for such information? But the unsuspecting and confiding inquirer who does so is thoroughly "sold and hookwinked" by the quiet and "innocent looking youth who when thus interrogated immediately raps out some consultant's name"—at least that is the statement made in the letter published in an American medical journal for the information of medical men across the Atlantic.

This instructive correspondent next proceeds to relate how this is done and the statements he makes in that part of his letter are of such a nature that we will not venture to give them in abstract. After referring to the importance attached by English people to a physician's prescription and the anxiety to have it carefully dispensed, the writer says:—

"The youth to whom the prescription is handed looks at it sardonically, and remarks contemptuously, 'For piles?' Of course the patient is very much taken aback at this, and exclaims, 'Bless me! no! For bronchitis!' The youth has achieved his end, and the surprised and startled patient's confidence in the man he has just consulted is irrevocably shaken. That he should have got a prescription for piles when he went about his bronchitis, comes to him as a very unpleasant revelation. It is not only that he has spent his money in vain, but that he has been cheated into risking his health, and possibly ruining his constitution, by having the wrong medicine prescribed; the thought is very shocking that he should thus have been trifled with by ignorance or carelessness. In the midst of his perturbation he gasps out, 'Who is the best man to consult about brochitis?' The placid answer is, 'Oh, Dr. Vitreous Tendon, of course!' The deed is done; an assassin-like stab has been given to the reputation of an unoffending man, and the young scoundrel chuckles at the skilful manner in which the blow has been delivered. The patient goes away wrathful and indignant that the doctor he had just consulted should have treated him so badly, and vows with genuine earnestness that he himself will never consult him again; 'No; nor, by Jove, shall anybody I know consult him either, if I can help it!' Away he goes circulating the story among his acquaintances, getting this unlucky physician a bad name so far as he can. Now, this is certainly diabolical wickedness; and the apparent artlessness with which it is done disarms all suspicion. That the chemist's assistant had any motive other than of saving him from taking a medicine unsuitable if not possibly dangerous, any ulterior design in his apparently friendly action, never crosses the victim's imagination. It is the apparent innocence of the scoundrelism which is at once it strength and its protection. The utter guilelessness of the ingenious surprise of the young man behind the counter 'fetches' the victim, who never detects the trap that is so skilfully laid for him. That that young villain, that moral assassin, is 'squared,' there can be no doubt; and possibly enough he does not realize the injury he is doing to the unoffending physician to whose reputation he has delivered a nasty stab; but he does it all the same, and as effectually as if his conduct had been inspired by the most deliberate malice. He wished to put a fee into the pocket of Dr. VITREOUS TENDON, that was his main object; we will hope, for the sake of humanity, that he does not realize the injury he is doing to another man. A less indecent but equally effective plan is for the chemist's assistant to have three names on a card, and when asked about whom to consult, he declares his inability to decide, until the question is put home to him, 'Whom would he consult, if necessary?' He then mentions the lowest name on the list. The apparent absolute *bona fides* of this crafty villain allays any possible suspicion of 'a plant' which might arise in the mind of the sold individual, and the inquirer goes away perfectly satisfied."

As regards the motive for such conduct as that described in the above paragraph very little more than insinuation is ventured upon by the writer of the letter who evidently perceives that some of the dirt he seeks to cast at chemists and druggists must stick to his brother physicians, for we are told there are two kinds of physicians, one like the writer who says "Take your prescription to any good chemist," without recommending anyone in particular. Then the phrase "secret understanding between prescriber and dispenser" is slipped in and a story is told of a particular medical man being recommended by a chemist and druggist for syphilis, stricture, hemorrhoids, heart disease and every ill that man is heir to.

In this way the suggestion of a dishonest influence is conveyed to the minds of the reader, and then we have the remark "By what underground communi-"cation the chemist's assistant is rewarded for his "share in the unholy compact has not yet transpired; "but it is quite obvious some arrangement does "exist." It is almost suggested that the chemist and druggist is the prime mover of the arrangement as well as the only culpable participator in it, for it is anticipated that "doubtless the chemists' journals will resent what is here written," and "will cast doubts on the statements here made." No such resentment is referred to, however, as being likely to come from the medical journals, for the charge is adroitly made only to affect chemists and druggists and "black sheep" in the medical profession. Perhaps a reason for this is to be found in the letter itself, since the writer says he has heard of a chemist and druggist's assistant who stated that "There was no such medical man in London." Such ignorance may be more reprehensible than we are disposed to consider it, but it certainly does not justify the designation of the assistant as a "youthful young sprig of rascality."

It is very difficult to come to any conclusion concerning such an effusion as the one we have above dealt with. Charity forbids us to entertain the latent suspicion that it is an ingenious mode of obtaining the "bold advertisement" so much sought after by professional as well as trading men. But we cannot any the more regard it as wholesome criticism since it lacks the truthfulness and temperance that should always characterize a critic. More likely it is the result of an illusion provoked by the circumstance of being unknown to some chemist and druggist's assistant, and that the writer brooding on this indignity has conjured up the form and semblance of a foeman worthy of his steel and madly possessed by this idea has made himself as ridiculous as CERVANTES' lanky and lugrubrious knight in attacking a harmless and inoffensive windmill.

BRITISH PHARMACEUTICAL CONFERENCE.

BY the courtesy of the Secretaries we have been favoured with the following list of papers to be read at the meeting of the British Pharmaceutical Conference, at Sheffield, August 19 and 20:—

1. Report on the Aconite Alkaloids. C. R. A. WRIGHT, D.Sc., F.C.S.
2. The Capacity of Different Organs to Absorb and Retain Arsenic in Cases of Chronic Poisoning. N. P. HAMBERG, M.D., H.M.P.S.
3. The Growth and Development of Ergot. W. W. STODDART, F.I.C., F.C.S.
4. The Application of Chloroform in the Testing of Drugs. LOUIS SIEBOLD, F.I.C., F.C.S.
5. Note on the Specific Gravity of Liquids. LOUIS SIEBOLD, F.I.C., F.C.S.
6. Proximate Analysis of the Rhizome of *Zingiber officinalis.* J. C. THRESH, F.C.S.
7. Soluble Essence of Ginger. J. C. THRESH, F.C.S.
8. The Polarimeter and its Use in Pharmacy. C. SYMES, Ph.D.
9. The Assay of Commercial Disinfecting Powders containing Carbolic Acid. A. H. ALLEN, F.I.C., F.C.S.
10. Notes on Petroleum Spirit. A. H. ALLEN, F.C.S.
11. Cinnamon Bark. Mr. A. H. JACKSON.
12. The Gelatinization of Tincture of Kino. Mr. T. H. BAMFORD.
13. Amylic Alcohol and Amylic Nitrite. Mr. DOTT.
14. Extraction of Pilocarpine. Mr. A. W. GERRARD.
15. Anhydrous Air as a Therapeutic Agent. G. A. KEYWORTH, F.C.S.
16. Quillaia Bark, its Chemical Composition and Use in Pharmacy. Mr. H. COLLIER.
17. Note on Aricine. JOHN ELIOT HOWARD, F.R.S.
18. The Chemistry of Chaulmoogra. J. MOSS, F.I.C.
19. The Determination of Water in Iodine. E. DAVIES, F.I.C., F.C.S.
20. The Presence of Tannin in Gentian Root. E. DAVIES, F.I.C., F.C.S.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, August 6, 1879.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Gostling, Hampson, Hills, Mackay, Rimmington, Savage, Symes, Williams and Woolley.

The minutes of the previous meeting were read. Previous to their being signed,

Mr. WOOLLEY said he wished to make an observation on two matters arising out of the minutes. The first referred to the conversation which took place respecting the Sale of Food and Drugs Act Amendment Bill. A friend of his had commiserated with him on the rap over the knuckles which it was thought he had received in the matter, but he did not want to say anything about that, except that he had never seen the Bill before. The important point was that this Bill was ordered to be printed on April 29, but it did not seem to have ever been brought before the Law and Parliamentary Committee, and carefully considered. He was not one of those who complained of the Adulteration Act, which in many instances had been of great advantage, but that it needed amendment was evident from the new Act having been passed, and as this bore so directly on the trade, the Committee ought at all events to have gone through it and seen whether some improvements could not be suggested. For instance, it was a great hardship that an innocent man could never recover his costs. He should like to ask how it was that the Bill had not been brought before the Committee.

The PRESIDENT thought it had been many times mentioned at that table or in the Committee.

Mr. WOOLLEY thought it ought to have been brought regularly before the specially appointed Committee for considering such questions, and gone through in a proper way.

Mr. RIMMINGTON said the Bill in the first place only referred to the strength at which spirit should be sold, and excited very little interest even in parliament.

The PRESIDENT said that one gentleman who was examined before the Committee, the government analyst from Somerset House, called on him respecting a matter, which had been incidentally referred to and which would have affected chemists; that was mentioned at the Council table on more than one occasion. There never was any attempt on the part of the promoters of the Bill to introduce any clause which would specially affect chemists and druggists, and he had never heard a suggestion made by the Committee or Council that alterations were required. So far as Mr. Woolley had been in error, he thought all the members of Council were in the same boat, for none of them were aware of the last line in the Bill when the matter was discussed at the last meeting of Council.

Mr. WOOLLEY said the other matter he wished to refer to was the increase of salary voted to the Editor and Sub-Editor at the last meeting. He thought this was a matter of sufficient importance to appear in the report of the Council proceedings.

The PRESIDENT said the members of the Society were apprised of any alterations in these matters by the balance sheet issued preparatory to the annual meeting.

Mr. WILLIAMS said this matter arose out of the proceedings of a Committee. If they were to publish all the reports of the Committees as well as the Council it would become a very serious matter. Unless it were made a practice to publish the reports of the Committees, such matters could not very well be published.

Mr. HAMPSON thought Mr. Williams's view was scarcely accurate, because the report very frequently contained a statement of what had been done by the Committee. For instance, in the General Purposes Committee, certain prosecutions were agreed to, and a notification of this effect was frequently made.

Mr. ATKINS was disposed to support the view taken by Mr. Woolley, though perhaps it would be discussed better at a later period in connection with a motion to which Mr. Symes had given notice.

The minutes were then confirmed.

THE INDIA MUSEUM.

The PRESIDENT said the Council was aware that it was the intention of the Government to break up the India Museum, and the Curator, Mr. Holmes, on going over it was informed that if the Society made application in all probability it would obtain certain things which were very interesting. He (the President) thereupon wrote to the Honourable E. Stanhope on the subject, and had received a reply, promising to lay the matter before the Secretary of State for India in Council for his consideration, so that he hoped, if any distribution of this collection were made, the Society would be thought of.

The VICE-PRESIDENT wished it was within the province of the Council to express a disapproval of the course which the Government had thought fit to adopt. A more unfortunate resolution he could hardly conceive than that of scattering this fine collection of Indian products.

DIPLOMAS TO PHARMACEUTICAL CHEMISTS

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a Diploma stamped with the seal of the Society:—

Alcock, Frank Harris.
Allan, James Henry.
Betts, George.
Bird, Henry.
Dutton, Hugh Odard.
Grimble, Albert.
Horton, Thomas.
Lapthorn, George.
Lomax, Alban Edward.
Mayger, William John.
Nowell, Barnes.
Pisani, Orestes Victoriano.
Porter, Thomas.
Ratcliffe, Henry Norman.
Remfry, Samuel Alfred.
Russell, James Lawson.
Shirley, Stephen Shillito.
Smithson, Thomas Henry.
Villar, Arthur.

ELECTIONS.

MEMBERS

Pharmaceutical Chemists.

The following, having passed the Major examination and having tendered their subscriptions for the current year, were elected Members of the Society:—

Alcock, Frank Harris ....Stoke-on-Trent.
Allan, James Henry..............Stockton-on-Tees.
Betts, George ....Scottow.
Horton, Thomas ....Burton-Overy.
Lapthorn, George...................Southsea.
Lomax, Alban Edward ....Birkenhead.
Mayger, William John ....Northampton.
Nowell, Barnes.......................London.
Ratcliffe, Henry Norman ......Malmesbury.
Smithson, Thomas Henry ......Thirsk.
Villar, Arthur ....Taunton.

The following, an Associate of the Society before 1842, having tendered his subscription for the current year, was elected a Member of the Society:—

Ashmall, George ....Wallingford.

Chemists and Druggists.

The following, who was in business on his own account before August 1, 1868, having tendered his subscription for the current year was elected a "Member" of the Society:—

Moore, Francis Samuel ....Castle Cary.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Davis, Henry John ....Newbury.
Hulland, Charles Richard ......Framlingham.
Pickles, Walter.....................Dewsbury.

ASSOCIATES.

The following, having passed the Minor examination and tendered or paid (as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Ballard, Frank English .. ..Aylesbury.
Bourne, Charles M. K. ...... Wolverhampton.
Bown, John Quinton ....Nottingham.
Bridge, George Edward ....Maidstone.
Carter, Francis ....London.
Clerke, William Burdett.........Leamington.
Crow, William......................Berwick-on-Tweed.
Crowther, Arthur..................Tickhill.
Davies, Thomas ....Bridgend.
De Peare, John Thomas ....Spalding.
Drew, Henry William...........Southwark.
Feaver, William ....Truro.
Green, William James............Yeovil.
Harburn, Alfred ....London.
Hope, Arthur Peach ....Uppingham.
Humphreys, Griffith ....Corwen.
Kelly, Francis Charles ....Great Yarmouth.
Lindewald, Wilhelm Edvard ...London.
Macaulay, William Henry ......Rotherham.
Manning, Alfred ....Strood.
Morgan, John Daniel ....Swansea.
Morris, David ....Cardigan.
Olden, Loathan.....................Romsey.
Peck, Frederick William.........Cambridge.
Plattin, Henry Ramm............Fakenham.
Powell, William ....Swansea.
Ratcliffe, George ....London.
Rossiter, Thomas Edward ......Tiverton.
Roughton, William ....Loughborough.
Selleck, William Robert ....Bovey Tracey.
Shrivell, Frederick William E....Hadlow.
Smith, John Thomas ....Spalding.
Stableforth, John William ......London.
Stedman, Walter ....West Malling.
Taylor, James Bennett ....Bedford.
Thompson, Arthur Stevens......Barking.
Topliss, Walter George ....Wainfleet.
Wild, George Frederick ....Hyde.
Willis, Henry James ....London.
Willis, Joseph Darrington ......Northampton.
Wimshurst, Frederick............Southborough.
Wood, Robert ....Loughborough.
Wyatt, Charles Frederick ......Old Brompton.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Baron, Richard Edward ....Alderney.
Barnett, Henry Frederick ......Uttoxeter.
Bruce, Alexander Gibb ....Broughty Ferry.
Butler, Ernest F. N. G. ....London.
Callow, Ewan ....Douglas.
Clayton, Walter Flower ....London.
Cubey, Robert Hewison ....South Shields.
Edwards, Henry ....Liverpool.
Ellisson, Charles ....Barnsley.
Farthing, Thomas William......Devonport.
Gibson, Matthew Henry.........Matlock Bath.
Gooch, Stephen Leeds............Reepham.
Green, Frederick ....London.
Grey, William ....Blyth.
Grigs, Emerson Fenwick G. ...North Shields.
Grimwade, Edward H............Croydon.
Hopper, James Henry............Ryde.
Hutchinson, John..................Kendal.
Inman, Thomas Leonard.........Batley.
Joye, Joseph ....Southport.
Knox, John ....March.
Lawton, Ernest.....................Barnsley.
McEwan, David ....Perth.
Melhado, Howard Emanuel ...Ramsgate.
Moore, Joseph Edward ....Bristol.
Morris, Harold Edward ....London.
Morgan, Richard ....London.
Owen, William ....Towyn.
Pawson, Frederick Thomas......Banbury.
Pumphrey, Arthur ....York.
Roberts, Griffith ....London.
Robinson, Thomas ....Wigton.
Shepperd, William John.........Newport, I. of W.
Taylor, George ....Fairfield.
Whaley, Thomas Cope............Barnsley.
Young, John.........................Arbroath.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons who have severally made the required declarations and paid a fine of one guinea were restored to the Register of Chemists and Druggists:—

William Halket, 74, Talbot Road, Bayswater, London, W.,
Richard Hammersley Forrester, 2, Merthyr Road, Abergavenny.

ADDITION TO THE REGISTER.

The Secretary reported that—

Thomas Farren Humble, Abergavenny,

having made a statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been duly supported by medical practitioners, his name had been placed on the Register.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and various accounts ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included recommendations of the following grants:—

£10 to the widow of a registered chemist and druggist.

£15 to aid in the education of the younger son of the widow of a registered chemist and druggist. The applicant has had two previous grants.

£10 to the widow of a pharmaceutical chemist. Applicant had a grant of £15 in September last.

£17 for continuing the education of an orphan in an establishment in Belgium for another year. This case stood over last month for further consideration.

£5 to a registered chemist and druggist who recently sustained an accident and had a grant of £10 in February last.

A letter was read from Annie Isherwood, stating that she had a very happy and comfortable home.

The Committee had declined to entertain one application, as it appeared that the applicant was of intemperate habits.

The report and recommendations of the Committee were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee included the usual report from the Librarian, to the following effect:—

Attendance during the day: highest, 26, lowest, 10, average, 20; evening, highest, 17, lowest, 7, average, 10. Circulation of books: town, 154; country, 49; carriage paid, £1 5*s.* 9½*d.* He had also reported the following donations to the Library:—

Cooley (A. J.), Cyclopædia of Practical Receipts, 6 ed., 1879, pt. 13. From Messrs. Churchill.

Dragendorff (G.), Bemerkungen in Bezug auf die Nachweisbarkeit des Strychnins in verwesenden Cadavern, 1879.

Mandelin (K. F.), Chinincitrater, 1879.

Scheibe (E.), Darstellung und Beschreibung der Borcitronensäure and ihrer Salze, 1879. From Professor Dragendorff.

Tilden (Dr. W. A.), Theory of Solution and Crystallization, being the substance of a Lecture given to the Bristol Naturalists' Society, 1878. From the Author.

Pifferi (G.), Breve cenno e preparazione di un nuovo composto di chinina, 1879. From the Author.

The Committee recommended that the usual letters of thanks be forwarded.

The Committee recommended the purchase of the following books for the Library:—

General Fund:—

Allen (A. H.), Introduction to Commercial Organic Analysis; vol. i. Cyanogen Compounds, Alcohols, Phenols, Acids, etc., 1879.

Hermann (L.), Elements of Human Physiology, translated by A. Gamgee, 2 ed., 1878.

Neubauer (C.), and J. Vogel, Guide to Qualitative and Quantitative Analysis of Urine, translated by W. O. Markham, 1863.

Squire (P.), Pharmacopœias of London Hospitals, 4 ed., 1879.

Unity of Medicine, its Corruptions and Divisions; by F.R.C.S., 1858.

Yvon (P.), Traité de l'Art de Formuler, comprenant un abrégé de pharmacie chimique, etc., 1879.

Hanbury Fund:—

Baillon (H.), Natural History of Plants, vols. 1–5, 1871–8, and vol. 6 when published.

Siebold and Zuccarini, Flora Japonica, 1825–70, 2 v., 150 coloured plates.

Wallich (N.), Plantæ Asiaticæ rariores, 1829–32, 300 coloured plates.

The Curator had reported the attendance in the Museum to have been as follows:—During the day, average, 17; evening, average, 6. He had also reported the following donations to the Museum:—

Ninety-five specimens of drugs used in the United States and eleven specimens of active principles, comprising three specimens of Podophyllin; two specimens of Hydrastine, one precipitated and the other crystallized; Cimicifugin; Berberine; Sulphate, Hydrochlorate and Hypophosphite of Berberine; and Nitrate of Sanguinarina. From the Philadelphia College of Pharmacy.

Specimens of Paracoto Bark and the following substances obtained from it:—Paracotoin, Hydrocotoin, Dinitro-coton, Leucotin, Oxyleucotin and Dibenzoyl-hydrocoton.*

Coto bark and Cotoin, Sulpho-carbolate of Quinine, Quinine, Chinamine, Aricine, Cusconine, Paricine; and the following active principles of Opium, Laudanine, Cryptopine, Cryptopine Oxalate, Pseudo Morphine.

Also the following liquids:—

a. Paracotol, $C_{15}H_{24}O$.
b. Paracotol, $C_{18}H_{40}O_2$.
c. Paracotol, $C_{28}H_{40}O_2$.
Paracoto-oil.

The particulars concerning these bodies are promised in a future communication. From Dr. O. Hesse.

Specimens of the undermentioned essential oils, in illustration of a paper read by Mr. W. E. Bush at the Students' Association:—

Almond, Aniseed, Bergamot, Camomile, Caraway, Cassia, Cinnamon, Cinnamon leaf, Citronelle, Cloves, Copaiba, Coriander, Cubebs, Dill, Geranium (Spanish), Juniper, Lavender (Exotic and Mitcham), Lemons, pure, Mustard, Mustard (artificial), Neroli, Nutmeg, Orange peel, Origanum, Parsley, Peppermint (Mitcham), Petit Grain, Pimento, Sassafras, Rose, Rosemary. From Messrs. W. J. Bush and Co.

The Committee recommended that the usual letters of thanks be forwarded, with a special one for the Philadelphia College of Pharmacy.

The Curator had reported that a shark's skin had been sent by Mr. Fresson of Demerara, but as it was not suitable for the Society's Museum, it was suggested that it should be offered to some society collecting natural history specimens.

Professor Bentley had reported that his class was progressing favourably, and had kept up better at the gardens than on any former occasion. Professor Redwood had stated that there was no special matter to report in reference to his class.

It had been ordered that the Library and Museum be closed in the evenings during the months of August and September.

A letter had been submitted from an assistant residing in the country, requesting that the regulation requiring the guarantee of a member for the safe keeping and due return of books might in his case be relaxed. The Committee did not deem it advisable to make any exceptions to this rule.

The Committee recommended that the Librarian should attend the annual meeting of the Library Association to be held in Manchester in September, and that ten guineas be allowed for his expenses.

The Sub-Editor had reported that the manuscript of the Index to the Journal from 1868 to 78 was complete, and the Committee had directed that an estimate be obtained for printing the same.

Professor Redwood had reported that he had made considerable progress with the continuation of Jacob Bell's 'Historical Sketch of Pharmacy,' which he thought would make about 300 pages octavo, and he had suggested that the earlier part should be put into the hands of the printer in order that the manner in which he was continuing the work might be submitted to the Committee for approval.

The Committee recommended that estimates should be obtained for printing the book in the form suggested by the Professor.

The Committee also recommended that the Editor and Sub-Editor should attend the meeting of the Pharmaceutical Society of Germany at Hanover, and that £20 be allowed to meet expenses.

The PRESIDENT said it would be noticed that the Hanbury Fund was exhausted, and he believed it had been as well laid out as possible.

Mr. RIMMINGTON asked if the index could be bound with the previous index.

Mr. WILLIAMS said it would be a different size, owing to the change in the size of the Journal.

Mr. BOTTLE said the same point had occurred to his mind, and he should like to know if it was a matter of

---

* With regard to these substances Dr. O. Hesse states that leucotin, oxyleucotin and dibenzoyl-hydrocoton are ethers of the hexatomic alcohol, hydrocoton; that dinitro-coton stands to hydrocoton in nearly the same relation as chinone to hydrochinone; and that the formation of dinitro-coton is the origin of the peculiar coloration of leucotin and oxyleucotin and dibenzoyl-hydrocoton when these are touched with strong nitric acid.

necessity that the index should be of the same size as the Journal.

The Assistant-Secretary said the estimate had been obtained and all arrangements made on the footing of the index being the size of the Journal.

Mr. Williams hoped that a sufficient number would be printed both of the index and of the "Historical Sketch," to allow of sending a copy to each member and associate of the Society.

Mr. Hampson wished to know if the manuscript of the "Historical Sketch" were complete. He thought it would be premature to make arrangements for printing before it was complete.

Mr. Williams did not see how the Council or the Committee could sit in judgment on the work of two literary gentlemen to whom it had been entrusted.

Mr. Rimmington said he should certainly object to giving these things away broadcast. The cheaper anything was made, the less it was appreciated. If people would not give 1*s*. or 2*s*. for a copy of the "Historical Sketch," it was quite clear they did not want it, and to give them what they did not want was simply to waste. The same with regard to the index. It was certainly worth 2*s*. to anyone who had the Journal, and if a person had not the set it would be entirely thrown away. Comparatively few kept their Journals and bound them, perhaps not one in one hundred.

The President thought the time had hardly arrived for settling these details. The present question was, who should print it.

The Vice-President thought it was premature to discuss the printing of the "Historical Sketch" until the manuscript was in a more complete condition. The Council did not know how much of it was ready. He thought it would be better to send the whole matter back to the Committee.

The President thought the Council should adopt the recommendation of the Committee that when the "Historical Sketch" was printed it should be in the form suggested, of which specimens were submitted. But the Council might suggest to the Committee that the printing should not be commenced until the manuscript was complete or nearly so.

Mr. Williams said the manuscript of the index was quite complete. The question to be decided was whether it should be printed for sale, in which case 1000 copies would be ample, or if copies should be given away, in which case 5000 would be required.

Some details having been given as to the estimates which had been obtained,—

Mr. Woolley thought it would be useless to give away the copies of the index.

Mr. Mackay said he should not be in favour of giving away a single copy.

The Vice-President thought it would be a mistake to distribute these things gratis. This might seem somewhat different to the opinion he had expressed on a former occasion, but the subject matter was different. When the catalogue of the museum was published he was anxious that it should be given away, because he considered it had a certain educational value in itself; but this index had no educational value, it was simply a matter of convenience to those who wanted to use the index. The "Historical Sketch" too, ought, he thought, to be paid for by those who desired to possess it.

Mr. Atkins asked if a *via media* could not be adopted, to give the index to any person who applied for it.

Mr Williams said this index was far superior to the one appended to each volume.

Mr. Atkins said it seemed to him rather strange to charge for an index to a book which was supplied to all members in return for their subscriptions. He thought perhaps it would be wise to give it on application.

The President said that was the regulation with regard to the catalogue.

Mr. Savage said he was at first in favour of adopting the same rule, but on further consideration he thought those who wanted the index should pay for it; that which was a small matter individually became a large matter collectively.

Mr. Williams could not agree with what seemed to be the opinion of the Council, and thought it was a pity it had undertaken the publication of the "Historical Sketch" if this was to be the result. It would be mere waste of money to bring out books the circulation of which it was known would be very limited if they were sold. When the matter was initiated he trusted it would have done much good by arousing an interest in pharmacy and in the Journal, by members receiving the index for the last ten years. If members had been foolish enough to throw their numbers away they would probably regret it. He should not have taken so much interest in the matter unless he had thought the Council was going to carry it out in the liberal manner which it had lately talked so much about encouraging.

Mr. Gostling sympathized very much with the remarks of Mr. Williams. It was quite possible more energy and enthusiasm might be put into the members if something were put before them. There was a work undertaken for the benefit of all, so that anything that had been published in the Journal for ten years might be referred to, and he thought it should be sent to every member even if it were in paper covers.

The President said he was informed that the original proposition was that a copy should be sent to every member. The better plan would be to refer it back to the Committee to ascertain.

Mr. Rimmington asked how many catalogues had been applied for.

The Secretary said very few.

The Vice-President asked what was the object of the Librarian attending the meeting of the Librarians' Association; and on what ground the Committee recommended the expenditure of ten guineas in this way.

The President said when the Society of Librarians was established the Librarian attended the meeting at the request of the Committee. He was a member of the Association, of course as representing the Society, and he had quite satisfied the Committee that it would be an advantage that he should attend the conference.

Mr. Williams said it was not a question of pharmacy but of libraries. The Society's was a large public library, and he thought it essential the Librarian should be in correspondence and communication with other librarians, and in fact be a part of the commonwealth of librarians. He was very glad to find that the Society's Librarian took so much interest in the matter.

Mr. Savage desired to endorse all that Mr. Williams had said. It was very important that the Council should be in possession of all the information accessible with regard to the arrangement and management of libraries in general.

The President added that the same thing was done last year.

Mr. Williams thought it was very desirable in the interest of the Journal that the Editor and Sub-Editor should attend the Conference in Hanover. The Editor came into personal contact with many gentlemen from whom he might afterwards receive communications which would be of interest.

It was then resolved that the printing of the "Historical Sketch" be deferred until the completion of the work, and that further estimates be obtained for the printing of the index, and that the Committee report again to the Council. The remainder of the report of the Committee was adopted.

Mr. Bottle having remarked that the shark's skin referred to in the Committee's report would be acceptable to the Dover Museum, it was unanimously resolved on the motion of Mr. Williams that it be presented to that body.

HOUSE.

The Secretary had submitted to this Committee a table showing the quantity of gas consumed each year during the years 1873–79, by which it appeared that the late increase still continued. Professor Redwood had attended and stated the result of experiments he had made, showing that there was no leakage anywhere, but that there was a greater day pressure than formerly, and to this circumstance, together with the more abundant supply which the companies had recently provided, he ascribed the increased consumption.

The Committee recommended that the gas used in the laboratories should pass through a separate meter.

Mr. Atkins said he had mentioned on a former occasion that he had had his gas meter repaired; but the result did not answer his expectations, for he found the consumption for the last quarter almost double that of the corresponding quarter in last year. He was satisfied, having taken great pains about it, that he burned less gas, and he therefore consulted the gas manager who told him that the complaint was very general, and his explanation was, that owing to complaints of insufficient pressure, the plant had been largely increased, and there was more than double the pressure and therefore more gas passed through the burners. The manager advised him to regulate the supply at the meter, and not allow more gas to pass than was requsite for a due supply to the burners; and having done so he was satisfied there would be a reduction.

Mr. Woolley said Mr. Atkins was quite right. He himself had Carnaby's apparatus in use, which could be put up in any convenient place, and by it he could regulate the supply at the meter down to a single burner if required.

The report of the Committee was received and adopted.

THE CONFERENCE.

The Vice-President, as representing the British Pharmaceutical Conference, said last year delegates were appointed to that body from the Council and it would be considered an honour if the same course were followed now.

It was moved by Mr. Mackay, seconded by Mr. Bottle, and carried unanimously—

"That the President and such members of the Council as are present at the meeting of the British Pharmaceutical Conference be requested to represent the Society as delegates."

GENERAL PURPOSES.

This Committee had received the reports from the Professors as to the prize examinations, and opened the motto envelopes to ascertain the names of the successful candidates.

Botany and Materia Medica.

Professor Bentley had reported that six candidates had presented themselves for examination for the bronze medal and certificates of merit, all of whom passed a satisfactory examination and three were worthy of special distinction. With regard to the Terminal examination for the silver medal and certificates of honour and merit for the session 1878–9, fourteen candidates had presented themselves, being rather over the average for the last five years, and the answers of the majority were highly creditable. The number of students attending his class during the last session had been notably in advance of last year, and the general attendance and uniform good conduct of the students, both at Bloomsbury Square and at the Botanic Gardens, proved that the school maintained its high character for order, progress and discipline.

Herbarium Prize.

Professor Bentley had reported that four collections had been sent in. The first in order of merit, that of Mr. Perkins was eminently worthy of the silver medal, it containing over 800 specimens. The second contained nearly 600 and reflected great credit on Mr. Walker, to whom he recommended that the bronze medal be awarded. The third also showed great merit and he recommended that a certificate of merit be awarded to Mr. Norman.

Chemistry and Pharmacy.

Professor Redwood had reported that in this class, the general conduct and industry of which had been very satisfactory, there were eleven competitors for the silver medal and certificates, the first six having furnished papers to which he had attached values entitling the authors to some marks of distinction. In the competition for the bronze medal and certificates there had been seven competitors, five of whom had acquitted themselves well, the first two remarkably so.

Practical Chemistry.

Professor Attfield had presented a report showing the number of marks obtained by the first eight out of seventeen competitors.

Council Examination Prizes.

Mr. Moss on behalf of Mr. Southall and himself had presented a report of this examination, giving the mottoes and number of marks of the seven competitors.

Legal and Parliamentary.

The Solicitor had presented to the Committee his usual report. It stated that

William B. Mason, 14, Arcade, Briggate, Leeds, had, prior to the hearing of the case against him, paid the amount of penalty and costs into Court, amounting to £5 8*s.* 3*d.* He had also reported that the Special Committee on the Medical Act had concluded its sittings, and that no point had arisen in which the Society was specially interested. Various cases of alleged infringement had been brought before the Committee, five of which were recommended to be placed in the Solicitor's hands with a view to taking proceedings. The consideration of the question of the sale of patent medicines had been deferred.

The Council considered in Committee, as usual, some of the cases of alleged infringement, and ultimately the report and recommendations of the Committee were received and adopted.

Prize Awards.

The following awards were made on the recommendation of the General Purposes Committee:—

Chemistry and Pharmacy.

[Five months' course.]

Bronze Medal..........Thomas Horton.
Certificates of Merit..........Henry William Drew. William Herbert Hyatt. George Wale. William Inchle Gulliver.

[Ten months' course.]

Silver Medal..........James B. Lillie Mackay.
Certificates of Honour..........Thomas Horton. Edward Jarrett Eaton. James Henry Allan.
Certificates of Merit..........Frank Harris Alcock. Henry William Drew.

Botany and Materia Medica.

[Five months' course.]

Bronze Medal..........Thomas Horton.
Certificates of Merit..........Henry William Drew. William Inchle Gulliver.

[Ten months' course.]

Silver Medal..........James B. Lillie Mackay.
Certificates of Honour..........Thomas Horton. Frank Harris Alcock. Henry William Drew. Edward Jarrett Eaton.

Certificates of Merit	James Edward Williams. William Inchle Gulliver. Fred. Wm. Ed. Shrivell. James Henry Allan. Percival C. Powrie. Isaac Leach.

Practical Chemistry.

Silver Medal	Frank Harris Alcock.
Bronze Medals	Fredk. Walmsley Warrick Robert John Price.
Certificates of Merit	Edward Jarrett Eaton. James B. Lillie Mackay. William Inchle Gulliver. Beresford F. H. Maudson. Thomas Horton.

Botanical Prize.

Silver Medal	Thos. Frampton Perkins.
Bronze Medal	Charles Walker.
Certificate of Merit	William Francis Norman

Council Examination Prizes.

Pereira Medal (silver); and Books value £5, presented by Mr. T. H. Hills.

Frank Harris Alcock.

Pharmaceutical Society's Medal (silver); and Books value £3, presented by Mr. T. H. Hills.

Marshall Leigh.

Pharmaceutical Society's Medal (bronze); and Books value £2, presented by Mr. T. H. Hills.

Henry Allen.

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Committee appointed to award these scholarships, subject to the approval of the Council, reported that the examination was held on July 1, when eleven candidates competed, viz., in London, 8; Brighton, 1; Manchester, 1; Nottingham, 1.

The mottoes adopted by the two candidates who had obtained the highest number of marks were "Alere flammam" and "Minimus," and the Committee recommended that the scholarships should be awarded to the competitors who had used those mottoes.

The Committee had opened the envelopes bearing those mottoes, and the successful candidates were found to be—

William Elborne
and
John Thomas.

Superintendents of Examinations.

The following list of Superintendents and Deputy-Superintendents of written examinations for the ensuing year was agreed to:—

Aberdeen	Davidson, Charles.
Birmingham	Southall, William.
Brighton	Gwatkin, James Thomas.
Bristol	Stroud, John.
Cambridge	Deck, Arthur.
Canterbury	Bing, Edwin.
Cardiff	Hollway, A. B.
Carlisle	Thompson, Andrew.
Carmarthen	Davies, R. M.
Carnarvon	Lloyd, William.
Cheltenham	Smith, Nathaniel.
Darlington	Robinson, James.
Douglas, Isle of Man	Brearey, William A.
Dundee	Hardie, James.
Edinburgh	Mackay, John.
Exeter	Delves, George.
Glasgow	Kinninmont, Alexander.
Guernsey	Arnold, Adolphus.
Hull	Bell, Charles B.
Inverness	Galloway, George R.
Jersey	Ereaut, John, jun.
Lancaster	Bagnall, William Henry.
Leeds	Reynolds, Richard.
Lincoln	Maltby, Joseph.
Liverpool	Abraham, Thomas Fell.
London	Taylor, George Spratt.
Manchester	Wilkinson, William.
Newcastle-on-Tyne	Martin, Nathaniel H.
Northampton	Bingley, John.
Norwich	Sutton, Francis.
Nottingham	FitzHugh, Richard.
Oxford	Prior, George T.
Peterborough	Heanley, Marshall.
Sheffield	Ward, William.
Shrewsbury	Cross, William Gowen.
Southampton	Dawson, Oliver R.
Truro	Percy, Thomas B.
Worcester	Virgo, Charles.
York	Davison, Ralph.

Deputy-Superintendents of Examinations.

Aberdeen	Kay, James Petrie.
Birmingham	Churchill, Walter J.
Brighton	Gwatkin, James Ross.
Bristol	Tucker, Robert Lewis.
Cambridge	Church, Henry James.
Canterbury	Amos, Daniel.
Cardiff	Sanders, W. J.
Carlisle	Hallaway, John.
Carmarthen	Davies, R. M., jun.
Carnarvon	Hughes, Richard.
Cheltenham	Barron, William.
Darlington	Hutchinson, Rev. E.
Douglas, Isle of Man	Brearey, Arthur W.
Dundee	Kerr, Charles.
Edinburgh	Ainslie, William.
Exeter	Lake, J. H.

REPORTS OF THE COUNCIL PROCEEDINGS.

Mr. SYMES moved a resolution of which he had given notice, though he had slightly modified the wording of it to this effect:—

"That when any matter is considered in Committee during the Council proceedings, a record of the fact be stated in the Journal report of the Council proceedings, except under some special circumstances where the Council by vote decide that it is undesirable."

His idea was that everything taken into Committee should be reported in name, not necessarily in detail, but that the Council should still have the power by a special vote to decide that it was undesirable that some special matter should be reported. He scarcely knew whether it was necessary to say much in support of the motion, but he had brought it forward under the full impression that there was a necessity for something of the kind. The first impression perhaps on reading it would be that it implied nothing which was not now provided for, and he did not wish to propose any innovation; but it occurred to him that on several occasions the Council had gone in and out of Committee, and the members had hardly known where they were; it had occurred that day and he was informed it had occurred frequently before, which rather showed that when the Council went into Committee it should do so more formally. The motion also suggested that at present the report was not as full as it might be, that it was not adequate to the importance or commensurate with the amount of work which the Council did. Its constituency had a right to be fully informed of the method of procedure by which it was governed, and not only members of the Society, but chemists and druggists, for whom it legislated, had a right to be informed, not merely of the skeleton of its proceedings, but to have something more of the substance of them. It was complained sometimes that the members of the calling did not take as much interest in the proceedings of the Society as they might do, and the latter retaliated, when they had the opportunity, by saying that the Council did not consider their interests. It occurred to him that one means by which the Council might more fully do its part, would be by more deeply interesting these gentlemen in what it was doing. There was scarcely a subject considered there, of however little importance it might appear, the bearings of which had not some importance for persons who were concerned in the business in other matters. A report in the Journal would help to excite that interest which he was desirous of creating. They had been told that day that a matter which was not reported would appear in the balance sheet at the Annual Meeting, but if it were of sufficient interest to be stated there, it would be of more interest if it were found in the ordinary proceedings. The Annual Meeting lasted but a few hours, and when on the last occasion a gentleman got up and asked for figures, they all felt that he was straining a point too far in asking for such details. Probably he would not have asked for any figures at all if he had been able to read in the ordinary reports what had been done with the money of the Society. The Council met to conduct the business of the Society and to expend the money obtained from individual members. If those subscriptions came from wealthy men, it would not so much matter how they were expended, provided it was done wisely and not extravagantly, but many of these subscriptions came from men in a small way of business to whom it was really a tax, and they looked to get some equivalent for it. Their connection with the Society was the equivalent and they ought to have as much as possible for their money. By making the reports more full this would be done. The most interesting part of the work was generally done in Committee, and that the members of the Council should keep the most interesting part to themselves and hand over the least interesting part to their constituents, seemed a proceeding which it was not necessary to argue upon.

Mr. Atkins seconded the motion. He did not precisely know how it could be carried out, but he had had a strong conviction in his own mind for years that the constituency had a right to know what went on. He had known interesting questions occupy the Council for an hour or more, and yet in the country he had been asked why they had not been mentioned. He knew there might be a difficulty often as to what should be eliminated, but it had occurred to him that there was a middle course which did not require a great amount of discrimination to find, viz., to intimate that at a particular stage the Council resolved itself into Committee and discussed such and such a matter. Names need not be mentioned or any particulars which would frustrate legal action, if legal action were to be taken, but the fullest report consistent with prudence ought to be furnished. Certainly the unjust criticism which took place outside ought to be disarmed, that after spending four, five or six hours at the Council Board there was but a very sparse report of what had occupied the best intellects there for a number of hours. He hoped some means would be found of complying with the very reasonable suggestion contained in the motion.

The President said he had no objection to the motion, the modification introduced having entirely taken the sting out of it. There was a very good example of unauthorized reporting in the *Chemist and Druggist* with regard to the proceedings last month, for as there put it was altogether a misrepresentation of the facts.

Mr. Hampson said the Council had the cure in its own hands. If there had been an unofficial reporter present he would not have fallen into the error. He should be in favour of another reporter being admitted.

The President said the inference expressed in the words he had quoted could not be drawn from the report which appeared in the Journal.

Mr. Gostling said he had felt very strongly the injustice of the report which appeared in the *Chemist and Druggist*, and on reading it he thought he could not vote for Mr. Symes's motion. What the Council did last month was perfectly consistent with the interests of the trade, viz., not to publish what was said with regard to the prosecution of co-operative stores generally. As the motion was now altered, he could vote for it with pleasure. There was a good deal of point in some of the remarks made as to extending information amongst members as to what was done in Committee.

The President, having read the Journal report, repeated that it contained nothing to justify what appeared in the *Chemist and Druggist*.

Mr. Rimmington said he should like to know who communicated that to the *Chemist and Druggist*.

The President said he was quite unable to answer that question.

Mr. Williams said he had thought over this subject a good deal, and had long been of opinion that it would be well if the reports of Council meetings were fuller and more complete; but the present motion did not seem to him practical enough to be of real service, and he should like to see it modified so as to make it really practical instead of a mere expression of opinion. He thought he could see how the Council could get out of the difficulty. He could quite understand the difficulty which the reporter felt sometimes in knowing what to report and what to omit, and of course when the Council went into Committee he did not take down anything of the discussion, though frequently it turned out that there was no reason why the discussion should not be reported. He thought the best plan would be to have full notes taken of all transactions, whether in Council or Committee; but that before being published they should be submitted to some one, either an individual or a Committee, who should take the responsibility of what was fit to be published, or rather of what it was necessary to omit. In his own opinion the President for the the time being would be the most suitable to undertake this office. If any check were required it could be afforded by the original notes with the alterations being placed before the next Council meeting. He thought it would be found in practice that very little alteration was required.

Mr. Hampson asked if the doctoring would be done in the Editor's room or there.

Mr. Williams said certainly not in the Editor's room. He should object to placing any paid servant of the Society in such a position. He only wished to prevent the publication of matter which would be decidedly objectionable, but to have as much unobjectionable matter as possible published.

Mr. Mackay said he quite agreed with the principle of the motion, for he had always argued that the proceedings of the Council as reported were not satisfactory to the outside members. He had always felt that they were far too short, but he also felt that if the motion as originally drawn were carried, and everything that transpired were put into print the members of the Council would be running their heads against a post. As an addition had been made to the original motion that difficulty was avoided, and therefore he could vote for it. He could see, however, that there would be some difficulty in carrying it out in detail. But Mr. Williams's suggestion, he thought, was about the most unpractical he had ever heard; he did not think the man was born who would take the office of President if he had to do what Mr. Williams suggested—to be reponsible, first for reporting what took place, and next to be called over the coals a month afterwards for having either published or omitted something he ought not. He had more than once advocated, and would again throw out the suggestion that the Editor should have a seat at the reporter's table, and be responsible for giving a full account of the Council's proceedings. Let him be furnished with full notes of what took place and be responsible for what appeared.

Mr. Bottle said, with every desire to follow up Mr. Symes's wish to have a full account of all that occurred at the Council table, he could not help feeling that the mode in which the motion had now been put was peculiarly unfortunate, inasmuch as it would require that the Council should publish to its constituents that it had voted that a certain something should not be communicated to them. The members were to consider a certain thing n Committee and then in Council resolve that what they had done should be kept secret. He would rather put it the other way and let it be the vote of the Council that such and such a thing should be communicated.

Mr. Symes said he was pleased to find that the opinion of the Council was so entirely with him, as he had indeed expected; but he should like to reply to some of the remarks which had been made. If the report of the proceedings were a *verbatim* one there would be no difficulty in the matter, because everything uttered would be reported; but the Council now threw on the reporter a very serious responsibility. Mr. Mackay said the President would not think of undertaking such a responsibility, and yet at every meeting the Council threw on the reporter the responsibility of sifting out what he thought desirable to report. Now the President, being a chemist and druggist, would have to some extent a long education in what was required by chemists and druggists to be known; but the reporter was a professional reporter, who could hardly be expected to be able to select such matter as would be interesting to chemists and druggists throughout the country, and it was most unfair to him to cast this duty upon him. He had nothing to complain of as to the manner in which the reporter did his duty, but he was put in a false position. As to that report in the *Chemist and Druggist*, the first thing which occurred to him was that some one had been breaking faith in communicating it, but the second reflection was that no one had done so, but that it was a deduction from the official report, and it illustrated his position most forcibly. It showed that by giving these meagre reports and half sentences more danger was really introduced than a full report of the discussion would have done. There seemed a good deal of mystery about the reporting. One gentleman at the last meeting, who had been a member of Council ten years, said he did not know what became of the report when it left there,—whether the reports published were the same as the reporter furnished or not. He had no wish to suggest that the report was altered; he hoped it was not; but there seemed to be a vast amount of ignorance prevailing as to whether the reporter handed to the Editor certain matter which he was to publish, or whether the Editor had any right to alter it or cut it down. He quite agreed that it was desirable to make some suggestion of how the resolution should be carried out. He had had some difficulty in maturing a plan; but it occurred to him that the vote could be taken in Committee in connection with the subject under discussion, so that if it were decided not to publish it, the vote would be part of the matter which would not be published, but if the majority of the Council thought it well to publish it, the fact might be stated. That would be a healthy thing too, as it would give the constitituency an opportunity of seeing how far the Council was disposed, and which of its members were disposed, to give them a larger share of the information which they thought they ought to possess. The only thing he would suggest was that when the Council went into Committee—and it ought to go in and out of Committee more formally than it often did—then it should ask the reporter to state what he proposed to report as the result of the discussion, or it might suggest to him what he should report. That seemed the only solution: that the Council should decide on the spot what should be reported, the form in which it should be reported, or how much and also what was not to be reported.

The Vice-President wished to know in what respect the motion, if carried, would alter the existing state of things.

Mr. Symes said it made a rule for what was now optional.

The motion was then put and carried.

The President stated that according to usual custom no business beyond what was absolutely necessary would be brought forward at the September meeting, so that only a quorum, which could be obtained in London, need attend.

SOCIETY OF ARTS.

THE HISTORY OF ALIZARIN AND ALLIED COLOURING MATTERS, AND THEIR PRODUCTION FROM COAL TAR.*

BY W. H. PERKIN, F.R.S.

(*Continued from page* 98.)

The anthracene, after the treatment with naphtha, should contain about 50 per cent of pure anthracene. It is not distilled in the same manner as for the preparation of dichloranthracene, but is heated in a retort, or more generally, in a semicircular iron pot. The lid of this is furnished with a safety valve, and also a steam pipe. The receiver consists of a tank, the top of which is sometimes made of canvas; a perforated tube passes round this tank near the top, which is supplied with water and produces a gentle spray, which facilitates the condensation of the anthracene. When working this arrangement, a known weight of anthracene is introduced into the iron pot, which may be called a subliming pot, and is heated until it is quite fluid. Steam is then blown in; this carries the anthracene vapour forward with it into the receiver, when both are condensed by the spray of cold water.

The condensed anthracene is found in a wet and extremely finely divided state, very suitable for oxidation. Its weight is known from the amount of washed anthracene used in the operation. Other methods of condensing the anthracene and steam are used, but the above, I believe, is the most common. Obtaining the anthracene in this finely divided state is a great improvement upon the old process of grinding it.

The oxidation of this anthracene is performed much more slowly than it was at first, the solution of potassic bichromate and sulphuric acid being kept more diluted. In this way the amount of oxidizing agent required is smaller, less being expended on the useless impurities.

In carrying out this operation in its present form, the potassic bichromate is first dissolved in water, and the wet anthracene well mixed with it. The requisite quantity of sulphuric acid, previously diluted with water, is then added by degrees, and the mixture kept gently boiling for ten or twelve hours. A Korting's air injector should be used with the steam, to keep up the agitation of the mixture. The oxidized anthracene, which has the appearance of a yellow powder, is then collected in woollen bags, thoroughly washed, pressed and dried.

The amount of potassic bichromate used is regulated principally by the proportion of pure anthracene contained in the product to be oxidized. Pure anthracene requires about 1·66 times its weight of potassic bichromate to convert it into anthraquinone. The amount used by different manufacturers varies, some employing a little under two parts, others more; but no fixed quantity can be given, as the amount required evidently must differ with the kind of impurities contained in different parcels of anthracene, some of these oxidizing more freely than others. It is remarkable that so little answers the purpose, and shows that the anthracene takes up the oxygen more greedily than the impurities. Too much oxidizing agent is injurious.

The anthraquinone is still very crude, and needs purification. The method that has been most generally adopted consists in treating it with concentrated sulphuric acid. This dissolves the anthraquinone, but does not act upon it. The impurities, however, become soluble in water, being converted in sulpho acids, etc., so that after treating the crude anthraquinone in this manner, and then mixing the product with water, nearly pure anthraquinone is alone precipitated. This method of subliming anthracene, oxidizing it and purifying it with sulphuric acid, was first proposed, I believe, by H. Caro. The process is carried out as follows:—The crude anthraquinone is placed in large iron, semicircular, cast iron pots, capable of holding a ton or more of the product. These are furnished with a steam jacket, and a strong stirrer, also of cast iron, and worked by machinery, the blades being arranged so as to work the mixture constantly upwards. These pots are charged with crude anthraquinone and sulphuric acid, in the proportion of one of the former to three or four of the latter; the steam is turned on to the jacket, and the mixture heated with continuous stirring for about twenty-four hours. The product is then run into shallow leaden trays, and exposed to the air, or the trays are arranged in a proper chamber, the atmosphere of which is kept moist by steam. In this way the acid becomes very gradually diluted, causing the anthraquinone to crystallize out. In a proper chamber this occupies about two days. The crystalline product is boiled with water, and then washed by decantation, any anthraquinone found in the liquors being afterwards collected. The anthraquinone is then pressed and dried, and is usually so pure as to contain over 95 per cent. of anthraquinone.

Instead of placing it on trays and allowing it to crystallize by the absorption of moisture by the sulphuric acid, some manufacturers pour it at once into water, boil the resulting mixture and wash it in filter presses.

During the last year or two, a modification of our original process has been coming into use; I mean the process of sublimation. The modification principally consists in assisting the process by passing superheated steam through the subliming retort, and this is important.

Although anthraquinone is such a remarkably stable body, we often noticed that a good deal of loss occurred in our subliming operations, apparently from reduction, and especially if the charges were large, because they then required a high temperature continued for a long time, the residues being bad conductors of heat. This reduction is probably caused by the steam and anthraquinone coming in contact with the iron of the retort. To avoid this loss, it is evident that the temperature should not be higher than absolutely necessary, and the charge should also be spread out in thin layers, so as to be quickly volatilized. The anthraquinone vapour and steam may be condensed in a similar manner to anthracene. The sublimed anthraquinone, which is pressed and dried, has to be still further purified. It will be remembered that we used coal-tar naphtha for the purpose, but the sulphuric acid process above described, I believe, is now always employed.

The large amount of chrome alum liquors produced in the manufacture of anthraquinone has always been a source of trouble to manufacturers, their dark green colour and acid character making them objectionable in the drains, and chrome alum being of itself of very limited consumption. Processes, however, have been now devised for working this up again into a chromate.

There is, however, another residue which, so far as I am aware, has not been turned to account, and that is the acid liquors from the purification of anthraquinone, consisting of sulphuric acid, sulpho acids, etc., and it is difficult to see to what use they can be turned, especially as such enormous quantities are produced, probably over 3,000 tons of sulphuric acid being used in this process yearly. If the original process of crystallizing the sublimed anthraquinone from naphtha were adopted, this difficulty would not exist.

In converting the anthraquinone into the sulpho acids, we at first used Nordhausen sulphuric acid, and heated the mixture in glass retorts, such as are used in the con-

* From the *Journal of the Society of Arts*.

centration of sulphuric acid, but, owing to the fragility of these vessels, we were induced to try cast iron pots. These we found to answer very well, though not quite so well as glass.

On account of the expense and difficulty in getting Nordhausen sulphuric acid imported into this country—few vessels liking it as a cargo—we commenced working with ordinary sulphuric acid. We usually employed four or five parts of this to every one part of anthraquinone, and heated the mixture up to 270°—280° C. The anthracene, as it sublimed from the operation, was put back into the acid. The sulpho acids produced in this way were treated with lime, etc., just as those obtained from dichloranthracene, and already described.

I find we employed this process principally in our works until the middle of June, 1870. We then began to work on a larger scale than we had hitherto done with dichloranthracene, and carried both processes on for a time; but finding the latter the most economical, partially on account of the ease with which it yielded the sulpho acids with ordinary sulphuric acid, we employed it almost exclusively after a time, although frequently making colouring matter by the other method.

As already mentioned, in the early experiments made with anthraquinone, it was noticed that, by reducing the amount of sulphuric acid with which it was heated and keeping the temperature as low as practicable that the colouring matter produced with the resulting sulpho acids gave purples on mordanted cloth more closely resembling those produced with madder than when a large excess of sulphuric acid had been employed. The cause of this was not understood for some time, until it was eventually found out that a monosulpho acid was required to produce alizarin. I believe this was first discovered by Messrs. Meister, Lucius and Brüning, as they were the earliest to send practically pure alizarin into the market.

The production of the monosulpho acid of anthraquinone as the chief product, by means of ordinary sulphuric acid, is difficult. I have generally thought it best to work with an excess of anthraquinone, to use a high temperature and only small operations, so that they may be quickly finished. When using ordinary sulphuric acid, every facility should be given for the escape of aqueous vapour which forms, so as to keep the acid as concentrated as possible. At temperatures over 260° C. sulphuric acid commences to oxidize anthraquinone, carbonic anhydride being slowly formed, so that high temperature should not be long continued.

The large quantity of ordinary sulphuric acid which had to be employed to convert anthraquinone into the sulpho acids, and the high temperature which had to be used, causing a certain amount of destruction to take place, evidently showed that it was desirable to employ fuming sulphuric acid in this process. In this country we found it costly, but as it was more readily procurable in Germany, the manufacturers there used it. They were afterwards supplied with a very strong fuming acid from Bohemia, containing about 40 per cent. of sulphuric anhydride. This was prepared, I believe, by distilling the sulphuric anhydride from one portion of ordinary Nordhausen sulphuric acid into another. This very strong acid was found to be without action upon ordinary tinned iron and it is now actually stored in vessels made of that material.

Within the last few years a very elegant process* has been devised by Dr. Messel and Mr. Squire for the production of sulphuric anhydride and fuming sulphuric acid. Sulphuric acid, when strongly heated, dissociates into steam, sulphurous anhydride and oxygen, thus:—

$$SO_4H_2 = OH_2 + O + SO_2.$$

* Patented 18th September, 1875, and now manufactured largely in this country by Chapman, Messel and Co. Professor C. Winkler a short time afterwards also showed that fuming acid could be made in this manner.—*Dingler, Polyt. Journ.*, ccxviii., 128—139.

This decomposition is taken advantage of to give supply of sulphurous anhydride and oxygen in the proportions required, the water being condensed and thoroughly removed by passing the gases through sulphuric acid.

The mixed gases are afterwards combined by passing them over heated platinized asbestos, and thus form sulphuric anhydride.

$$SO_2 + O = SO_3.$$

The sulphuric anhydride is then condensed, either alone or in ordinary sulphuric acid. It is remarkable that acid containing 60 to 70 per cent. of anhydride is liquid even below 0° C., acid containing 40 to 50 per cent. is solid, and acid containing 20 to 30 per cent., liquid. By this means fuming acid can be produced in any quantity, and of any strength; that usually employed in the manufacture of alizarin containing 40 or 50 per cent. of anhydride. We thus see that the demand for this acid in the production of artificial alizarin has created a new industry.

On treating anthraquinone with fuming sulphuric acid, iron pots somewhat similar to those described for the conversion of dichloranthracene into sulpho acids are used, but, as but little acid vapours escape, very little provision need be made for condensing them. In fact, if the anthraquinone be pure, there is no reason why they should not be entirely closed, though, of course, it would be desirable to have a safety valve, or some similar sort of arrangement.

The sizes of the iron pots used for treating anthraquinone with fuming sulphuric acid vary, but usually hold from 30 to 40 gallons. They should be fitted with stirrers, especially when required for the preparation of the monosulphanthraquinonic acid, and heated by means of an oil bath. The fuming acid, after being sufficiently heated to render it fluid, is emptied into these pots by means of a syphon, or by piercing the tins, after having placed them over the pots by passing an iron bar right through the top and then through the bottom; the upper hole thus made serves as an inlet for the air, and allows the acid to flow freely through the hole in the bottom of the tin.

When the monosulphanthraquinonic acid is required, a mixture of about one part of fuming acid, containing 40 to 50 per cent. of anhydride, is very thoroughly mixed with from one to one and a quarter parts of anthraquinone. The mixture is then gradually heated up to about 170°, or even to 190°, and kept at this temperature for eight or ten hours, the stirrer being kept constantly in motion. The product thus formed consists chiefly of monosulphanthraquinonic acid, together with a little of the disulpho acid and unchanged anthraquinone. It is then removed from the pots whilst rather hot and diluted with water. The anthraquinone is then separated by passing this solution through a filter press or other convenient arrangement.

The monosulpho acid is easily separated from the disulpho acid by converting it into its soda salt, which is difficultly soluble in water, this solvent dissolving only about 5 per cent. at the ordinary temperature. The filtrate is, therefore, nearly neutralized with caustic soda. This causes it to become a thick crystalline mass, which is then thoroughly pressed from the mother liquors; if required still purer, it can be re-crystallized, or purified by mixing it with about 15 or 20 per cent. of sulphuric acid, diluting with a little water and again pressing and washing with water. This salt forms beautiful small brilliant white pearly scales.

When pure, sodic monosulphanthraquinonate gives, on heating with caustic soda and chlorate of potash, practically pure alizarin. This operation I have already remarked upon.

To make the disulpho acid from anthraquinone, an excess of fuming sulphuric acid is used, about twice as much, or rather more, than in the preparation of the monosulpho acid; the temperature is also raised (as combination of the products takes place) considerably higher;

it may be allowed to rise, if a very red shade of colour is to be made, as high as 260°, but should not be taken much higher for any length of time.

The product thus obtained is perfectly soluble in water, and, when sufficiently cool, should be removed from the pots and diluted. It may then be treated with lime, as when dichloranthracene has been used, or, as some prefer, neutralized at once with caustic soda. It will then, of course, be mixed with a considerable quantity of sodic sulphate, and, so far as my experience goes, I have always found that the purer the soda salt the better it worked when treated with caustic soda to convert it into colouring matter.

Dichloranthracene, if treated with about twice its weight of fuming acid, containing 25 per cent. of anhydride, instead of with five times its weight of ordinary acid, works very well, and undoubtedly could be used at once by neutralizing with caustic soda.

It is remarkable that the artificial alizarin produced from disulpho acids, prepared from anthraquinone, does not yield such pure shades of colour on mordants as that made with the disulpho acids prepared from dichloranthracene. The latter colouring matter gives the calico printer more delicate pink and red shades, and is, therefore, also much liked by Turkey red dyers; and, notwithstanding it is sent into the market in a weaker form than the corresponding anthraquinone colouring matter, still it demands a higher price. Taking both circumstances together, the price it fetches is about 25 per cent. more than the colouring matter produced with anthraquinone.

The process with dichloranthracene has also the great advantage of always giving an artificial alizarin producing uniform shades of colour, according as ordinary or fuming sulphuric acid is used, whereas with anthraquinone it is impossible to tell with certainty the exact tint the product you are making will give.

Curiously, Continental manufacturers do not appear to have been as yet successful in manufacturing artificial alizarin from dichloranthracene in quantity, and what little they have produced in this way does not seem to have been equal in quality to that produced in this country.

The dichloranthracene and anthraquinone processes I have described are the only ones employed for the production of artificial alizarin. The method of converting anthracene into sulpho acids, and then oxidizing them so as to form sulpho acids of anthraquinone, although apparently very simple, does not work satisfactorily, the yield of colouring matter being small. The only process I have found to approach those in use is that patented by Meister, Lucius and Brüning, in which mononitroanthraquinone is used. By this process the only colouring matter dyeing mordants produced is alizarin, and from experiments I made I found the yield of colouring matter to be, on the whole, satisfactory. It is, however, obtained in a brown and impure condition.

When commencing to supply dyers and printers with artificial alizarin, we knew that we had to compete with madder. And although the new product possessed certain advantages, yet we felt it was useless to ask prices relatively much higher than those of that product, and from the first we endeavoured to act upon this principle.*

At first, nearly all the artificial alizarin we made was consumed by the Turkey red dyers of Glasgow and Manchester. The colour at this time contained large quantities of anthrapurpurin, and therefore produced a more scarlet shade than madder or garancine, and for some time it was used along with garancine, as by this means shades of colour were produced which were far more brilliant than when garancine alone was employed; but at the same time not too scarlet to be disliked by the Turkey red buyers. Of course, the use of garancine with artificial alizarin has now ceased, and much better results are obtained by employing a mixture of the red shade and blue shade.

Unfortunately, the market is now supplied, not only with the red or anthrapurpurin shade, and blue or pure alizarin shade, but mixtures of these in various proportions, so that there are more than a dozen shades in the market, and thus much of the manufacturer's time is occupied with preparing these; moreover, he is forced to keep a considerable stock of colour on hand.

It would appear that on the Continent great difficulties were experienced in the use of artificial alizarin for Turkey red dyeing,* whereas in this country it was employed for this purpose from the very first, and no difficulties worth mentioning were experienced, the chief modification being, I believe, the use of soap only in the clearing process, instead of soap and an alkaline carbonate. Several modifications, however, have since been made in oiling and mordanting the goods, which have rendered the process more simple; and the colouring matter being a purer product than madder or garancine, the clearing operations can be performed with greater facility.

In dyeing ordinary printed goods the process can be conducted much more rapidly than when madder is used, as no loss of colouring matter is experienced by using a high temperature at once, as I showed you was the case with madder; however, I believe, when good pink and red shades are to be dyed, dyers do not usually allow their dye bath to rise much above 80°—85° C.

The use of a product called "oleine," prepared by treating castor and other oils with sulphuric acid, has been found of great service, as it increases the brilliancy of the shades, especially the red or scarlet ones.

A good deal of artificial alizarin is used for topical printing. To fit it for this purpose it is mixed with a few per cent. of its weight of acetate of lime, and by dyeing patterns with light shades, say, with pure alizarin, and then printing on dark shades with anthrapurpurin, very beautiful results can be obtained.

The use of artificial alizarin, in place of madder or garancine, has a very important influence in the pollution of our rivers, as when this is used the water from the dye baths is nearly pure, whereas when madder and garancine are employed it is full of ground woody matter and I think I shall be making a very low estimate if I say that over 10,000 tons of this was annually passed into our rivers before the introduction of artificial alizarin. Surely this is a great advantage in itself.

Now that the production of artificial alizarin is equal to the demand, it is interesting to find that the supply of raw material anthracene, has been quite adequate, so that all the fears that were entertained on this subject have proved groundless; and it is also well to remember that up to the present time the anthracene contained in pitch has not been extracted to any large extent, so that much more anthracene could yet be produced if required.

(To be continued.)

* The prices given in the *Moniteur Scientifique* (April, 1879, p. 420), for the years 1870—1873, are very much higher than those ever obtained in this country.

Parliamentary and Law Proceedings.

Sale of Food and Drugs Act Amendment Act, 1879.

The following is the text of this Act, which has now received the Royal Assent:—

Whereas conflicting decisions have been given in England and in Scotland in regard to the meaning and effect of section six of the Sale of Food and Drugs Act, 1875, in this Act referred to as the principal Act, and it is expedient, in this respect and otherwise, to amend the said Act: Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal and Commons, in this present

Parliament assembled, and by the authority of the same, as follows:

1. This Act may be cited for all purposes as the Sale of Food and Drugs Act Amendment Act, 1879.

2. In any prosecution under the provisions of the principal Act for selling to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser, it shall be no defence to any such prosecution to allege that the purchaser, having bought only for analysis, was not prejudiced by such sale. Neither shall it be a good defence to prove that the article of food or drug in question, though defective in nature or in substance or in quality, was not defective in all three respects.

3. Any medical officer of health, inspector of nuisances, or inspector of weights and measures, or any inspector of a market, or any police constable under the direction and at the cost of the local authority appointing such officer, inspector, or constable, or charged with the execution of this Act, may procure at the place of delivery any sample of any milk in course of delivery to the purchaser or consignee in pursuance of any contract for the sale to such purchaser or consignee of such milk; and such officer, inspector, or constable, if he suspect the same to have been sold contrary to any of the provisions of the principal Act, shall submit the same to be analysed, and the same shall be analysed, and proceedings shall be taken, and penalties on conviction be enforced in like manner in all respects as if such officer, inspector, or constable had purchased the same from the seller or consignor under section thirteen of the principal Act.

4. The seller or consignor, or any person or persons entrusted by him for the time being with the charge of such milk, if he shall refuse to allow such officer, inspector, or constable to take the quantity which such officer, inspector, or constable shall require for the purpose of analysis, shall be liable to a penalty not exceeding ten pounds.

5. Any street or open place of public resort shall be held to come within the meaning of section seventeen of the principal Act.

6. In determining whether an offence has been committed under section six of the said Act by selling, to the prejudice of the purchaser, spirits not adulterated otherwise than by the admixture of water, it shall be a good defence to prove that such admixture has not reduced the spirit more than twenty-five degrees under proof for brandy, whisky, or rum, or thirty-five degrees under proof for gin.

7. Every liberty having a separate court of quarter sessions, except a liberty of a cinque port, shall be deemed to be a county within the meaning of the said Act.

8. The town council of any borough having a separate court of quarter sessions shall be exempt from contributing towards the expenses incurred in the execution of the principal Act in respect of the county within which such borough is situate, and the treasurer of the county shall exclude the expenses so incurred from the account required by section one hundred and seventeen of the Municipal Corporation Act, 1835, to be sent by him to such town council.

9. The town council of any borough having under any general or local Act of Parliament, or otherwise, a separate police establishment, and being liable to be assessed to the county rate of the county within which the borough is situate, shall be paid by the justices of such county the proportionate amount contributed towards the expenses incurred by the county in the execution of the principal Act by the several parishes and parts of parishes within such borough in respect of the rateable value of the property assessable therein, as ascertained by the valuation lists for the time being in force.

10. In all prosecutions under the principal Act, and notwithstanding the provisions of section twenty of the said Act, the summons to appear before the magistrates shall be served upon the person charged with violating the provisions of the said Act within a reasonable time, and in the case of a perishable article not exceeding twenty-eight days from the time of the purchase from such person for test purposes of the food or drug, for the sale of which in contravention to the terms of the principal Act the seller is rendered liable to prosecution, and particulars of the offence or offences against the said Act of which the seller is accused, and also the name of the prosecutor, shall be stated on the summons, and the summons shall not be made returnable in a less time than seven days from the day it is served upon the person summoned.

Poisoning by Carbolic Acid.

An inquest has been held in the Coventry and Warwickshire Hospital, touching the circumstances attending the death of a girl named Edgington, from poisoning by carbolic acid. It appeared that some carbolic acid, which had been obtained for sanitary purposes had been placed on a shelf in a bottle similar to that in which some wine was usually kept, and for which it is probable that the deceased mistook it. A verdict was returned that deceased died from the effects of carbolic acid taken inadvertently, and the jury added a rider suggesting to the sanitary authorities of the town that in future a poison label should be attached to every bottle in which the acid was contained.

Tincture of Kino.

Sir,—After the interesting paper by Mr. R. Rother, which appeared in the Journal of August 2, perhaps the following note may be of some value.

Some fifteen or sixteen years ago, the idea occurred to my mind that the addition of a small quantity of glycerine to tincture of kino, might, by preventing the aggregation of the gum particles, do away with the annoying tendency to gelatinization.

I found it answer the purpose admirably and have never been troubled with gelatinized tincture since.

The proportion of glycerine I use is 5 per cent.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from Vol. IX, page* 1035.)

SPILANTHES OLERACEA, *Linn.*, COMPOSITÆ; PARA CRESS OF BRAZIL. *Vernacular*: AKURKURA (Bomb)., is commonly cultivated in gardens in Bombay. It is a small annual plant with round smooth succulent branching stems; the leaves are opposite, petioled, subcordiform, subdentate. The flowerheads are solitary, at the ends of pedicels longer than the leaves, of a conical form and of the size of an acorn; they are entirely composed of yellow or brownish yellow hermaphrodite tubular flowers.

The achenes are compressed with ciliated margins and are surmounted by two naked awns. The whole plant is very acrid, but the flower heads are especially so, having a hot burning taste which causes profuse salivation. It is on this account that the plant has been named Akurkura by the gardeners. The name properly belongs to the pellitory root of the shops. The flower heads are sometimes chewed to relieve toothache. The *S. acmella* is a native of India and has similar properties.

———

ARTEMISIA INDICA, *Willd.*, COMPOSITÆ. *The plant.* *Vernacular*: NAGDOWN (Hind., Beng.); DAUNA (Bomb.); MACHIPATRI (Tam.).

History, Uses, etc.—This plant, in Sankrit Nagadamani, may be regarded as the wormwood of India. The Hindus consider it to be a valuable stomachic, deobstruent, and antispasmodic; they prescribe it in infusion and electuary, in cases of obstructed menses and hysteria. Externally it is used in fomentations. In Hindu temples downa is placed upon the heads of the goddesses, but not on those of the gods. *A. Indica* is probably one of the kinds of afsanteen described in Mahometan works, but owing to the number of species which belong to the genus, and which all have very similar properties, it is difficult to decide this point.

The authors of the Pharmacopœia of India say the strong aromatic odour and bitter taste of this plant, scarcely distinct from *A. vulgaris*, indicate stomachic and tonic properties. Dr. Wight (Illust., ii., 92) states that the leaves and tops are administered in nervous and spasmodic affections connected with debility, and also that an infusion of them is used as a fomentation in phagedenic ulceration. Dr. L. Stewart describes an infusion of the tops and leaves as "a good mild stomachic tonic."

Description.—Erect, suffruticose; leaves ashy and tomentose beneath, lower pinnatifid, upper trifid, uppermost undivided or with lanceolate lobes; lobes of the lower leaves toothed or cut. Heads of the flowers racemose-panicled, ovate; panicle leafy, spreading partial racemes pendulous before flowering, young involucre a little tomentose, at length glabrous; exterior scales foliaceous, acute, interior membranaceous, obtuse; corolla naked (Roxb. Fl. Ind., iii., 419).

Commerce.—The dry plant is sold by the herbalists and the fresh tops in the markets. Value Rs. 6 per Surat maund of 37½ lbs.

———

ARTEMISIA STERNUTATORIA. *The plant.* *Vernacular*: NAKK-CHIKNEE (Hind., Beng., and Bomb.).

Description, Uses, etc.—According to Roxburgh this plant appears during the latter part of the cold season, on cultivated land. The whole plant does not cover a space more than about 6—8 inches in diameter. Root simple, the stems several, branchy, pressing on the earth; all are somewhat woolly. Leaves numerous, sessile, wedge-shaped, deeply dentate, villous. Flowers axillary, or in the divisions of the branches, solitary sessile, subglobular, hermaphrodite. Florets, from 10—12 in the centre, with their border 4-toothed, coloured and expanding; the female ones very numerous in the circumference, most minute, with the border seemingly 3-toothed, and the toothlets incurved. Receptacle naked. It differs from *A. minima* in having sessile downy leaves and numerous flosculi in each flower. The minute seeds are used as a sternutatory by the Hindus, also the powdered herb. The plant does not grow in this part of India, but the dry herb, both entire and in powder, is always to be obtained in the druggists shops. Value about annas 6 per lb.

———

DORONICUM SCORPIOIDES? COMPOSITÆ. *The rhizome.* *Vernacular*: DARUNAJ-I-AKRABI (Pers., Bomb.).

History, Uses, etc.—The author of the 'Makhzan-ul-Adwiya tells us that Darunaj is a scorpioid knotted root, with a greyish exterior and white interior; that it is hard, faintly bitter and aromatic. He describes the plant as having fleshy yellowish leaves of the shape of those of the almond, which lie flat upon the ground. The flower stem he says is hollow; it rises from the midst of the leaves to a height of two cubits, and bears from 5—7 scattered leaves, thinner and longer than the lower leaves. The flower is yellow and hollow. The plant grows in Andalusia and the mountainous parts of Syria, especially about mount Yabroorat, where it goes by the name of Akrabi. There are two varieties of the drug, Persian and Turkish; the latter is most esteemed. With regard to its medicinal properties, he says that it is a resolvent of phlegm, a remedy against bile and flatulencies, cardiacal and tonic, useful in nervous depression, melancholy and impaired digestion, also in pain of the womb and flatulent dyspepsia.

Besides this it is prescribed for persons who have been bitten by scorpions and other venomous reptiles, and is hung up in houses to keep away the plague. Pregnant women wear it round the waist suspended by a silken thread, which must be made by the wearer. It is supposed to act as a charm, protecting the fœtus and procuring a painless delivery. Hung up over the bed it prevents night terrors and ensures pleasant dreams. There would appear to be a demand for it in Bombay, as it is kept by all Mahometan druggists.

Description.— Rhizomes scorpioid, occasionally branched, flat, jointed, of a dirty white colour, 3—4 inches long, ½—¾ inch broad, and about $\frac{1}{10}$ inch thick. Upper surface scaly, under surface marked by the scars of numerous rootlets, a few of which sometimes remain attached; substance brittle and horny, yellowish white, central portion somewhat spongy, odourless; taste at first insipid, but after a few minutes a sensation of warmth and pricking is felt upon the tongue.

Microscopic structure.—Sections show that the bulk of the rhizome consists of a parenchyma, each cell of which is occupied by a mass having the appearence of inulin, inactive in polarized light, but which is coloured intensely black by iodine; towards the circumference the cells become gradually smaller, and upon the surface become scaly, forming a greyish epidermis. The vascular bundles are of a bright yellow colour, and consist of spiral vessels; they form one irregular ring round the rhizome, about midway between the circumference and centre. No starch grains are to be seen in any part of the rhizome.

TRICHOLEPIS PROCUMBENS, *Wight, Ic.*: COMPOSITÆ. *Plant. Vernacular*: BADAWARD (Pers. and Bomb.).

This drug is described by Mahometan writers as the shaukat-ul-baida of the Arabs, the loofiniki of the Turks and the sanakhurd of the Syrians. Other Persian names given for it are kangar-i-sufed and asfar-i-baree. It is generally described as a thorny plant about two cubits high with downy triangular stems as thick as the thumb, or larger; heads of seed like those of a thistle, thorny and full of down; flowers purple; seeds like these of carthamus, but rounder. M. Husain says, "Some have supposed this plant to be the same as the shukai; this is not the case, but the two plants are nearly related. The true badaward has slender, white, round stems, little more than a span high, slightly downy; flower heads white, surrounding them are three delicate soft spines like needles, so that altogether they have much the appearance of a brooch. Within is a quantity of white down, which when the seeds are ripe causes them to be carried about by the wind; hence the name badaward. Medicinally the plant has tonic, aperient and deobstruent properties. It is said to drive away noxious reptiles when kept in the house" ('Makhzan' article "Badaward").

The badaward of Bombay shops agrees with the description of Meer Muhammad Husain. *T. procumbens* is found on sandy ground in Guzerat, and is thus described in the 'Bombay Flora,' "Stem flexuose, short, ramous; branches diffuse, procumbent, angularly striated, subglabrous; leaves shortly pubescent or subglabrous, those of the stem lyrate, of the branches sinuately pinnatifid, the lobes spinously mucronate; involucre ovate; scales ovate, at the base araneose, terminating in a prickle-like appendage; flowers purple, appear in the cold weather; common in light soils in Guzerat." Syn.: *Carduus ramosus*, Roxb. Fl. Ind., iii., 407. The drug has a bitter taste. It is imported from Persia.

NYCTANTHES ARBOR TRISTIS, *Linn.*: JASMINACEÆ. *Flowers, leaves and fruit. Vernacular*: HARSINGHAR (Hind.); SIULI (Beng.); PARTAK (Bomb.); PAGALA MULLAI (Tam.).

History, Uses, etc.—Royle in his 'Himalayan Botany' tells us that this tree is extremely common along the foot of the mountains which skirt the Deyra Dhoon, and may be seen for several hundred feet above Rajpore in the ascent to Mussooree.

Dr. Wallich found it in a wild state near the banks of the Irrawaddy, on the hills near Prome. In Western India it is one of the commonest cultivated trees. Its flowers open at sunset, and fall before morning; they have very strong perfume. The Sanskrit names for the tree are sephalika, parajatak, and rajanikasa. The author of the 'Makhzan' gives a minute description of all parts of the tree and tells us that the Indians use the white portion of the flowers as a purple dye, which they call gul kamah, and the orange part as a yellow dye. The seeds and leaves are considered by them to have medicinal properties. Six or seven of the young leaves are rubbed up with water and a little fresh ginger and administered in obstinate fevers of the intermittent type; at the same time a purely vegetable diet is enforced. The powdered seeds are used to cure scurfy affections of the scalp. Directions for the preparation of gul kamah will be found in the 'Karabadeen-i-kabir.' Chakradatta mentions the use of the leaves in fever and rheumatism. A decoction of the leaves prepared over a gentle fire is recommended by several writers as a specific for obstinate sciatica (Confer. Dutt's 'Hindu Mat. Med.,' p. 189).

Description.— Tree, 15—20 feet; young shoots four-sided: leaves opposite, short-petioled, cordate or oblong, pointed, entire or coarsely serrate, scabrous; panicles terminal, composed of smaller six-flowered terminal umbellets; calyx companulate, slightly five-notched, downy; corolla tube cylindric, as long as the calyx, segments 5—7; involucre of four inverse, cordate, opposite, sessile leaflets; flowers numerous; tube orange-coloured; border white, fragrant (Drury). The fruit is a dry, flat, oblong, mucronate capsule, prominently veined, $\frac{3}{4}$ inch long by $\frac{1}{2}$ broad. It is of a brown colour when ripe and is divided into two cells each of which contains a flat foliaceous seed of a light brown colour; the testa of the seed is thin, the kernel white, bitter and very astringent. The leaves have similar properties and stain the saliva yellow when chewed.

CALOTROPIS GIGANTEA, *R.Br.*; CALOTROPIS PROCERA, *R.Br.*: ASCLEPIADEÆ. *The root, leaves and flowers. Vernacular*: AK, MUDAR (Hind.); AKANDA (Beng.); AKRA, RUI (Bomb.); ERUKKU ERUKKAM (Tam.).

History, Uses, etc.—The same Indian names are applied to both of these plants; Sanskrit writers, however, notice two varieties, which are distinguished by the colour of their flowers, viz., alarka or white and arka or red. Dutt ('Hindu Mat. Med.'), gives us the following summary of the uses of the plant, extracted from Sanskrit works, chiefly that of Chakradatta. "The root bark is said to promote the secretions and to be useful in skin diseases, enlargements of the abdominal viscera, intestinal worms, cough, ascites, anasarca, etc. The milky juice is regarded as a drastic purgative, and caustic, and is generally used as such in combination with the milky juice of *Euphorbia neriifolia.* The flowers are considered digestive, stomachic, tonic and useful in cough, asthma, catarrh and loss of appetite. The leaves mixed with rock salt are roasted within closed vessels, so that the fumes may not escape. The ashes thus produced are given with whey in ascites and enlargements of the abdominal viscera. The following inhalation is prescribed for cough :—Soak the powdered root bark of arka in its own milky juice and dry. Bougies are then prepared from the powder, and their fumes inhaled. The root bark, reduced to a paste with sour congee, is applied to elephantiasis of the legs and scrotum. The milky juices of *C. gigantea* and *Euphorbia neriifolia* are made into tents with the powdered wood of *Berberis Asiatica*, for introduction into sinuses and fistulæ in ano. The milky juice is applied to carious teeth for relief of pain." An oily preparation (arkataila), made by boiling together 8 parts sesamum oil, 16 parts calotropis juice, and one part turmeric, is said to be useful in eczema and other eruptive skin diseases.

In Western India and probably elsewhere there is a curious superstition that a leaf of the akra, fetched from the tree with certain ceremonies, is of use in tedious labour. The friends of the woman take a packet of betel nut and leaf, and a piece of money, and proceed to the plant, which they address in the most respectful manner, placing the betel packet at its root and asking for the loan of one of its leaves which they promise to return shortly. They then take away a leaf and place it upon the head of the parturient woman, where it remains for a short time and is afterwards returned to the plant. This practice appears to be connected with the worship of Marootee which is popular in this part of the country. He is the god of wind, and was born from a pinda under the shelter of an akra tree. The tree is considered sacred to him, as it afforded him protection when all the other trees had been destroyed. Mahometan writers describe it under the Arabic name of ushar. In Persian it is called khark. Meer Muhammad Husain gives a good description of the plant, and notices the use of the silky cotton of the pods by the wandering Arabs and Tartars to make their makhad twist or yalish (tinder). He says there are three varieties, 1st. A large kind with white flowers, large leaves, and much milky juice. It is found near towns and the habitations of man. 2nd. A smaller kind with smaller leaves, the flowers white externally but lilac within. 3rd. A still smaller plant, with pale yellowish green flowers. The second and third kinds grow in sandy deserts. The properties of all three are similar, but the first kind is to be preferred as it produces the largest quantity of milk. The juice is described as caustic, a purge for phlegm, depilatory, and the most acrid of all milky juices. Tanners use it to remove the hair from skins. Medicinally it is useful in ringworm of the scalp, and to destroy piles; mixed with honey it may be applied to aphthæ of the mouth; a piece of cotton dipped in it may be inserted into a hollow tooth to relieve the pain. Hakeem Meer Abdul Hameed in his commentary upon the Tuhfat strongly recommends it in leprosy, hepatic and splenic enlargements, dropsy and worms. A peculiar method of administration is to steep different kinds of grain in the milk and then administer them. The milk itself is a favourite application to painful joints, swellings, etc.; the fresh leaves also, slightly roasted, are used for the same purpose. Oil in which the leaves have been boiled is applied to paralysed parts; a powder of dried leaves is scattered upon wounds to destroy excessive granulation and promote healthy action.

All parts of the plant are considered to have valuable alterative properties when taken in small doses. Lastly, some of our Mahometan writers give very exaggerated accounts of the poisonous properties of the plant. *C. procera* was observed in Egypt by Prosper Alpinus (1580—84), and upon his return to Italy was figured, and some account given of its medicinal properties ('De plantis Ægypti,' Venet. 1592, cap. 25). *C. gigantea* was figured by Rheede in 1679 ('Hort. Malabar.' ii. tab. 31).

Ainslie in his 'Materia Medica of Hindustan' (1813) mentions two kinds of calotropis, and in the 'Materia Indica,' he says, "Both plants in their leaves and stalks contain much milky juice which when carefully dried is considered as powerfully alterative and purgative, and has been long used as an efficacious remedy in the hoostum (*lepra Arabum*) of the Tamools; the dose about the quarter of a pagoda weight in the day, and continued for some weeks. The root of the yercum has a bitter and somewhat acrid, or rather warm taste; it is occasionally given in infusion as a stimulant in low fever. Of the other variety, the vullerkoo, the bark is warmish and when powdered and mixed with a certain portion of margosa oil, is used as an external application in rheumatic affections. In the higher provinces of Bengal the arka (*C. gigantea*) is supposed to have antispasmodic qualities. Mr. Robinson has written a paper on elephantiasis, which may be seen in vol. x. of the *Medico-Chirurgical Society*, extolling the mudar root (*Yercum vayr*) as most efficacious in that disease, as also in venereal affections. In the elephantiasis he gave it in conjunction with calomel and antimonial powder, in a pill consisting of half a grain of calomel, three of antimonial powder, and from six to ten of the bark of the root mudar, every eight hours. Mr. Playfair has also written a paper on the same root, which may be seen in vol. i. of the *Edinburgh Medical Chirurgical Transactions*, p. 414, wherein he speaks in praise of the alterative, stimulant, and deobstruent virtues of the bark, or rather rind below the outer crust of the root, reduced to fine powder, in cases of syphilis, leprohectic fever, etc.; dose from gr. 3--10 or 12, three times in the day, gradually increasing it. Messrs. Robertson, Playfair, and others seem chiefly to dwell on the virtues of the rind or bark of the root; but I must observe that in lower India, where I was for many years, I found the simple dried milky juice considered as infinitely more efficacious, and later communications from the East confirm me in this opinion ('Materia Indica,' vol. i., p. 487). The emetic properties of mudar were first brought to the notice of the profession by Dr. Duncan in 1829 (*Edinburgh Medical and Surgical Journal*, vol. xxxii., p. 65). They are noticed in the Bengal 'Dispensatory,' where the drug is recommended as a substitute for ipecacuanha. Since the publication of that work abundant testimony in its favour has been collected, a summary of which will be found in the Pharmacopœia of India. Duncan made a chemical examination of the root bark, the activity of which he referred to an extractive matter which he termed mudarine.

Description.—The root barks of *C. gigantea* and *C. procera* are similar in appearance, as collected in Bombay, where they are removed by a few blows with a hammer or piece of hard wood. They occur in short quilled pieces $\frac{1}{8}$ to $\frac{1}{4}$th of an inch thick. The outer surface is yellowish-grey, soft and corky, fissured longitudinally, and can be easily separated from the middle cortical layer, which is white, friable, and traversed by narrow brown liber rays. The taste is mucilaginous, bitter and acrid, and the odour peculiar.

Microscopic structure.—In both kinds of root bark the suber consists of large thin-walled cells, generally polyhedral. The parenchyma of the middle cortical layer is loaded with starch and contains some sclerenchymatous cells. The cells of the medullary rays also contain starch and crystals of oxalate of lime. In the middle layer are numerous lacticiferous vessels, the contents of which are of a brown colour.

Chemical composition.—The authors of the 'Pharmacographia,' following Duncan's process, failed to obtain anything like his mudarine, they found, however, that the plant contains an acrid, bitter resin, which is probably the active principle.

(*To be continued.*)

PHARMACEUTICAL EXTRACTS.*

CRITICAL CONSIDERATIONS UPON THEIR PREPARATION, CLASSIFICATION, GENERAL CHARACTERS, USES, ETC.

BY E. SCHMITT,

Professor of Medicine and Pharmacy at Lille.

(*Concluded from page* 86.)

III. The extract should contain all the soluble principles of the vegetable or animal substance to the exclusion of inert matters. The number of principles contained in a vegetable juice is very large; but without entering into details apart from the subject it may be said that such juices contain immediate principles that are alkaline, neutral or acid, volatile oils, gums and mucilages, resins and gum resins, pectic and albuminoid matters, sugars, tannins, soluble and insoluble fecula, fatty and waxy matters, organic and inorganic salts (especially those having lime and potash for a base), chlorophyll, *débris* of fibre and parenchyma (for the feculent extracts), and lastly, extractive matters, *i.e.*, badly defined substances, possibly belonging to one of the previous groups, or resulting from their transformation and slow destruction.

The extractive is characterized by its solubility in water. It may comprehend all the so-called colouring, bitter and depurative principles. It may exist in very small proportions in the fresh juice; but with time, by the action of air, heat, ferments, etc., it may gradually augment in a preparation of extract, and frequently finish, in a badly prepared extract, by constituting the whole of the mass.

It is very difficult to follow all these successive states of transformation, but some idea may be formed of them by recalling the modifications that crystallizable sugar undergoes under the influence of water and heat, starting with uncrystallizable barley sugar and finishing with caramel. The sugar is submitted to the phenomena of hydration and oxidation; the oxygen of the air burns a part of the hydrogen and a little carbon; vapour of water and carbonic acid are disengaged, and eventually there remains a compound richer in carbon and strongly coloured like caramel. The caramel is still soluble in water; but in the preparation of extract there is always produced a more or less large proportion of a new substance, coloured brown, green or black, and insoluble in water. This substance dissolves in alkaline liquors and acids re-precipitate it from this solution. It has much analogy with humic acid, and Berzelius named it "oxygenated extractive or apotheme." Apotheme is very little known; it is a very complex substance, and it remains as a residue when extracts are dissolved. Probably it ought not to exist in a typical or ideal extract, and it may be affirmed that the more care there is given to the preparation of extracts the less oxygenated extractive will be found in them.

In generalizing the phenomena that take place in the preparation of extracts,—phenomena of hydration, oxidation, or others,—it may be said that the volatile principles disappear or are altered, that they are retained partially by the apotheme, either alone or united with fatty or resinous matters: the aqueous extract of valerian may be quoted for an example. These volatile principles at the moment of their elaboration are hydrocarbons, which become hydrated and oxidized and yield a series of alcohols, aldehydes and ethers that in the course of the operations are volatilized, decomposed or resinified. The sugar becomes glucose, and the fecula, bassorin and cerasin become soluble.

The tannins alter more rapidly still, and it is probable that to the alteration of the astringent principles is due the greater part of the apotheme, which contains also the products of coagulation and destruction of pectic and albuminoid matters.

* *Répertoire de Pharmacie*, vol. vii., p. 249.

It may be concluded from this rapid glance at the phenomena that occur during the preparation of an extract that the alteration would be most rapid in the extracts of juices and that this alteration would diminish in energy from the aqueous extract to the ethereal, which of them all is that which contains the least amount of alterable principles. It may be concluded also, that the preparation of extracts by congelation, when it shall have become more practical, will be the most rational, because all the principles that represent the juice of the plant will be certainly thus the least altered, cold being a condition of conservation and heat of destruction.

IV. Should extracts be submitted to a pharmaceutical classification? Rouelle has divided the extracts into saponaceous extracts (containing only extractive matters), gummy extracts, gum-resinous extracts and resinous extracts. This classification is very primitive and incomplete; it does not include nearly all the extracts employed at the present day.

Without taking note of consistence, it appears to me more simple and more rational, from the pharmaceutical point of view, to classify the extracts according to the nature of the menstruum used in their preparation; but it is necessary first to divide them into simple and compound extracts. The simple extract represents the active principles of a single species of a plant or animal; the compound extract represents, on the contrary, a mixture of principles belonging to several plants, as the compound extract of rhubarb and the compound extract of colocynth. The compound extracts are little known and not much employed in France.

For the simple extracts I propose the following classification:—

1. Aqueous Extracts.
    - *a.* Commercial Extracts (aloes, catechu, etc).
    - *b.* Extracts of juices (feculent or defecated, robs).
    - *c.* Aqueous Extracts, properly so-called.
2. Alcoholic Extracts.
3. Ethereal Extracts.
4. Acetic Extracts.
5. Mixed Extracts.

It is necessary also to define clearly the part of the plant which has yielded the extract, so as not to confound the extract of aconite root or of henbane seeds with the extracts of the leaves of the same plants.

The pharmacist has nothing to do with a therapeutic classification of these extracts, but it may be remarked that from this special point of view these preparations ought to be classified so as to take into account the pharmacodynamic object the medical man proposes to attain. The object being well defined, the physician and the pharmacist ought essentially to remember that the part of the plant, the menstruum and the consistence of the extracts are the elements which should occupy their attention, especially from a posological point of view. To cite only one example, it may be said there exist five extracts of aconite: the defecated and feculent extracts of the juice of the leaves, the aqueous and alcoholic extracts of the leaves and the alcoholic extract of the root, and that this last, the most active of all, is given in doses of some milligrams. The pharmacist, on the simple prescription of "extract of aconite," will dispense in France, the soft defecated extract of the juice; in Belgium, a dry extract, with aconite powder added, under the form of a greenish grumous powder; in Germany, the alcoholic extract of the roots. It may be mentioned also that the ergotine of Wiggers would be dangerous in the ordinary dose of that of Bonjean, which is itself more active than the aqueous extract of ergot.

The necessity has thus incidentally been made manifest for a Universal Pharmacopœia, especially for very active medicines; this necessity has long been recognized by physicians having foreign patients and by travellers requiring the same prescription to be made up in different countries through which they pass.

V. The next point is the general characters of the extracts. Extracts ought to have, before all, the prescribed consistence; they are always coloured brown or green, but should not be black, as happens with extracts prepared over the bare fire. They should have the odour and taste of the substance they represent, and especially should they be free from any empyreumatic odour. The surface should be smooth, not grumous; further, it should not be covered with mould or puffed up with bubbles of gas, which would be a sign of fermentation.

The aqueous extract ought to be nearly entirely soluble in water; it dissolves better in water containing alcohol and in saccharine liquids than in pure water, so that in the preparation of a mixture it is often an advantage for the pharmacist to diffuse the extract in the syrup. The alcoholic and ethereal extracts ought to dissolve completely in their original menstruum.

Very fine crystallizations of organic or inorganic products are often found at the bottom of pots containing soft extracts; for instance, asparagin, oxalate of lime, chloride of sodium, nitrate and sulphate of potash. The extracts of bellodonna, henbane, borage and taraxacum are those which most frequently present these crystallizations; they are confined nearly always to the vegetable juices, and may also sometimes be the result of the action of atmospheric oxygen, as in the case of the nitrates.

Besides these general characters, extracts present specific or even generic characters. Some are characterized by their colour (rhatany and campeachy), odour (valerian), or taste (aloes and rhubarb); others by their chemical characters, such as the alkaloids in opium, cinchona and the narcotic plants, the astringent principles in catechu and rhatany, and the acids in opium, cinchona and the juices of fruits. Some extracts can be recognized rapidly by the action of certain reagents which produce a special odour or colour; for instance, the odour produced by the action of caustic potash upon extract of conium, or the colour produced by the action of alkalies upon the colouring matter of rhubarb. These chemical characters have been given with care by MM. Patrouillard and Lepage in their 'Guide Pratique de l'Essai des Médicaments;' but for the greater part of the extracts, and especially the "saponaceous extracts" of Rouelle, they are difficultly applicable. The study of the extractive is far from being complete, perhaps it never can be completed in consequence of the modifications which continue to take place even in the finished preparation. If this problem, then, be one of the most arduous, if the spontaneous alteration of extracts be often inevitable, and if their adulteration be difficult to detect, it will be manifest that it is the duty, as well as the interest, of pharmacists to prepare their own extracts.

This is not all; the extract has issued from the shop of the pharmacist and become a food product. Originally a medicine and even a poison in the laboratory it has become an aliment in the manufactory. The scientific preparation of extracts upon the largest scale in the present day provides for food Liebig's extract of meat, extract of milk or condensed milk, extract or essence of coffee, and the extracts of peas, hops, malt, etc. It would be easy to discuss the alimentary value of Liebig's extract and to indicate the services rendered by concentrated milk, but to broach these questions in this paper would be to go completely outside the pharmaceutical domain.

THE PREPARATION OF SALTS OF BERBERINA.*

BY J. U. LLOYD.

How can the salts of berberina be most easily prepared from the root of *Hydrastis Canadensis?* What will be the practical yield and what are the solubilities of the different salts?

Of the many processes investigated, I suggest the following as applicable to small amounts. Owing to the slight yield of this yellow alkaloid, it is hardly advisable for experimenters to work lots of less than ten pounds of hydrastis.

Moisten sixteen troy ounces of *Hydrastis canadensis* in fine powder with eight fluid ounces of alcohol; press firmly into a cylindrical percolator not exceeding three inches in diameter, previously prepared for percolation; cover the surface of the powder with a piece of blotting-paper, held in position with a few fragments of glass; add alcohol until the percolate appears at the exit, then close the orifice, cover the top of the percolator tightly by tying over it a sheet of soft rubber and place the percolator in a warm situation; macerate twenty-four hours; remove the rubber and replace with a cover of glass or tin. Cautiously open the exit and graduate the dropping so that the passage of each fluid ounce will occupy about thirty minutes. Suspend the operation when five fluid ounces have been obtained. Macerate until the next day under the former conditions and again procure five fluid ounces of percolate, observing the preceding directions. A continuous supply of alcohol must be provided. The surface of the powder must not become exposed during the operation. Mix the percolates, surround the vessel with ice and reduce the temperature, then add sulphuric acid in excess and stir well. Keep the mixture cold for twelve or more hours, then pour it upon a muslin strainer or a filtering paper, and when the liquid ceases to pass return the precipitate to a vessel containing eight fluid ounces of cold alcohol; mix well together and again separate the crystalline precipitate of impure sulphate of berberin. Dry by exposure to atmosphere.

Sulphate of Berberina.—Add one part of impure sulphate of berberina, obtained as above, to sixteen parts of cold distilled water and cautiously drop in, with constant stirring, ammonia water until in slight excess, allow the mixture to stand in a cool place from twelve to twenty-four hours, then filter and surround the vessel containing the filtrate with ice and stir sulphuric acid into the solution until the ammonia and alkaloid are saturated. In a few hours the magma of minute crystals of sulphate of berberina can be separated with a muslin strainer or a filtering paper. Care must be taken to avoid an excess of sulphuric acid. If this occur the moist magma should be removed to a vessel containing cold alcohol, washed by decantation and drained on a muslin strainer. Lastly, dry the salt by exposure to atmosphere.

Sulphate of berberina is of an orange colour, soluble in about 100 parts of water, temperature 60° to 80° F. It is readily decomposed by alkalies when in solution, yielding free berberina.

I obtain from eighteen to twenty-one ounces from a hundred pounds of hydrastis. The specimen of salts exhibited represents the sulphate of berberina from a fifteen hundred pound batch of root. This batch yielded very nearly three hundred ounces. Although the exhaustion was incomplete, with economy I could not carry the percolation farther.

Sulphate of berberina is permanent; exposure to atmosphere does not affect it. If moisture be absorbed, either the salt is impure from hygroscopic extractive matter or free sulphuric acid.

Berberina.—Rub eight parts sulphate of berberina in a Wedgewood mortar, cautiously adding ammonia water until in slight excess. Pour the dark liquid into thirty-two parts of boiling alcohol and allow the mixture to stand thirty minutes, then filter. Stir into the filtrate thirty-two parts cold sulphuric ether and cover tightly. Surround the vessel with ice and allow it to stand from twelve to twenty-four hours, then separate the magma of minute crystals of berberina with a muslin strainer or filtering paper and dry by exposure to atmosphere.

Berberina is lemon-yellow when pure. It should not be dark or orange, which shade denotes impurity. It unites directly with acids and is a beautiful organic base.

* From the 'Proceedings of the American Pharmaceutical Association,' 1878.

It forms salts, some of which are very soluble, as, for example, the pyrophosphate; others almost insoluble. I find it impossible to make one part of carbazotate of berberina dissolve in forty-five thousand parts of cold distilled water. Berberina and all its soluble salts are bitter. The carbazotate will not impart a trace of bitterness to distilled water, notwithstanding its constituents are both intensely bitter; therefore, I believe it to be almost if not absolutely insoluble.

Berberina is soluble in about four and a half parts of water, temperature 60° to 80° F. It dissolves moderately in officinal alcohol, is insoluble in ether and chloroform. It changes to orange colour when heated to 150° F., and slowly resumes its original shade when cooled.

Phosphate of Berberina.—Dissolve berberina in its weight of boiling water and add two parts of dilute phosphoric acid, drain and dry the precipitate by exposure to atmosphere. Care must be taken that the acid be made from phosphorus and perfectly free from nitric acid.

The orthophosphate is, according to Mr. Lord, soluble in 280 parts of water.

Hypophosphite of Berberina.—This salt may be prepared by substituting in the above formula hypophosphorous acid for phosphoric. Hypophosphite of berberina is soluble to the extent of from five to ten grains in the ounce of water.

Muriate of Berberina.—Dissolve berberina in sixteen times its weight of distilled water and cautiously stir in hydrochloric acid until in slight excess; drain the precipitate and dry by exposure to atmosphere.

Muriate of berberina was the first preparation of this alkaloid introduced to the medical profession from hydrastis. It was discovered accidentally. It is soluble in about five hundred parts of water 60° to 80° F., scarcely soluble at all in cold alcohol, ether and chloroform. It is the most difficult of the berberina salts to decompose, holding its acid in presence of alkalies, and even long digestion with litharge fails to thoroughly remove it. Oxide of silver at once frees the berberina from a heated solution. When dry it is changed from the natural light lemon colour to orange by a heat of from 130° to 150° F. Upon cooling the lemon colour is resumed. It is rapidly falling into disuse, giving place to the more soluble salts.

Nitrate of Berberina.—This salt can be obtained by substituting nitric acid for the muriatic acid of the preceding formula. It is of greenish yellow colour, soluble in about five hundred parts of water, temperature 60° to 80° F., more soluble in hot water, scarcely soluble in alcohol, ether or chloroform. Its use is limited.

Remarks.—Alcohol extracts from *Hydrastis canadensis* in addition to berberina a greenish fixed oil, an acrid resin, a white alkaloid, a vegetable acid, yellow colouring matter and small amounts of other substances of little interest here. The materials named are intimately associated or combined while in the root; such combinations being broken up by the addition of the acid, resulting perhaps simply in the formation of sulphate of the white alkaloid, *hydrastia;* sulphate of the yellow alkaloid, *berberina,* and the liberation of the resinous substances, colouring matter and acid.

The yellow sulphate of berberina quickly crystallizes, carrying down some of the other materials, the larger amount of the latter, however, remains in solution. This impure sulphate of berberina is difficult to dry even if well washed, the reason being the mechanical admixture of the oil alluded to; consequently at this stage it has a greenish cast and imparts an unctuous feeling when rubbed between the fingers.

Sulphate of berberina is decomposed by alkalies with the liberation of the alkaloid berberina. When we add ammonia water in slight excess to a mixture of the impure sulphate of berberina and water, sulphate of ammonium is formed, which dissolves, together with the liberated berberina, an alkaloid very soluble in water and alkaline solutions. The slight excess of ammonia precipitates the hydrastia in an amorphous state, which, with the adhering resin and oil, are separated by filtration; afterwards sulphuric acid, added to the filtrate again, forms sulphate of berberina, which crystallizes. This is pure enough for all practical purposes. It contains a small amount of sulphate of ammonium and a little foreign matter. It can be purified further if desirable by repeating the last operation, dissolving in hot alcohol and crystallizing. For practical purposes this is unnecessary.

When ammonia water is added to sulphate of berberina the salt is decomposed with formation of sulphate of ammonium and the liberation of berberina. Both substances remain in solution, the berberina imparting a dark red colour. The addition of the hot alcohol precipitates the larger portion of the sulphate of ammonium, and when the filtrate containing the berberina is poured into sulphuric ether, that alkaloid crystallizes in consequence of its slight solubility in ether and a mixture of alcohol and ether. The impurities may be traces of sulphate of ammonium.

The other salts, simply combinations of berberina and the acids, do not require mention. Almost any salt may be produced in like manner by the substitution of various acids.

I have met with little success in endeavouring to obtain berberina by evaporation of a solution of the alkaloid, unless by spontaneous evaporation, the heat of expanded steam 150° to 180° F. seeming to decompose it.

Fixed Oil of Hydrastis.—After separating the sulphate of berberina from the tincture, add to the liquid its bulk of water and evaporate the alcohol. Allow the residuum to remain in a cool place some days and carefully skim off the green oil which collects on the surface of the water associated with a little resin. It can be purified by dissolving in sulphuric ether.

This oil has a disagreeable odour and taste, but is not bitter. It turns reddish-brown by age.

Volatile Oil of Hydrastis.—In addition hydrastis contains a very small amount of volatile oil, which imparts the peculiar odour of the root. It may be procured in minute quantities by distilling water in contact with the root.

Resinous Substances.—Decant the aqueous solution from which the oil was separated, and at the bottom of the vessel will be found a black tarry substance, thickly interspersed with yellow particles. Usually a yellow shining layer covers the top. This consists of resin, a little oil and mixtures of both the white and yellow alkaloids, with the resin and yellow colouring matter. Perhaps a combination exists between this substance and the alkaloids which settle with it. It is difficult to separate them by simply washing in hot water, which should scarcely be the case if they are disassociated, inasmuch as the sulphates of both alkaloids are quite soluble in this menstruum; wash the precipitate well and dry. The black resinous substance is acrid to the taste, slightly soluble in hot water and dilute acids, soluble in concentrated sulphuric acid, to which it imparts a deep red colour and from which it is separated by the addition of water. It may be a mixture of several proximate principles.

In some respects this substance reminds us of the amorphous material obtained from cinchona, known as chinoidine, and it may perhaps be largely composed of a principle from hydrastis, bearing a somewhat similar relation to hydrastia that chinoidine bears to the crystallizable alkaloids of the cinchonas.

Hydrastia.—This white or yellowish-white alkaloid exists as sulphate in the liquid decanted from the last-named preparation. It is associated with small amounts of all the preceding substances and a soluble vegetable acid. To obtain it add an alkali, preferably ammonia water, in excess to the cold liquid and allow the brown or brownish-yellow precipitate to settle; then decant the supernatant liquid and wash the precipitate with cold water. Add cold water enough to the drained precipitate to bring to the original volume and then slight excess of sulphuric acid. Allow it to stand in a cold place twenty-four hours and filter. To the filtrate add an alkali in excess and wash the precipitate as before. Dry the precipitate, dissolve in boiling alcohol, filter and crystallize. These crystals are of a deep dark yellow colour. They are not bitter, but impart a disagreeable acrid sensation to the throat and fauces. The yellow colour results from the intimate admixture of a yellow substance, very soluble in acid solutions and imperfectly in neutral and alkaline. It is not berberina.

Purify hydrastia by dissolving in a dilute acid, digesting with animal charcoal and filtering, repeating the operation several times. Or dissolve the crystals of impure hydrastia in boiling alcohol and crystallize, repeating the operation several times. Specimens of small hydrastia crystals, apparently white, are found to be yellow when crystallized in large masses. It is very difficult to obtain an article free from yellowness if the crystals be large. I have none.

Hydrastia is insoluble or nearly insoluble in water, freely soluble in cold chloroform and to an extent in cold alcohol, very soluble in boiling alcohol, from which it crystallizes in beautiful crystals. It forms salt with acids, mostly very soluble in water, uncrystallizable or crystallizing with difficulty.

These incidental products are of little general interest to manufacturers, as only berberina salts are in demand.

I have already digressed from the direct line of my query. I will close by saying that there is a doubt in my mind as to the relations of these several principles while associated in the plant. I cannot believe they are as simple as we might expect and is generally believed. I doubt even if berberina and hydrastia are not mutually combined with other bodies. The splitting up of these organic compounds under the influence of chemical agents, drying the plants and the action of solvents, is with me very obscure.

ARGAN OIL.*

Except a brief notice of the exportation into Europe of Argan oil by the Danish Councillor of State, Georges Höst, who travelled in the kingdoms of Marocco and Fez during the years 1766—1768, the only published account of the uses of the Argan is given in a very little known Danish work, published by P. K. A. Schousboe, entitled 'Iagttagelser over Vœxtriget i Marokko.' Forste Stycke. Kiobnhavn, 1800, 4, 7 tab., of which a German edition appeared in 1801, in 8vo, by J. A. Markussen. It gives an account of some Marocco plants; and, after an introductory sketch of the physical geography of Marocco, it contains descriptions of the plants of the country in Latin and German, with occasional observations in German. The account of the Argan under Retz's name of *Elæodendron Argan* is long: first comes a technical description, followed by a history of its synonymy, and then the following notes (kindly translated for us by Mr. Bentham):—

"It is surprising that this tree should hitherto have been so little known; as it is found in a country near Europe, and visited by many travellers, who speak in their diaries and descriptions of oil of Argan and of Argan trees, these last as constituting a considerable proportion of the forests of the country. It is, however, not to be met with in the northern provinces, but only towards the south. All those persons from whom I have sought more accurate information on the subject are unanimous in stating that it only grows between the rivers Tansif and Sus—that is, between the 29° and 32° N. lat.—and there constitutes forests of considerable extent. It flowers in the middle of June, and the fruit remains on the tree the greater part of the year. The young fruit sets in the end of July or beginning of August, and grows slowly till the rainy season commences towards the end of September. It now enlarges rapidly and attains its full size during that season, so as that by the middle or end of March it is ripe enough to be gathered for economical uses. Both the fruit and the wood are serviceable, but especially the former; for from the kernel an oil is extracted which is much employed for domestic purposes by the Moors, and is an important production of the country, as it saves much olive oil, which can thus be thrown into commerce and made to bring money into the country. It is calculated that in the whole Argan region 1000 cwt. of oil is annually consumed, thus setting free an equal quantity of olive oil for exportation to Europe. Our countryman, Höst, in his 'Efterretninger om Marokos,' p. 285, says that the Argan oil is exported to Europe, where it is used in manufactures. Such may have been the case in former times when it might be cheaper; but now there would be no advantage in doing so, as it costs almost as much as olive oil. At present no Argan oil whatever is exported.

"As the practice in preparing this oil is somewhat different from that of common olive oil, it may be useful to enter into some details on the subject. I have myself been present during the whole operation, and consequently speak from experience.

"In the end of March the countryman goes into the wood, where the fruits are shaken down from the trees and stripped of their husks on the spot. The green fleshy pericarp, which is good for nothing else, is greedily eaten by ruminating animals, such as camels, goats, sheep and cows, but especially by the first two. Therefore, when the Arab goes into the wood to collect Argan nuts, he gladly takes with him his herds of the above animals, that they may eat their fill of the green husks whilst he and his family are collecting and shelling the nuts. The horse, the ass and the mule, on the contrary, do not like this food. When a sufficient quantity of nuts are collected they are brought home, the hard wooden shell is cracked between stones and the inner white kernels are carefully extracted. These are roasted or burnt like coffee on earthen, stone or iron plates; in order that they may not be too much done they are constantly stirred with a stick. When properly roasted they should be all over of a brown colour, but not charred on the outside. The smoke which is disengaged during the process has a very agreeable odour. As soon as the kernels have cooled, they are ground in a handmill into a thick meal, not unlike that of pounded almonds, only that it is of a brown colour, and the meal is put into a vessel in which the oil is separated, which is done by sprinkling the mass now and then with hot water, and keeping it constantly stirred and kneaded with the hand. This process is carried on until the mass becomes so hard that it can no longer be kneaded: the harder and firmer are the residuary coarse parts, the more completely is the oil extracted. At the last, cold water is sprinkled upon it, in order, as they say, to expel the last particles of the oil. During the operation the oil runs out at the sides, and is from time to time poured into a clean vessel. The main point to be attended to in order to extract the greatest quantity and the best quality of oil, is that it should be well kneaded, and that the proper proportion of hot water for the extraction of the oil should be used; it is always safer to be sparing of it than to be too profuse. The residuary mass, often as hard as a stone, is of a black-brown colour, and has a disagreeable bitter flavour. The oil itself, when it has settled, is clear, of a light brown colour and has a rancid smell and flavour. When it is used without other preparations in cooking, it has a stimulating and pungent taste which is long felt on the gums. The vapour which arises when anything is fried in it affects the lungs and occasions coughing. The common people use it generally without preparation, but in better houses it is the custom, in order to take off

* From the *Gardeners' Chronicle*, August 2, 1879.

that pungency, to mix it previously with water, or to put a bit of bread into it and let it simmer before the fire.

"The wood, which is hard, tough, fine-grained and of a yellow colour, is used in house carpentry and for other purposes."

MORPHIOMETRIC PROCESSES FOR OPIUM.*

BY ALBERT B. PRESCOTT, M.D.

The following pharmacopœial assay process for opium is submitted to the Committee of Revision:—

Opium, when dried (in powder) at (about) 100° Centigrade (212° Fahrenheit) until it ceases to lose weight, should yield (from 10 to 12?) per cent. of morphia.†

The proportion of morphia may be determined by the following process:—Take of opium, in powder and dried as above required, 6½ grams (100·3 grains); lime, freshly slaked with one-third its weight of water, 3 grams (46·3 grains); chloride of ammonium, in powder, 4½ grams (69·4 grains); benzole (see List of Reagents), 50 cubic centimetres (the volume of 772 grains of water); washed ether (List of Reagents), 6 cubic centimetres (the volume of 92 grains of water); distilled water, 70 cubic centimetres (1080 grains), or a sufficient quantity. Place the opium in a paper filter of 4 inches (10 centimetres) diameter, in a small funnel; add benzole to fill and cover the powder, and when the filtrate begins to drop, close the neck of the funnel and leave to macerate one hour. Then percolate, by adding the remainder of the benzole, and dry the filter and its contents at a gentle heat until the odour of benzole has disappeared. Carefully transfer the contents of the filter (which is to be preserved) to an exactly weighed flask, of the capacity of 100 to 120 cubic centimetres, add the lime, with 20 to 30 cubic centimetres of distilled water, agitate for several minutes, then stopper the flask and shake till a uniform mixture is obtained. Add distilled water enough to make the contents of the flask weigh 74½ grams (1149·7 grains). Digest, by immersing the flask in nearly boiling water, with occasional agitation, for one hour. Cool, and add distilled water to restore the exact weight of 74·5 grams. Filter, through the paper filter previously used, into a test-tube or other cylindrical glass of the capacity of 80 to 90 cubic centimetres, and previously marked for the volume of 50 cubic centimetres (771·6 grains of water), until the filtered liquid reaches the mark. Should the filtrate lack a few drops of the required volume, the filter-contents are gently pressed to bring the liquid to the mark, but in any case no more than this volume is received. To the filtered liquid (now representing 5 grams of the opium), add eight drops of the benzin, and 3 cubic centimetres of the washed ether (the volume of 46 grains of water), then stopper the tube and agitate. Add the chloride of ammonium, and when it has dissolved, agitate again, and set aside in a cool place for three to three and a-half hours. The crystalline deposit is now gathered by filtration, in a small filter previously weighed and moistened, collecting the deposit, and washing the filter with several portions of distilled water, using but a few drops in each portion. The filter-contents are now dried at about 50° Centigrade (122° Fahrenheit), washed with the remainder of the washed ether (3 cubic centimetres), dried again and weighed.‡ The weight represents the morphia in 5 grams (77·16 grains) of opium. The per cent. is found by multiplying the weight in grams by 2, or by dividing the weight in grains by 0·7716.

The plan of Mohr: The use of lime solution in excess to dissolve morphia from opium or its infusion, and the use of ammonium chloride to neutralize the lime and precipitate the alkaloid—a plan corresponding to the successive use of potassa and ammonium chloride for aluminium separation—has been well approved by the best authorities for the practical assay of opium. It has been adopted in the British Pharmacopœia, with exhaustion of the opium with water before adding the lime, and with acidulation with hydrochloric acid and then evaporation, before adding ammonia to throw down the morphia. The addition of a little ether and benzole to hasten the crystallization of the morphia, and especially to prevent the crystals from adhering to the sides of the dish, was recommended by Hager (*Phar. Centralhalle*, Jg. 9, No. 1, u. 2), and the process so executed was designated Hager's later process. Hager directed to deduct one-tenth the weight of the crystalline precipitate for impurities. In view of the fact that some of the narcotina is dissolved by the lime solution, and crystallizes with the morphia, Jacobsen advised to wash the dried crystals with chloroform; this suggestion, with preference of ether instead of chloroform, Hager accepted, directing the deduction of one-thirtieth for impurities. Hager Jacobsen's process, with the lime solution of 5 grams of opium all washed through the filter (and consequent concentration of the filtrate) is chosen by Dragendorff, in his 'Werthbestimmungen starkwirkender Droguen' (1874), p. 93, as the best process for practical uses, and only second to Schacht's prooess, with correction by amyl alcohol extraction and volumetric estimation, for a method of greatest exactness. Then Hager devised the improvement of taking 6½ grams of opium, and having 65 grams of water in the lime solution, taking the first 50 grams of filtrate, to represent 5 grams of the opium, thereby *avoiding the washing of the filter and the concentration of the filtrate*, saving the morphia from waste by wet heat, and shortening the operation. This form of Hager-Jacobsen's process is given in Hager's 'Untersuchungen,' ii., 176; also in Hoffmann's 'Examination of Medicinal Chemicals,' p. 268. I submit the process, very nearly as given in the two works last named, but with addition of the preliminary treatment with benzole, for the consideration of the Committee of Revision.*

With the desire to contribute some proof of the comparative exactness of different processes of morphiometric assay, I have instituted a series of comparative trials, each process being applied in turn to each one of a set of samples of opium, holding the conditions as nearly parallel as possible. Then, as a test of each result, the purity of the morphia was estimated volumetrically by Mayer's solution, and the morphia remaining uncrystallized in the mother liquor was sought to be extracted by amyl alcohol and estimated volumetrically; these means of correction, the one against overvalue and the other against undervalue, being essentially those which were proposed and used by Dragendorff, in his 'Werthbestimmungen starkwirkender Droguen.' All the operations here reported were intrusted to the execution of Mr. Henry Stecher,† and I desire to acknowledge, still farther, the benefit of his counsel in conducting the work throughout the investigation.

* From the 'Proceedings of the American Pharmaceutical Association,' 1878.

† I would suggest, as others have done, that opium ought to be limited in maximum as well as in minimum strength. The Pharmacopœia can hardly depend upon commercial interest *always* to carry over-rich opium to the morphia manufacturer. But I am not confident as to what limits should be fixed, and it seems to me that a requirement permitting a variation of only 2 per cent. is more strict than can be enforced.

‡ Hager (after Jacobsen) directs to *subtract from this weight its one-thirtieth* for impurities (not removed by ether washing of the morphia previous). In his process, however, there is no treatment of the opium with benzole. This treatment with benzole lessens the impurities of the morphia weighed, and probably wastes some morphia (not over $\frac{1}{2000}$ of the weight of the benzole used). The subtraction of one-thirtieth is more fully discussed farther on.

* A strong approval of Hager-Jacobsen's process, by Dr. Schlosser, is given in the *Am. Jour. Phar.*, 1871, p. 224.

† Mr. Stecher has been Assistant in the Chemical Laboratory at Michigan University.

The following named processes were tried:—

A. The process here proposed for the U. S. P., Hager-Jacobsen's, with a preliminary treatment of the opium with a limited quantity of cold benzole.

B. The same, Hager-Jacobsen's process, modified in treatment of the opium at the start with a *sufficient* quantity of hot benzole.

C. Hager-Jacobsen's process, as given by Hager, without initiatory treatment of the opium with benzole. The results being taken before as well as after washing the morphia with ether.

D. Procter's Staples's process ('Am. Pharm. Asso. Proceed.,' 1870, p. 130), the plan of the preparation of morphia by U. S. P., 1870, with initiatory treatment of the opium with benzole.

E. Schachtrupp's process for estimation of morphia and narcotina ('Zeitschrift für Analyt. Chemie,' 1868, vii., 509). The plan of this method consists in exhaustion of the opium, made alkaline and dried, with hot benzole, the benzole solution being evaporated and its residue dissolved in acidulated water and titrated with Mayer's solution, for narcotina, when the benzole-washed opium is exhausted with amyl alcohol, this solution evaporated, and its residue taken up in acidulated water, and ammonia added, for the crystallization of the morphia, so estimated, gravimetrically. The morphia gravimetric results of this process, as of the others, were subjected to volumetric trial.

Four of the samples of opium used were obtained at different drug stores in Ann Arbor, and one was taken from the laboratory stock, all being "powdered opium." The samples were all dried at 100° C., till drying ceased to diminish the weight. Except for process C, only four samples were worked in the trial of each process.

A. *The process proposed by the writer, for the U. S. P.*, as described at the beginning of this paper, Hager-Jacobsen's process, with initiatory treatment of the opium with a limited quantity of benzol not heated. The results represent 5 grams of opium (6·5 grams being taken), as the directions stipulate. Corrections were undertaken, by volumetric estimation of the precipitates, and also of the amyl alcohol extract of the filtrates, with Mayer's solution of potassium mercuric iodide, as described in detail below:—

Process A.

	Percentages. No. 1.	No. 2.	No. 3.	No. 4.	Mean.
a. Crystalline precipitate of crude morphia* .	12·20	13·10	12·32	12·05	12·42
b. Ether-washed morphia	10·74	11·94	11·84	11·68	11·55
c. By estimating *b* with Mayer's solution . .	7·40	8·80	8·48	8·80	8·37
d. From filtrate, by amyl alcohol and Mayer's solution	2·12	1·92	2·76	3·21	2·50
e. Total morphia by Mayer's solution ($c+d$)	9·52	10·72	11·24	12·01	10·87
f. Subtracting from *b* $\frac{1}{30}$ (Jacobsen)	10·38	11·54	11·44	11·29	11·16
g. Subtracting from *a* $\frac{1}{10}$ (Hager)†	10·98	11·79	11·09	10·85	10·18

The quantities of benzole used upon the opium in this series of trials were larger than the directions specify, being, for No. 1, 100 c.c.; for No. 2, 80 c.c.; for No. 3, 80 c.c.; for No. 4, 70 c.c. Even these quantities did not complete the removal of colour by the benzole, the last portions being still slightly coloured. The reason for restricting the quantity of benzole, and using it cold, is given under process B.

For *estimation with Mayer's solution*, the volumetric potassium mercuric iodide, the *precipitates* were dissolved in sulphuric acidulated water, and so diluted that, at the final reaction in titrating, the solution should be about 200 parts to 1 part of morphia (as Dragendorff advises). Mayer's solution* is made by dissolving 13·55 grams mercuric chloride and 49·84 grams potassium iodide, both strictly dry, in water to make 1 litre. The solution is, therefore, twentieth normal (old decinormal) of $HgCl_2+6KI$. Mayer gave the value of 1 c.c. of the solution as 0·020 of alkaloid. Dragendorff reports trials giving (in solutions of 200 to 1) 0·0224 and 0·0221 of crystallized morphia, and of morphia, dried at 120° C., 0·0191 and 0·0205, respectively, for 1 c.c. Again, 0·020 of crystallized alkaloid. The precipitate is not insoluble in water; therefore a uniform dilution of 200 to 1 is advised. If four molecules of morphia salt react with three molecules of the iodomercurate $[(KI)_2HgI_2+2KI?]$, then 0·0202 should be the value of 1 c.c. of the solution, in crystallized morphia, $C_{17}H_{19}NO_3 \cdot H_2O=303$, no allowance being made for the solubility of the precipitate in water. Dragendorff has stated that the precipitate was visible in a solution of morphia salt in 2500 parts of water. From all the evidence at command, and some trials with crystallized morphia, I believe that titration of morphia with Mayer's solution, at 0·020 alkaloid to the c.c., gives results certainly not too high, and possibly a little too low; also that these results of titration are closer than can be obtained gravimetrically by methods of purification of the crystals. Nevertheless, more investigation is needed as to the conditions of accuracy in titrating with Mayer's solution.

The final reaction was found by patiently waiting for the precipitate to subside after each addition liable to be final, then taking a drop with a glass rod, upon a glass plate resting on black colour, and adding thereto a drop from the burette. If a precipitate appears, these drops are rinsed from the glass plate, into the solution, with a drop or two of water.

In undertaking *to exhaust the mother liquors* (the filtrates) of their remaining morphia,† the following plan, after Dragendorff, was adopted:—The crude morphia was filtered out, at the time specified by the process, and the filtrate set aside some time longer for additional crystallization of morphia. The precipitate so obtained was filtered out, washed slightly with water, dried, and washed with ether, dissolved in sulphuric acidulated

* The weight of these precipitates were, respectively for the four samples, 1st, 0·610; 2nd, 0·655; 3rd, 0·616; 4th, 0·6025 grams.

† Hager's directions to subtract $\frac{1}{10}$ from the crude precipitate and take the remainder for morphia, as well as Jacobsen's direction, accepted by Hager, to subtract $\frac{1}{30}$ from the ether-washed precipitate and take the remainder as the morphia, were both given for processes without initiatory benzole washing of the opium.

* F. F. Mayer, 'Pro. Am. Pharm. Asso.,' 1862, x., 238; *Am. Jour. Pharm.*, 1863, xxxv., 20; *Chem. News*, 1863, 159. George Dragendorff: 'Werthbestimmungen starkwirkender Droguen' (1874), 9; 'Gerichtlich-chemische Ermittelung von Giften' (1868), 227.

† The solubility of morphia in pure water is about 1 milligram to 1 cubic centimetre, and Cleaver (*Phar. Jour. and Trans.*, vii., 243, 1876) advises to add to the weight of purified morphia crystals, one-thousandth of the weight of all the water of the mother liquors and washings, to compensate for the morphia so held in solution. It is of interest to note that this correction, with the 50 grams of mother liquor in the Hager-Jacobsen process, just makes one-tenth the morphia of U. S. P. standard opium, the correction formerly advised by Hager to be deducted for impurities (see result *g* of process A, above). But it has been clearly shown that opium mother waters, even when non-alcoholic, dissolve more morphia than pure water does. Cleaver states that "solutions of opium from which the morphia has been precipitated, if allowed to stand until the smell of ammonia has disappeared, will re-dissolve large quantities of morphia." If, however, much excess of ammonia is left in the liquid, the amount of dissolved morphia is much greater (*Phar. Jour.*, 1876, vii., 242).

water, and titrated with Mayer's solution. The opium filtrate (from the morphia precipitate) was then shaken in a large test-tube with amyl alcohol, and the separated alcohol removed, three portions respectively of 15, 10 and 5 c.c. of amyl alcohol being so applied, each portion being heated in a mixture. The united amylic solutions were then evaporated to dryness, the residue dissolved in sulphuric acidulated water, and this solution titrated with Mayer's solution. The following results were obtained:— In the work with Nos. 1 and 2, after treatment with ammonium chloride, the solutions were left twelve hours, and in Nos. 3 and 4, four hours, instead of the "three to three and a-half hours" of the process, for the precipitate to form.*

Supplementary to Process A.

	Percentages. No. 1.	No. 2	No. 3.	No. 4.	Mean.
a. Additional precipitates, estimated by Mayer's solution	0·36	0·20	0·80	0·28	0·41
b. From last filtration by amyl alcohol and Mayer's solution .	1·76	1·72	1·96	2·93	2·09

(*To be continued.*)

ANTISEPTIC GAUZE AND COTTON.†

Although we have already given one or the other of the below-mentioned formulæ for the preparation of antiseptic gauze, we take this occasion to republish a series of the most approved formulæ, in order to answer the inquiries of several correspondents:—

1. *Lister's Carbolized Gauze.*

Paraffin	7 parts.
Resin	5 parts.
Carbolic Acid	1 part.

Melt the paraffin and resin and add the carbolic acid. The mixture contains 7·7 per cent. of carbolic acid. The original formula of Dr. Lister prescribed that the mixture should be applied by means of a syringe, provided with a sprinkling nozzle, upon the gauze, and that the latter should then be heated under pressure in an air-tight apparatus. For some time past, manufacturers of this gauze have found it more advantageous to dip the gauze into the mixture, and then pass it through rollers in order to remove the excess.

All carbolized gauze must be kept in air-tight boxes, to prevent evaporation of the carbolic acid.

2. *Bruns' Carbolized Gauze.*

Resin, in coarse powder . .	400 gms. (14 av. oz. 48 grs.)
Castor Oil . .	40 gms. (1 av. oz. 180 grs.)
Carbolic Acid .	100 gms. (3 av. oz. 230 grs.)
Alcohol . . .	2 litres ($67\frac{1}{2}$ fl. ℥.)

Dissolve the first three ingredients in the alcohol. Saturate the gauze with it thoroughly, wring it out and dry it by hanging it up horizontally, or by shaking it, spread out in lengths of about seven yards; if done in the latter way, two persons holding the two ends and shaking it up and down, it will be sufficiently dry in a few minutes.

This gauze is much softer and pliable than Lister's, and is free from the drawback of irritating the skin, which is sometimes caused by paraffin.

The above solution contains 10 per cent. of carbolic acid.

3. *Eilau's Carbolized Gauze.*

Linseed Oil, boiled	4 ounces.
Yellow Wax	2 ounces.
Resin	4 ounces.
Oil of Turpentine	8 ounces.
Carbolic Acid, Calvert's No. 2 .	1 ounce.

Melt the first three ingredients, then add the other two. Immerse the fabric in the liquid and pass it through a clothes wringer several times; then fold it, wrap it in oiled silk or carbolized paper, and keep it in a well closed tin box. The above solution contains a little over 5 per cent. of carbolic acid.

4. *Pohl's Carbolized Gauze.*

Deprive the gauze of fat or grease by treatment with caustic soda, thorough washing and drying. Then make a mixture of 100 parts of pure carbolic acid and 5 parts of strong alcohol, of which about 4 grams (1 ʒ) are sprinkled upon each square metre (a little over a yard) of the fabric. This is then introduced into a copper boiler which is provided with a safety valve, and is to be hermetically closed, where it is heated to a temperature of 120° C. (=248° F.).

5. *Benzoated Gauze or Cotton* (Bruns).

This is either made with a 5 per cent. or with a 10 per cent. solution, namely:—

a. 5 per cent. solution.

Benzoic Acid . .	50 gms. (1 av. oz. 334 grs.)
Castor Oil . . .	20 gms. (309 grs.)
or Castor Oil .	10 gms. (154 grs.)
Resin . . .	10 gms. (154 grs.)
Alcohol	2430 c.c. (82 fl. oz. 110 min.)

b. 10 per cent. solution.

Benzoic Acid . .	100 gms. (3 av. oz. 231 grs.)
Castor Oil . . .	20 gms. (309 grs.)
or Castor Oil	10 gms. (154 grs.)
Resin . .	10 gms. (154 grs.)
Alcohol	2360 c.c. (79 fl. oz. 447 min.)

The gauze or cotton (which latter should have previously been deprived of oil), is dipped in the liquid, expressed, and dried at a gentle heat.

6. *Salicylated Gauze or Cotton* (Bruns).

a. 5 per cent. solution, and *b.* 10 per cent. solution are prepared exactly like the preceding.

7. *Benzoated or Salicylated Gauze or Cotton* (Thiersch).

These are prepared like those under Nos. 5 and 6; only in place of castor oil an equal quantity of glycerin is used. But this is found not to entirely prevent the loss of benzoic or salicylic acid in the shape of fine dust on handling.

8. *Borated Gauze or Cotton.*

Boracic Acid	10 oz.
Glycerin	4 fl. oz.
Water	q. s. to make 100 fl. oz.

Dissolve by the aid of a heat, which should not be raised higher than necessary, but should be kept up during the saturation of the cotton, so that the acid will not crystallize upon it. The cotton must have been previously deprived completely of its fat by boiling with soda, and subsequent thorough washing and drying.

9. *Borated Lint.*

Dr. Vulpius, of Heidelberg, directs to dissolve 1 part of boracic acid in 4 parts of boiling water, to saturate 1 part of lint with this solution, and to dry.

* Dragendorff reports, from Mr. Fricker's work ('Werthbestimmung,' 92):—

1. Morphia by Hager's process, 5·9 per cent.; by three days' crystallization, 0·3 per cent.; by amyl alcohol, 1·06 per cent.

2. Morphia by Hager's process, 5·8 per cent.; by three days' crystallization, 0·85 per cent.; by amyl alcohol, 0·73 per cent.

3. Morphia by Hager's process, 7·3 per cent.; by three days' crystallization, 1·27 per cent.; by amyl alcohol, 0·56 per cent.

4. Morphia by Hager's process, 6·24 per cent.; by three days' crystallization, 0·80 per cent.; by amyl alcohol, 0·46 per cent.

5. Morphia by Hager's process, 0·38 per cent.; by three days' crystallization, 0·07 per cent.; by amyl alcohol, 0·62 per cent.

† From *New Remedies*, August, 1879.

The Pharmaceutical Journal.

SATURDAY, AUGUST 16, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE MEETING.

BY the time this Journal reaches the hands of its readers many of them will, it is hoped, be turning their thoughts towards the steel metropolis and the gathering there of the British Pharmaceutical Conference during next week. It will, therefore, be of interest to them to know what are the arrangements made for that event by the Local Committee.

The meeting will be commenced on Tuesday morning, the 19th inst., at half past ten, in the Freemasons' Hall, Surrey Street, under the presidency of Mr. GEORGE FREDERICK SCHACHT, of Clifton. After the usual preliminary business, the reception of the Report of the Executive and the Address of the President, the reading of papers—a partial list of which appeared in this Journal last week—will be commenced; this will be continued until five o'clock, and resumed on the following day at half-past ten.

On each day there will be an adjournment, extending from one until half-past two o'clock, for luncheon, and on Tuesday the members will have the opportunity during this interval of visiting the extensive cutlery works of Messrs. RODGERS and SON, under the guidance of some appointed members of the Local Committee. In the evening of the same day special cars will be provided to convey visitors to the Armour Plate Works of Messrs. J. BROWN and Co., Limited.

On Wednesday morning, at half-past nine, members of the Local Committee will be in attendance to accompany visitors to electro-plate and other works, previous to the resumption of the Conference. No arrangement has been made for Wednesday evening, in order that members may be at liberty to hear the Inaugural Address of Professor ALLMAN, the President of the British Association.

After two days of hard work the members of the Conference will be ready for a holiday, and should this most unseasonable of summers prove capable of yielding one more fine day on Thursday, the 21st, the Excursion to which the Local Committee invites the visitors, both ladies and gentlemen, should be a most enjoyable one. Starting at nine o'clock the company will be conveyed in carriages *viâ* Owler Bar, Froggatt Edge, Calver and Bakewell to Haddon Hall, an old baronial mansion, situated on the banks of the Wye, and belonging to His Grace the Duke of RUTLAND. This will be the most distant point of the excursion and here lunch will be provided. After ample opportunity has been given for exploring the old mansion, the company will leave for Chatsworth, where the celebrated mansion of the Duke of DEVONSHIRE will be thrown open to the visitors. After a ramble through the park the road back to Sheffield will be struck where it crosses the Derwent at the village of Baslow. But before proceeding further "high tea" will be served at the Wheatsheaf Arms. This it is expected will be brought to a close about half-past eight, and then the company will make their way northward to Sheffield.

We do not presume to say which part of this programme is most enticing, the scientific conference or the scientific outing; but we think that as a whole it is sufficient to decide the minds of any waverers in favour of being present at the Sixteenth Meeting of the Conference. We are glad to learn that, so far as can be judged from the number who have applied to Mr. MALEHAM, the Honorary Local Secretary, to secure them accommodation, there are already indications of its being a most successful gathering.

PHARMACOPŒIA REVISION.

As mentioned on several occasions recently the question of Pharmacopœia revision has been taken up by the pharmacists of the United States with considerable vigour. In that country the construction of the Pharmacopœia is not at present controlled by legislation, and among the consequences of this freedom are a multitude of suggestions and a large amount of volunteer work from pharmacists which under proper guidance will probably leave a beneficial impress upon future editions of the United States Pharmacopœia and at the same time profit pharmacy generally. Such guidance may be expected from the American Pharmaceutical Association, which has shown considerable interest in the work, and a report of a committee of that body, presented at the last annual meeting at Atlanta, describes the general principles which it is recommended should be followed in the next revision.

Language is the first subject dealt with, and with respect to this it is distinctly stated that whatever might be urged in favour of the use of the Latin language in European pharmacopœias, it would be impracticable in the United States, for that if it were adopted the original text would be seldom consulted and most pharmacists would use a translation.

In the arrangement it is proposed to abolish the division of the materia medica into primary and secondary lists,—a practice which has been recommended more than once for imitation in this country,—and to arrange all the articles in one alphabetical order, retaining however such headings as aquæ, infusa, decocta, etc., where it is thought desirable to give general directions referring to a whole class. It is also proposed to continue the plan of placing the name of a plant first, followed by the name of the particular part.

The question as to the elimination of articles at present in the Pharmacopœia and the introduction of others is next discussed and lists are given which are too long to quote entire. Among those it is proposed to discard are several indigenous remedies, some of which have more or less been recommended as substitutes for foreign ones, such as Americian elder flowers, *Cannabis americana*, *Euphorbia Ipecacuanha*, *Gentiana Catesbœi*. Chiretta and oil of rue are also included in this list. Among the crude drugs proposed to be added may be mentioned coca, guarana, tea, *Eriodictyon Californicum*, *Eucalyptus globulus*, *Rhamnus Frangula*, *Fucus vesiculosus*, *Grindelia robusta* and *G. squarrosa*, *Hamamelis Virginica* and jaborandi. Seventy chemicals are proposed to be added, including chrysophanic, dilute hydrobromic, purified oleic and salicylic acids, cinchonine and sulphate of cinchonidine, salicylates of iron, lithium and quinine, hypophosphites of calcium, iron, potassium, and sodium, and pilocarpine hydrochlorate. The list of pharmaceutical preparations is still larger, and includes a number of extracts, oleates of the alkaloids and of mercury, tincture of gelsemium, hydrastin, viburnin, and leptandrin, and solutions of the silicates of potassium and sodium.

The descriptions of crude drugs are to be sufficient to indicate the distinctive characteristics visible to the naked eye and when necessary such as are visible under an ordinarily good pocket lens. Common admixtures and falsifications are to be mentioned and the differences pointed out. The Committee further recommends that all chemicals of definite composition should have their formulæ added, according to both the old and the new notation, together with their atomic weights; but that except when differences of process would give different results, chemicals should only be described and defined by concise but complete tests of identity and purity. Also, that temperatures should be stated both in degrees of Centigrade and Fahrenheit.

In the expression of quantities the Committee thinks that all measures of capacity should be abandoned and quantities expressed only in parts by weight. It also recommends that the opportunity afforded by the reconstruction of the formulæ for this purpose should be taken advantage of, in cases where a slight variation of dose is of no importance, to make the tinctures, wines, etc., of uniform strength, so far as relates to the proportion of the crude drug used to a definite quantity of product, and that in doing so the quantities of the ingredients entering into a compound should be expressed in the simplest possible terms and whenever possible in a decimal ratio; but that in the case of very active preparations the present strength should be as nearly as possible preserved.

In cases where certain weights of ingredients are directed to be combined under conditions that may involve a partial loss of any of them—as for instance, when a variable quantity of water may be lost by heat—it is recommended that the weight of the end-product should be specified. Recognition of the progress the metric system is making in the United States is indicated in the proposition that wherever it is necessary to employ definite expressions of weight the quantity should be expressed both in apothecaries' and decimal weights.

The fluid extracts appear to be the most difficult problem the Committee has to deal with. It has decided to recommend that in regard to strength they shall all represent the drug, grain for grain; but as to the practical process for their preparation the Committee hesitates between an improvement of PROCTER's process and SQUIBB's process of repercolation recently described in this Journal. Co-operative experiments are still being carried on under the superintendence of Professor DIEHL to assist the Committee to come to a decision on this point.

As an Appendix the Committee think the next edition of the United States Pharmacopœia should be provided with a table of solubilities of the officinal chemicals in water and in alcohol, at 60° F., and the boiling points; a table of maximum safe doses of powerful remedies; an alcoholometric table; an acidimetric table; a table of reagents; a list of synonyms; a weight and volume table, to facilitate the introduction of the metric system in prescribing; and a table comparing the strength of powerful galenical preparations of other pharmacopœias with that of the corresponding preparations in the United States Pharmacopœia.

BRITISH MEDICAL ASSOCIATION.

THE Annual Meeting of this Association was held in Cork last week, commencing on Tuesday the 5th inst. The number of members present in the city on the first day is estimated at four hundred; there were also many eminent foreign practitioners present. The new President is Dr. O'CONNOR. The Address in Medicine was delivered by Dr. A. HUDSON, of Dublin, and that in Surgery, by Mr. SAVORY, the subject of the former being the labours of LAENNEC and their influence in medicine, and the latter being mainly a criticism of LISTER's antiseptic method. Amongst the business transacted was the award of the gold medal of the Association, for distinguished merit, to Surgeon-Major REYNOLDS, in recognition of his services at Rorke's Drift.

SIR WILLIAM JENNER.

WE learn from the medical journals that Sir WILLIAM JENNER is suffering from an attack of whooping cough, and that he has ceased to practise for the present in order that he may not spread the disease.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the above Association was held at the rooms, Halford Street, on Tuesday, August 5, 1879, the Vice-President, Mr. Brampton, in the chair. After transacting some preliminary business the following report was read and adopted:—

"In submitting the report of the proceedings of the Association for the past session, your Committee congratulate the members upon the fact that the Association has now completed its twenty-first session. In looking at the results attained in the past through the medium of the Association, your Committee have every reason to be highly gratified; whilst at the same time they are assured that with the appliances they now possess, much greater success may reasonably be looked for in the future.

"Your Committee regret to notice that the attendance of members has not been so good as could be desired, but are pleased that the rooms have been used by the members for private study on other than class nights to a considerable extent.

"Your Committee are highly gratified at the success of the botany class which has been conducted by Mr. W. J. Harrison, F.G.S., in connection with the Science and Art Department of South Kensington. At the Government examination held in May, the following members were successful:—First Class, Mr. Burford; Second Class, Messrs. Brampton, Lewitt, Llewellyn, Shuttlewood and Raynor.

"Three lectures have been delivered during the past session, viz.:—By the Rev. E. Atkins, B.Sc., on 'Electrolysis;' Mr. W. B. Clark, on 'Chemical Toxicology,' and J. E. Weatherhead, Esq., on 'Cetacea;' to these gentlemen your Committee tender their sincere thanks for the very able and interesting lectures with which they have favoured the Association.

"Your Committee are pleased to notice that a member of the Association, Mr. Raynor, has passed the Minor examination.

"The library is in a flourishing condition, and the valuable books it contains have been in constant requisition.

"In conclusion, your Committee desire to thank those who have rendered help in the past, and to remind the members that the welfare of the Association depends, to a great extent, upon the efforts put forth by each individual member to further the interests of the Association."

The Treasurer's report, showing a balance in hand of 8*s.* 8½*d.*, having been received and adopted,

Mr. Clark proposed that the Secretary be instructed to forward to the late President the following resolution:—

"The members of this Association having heard with regret of the departure from Leicester of Mr. Raynor, beg him to accept their thanks for the many services he has rendered, and assure him that in whatever position he may be placed, he will have their best wishes for his future welfare."

Mr. Shuttlewood seconded the resolution.

The Chairman having put it to the meeting, it was carried unanimously.

The meeting then proceeded to the election of a Committee for the ensuing session, with the following result:—President, Mr. J. J. Edwards; Vice-President, Mr. W. S. H. Brampton; Honorary Secretary, Mr. S. F. Burford; Treasurer, Mr. W. B. Clark; Messrs. Lewitt, Shuttlewood, Thirlby.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The History of Alizarin and Allied Colouring Matters, and their Production from Coal Tar.*

BY W. H. PERKIN, F.R.S.

(*Concluded from page* 119.)

The tars from different gasworks yield very different quantities of anthracene; this is to a great extent due to the kind of coal employed and the temperatures to which the retorts are heated in the gasworks. To take two extreme cases. Newcastle coal yields a tar which is very suitable for the preparation of anthracene, whereas cannel coal gives a tar containing but little anthracene and a great deal of paraffin. Now, at some gasworks cannel coal is principally used, as in Scotland. At others, some is often mixed with Newcastle or other variety of coal to increase the illuminating power of the gas; this is done frequently in cold weather. Thus tars of all sorts of qualities are formed, and consequently, the kind and quantity of impurities in the anthracene prepared from them differ.

Further complications also arise in the tar works according to the way the distillation of the tar is conducted. If it is carried only so far as to leave a soft pitch in the still, it does not contain so many varieties of impurities as when the distillation is carried on until hard pitch is produced, or the pitch coked. Crude anthracene is, therefore, found to be not altogether of value according to the percentage of anthracene it contains, but to a considerable extent upon the nature of the impurities associated with it. Thus, anthracene obtained from pitch is scarcely a saleable article to those who purify their anthracene by washing it with naphtha, and then by sublimation.

It would be very interesting to see if it would not be worth while distilling coal near the pit's mouth, for the purpose of manufacturing benzol, anthracene, and other useful products, selecting the most suitable qualities of coal, and employing temperatures which experiment proved to be the most suitable. The gas and coke, of course, could be utilized as fuel. Should the supply of coal tar from any circumstance become insufficient, as, for example, by gas being superseded by the electric or any other source of light, this undoubtedly would have to be done, and it would be a great advantage to get products of a uniform quality.

It will, perhaps, be of interest here to record the prices paid for anthracene during the first year or two of the manufacture of artificial alizarin. In 1870—1871, we gave from 9*d.* to 1*s.* 6*d.* per cent. per cwt., and in 1872 from 1*s.* 6*d.* to 5*s.*, and a small quantity at 5*s.* 6*d.* This shows how the price advanced with the demand;† since then there have been great variations, and much higher prices are said to have been given by some buyers.

The anthracene was at first valued by the bisulphide of carbon or petroleum and bisulphide of carbon tests, and also, by the alcohol process, the present anthraquinone method not being then proposed. For our own information, we employed from nearly the first an anthraquinone test, which consisted in oxidizing about ten grams of the anthracene, previously purified with petroleum and distillation with caustic potash, subliming off the anthraquinone in a retort, crystallizing it from naphtha and then weighing. This, although not very accurate, we found to be practically of much value to us.

As to the advantage of the use of naphtha or petroleum spirit for purifying anthracene, manufacturers differ in opinion. It is evident, however, that petroleum spirit has the great advantage of dissolving less anthracene, and, at the same time, the other impurities are sufficiently soluble

---

* From the *Journal of the Society of Arts.*

† The prices of anthracene given in the *Moniteur Scientifique*, April 19, p. 420, are much too high.

in it to be removed if enough be employed, say two or three times as much as the crude anthracene to be purified; it is also easily removed from the purified anthracene by steam, on account of its volatility. Coal-tar naphtha, however, dissolves out a good deal of anthracene; so that the impurities dissolved by it, and left after it has been distilled off, contain often seven or eight per cent. of anthracene, which is difficult to recover. Neither naphtha nor petroleum remove much of the carbazol. The following is a table of solubilities of anthracene, etc., in benzene and petroleum:—

	Petroleum. B.P. 70°–100° C.	Benzene. B.P. 80°–100° C.
Anthracene	·115 per cent.	·976 per cent.
Phenanthrene	3·206 ,,	21·94 ,,
Carbazol	·016 ,,	·51 ,,
Dichloranthracene	·137 ,,	·52 ,,
Anthraquinone	·013 ,,	·166 ,,

There is an impurity in anthracene which is sometimes very troublesome, and that is paraffin. This paraffin is of high fusing point, and of little solubility either in petroleum or in naphtha—very different in this respect from ordinary paraffin. It will dissolve in these solvents when they are hot, but on cooling is almost entirely deposited again. A small quantity of this left in the anthracene frequently greatly impedes the filtration in the succeeding operations, and being a stable compound, passes through most of the processes; it is, therefore, a very troublesome substance, and interferes with the value of a crude anthracene containing it. Crude anthracene is very much purified by being hot-pressed, so much so, that if it is thoroughly done, it is scarcely needful to treat it with naphtha or petroleum. The anthracene, which dissolves in the fused impurities and is then pressed out, may be afterwards recovered.

I will now make a few remarks upon the process of distilling anthracene with caustic potash. This process has been very much spoken against, as destroying a considerable quantity of the anthracene. I may remark that anthracene is not acted upon by heating with caustic potash; and from all the experiments I have made on the subject, which are very numerous, I have not found that there is any more loss of anthracene by distilling it with caustic potash than by distilling it alone.

The effect of caustic potash on crude anthracene is very remarkable, sometimes as much as forty and fifty per cent. of impurities being removed by distilling it with this alkali. The action appears to be twofold: first, it chars all the difficultly volatile and unstable products and bodies of a phenolic character; and, secondly, it combines with the carbazol, forming with it a remarkable compound. Carbazol is present in considerable quantities; crude anthracene, after being washed with naphtha, containing from ten to twelve per cent. of carbazol; washed anthracene, which has been distilled with caustic potash, consists chiefly of anthracene and phenanthrene.

For the economical production of dichloranthracene, we found anthracene which had been purified by distillation with potash essential. This, when properly chlorinated, gives a beautifully crystalline mass, containing a certain amount of oily bodies, which can easily be removed by pressure. Whereas anthracene, which has not been treated with potash, yields a confusedly crystalline mass mixed with sticky impurities, which cannot be pressed out until rendered fluid by the addition of coal-tar naphtha, which results in a considerable loss of product.

One advantage of this process of treating anthracene is that it brings anthracenes of different origins to similar conditions—even pitch anthracene works perfectly well after being subjected to this process. It is also useful as indicating the origin of the anthracene. The further the distillation of the tar has been carried, it will be found the greater the loss of weight the crude anthracene obtained from it will suffer on distillation with potash, on account of the impurities it contains being more easily charred.

There is one curious fact in connection with the process. If anthracene which has been well washed with naphtha or petroleum be distilled with potash, it will be found that on treatment with these solvents again, a considerable amount of impurity will freely dissolve out, apparently consisting chiefly of phenanthrene.

I know of no method of procuring anthracene in a pure state easily and in quantity but by purifying it by distillation with caustic potash. Anthracene thus treated, if washed with benzol or other suitable solvents, and then dissolved in boiling benzole, will crystallize out on cooling in a most beautiful manner in nearly colourless plates with a blue fluorescence, one or two crystallizations rendering it perfectly pure. And this brings me to the subject of the use of pure anthracene in the manufacture of alizarin.

Generally speaking, as a manufacture advances, so the quality of the materials used are improved, and I quite think that the need of anthracene in a pure or purer condition than it is now employed in, will be found to be very desirable in the production of artificial alizarin. Just before I left off manufacturing this product, at the end of 1873, I was engaged upon experiments in this direction, for the purpose of improving the method of preparing dichloranthracene, so as to reduce the amount of chlorine oils formed, or to avoid their formation altogether. As chlorine forms, with pure anthracene, the theoretical amount of dichloranthracene, it is evident that if some convenient method were adopted to allow these bodies to freely react upon each other, pure dichloranthracene could be produced very cheaply, as there would be no loss and no purification needed. I quite think this might be accomplished.

The oxidation of pure anthracene for the preparation of anthraquinone does not succeed well by the process at present adopted, so that this would likewise have to be modified; but if it could be obtained pure, or nearly pure, at once, instead of having to be dissolved in oil of vitriol, or sublimed and then treated with this acid, it would be a great advantage. To obtain anthracene in a pure or nearly pure state on the large scale, I think that it would probably be found best to distil hot-pressed anthracene with potash; then to grind it fine, wash it with petroleum or naphtha and lastly crystallize it from naphtha.

I may here, perhaps, make a few remarks upon carbazol, as it is quite probable that it may yet be found to be a valuable product. To obtain it, anthracene, preferably hot-pressed or washed with naphtha, is distilled with caustic potash until no more anthracene passes over. The black residue is then freed from potash by being well washed with water, and on being distilled yields carbazol; as I mentioned before, crude anthracene gives as much as 10 or 12 per cent. of this substance. Another method consists in boiling the anthracene with fused caustic potash in a cylinder, until free from water, and then allowing the mixture to stand to cool. On opening the cylinder, the anthracene will be found as a layer on the top of the potash containing the carbazol, and can be scaled off. After this is removed, the remaining product is treated as just indicated.*

This remarkable compound of potash and carbazol, when heated to redness, gives off large quantities of hydrogen gas, the carbazol being decomposed. From experiments I have made, this compound appears to contain one atom of potassium to one of carbazol, its formula probably being $C_{12}H_8KN$. It is now under investigation.

* The process of distilling crude anthracene with caustic potash was communicated to H. Caro, of the Badische Aniline and Soda Fabrik, and it was by this means that the carbazol investigated by Graebe and Glaser was obtained.

Carbazol is a beautifully crystallized body, not unlike anthracene. When heated with mercuric chloride, or various other oxidizing agents, it produces a blue colouring matter. This, however, has not been found to be of practical value. It is probably the substance which was described several years ago as anthracene blue, the anthracene used probably containing carbazol.

In crude anthracene and oil, accompanying it, there is a peculiar organic base called acridine, having the formula $C_{12}H_9N$. It was first observed by Caro, and investigated by Graebe and Caro. It crystallizes in brownish yellow four-sided rectangular prisms, and is a most stable compound. The vapour causes sneezing and coughing, and it gives to the oils accompanying anthracene a very irritating action when rubbed on the skin. In hot weather the workmen employed in pressing or otherwise working with crude anthracene sometimes suffer very considerably from the pain it temporarily produces.

Some improvement in the treatment of sulpho acids of anthraquinone with caustic soda in the production of colouring matter is very desirable. The amount of alkali used is often six or eight times more than indicated by theory, and, as no suitable means have been obtained for recovering this before precipitating the colouring matter, it is all converted into sodic sulphate, for which a large amount of sulphuric acid has also to be employed. The sulphate of soda, being in solution, does not pay for evaporation, otherwise it might be reconverted into caustic soda.

Some experiments have been made to precipitate the colouring matter from the alkaline solution with lime, but this, unfortunately, especially with red shades of colours, acts very imperfectly, and is therefore of no value. It is also very desirable that the condition under which the α and β disulphoanthraquinonic acids are formed as also of the disulpho acid giving the sulpho acid of alizarin should be studied, so that their separate formation may be effected at will.

Having now given an account of the manufacture of artificial alizarin, it will be interesting to inquire into the commercial results of this industry, and, firstly, what has been its influence upon the sale of madder and its derivatives. I mentioned at the commencement of this paper that the annual value of the imports into the United Kingdom of madder and garancine, from 1859 to 1868, amounted to about £1,000,000 sterling, with prices averaging for madder 45*s.* and 50*s.* per cwt., and for garancine, 150*s.* In the subjoined table will be seen the remarkable changes that have taken place in the imports, and also the great reduction in price:—

Average Annual Imports of Madder and Garancine into the United Kingdom.

Year.	Madder.	Garancine.	French madder.	Turkey roots.	Garancine.
	cwts.	cwts.	*s.*	*s.*	*s.*
1859–1868	305,840	45,560	45	50	150
1875	100,280	25,860	—	—	—
1876	59,137	15,396 or 6,436	—	—	—
1877	38,711	8,875	—	—	—
1878	32,990	2,790	18	17	65

Up to and during 1876 considerable quantities of artificial alizarin were imported from the Continent, and entered at the Customs as garancine or madder, which having been brought to the notice of the officials, the returns made subsequently are more reliable. The imports of garancine were returned by the Board of Trade in 1876 as 15,396 cwts. when first published, but in the following year, when the figures for 1876 were given for comparison with those of 1877 and 1878, the returns were stated as only 6436 cwts. The erroneous entries were most probably made to evade the penalties for the infringement of patent rights.*

Dutch ground madder has been relatively much higher in price than the other qualities. This is owing to its extensive use in wool dyeing. For various reasons artificial alizarin has made but little progress in its application to wool dyeing, and Dutch madder being mostly used for this purpose, its prices have been maintained at from 28*s.* for ordinary "Ombro" to about 40*s.* to 45*s.* for crop madder. The wool dyers have, however, been working cautiously with artificial alizarin, and now some of them are using it somewhat largely, and, considering its cheapness as compared with Dutch madder, no doubt they will soon find how to use it successfully, and cease to employ madder.

The decline in the sale of madder is still rapidly going on. During the first two months of last year the imports were—

Madder . . . . 6846 cwts.
Garancine . . . . 533 „

During the first two months of this year they were—

Madder . . . . 2185 cwts.
Garancine . . . . 175 „

Or about two-thirds less. And not only so, but the price is still declining. Turkey roots may now be bought at 11*s.* per cwt., whereas before artificial alizarin was introduced they were sold, on an average, at 50*s.* At the present prices of madder its cultivation is unremunerative, and will undoubtedly be soon a thing of the past. Such has been the success of artificial alizarin in competing with madder and garancine in this country, and it is equally true of other countries. The quantity of madder grown in all the madder-growing countries of the world prior to 1868 is estimated at about 70,000 tons per annum. The amount of artificial alizarin now produced is equal in dyeing power to considerably more than this; in fact, the lowest estimate I have been able to get for 1878, and which is confirmed from other sources, is 9500 tons, which is equivalent to 950,000 tons of madder. This remarkable result has been arrived at in ten years only.

To produce this quantity of artificial alizarin there are about nine manufacturers on the Continent and one in this country, Messrs. Burt, Bolton and Haywood, who have two large works for its production, viz., the original works at Greenford Green, and new ones at Silvertown.

Graebe and Liebermann, in their paper in the *Moniteur Scientifique*,† give some statistics of the production of artificial alizarin, which, however, require correcting. They also leave out the years 1869 and 1870. In 1869 we had advanced in the manufacture so far as to send colour into the market, the first invoice being dated October 4th, and that year we produced about one ton. In 1870 we produced 40 tons; in 1871, 220 tons; in 1872, 300 tons; and in 1873, 435 tons. Up to the end of 1870 we were practically the only makers of this product. One of the largest chemical and coal-tar colour manufacturing firms of Germany, with whom we were in correspondence, stating that in November, 1870, they had only lately commenced producing 50 pounds of alizarin, 10 per cent. quality, per day, and that no one else in that country was supplying artificial alizarin; and in 1871 we were practically the only producers of quantity, at any rate during the first part of the year, for in March, 1871, the firm already referred to, and who had great opportunities of knowing what was being done in their country, wrote that they had not received know-

* A method so often resorted to as to render English chemical patents nearly useless as a protection against infringements by foreign manufacturers, the results of this being alike detrimental to the inventor and injurious to the national interests.

† April, 1879, p. 416.

ledge of any establishment but their own manufacturing artificial alizarin.

In November, 1871, however, Messrs. Gessert Frères announced to the Industrial Society of Mulhouse that they had produced 30,792 kilogrammes of alizarin in paste. This is equal to about 30 tons, an amount which was evidently considered by them a very large quantity.*

Graebe and Liebermann's statistics are as follows compared with our production:—

	Graebe and Liebermann. Tons.	Perkin and Son's Productions. Tons.
1869		1
1870		40
1871	125— 150	220
1872	400— 500	300
1873	900—1000	435

Without wishing to detract from Graebe and Liebermann's original discovery, we may say that the birthplace of the manufacture of artificial alizarin was in England. It was in this country that the difficulties and doubts about the manufacture and supply of the raw material, anthracene, were solved, and the production of artificial alizarin by new processes successfully accomplished. After these results were obtained in this country, continental chemists were encouraged to manufacture on a comparatively large scale, but up to the end of 1873 the English manufacturers had practically no competition in the home market.

Having considered the amount of artificial alizarin now manufactured, it will be of interest to see what its money value is.

Taking the lowest estimate, viz., 9500 tons, and calculating its selling prices at £150 per ton, the annual value amounts to no less than £1,425,000, or nearly a million and a-half.

As a dye, it is now at most not more than one-third of the average price of madder in 1859–1868. Consequently, in the United Kingdom, when the annual value of madder imported was £1,000,000, the annual saving is very great.

While collecting the statistics about alizarin, I thought it would be of interest to get, if possible, the statistics of the entire coal-tar colour industry, and to the kindness of H. Caro, of the Badische Aniline and Soda Fabrik, I am indebted for most of the following particulars:—

Estimated Value of the Production of Coal-Tar Colours in 1878.

Germany . .	£2,000,000	of which four-fifths are exported.
England . .	450,000	
France . . .	350,000	
Switzerland	350,000	
Total. .	£3,150,000	

In referring to the works which have been set up for the purpose of making coal-tar colours, I thought it would be of interest to show a copy of a rough sketch of the first works erected for this purpose as they appeared in 1868, two years after the patent for the mauve was taken out.

These works were not one year old when sketched, and the practicability of making the mauve commercially had only been proved a short time. In 1873 they had increased to such an extent as to cover about six acres.

There are now in this country six coal-tar colour works; in Germany, no less than seventeen; in France, about five; and in Switzerland, four. There are also three works in Germany and three in France which manufacture aniline in enormous quantities for the production of coal-tar colours.

Such is the wonderful growth of this industry, which dates only from 1856. It is the fruit of scientific researches in organic chemistry, conducted mostly from a scientific point of view; and, while this industry has made such a great progress, it has, in its turn, acted as a handmaid to chemical science, by placing at the disposal of chemists products which otherwise could not have been obtained, and thus an amount of research has been conducted through it so extensive that it is difficult to realize, and this may before long produce practical fruit to an extent we have no conception of. One very important colouring matter related to coal-tar, and one of the original sources of aniline—a product of as great importance as alizarin—has yet to be produced on the large scale. I refer to indigo. Baeyer has shown that it can be produced artificially, but at present no practical means of accomplishing it have been discovered. No doubt, however, it will not be many years before this is achieved, and the cultivation of the indigo plant share the fate of madder.

* *Moniteur Scientifique*, April 1879, 416.

ROYAL INSTITUTION OF GREAT BRITAIN.

A New Chemical Industry, Established by M. Camille Vincent.*

BY PROFESSOR ROSCOE, LL.D., F.R.S.

"After I had made the discovery of the *marine acid air*, which the vapour of spirit of salt may properly enough be called, it occurred to me that, by a process similar to that by which this *acid* air is expelled from the spirit of salt, an *alkaline* air might be expelled from substances containing the volatile alkali. Accordingly I procured some volatile spirit of sal-ammoniac, and having put it into a thin phial and heated it with the flame of a candle, I presently found that a great quantity of vapour was discharged from it, and being received into a basin of quicksilver it continued in the form of a transparent and permanent air, not at all condensed by cold." These words, written by Joseph Priestley rather more than one hundred years ago, describe the experiment by which ammonia was first obtained in the gaseous state.

Unacquainted with the composition of this alkaline air, Priestley showed that it increased in volume when electric sparks are passed through it, or when the alkaline air (ammonia) is heated the residue consists of inflammable air (hydrogen).

Berthollet, in 1785, proved that this increase in bulk is due to the decomposition of ammonia into nitrogen and hydrogen, whilst Henry and Davy ascertained that two volumes of ammonia are resolved into one volume of nitrogen and three volumes of hydrogen.

The early history of sal-ammoniac and of ammonia is very obscure. The salt appears to have been brought into Europe from Asia in the seventh century, probably from volcanic sources. An artificial mode of producing the ammoniacal salts from decomposing animal matter was soon discovered, and the early alchemists were well acquainted with the carbonate under the name of *spiritus salis urinæ*. In later times sal-ammoniac was obtained from Egypt, where it was prepared by collecting the sublimate obtained by burning camels' dung.

Although we are constantly surrounded by an atmosphere of nitrogen, chemists have not yet succeeded in inducing this inert substance to combine readily, so that we are still dependent for our supply of combined nitrogen, whether as nitric acid or ammonia, upon the decomposition of the nitrogenous constituents of the bodies of plants and animals. This may be effected either by natural decay, giving rise to the ammonia which is always contained in the atmosphere, or by the dry distillation of the same bodies, that is, by heating them strongly out of contact with air; and it is from this source that the world derives the whole of its commercial ammonia and sal-ammoniac.

Coal, the remains of an ancient vegetable world, contains about 2 per cent. of nitrogen, the greater part of which is obtained in the form of ammonia when the coal undergoes the process of dry distillation. In round numbers two million tons of coal are annually distilled for the manufacture of coal gas in this country, and the

* Read at the Weekly Evening Meeting, Friday, February 21, 1879.

ammoniacal water of the gas works contains the salts of ammonium in solution.

According to the most reliable data 100 tons of coal were distilled so as to yield 10,000 cubic feet of gas of specific gravity 0·6, giving the following products, in tons:—

Gas.	Tar.	Ammonia Water.	Coke.
22·25	8·5	9·5	59·75 average.

This ammonia water contains about 1·5 per cent. of ammonia, hence the total quantity of the volatile alkali obtainable from the gasworks in England amounts to some 9000 tons per annum.

A singular difference is observed between the dry distillation of altered woody fibre as we have it in coal, and woody fibre itself. In the products of the first operation we chiefly find in the tar the aromatic hydrocarbons, such as benzene, whilst in the second we find acetic acid and methyl alcohol are predominant.

The year 1848 is a memorable one in the annals of revolutionary chemistry, for in that year Wurtz proved that ammonia is in reality only one member of a very large family. By acting with caustic potash on the nitriles of the alcohol radicals he obtained the first series of the large class of compound ammonias, the primary monamines. Of these methylamine is the first on our list:—

$$\left.\begin{matrix}CH_3\\CO''\end{matrix}\right\}N+2\,KOH=\left.\begin{matrix}CH_3\\H_2\end{matrix}\right\}N+CO''\left\{\begin{matrix}OK\\OK\end{matrix}\right.$$

The years that followed, 1849–51, were prolific in ammoniacal discoveries. Hofmann pointed out that not only one atom of hydrogen in ammonia can be replaced by its equivalent of organic radical, but that two or all the three atoms of the hydrogen in ammonia can be likewise replaced, giving rise to the secondary and tertiary amines, by the following simple reactions:—

$$1.\quad CH_3I+\left.\begin{matrix}H\\H\\H\end{matrix}\right\}N=HI+\left.\begin{matrix}CH_3\\H\\H\end{matrix}\right\}N$$

$$2.\quad CH_3I+\left.\begin{matrix}CH_3\\H\\H\end{matrix}\right\}N=HI+\left.\begin{matrix}CH_3\\CH_3\\H\end{matrix}\right\}N$$

$$3.\quad CH_3I+\left.\begin{matrix}CH_3\\CH_3\\H\end{matrix}\right\}N=HI+\left.\begin{matrix}CH_3\\CH_3\\CH_3\end{matrix}\right\}N$$

To these bodies the names of methylamine, dimethylamine, and trimethylamine were given. They resemble ammonia in being volatile alkaline liquids or gases, which combine with acids to form crystalline and well-defined salts.

Hitherto these compound ammonias have been chemical curiosities; they have, however, recently become, as has so often been the case in other instances, of great commercial importance, and are now manufactured on a large scale.

We are all well aware that the French beet-root sugar industry is one of great magnitude, and that it has been largely extended in late years. In this industry, as in the manufacture of cane sugar, large quantities of molasses or treacle remain behind after the whole of the crystallizable sugar has been withdrawn. These molasses are invariably employed to yield alcohol by fermentation. The juice of the beet, as well as that of cane sugar, contains, in addition to the sugar, a large quantity of extractive and nitrogenous matters, together with considerable quantities of alkaline salts. In some sugar-producing districts the waste-liquors or spent-wash from the stills—called *vinasses* in French—are wastefully and ignorantly thrown away, instead of being returned to the land as a fertilizer, and thus the soil becomes impoverished. In France it has long been the custom of the distiller to evaporate these liquors (*vinasses*) to dryness, and to calcine the mass in a reverberatory furnace, thus destroying the whole of the organic matter, but recovering the alkaline salts of the beet-root. In this way 2000 tons of carbonate of potash are annually produced in the French distilleries. For more than thirty years the idea has been entertained of collecting the ammonia water, tar, and oils which are given off when this organic matter is calcined, but the practical realization of the project has only quite recently been accomplished, and a most unexpected new field of chemical industry thus opened out through the persevering and sagacious labours of M. Camille Vincent, of Paris.

The following is an outline of the process as carried out at the large distillery of Messrs. Tilloy, Delaune and Co., at Courrières. The spent-wash having been evaporated until it has attained a specific gravity of 1·31, is allowed to run into cast-iron retorts, in which it is submitted to dry distillation. This process lasts four hours; the volatile products pass over, whilst a residue of porous charcoal and alkaline salts remains behind in the retort. The gaseous products given off during the distillation are passed through coolers, in order to condense all the portions which are liquid or solid at the ordinary temperature, and the combustible gases pass on uncondensed and serve as fuel for heating the retorts.

The liquid portion of the distillate is a very complex mixture of chemical compounds, resembling in this respect the corresponding product in the manufacture of coal-gas. Like this latter, the liquid distillate from the spent-wash may be divided into—

1. The ammonia water.
2. The tar.

The ammonia water of the *vinasse* resembles that of the coal-gas manufacture in so far as it contains carbonate, sulphydrate and hydrocyanide of ammonia; but it differs from this (and approximates to the products of the dry distillation of wood) by containing in addition methyl alcohol, methyl sulphide, methyl cyanide, many of the members of the fatty acid series and, most remarkable of all, *large quantities of the salts of trimethylamine.*

The tar, on re-distillation, yields more ammonia water, a large number of oils, the alkaloids of the pyridene series, solid hydrocarbons, carbolic acid and, lastly, a pitch of fine quality.

The crude alkaline aqueous distillate is first neutralized by sulphuric acid, and the saline solution evaporated, when crystals of sulphate of ammonia are deposited; and these, after separating and draining off, leave a mother liquor, which contains the more soluble sulphate of trimethylamine. During the process of concentration, vapours of methyl alcohol, methyl cyanide, and other nitrils are given off, these being condensed, and the cyanide used for the preparation of ammonia and acetic acid by decomposing it with an alkali.

Trimethylamine itself is at present of no commercial value, though perhaps the time is not far distant when an important use for this substance will be found. The question arises as to how this material can be made to yield substances capable of ready employment in the arts. This problem has been solved by M. Vincent in a most ingenious way. He finds that the hydrochlorate of trimethylamine, when heated to a temperature of 260°, decomposes into (1) ammonia, (2) free trimethylamine, and (3) chloride of methyl.

$$3\,NMe_3HCl=2\,NMe_3+NH_3+3\,MeCl.$$

By bubbling the vapours through hydrochloric acid the alkaline gases are retained, and the gaseous chloride of methyl passes on to be purified by washing with dilute caustic soda and drying with strong sulphuric acid. This is then collected in a gas-holder, whence it is pumped into strong receivers and condensed. These receivers are wrought-iron cylinders, tested to resist a pressure of 20 kilos. per square centimetre, and containing 50, 110, 220 kilos. chloride of methyl.

Both ammonia and chloride of methyl are, however, substances possessing a considerable commercial value. The latter compound has up to this time, indeed, not been obtained in large quantities, but it can be employed for two distinct purposes: (1) it serves as a means of producing artificial cold; (2) it is most valuable for preparing methylated dyes, which are at present costly, inasmuch as they have hitherto been obtained by the use of methyl iodide, an expensive substance.

Methyl chloride was discovered in 1804 by MM. Dumas and Péligot, who obtained it by heating a mixture of common salt, methyl alcohol and sulphuric acid. It is a gas at the ordinary temperature, possesses an ethereal smell and a sweet taste and its specific gravity is 1·738. It is somewhat soluble in water (about 3 volumes), but much more in acetic acid (40 volumes) and in alcohol (35 volumes). It burns with a luminous flame, tinged at the edges with green, yielding carbonic and hydrochloric acids. Under pressure, methyl chloride can be readily condensed to a colourless, very mobile liquid, boiling at −23° C. under a pressure of 760 mm. As the tension of the vapour is not high, and as it does not increase very rapidly with the temperature, the liquefaction can be readily effected, and the collection and transport of the liquefied chloride can be carried on without danger.

The following table shows the tension of chloride of methyl at varying temperatures:—

At 0°	the tension of	CH_3Cl is	2·48	atmospheres.
„ 15°	„	„	4·11	„
„ 20°	„	„	4·81	„
„ 25°	„	„	5·62	„
„ 30°	„	„	6·50	„
„ 35°	„	„	7·50	„

From these numbers we must of course subtract one to obtain the pressure which the vapour exerts on the containing vessel.

As a means of producing low temperatures chloride of methyl will prove of great service both in the laboratory and on a larger industrial scale. When the liquid is allowed to escape from the receiver into an open vessel, it begins to boil, and in a few moments the temperature of the liquid is lowered by the ebullition below −23°, the boiling point of the chloride. The liquid then remains for a length of time in a quiescent state, and may be used as a freezing agent. By increasing the rapidity of the evaporation by means of a current of air blown through the liquid, or better by placing the liquid in connection with a good air-pump, the temperature of the liquid can in a few moments be reduced to −55°, and large masses of mercury easily solidified. A small freezing machine employed by M. Camille Vincent consists of a double-cased copper vessel, between the two casings of which the methyl chloride is introduced. The central space is filled with some liquid, such as alcohol, incapable of solidification. The chloride of methyl is allowed to enter from the cylindrical reservoir by a screw tap, and the screw left open to permit of the escape of the gas. As soon as the whole mass of liquid has been reduced to a temperature of −23°, ebullition ceases, the screw may be replaced and, if a temperature lower than −23° be required, the tube placed in connection with a good air-pump. By this simple means a litre of alcohol can be kept for several hours at temperatures either of −23° or −55°, and thus a large number of experiments can be performed for which hitherto the expensive liquid nitrous oxide or solid carbonic acid was required.

M. Vincent has recently constructed a much larger and more perfect and continuous form of freezing machine, in which by means of an air-pump and a forcing pump the chloride of methyl is evaporated in the freezing machine and again condensed in the cylinders. This enlarged form of apparatus will probably compete favourably with the ether and sulphurous acid freezing machines now in use, as they can be simply constructed, and as the vapour and liquid do not attack metal and are non-poisonous, and as the frigorific effects which it is capable of producing are most energetic.

The second, and perhaps more important, application of methyl chloride is to the manufacture of methylated colours.

It is well known that rosaniline or aniline-red, $C_{20}H_{19}N_3$, yields compounds possessing a fine blue, violet, or green colour, when a portion of the hydrogen has been replaced by the radicals methyl or ethyl, and the larger the proportion of hydrogen replaced the deeper is the shade of violet which is produced. Thus we have triethyl rosaniline or Hofmann's* violet, $C_{20}H_{16}(C_2H_5)_3N_3$.

By replacing one or two atoms of the hydrogen of aniline by methyl and by oxidizing the methyl anilines thus obtained, Charles Lauth obtained fine violet colours, whilst about the same time Hofmann observed the production of a bright green colouring matter, now known as iodine green, formed during the manufacture of the violet, and produced from the latter colour by the action of methyl iodide.

In order to prepare aniline green from the pure chloride of methyl, a solution of methyl-aniline violet in methyl alcohol is placed in an iron digester and the liquid rendered alkaline by caustic soda. Having closed the digester, a given quantity of liquid chloride of methyl is introduced by opening a tap, and the digester thus charged is placed in a water-bath and heated by a jet of steam until the temperature reaches 95° and the indicated pressure amounts to from four to five atmospheres. As soon as the reaction is complete, the hot water is replaced by cold and the internal pressure reduced by opening the screw tap of the digester. The product of this reaction, heated and filtered, yields the soluble and colourless base, whose salts are green. To the acidulated solution a zinc salt is added to form a double salt and the green compound is then precipitated by the addition of common salt. By adding ammonia to a solution of the green salt a colourless liquid is obtained, in which cloth mordanted with tannic acid and tartar emetic becomes dyed of a splendid green.

If rosaniline be substituted for methyl aniline in the preceding reaction, Hofmann's violet is obtained. The application of methyl chloride to the preparation of violets and greens is, however, it must be remembered, not due to M. Vincent; it has been practised for some years by aniline-colour makers. M. Vincent's merit is in establishing a cheap method by which perfectly pure chloride of methyl can be obtained, and thus rendering the processes of the manufacture of colours much more certain than they have been hitherto.

The production of methyl violet from di-methyl aniline may be easily shown by heating this body with a small quantity of chloral hydrate and then introducing some copper turnings into the hot liquid. On pouring the mixture into alcohol the violet colour is well seen.

In reviewing this new chemical industry of the beetroot *vinasses*, one cannot help being struck by the knowledge and ability which have been so successfully expended by M. Camille Vincent on the working out of the processes.

Here, again, we have another instance of the utilization of waste chemical products and of the preparation on a large scale of compounds hitherto known only as chemical rarities.

All those interested in scientific research must congratulate M. Camille Vincent on this most successful issue of his labours.

Parliamentary and Law Proceedings.

Prosecution for the Sale of Adulterated Sweet Spirit of Nitre.

At the Leeds Town Hall, on Friday the 8th inst., William Greenwood, of Commercial Road, Kirkstall,† was summoned by the Corporation under the Sale of Food

* Hofmann, 'Proc. Roy. Soc.,' xiii., 13 (1863).

† Not on the Register of Chemists and Druggists.—Ed. P. J.

and Drugs Act, 1875. The Town Clerk appeared on behalf of the Corporation, and stated that the proceedings were instituted under the 6th section of the above Act, which provided that "no person shall sell to the prejudice of the purchaser any article of food or any drug which is not of the nature, substance, and quality of the article demanded by such purchaser, under a penalty not exceeding £20."

It appeared that Inspector Handford went on July 10th to the shop kept by the defendant and asked for six ounces of spirit of sweet nitre, for which he paid him 1*s*. 6*d*. He told the defendant he had purchased the nitre for the purpose of having it analysed by the public analyst.

The Public Analyst stated that the medicinal value of the liquid depended chiefly on the quantity of nitrous ether contained therein, and that the sample submitted to him contained scarcely any of that element. The defendant stated that he had bought the spirit of nitre as it was from two chemists in the town.

The defendant was fined 20*s*. and costs.—*Leeds Mercury*.

Obituary.

Notice has been received of the death of the following:—

On the 6th of July, 1879, Mr. Thomas Britten, Chemist and Druggist, Liverpool Road, Southport. Aged 56 years.

On the 10th of July, 1879, Mr. William Griffiths, Chemist and Druggist, Aberayron, Cardiganshire. Aged 51 years.

On the 13th of July, 1879, Mr. Thomas Eyre, Chemist and Druggist, Hayfield, Derbyshire. Aged 31 years.

On the 24th of July, 1879, Mr. David Moir Mackay, Chemist and Druggist, Aberdeen. Aged 52 years.

On the 3rd of August, 1879, Mr. Walter Ferguson Leadbitter, Chemist and Druggist, Sunderland. Aged 71 years.

On the 8th of August, 1879, Mr. Edward Thurland, Pharmaceutical Chemist, Magdalen Street, Oxford. Aged 85 years. Mr. Thurland had been a Member of the Pharmaceutical Society since 1853.

BOOKS, PAMPHLETS, ETC., RECEIVED.

An Introduction to the Practice of Commercial Organic Analysis. By Alfred H. Allen, F.C.S. Vol. I. London: J. and A. Churchill, 1879. From the Publishers.

International Medical-Pharmaceutical Dictionary, in Three Languages: French, English and German. Compiled by George Herman Moeller. Munich: J. Grubert. 1879. From the Publisher.

Elements of Modern Chemistry. By Adolphe Wurtz. Translated and Edited from the Fourth Edition, by Wm. H. Greene, M.D. Illustrated. London and Philadelphia: J. B. Lippincott and Co. 1879. From the Publishers.

Notes and Queries.

[621]. SULLIVAN'S AMALGAM.—The reason of the non-amalgamation is, your precipitate was in too fine powder.

Let the zinc remain twice as long in contact with the solution; the result will be grains the size of ordinary filings. The fine powder should be thrown away with the washings.

Dingwall. P. J. Dewar.

[623]. EMP. COLCHICI.—I have several times had emp. colchici prescribed. It is an American preparation. Having failed to procure it from the wholesale house I shall feel greatly obliged if you will ask for the formula for making the same.

M. R. J.

THE INTRODUCTION OF CHLOROFORM AS AN ANÆSTHETIC.—The following letter on this subject, from Mr. Henry Brown, of Northallerton, has appeared in the *British Medical Journal*:—

The subject of anæsthesia is one ever of interest, and many have not taken the trouble to read the literature of thirty or forty years ago bearing upon the question. I have for some time doubted the priority of Sir J. Y. Simpson's discovery; but he must be credited with great patience and enormous working power; and he never threw away a palpable suggestion, even if emanating from a babe in science, literature, or medicine.

In regard to the composition of the chloric ether (or shall I say chloroform?) introduced into the practice of the Liverpool medical men, in 1838, by Mr. Waldie, I can find no reliable data. I am now referring to exact chemical composition. Whether the chloroform, as suggested by Mr. Waldie to Sir James Simpson, was the chloric ether of Thomson, Robiquet, and Colin, I am not able to say. I leave Liebig out of the discussion altogether: his analysis was defective and inaccurate, inasmuch as hydrogen is completely omitted in his calculation.

In 1834, Dumas determined the true composition of chloroform, and gave it the name by which it is universally known. Mr. Guthrie, of America, and Soubeiran, of France, in 1831, prepared chloroform; but does Guthrie's description at all correspond to our modern article? He writes, in 1832, that "he had used the product very freely during the previous six months to the point of intoxication; that he had found it singularly grateful, producing promptly a lively flow of animal spirits and consequent loquacity, and leaving little of the depression consequent on the use of ardent spirits; that it promises much as a remedy in cases requiring a safe, quick, energetic, and palatable stimulus; and that, for drinking, it requires an equal weight of water."

Dr. Black, of Bolton, speakes of it, in 1833, as a new remedy, and considers it useful in asthma and adynamic conditions of the system.

In 1847, the *United States' Dispensatory*, published in July, describes it thus: "It acts as a diffusible soothing stimulus *in the same manner as sulphuric ether*, but with this decided advantage, that, when sufficiently diluted, it possesses a bland sweet taste, which renders its administration easy even to children. The dose for an adult is a teaspoonful diluted with water. In affections characterized by difficult respiration it may be used by inhalation."

We have thus Guthrie and the *United States' Dispensatory* speaking of a something called "chloroform," but which is miscible with water. Now we know chloroform is only soluble in water to the extent of one in two hundred, and barely soluble in an equal weight of rectified spirit; how, then, could pure chloroform be described by Guthrie and the *United States Pharmacopœia* as possessing the properties above mentioned? I believe it was a spirituous solution of chloroform that Waldie introduced into Liverpool, and it was called chloric ether; but it was not the chloride of olefiant gas of Thomson and others. The question may be asked, Was it chloroform as we now know it that was used by Sir James Simpson in his first experiments, or was it the spirituous solution? I have searched all available records, and confess that upon this point we are in ignorance. I know it is stated a liquid, by some means or other put aside, was used, and most unexpectedly answered the purpose—*i.e.*, of anæsthesia. The party grew exhilarated, we are told, and some become insensible. I need not refer to the fact that, for more than ten years, ether and ether-anæsthesia were the rage, and every medical and pharmaceutical journal literally teemed with accounts of ether-inhalation and descriptions of apparatus up to 1847. Mr. Jacob Bell, editor of the *Pharmaceutical Journal*, in a note on p. 357, No. viii., for February, 1847, thus writes: "Chloric ether has been tried in some cases with success; it is more pleasant to the taste, but appears to be rather less powerful in its effects than sulphuric ether."

Of the dead we must say nothing but in praise; but I am bound to add, Sir James Simpson got his first hint in regard to the anæsthetic power of chloroform from Mr. Waldie; but the name of Jacob Bell must not be overlooked. Bell's note was written in February, 1847, and Waldie's suggestion was offered in November of the same year. I thus leave the subject; but with ample material behind to prove that, although Sir James Simpson was the first to put thoroughly to the test the anæsthetic power of chloroform or chloric ether of 1847, he was indebted to others for the suggestion, and Mr. Waldie followed in the wake of Mr. Jacob Bell. Mr. Bell does not inform us as to his authority; but anæsthesia with ether, and no doubt with chloric ether, was practised for reality's sake, or for the purpose of scientific curiosity, years before the discovery of Sir James Simpson took the medical and civil world by storm.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[334]. In this prescription "An Apprentice" does not give the quantity of calomel, and from the general character of the formula I should be disposed to regard it as one of those lay recipes which are dispensed from time to time rather than as the prescription of a qualified practitioner. In dispensing these the pharmacist has to draw largely as a rule on his judgment, and if the dose of calomel be not excessive I think "An Apprentice" would find mucilage of acacia go far to remove his difficulty. At the same time it is hard to see the object of the combination of calomel and bals. copaibæ.

GULIELMUS.

[335]. In answer to "Nihil" the following formula for emp. iodinii is from Beasley's 'Pocket Formulary,' p. 126:

Lead Plaster	ʒvj
Resin Plaster	ʒij

Melt together and add iodine ℈j rubbed with olive oil ʒss. In the same work may also be found formulæ for emplastrum iodinii compositum and emp. iodinii c̄. belladonnâ, and in Squire's 'Hospital Pharmacopœias,' a formula for emp. iodi co. as follows:—

Iodine	ʒij
Potass. Iodid.	ʒiij
Emplast. Plumbi.	℥xvj
Emp. Opii	℥vj

As the prescription ordered emp. iodinii merely, I should think the first of these formulæ the proper plaster to have used.

GULIELMUS.

An answer has also been received from "Lavandula."

[337]. In reply to query No. 337, I think "G. W. W." must have used hard water. Pure distilled water will make a perfectly clear solution with liq. ferri dialysati and syr. aurant., but if the mixture be only slightly alkaline, the iron will be immediately precipitated.

T. A. TAIT.

Correspondence.

THE BENEVOLENT FUND.

Sir,—In reading over the reports of the Benevolent Fund Committee, which are given in your Journal from time to time, there is food for much reflection, yet, strangely enough, there is too much reason to suppose that, by the vast majority in our community, they are not treated with the attention they deserve.

Lying quite outside the pale of pharmaceutical politics, away from scientific controversy, and rigidly apart from all questions of trade and trade interests, there exists in our midst a neutral ground—a border-land, where charity and goodwill reign supreme, and where the cry of the sorrow-stricken is seldom heard in vain.

When one sees, month after month, a system of relief, extended without ostentation to decayed fellow workers, to bereaved and desolate women, to orphans who have been dearer than life itself to those who have gone before, surely silence can be stretched beyond the point of endurance and the iron-grip of apathy clog the efforts of good men who were working so wisely and so well.

How it is possible for any individual amongst us to withhold his practical sympathy from a work which so persistently proves its nobility it is indeed difficult to say, and it would be a thought reflecting bitterly upon our boasted intelligence as a class if we could for one moment suppose that there existed the man who realized to the full the generous nature of the work done and who still could give some plausible reasons why he should not enlist side by side with those whose only object is to relieve the suffering and distress of fellow creatures—brothers in the close communion of a hard and earnest calling, and whose "crown of sorrow" may be the remembrance of brighter and better days.

Surely, in such a course as this, argument must be unnecessary. I will simply ask my reader, if he should chance to be a non-subscriber to this fund, to turn through some of the back numbers of this Journal, to read over these records of charity—charity in the true sense of the word—to give them a few moments' quiet thought, and then to ask himself "Can no more be done?" The issue I am content to leave to himself and his conscience.

Kilburn, N.W. CHARLES B. ALLEN.

TINCTURE OF KINO.

Sir,—Those who have been troubled with a gelatinized tinct. kino will, I am sure, be pleased to know that the remedy suggested by Mr. Merrikin is of the utmost value. But (having had at one time and another, considerable trouble with this preparation) I would suggest that the percentage of glycerine which he advises be doubled. As a revision of the B.P. is occasionally talked of, would it not be advisable to discard the present tincture and introduce a liquor kino in its place? A preparation which I have used for some time, and which has given the utmost satisfaction, has been prepared as follows:—

Kino in coarse powder	ʒij
Sp. V. Rect	℥v
Glycerine	℥v
Aquæ Dest.	℥x

Macerate for seven days.

I have found the above to make a preparation which may be confidently relied upon, and I would therefore suggest to those who have been troubled in this matter to give it one trial. I am sure they will be pleased.

"CAREY."

G. J. Gostling.—We do not know, and must refer you to the gentlemen mentioned for the information.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mitchell, Harrison, Cairns, Watts, Cherry, Reynolds, Hesse, D. Howard, Rump, Maw, Minor, Dewar.

The Pharmaceutical Journal.

SATURDAY, AUGUST 23, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE CONFERENCE MEETING.

AFTER an interval of six years the British Pharmaceutical Conference has again visited the county of the ridings and for the second time experienced the hospitality of their Yorkshire *confrères*. In point of numbers the meeting has been a most successful one, one hundred and forty-five names having been signed in the visitors' book. The company included many of the best known pharmacists in the three Kingdoms as well as delegates from several kindred associations, amongst them, notably, the Pharmaceutical Societies of Great Britain and Ireland, which were represented by their respective Presidents and several members of their Councils. Nor do we think that the general verdict upon the papers read and the discussions, as compared with those of former years, will be an unfavourable one. Early in the meeting, however, one most unwelcome fact was revealed in the reading of the report, namely, that the Senior General Secretary, Professor ATTFIELD, to whose energy and enthusiasm the present position of the Conference may be in a large measure attributed, had unexpectedly intimated his intention of resigning his present office, although at the request of the Committee he had consented to hold it during one more year. The appreciation of his services by the Executive Committee was evinced by the prompt formation of a provisional committee, to which many other members present added their names. The Honorary Secretary is Mr. M. CARTEIGHE, and the business of the Committee will be to consider the best method of testifying to Professor ATTFIELD the sense of the Conference as to its indebtedness to him.

The Presidential Address was chiefly devoted to carrying out the contrast between the ideal and actual position of the pharmacist in Great Britain which Mr. SCHACHT had presented to the Conference last year. As the Address itself will be found *in extenso* at another portion of this Journal, we leave any more detailed reference to it until a future occasion.

Once more Dr. WRIGHT has provided a report on the aconite alkaloids, the present one being devoted to the alkaloids from Japanese aconite, atis root, and the leaves, flower and stalks of English grown aconite. From Japanese aconite Dr. WRIGHT reports that he has obtained a crystallizable alkaloid, agreeing in composition with the formula $C_{66}H_{88}N_2O_{11}$, which is itself in some respects more stable than aconitine and pseudaconitine, in not yielding "apo" derivatives, and he appears to think it may be a dehydrated derivative of a hypothetical parent base. As an incident of the research he also reports that "treatment with alcohol alone, unacidulated by any acid at all, extracted practically all the alkaloids present in the roots examined." These results confirm those obtained when Japanese aconite was first examined two years ago* in regard to the points of pharmaceutical interest, namely, that Japanese aconite contains more alkaloid—amounting to about 2·5 per cent. soluble in ether—than any other kind of aconite, and that the crystallizable alkaloid obtainable from it is of a specific nature. In the course of the discussion Mr. GREENISH suggested the desirability of ascertaining the botanical origin of the Japanese aconite roots worked upon, and expressed the opinion that as met with in commerce this drug is not always of the same character. This point is of special importance, as this kind of aconite, as pointed out by Mr. UMNEY, is now the kind almost exclusively met with in the market. The examination of atis roots (*Aconitum heterophyllum*) has not led to any definite results sufficient either to confirm or controvert those recorded by BROUGHTON, some years ago, in reference to the substance he termed "atisine." In the examination of the flowers, leaves and stalk of aconite plants no definite result was obtained, and although the quantity of material worked upon amounted to nearly three hundredweight, it was only by inference from the comparative absence of inconvenience experienced in working that the non-existence of poisonous alkaloids was conjectured.

The next report presented to the Conference contained a statement of the results obtained by Mr. THRESH in carrying out the investigation of commercial ginger, for which a grant was placed at his disposal last year. These results show that ordinary Jamaica ginger contains, in the portion extracted by ether—(1) a crystalline fat, consisting of a dark red, tasteless and odourless portion, insoluble in strong alcohol, a white amorphous tasteless and odourless portion, soluble in alcohol, and a wax-like tasteless and odourless resin; (2) a red fatty substance, very pungent and soluble in alcohol; (3) a limpid, volatile, straw-coloured oil of an aromatic, somewhat camphoraceous taste, having a sp. gr. of 0·853 at 15° C.; (4) a neutral resin, soluble in strong alcohol; and (5) acid resins of a dark brown colour. The pungent or active principle of ginger, to which Mr. THRESH gives the name of "gingerol," is a viscid odourless liquid, about the consistency of treacle, readily soluble in alcohol even when dilute.

* *Pharm. Journ.* [3], vol. viii., p. 172, and 'Year-Book' (1877), p. 469.

That portion of ginger which is insoluble in ether consists chiefly of mucilage, inorganic constituents, a substance precipitated by tannin, metarabin, cellulose, albumenoids, etc. The comparative examination of different kinds of ginger showed that the variety most esteemed contains only half as much essential oil as the others, also less active principle than African or common Jamaica. The volatile oil of fine Jamaica ginger has, however, the finest bouquet.

The first paper read after the presentation of these reports was on the "Soluble Essence of Ginger," and it described a modification of the method originally proposed by Mr. Thresh for its preparation. The *rationale* of this process was to be gathered from a consideration of the constituents of ginger root; in carrying it out, the alcoholic tincture which contains, together with the extractive soluble in water, neutral and other resins, gingerol, mall quantities of the red fat, wax, etc., is mixed with slacked lime, by which the greater part of the resin is precipitated. On adding dilute sulphuric acid to the clear liquid the dissolved lime is precipitated, and by diluting the resulting clear liquid, and filtering through powdered pumice or silica, the wax, fat, extractive, and the rest of the resin is got rid of, together with any excess of volatile oil.

The next paper gave an account of an investigation conducted by Mr. Stoddart, to ascertain the cause of a periodical fatality amongst sheep in the neighbourhood of Bristol. Though the inquiry was not originally of any apparent pharmaceutical interest, it incidentally furnished results of value in regard to the period at which ergot should be gathered for medicinal purposes. It was observed that the sheep fed on natural herbage always had foot-rot, even in summer, and other circumstances led Mr. Stoddart to suspect that the mischievous effects might be due to ergotism. On examining the old mature plants of *Lolium perenne* he noticed well-formed purplish dark coloured ergots, but could not discover these upon the younger plants, which were greedily devoured by the lambs, while they sought to avoid the old plants. In the following spring Mr. Stoddart obtained specimens of *Lolium perenne* the inflorescence of which was just commencing, and he traced the development of the ergot from this stage of its growth until the commencement of August, at which period he found the fungus had reached the limit of its vegetative or myceloid growth. It is at this stage that the peculiar medical effect of the *Claviceps* on the animal economy exists in greatest intensity, and it was at this period that the effect produced upon the sheep was greatest. After carrying out these observations for six or seven years he came to the conclusion that for all medicinal purposes ergot should be gathered in the months of August or September, because at the end of the vegetative period its action is greatest.

Dr. Symes then read a paper describing the construction and principles of the different forms of polarimeter and its application in pharmacy. Among other illustrations of this he gave the results of the determination of the rotatory power of a number of essential oils. Another illustration of the utility of the polarimeter had reference to the examination of urine, a legitimate branch of the pharmacist's calling, not subject to the influence of unfair competition on the part of uneducated outside traders.

Next in order were three papers by Mr. Siebold. The first described the application of chloroform in the testing of drugs, and was based upon the principle indicated by Dr. Himley, that the presence of mineral adulterants in flour can be detected by their sinking in that liquid, while the normal constituents of the flour float at the surface. Mr. Siebold described the results obtained in this way as being more satisfactory than those obtained by incineration. The second paper suggested that the difference in the coloration of chloroform by iodine according to the presence or absence of alcohol afforded a means of detecting the presence of alcohol in chloroform. With a mixture of chloroform and alcohol the brown colour of the alcoholic solution of iodine predominates over the purple colour of the chloroform solution sufficiently to give indications to satisfy the requirements of the pharmacist, as in this way the presence of half per cent. of alcohol can be detected. The third paper was on the use of the hydrometer in determining the specific gravity of liquids, and described a number of experiments undertaken with the object of deciding whether the indications of the hydrometer can be depended upon with liquids containing undissolved powders, oils, resins, etc., uniformly suspended. The results tended to show that the presence of such substances does not affect the indications of carefully made hydrometers.

The last paper read at Tuesday's sitting of the Conference was by Mr. Gerrard, on the extraction of pilocarpine by ammoniated alcohol, which he has found to be a much more convenient solvent than those hitherto used, it furnishing a larger amount of product and effecting the separation of the alkaloid from the dark colouring matter much more readily. It was pointed out by Mr. Williams, in the course of the discussion on this paper, that the use of ammoniated alcohol may possibly be adopted with advantage in the extraction of alkaloids from other materials.

On the second day's sitting the business was commenced by the reading, by Mr. Allen, of some "Notes on Petroleum Spirit," describing some characteristic reactions of petroleum spirit as compared with those of benzene from coal tar, as well as a method of testing mixtures of petroleum spirit and benzole. The different behaviour of these substances when treated with nitric acid furnished the basis for this method of testing.

Mr. F. W. FLETCHER then read a paper on the "Valuation of Citrate of Iron and Quinine." After adverting to the circumstance that the Pharmacopœia test furnished no indication whether the alkaloid obtained by its directions was or was not quinine, the author suggested the application of the plan of fractional crystallization to the sulphate as a means of detecting the presence of cinchonidine. The necessity of employing this test was shown by the mention of the circumstance that certain foreign makes of "sulphate of quinine" invariably contain a large proportion of cinchonidine sulphate.

Two papers by Mr. E. DAVIES were then read. The first, on the "Estimation of Water in Iodine," by combining a known quantity of iodine with a weighed excess of mercury, and weighing the dried residue, elicited some useful information. The other paper, on the "Presence of Tannin in Gentian Root," suggested the possibility that the tannin contained in the root is liable to decomposition when the gentian is powdered, or that tannin is not a uniform constituent of gentian root.

A paper on "Amylic Alcohol and Amylic Nitrite," by Mr. DOTT, consisted mainly of a reply to certain criticisms* of the paper read by Mr. DOTT upon this subject at the meeting of the Conference last year.† The author maintained the correctness of the statements in his original paper and he was supported in that position by speakers who stated their experience in the course of the discussion.

The "Gelatinization of Tincture of Kino" formed the subject of a paper by Mr. BAMFORD. The author suggested frequent agitations of the tincture as an efficient remedy of the inconvenience experienced by many dispensers from the behaviour of tincture of kino. In the course of the discussion that followed the reading of this paper it soon became evident that gelatinization of tincture of kino is not by any means invariably experienced. Some of the speakers had never seen a case during many years; others had observed it only on one or two occasions, and it was suggested that the result was probably due to some peculiarity in the kino used rather than a constant characteristic of this drug. Amongst other preventives of gelatinization the effect of the addition of glycerine, as suggested by Mr. ELLINOR, was in the main spoken of favourably, but it was also remarked that the glycerine might to some extent counteract the astringent action of the kino. The judicious selection of the proper kind of kino for the preparation of tincture of kino will probably be the most effective remedy for this kind of difficulty and its attainment may therefore be intrusted to the relative intelligence of wholesale houses.

The use of Anhydrous Air as a Therapeutic Agent was described in a paper by Mr. KEYWORTH, who had found that its application as an absorbent of moisture gave relief from the pain and inconvenience caused by tension in various morbid conditions, such as cancerous growths, ulcers, etc. A jet of dried air applied for an hour in the evening was said to have been found to cause cessation of pain for several hours and secure a good night's rest.

Mr. H. COLLIER read a paper on the use of tincture of quillaia bark as an emulsifying agent, in which he described the efficacy of this preparation in producing emulsions with materials of a resinous or oily nature and suggested that on this account it was deserving of consideration as a pharmaceutical agent. Some strong doubts were expressed in the discussion of this paper that the peculiar activity of quillaia bark would render it inappropriate for use as the means of effecting emulsification, but the remarkable efficacy of the tincture in causing the rapid subdivision of mercury was considered to promise well for its application in the preparation of sheep ointment.

Another paper by Mr. COLLIER dealt with the chemical condition in which saponin exists in the quillaia bark.

Next in order was a note on Aricine, by Mr. JOHN ELIOT HOWARD. Referring to the recent paper on this subject by Dr. HESSE, and to the specimen of aricine presented by that chemist to the museum of the Society, the author stated that he had compared this sample with the one deposited in the museum by himself in 1852 and was satisfied as to their identity. He also found the bark from which Dr. HESSE obtained his alkaloid to be exactly like his own, namely, the *jaune de Cuzco* of DELONDRE and BOUCHARDAT, which was imported as Calisaya in 1829. This, Mr. HOWARD believes, is the only bark from which aricine has been obtained, and he points out that the suggestion of the existence of aricine among the alkaloids of *Cinchona succirubra* is merely matter of conjecture. Mr. HOWARD disavows any claim to the discovery of aricine, though he has satisfied himself of the substantial accuracy of PELLETIER'S observations, and has therefore maintained the existence of the alkaloid described by him as aricine, although it has generally been denied. It is suggested that the further examination of bark yielding aricine promises to be of interest as regards the classification of different species of the genus *Cinchona*, and that in connection with this inquiry it will also be desirable to study the physiological action of aricine, as well as that of paricine, which appears to occur among the alkaloids of *Cinchona succirubra*.

A paper on the "Chemistry of Chaulmoogra Oil," by Mr. MOSS, showed that the existence of any alkaloidal substance in this oil was doubtful, at least so far as to account for any medicinal efficacy. Chemically, the specific characteristic of chaulmoogra oil consists, according to the author's results, in its containing a peculiar fatty acid, gynocardic acid, associated with palmitic acid, hypogœic acid and cocinic acid.

* *American Journal of Pharmacy*, for February, and *Pharm. Journ.* vol. ix, p. 899.
† *Pharm. Journ.* [3], vol. ix. p. 172.

Dr. Hamberg's paper on the "Capacity of Different Organs to absorb and retain Arsenic in Cases of Chronic Poisoning" described the chemical results obtained in a physiological investigation carried out for the purpose of elucidating this subject.

The last paper read was on the "Estimation of Morphia in Turkey Opium," by Professor Fluckiger. The author recommended the exhaustion of the opium with cold water as being the most convenient for extracting the morphia. The clear liquid is then mixed with definite proportions of alcohol, ether and ammonia, and after shaking crystals of morphia are formed at the surface of the layer of ether. After a day or two, the whole of it is deposited and can be collected and weighed.

At the conclusion of the reading of papers, a ballot was taken for the election of officers of the Conference for the ensuing year, which resulted in the choice of Mr. William Southall, of Birmingham, as President. The place of the next meeting, decided in accordance with the previous custom of accompanying the meeting of the British Association, is Swansea, and Mr. J. Hughes, of that town, has been elected Local Secretary; the Vice-Presidents being Mr. Grose, of Swansea, Mr. Reynolds, of Leeds, Mr. Ward, of Sheffield, and Mr. Sandford, of London.

The usual votes of thanks for the services rendered by the members of the Local Committee were then proposed, special mention being made of the names of Mr. Ward, President of the Sheffield Chemical and Pharmaceutical Association, Mr. Maleham, the Local Secretary of the Conference, and Mr. Learoyd, who has actively assisted him. These complimentary acknowledgments of the service rendered to the Conference were never more thoroughly well merited, and we think that all who were present at this meeting will share the opinion expressed by a Yorkshire man, that Yorkshire has reason to be proud of the way that Sheffield has received the Conference and maintained the credit of the county.

On the following day the prospects of fine weather at an early hour were very slender, but at the time fixed for meeting at the Freemasons' Hall it had so far improved that there was a large muster of members, a few of whom were accompanied by ladies, and the excursion was carried out in accordance with the programme indicated last week. With the exception of one brisk shower, a kicking mare and some mountain dew there was nothing to mar the enjoyment of the entertainment that had been provided by the zealous exertions of the Local Committee. Before eleven o'clock at night the whole party had returned safely to Sheffield without any mishap and highly delighted with the excursion.

Besides providing for the convenient lodging accommodation of visitors and for their amusement the efforts of the Local Committee were extended to obtaining for them access to some of the interesting manufactories existing in Sheffield. First amongst these must be mentioned the works where the manufacture of steel according to the Bessemer method is carried on in the manner described in this Journal when the process was only in its infancy. It was naturally at Sheffield that the inauguration of this method took place, and those who had an opportunity of witnessing the enormous extent to which it has developed during the last thirty years have great reason to be grateful to the Local Committee for having procured for them an opportunity of witnessing the operations of this interesting branch of manufacture. In addition to the treat thus afforded, the members were also enabled to visit the electro-plating works of Messrs. Walker and Hall and the show-rooms of Messrs. Rodgers, and so to obtain an actual knowledge of the way in which two of the chief manufacturing trades in Sheffield are carried out. For these facilities the members are under great obligation to the Local Committee, and they are no less indebted to the proprietors of the works visited, as well as to the various officials connected with them, for the extreme liberality with which everything was shown, and for the courtesy and attention displayed, no doubt at the cost of some considerable personal inconvenience.

In this superficial sketch of the Pharmaceutical Conference at Sheffield it has only been possible to indicate some of its most salient features, and there are many things we should have been glad to speak of had time and space permitted. But we may, from a general point of view, say that this has been, in every respect, one of the most successful and satisfactory meetings that have yet been held.

THE BRITISH ASSOCIATION.

The customary proceedings of the British Association commenced on Wednesday evening with the delivery of the Presidential Address, the attendance at which was far from sufficient to fill the Albert Hall. A portion of this Address will be found at another part of the Journal. On Thursday the business of the sections commenced with the delivery of addresses, some of which we hope to print in subsequent numbers. Up to the present time the number of visitors appears to be somewhat small.

THE WEIGHTS AND MEASURES ACT.

The following Order in Council, creating new denominations of standards of apothecaries' weights and measures under this Act, appeared in the *London Gazette* of the 15th inst. It will be observed that it differs from the draft Schedule forwarded by the Board of Trade to the Council of the Pharmaceutical Society* in including the half a scruple weight, and there is no doubt that this important concession is due to the representation of the Council on the subject. Nothing is said as to the stamping of the small weights and subdivisions of

* See *Pharm. Journ.* [3], vol. ix., p. 1003.

glass measures, but probably, as suggested in the letter of the President to Mr. TREVOR, of the 9th of May, the arrangements for carrying this out will be provided for in a less formal manner.

At the Court at *Osborne House, Isle of Wight*, the 14th day of *August*, 1879.

Present—The Queen's Most Excellent Majesty in Council.

Whereas by "The Weights and Measures Act, 1878," it is (among other things) provided that the Board of Trade shall from time to time cause such new denominations of standards, being either equivalent to or multiples or aliquot parts of the imperial weights and measures ascertained by the said Act, as appear to them to be required in addition to those mentioned in the Second Schedule to the said Act, to be made and duly verified, and that those new denominations of standards, when approved by Her Majesty in Council, shall be Board of Trade Standards in like manner as if they were mentioned in the said Schedule:

And whereas it has been made to appear to the Board of Trade that new denominations of standards of apothecaries' weight and measure, being multiples and aliquot parts of the imperial weights and measures ascertained by the said Act, are required, and they have caused the same to be made and duly verified and deposited in their custody:

And whereas the Board of Trade have given to the said new standards of apothecaries' weight and measure the several denominations set forth in the Schedule hereto:

Now, therefore, Her Majesty, by virtue of the power vested in Her by the said Act, by and with the advice of Her Privy Council, is pleased to approve the several denominations of standards of apothecaries' weight and measure set forth in the Schedule hereto as new denominations of standards, and doth direct that the same shall be Board of Trade Standards in like manner as if they were mentioned in the Second Schedule to "The Weights and Measures Act, 1878." *C. L. Peel.*

SCHEDULE.

DENOMINATIONS OF STANDARDS OF APOTHECARIES' WEIGHT AND MEASURE.

1. *Apothecaries' Weight.*

Denomination.		Weight in grains in terms of the Imperial Standard Pound which contains 7000 such grains.
Ounces.	10 ounces	4800 grains
	8 "	3840 "
	6 "	2880 "
	4 "	1920 "
	2 "	960 "
	1 ounce	480 "
Drachms.	4 drachms or half an ounce	240 "
	2 drachms	120 "
	1 drachm	60 "
Scruples.	2 scruples	40 "
	1½ " or half a drachm	30 "
	1 scruple	20 "
	half a scruple	10 "
	6 grains	6 "
	5 "	5 "
	4 "	4 "
	3 "	3 "
	2 "	2 "
	1 grain	1 grain
	half a grain	0·5 "

2. *Apothecaries' Measure.*

Denomination.	Containing the following weight of Distilled Water. Temperature=62° Farenheit. Barometer=30 inches. Imperial Pound=7000 grains.
A fluid ounce and the multiples thereof from one to 40 fluid ounces. Half a fluid ounce	One fluid ounce contains 437·5 grains weight, or $\frac{1}{160}$ imperial gallon.
A fluid drachm and the multiples thereof from one to 16 fluid drachms. Half a fluid drachm	One fluid drachm equals $\frac{1}{8}$ fluid ounce.
A minim and the multiples thereof from one to 60 minims	One minim equals $\frac{1}{60}$ fluid drachm.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, August 6, 1879.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President; Sir George Owens, M.D., Dr. Collins, Messrs. Allen, Brunker, Doran (Bray), Goodwin, Hayes, Hodgson, Holmes, Simpson.

The minutes of the meeting held on July 2, were read and signed.

Read a letter from Messrs. Ennis and Son, solicitors, with reference to proposed prosecutions, and also, in connection therewith, the Report of the Law Committee.

Proposed by Mr. Simpson, seconded by Mr. Allen, and resolved—

"That Messrs. Ennis be instructed to take legal proceedings against the offenders in the two cases of illegal compounding in which proof has been obtained, as recommended by the Committee."

Read a letter from Mr. Harry N. Draper, Dublin, together with a correspondence which he had had with the Clerk of the Peace, respecting his being summoned as a grand juror to the county court, at Kilmainham, and fined for non-attendance; although as a pharmaceutical chemist he was exempt from service, under the provisions of the Juries Procedure (Ireland) Act, 1876.

Proposed by Mr. Brunker, seconded by Mr. Hayes, and resolved—

"That Mr. Fennell be directed to send to the clerks of the North and South Dublin Unions a copy of a list of licentiate pharmaceutical chemists and request that they shall be returned as exempt in all future lists of persons liable to serve as jurors for the county or city of Dublin, and at the same time to state that this course has been rendered necessary by the fact that several of our body have been replaced on the jury lists after having been struck off in previous years."

Read a letter from Professor Schaer, of Zurich, thanking the Council for the books relating to the history of pharmacy in Ireland, which they had sent him.

The reports of the examinations held in July were laid on the table. At the examination for Pharmaceutical Chemists, held on July 2, *five* candidates presented themselves. The following *three* passed—

Thomas Batt, jun., 48, Fontenoy Street, Dublin.
Robert James Hardy, Tandragee.
John Patrick Henry, 160, York Street, Belfast.

Eighteen candidates presented themselves at the Preliminary examinations held on July 7 and 8, of whom *sixteen* passed and *two* were rejected.

William Whitla, M.D., 41, Victoria Place, Belfast, who was proposed and seconded at the July meeting, was now elected a member of the Society.

On the motion of Mr. Hodgson, the Treasurer, seconded by Mr. Doran, it was resolved that £300 of the Society's funds be invested in 3 per cent. Consols, in the names of the President, the Vice-President, and the Treasurer.

Proposed by Mr. Holmes, seconded by Mr. Doran, and resolved—

"That the Pharmaceutical Society of Ireland be represented at the forthcoming Meeting of the Pharmaceutical Conference, to be held in Sheffield in August, and that the following be accredited as representatives:—the President; Mr. R. W. Pring, Belfast; Mr. H. N. Draper; Mr. W. Hayes; Mr. E. M. Hodgson.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The Sixteenth Annual Meeting of the British Pharmaceutical Conference was commenced on Tuesday, the 19th of August, in the Freemasons' Hall, Surrey Street, Sheffield. The chair was taken at half-past ten o'clock by the President, G. F. Schacht, F.C.S.

Prior to the commencement of the general business—

Mr. W. Ward (Sheffield) welcomed the members of the Association on behalf of the Sheffield Committee, and after adverting to the pleasurable anticipation he and his *confrères* had enjoyed in the prospect of the visit of the Association to the town, said he trusted that the arrangements made were such that the members would carry away many vivid and lively impressions that would live in their memories for years to come.

Reception of Delegates.

The Senior General Secretary then read the following list of gentlemen representing other associations at the Conference:—

From the *Pharmaceutical Society of Great Britain.*—Mr. G. W. Sandford, President, Mr. G. F. Schacht, Vice-President, T. Greenish, F.C.S., Treasurer, and Messrs. J. Robbins, W. D. Savage, J. Shaw, C. Symes and J. Williams.

From the *Pharmaceutical Society of Ireland.*—Professor Tichborne, President, and Messrs. J. E. Brunker, H. N. Draper, W. Hayes, E. M. Hodgson and R. W. Pring.

From the *Bradford Chemists' Association.*—Mr. Silson.

From the *Bristol Pharmaceutical Association.*—Messrs. Pitman, W. W. Stoddart and G. F. Schacht.

From the *Brighton Association of Pharmacy.*—Messrs. T. Billing and W. D. Savage.

From the *Glasgow Chemists' Association.*—Mr. E. C. C. Stanford.

From the *Hull Chemists' Association.*—Messrs. C. B. Bell and J. Oldham.

From the *Leeds Chemists' Association.*—Messrs. P. Jefferson, R. Reynolds and E. Yewdall.

From the *Leicester Chemists' Association.*—Mr. J. W. Clark.

From the *Liverpool Chemists' Association.*—Messrs. T. F. Abraham, A. H. Mason, R. Sumner and C. Symes.

From the *Manchester Chemists and Druggists' Association.*—Messrs. F. B. Benger, Robinson, L. Siebold and W. Wilkinson.

From the *Sheffield Chemical and Pharmaceutical Association.*—Messrs. G. Carr, J. T. Dobb, G. T. W. Newsholme, J. Preston, J. Turner and J. Watts.

Mr. F. Baden Benger, General Secretary, then read the following—

Report of the Executive Committee.

During the past year the various objects of the Association have been successfully promoted or accomplished.

It is again the pleasant duty of your Committee to report a satisfactory condition of the British Pharmaceutical Conference. The annual Year-Book was issued in good time and fully maintained the reputation of its predecessors as a faithful *résumé* of pharmaceutical progress. The MSS. of the 1879 volume is now in the hands of the printer, and its issue to members will take place as soon as the report of the forthcoming meeting and the Editor's introductory chapter can be added to it.

At a meeting of your Committee, held in London on October 2nd of last year, applications for grants of money to aid authors to defray the cost of materials used in carrying out stated researches were received and considered. It was resolved—"That £10 be placed at the disposal of Mr. Thresh for the purchase of materials for an analysis of the rhizome of *Zingiber officinalis*, and a Comparative Examination of the gingers of trade; that £10 be at the disposal of Mr. Gerrard and Dr. Senier for the purchase of the drug termed *Pituri*, and for the materials for its pharmaceutical and chemical examination; and, that £40 be placed at the disposal of Dr. Wright towards the cost of the materials for an investigation of the active principle or principles of Japanese aconite, and for an investigation of the active principles in the leaves and flowers of ordinary aconite."

Reports by these gentlemen will be presented.

At a second Committee meeting, held on July 2nd, Professor Attfield, Senior General Secretary, reported in detail the work done since the last meeting of Committee, including matters relating to the editing, printing and publishing, and delivery to members of the Year-Book; the grants in aid of research; correspondence respecting improper use of the membership of the Conference; correspondence respecting the Bell and Hills Fund books; compilation and distribution of the list of subjects for research; collection of subscriptions; organization of the approaching meeting at Sheffield; correspondence with members likely to work on the Executive Committee in 1879–80; and arrangements for inviting all registered chemists and druggists not already members to join the Conference.

The very successful meeting held in Dublin last year will be still fresh in your memories. The pleasant relationships with our Irish brethren then formed or strengthened fully justified (if justification were needed) our acceptance of the invitation to visit Ireland, and proved with what satisfactory results two societies may form one conference. In returning once more to its native land, approaching indeed its very birthplace, the Conference is welcomed with a heartiness which must be highly gratifying to its members, but which is so invariably extended to it that there is danger of our accepting it more as a right than a privilege. On the present occasion we have perhaps a special reason for remarking on the thoughtfulness which has characterized the arrangements of the Local Committee. It has been repeatedly urged that the objects of the Conference are best promoted by the avoidance of formal entertainments, and whilst fully appreciating the generous impulse which has so often in the past disregarded this perhaps not sufficiently strongly expressed conviction, your Committee venture to hope that the action of the Sheffield Local Committee in this particular may be allowed to form a precedent. The excursion, which usually takes place on the Thursday following the business meetings, affords an admirable opportunity for the renewal of old friendships and the formation of new ones; or to quote the words of the first article of our constitution, of promoting "the friendly reunion of those engaged in the practice or interested in the advancement of pharmacy." The organization of reunions of this kind will, your Committee is assured, be always gratefully accepted by the Conference as an ample indication of the hospitable feelings of its entertainers.

Sufficient papers of pharmaceutical interest have been received to fully occupy the time which can be devoted to their reading and discussion at the present meeting. The names of many old and valued friends of the Conference appear in this list, as well as those of new contributors, to whom a cordial welcome will be given.

The Committee have to announce with much regret that at a meeting held last evening they received a formal communication from their valued Senior Honorary Secretary, in which he tenders his resignation of the post he has so long filled with such distinguished success. The communication runs as follows—

"Ashlands, Watford,
"August 16, 1879.

"To the President of the British Pharmaceutical Conference:—

"Dear SCHACHT,

"After sixteen years of pleasant labours as one of the Honorary Secretaries of our Association, I regretfully, and yet with a feeling of satisfaction at having done useful service, place my resignation in your hands. I thank my colleagues for the opportunities they have given me of joining them in promoting scientific development in pharmacy and good fellowship amongst pharmacists. From the birth of our organization we have all worked together with the utmost heartiness and harmony, and although I now return to the ranks, I trust I shall be allowed to continue to support the objects of the Conference with undiminished enthusiasm and with all the experience and knowledge I have gained as a member of the staff. I hope and believe that the welfare of the Conference and its objects has not suffered either at my hands as a secretary or during my secretaryship, and I do not resign until I have assured myself that that welfare will be maintained, if not enhanced, by the change or changes that will, I know, necessarily be consequent on my resignation.

"I am, Dear SCHACHT,
"Yours faithfully,
"JOHN ATTFIELD."

The Committee felt that the changes involved in Professor Attfield's resignation were of so serious a nature that they shrank from the responsibility of accepting it until a very mature consideration had provided the means for meeting them with a fair prospect of efficiency, and at their earnest request Professor Attfield consented to continue the duties for one year more, in order to afford them the necessary time. The Committee are sure every member of the Conference will concur in a feeling of real gratitude to Professor Attfield for this further manifestation of his self-denying devotion to the best interests of the Conference.

Professor Attfield then read the financial statement, and the statement of the Hon. Treasurer in account with the Bell and Hills Library Fund, which is printed on p. 148.

The President moved the adoption of the report and financial statement, and referred with great satisfaction to the fact that Professor Attfield had, waiving all personal feeling, decided to continue his services for one year longer, and said he had no doubt that he would act with the same energy, ability and skill as heretofore.

Mr. G. Ellinor (Sheffield), in seconding the motion, adverted to the prosperous condition of the funds, which he was sure would be used well in promoting pharmacy in general in connection with the Conference.

The motion was then put to the Conference, and carried unanimously.

Professor Attfield read a communication which the President had received from Mr. H. B. Brady, one of the oldest friends of the Conference, apologizing for not being able to attend, and mentioning as evidence of the wide-spread influence of the Conference that he had observed in Japan that a native firm of booksellers offered the Year-Books for sale at four and a-half dollars per volume.

THE GIFT OF BOOKS.

Professor Attfield explained that the sum of ten guineas, placed at the disposal of the Committee from the Bell and Hills Library Fund, had been expended for the purchase of such books as the officers of the Local Association thought would be the most useful in their library. In addition to those books there were two others—Hanbury's 'Science Papers,' and Flückiger and Hanbury's 'Pharmacographia,' presented to the Local Association in memory of Daniel Hanbury by his brother Thomas Hanbury. There were, moreover, along with these books, engravings of Jacob Bell, William Allen and Jonathan Pereira offered to the Local Association by Mr. Thomas Hyde Hills.

Mr. Ward and Mr. Learoyd returned thanks on behalf of the Sheffield Association.

Mr. Schacht then proceeded to read the following:—

PRESIDENT'S ADDRESS.

Amidst the customs which rule this Conference in its relations with its President are two that in their co-existence may not always conduce to fortunate results. The same individual is retained in his exalted position for two consecutive years, and he is expected to deliver an address on the occasion of each Annual Meeting.

In defence of the latter, it may perhaps, with other considerations, be reasonably urged that he who is selected by the voice of this Association to a dignity so distinguished as the occupancy of this chair, may fairly be expected to have something to say to his fellow pharmacists, gathered from either his personal knowledge, his experience or his aspirations, worthy of being uttered. But when he finds himself called upon to repeat the duty after the short interval of one year, he may be excused for feeling, as I feel, that his chance of enlisting the interest of those who listen is sadly diminished, and that he must, even more earnestly than on the occasion of his former effort, hope for indulgent sympathy.

In days gone by, the course of events during the current year, so far as they affected scientific pharmacy, assisted much to indicate the plan and scheme of a Presidential Address; and some of the ablest discourses recorded in our annals consist chiefly of judicious summaries of the progress of the sciences connected with our calling and of such movements within and outside our body as appeared to affect pharmaceutical culture. But the conditions which rendered such a course wise in the earlier Conference days are now much changed. The same interest, perhaps even greater interest, is felt in those matters, but the work of summarizing them appears to have passed to other hands.

The press, which is ubiquitous, and whose chiefest apparent function is to absorb most other functions, has grown strong in our midst, and able editors obligingly offer to us all month by month, and journal by journal, a taste of the plums and a slice of the pie your President might otherwise be fondly regarding as destined for his own gathering and maturing as a *bonne bouche* for his expected guests; and to complete his discomfort lurks the conviction that should even a stray blossom escape this scrutiny and he succeed in impressing it to his service, the Conference itself, in its own elaborate and well ordered Year-Book, will, a few weeks later, completely extinguish his puny entertainment and make the remembrance of it stale and flat.

The area for my choice appearing thus somewhat narrowed, I endeavoured last year to select a subject which for complete consideration would afford matter for two addresses, and which yet could be so arranged that the portion first delivered might stand fairly well by itself should any cross stream of events interfere with the original purpose, and I finally determined to make, as well as I could, two presentments of the same fact, viz.,

Examined and found correct, W. HAYES, Dublin. G. A. CUBLEY, Sheffield. *Auditors.*

the pharmacist as we see him ourselves, and the pharmacist as seen by others; and further, should those two images be found to differ (and I scarcely expected them to coincide) to reflect upon some of the points that difference might suggest.

Last year then I offered the first part of this scheme, a view of the pharmacist as seen by ourselves.

It would doubtless be wrong to assume that the picture then offered was universally approved; but I know it to have been the result of truth-seeking observation, and twelve months' further experience assures me that it was fairly correct. I find that the more I know of my fellow labourers, the more good stuff I see in them, and the closer I become familiarized with the work they are doing the more I am able to respect it. Hence I feel no hesitation in repeating the opinion expressed last year, that the typical pharmacist "stands the illustration of a high order of citizen."

But, lest there be danger that such an estimate resting long unchallenged provoke conceit, let me turn to what may prove an antidote of the severest kind, viz., the estimate of ourselves by others.

Already I can fancy that the recollection of a well-worn couplet has passed through many minds, and has prepared their conceit, had it begun to develop, for a heavy fall—

"Oh wad some power the giftie gie us
To see ourselves as others see us:"—

for whatever was really prevailing in the poet's mind when he penned those lines, the usual sense in which they are quoted is one that implies erroneous self-estimate, on the one hand, and wisdom, superior if not supreme, on the other; and by this reading I and those who are inclined to support my views ought to stand convicted by a jury of our own choice, not only of great conceit, but of great folly also. But to such a position and to such a verdict I demur. A solicitude to ascertain what others think of us need not necessarily coincide with any such relation. "Whom do men say that I am?" was the inquiry of one we should be little inclined to charge with folly or conceit; it was "men," not the speaker, that were likely to be the better for a correct appreciation of the speaker's self; and at the risk of being charged with an unwise comparing of small things with great, I venture the opinion that what the public think of us pharmacists is of graver import to the public than to us.

Every art must rest its claim for existence upon some great public want. The universality of disease created the art of medicine. The cure or relief of human suffering is the great aim and purpose of that art, and hence in its pure and wholesome progress, every single creature of the public must ever have the profoundest interest. If public ignorance or public prejudice in any way warps that wholesome progress, it is the public that chiefly suffer; they are the many, we are the few; the penalties we may be called upon to pay are but sectional, theirs must be universal. We have but to accommodate ourselves to the conditions, they have to endure them. Conversely, should the public wisdom tend, but in the least degree, to favour the full, fair, scientific progress of medicine, the benefit must be experienced in a thousand-fold degree where there is a thousand times the capacity for its reception.

Does that wisdom then display itself in a fashion most conducive to the best interests of the public? Let us frankly and gratefully answer, that in many respects it is manifested with high intelligence, and with noble generosity. The hospitals that adorn our entire land, and many of the laws that grace our statute books stand among the living monuments of both; moreover few of the recognized professors of medicine pass through the labour of their lives without achieving fair reward in honour or in money, perhaps I might truthfully say in honour *and* in money. And if the same or similar sentiments prevailed towards pharmacy and its professors, the two presentments I am supposed to be offering would probably coincide, and I should have to say but little more on this topic to-day. But with the majority of the public, certainly with the section that is called "society," this is not the case, and but little of the honour, and as little as possible of the money, is given to us in exchange for our life-long work. The sole monuments of *our* professional existence are of our own raising, and "a House" can scarcely be got together to consider a bill, having for its object the regulation of so *un*interesting a matter as pharmacy. It is true we are credited with being concerned in a "clean" sort of business, from which we are oddly enough accused of making very small incomes out of very large profits; we are admitted to possess decent shops which it is not unseemly to enter, and which indeed it is quite correct to make use of for any purpose not demanding a fee; we are supposed to be bound by some law of custom (certainly not by any sense of duty) to obey all behests, at all hours, on all days; we are credited, in short, with being "society's" most obliged and humble servants, slavishly ready to do whatever is told us, and to take for payment whatever cannot be conveniently bestowed upon the professional man on the one hand or the co-operative stores on the other. To find a man or woman "in society" content to be publicly seen in friendly talk with a pharmacist, or indeed permitting the association of their children with ours at a public school, is to see a phenomenon of rare order. The doctor is the lady's and sometimes the gentleman's hero; the pharmacist is the tradesman to both.

Such, I fear is the view very generally taken of us by others, and I need scarcely say this presentiment does not coincide with the one I offered last year. Shall I endeavour to account for the difference before passing to other reflections?

With my already declared estimate of ourselves, and of our art (so different from my lady's), it is natural I should conceive that the phenomenon may be traced through a course that lies mainly outside us; and remembering how many-headed is that great outside public, how prone to the instinct of speciation, and how prone is each species to become absorbed in matters of its own concern, taking impressions of other things mainly at second hand, seldom by original effort; I have thought that the first step should consist in the search for that section of the outside world which is likely to be chiefly responsible for the delivery of the initiatory bias.

A very short consideration leads to the suggestion that the public would almost instinctively assume that the doctors would know more about pharmacy and pharmacists than anyone else, and therefore that what they thought about us, and the attitude they assumed towards us, would be the proper thing to adopt and to imitate. And the public would have much to justify such an assumption.

More or less the story is known to all (and the more it is remembered the better) that for a long period, until in fact quite recent times, pharmacy constituted both practically as well as theoretically an integral portion of the medical art, and the pharmacist and the physician were one man. It is true this latter condition no longer obtains; it has been found desirable to entrust the different departments to distinct sets of hands in order that each may be worked to its fullest perfection, and under the completest personal responsibility. But the art remains the same, one portion being no more capable of repudiating another or declaring its independence of the rest than is the eye or the heart of the human body.

And hence this assumption of a kind of perpetual alliance between the professors of all its departments would be both instinctive and reasonable, and the estimate of the one by the others would be deemed authoritative.

Whatever, then, the public estimate of us may be, I think it is mainly the echo and the reflection of that previously adopted by our neighbours the doctors. I do not mean that they would pronounce as right the treatment which I have asserted so many of us receive at the hands of the public, but that their general tone and manner towards us have furnished the germ which has thus fructified.

But does our experience with the profession justify this interpretation of their views towards us?

I have heard of cases, and have experience of cases, in which individual members of the profession have manifested, by their thoughtful treatment of all pharmaceutical matters, an appreciation of their importance so high and just, and a respect for those engaged in them so fair, that, were the question to be answered from such examples, the reply would be to the effect that there is no justification for it whatever. I fear, however, that these cases are exceptional.

Of the large majority, some, the greater proportion, are as nearly as possible indifferent to ourselves and to our work.

There exists, however, a third section of the profession, and I trust it is a diminishing one, that holds us at a very low estimate, that professes to believe us systematically familiar with mean doings, and open to mean temptations.

From the first of these divisions I pass with a cordial expression of respect, my chief hopes for the bettering of pharmacy in the future resting with its honoured members—from the last with a hope that they may be speedily delivered from their delusion; and our business for the present lies with the indifferentism that remains, and which is unfortunately only something less damaging than actual hostility. How is it to be accounted for?

I believe it to be mainly due to want of knowledge in two important directions. This large majority of medical men do not know enough of *our* subjects to appreciate them at their proper value, and they do not know the extent of our professional qualifications sufficiently well to give us due credit for them. Notwithstanding the fact to which I have already referred, the essential oneness of all the subjects that together make up the art of medicine, in no modern medical school do chemistry, botany and pharmacy rank in educational importance with, let us say, anatomy, surgery and medical practice; the former are the off-subjects, and are very generally done any-how or no-how; the latter are among the prime subjects and must be done well. The traditions of the school enlist all the student's enthusiasm for what are called the medical subjects proper, and as an inevitable consequence, a sentiment near akin to contempt pervades his view of the rest. Caring but little for them in the abstract, and taught to think but little of their practical value to his art, the student of medicine when he becomes the professor is but little likely to respect very highly even those he is compelled to admit as their recognized professors, and from the curious separation that has hitherto characterized the training of the pharmaceutical and the medical student, all that the latter knows of the former amounts to but hearsay, and he finds no particular reason in after life to mature or enlarge his information.

For this state of things we must ourselves take some share of blame. There is no doubt that ignorance of matters that should have ranged within our knowledge did, in past times, prevail, and, since miraculous changes in social phenomena do not frequently occur, that ignorance may not have entirely yielded yet; but a great effort for improvement has been made, an effort be it remembered entirely from within our own body, and its practical results have been sufficiently remarkable to suffice in a large degree to absolve us from that portion of the blame.

But the very circumstance that appears to stamp pharmaceutical progress as unique, and to give it a special dignity, I mean its self-originating and self-sustained character, has largely tended to limit all knowledge of it to those who have specially watched the phenomenon or taken part in it.

The policy of those who initiated, as of those who continued the effort was one that all can respect for its independence, but which I cannot but fear time and experience will show to have been, in this one important respect, unwise. It has served to intensify isolation where unification should prevail. The withdrawal of ourselves and our educational processes from the general professional ken has tended to encourage the elimination of the sciences we specially cultivate from the complete medical curriculum, and to foster the notion I have already deplored that they are accessories of inferior value, and non-essential to medical culture. For this we must still bear our share of the blame.

But wheresoever the blame should chiefly lie I think that the fact of the practical isolation of pharmacy and its professors, from the rest of medicine is due to the general defective acquaintance on the part of the professed medical man with both our subjects and our men.

I must now pass to a consideration of the loss to the art of medicine that accrues from so extended an indifference to the pharmaceutical sciences. It would perhaps be in better taste to let others speak to this point rather than myself. I am content, therefore, simply to remind you of the frequent publicly expressed lament of many distinguished physicians that so much of their practice is still perforce empirical, and of their equally emphatic rejoicings when some ardent student of science has succeeded in wresting from its mysteries some secret that has offered a glimmer of firmer resting ground for their doctrines. The teaching of her highest authorities tells us that medicine cannot afford to fling away the help of her natural allies; that she is exposed to constant attack at almost every point; that her growth is not in perfect comeliness and undisturbed proportions, but is liable to distortions and excrescences of formidable type; and that her best hopes for future progress rest in the patient scientific work of her acutest and largest-brained sons—men who have the power to enlist within their sympathies every department of knowledge that can bring its modicum of truth and focus all upon that one supreme point, the great problem, life.

I think that among the first regions such men would wish to explore are the very subjects in which we are daily engaged; and with such aspirations animating the great mind of medicine on the one hand, and such opportunities existing for practical co-operation on the other, is it not the simplest of all possible deductions that an effort serving to bring all into better mutual estimation and closer mutual confidence, must be attended with a fair hope of distinct gain to the art itself?

So far I have attempted to show what the public estimate of us is; who are chiefly responsible for it; the probable causes that have led to it, and the mischief to medicine that attends it.

One more consideration mnst be stated in order to show that the error is, as I have said, of great practical interest to the public itself.

We are not above the influence of that estimate.

Who in this world, whether the question be asked of individuals or of communities, is so strong, either in good or evil as to be able to resist such influence? Is "the publican" likely to become a patriot for being daily declared to be an outcast? Branded as a social enemy, an enemy he will continue or become. Should we presume to expect brave deeds in the field if we systematically treated our soldiers as cowards? Brave deeds alone being assumed as possible, brave deeds are done. In short the opinion of society reacts in a thousand ways upon society's elements; and I fear the constant treatment to which some of us are subjected,—that says more forcibly than words can say, "You druggists are but hirelings, labouring like other hirelings for greed; take your pay and be thankful"—exerts a power for degradation that cannot fail to promote the very condition it professes to reprobate.

I say that for its own sake the public should make haste to see that we are of stuff much better than this.

I am quite aware that at every step of these statements their accuracy may be challenged; I have attempted to do this myself in many ways, and during the process have had to admit, from our own side, how often my standard of pharmaceutical excellence is missed, and that ignorance, carelessness and looseness of principle are to be found amongst us; and from the other side, that many just and considerate individuals can be found in English society, as also doctors whose scientific culture is as ample, and whose disposition to make the most of ours is as generous as heart could desire. Nevertheless, having taken these and kindred facts into full consideration, I allow the statements to stand as what I believe to be the truth.

But to another challenge I have perhaps also laid myself fairly open, namely, to suggest some remedy for the condition of things I profess to have studied and to deplore. To this challenge I have but what may appear a feeble reply, I am prepared with no mature scheme, and can offer nothing that can claim to be regarded as a cure for all that is wrong, but being most anxious to see ground broken in the direction that appears to me most hopeful for the extinction of the isolation that besets us and thus give opportunity for a clearer view of ourselves and our doings to the rest of the profession, I am ready to suggest a first step. It is, that every student in medicine, whatever department of the art he may be aiming for as the sphere of his ultimate work, be brought at some period of his training through one single portal. So many practical objections have been found to exist against the mingling of medical and pharmaceutical students during their attendance at classes or during any portion of their actual studies, that I think the portal would have to consist of one of the sets of examinations; but if that examination could be made a common one for all, whether ultimately destined for Medicine or Pharmacy, the step would be a useful one. It would serve to declare with authority that certain scientific studies were equally essential in all the departments of the medical art; and it would demand of every student that he attain the required standard of proficiency in them. He would thus be prepared by actual personal knowledge (not through the traditions of his school) to estimate aright the proportionate value of those attainments towards his full professional equipment; he would realize the serious amount of effort required to achieve that knowledge, and he would naturally conceive a feeling of respect for all who had laboured for its acquisition even as he himself had laboured.

Whether such an experiment would be attended with results proportionate to the distinctness of the change, requires a better prophet than myself to declare. As far as we are concerned it would be the commencement of a reversal of much of our past policy. It would tend *from* isolation *towards* unification, *from* estrangement *towards* co-operation, *from* suspicion *towards* trust; but these very words seem to me to be full of hope.

One possible comment upon the suggestion itself I should like to anticipate; it may appear to some to involve the placing of our examinations in the hands of the medical profession.

Were this the only course open for adoption, I should not shrink from its close consideration, nor fail to entertain it with great hope of ultimate benefit; but at present I do not think this by any means a necessary consequence. The story of our own progress, and my personal knowledge of the completeness of the organization that lies within our midst, suggest rather the alternative, that for every man's certificate of qualification in *our* subjects he might be required to come to *our* examinations; I say "at present," for in speaking of "ourselves" and "medical men" as distinct organizations I shall hope to be using but the language of to-day.

My subject, however, now approaches somewhat too nearly the region of pharmaceutical politics to be continued here; the arena for its discussion in detail lies elsewhere. But I sincerely hope and think that in urging it from this place to the point at which I now leave it, I have acted in sympathy with the pervading spirit of the Conference. To this extent, at any rate, I know that I must carry with me the sympathy of all its members, namely, in a warm desire to exalt the dignity of Pharmacy and in an earnest hope that we pharmacists may ever be found, as truly in fact as in aspiration, Pharmacy's worthy representatives.

Mr. W. H. Maleham (Sheffield) said the members of the Conference were much indebted for the exhaustive address delivered by the President, Mr. Schacht, and he had great pleasure in moving a vote of thanks to the President for his valuable address. The time was rapidly coming when they must make a stand against the attacks launched against them, and it was by such addresses that they could gain valuable information to aid them in repelling opposition.

Mr. G. W. Sandford seconded the motion, and observed how ardently the President loved the science he had adopted as his calling, and how anxious he was not only to elevate pharmacy but pharmacists. He could not refrain from saying, as a delegate of the Pharmaceutical Society of Great Britain, how heartily that Society appreciated the work of the Conference. It was his privilege to be connected with the Pharmaceutical Council, and he thought he was the President when this Conference was established. The objects of the Conference and the objects of the Society were identical, and he thought he might congratulate the Members of the Conference on having throughout the course of their work done much towards elevating pharmacy and pharmacists. Regretting that they would soon see the end of Mr. Schacht's presidency, yet hoping the same good work would continue, he must say the Pharmaceutical Conference deserved great credit for the results it had already achieved.

Mr. R. Reynolds, Vice-President, in putting the motion to the Conference, said it was an easy task when they were all agreed, and referred in terms of eulogy to Mr. Schacht's philosophical condideration of the position of pharmacy and his great interest in the welfare and elevation of pharmacists.

The motion was carried unanimously.

The President, in acknowledging the resolution, thanked the members of the Conference for the expressions of emotion that had graced the vote, and said he was very grateful for their approval. He wished to say, however, that it must be understood that any expression of opinion on matters he had thought fit to introduce must be regarded simply as his opinion, for he should be very sorry to commit the Conference, outside those walls, to opinions which were only held by an individual. In expressing those opinions he wished rather to suggest the present position to maturer intellects, so that these questions, might be pondered, not only for the benefit of pharmacists but of the community.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The meeting of the above Association commenced on Monday, August 18, at Sheffield, under the Presidency of G. J. Allman, M.D., LL.D., F.R.SS.L. and E., M.R.I.A., Pres. L.S., who delivered the opening address:—

The President's Address.

It is no easy thing to find material suited to an occasion like the present. For on the one hand there is risk that a presidential address may be too special for an audience necessarily large and general, while on the other hand it may treat too much of generalities to take hold of the sympathies and command the attention of the hearers.

It may be supposed that my subject should have been suggested by the great manufacturing industries of the town which has brought us together; but I felt convinced that a worker in only the biological sciences could not do justice to the workers in so very different a field.

I am not therefore going to discourse to you of any of those great industries which make civilized society what it is,—of those practical applications of scientific truth which within the last half century have become developed with such marvellous rapidity, and which have already become interwoven with our everyday life, as the warp of the weaver is interwoven with the woof. Such subjects must be left to other occupiers of this chair, from whom they may receive that justice which I could not pretend to give them; and I believe I shall act most wisely by keeping to a field with which my own studies have been more directly connected.

I know that there are many here present from whom I have no right to expect that previous knowledge which would justify me in dispensing with such an amount of elementary treatment as can alone bring my subject intelligibly before them, and my fellow members of the British Association who have the advantage of being no novices in that department of biology with which I propose to occupy you, will pardon me if I address myself mainly to those for whom the field of research on which we are about to enter has now been opened for the first time.

I have chosen, then, as the matter of my address to you to-night, a subject in whose study there has during the last few years prevailed an unwonted amount of activity, resulting in the discovery of many remarkable facts, and the justification of many significant generalizations. I propose, in short, to give you in as untechnical a form as possible some account of the most generalized expression of living matter, and of the results of the more recent researches into its nature and phenomena.

More than forty years have now passed away since the French naturalist Dujardin drew attention to the fact that the bodies of some of the lowest members of the animal kingdom consist of a structureless, semi-fluid, contractile substance, to which he gave the name of Sarcode. A similar substance occurring in the cells of plants was afterwards studied by Hugo von Mohl, and named by him Protoplasm. It remained for Max Schultze to demonstrate that the sarcode of animals and the protoplasm of plants were identical.

The conclusions of Max Schultze have been in all respects confirmed by subsequent research, and it has further been rendered certain that this same protoplasm lies at the base of all the phenomena of life, whether in the animal or the vegetable kingdom. Thus has arisen the most important and significant generalization in the whole domain of biological science.

Within the last few years protoplasm has again been made a subject of special study, unexpected and often startling facts have been brought to light and a voluminous literature has gathered round this new centre of research. I believe, therefore, that I cannot do better than call your attention to some of the more important results of these inquiries, and endeavour to give you some knowledge of the properties of protoplasm, and of the part it plays in the two great kingdoms of organic nature.

As has just been said, protoplasm lies at the base of every vital phenomenon. It is, as Huxley has well expressed it, "the physical basis of life." Wherever there is life, from its lowest to its highest manifestations, there is protoplasm; wherever there is protoplasm, there too is life. Thus co-extensive with the whole of organic nature —every vital act being referable to some mode or property of protoplasm—it becomes to the biologist what the ether is to the physicist; only that instead of being a hypothetical conception, accepted as a reality from its adequacy in the explanation of phenomena, it is a tangible and visible reality, which the chemist may analyse in his laboratory, the biologist scrutinize beneath his microscope and his dissecting needle.

The chemical composition of protoplasm is very complex, and has not been exactly determined. It may, however, be stated that protoplasm is essentially a combination of albuminoid bodies, and that its principal elements are, therefore, oxygen, carbon, hydrogen, and nitrogen. In its typical state it presents the condition of a semi-fluid substance—a tenacious, glairy liquid, with a consistence somewhat like that of the white of an unboiled egg. While we watch it beneath the microscope movements are set up in it; waves traverse its surface, or it may be seen to flow away in streams, either broad and attaining but a slight distance from the main mass, or else stretching away far from their source, as narrow liquid threads, which may continue simple, or may divide into branches, each following its own independent course; or the streams may flow one into the other, as streamlets would flow into rivulets and rivulets into rivers, and this not only where gravity would carry them, but in a direction diametrically opposed to gravitation; now we see it spreading itself out on all sides into a thin liquid stratum, and again drawing itself together within the narrow limits which had at first confined it, and all this without any obvious impulse from without which would send the ripples over its surface or set the streams flowing from its margin. Though it is certain that all these phenomena are in response to some stimulus exerted on it by the outer world, they are such as we never meet with in a simply physical fluid—they are spontaneous movements resulting from its proper irritability, from its essential constitution as living matter.

Examine it closer, bring to bear on it the highest powers of your microscope—you will probably find disseminated through it countless multitudes of exceedingly minute granules; but you may also find it absolutely homogeneous, and, whether containing granules or not, it is certain that you will find nothing to which the term *organization* can be applied. You have before you a glairy, tenacious fluid, which, if not absolutely homogeneous, is yet totally destitute of structure.

And yet no one who contemplates this spontaneously moving matter can deny that it is alive. Liquid as it is, it is a living liquid; organless and structureless as it is, it manifests the essential phenomena of life.

The picture which I have thus endeavoured to trace for you in a few leading outlines is that of protoplasm in its most generalized aspect. Such generalizations, however, are in themselves unable to satisfy the conditions demanded by an exact scientific inquiry, and I propose now, before passing to the further consideration of the place and purport of protoplasm in nature, to bring before you some definite examples of protoplasm, such as are actually met with in the organic world.

A quantity of a peculiar slimy matter was dredged in the North Atlantic by the naturalists of the exploring ship "Porcupine" from a depth of from 5000 to 25,000 feet. It is described as exhibiting, when examined on the spot, spontaneous movements, and as being obviously endowed with life. Specimens of this, preserved in spirits, were examined by Professor Huxley, and declared by him to consist of protoplasm, vast masses of which must thus in a living state extend over wide areas of sea bottom. To this wonderful slime Huxley gave the name of *Bathybius Haeckelii.*

Bathybius has since been subjected to an exhaustive examination by Professor Haeckel, who believes that he is able to confirm in all points the conclusions of Huxley, and arrives at the conviction that the bottom of the open ocean, at depths below 5000 feet, is covered with an enormous mass of living protoplasm, which lingers there in the simplest and most primitive condition, having as yet acquired no definite form. He suggests that it may have originated by spontaneous generation, but leaves this question for future investigators to decide.

The reality of Bathybius, however, has not been universally accepted. In the more recent investigations of the "Challenger" the explorers have failed in their attempts to bring further evidence of the existence of masses of amorphous protoplasm spreading over the bed of the ocean. They have met with no trace of Bathybius in any of the regions explored by them, and they believe that they are justified in the conclusion that the matter found in the dredgings of the "Porcupine" and preserved in spirits for further examination was only an inorganic precipitate due to the action of the alcohol.

It is not easy to believe, however, that the very elaborate investigations of Huxley and Haeckel can be thus disposed of. These, moreover, have received strong confirmation from the still more recent observations of the Arctic voyager, Bessels, who was one of the explorers of the ill-fated "Polaris," and who states that he dredged from the Greenland seas masses of living undifferentiated protoplasm. Bessels assigns to these the name of Protobathybius, but they are apparently indistinguishable from the Bathybius of the "Porcupine." Further arguments against the reality of Bathybius will therefore be needed before a doctrine founded on observations so carefully conducted shall be relegated to the region of confuted hypotheses.

Assuming, then, that Bathybius, however much its supposed wide distribution may have been limited by more recent researches, has a real existence, it presents us with a condition of living matter the most rudimental it is possible to conceive. No law of morphology has as yet exerted itself in this formless slime. Even the simplest individualization is absent. We have a living mass, but we know not where to draw its boundary lines; it is living matter, but we can scarcely call it a living being.

We are not, however, confined to Bathybius for examples of protoplasm in a condition of extreme simplicity. Haeckel has found, inhabiting the fresh waters in the neighbourhood of Jena, minute lumps of protoplasm, which when placed under the microscope were seen to have no constant shape, their outline being in a state of perpetual change, caused by the protrusion from various parts of their surface of broad lobes and thick finger-like projections, which, after remaining visible for a time, would be withdrawn, to make their appearance again on some other part of the surface.

These changeable protrusions of its substance, without fixed position or definite form, are eminently characteristic of protoplasm in some of its simplest conditions. They have been termed "Pseudopodia," and will frequently come before you in what I have yet to say.

To the little protoplasmic lumps thus constituted, Haeckel has given the name of *Protamœba primitiva*. They may be compared to minute detached pieces of Bathybius. He has seen them multiplying themselves by spontaneous division into two pieces, which, on becoming independent, increase in size and acquire all the characters of the parent.

Several other beings as simple as *Protamœba* have been described by various observers, and especially by Haeckel, who brings the whole together into a group to which he gives the name of MONERA, suggested by the extreme simplicity of the beings included in it.

But we must now pass to a stage a little higher in the development of protoplasmic beings. Widely distributed in the fresh and salt waters of Britain, and probably of almost all parts of the world, are small particles of protoplasm closely resembling the *Protamœba* just described. Like it, they have no definite shape, and are perpetually changing their form, throwing out and drawing in thick lobes and finger-like pseudopodia, in which their body seems to flow away over the field of the microscope. They are no longer, however, the homogeneous particle of protoplasm which forms the body of *Protamœba*. Towards the centre a small globular mass of firmer protoplasm has become differentiated off from the remainder, and forms what is known as a nucleus, while the protoplasm forming the extreme outer boundary differs slightly from the rest, being more transparent, destitute of granules, and apparently somewhat firmer than the interior. We may also notice that at one spot a clear spherical space has made its appearance, but that while we watch it has suddenly contracted and vanished, and after a few seconds has begun to dilate so as again to come into view, once more to disappear, then again to return, and all this in regular rhythmical sequence. This little rhythmically pulsating cavity is called the "contractile vacuole." It is of very frequent occurrence among those beings which lie low down in the scale of life.

We have now before us a being which has arrested the attention of naturalists almost from the commencement of microscopical observation. It is the famous *Amœba*, for which ponds and pools and gutters on the house-roof have for the last two hundred years been ransacked by the microscopist, who has many a time stood in amazement at the undefinable form and Protean changes of this particle of living matter. It is only the science of our own days, however, which has revealed its biological importance, and shown that in this little soft nucleated particle we have a body whose significance for the morphology and physiology of living beings cannot be overestimated, for in *Amœba* we have the essential characters of a CELL, the morphological unit of organization, the physiological source of specialized function.

The term "cell" has been so long in use that it cannot now be displaced from our terminology; and yet it tends to convey an incorrect notion, suggesting, as it does, the idea of a hollow body or vesicle, this having been the form under which it was first studied. The cell, however, is essentially a definite mass of protoplasm having a nucleus imbedded in it. It may, or may not, assume the form of a vesicle; it may, or may not, be protected by an enveloping membrane; it may, or may not, contain a contractile vacuole; and the nucleus may, or may not, contain within it one or more minute secondary nuclei or "nucleoli."

Haeckel has done good service to biology in insisting on the necessity of distinguishing such non-nucleated forms as are presented by *Protamœba* and the other *Monera* from the nucleated forms as seen in *Amœba*. To the latter he would restrict the word *cell*, while he would assign that of "cytode" to the former.

Let us observe our *Amœba* a little closer. Like all living beings it must be nourished. It cannot grow as a crystal would grow, by accumulating on its surface molecule after molecule of matter. It must *feed*. It must take into its substance the necessary nutriment; it must assimilate this nutriment and convert it into the material of which it is itself composed.

If we seek, however, for a mouth by which the nutriment can enter into its body, or a stomach by which this nutriment can be digested, we seek in vain. Yet watch it for a moment as it lies in a drop of water beneath our microscope. Some living denizen of the same drop is in its neighbourhood, and its presence exerts on the protoplasm of the *Amœba* a special stimulus which gives rise to the movements necessary for the prehension of nutriment. A stream of protoplasm instantly runs away from the body of the *Amœba* towards the destined prey, envelops it in its current, and then flows back with it to the central protoplasm, where it sinks deeper and deeper into the soft yielding mass, and becomes dissolved, digested and assimilated in order that it may increase the size and restore the energy of its captor.

But again, like all living things, *Amœba* must multiply itself, and so after attaining a certain size its nucleus divides into two halves, and then the surrounding protoplasm becomes similarly cleft, each half retaining one half of the original nucleus. The two new nucleated masses which thus arise now lead an independent life, assimilate nutriment, and attain the size and characters of the parent. .

We have just seen that in the body of an *Amœba* we have the type of a cell. Now both the fresh waters and the sea contain many living beings beside *Amœba* which never pass beyond the condition of a simple cell. Many of these, instead of emitting the broad lobe-like pseudopodia of *Amœba*, have the faculty of sending out long thin threads of protoplasm, which they can again retract, and by the aid of which they capture their prey or move from place to place. Simple structureless protoplasm as they are, many of them fashion for themselves an outer membranous or calcareous case, often of symmetrical form and elaborate ornamentation, or construct a silicious skeleton of radiating spicula, or crystal clear concentric spheres of exquisite symmetry and beauty.

Some move about by the aid of a flagellum, or long whip-like projection of their bodies, by which they lash the surrounding waters, and which, unlike the pseudopodia of *Amœba*, cannot, during active life, be withdrawn into the general protoplasm of the body; while among many others locomotion is effected by means of cilia—microscopic vibratible hairs, which are distributed in various ways over the surface, and which, like the pseudopodia and flagella, are simple prolongations of their protoplasm.

In every one of these cases the entire body has the morphological value of a cell, and in this simple cell reside the whole of the properties which manifest themselves in the vital phenomena of the organism.

The part fulfilled by these simple unicellular beings in the economy of nature has at all times been very great, and many geological formations, largely built up of their calcareous or silicious skeletons, bear testimony to the multitudes in which they must have swarmed in the waters of the ancient earth.

Those which have thus come down to us from ancient times owe their preservation to the presence of the hard persistent structures secreted by their protoplasm, and must, after all, have formed but a very small proportion of the unicellular organisms which peopled the ancient world, and there fulfilled the duties allotted to them in nature, but whose soft, perishable bodies have left no trace behind.

In our own days similar unicellular organisms are at work, taking their part silently and unobtrusively in the great scheme of creation, and mostly destined, like their predecessors, to leave behind them no record of their existence. The Red Snow Plant, to which is mainly due the beautiful phenomenon by which tracts of Arctic and Alpine snow become tinged of a delicate crimson, is a microscopic organism whose whole body consists of a simple spherical cell. In the protoplasm of this little cell must reside all the essential attributes of life; it must grow by the reception of nutriment; it must repeat by multiplication that form which it has itself inherited from its parent; it must be able to respond to the stimulus of the physical conditions by which it is surrounded. And there it is, with its structure almost on the bounds of extremest simplification, taking its allotted part in the economy of nature, combining into living matter the lifeless elements which lie around it, redeeming from sterility the regions of never-thawing ice, and peopling with its countless millions the wastes of the snow land.

But organization does not long rest on this low stage of unicellular simplicity, for as we pass from these lowest forms into higher, we find cell added to cell, until many millions of such units become associated in a single organism, where each cell, or each group of cells, has its own special work, while all combine for the welfare and unity of the whole.

In the most complex animals, however, even in man himself, the component cells, notwithstanding their frequent modification and the usual intimacy of their union, are far from losing their individuality. Examine under the microscope a drop of blood freshly taken from the human subject, or from any of the higher animals. It is seen to be composed of a multitude of red corpuscles, swimming in a nearly colourless liquid, and along with these, but in much smaller numbers, somewhat larger colourless corpuscles. The red corpuscles are modified cells, while the colourless corpuscles are cells still retaining their typical form and properties. These last are little masses of protoplasm, each enveloping a central nucleus. Watch them. They will be seen to change their shape; they will project and withdraw pseudopodia, and creep about like an *Amœba*. But, more than this, like an *Amœba* they will take in solid matter as nutriment. They may be fed with coloured food, which will then be seen to have accumulated in the interior of their soft transparent protoplasm; and in some cases the colourless blood corpuscles have actually been seen to devour their more diminutive companions, the red ones.

Again, there are certain cells filled with peculiar coloured matters, and called pigment cells, which are especially abundant, as constituents of the skin in fishes, frogs and other low vertebrate, as well as many invertebrate animals. Under certain stimuli, such as that of light, or of emotion, these pigment cells change their form, protrude or retract pseudopodial prolongations of their protoplasm, and assume the form of stars or of irregularly lobed figures, or again draw themselves together into little globular masses. To this change of form in the pigment cell the rapid change of colour so frequently noticed in the animals provided with them is to be attributed.

The animal egg, which in its young state forms an element in the structure of the parent organism, possesses in the relations now under consideration a peculiar interest. The egg is a true cell, consisting essentially of a lump of protoplasm enclosing a nucleus, and having a nucleolus included in the interior of the nucleus. While still very young it has no constant form, and is perpetually changing its shape. Indeed, it is often impossible to distinguish it from an *Amœba;* and it may, like an *Amœba*, wander from place to place by the aid of its pseudopodial projections. I have shown elsewhere that the primitive egg of the remarkable hydroid *Myriothela* manifests amœboid motions: while Haeckel has shown that in the sponges certain amœba-like organisms, which are seen wandering about in the various canals and cavities of their bodies, and had been until lately regarded as parasites which had gained access from without, are really the eggs of the sponge; and a similar amœboid condition is presented by the very young eggs of even the highest animals.

Again, Reichenbach has proved that during the development of the crayfish the cells of the embyro throw out pseudopodia by which, exactly as in an Amœba, the yolk spheres which serve as nutriment for the embryo are surrounded and engulphed in the protoplasm of the cells.

I had shown some years ago that in *Myriothela* pseudopodial processes are being constantly projected from the walls of the alimentary canal into its cavity. They appear as direct extensions of a layer of clear, soft homogeneous protoplasm which lies over the surface of the naked cells lining the cavity, and which I now regard as the "Hautschicht," or cortical layer of these cells. I then suggested that the function of these pseudopodia lay in seizing, in the manner of an amœba, such alimentary matter as may be found in the contents of the canal, and applying it to the nutrition of the hydroid.

What I had thus suggested with regard to *Myriothela* has been since proved in certain planarian worms by Metschnikoff, who has seen the cells which line the alimentary canal in these animals act like independent Amœbæ, and egulph in their protoplasm such solid nutriment as may be contained in the canal. When the Planaria was fed with colouring matter these amœboid cells became gorged with the coloured particles just as would have happened in an amœba when similarly fed.

But it is not alone in such loosely aggregated cells as those of the blood, or in the amœboid cells of the alimentary canal, or in such scattered constituents of the tissues as the pigment cells or in cells destined for an ultimate state of freedom, as the egg, that there exists an independence. The whole complex organism is a society of cells, in which every individual cell possesses an independence, an autonomy, not at once so obvious as in the blood cells, but not the less real. With this autonomy of each element there is at the same time a subordination of each to the whole, thus establishing a unity in the entire organism, and a concert and harmony between all the phenomena of its life.

In this society of cells each has its own work to perform, and the life of the organism is made up of the lives of its component cells. Here it is that we find most distinctly expressed the great law of the physiological division of labour. In the lowest organisms, where the whole being consists of a single cell, the performance of all the processes which constitute its life must devolve on the protoplasm of this one cell; but as we pass to more highly organized beings, the work becomes distributed among a multitude of workers. These workers are the cells which now make up the complex organism. The distribution of labour, however, is not a uniform one, and we are not to suppose that the work performed by each cell is but a repetition of that of every other. For the life processes, which are accumulated in the single cell of the unicellular organism become in the more complex organism differentiated, some being intensified and otherwise modified and allocated to special cells, or to special groups of cells, which we call organs, and whose proper duty is now to take charge of the special processes which have been assigned to them. In all this we have a true division of labour,—a division of labour, however, by no means absolute; for the processes which are essential to the life of the cell must still continue common to all the cells of the organism. No cell, however great may be the differentiation of function in the organism, can dispense with its irritability, the one constant and essential property of every living cell. There thus devolves on each cell or group of cells some special work which contributes to the well-being of all, and their combined labours secure the necessary conditions of life for every cell in the community, and result in those complex and wonderful phenomena which constitute the life of the higher organisms.

We have hitherto considered the cell only as a mass of active nucleated protoplasm, either absolutely naked or partially enclosed in a protective case, which still permits free contact of the protoplasm with the surrounding medium. In very many instances, however, the protoplasm becomes confined within resisting walls, which entirely shut it in from all direct contact with the medium which surrounds it. With the plant this is almost always so after the earliest stages of its life. Here the protoplasm of the cells is endowed with the faculty of secreting over its surface a firm, resisting membrane, composed of cellulose, a substance destitute of nitrogen, thus totally different from the contained protoplasm, and incapable of manifesting any of the phenomena of life.

Within the walls of cellulose the protoplasm is now closely imprisoned, but we are not on that account to suppose that it has lost its activity, or has abandoned its work as a living being. Though it is now no longer in direct contact with the surrounding medium, it is not the less dependent on it, and the reaction between the imprisoned protoplasm and the outer world is still permitted by the permeability of the surrounding wall of cellulose.

When the protoplasm thus becomes surrounded by a cellulose wall it seldom retains the uniform arrangement of its parts which is often found in the naked cells. Minute cavities or vacuoles make their appearance in it; these increase in size and run one into the other, and may finally form one large cavity in the centre, which becomes filled with a watery fluid, known as the Cell Sap. This condition of the cell was the first observed, and it was it which suggested the often inapplicable term "cell." By the formation of this central sap cavity the surrounding protoplasm is pushed aside, and pressed against the cellulose wall, over which it now extends as a continuous layer. The nucleus either continues near the centre, enveloped by a layer of protoplasm, which is connected by radiating bands of protoplasm with that of the walls, or it accompanies the displaced protoplasm, and lies embedded in this on the walls of the cell.

We have abundant evidence to show that the imprisoned protoplasm loses none of its activity. The *Characeæ* constitute an exceedingly interesting group of simple plants, common in the clear water of ponds and of slowly running streams. The cells of which they are built up are comparatively large, and, like almost all vegetable cells, are each enclosed in a wall of cellulose. The cellulose is perfectly transparent, and if the microscope, even with a low power, be brought to bear on one of these cells, a portion of its protoplasm may be seen in active rotation flowing up one side of the long tubular cell and down the other, and sweeping on with it such more solid particles as may become enveloped in its current. In another water plant, the *Valisneria spiralis*, a similar active rotation of the protoplasm may be seen in the cells of the leaf, where the continuous stream of liquid protoplasm sweeping along the green granules of chlorophyll, and even carrying the globular nucleus with it in its current, presents one of the most beautiful of the many beautiful phenomena which the microscope has revealed to us.

In many other cells with large sap cavities, such as those which form the stinging hairs of nettles and other kinds of vegetable hairs, the protoplasmic lining of the wall may send off into the sap cavity projecting ridges and strings, forming an irregular network, along which, under a high power of the microscope, a slow streaming of granules may be witnessed. The form and position of this protoplasmic network undergo constant changes, and the analogy with the changes of form in an *Amœba* becomes obvious. The external wall of cellulose renders it impossible for the confined protoplasm to emit, like a naked *Amœba*, pseudopodia from its outer side; but on the inner side there is no obstacle to the extension of the protoplasm, and here the cavity of the cell becomes more or less completely traversed by protoplasmic projections from the wall. These often stretch themselves out in the form of thin filaments, which, meeting with a neighbouring one, become fused into it; they show currents of granules streaming along their length, and after a time become withdrawn and disappear. The vegetable cell, in short, with its surrounding wall of cellulose, is in all essential points a closely imprisoned Rhizopod.

Further proof that the imprisoned protoplasm has lost by its imprisonment none of its essential irritability, is afforded by the fact that if the transparent cell of a Nitella, one of the simple water-plants just referred to, be touched under the microscope with the point of a blunt needle, its green protoplasm will be seen to recede, under the irritation of the needle, from the cellulose wall, If the cellulose wall of the comparatively large cell which forms the entire plant in a Vaucheria, a unicellular alga, very common in shallow ditches, be ruptured under the microscope, its protoplasm will escape, and may then be often seen to throw out pseudopodial projections and exhibit amœboid movements.

Even in the higher plants, without adducing such obvious and well-known instances as those of the Sensitive Plant and Venus's Flytrap, the irritability of the protoplasm may be easily rendered manifest. There are many herbaceous plants in which if the young succulent stem of a vigorously growing specimen receive a sharp blow, of such a nature, however, as not to bruise its tissues, or in any way wound it, the blow will sometimes be immediately followed by a drooping of the stem commencing at some distance above the point to which the stroke had been applied: its strength appears to have here suddenly left it, it is no longer able to bear its own weight, and seems to be dying. The protoplasm, however, of its cells, is in this instance not killed, it is only stunned by the violence of the blow, and needs time for its restoration.

After remaining, it may be for some hours, in this drooping and flaccid state, the stem begins to raise itself, and soon regains its original vigour. This experiment will generally succeed well in plants with a rather large terminal spike or raceme when the stroke is applied some little distance below the inflorescence shortly before the expansion of the flower.

In the several instances now adduced the protoplasm is in the mature state of the plant entirely included within a wall of cellulose. Some recent beautiful observations, however, of Mr. Francis Darwin, have shown that even in the higher plants truly naked protoplasm may occur. From the cells of certain glandular hairs contained within the cup-like receptacles formed by the united bases of two opposite leaves in the Teazel (*Dipsacus*) he has seen emitted long pseudopodia-like projections of the protoplasm. What may be the significance of this very exceptional phenomenon is still undetermined. It is probably, as Mr. Darwin supposes, connected with the absorption of nitrogenous matter.

That there is no essential difference between the protoplasm of plants and that of animals is rendered further evident by other motor phenomena, which we are in the habit of regarding as the exclusive attribute of animals. Many of the more simply organized plants give origin to peculiar cells called "spores," which separate from the parent, and, like the seeds of the higher plants, are destined to repeat its form. In many cases these spores are eminently locomotive. They are then termed "swarm-spores," and their movements are brought about, sometimes by changes of shape, when they move about in the manner of an *Amœba*, but more frequently by minute vibratile cilia, or by more strongly developed flagella or whip-like projections of their protoplasm. These cilia and flagella are absolutely indistinguishable from similar structures widely distributed among animals, and by their vibratory or lashing strokes upon the surrounding water the swarm-spores are rapidly carried from place to place. In these motions they often present a curious semblance of volition, for if the swarm-spore meet with an obstacle in its course, it will, as if to avoid it, change the direction of its motion, and retreat by a reversion of the stroke of its cilia. They are usually attracted by light, and congregate at the light side of the vessel which contains them, though in some cases light has the opposite effect on them and they recede from it.

Another fact may here be adduced to show the uniform character of protoplasm and how very different are its properties from those of lifeless matter, namely, the faculty which all living protoplasm possesses of resisting the entrance of colouring matter into its substance. As many here present are aware, microscopists are in the habit of using in their investigations various colouring matters, such as solutions of carmine. These act differently on the different tissues, staining some, for example, more deeply than others, and thus enabling the histologist to detect certain elements of structure which would otherwise remain unknown. Now if a solution of carmine be brought into contact with living protoplasm, this will remain, so long as it continues alive, unaffected by the colouring matter. But if the protoplasm be killed the carmine will at once pervade its whole substance, and stain it throughout with a colour more intense than even that of the colouring solution itself.

But no more illustrative example can be offered of the properties of protoplasm as living matter, independently of any part it may take in organization, than that presented by the Myxomycetæ.

The Myxomycetæ constitute a group of remarkable organisms, which from their comparatively large size and their consisting, during a great part of their lives, of naked protoplasm, have afforded a fine field for research, and have become one of the chief sources from which our knowledge of the nature and phenomena of protoplasm has been derived.

They have generally been associated by botanists with the Fungi, but though their affinities with these are perhaps closer than with any other plants, they differ from them in so many points, especially in their development, as to render this association untenable. They are found in moist situations, growing on old tan or on moss, or decaying leaves or rotten wood, over which they spread in the form of a network of naked protoplasmic filaments, of a soft creamy consistence and usually of a yellowish colour.

Under the microscope the filaments of the network exhibit active spontaneous movements, which in the larger branches are visible under an ordinary lens, or even by the naked eye. A succession of undulations may then be noticed passing along the course of the threads. Under higher magnifying powers, a constant movement of granules may be seen flowing along the threads, and streaming from branch to branch of this wonderful network. Here and there offshoots of the protoplasm are projected, and again withdrawn in the manner of the pseudopodia of an *Amœba*, while the whole organism may be occasionally seen to abandon the support over which it had grown, and to creep over neighbouring surfaces, thus far resembling in all respects a colossal ramified *Amœba*. It is also curiously sensitive to light, and may be sometimes found to have retreated during the day to the dark side of the leaves, or into the recesses of the tan over which it had been growing, and again to creep out on the approach of night.

After a time there arise from the surface of this protoplasmic net oval capsules or spore-cases, in which are contained the spores or reproductive bodies of the Myxomycetæ. When the spore-case has arrived at maturity, it bursts and allows the spores to escape. These are in the form of spherical cells, each included in a delicate membranous wall, and when they fall into water the wall becomes ruptured, and the little cell creeps out. This consists of a little mass of protoplasm with a round centre nucleus, enclosing a nucleolus and with a clear vacuole, which exhibits a rhythmically pulsating movement. The little naked spore thus set at liberty is soon seen to be drawn out at one point into a long vibratile whip-like flagellum, which by its lashing action carries the spore from place to place. After a time the flagellum disappears, and the spore may now be seen emitting and withdrawing finger-like pseudopodia, by means of which it creeps about like an *Amœba*, and like an *Amœba* devours solid particles by engulphing them in its soft protoplasm.

So far these young amœba-like Myxomycetæ have enjoyed each an independent existence. Now, however, a singular and significant phenomenon is presented. Two or more of these Myxamœbæ, as they have been called, approach one another, come into contact, and finally become completely fused together into a single mass of protoplasm, in which the components are no longer to be distinguished. To the body thus formed by the fusion of the Myxamœbæ the name of "plasmodium" has been given.

The plasmodium continues, like the simple amœbiform bodies of which it is composed, to grow by the ingestion and assimilation of solid nutriment, which it envelops in its substance; it throws out ramifying and mosculating processes, and finally becomes converted into a protoplasmic network, which in its turn gives rise to spore-cases with their contained spores and thus completes the cycle of its development.

Under certain external conditions the Myxomycetæ have been observed to pass from an active mobile state into a resting state, and this may occur both in the amœbiform spores and in the plasmodium. When the plasmodium is about to pass into a resting state, it usually withdraws its finer branches and expels such solid ingesta as may be included in it. Its motions then gradually cease, it breaks up into a multitude of polyhedral cells, which, however, remain connected, and the whole body dries into a horny brittle mass, known by the name of 'sclerotium.'

In this condition, without giving the slightest sign of life, the sclerotium may remain for many months. Life, however, is not destroyed, its manifestations are only suspended, and if after an indefinite time the apparently dead sclerotium be placed in water, it immediately begins to swell up, the membranous covering of its component cells becomes dissolved and disappears, and the cells themselves flow together into an active amœboid plasmodium.

We have already seen that every cell possesses an autonomy or independent individuality, and from this we should expect that, like all living beings, it had the faculty of multiplying itself, and of becoming the parent of other cells. This is truly the case, and the process of cell-multiplication has of late years been studied, with the result of adding largely to our knowledge of the phenomena of life.

The labours of Strasburger, of Auerbach, of Oscar Hertwig, of Eduard van Beneden, Bütschli, Fol, and others, here come prominently before us, but neither the time at my disposal nor the purport of this address will allow me to do more than call your attention to some of the more striking results of their investigations.

By far the most frequent mode of multiplication among cells shows itself in a spontaneous division of the protoplasm into two separate portions, which then become independent of one another, so that instead of the single parent cell two new ones have made their appearance. In this process the nucleus usually takes an important part. Strasburger has studied it with great care in certain plant cells, such as the so-called "corpuscula" or "secondary embryo-sacs" of the Coniferæ and the cells of Spirogyra; and has further shown a close correspondence between cell division in animals and that in plants.

It may be generally stated as the results of his observations on the corpuscula of the Coniferæ, that the nucleus of the cell about to divide assumes a spindle shape, and at the same time presents a peculiar striated differentiation, as if it were composed of parallel filaments reaching from end to end of the spindle. These filaments become thickened in the middle and there form by the approximation of the thickened portions a transverse plate of protoplasm (the "nucleus-plate"). This soon splits into two halves, which recede from one another towards the poles of the spindle, travelling in this course along the filaments, which remain continuous from end to end. When arrived near the poles they form there two new nuclei, still connected with one another by the intervening portion of the spindle.

In the equator of this intervening portion there is now formed in a similar way a second plate of protoplasm (the "cell-plate"), which, extending to the walls of the dividing cell, cuts the whole protoplasm into two halves, each half containing one of the newly formed nuclei. This partition plate is at first single, but it soon splits into two laminæ, which become the apposed bounding surfaces of the two protoplasm masses into which the mother cell has been divided. A wall of celluose is then all at once secreted between them, and the two daughter cells are complete.

It sometimes happens in the generation of cells that a young brood of cells arises from the parent cell by what is called "free cell formation." In this only a part of the protoplasm of the mother cell is used up in the production of the offspring. It is seen chiefly in the formation of the spore of the lower plants, in the first foundation of the embryo in the higher, and in the formation of the endosperm—a cellular mass which serves as the first nutriment for the embryo—in the seeds of most Phanerogams. The formation of the endosperm has been carefully studied by Strasburger in the embryo-sac of the kidney bean, and may serve as an example of the process of free cell formation. The embyro-sac is morphologically a large cell with its protoplasm, nucleus, and cellulose wall, while the endosperm which arises within it is composed of a multitude of minute cells united into a tissue. The formation of the endosperm is preceded by the dissolution and disappearance of the nucleus of the embryo-sac, and then in the midst of the protoplasm of the sac several new nuclei make their appearance. Around each of these as a centre the protoplasm of the mother cell is seen to have become differentiated in the form of a clear spherule, and we have thus corresponding to each of the new nuclei a young naked cell, which soon secretes over its surface a membrane of cellulose. The new cells, when once formed, multiply by division, press one on the other, and so combining into a cellular mass, constitute the completed endosperm.

Related to the formation of new cells, whether by division or by free cell formation, is another very interesting phenomenon of living protoplasm known as "rejuvenescence." In this the whole protoplasm of a cell, by a new arrangement of its parts, assumes a new shape and acquires new properties. It then abandons its cellulose chamber, and enters on a new and independent life in the surrounding medium.

A good example of this is afforded by the formation of swarm-spores in Oedogonium, one of the fresh-water Algæ. Here the whole of the protoplasm of an adult cell contracts, and by the expulsion of its cell sap changes from a cylindrical to a globular shape. Then one spot becomes clear, and a pencil of vibratile cilia here shows itself. The cellulose wall which had hitherto confined it now becomes ruptured, and the protoplasmic sphere, endowed with new faculties of development and with powers of active locomotion, escapes as a swarm spore, which, after enjoying for a time the free life of an animal, comes to rest, and develops itself into a new plant.

The beautiful researches which have within the last few years been made by the observers already mentioned, on the division of animal cells, show how close is the agreement between plants and animals in all the leading phenomena of cell division, and afford one more proof of the essential unity of the two great organic kingdoms.

There is one form of cell which, in its relation to the organic world possesses a significance beyond that of every other, namely, the egg. As already stated, the egg is, wherever it occurs, a typical cell, consisting essentially of a globule of protoplasm enveloping a nucleus (the "germinal vesicle"), and with one or more nucleoli (the "germinal spots") in the interior of the nucleus. This cell, distinguishable by no tangible characters from thousands of other cells, is nevertheless destined to run through a definite series of developmental changes, which have as their end the building up of an organism like that to which the egg owes its origin.

It is obvious that such complex organisms as thus result—composed, it may be, of countless millions of cells—can be derived from the simple egg cell only by a process of cell multiplication. The birth of new cells derived from the primary cell or egg thus lies at the basis of embryonic development. It is here that the phenomena of cell multiplication in the animal kingdom can in general be most satisfactorily observed, and the greater number of recent researches into the nature of these phenomena have found their most fertile field in the early periods of the development of the egg.

A discussion of the still earlier changes which the egg undergoes in order to bring it into the condition in which cell multiplication may be possible, would, however full of interest, be here out of place; and I shall therefore confine myself to the first moments of actual development—to what is called "the cleavage of the egg"—which is nothing more than a multiplication of the egg cell by repeated division. I shall further confine myself to an account of this phenomenon as presented in typical cases leaving out of consideration certain modifications whish would only complicate and obscure our picture.

The egg, notwithstanding the preliminary changes to which I have alluded, is still, at the commencement of development, a true cell. It has its protoplasm and its nucleus, and it is, as a rule, enveloped in a delicate membrane. The protoplasm forms what is known as the vitellus, or yolk, and the surrounding membrane is called the "vitellary membrane." The division which is now about to take place in it is introduced by a change of form in the nucleus. This becomes elongated, and assumes the shape of a spindle, similar to what we have already seen in the cell division of plants. On each pole of the spindle transparent protoplasm collects, forming here a clear spherical area.

At this time a very striking and characteristic phenomenon is witnessed in the egg. Each pole of the spindle has become the centre of a system of rays which stream out in all directions into the surrounding protoplasm. The protoplasm thus shows, enveloped in its mass, two sun-like figures, whose centres are connected to one another by the spindle-shaped nucleus. To this, with the sun-like rays streaming from its poles, Auerbach gives the name of "Karyolitic figure," suggested by its connection with the breaking up of the original nucleus, to which our attention must next be directed.

A phenomenon similar to one we have already seen in cell division among plants now shows itself. The nucleus becomes broken up into a number of filaments, which lie together in a bundle, each filament stretching from pole to pole of the spindle. Exactly in its central point every filament shows a knot-like enlargement, and from the close approximation of the knots there results a thick zone of protoplasm in the equator of the spindle. Each knot soon divides into two halves, and each half recedes from the equator and travels along the filament towards its extremity. When arrived at the poles of the spindle each set of half knots becomes fused together into a globular body, while the intervening portion of the spindle becoming torn up, and gradually drawn into the substance of the two globular masses, finally disappears. And now, instead of the single fusiform nucleus whose changes we have been tracing, we have two new globular nuclei, each occupying the place of one of its poles, and formed at its expense. The egg now begins to divide along a plane at right angles to a line connecting the two nuclei. The division takes place without the formation of a cell plate such as we saw in the division of the plant cell, and is introduced by a constriction of its protoplasm, which commences at the circumference just within the vitelline membrane, and, extending towards the centre, divides the whole mass of protoplasm into two halves, each including within it one of the new nuclei. Thus the simple cell which constituted the condition of the egg at the commencement of development becomes divided into two similar cells. This forms the first stage of cleavage. Each of these two young cells divides in its turn in a direction at right angles to the first division-plane, while by continued repetition of the same act the whole of the protoplasm or yolk becomes broken up into a vast multitude of cells, and the unicellular organism—the egg, with which we began our history—has become converted into an organism composed of many thousands of cells. This is one of the most widely distributed phenomena of the organic world. It is called "the cleavage of the egg," and consists essentially in the production, by division, of successive broods of cells from a single ancestral cell—the egg.

It is no part of my purpose to carry on the phenomena of development further than this. Such of my hearers as may desire to become acquainted with the further history of the embryo, I would refer to the excellent address delivered two years ago at the Plymouth meeting of the Association by one of my predecessors in this chair—Professor Allen Thompson.

That protoplasm, however, may present a phenomenon the reverse of that in which a simple cell becomes multiplied into many, is shown by a phenomenon already referred to—the production of plasmodia in the Myxomycetæ by the fusion into one another of cells originally distinct.

The genus Myriothela will afford another example in which the formation of plasmodia becomes introduced into the cycle of development. The primitive eggs are here, as elsewhere, true cells with nucleolated nuclei, but without any boundary membrane. They are formed in considerable numbers, but remain only for a short time separate and distinct. After this they begin to exhibit amœboid changes of shape, project pseudopodial prolongations which coalesce with those of others in their vicinity, and finally a multitude of these primitive ova become fused together into a common plasmodium, in which, as in the simple egg cell of other animals, the phenomena of development take place.

In many of the lower plants a very similar coalescence is known to take place between the protoplasmic bodies of separate cells, and constitutes the phenomenon of conjugation. Spirogyra is a genus of Algæ, consisting of long green threads common in ponds. Every thread is composed of a series of cylindrical chambers of transparent cellulose placed end to end, each containing a sac of protoplasm with a large quantity of cell sap, and with a green band of chlorophyll wound spirally on its walls. When the threads have attained their full growth they approach one another in pairs, and lie in close proximity, parallel one to the other. A communication is then established by means of short connecting tubes between the chambers of adjacent filaments, and across the channel thus formed the whole of the protoplasm of one of the conjugating chambers passes into the cavity of the other, and then immediately fuses with the protoplasm it finds there. The single mass thus formed shapes itself into a solid oval body, known as a "zygospore.' This now frees itself from the filament, secretes over its naked surface a new wall of cellulose, and, when placed in the conditions necessary for its development, attaches itself by one end, and then, by repeated acts of cell division, grows into a many-celled filament like those in which it originated.

The formation of plasmodia, regarded as a coalescence and absolute fusion into one another of separate naked masses of protoplasm, is a phenomenon of great significance. It is highly probable that, notwithstanding the complete loss of individuality in the combining elements, such differences as may have been present in these will always find itself expressed in the properties of the resulting plasmodia—a fact of great importance in its bearing on the phenomena of inheritance. Recent researches, indeed, render it almost certain that fertilization, whether in the animal or the vegetable kingdom, consists essentially in the coalescence and consequent loss of individuality of the protoplasmic contents of two cells.

In by far the greater number of plants the protoplasm of most of the cells which are exposed to the sunlight undergoes a curious and important differentiation, part of it becoming separated from the remainder in the form usually of green granules, known as chlorophyll granules. The chlorophyll granules thus consist of true protoplasm, their colour being due to the presence of a green colouring matter, which may be extracted, leaving behind the colourless protoplasmic base.

The colouring matter of chlorophyll presents under the spectroscope a very characteristic spectrum. For our knowledge of its optical properties, on which time will not now permit me to dwell, we are mainly indebted to the researches of your townsman, Dr. Sorby, who has made these the subject of a series of elaborate investigations, which have contributed largely to the advancement of an important department of physical science.

That the chlorophyll is a living substance, like the uncoloured protoplasm of the cell, is sufficiently obvious. When once formed, the chlorophyll granule may grow by intussusception of nutriment to many times its original size, and may multiply itself by division.

To the presence of chlorophyll is due one of the most striking aspects of external nature—the green colour of the vegetation which clothes the surface of the earth; and with its formation is introduced a function of fundamental importance in the economy of plants, for it is on the cells which contain this substance that devolves the faculty of decomposing carbonic acid. On this depends the assimilation of plants, a process which becomes manifest externally by the exhalation of oxygen. Now it is under the influence of light on the chlorophyll-containing cells that this evolution of oxygen is brought about. The recent observations of Draper and of Pfeffer have shown that in this action the solar spectrum is not equally effective in all its parts; that the yellow and least refrangible rays are these which act with most intensity; that the violet and other highly refrangible rays of the visible spectrum take but a very subordinate part in assimilation; and that the invisible rays which lie beyond the violet are totally inoperative.

In almost every grain of chlorophyll one or more starch granules may be seen. This starch is chemically isomeric with the cellulose cell wall, with woody fibre, and other hard parts of plants, and is one of the most important products of assimilation. When plants whose chlorophyll contains starch are left for a sufficient time in darkness, the starch is absorbed and completely disappears; but when they are restored to the light the starch reappears in the chlorophyll of the cells.

With this dependence of assimilation on the presence of chlorophyll a new physiological division of labour is introduced into the life of plants. In the higher plants, while the work of assimilation is allocated to the chlorophyll-containing cells, that of cell division and growth devolves on another set of cells, which, lying deeper in the plant, are removed from the direct action of light, and in which chlorophyll is therefore never produced. In certain lower plants, in consequence of their simplicity of structure and the fact that all the cells are equally exposed to the influence of light, this physiological division of labour shows itself in a somewhat different fashion. Thus in some of the simple green algæ, such as *Spirogyra* and *Hydrodictyon*, assimilation takes place as in other cases during the day, while their cell division and growth takes place chiefly, if not exclusively, at night. Strasburger, in his remarkable observations on cell divisions in *Spirogyra*, was obliged to adopt an artificial device in order to compel the *Spirogyra* to postpone the division of its cells to the morning.

Here the functions of assimilation and growth devolve on one and the same cell, but while one of these functions is exercised only during the day, the time for the other is the night. It seems impossible for the same cell at the same time to exercise both functions, and these are here accordingly divided between different periods of the twenty-four hours.

The action of chlorophyll in bringing about the decomposition of carbonic acid is not, as was recently believed, absolutely confined to plants. In some of the lower animals, such as *Stentor* and other infusoria, the Green Hydra, and certain green planariæ and other worms, chlorophyll is differentiated in their protoplasm, and probably always acts here under the influence of light exactly as in plants.

Indeed, it has been proved by some recent researches of Mr. Geddes, that the green planariæ when placed in water and exposed to the sunlight give out bubbles of gas which contain from 44 to 55 per cent. of oxygen. Mr. Geddes has further shown that these animals contain granules of starch in their tissues, and in this fact we have another striking point of resemblance between them and plants.

A similar approximation of the two organic kingdoms has been shown by the beautiful researches of Mr. Darwin—confirmed and extended by his son, Mr. Francis Darwin—on Drosera and other so-called carnivorous plants. These researches, as is now well known, have shown that in all carnivorous plants there is a mechanism fitted for the capture of living prey, and that the animal matter of the prey is absorbed by the plant after having been digested by a secretion which acts like the gastric juice of animals.

Again, Nägeli has recently shown that the cell of the yeast fungus contains about 2 per cent. of peptine, a substance hitherto known only as a product of the digestion of azotized matter by animals.

Indeed, all recent research has been bringing out in a more and more decisive manner the fact that there is no dualism in life—that the life of the animal and the life of the plant are, like their protoplasm, in all essential points identical.

But there is, perhaps, nothing which shows more strikingly the identity of the protoplasm in plants and animals, and the absence of any deep-pervading difference between the life of the animal and that of the plant, than the fact that plants may be placed, just like animals, under the influence of anæsthetics.

When the vapour of chloroform or of ether is inhaled by the human subject, it passes into the lungs, where it is absorbed by the blood and thence carried by the circulation to all the tissues of the body. The first to be affected by it is the delicate nervous element of the brain, and loss of consciousness is the result. If the action of the anæsthetic be continued, all the other tissues are in their turn attacked by it and their irritability arrested. A set of phenomena entirely parallel to these may be presented by plants.

We owe to Claude Bernard a series of interesting and most instructive experiments on the action of ether and chloroform on plants. He exposed to the vapour of ether a healthy and vigorous sensitive plant, by confining it under a bell-glass into which he introduced a sponge filled with ether. At the end of half an hour the plant was in a state of anæsthesia, all its leaflets remained fully extended, but they showed no tendency to shrink when touched. It was then withdrawn from the influence of the ether, when it gradually recovered its irritability, and finally responded, as before, to the touch.

It is obvious that the irritability of the protoplasm was here arrested by the anæsthetic, so that the plant became unable to give a response to the action of an external stimulus.

It is not, however, the irritability of the protoplasm of only the motor elements of plants that anæsthetics are capable of arresting. These may act also on the protoplasm of those cells whose function lies in chemical synthesis, such as is manifested in the phenomena of the germination of the seed and in nutrition generally, and Claude Bernard has shown that germination is suspended by the action of ether or chloroform.

Seeds of cress, a plant whose germination is very rapid, were placed in conditions favourable to a speedy germination, and while thus placed were exposed to the vapour of ether. The germination, which would otherwise have shown itself by the next day, was arrested. For five or six days the seeds were kept under the influence of the ether, and showed during this time no disposition to germinate. They were not killed, however, they only slept, for on the substitution of common air for the etherized air with which they had been surrounded, germination at once set in and proceeded with activity.

Experiments were also made on that function of plants by which they absorb carbonic acid and exhale oxygen, and which, as we have already seen, is carried on through the agency of the green protoplasm or chlorophyll, under the influence of light—a function which is commonly, but erroneously, called the respiration of plants.

Aquatic plants afford the most convenient subjects for such experiments. If one of these be placed in a jar of water holding ether or chloroform in solution, and a bell-glass be placed over the submerged plant, we shall find that the plant no longer absorbs carbonic acid or emits oxygen. It remains, however, quite green and healthy. In order to awaken the plant, it is only necessary to place it in non-etherized water, when it will begin once more to absorb carbonic acid and exhale oxygen under the influence of sunlight.

The same great physiologist has also investigated the action of anæsthetics on fermentation. It is well known that alcoholic fermentation is due to the presence of a minute fungus, the yeast fungus, the living protoplasm of whose cells has the property of separating solutions of sugar into alcohol, which remains in the liquid, and carbonic acid, which escapes into the air.

Now, if the yeast plant be placed along with sugar in etherized water it will no longer act as a ferment. It is anæsthesiated, and cannot respond to the stimulus which, under ordinary circumstances, it would find in the presence of the sugar. If, now, it be placed on a filter, and the ether washed completely away, it will, on restoration to a saccharine liquid, soon resume its duty of separating the sugar into alcohol and carbonic acid.

Claude Bernard has further called attention to a very significant fact which is observable in this experiment. While the proper alcoholic fermentation is entirely arrested by the etherization of the yeast plant, there still goes on in the saccharine solution a curious chemical change, the cane sugar of the solution being converted into grape sugar, a substance identical in its chemical composition with the cane sugar, but different in its molecular constitution. Now it is well known from the researches of Bertholet that this conversion of cane sugar into grape sugar is due to a peculiar inversive ferment, which, while it accompanies the living yeast plant, is itself soluble and destitute of life. Indeed it has been shown that in its natural conditions the yeast fungus is unable of itself to assimilate cane sugar, and that in order that this may be brought into a state fitted for the nutrition of the fungus, it must be first digested and converted into grape sugar, exactly as happens in our own digestive organs. To quote Claude Bernard's graphic account:—

"The fungus ferment has thus beside it in the same yeast a sort of servant given by nature to effect this digestion. The servant is the unorganized inversive ferment. This ferment is soluble, and as it is not a plant, but an unorganized body destitute of sensibility, it has not gone to sleep under the action of the ether, and thus continues to fulfil its task."

In the experiment already recorded on the germination of seeds the interest is by no means confined to that which attaches itself to the arrest of the organizing functions of the seed, those, namely, which manifest themselves in the development of the radicle and plumule and other organs of the young plant. Another phenomenon of great significance becomes at the same time apparent—the anæsthetic exerts no action on the concomitant chemical phenomena which in germinating seeds show themselves in the transformation of starch into sugar under the influence of diastase (a soluble and non-living ferment which also exists in the seed), and the absorption of oxygen with the exhalation of carbonic acid. These go on as usual, the anæsthesiated seed continuing to respire, as proved by the accumulation of carbonic acid in the surrounding air. The presence of the carbonic acid was rendered evident by placing in the same vessel with the seeds which were the object of the experiment a solution of barytes, when the carbonate became precipitated from the solution in quantity equal to that produced in a similar experiment with seeds germinating in unetherized air.

So, also, in the experiment which proves the faculty possessed by the chlorophyllian cells of absorbing carbonic acid and exhaling oxygen under the influence of light may be arrested by anæsthetics, it could be seen that the plant, while in a state of anæsthesia, continued to respire in the manner of animals: that is, it continued to absorb oxygen and exhale carbonic acid. This is the true respiratory function which was previously masked by the predominant function of assimilation, which devolves on the green cells of plants, and which manifests itself under the influence of light in the absorption of carbonic acid and the exhalation of oxygen.

It must not, however, be supposed that the respiration of plants is entirely independent of life. The conditions which bring the oxygen of the air and the combustible matter of the respiring plant into such relations as may allow them to act on one another are still under its control, and we must conclude that in Claude Bernard's experiment the anæsthesia had not been carried so far as to arrest such properties of the living tissues as are needed for this.

The quite recent researches of Schützenberger, who has investigated the process of respiration as it takes place in the cell of the yeast fungus, have shown that vitality is a factor in this process. He has shown that fresh yeast, placed in water, breathes like an aquatic animal, disengaging carbonic acid, and causing the oxygen contained in the water to disappear. That this phenomenon is a function of the living cell is proved by the fact that, if the yeast be first heated to 60° C. and then placed in the oxygenated water, the quantity of oxygen in the water remains unchanged; in other words, the yeast ceases to breathe.

Schützenberger has further shown that light exerts no influence on the respiration of the yeast cell—that the absorption of oxygen by the cell takes place in the dark exactly as in sunlight. On the other hand, the influence of temperature is well marked. Respiration is almost entirely arrested at temperatures below 10° C., it reaches its maximum at about 40° C., while at 60° C., it again ceases.

All this proves that the respiration of living beings is identical, whether manifested in the plant or in the animal. It is essentially a destructive phenomenon—as much so as the burning of a piece of charcoal in the open air, and, like it, is characterized by the disappearance of oxygen and the formation of carbonic acid.

One of the most valuable results of the recent careful application of the experimental method of research to the life phenomena of plants is thus the complete demolition of the supposed antagonism between respiration in plants and that in animals.

I have thus endeavoured to give you in a few broad outlines a sketch of the nature and properties of one special modification of matter, which will yield to none other in the interest which attaches to its study, and in the importance of the part allocated to it in the economy of nature. Did the occasion permit I might have entered into many details which I have left untouched; but enough has been said to convince you that in protoplasm we find the only form of matter in which life can manifest itself; and that, though the outer conditions of life—heat, air, water, food—may all be present, protoplasm would still be needed, in order that these conditions may be utilized, in order that the energy of lifeless nature may be converted into that of the countless multitudes of animal and vegetable forms which dwell upon the surface of the earth or people the great depths of its seas.

We are thus led to the conception of an essential unity in the two great kingdoms of organic nature—a structural unity, in the fact that every living being has protoplasm as the essential matter of every living element of its structure; and a physiological unity, in the universal attribute of irritability which has its seat in this same protoplasm, and is the prime mover of every phenomenon of life.

(*To be continued.*)

Correspondence.

Messrs. McIlwaine and Marshall.—We are not aware that any such code of rules has been published.

E. Ware.—Artemisia vulgaris.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Radclyffe, Wheeler, George, Reynolds, McIlwaine and Marshall, Ware, Jarmay, Talbot, J. K. Nicol, Secretary of Leicester Association, Inquirer, Pendennis, Country Apprentice, H. S. N.

"THE MONTH."

When those industrious little insects, the bees, cease working, or at all events collect but little honey, on account of the weather, it is hardly to be expected that flowers under such circumstances should prove more attractive to human beings, unless, like the Ligurian bees, they defy the weather. Studying plants under an umbrella is by no means an agreeable operation, and as sunny skies seem out of the question at present, our floral calendar this month may well be a short one.

The terrific thunderstorm early in this month, which spent its fury chiefly in the neighbourhood of Kew and Richmond, committed such havoc, that the conservatories have had to be closed against the public for repairs, no less than 16,000 panes of glass having been destroyed. The house containing medicinal plants, however, appears to have been comparatively uninjured, although great damage was done in its immediate neighbourhood.

In the Economic House, at Kew, the cacao tree has the upper portion of its diminutive trunk and the lower branches studded with little white flowers, the size of which is absurdly small when compared with the large fruit, which is often a foot in length. The Indian variety of the arrowroot and the papaw tree (male plant) are also in flower, and the *Guizotia oleifera*, which yields the niger seed of commerce, is covered with handsome yellow flowers bearing some resemblance to those of the corn marigold (*Chrysanthemum segetum*). *Cinchona anglica* is now in bud, and will shortly expand its flowers. *Chloranthus officinalis*, used in Java as an aromatic stimulant in typhus fever, is also opening its minute green flowers. *Adenanthera pavonina*, which yields the bright scarlet seeds often used as necklaces, and which are used by jewellers in the east as weights, since they weigh almost uniformly 4 grains, is just showing its small yellowish flowers; these are most disappointing when compared with the brilliant colour and polish of the seeds.

On the outside wall of the Economic House the jalap plant may be seen flowering freely. In the Herbaceous Ground several American medicinal plants may now be seen in blossom, including *Eupatorium purpureum*, *Liatris spicata*, *Leptandra virginica* and *Monarda didyma*. *Leptandra virginica* is not unlike the ordinary *Veronica gentianoides* grown in gardens, but is a taller plant with rather smaller flowers. It has, however, a very pretty and neat appearance and seems to flourish well in the open air. Now that the root, or rather its active principle, leptandrin, is coming into use in this country, it might be worth cultivating. *Monarda didyma* is a very handsome plant; its head of brilliant crimson flowers and bracts forming a most striking object when surrounded by plenty of green foliage. The upper lip of the ringent corolla is remarkably long and narrow and conceals the two anthers.

At Mr. Ware's Nursery, at Tottenham, may now be seen in flower a mass of *Nardostachys Jatamansi*, the plant supposed to be the spikenard of Scripture. It is said to bear cultivation well. It is not, however, a very handsome plant. The leaves are lanceolate and the flower stems are only 3—6 inches long, terminated by a cluster of small and not very attractive violet-coloured blossoms. The odour of the root somewhat resembles that of patchouli.

Other medicinal plants in blossom now are *Althœa officinalis*, *Cannabis sativa*, *Lactuca virosa*, *Artemisia Absinthium*, *Lobelia syphilitica* and *Origanum Dictamnus*.

On chalky or calcareous banks the wild marjoram, *Origanum vulgare*, may now be seen giving quite a gay appearance to the waste places where it grows in any abundance; indeed it is to this fact that it owes its name, derived from two Greek words *oros* and *ganos*, meaning mountain joy.

This plant has a very ancient reputation, as it was used by the Greeks, both internally and for fomentations, and considered as a remedy for narcotic poisons, such as opium and hemlock. Gerarde speaks of it as being a diuretic, useful in dropsy, and externally of service in some skin diseases.

The English or wild marjoram propagates itself extensively by slender stolons. Two forms are recognized in 'English Botany,' one with ovate few-flowered spikes, and the other with few prismatic many-flowered spikes. Specimens with pale pink and white flowers may occasionally be met with.

The marjoram used as a sweet herb is not this plant, but *O. Majorana* or *O. Onites*. The former has small, roundish spikes and small, stalked, elliptical, smooth leaves, and the latter, oblong spikes and downy cordate leaves. Neither have the pretty appearance of the wild marjoram, which is largely due to the coloured bracts that subtend the flowers.

There are few, probably, do not—

"Know a bank where the wild thyme blows."

But a few other facts connected with thyme do not appear to be so generally known as might be expected in these days of advanced education. In the advertisement columns of a contemporary may be noticed the statement that thymol is obtained from "wild thyme (*Origanum vulgare*)." Wild thyme (*Thymus Serpyllum*, L.) includes two forms, which by some authors are regarded as species. The form described in 'Babington's Manual' under the name of *T. Serpyllum*, L., forms dense cushions, consisting in great measure of barren shoots with comparatively few short, erect flowering stems rising one or two inches above the tuft. The other *Thymus Chamœdrys* grows in loose tufts with long slender flowering stems, five or six inches or more in height, and has altogether a different habit, by which, indeed, rather than by any good botanical characters, it is distinguished. In the latter plant the upper corolla lip is more rounded and less notched than in *T. Serpyllum*. The common thyme of the gardens, *Thymus vulgaris*, L., is distinguished by its erect habit and revolute leaves, and is a native of the South of Europe. It is from this plant that the *Oleum origani* of the shops is obtained, and of which, when pure, thymol is said to form about one half. Thymol has, however, been obtained of late years from the essential oil of the seeds of *Ptychotis Ajowan*, an umbelliferous plant grown in India. The lemon thyme used as a culinary herb is *Thymus citriodorus*, Schreb.

A good idea of the variety of forms to which plants are subject may be obtained by studying the varieties of the common dandelion. The true naturalist will not be satisfied with knowing merely the typical form of any species, but will seek a knowledge of the life-history of the commoner plants which come under his daily notice. With regard to the dandelion it would be an interesting inquiry as to which of the various forms yield the largest amount and best quality of extract, and how far the medicinal properties and forms of the plant are affected by the circumstances under which it grows.

In Sowerby's 'English Botany,' four varieties are described, α *genuinum*, with bright green decidedly runcinate leaves, and the outer bracts of the involucre recurved; β *erythrospermum*, having dull green, deeply runcinate leaves, the segments reaching almost to the midrib, and the outer bracts of the involucre spreading horizontally; γ *lævigatum*, with dull green leaves, deeply pinnatifid with triangular strap-shaped lobes, and the outer bracts loosely adpressed to the involucre; and δ *palustre*, with dull green leaves, having few broad spreading lobes, or almost entire. Var. β prefers a dry sandy soil, and flowers in early summer. Var. δ grows in moist situations and flowers in the beginning of autumn. Those who are interested in knowing more of our common plants, will find useful monthly notes in our excellent contemporary *Science Gossip*, under the heading of "Botanical Work for the Month."

In the *Bulletin de la Société de Pharmacie de Bordeaux*, M. Léon Périer gives an account of the hairs found on the leaves of digitalis. The structure of these hairs enables the microscopist to recognize the leaves of digitalis, even when powdered, from those of henbane, tobacco, aconite, stramonium, hemlock, etc., with the greatest ease, as anyone may find who will take the trouble to compare the hairs of these plants, first in their perfect state and then as found in powdered leaves.

The present number of 'Medicinal Plants' contains figures of *Balsamodendron Myrrha*, *Aloe spicata*, *Roccella tinctoria*, *Cetraria islandica*, *Claviceps purpurea*, *Fucus vesiculosus*, *Chondrus crispus* and *Gracilaria lichenoides*. Much light has been thrown upon the plants producing myrrh and the allied gum-resins mixed with it, by the excellent specimens collected by Mr. Wykeham Perry, and presented to Kew Gardens, where the bissa-bol plant is still growing, although the myrrh plant is unfortunately dead. The authors think that *B. Kafal* will probably turn out to be the plant yielding bissa-bol. Until the specimen at Kew flowers, however, this point cannot be satisfactorily determined. Those who choose to supplement the article on myrrh by the information contained on p. 81 of the current volume of this Journal will be in possession of the most recent contributions to our knowledge of this interesting subject. *Aloe spicata*, the drawing of which is a very characteristic one, has not previously been figured. The authors have followed Mudd in uniting *Roccella phycopsis*, Ach., and *R. tinctoria*, DC., and perhaps rightly so. So far as the writer has observed *R. phycopsis*, Ach., is the only form which occurs in this country, and may be readily distinguished when gathered by the yellowish colour of its point of attachment to the rock; that of *R. fuciformis* and of *R. tinctoria* (at all events in dried specimens) being always white. No notice is taken of *Roccella Montagnei*, Bél., as a plant yielding litmus or archil, although a large quantity arrives in this country for commercial purposes. This species is easily distinguished from *R. fuciformis* by its soft texture. *Variolaria*, which the authors quote, is now not recognized as a genus of lichens. The article on ergot is a remarkably clear and concise *résumé* both of the botany and chemistry of the subject and is brought up to the most recent date. It may interest some readers to know that specimens of all the chemical principles obtained from ergot by Dragendorff, as well as crystallized ergotinine prepared by Tanret, may be seen in the Museum of the Pharmaceutical Society. The drawing of *Fucus vesiculosus* is a remarkably good one. The authors do not agree with Thuret in separating *Fucus platycarpus*, as a species. The two plants, besides differing in the shape of the organs of fructification, and in the latter plant being monœcious, may be seen growing together on the same shore and within a few yards of each other, preserving their distinctive characters.

From the anniversary report of the Royal Botanical Society, Regent's Park, it appears that 540 free students' and artists' tickets, for terms of one to six months each, have been issued during the year, and about 25,000 cut specimens given to the holders, besides which nearly 29,000 specimens of plants have been distributed to the several medical and art schools of the metropolis. The meteorological report of the same society shows that the mean temperature of the first six months of this year was 49·35 against 54·7 last year, and that the rain for the same period was in an excess of 3 inches over that of last year.

From the *Garden* we learn that in Germany nearly every town has its botanical garden for furnishing means of instruction in botany. Berlin has two, the larger of which supplies 120 institutions of learning, including 100 common schools, requiring 3,000,000 specimens. The plants are arranged in bundles and distributed in waggons. The flower described by the teacher is illustrated by a living specimen placed in the hand of each pupil. In a letter to the same journal, a correspondent suggests that the nosegays of flowers sent to hospitals should contain sweet smelling green plants along with the flowers, such as rosemary, lavender and gum cistus, an idea, which at first sight, when considered in connection with the ozone-producing power of some essential oils, would appear to be a very good one. It should not, however, be forgotten that the perfumes of some flowers are apt to cause headache and discomfort in peculiarly susceptible patients.

Most botanists are familiar with the odour possessed by the curious water plant *Chara fœtida*. This odour has recently been attributed to a kind of camphor, which its discoverer, Dr. Phipson,* has called characine. The name is perhaps ill-chosen, since he has obtained the substance also from *Palmella cruenta*, *Oscillaria autumnalis*, *O. tenuis* and *Nostoc*. It is obtained from *Palmella cruenta* (a purplish-red substance, found at the base of damp walls, etc.) by drying it in the air at less than summer heat, then placing it in a covered glass vessel; in thirty-six or more hours the characine forms a film on the water, and the clear decanted liquid is then shaken up with ether. On evaporation the ether leaves the characine as a white greasy substance having a strong marshy odour, lighter than water, and disappearing either by volatilization or oxidation. To this substance the marshy odour of fresh-water algæ in general is attributed by Dr. Phipson.

From the *Boston Journal of Chemistry* we learn that an analysis of a Florida orange gave 23·33 per cent. for the weight of the rind, 2·84 per cent. for the seeds and 73·83 per cent. for the pulp, the free acid in the latter consisting of about equal parts of malic and citric acids.

Reports from the Isle of Réunion state that most

* *Chemical News*, August 22, 1879, p. 86.

of the vanilla plantations there have been destroyed by a frightful cyclone of three days' duration, and that those which have not been destroyed are greatly damaged, so that there will be hardly any harvest this year; consequently, a high price for this article may be expected.

In a recent report on the Government plantations at Adelaide, South Australia, Dr. Schomburgk states that a great demand has arisen in that colony for the *Phytolacca decandra*, which is freely used by homœopaths in the treatment of diphtheria. The parts of the plant official in the Homœopathic Pharmacopœia are the roots and berries.

M. Colin, in the *Revue Hebdomadaire des Sciences*, states that santonin is a complete cure for the obstinate endemic diarrhœa of Cochin China, and that it acts by destroying the anguillulæ by which the disease is occasioned.

"There is no new thing under the sun," is a declaration generally accepted with the reverence due to the wise preacher who uttered it, but it was hardly to have been expected that the noble savage could claim priority of Dr. Maclagan in the use of salicin in the treatment of rheumatism. Nevertheless the special correspondent of the *Medical Times and Gazette* in Zululand relates that having, in the year 1861, prescribed the usual remedies for a Dutch woman suffering severely from rheumatic swellings and pain, and meeting her two months afterwards looking well and hearty, he was about to congratulate her when he was met by the exclamation, "De doktor goot had nict gehelp;" the interpretation of which is, "The doctor's medicine did not help a bit." Upon inquiring what had helped her, she said the old Hottentot shepherd had cured her with a decoction of the tips of willow, which fringe the banks of the Orange river. And yet, had a list of South African drugs, including "willow tips," been published at that time, it would probably not have attracted the least attention.

In a recent number of the *British Medical Journal* complaint is made by a correspondent of the variation in character of commercial euonymin, one specimen which was received from a first class house consisting of brown particles mixed with the greenish particles of euonymin in considerable quantity. The euonymin used by Professor Rutherford and made by a New York firm, did not contain the brown particles. From the description given it would appear as if the euonymin alluded to were a mixture of a watery and spirituous extract in powder. The euonymin prepared by the same process as podophyllin is a very hygroscopic substance and cannot easily be kept in a powdered state. It is time that some of our practical pharmacists should experiment as to the best means of making euonymin in a convenient and active form.

A correspondent of the *British Medical Journal* states that bromide of potassium given in doses of not more than 20 grains is a most valuable remedy for the sickness of pregnancy. Given in conjunction with other agents applicable to the local gastric irritation which may have ensued from the time sickness commenced, he has never found it to fail.

Another writer to the *Lancet* finds that hydrobromic acid in doses of 20 minims is very superior in its action to bromide of potassium in controlling the obstinate sickness arising from ulceration of the stomach.

In the *Louisville Medical News* sulphate of eserine has recently been recommended by Dr. Cheatham as a means of delaying the use of spectacles, so that they are not required for several years, this alkaloid having the power of stimulating the ciliary muscle and thus assisting accommodation. The strength used is one grain of the sulphate of eserine to an ounce of water. One drop of this solution is put in the eye at night or when required.

Professor Ladenberg, of Kiel University, has been studying the artificial production of atropine, and has succeeded in recombining tropic acid and tropine into atropine which is undistinguishable physically, chemically or physiologically from the original alkaloid. Among other interesting discoveries to which his inquiry has led is that of tropine being converted under special treatment with strong hydrochloric acid into a new oily base called tropidine, which bears a singular relation to conine and collidine. Thus, collidine has the formula $C_8H_{11}N$; tropidine $C_8H_{13}N$; and conine $C_8H_{15}N$.

H. Weidel (*Deut. Ch. Ges. Ber.*, xii., 410) has been repeating the experiment of Fleitmann, in the oxidation of berberine by means of nitric acid. Instead of obtaining oxalic acid, as reported by Fleitmann, he obtained a new tribasic nitrogenous acid, which he has named berberonic acid. It is prepared by heating berberine with eight or ten times its weight of nitric acid, concentrating the solution, and purifying the crystalline mass which separates on cooling by recrystallization from boiling water and conversion into a calcium salt. Upon decomposing this with an acid and crystallizing from hot water berberonic acid is obtained in groups of transparent prismatic crystals, sparingly soluble in alcohol and cold water, easily soluble in hot water, and insoluble in ether, benzene and chloroform. Freshly crystallized the composition is represented by the formula $C_8H_6NO_6+2H_2O$, but on exposure to air the crystals lose one molecule of water, and become opaque.

A test to distinguish between tartaric acid and citric acid is published by Cailletet (*Chem. Centralbl.*, 1879, p. 14), based upon the difference in the behaviour of these two acids towards a cold saturated solution of potassium bichromate, tartaric acid assuming a dark brown colour and giving off carbonic anhydride, whilst citric acid is affected only slowly and gives a light brown colour. If 10 c.c. of the potassium dichromate solution be added to a gram of pure citric acid the orange red colour is unaltered at the end of ten minutes; if 5 per cent. of tartaric acid be present a dark brown colour is produced, and if 1 per cent. a coffee-brown tint. Vinegar made from wine, and containing tartrate, may be distinguished by this test from vinegar made from fruit and beer or wood vinigar.

Another soluble albuminate of mercury for hypodermic use has been patented in Germany by a Mr. H. Drees. According to the specification it is prepared by mixing with an alkaline solution of albumen sufficient mercuric acetate to leave neither albumen nor mercury in excess, and removing excess of alkali together with the secondary salts produced in the reaction by dialysis or precipitation with carbonic acid gas and dilute alcohol. Or freshly precipitated mercuric oxide may be added to the alkaline solution of albumen, allowed to digest and the resulting albuminate separated as above. This albuminate is described as soluble in water rendered slightly alkaline by a trace of caustic alkalies, alkaline earths or ammonia.

Much confusion arises from the fact that benzol and benzin are often used as synonymous terms. In some works the name benzin is now applied to a light petroleum product. In the *Archiv der Pharmacie*, it is pointed out that benzol is soluble in one-half to three-quarters its weight of alcohol, while benzin (used in the sense just named) requires six times its weight, so that the two may be thus distinguished.

In the *Chemiker Zeitung*, Maumené states that he considers the best characteristic test for oils is the amount of heat liberated when 10 c.c. of concentrated sulphuric acid are mixed with 50 grams of the oil. The acid is added with a pipette and the mixture stirred with a thermometer. Under these conditions olive oil gives a temperature of 42° C. and linseed 103° C.

In the *Technologiste* it is stated that common rosin prevents the formation of acetic acid in fermented liquids without hindering alcoholic fermentation and the writer suggests that the peculiar effect of the hop may be due to its resinous matter rather than to its essential oil. The custom of using Burgundy pitch in lining beer-casks in Germany is thus evidently not without its value.

The *Lancet*, commenting upon a statement that has appeared in various journals to the effect that arsenic is present in paper collars, etc., states that it has been ascertained by analysis that arsenic is not present, but that the substance used for glazing or facing them is sulphate of baryta.

Mr. C. T. Gage, in *New Remedies* for this month, gives a paper on the structure and adulterations of powdered capsicum, with illustrations of the microscopical appearances of the drug. Out of seventeen samples analysed by him only three proved to be pure and free from adulteration, the chief adulterants being maize, wheat, oat and pea starches, with small quantities of black pepper, mustard and turmeric.

A writer in the *Deutsche Gartner-Zeitung* recalls the fact that a decoction of the stems and leaves of the tomato plant forms a useful insecticide for the greenhouse. He has found that when the decoction is syringed over plants attacked by insects it at once destroys black or green fly, caterpillars, etc., and that it leaves behind a peculiar odour which prevents insects from visiting the plants for a long time.

The *Scientific American*, which never misses an opportunity of extolling the progress of home industries in the United States, says that the manufacture of cream of tartar has so developed there that the imports of it from France have fallen in six years from 6,000,0C0 pounds yearly to none, whilst the price has been reduced from 32 to 24 cents per pound. In like manner the imports of citric acid from England have fallen from 250,000 pounds yearly to 27,000 pounds last year, the price having fallen to about one-half. In the case of borax the relations are even more completely reversed ; for in consequence of the development of the borax mines in Nevada, England now appears as a buyer of crude and refined borax in the United States market, where she used to be the principal seller.

In the *Moniteur Scientifique*, M. Bardy points out that the actual amount of acid contained in glacial acetic acid may be determined by the solubility of oil of turpentine in it. To a known volume of the acid 8 to 10 times its volume of the oil is added and the mixture stirred two or three times. If the mixture remains clear the acid contains 97 to 98 per cent. In order to obtain comparable results the samples operated on should be of the same temperature, 15° C. being most suitable. The author found that the percentage in the fifty-seven samples examined by him varied from 87 to 99·5 per cent.

In the same journal, M. Guyard describes the metal uralium, discovered by him in 1869 in commercial Russian platinum, as being, next to silver, the whitest metal known, and as malleable as platinum, but much more ductile and almost as soft as lead, while it is not volatile and its melting point is near that of platinum. Its sp. gr. is 20·25, its molecular volume 6·25, and its atomic weight 187·25.

The present year indeed promises to be an eventful one in the history of the elements. On the one hand scarcely a month passes without the reported discovery of some new substance to which this term is applied, and, on the other there is an accumulation of evidence that appears to give strength to the doubt whether more than a few, if any, known substances are entitled to that name. Some most interesting speculations have been put forward by Professor Victor Meyer in a lecture delivered at Zurich last month, based upon results obtained whilst working out the determination of the vapour densities of various bodies by the process invented by himself and Herr Carl Meyer, and described in this Journal last May (vol. ix., p. 936). At a temperature of about 1567° C., results were obtained indicating that the molecular constitution of mercury, oxygen, nitrogen and sulphur is correctly indicated by the formulæ usually adopted—Hg, O_2, N_2, and S_2. But it has been found that at this temperature the vapour density of chlorine is only two-thirds of what it is at 620° C., and that at 808° C. some kind of dissociation commences which becomes and remained constant at 1567°. Professor Meyer appears to think that the chlorine molecule as at present understood, having the molecular value of 70·4, must therefore contain at least six atoms of a hypothetic body, having the atomic weight of 11·4, and probably trivalent, and to this the name chlorogene is given ; the hypothetic atom of iodine is similarly named iogene. Mr. Watson Smith, in reporting this lecture to the *Chemical News* (Aug. 1), remarks that these results, considered in connection with the relationship between chlorine, bromine and iodine, and sulphur, selenium and tellurium, as to melting and boiling points, calculated from absolute zero, observed by Dr. Carnelly nd Mr. W. C. Williams (*Pharm. Journ.* [3], ix., 1066), suggests the probability that all these "so-called elements contain one and the same essence and will ultimately be decomposed so as to yield this essence common to all six."

But this is not all. Professor Meyer has proceeded to a practical investigation as to the constituents of chlorine, and following the hint of Berzelius, who looked upon chlorine as an oxygen compound, has tried to ascertain how far this opinion was based upon fact. After conducting his experiments with the utmost precaution, so as to eliminate causes of error as far as possible, he has arrived at the conclusion that "to all appearance" by heating chlorine oxygen is obtained. The theory put forward is that two atoms of oxygen exist combined with two atoms of a univalent body, to which the name "murium" is applied, and that at a high temperature this combination is broken up, half the oxygen being set free. Dr. Armstrong, writing upon this subject in *Nature* (Aug. 14), says that some results obtained by Mr. Norman Lockyer in the spectroscopic investigation of the non-metals are confirmatory of Professor Meyer's discovery, and that Mr. Lockyer has shown him that "with the spark at a particular tension the red line of oxygen is one of the most prominent lines in the spectrum of chlorine the freedom of which from admixed air is attested by the absence of the characteristic nitrogen and hydrogen lines."

In a letter to the *Chemical News* Mr. J. Gibbons suggests that the peculiar spectra sometimes observed in lightning may be due to metals with which the lightning comes into contact and that the instrumental observation of the spectroscopic character and direction of the lightning, with the interval of flash and report, would be sufficient to determine the character and situation of exposed metalliferous deposits in unexplored districts.

The veteran chemist, Chevreul, whose name is associated with researches on fats and fatty acids, although now in his ninety-third year, began his usual course of lectures on organic chemistry at the Museum of Natural History at Paris a short time since.

Mr. Holloway appears to be bent upon the perpetuation of his name as a benefactor of his species in more than one direction. According to *Nature* he has purchased and vested in trustees ninety-five acres of land at Egham, upon which he intends to erect a building for a college, the object and scope of which is to be to afford the best education suitable for women of the upper and upper middle classes. The contract for the building of the college within four years has been signed, the price being upwards of £250,000, exclusive of fittings. It is the founder's desire that power for the college to confer degrees should be sought at some future time, but that meanwhile students should qualify themselves to pass the women's examination of the London University. "Denominational theology" is not to be taught, and, instead of being regulated by the "traditions and methods of former ages," the system of education is to be mainly based upon studies and sciences which the experience of modern times has shown to be most valuable and best adapted for the intellectual and social requirements of the students. Mr. Holloway has also agreed to provide an endowment fund of £100,000, in addition to such proceeds as may be derived from the sale of any portion of the land not required for the purposes of the College.

It must be apparent from the continuous flow of inquiry that increased attention is being directed to these columns devoted to the difficulties which beset dispensers. The questions generally exhibit a very imperfect acquaintance even with prescriptions possessing no special characters, others refer to incompatibilities which must have escaped the observation of the writer, and some have reference to obscure preparations, the formulæ for which have never been published; but there are those also which indicate that sufficient attention is not paid to the information supplied by correspondents, and recorded continuously in the Journal. This latter is to be regretted as repetition occupies valuable space, and should, unless in quite exceptional instances be unnecessary.

The first question in the series refers to the result of a mixture of Donovan's solution with liq. hyd. perchlor. in No. 331. Immediately on the addition being made there is a decomposition with a copious separation, and ultimately a deposit of red iodide of mercury, which settles at the bottom, the supernatant liquid being pinky-white; the addition of a little iodide of potassium would render the mixture transparent, but, of course, this liberty cannot be taken with a prescription. The mixture is an inelegant one, and most probably the writer was not aware of the result of mixing liq. hyd. perch. with liq. arsen. et hydrarg. hydriod. (Donovan's solution), an already delicately balanced compound.

Gelatine is not suitable as a vehicle for tannin in pessaries or suppositories, as in No. 332. A decomposition occurs with the formation of tannate of gelatine, and the otherwise gelatinous vehicle breaks down in the preparation. In those instances where medical men require a gelatine vehicle it would be better that they left the most suitable relative proportions of the ingredients for that vehicle to the dispenser. It is usual to keep a gelatine medium ready prepared in proper proportions, and on liquefying this for the addition of the of the medicament, the pessaries are moulded in the usual manner. The usual vehicles for pessaries and suppositories are cacao butter or some such substance as a basis, on the one hand, and gelatine on the other, and it will be better for the prescriber to specify one or other of these, leaving the relative proportions to the dispenser, the writer of the prescription proportioning only the medicament. Very rarely do medical men give suitable proportions for the vehicle desired. The same may be said of pill masses. A dispenser is often at his wit's end in too literally interpreting the excipient and its quantity ordered in a prescription. The ingredients being written, those minor details, in fact, the mode of combining those ingredients so as to form a pill mass, may well be left to the practical experience of the dispenser.

The query No. 333 refers to ext. belæ liq. Made according to the formula in the B.P. the result may be termed a dark brown syrupy liquid, which on standing deposits, the supernatant liquid being clear, and the portion containing the deposited matter opaque. It will be obvious from these remarks that the appearance of the ext. belæ liq. will much depend on the time it has been allowed to stand subsequent to its preparation. The addition of spirit will also necessarily cause a separation of some of the constituents of the bael, which on standing deposits. The Pharmacopœia does not direct it to be filtered. It is presumable, therefore, that the ext. belæ liq. should be shaken each time that the prescription is dispensed, as the separated portion is not inert matter. If reference be made to the ext. ergot. liq. the distinction will be at once apparent. In that preparation the spirit is added to coagulate albumenoid matter, and then, after the addition of spirit, the liquid is directed to be filtered; but the spirit in the ext. belæ is more as a preservative than for the purposes of coagulation, though at the same time it probably promotes a subsidence of some of the proximate constituents of the bael, which forms an integral part of the finished preparation.

The recipe No. 334 is very likely one of those sometimes met with by the dispenser. In its present condition it is not complete, and it would not be judicious or safe to put calomel into such a mixture to be taken three times a day. It is scarcely possible that such a formula could emanate from a duly qualified medical practitioner. The usual method of mixing copaiba is to emulsify that substance by trituration with mucilage in a mortar, and gradually adding the other ingredients. In the presence of such a powerful agent as calomel, the dispenser, having no medical qualification, would not be justified in determining any proportion as a suitable addition to the other ingredients of the mixture.

There is no formula for emp. iodin. in the B.P.; but dispensers have facilities afforded them of referring to other works for their guidance in similar difficulties. One that is frequently found useful is Squire's 'Pharmacopœias of London Hospitals,' and again an extremely valuable little work, and one kept abreast of the time, is Beasley's 'Pocket Formulary.' When a preparation met with in a prescription is absent in the B.P., and therefore unofficial, every dispenser is not bound to go to the same source to supply the deficiency; one may take a formula from Beasley, another from a foreign pharmacopœia, and a third from a hospital pharmacopœia. This may account for the emp. iodinii as sent out by different establishments not being of the same colour. It must clearly be annoying to a dispenser to be told that he does not know his business; but if his reading be so limited that he stands aghast in the presence of such a small difficulty, he must expect some such a remark, and should profit by the hint. The formula for emp. iodinii in Beasley is given by "Gulielmus."

The formula for pomade, No. 336, corresponds with similar preparations which have been intended for promoting the growth of the hair.

There being no official preparation of dialysed iron, difficulties are very likely to occur with liquors of different makers. The strength generally accepted as suitable is a liquor containing 5 per cent. of oxide of iron. Should it ever become official, probably a strength equivalent to that of the tr. ferri perchlor., containing about 6 per cent. oxide would for the sake of uniformity be better. The prescription No. 337 is readily made, and does not separate or deposit, but forms a clear transparent mixture, which keeps well without apparent change. If the medical profession consider dialysed iron a remedial agent, having a therapeutic value, or some merit not possessed by other preparations of iron, which now occupy a place in the British Pharmacopœia, the sooner a definite strength be determined on the better, that is that it should contain a definite quantity of oxide of iron, and probably a liquor of the same strength as the tinct. ferri perchlor. would be the best that could be adopted. Advertised medicinal preparations of unknown strength should be discountenanced, and their places supplied by preparations of definite strength.

On this subject some remarks taken from a report on the progress of pharmacy, by Mr. C. L. Diehl, may be quoted here. He considers it under two heads: "The progress that is secured by research and by the furtherance of educational facilities," and, secondly, "The progress that is made by the discouragement of empiricism, and the establishment of a proper ethical and professional standard." The first need not be considered here; with regard to the second, he says:—"Pharmaceutic progress, as embraced under the second head, however, is not so satisfactory. The relations of pharmacists to the public, to each other, and to physicians, leave much to be desired, and instead of being progressive, appear rather to tend in the opposite direction. The demand of the public for cheap goods, the variety demanded, competition, the profuse supply of 'ready made' pharmaceuticals, and the disposition of physicians to prescribe medicines of a questionable composition or proprietary character, all have a tendency to reduce pharmacists to the condition of mere tradesmen, and to discourage those having higher aims."

CAVIAR.*

This substance, which is considered a great delicacy by gourmands, is the prepared roe of the sturgeon and has its origin in Russia. This roe differs materially from that of other fish, in being of a large size and very thin skinned, containing only an oily jelly which melts away in the mouth, leaving little or no residuum, and these are held together by a network of cellular tissue, fat and muscle in large masses, which generally exceed in size the head of the largest man.

A net of very small mesh, spread over a frame, does duty as a kind of coarse sieve, and the roes being lightly pressed and kneaded over this, the eggs are detached and fall into wooden tubs placed below, each grain being of a very dark brown or black colour, and utterly distinct from the others.

To make "grained caviar" the eggs are now sprinkled with salt ground very fine, of which from 3 to 5 pounds to thirty-six of eggs are used in the hotter months, while only $1\frac{3}{4}$ to $2\frac{1}{2}$ pounds are sufficient in cold weather, the least possible quantity of salt being a great desideratum. A wooden fork with from eight to ten prongs is used to stir in the salt, and the eggs become first doughy, then swell, and finally give out a noise like the stirring of small scales of glass, a sure proof that the process is completed, after which the caviar is close packed in hard-wood kegs.

In making "grain caviar" the eggs fall into tubs of brine stirred as before, and in lots of about one hundred-weight subjected to heavy pressure in coarse sacks, until the brine is expelled and the whole compressed into a cheesy mass.

Nearly one-third of the contents of the eggs are pressed out with the brine, and the caviar thus made is packed in large casks lined with napkin linen, from whence it is called *caviar à la serviette*, or "napkin caviar." *Caviar à sac*, as its name denotes, is choice pressed caviar, put up in linen sacks, and other choice preparations are shipped in hermetically sealed cans and boxes.

The fattest caviar, made in midsummer, is merely soaked in brine and packed, without pressing, in casks holding from 180 to 360 lbs. each. Much roe which is tender to the touch and half spoiled is soaked in very strong brine, packed in large casks holding from 900 to 1000 pounds, and is worth only from six to eight cents per pound, while the fat summer caviar brings from twelve to eighteen cents.

The choice kinds of fresh caviar packed in small kegs costs in Astrachan from sixty to seventy cents per pound, while the pressed brings but about forty-five to forty-eight cents; that of the "sterliad" and some especially choice makes are never exported.

Nearly 400,000 pounds are annually sent from Astrachan to Berlin, Dresden and Vienna, and England uses nearly 10,000 dollars worth yearly, but in the United States little is used except by foreigners, who have contracted a taste for it elsewhere.

THE USE AND ABUSE OF EXAMINATIONS.

THE leading journal has within the last few days directed attention to some of the evils of the examination system, and it has done good service by insisting upon the mischief likely to arise from the modern tendency to make examinations the sole test and crown of all processes of education. We quite agree with the opinion that this tendency entirely distorts every rational view of what education is and should be. But this is a result attributable more to the circumstance that too much faith has been placed in the virtue of examinations than to the absolute worthlessness of examinations as a test of merit, capacity and attainment; it is a result of the misuse of examinations that has led students to look upon the passing of them as being of more importance than the acquisition of sound khowledge, that has led teachers to devote their energies to the production of manuals by which superficial proficiency can be readily acquired, and candidates enabled to pass the ordeal of examination without its being really that test of educational training that it was designed to be.

From this point of view there is no doubt much reason to fear that however good examination may be when properly used, we are exposed to the possibility of having too much of a good thing, and as the *Times* remarks very many competent judges are already beginning to dread an educational surfeit in this respect. The exaggerated application of the examination system has not operated as a stimulus to sound and thorough education, but has rather called into existence and created a demand for facilities for passing examinations without undergoing the preparatory educational labour necessary for acquiring a proficiency in the subjects. In this way the pupil has been made a mere racer and one who contends for heavy pecuniary stakes, while the teacher is made a trainer whose whole prosperity depends, not on his power of imparting sound knowledge and drawing out the natural capacities of the mind, but on his skill in preparing his pupils for a particular examination. At the same time there is a tendency to make the examiner a judge not of mental capacity and general sound information, but of those qualities alone which are readily estimated in marks.

These results are undoubted evils, and there are others not much less serious which justify the question put by the *Times* as to whether it is not possible that, as so often happens, we have confounded ends with means and made a successful examination the paramount purpose instead of merely the indispensable test of educational training? But while admitting the existence of these we cannot share the opinion that the blame is entirely to be thrown upon examination. What in our opinion is needful as a remedy is not the abandonment of the examination system which some would recommend, but some means of reducing the exaggerated importance that has been attached to the passing of an examination.

In many cases examinations are necessary as rough tests of required attainments, and where they are to be tested for some specific purpose it is indeed scarcely possible to dispense with examinations altogether, but even then they should not be placed higher than the category of necessary evils.

Another remedy for the mischievous influence of the examination system in limiting and restricting sound education is by some believed to be attainable by the establishment of a compulsory curriculum, but we are far from sharing the opinion that such a plan would be effectual. At the best it would only furnish a guarantee that the student had enjoyed the opportunity of having the requisite education, but it would fail altogether to give assurance that he had made proper use of that opportunity. As regards this most important point we think that no real good would result from having recourse to the teacher's testimony as to the assiduity of his pupils in attending lectures, etc. It would be merely substituting for the fallacious evidence of success in examination, the equally fallacious evidence of formal compliance with the requirements of a curriculum. Neither is in itself sufficient to prove that the pupil has been properly educated.

To take the case of pharmaceutical education, involving as it does the acquisition of a sound knowledge of several branches of science and a practical training in their application to special objects, we are altogether averse to the establishment of a scholastic curriculum, because we do not believe it would ensure the education that is required. It is in the training of the apprentice in the shop that the proper curriculum of the pharmacist is to be sought for, and as the improvement in the practice of pharmacy in this country advances and becomes more general, it may be hoped that it will be found there more frequently than has been the case.

In many cases the nature of a chemist and druggist's business is not such as to afford apprentices much opportunity of studying science, but the deficiency in this respect might be largely compensated for by the local schools connected with provincial societies, and it is to be regretted that hitherto these provisions for the instruction of apprentices have not been more zealously taken advantage of.

VERIFICATION OF WEIGHTS IN NEW YORK.

It is a little curious that whilst pharmacists in Great Britain have recently been under some anxiety as to the course that would be adopted by the State in respect to the verification of their weights and measures, their brethren in New York have had a similar experience. Some time ago, it was mentioned in this Journal that a Bill had been introduced into the Legislature of the State of New York, providing for the appointment of an Inspector of Apothecaries' Weights, the amount of whose salary would have depended upon the number of penalties he succeeded in levying from persons whose weights he pronounced incorrect, although no provision was made that he himself should possess verified standard weights for use in the testing. The strong remonstrances of a committee of the New York College of Pharmacy procured the withdrawal of the Bill, upon a promise that the College would take the matter in hand and establish a bureau for the examination of apothecaries' weights, to be placed under the authority and control of the Board of Pharmacy for the city and county of New York.

The arrangements for carrying this promise into effect having now been completed, and special balances and sets of troy and decimal weights, which have been verified by the United States Standards, having been provided, the New York College has sent out an appeal to all apothecaries, whether members or not, to help in carrying out its plan as aiming at a "wise and conscientious self-government." It is proposed to deal with the weights first, leaving the measures untouched for the present. These the College offers to examine upon application of the owner, and to stamp as correct if found either absolutely identical with the standard or heavier up to a certain limit; if at all lighter or if heavier beyond the specified limit, they will be returned unstamped, and it is recommended that such weights should be at once destroyed. The limit of excess, as established for decimal weights ranges from not more than 0·200 gram in the 1000 grams or 1 kilo weight to not over 0·00025 gram in the 0·1 gram and lesser weights. In the troy weights the limit of excess ranges from not exceeding 1 grain in the 12 ounce weight to not over 0·01 grain in the $\frac{1}{4}$ grain weight.

The charge for examining weights, including the stamping of those found correct, is only five cents for each weight. The stamp of verification adopted consists of a monogram of the letters CP, and it will be noticed that it is proposed to apply it to weights so small as to be generally supposed to present almost insuperable difficulties in stamping them. Indeed the College offers to supply "correct and stamped sets of weights" of the decimal and troy systems reaching down to 1 milligram and $\frac{1}{100}$ of a grain respectively. If this offer is to be understood literally the method of carrying it out would probably not be devoid of interest to the Board of Trade officials in this country just at the present moment.

Provincial Transactions.

LEICESTER CHEMISTS AND DRUGGISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The first meeting of the twenty-second session of the Leicester Chemists' Assistants and Apprentices' Association was held at the Rooms, Halford Street, on Tuesday evening, August 12.

The proceedings of the evening were commenced by a tea, to which a good number of members sat down.

After tea the newly elected President, Mr. J. J. Edwards, delivered an inaugural address, and in commencing referred to the necessity for individual effort and advised each member to attend regularly, to put his shoulder to the wheel, and to do all in his power to make the Association a success. Referring to past members of the Association who had passed their examinations, he stated that many of them had acknowledged the valuable aid they had received from the Association. Referring to the question what to read, the President said it was much more difficult to know how to read, so as not to follow the example of some, "who, like sponges, return all they read in about the same condition, only a little dirtier;" nor of others, "who, like strain bags, merely retain the dregs of what they read." In concluding, the President reminded the members that not only was talent necessary to make a successful pharmacist, but it was imperative that there should be tact in conjunction with talent, for whilst "talent knows how to do it, tact does it;" whilst "knowledge is the treasury of the world, tact is the key to it;" and whilst "talent beats about the bush, tact catches the bird."

The President announced that during the forthcoming session several lectures on subjects connected with pharmacy would be delivered by gentlemen of repute.

Some remarks by Mr. W. B. Clark and Mr. Thirlby brought a very pleasant evening to a close.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The reading of papers was then proceeded with.

The first paper was a—

Report on the Aconite Alkaloids.

BY C. R. ALDER WRIGHT, D.SC. (LOND.).

Lecturer on Chemistry in St. Mary's Hospital Medical School.

§ 1.—*Alkaloids of Japanese Aconite Roots.*

In the report presented last year there were briefly described some preliminary results obtained in the examination of Japanese aconite roots. Since that date, several batches of roots have been examined with perfectly uniform results; as the numerical and other data on which these results are founded have been already published in the *Journal of the Chemical Society* (July, 1879, p. 387), it will be unnecessary to quote them here at full length.

The first batch (about $14\frac{1}{2}$ kilos of ground roots obtained from Messrs. Wright, Layman and Umney) was worked up by the reporter and Mr. A. P. Luff, by percolating with alcohol acidulated with tartaric acid (1 part of acid per 100 of roots being used in all). The percolate was condensed to a small bulk by distillation, treated with water, filtered from precipitated resin, rendered alkaline with carbonate of soda and repeatedly shaken with ether, the ethereal solution being subsequently shaken with tartaric acid. The acid tartrate solution thus obtained free from resinous matters was then treated with soda and ether; on spontaneous evaporation a copious crop of crystals was obtained, together with a quantity of varnish-like alkaloidal matters that would neither crystallize nor yield crystalline salts.

The total yield of alkaloids from this batch was as follows:—

Soluble in ether	crystallizable	about 12 grams	= 0·08 per cent.
	non-crystalline	„ 25 „	= 0·17 „
		37	0·25
Insoluble in ether	non-crystalline	„ 20 „	= 0·14 „
Total		57	0·39

The alkaloids insoluble in ether were separated by precipitating as mercuriodide, and decomposing the precipitate by sulphuretted hydrogen; they appeared to be mainly identical with the non-crystalline alkaloid that was dissolved out by ether, being prevented from complete solution in ether by the solvent action of the soda liquors, just as is often the case with alkaline solutions of alkaloids, *e.g.*, morphine and caustic potash, cotarnine and sodium carbonate.

The non-crystalline alkaloids appeared, like the similar bodies obtained by analogous means from *A. Napellus* and *A. ferox*, to contain a higher percentage of carbon than the crystallizable base, and to possess a lower molecular weight; on saponification with caustic potash, they yielded benzoic acid to nearly the same extent as the crystallizable base, whence it is probable that the two bodies are closely related.

The second batch of roots examined was worked up by Messrs. Hopkin and Williams in precisely the same way as the first, about a hundredweight of roots being employed. From the rough alkaloids extracted by ether, etc., and sent to the reporter for examination, about 60 per cent. was isolated as crystallizable base, and 40 as non-crystalline alkaloid.

These two quantities of crystallizable base were purified by recrystallization, conversion into crystallized salts (the nitrate and hydrobromide being selected), and regeneration by soda and ether. By fractional crystallization of the different portions, attempts were made to separate the crystals into two or more portions differing from one another. No success whatever attended these efforts; in every case absolutely identical analytical numbers were yielded by the several fractions; the melting point and general properties also were invariably the same, whence it results that only one alkaloid can be supposed to be present.

The numbers obtained agreed closely with those required for the formula, $C_{66}H_{88}N_2O_{11}$, and with no other. On heating the base with strong tartaric acid solution to 100° for several hours no change whatever was brought about in its composition (aconitine and pseudaconitine become dehydrated to apo-derivatives by this treatment).

From this circumstance it appears likely that the crystallized base was already as far dehydrated as possible, either by the effect of the tartaric acid in the alcohol used for extraction or by the heat alone. Accordingly, a third batch of roots was worked up, alcohol *not acidulated at all* being employed; one hundredweight of roots was thus treated by Messrs. Hopkin and Williams, and the condensed percolate sent to the reporter, who examined it (in conjunction with Mr. A. E. Menke) as before, *i.e.*, by treating with water, filtering, adding alkali and ether, etc.

The crystallizable alkaloid obtained from this batch amounted to about 50 grams or 0·10 per cent., the non-crystalline bases dissolved by ether being about 55 grams = 0·11 per cent. No difference whatever could be detected between the crystallized base thus obtained and the former samples, showing that if dehydration took place at all during extraction, it was brought about by the heat alone conjoined with the natural acids of the roots (the alcoholic extract was distinctly acid to test-paper). It is noticeable that the spent marc obtained in this process was percolated again by alcohol acidulated with sulphuric acid (about 30 grains of concentrated acid per gallon). This percolate, after condensation, was found to contain only between 2 and 3 grams of alkaloidal matter, of which half was non-crystalline, the other half crystallizable and identical with that above described; so that *treatment with alcohol alone unacidulated by any acid at all, extracted practically all the alkaloids present in the roots examined.*

On examining the action of benzoic anhydride on the crystallized alkaloid thus obtained, it was found to be different from that occurring with aconitine and pseudaconitine, inasmuch as *three* additional benzoyl radicals were thus introduced into the alkaloid per C_{33} present instead of one only. On treating the crystallized alkaloid with alcoholic potash, saponification ensued, benzoic acid being produced, and a new base very closely resembling aconine being formed. The following equations represent the actions of the benzoic anhydride and caustic potash:—

$$C_{66}H_{88}N_2O_{21} + 3(C_7H_5O)O = 2C_7H_6O_2 + (C_{26}H_{39}NO_7)(O.C_7H_5O)_4$$

$$C_{66}H_{88}N_2O_{21} + 3H_2O = 2C_7H_6O_2 + 2C_{26}H_{40}NO_{10}$$

These results may be conveniently represented, in harmony with the formulæ arrived at in the previous researches on aconitine and pseudaconitine, by supposing that the roots originally contain an alkaloid $C_{33}H_{47}NO_{12}$ differing from aconitine by containing H_4 more; and that this hypothetical parent base loses $1\frac{1}{2}$ molecules of water, producing the crystallized base above described, thus:—

Hypothetical Parent Base.

$$\left(C_{26}H_{39}NO_7\right)\begin{cases} /\,O.C_7H_5O. \\ -\,O.H. \\ -\,O.H. \\ \backslash\,O.H. \end{cases}$$

Crystallized Base above described.

$$\begin{array}{l} \left(C_{26}H_{39}NO_7\right)\begin{matrix} -\,O.C_7H_5O. \\ =O. \end{matrix} \\ \quad | \\ \quad O \\ \quad | \\ \left(C_{26}H_{39}NO_7\right)\begin{matrix} =O. \\ -\,O.C_7H_5O. \end{matrix} \end{array}$$

Product of the Action of Caustic Potash.

$$\left(C_{26}H_{39}NO_7\right)\begin{cases} /\,O.H. \\ =O. \\ \backslash\,O.H. \end{cases}$$

Product of Action of Benzoic Anhydride.

$$\left(C_{26}H_{39}NO_7\right)\begin{cases} /\,O.C_7H_5O. \\ -\,O.C_7H_5O. \\ -\,O.C_7H_5O. \\ \backslash\,O.C_7H_5O. \end{cases}$$

Aconitine.

$$\left(C_{26}H_{35}NO_7\right)\begin{cases} /\,O.C_7H_5O. \\ -\,O.H. \\ -\,O.H. \\ \backslash\,O.H. \end{cases}$$

Apoaconitine.

$$\left(C_{26}H_{35}NO_7\right)\begin{cases} /\,O.C_7H_5O. \\ -\,O.H. \\ \backslash\backslash\,O. \end{cases}$$

Apoaconine.

$$\left(C_{26}H_{35}NO_7\right)\begin{cases} /\,OH. \\ =O. \\ \backslash\,OH. \end{cases}$$

Dibenzoylapoaconine.

$$\left(C_{26}H_{35}NO_7\right)\begin{cases} /\,O.C_7H_5O. \\ =O. \\ \backslash\,O.C_7H_5O. \end{cases}$$

As above stated, attempts to isolate this hypothetical parent base in an unaltered state did not succeed; to avoid confusion it is proposed, for the present at any rate, to designate the crystallized base, $C_{66}H_{88}N_2O_{21}$, above described, as *japaconitine*, and the product of the action of potash upon it as *japaconine*. It is noticeable that the same tetrabenzoylated derivative is obtained when benzoic anhydride acts on japaconine as is formed with japaconitine itself.

Japaconitine and japaconine respectively resemble aconitine and aconine so closely that, saving by actual combustion or studying the effects of benzoic anhydride upon them, it is practically impossible to distinguish the one from the other. Japaconitine melts at 184° to 186° when purified as far as possible, the purest aconitine tested side by side melting at 183°–184°. In physiological action the two are very closely allied, if not identical, so far as the involuntary observations made whilst working with them go. Dr. Fraser, of Edinburgh, is now investigating the two bases and their derivatives in these respects.

Inasmuch as Japanese aconite roots appear to be considerably richer in crystallizable base than *A. napellus* roots, it is evident that this class of roots is likely to be in future a valuable source of active alkaloid; further, it is evident from the above experiments that in working out the active constituents of roots of the kind, it is not necessary to acidulate the alcohol used, whereby chance of alteration during extraction is diminished.

On contrasting the results above described with those obtained two years ago ('Year-Book of Pharmacy,' 1877, 469) by Paul and Kingzett, it is open to some doubt as to whether the body obtained by those gentlemen was actually japaconitine; their analytical numbers are quite compatible with their body being either japaconitine or pseudaconitine. On the one hand, they failed to obtain any crystallized salts from their alkaloid, whilst japaconitine yields a well crystallized nitrate, hydrobromide and hydrochloride with ease, pseudaconitine only yielding a crystallized nitrate by employing a particular mode of manipulation unknown at the time Paul and Kingzett's experiments were made; this would seem to indicate, as suggested at the time by the reporter, that the base examined by them was simply pseudaconitine. On the other hand, Paul and Kingzett found that their base showed much greater tendency to crystallize than pseudaconitine, and on boiling with dilute sulphuric acid it furnished a liquid capable of reducing Fehling's solution. Whilst japaconine, like aconine, reduces Fehling's solution pseudaconine does not do so; whence these circumstances would tend to indicate that the base isolated by Paul and Kingzett was actually japaconitine; a conclusion also in harmony with the fact that only japaconitine and *no other crystallizable alkaloid of any kind* was obtained from each of three different batches of roots examined by the reporter.

§ 2.—*Alkaloids of Atis Roots* (*A. heterophyllum*).

Through the kindness of Mr. E. M. Holmes, the reporter was enabled to examine the alkaloidal constituents of some 2 pounds of these roots. By percolating the coarsely powdered dry roots with alcohol containing a little tartaric acid, and evaporating the percolate, a condensed liquid was obtained containing scarcely any resin; by adding water, filtering, and shaking with ether after rendering alkaline, a small quantity of an alkaloid was extracted. This agreed very well with the description given by Broughton of *Atisine*; it was uncrystallizable but yielded a crystalline readily soluble hydrodichloride; its taste was intensely bitter without the slightest tendency to produce the tingling characteristic of the active aconite alkaloids. The quantity obtained was not quite so much as a gram (less than 0·1 per cent.), wherefore its purification was impossible, and still more was it impracticable to find out if it was a mixture of alkaloids. The following numbers were obtained on analysis of the gold salt, which formed a yellow flocculent precipitate almost insoluble in cold water. The substance examined was dried by standing several days over sulphuric acid; at 100° it fused, losing in weight and becoming apparently partially decomposed.

0·3710 gram gave 0·5175 CO_2 and 0·170 H_2O.

0·4565 gram burnt with soda lime gave 0·00882 nitrogen by titration, 0·070 Pt. by platinum salt.

0·3970 gram gave 0·1140 Au.

These numbers are close to those required for the formula, $C_{22}H_{31}NO_2$, HCl, $AuCl_3$.

	Calculated.	Found.
Carbon	38·82	38·04
Hydrogen	4·71	5·09
Nitrogen	2·06	1·93, 2·17
Gold	28·82	28·72

Broughton deduced from his analysis of his platinum salt the formula, $C_{46}H_{74}N_2O_5$, which requires, carbon = 39·09, hydrogen = 5·38, nitrogen = 1·98, gold = 27·76, assuming the gold salt to be $C_{46}H_{74}N_2O_5$, 2HCl, $2AuCl_3$. It cannot, however, be concluded with certainty from the above experiments that his formula requires modification owing to the minute quantity examined. *A priori* the formula, $C_{22}H_{31}NO_2$, seems somewhat more probable than his di-nitrogenous one. The alkaline fluid from which ether had extracted this base still contained a small quantity of alkaloid permanently dissolved; on slightly acidulating with acetic acid and addition of potassium mercuriodide, a dirty yellow precipitate was thrown down.

After washing and drying over sulphuric acid—

0·432 gram gave 0·321, Ag I, iodine = 40·16.

The formula, $C_{22}H_{31}NO_2$, HI, HgI_2, would require 41·19, whence it is very probable that the base dissolved by the soda was mainly the same as that dissolved out by the ether.

§ 3.—*Alkaloids of the Flowers, Leaves and Stalk of Aconite.*

In order to examine the nature of the alkaloids present in the aconite herbs (distinct from the roots), it was found to be necessary to wait until the present spring for fresh material. Messrs. Wright, Layman and Umney obligingly undertook to prepare the raw material, and ultimately succeeded in obtaining 300 pounds of fresh aconite herb grown at Foxton, Cambridgeshire. This was crushed under granite millstones, and the pulpy mass digested with 30 gallons altogether of methylated spirit of about 90 per cent. alcohol at the ordinary temperature for seven days, no acid of any kind being added; as much of the tincture as could be removed by draining was so recovered, and the marc pressed in cocoa fibre bags ultimately with a pressure of 1 ton to the square inch. The total tincture was then filtered and distilled in four portions, so as to expose to heat for as short a time as possible; the residues were not completely freed from alcohol by heat for the same reason; they were united and exposed to the air in shallow pans for a night to facilitate removal of some of the remaining alcohol, and then sent to the reporter as a brown aqueous fluid smelling somewhat agreeably, not unlike treacle, the total quantity being about 59 pounds.

This material was thus worked up by adding soda and repeatedly shaking with ether, the ethereal solution being shaken with tartaric acid, and then used over again. From the acid tartrates thus formed, there was obtained by shaking with soda and ether an ethereal solution which did not crystallize on quick evaporation in a watch glass. These operations having only been performed within the last few days, and the reporter being on the point of leaving town, it is impossible to report to the Conference, at this meeting, what is the nature of the alkaloids present. Judging from the comparative absence of inconvenience experienced in working out the crude alkaloid, the amount of active bases present is not large; the ethereal solution finally obtained is being abandoned to spontaneous evaporation in the hope that crystallizable bases will separate.

The author of the paper was not present, and it was read by Professor Attfield.

The PRESIDENT observed that Dr. Wright had given this subject very great attention, and had, in this last paper, arrived at much more definite conclusions.

Mr. J. WILLIAMS (London) said the most important point in Dr. Wright's investigation appeared to be the fact that he had now proved that it was no longer necessary to use acid in the preparation of aconitine, and it was proved pretty clearly that the use of acid was to be avoided. This was not known a year ago and therefore he thought the investigation was of great practical value. He had taken practical advantage already in a working sense of this discovery, and finding that it was really true that acid was not required, he might say that they as pharmacists had been benefited by an amount of knowledge they had not previously possessed. With regard to the recent aconite plant he thought it was a very interesting portion of the research, and he was surprised that no more distinct result had been obtained. He thought it went to prove that the process of separating the alkaloid to be adopted would have to be rather different to get a satisfactory result. The process of merely shaking up with ether and carbonate of soda would fail in extracting the alkaloid out of such a large bulk. The quantity of recent plant used he should have thought must have contained a large amount of alkaloid, although not so much as in the root. The plant was of a highly poisonous character, for their knowledge of the poisonous nature of aconite was not derived from the root, but the plant itself. It would have been satisfactory if Dr. Wright had been able to isolate and show them the alkaloid of the plant, and he trusted further investigation would enable him to do so.

Mr. UMNEY (London) said the great thing that had militated against Dr. Wright in his observations on the aconite plant was time. Dr. Wright had only had the extract three weeks, and he hoped they might hear something further from him on the matter. He was glad to find the deductions he had obtained from his chemical experiments confirmed what they knew, that Japanese aconite was of excellent quality. In London large quantities had been put in the market and used almost exclusively in pharmacy, and there could be no question that it was a more powerful drug than that grown in Germany and England.

Mr. GREENISH (London) was anxious to know what kind of aconite Dr. Wright had used, for the broad term "Japanese aconite" was not very definite. It was well known that in Japan there were at least three species of aconite. He had examined many samples of Japanese aconite, and had found at least two kinds continually mixed together, one root had a round, turnip shape, as described by Hanbury in 'Science Papers,' and the other root was more tapering. They were evidently to his mind distinct roots. It must leave Dr. Wright's experiments in an uncertain condition until he made them from one species of aconite. These two roots mixed together in the Japanese aconite differed in character when sections were made from them. He had submitted one to Professor Flückiger, who was of opinion that Japanese aconite was not from the same species as that which was imported from Germany, the produce of *Aconitum Napellus*. In course of time it might be ascertained from what aconites these roots were produced, and it was desirable that experiments should be made on the different roots, of which there were certainly two kinds, separately. Schroff had made experiments on aconite leaves, and had arrived at the conclusion that they contained but a very small portion of the alkaloid, even if they contained any.

Prof ssor ATTFIELD said the remarks made by Mr. Greenish were valuable, and members would like to know if he could suggest any method by which the experiments could be made on one species, and not on two or three different kinds. Unless some remedy were found he feared they must take Dr. Wright's work as it was.

Mr. UMNEY (London) said he could not state what was the particular aconite plant from which the Japanese aconite roots that had been used, had been derived, whether *Aconitum Napellus*, *Aconitum ferox* or *Aconitum paniculatum*, but he believed that Mr. Holmes was at the present time engaged in investigating the botanical source.

Mr. LUFF said that he had worked at the roots with Dr. Wright, and was able to state positively they only got one alkaloid from the Japanese roots, and the same alkaloid from the two batches.

Mr. GREENISH was of opinion that there would be little trouble in separating the aconites, and did not think they could arrive at a satisfactory conclusion, until they knew what species were used. If the species were separated, and the alkaloid were extracted from each species, he thought the investigators would arrive at something more definite.

The PRESIDENT, in moving a vote of thanks to Dr. Wright for his paper and able report, said he was glad to hear that the grant was not entirely expended, and consequently they might expect further communications from him on the subject.

The next paper read was the following:—

PROXIMATE ANALYSIS OF THE RHIZOME (DRIED AND DECORTICATED) OF ZINGIBER OFFICINALIS, AND COMPARATIVE EXAMINATION OF TYPICAL SPECIMENS OF COMMERCIAL GINGERS.

BY J. C. THRESH, F.C.S.,

Pharmaceutical Chemist.

Part I.—Proximate Analysis of Rhizome of Z. Officinalis.

The sample of ginger selected for analysis was a variety of what is known in commerce as Jamaica ginger. The decorticated irregular lobes were from 1 to 2 inches long, pale yellow brown externally, and yielded a decidedly brown powder; fracture slightly resinous. Preliminary experiments lead me to the conclusion that it would be best to treat the powder with the following solvents, in the order given;—ether, water, rectified spirit, 1 per cent. soda solution, 1 per cent. hydrochloric acid.

As the constituents soluble in ether were known to be those most worthy of investigation, I got Mr. Umney to exhaust 28 pounds of the ginger with ether, to distil off the solvent, and forward me the extract and the marc. This extract was of a deep red-brown colour, semi-fluid consistency, and had the strong characteristic odour and pungent taste of ginger. It dissolved readily and completely in ether, alcohol, chloroform and benzol, required a rather large proportion of 84 per cent. alcohol for complete solution, was imperfectly soluble in glacial acetic acid, and but slightly soluble in petroleum ether.

A part of the ethereal extract was agitated first with water, then with successive portions of petroleum ether, until the solvent came off nearly colourless. After being treated a great number of times with this ether, the residue continues to impart to it both a slight colour and pungency, hence it was not deemed advisable to continue the treatment more than three or four times. The solution was of a deep red colour and very pungent. Upon allowing the petroleum ether to evaporate spontaneously, a quantity of deep red, apparently crystalline, fatty matter was deposited. This was removed by filtration, washed with a little petroleum ether, and pressed between folds of bibulous paper. Let this be called "crystalline fatty matter."

The fluid which had passed through the filter was exposed to a current of warm air until the last trace of the petroleum ether* was removed, then placed in a flask and

* The petroleum ether employed boiled at 50° C.

a current of steam passed through it, and condensed so long as any volatile oil came over. The residue in retort consisted of a transparent red fat, about the consistence of lard. Call this "red fatty matter."

The residue of ethereal extract, insoluble in petroleum ether was of semi-fluid consistency, of a red-brown colour, with a scarcely perceptible odour, but intensely pungent taste. It dissolved readily in absolute and 84 per cent. alcohol, but when treated with 50 per cent. alcohol a residue was left which after washing with several successive quantities of alcohol of this strength, finally yielded nothing further to the solvent. This substance was of resinous consistency, nearly black in colour, and quite tasteless. "Neutral resin."

The dilute spiritous solution when evaporated left a soft transparent red-brown residue, which although I soon found evidence of its compound nature, has proved most troublesome to resolve into its proximate constituents. It dissolved readily in benzol, bisulphide of carbon, glacial acetic acid, dilute alcohol and alkaline solutions. Its alcoholic solution precipitated most copiously with neutral and basic lead acetates, milk of lime and baryta water. In each case the precipitate first thrown down by the reagent differed in colour from the portions precipitated afterwards. In the former case the precipitate was a pale orange brown, in the latter orange yellow, and the supernatant fluid after addition of excess of the precipitate was exceedingly pungent, and much paler in colour than the original solution. A quantity of the tincture was shaken with successive portions of slacked lime so long as anything was carried down, and the lime precipitate removed by filtration. After repeated washings with spirit it still retained some pungency, and when treated with hot spirit, what was previously a soft sticky flocculent precipitate fused into a semi-transparent mass which adhered tenaciously to the sides of the flask. This was digested in alcohol and sufficient sulphuric acid added to completely decompose it, excess of acid removed with baryta, the solution filtered and evaporated to dryness. The residue was a dark brown-black, brittle solid, possessed of a slightly pungent taste, but no odour. "Acid resins."

The 50 per cent. alcohol solution from which the resins had been removed by lime when acidified with sulphuric acid gave an abundant precipitate of sulphate of lime, indicating the presence of a lime salt in the solution. This fluid was carefully freed from excess of sulphuric acid, filtered and evaporated to dryness. The residue was semi-fluid, transparent, pale red, and intensely pungent. "Active principle."

There remains now to examine further—

1. Crystalline fatty matter.
2. Red fatty matter.
3. Volatile oil.
4. Neutral resin.
5. Resinous acids.
6. Active principle.

1. *Crystalline Fatty Matter.*—This had a slightly pungent taste, which, however, was easily removed by treatment with 84 per cent. alcohol, which when cold did not appear otherwise to affect the residue. Boiled with spirit, and filtered hot, the filtrate deposited voluminous flakes of brownish colour. The portion insoluble in 84 per cent. alcohol was a soft red fat, which has resisted all efforts to resolve it into simple constituents, and hence may be regarded as a proximate constituent of the ginger rhizome.

a. Soft Red Fat.—Properties, transparent, dark red, tasteless and odourless. Soluble in alcohol, petroleum ether, ether, benzol, carbon disulphide, and turpentine. Very slightly soluble in 84 per cent. alcohol, and forming with solution of potash an imperfect soapy solution. Not further examined.

The brownish flocculent matter deposited by the spirit upon cooling, when collected and placed on a water-bath, shrivelled up to an exceedingly small residue, of a pale brown colour and waxy consistency. I at first regarded this as a kind of wax, but when purified by being a great number of times dissolved in hot alcohol, and re-deposited on cooling, a very small quantity of a snow white amorphous substance remained.

b. White Amorphous Substance.—White, amorphous, pulverulent, odourless and tasteless. Heated on the mercurial bath to 250° C., it did not fuse, but began to exhibit a slight brown coloration. At a higher temperature it becomes darker in colour, melts and evolves inflammable vapours which burn with a luminous smokeless flame, emitting no characteristic odour. It is insoluble in water, acid or alkaline solutions. Its behaviour with other solvents is somewhat peculiar. Cold ether dissolves it very sparingly, but in boiling ether it is more soluble, depositing the excess as the fluid cools in a granular form. Benzol and carbon disulphide dissolve it rather more freely and the solutions when left to evaporate spontaneously, become covered with a transparent gelatinous film, which increases in thickness as the evaporation continues, until at length the residue is wholly of this consistence and the vessel may be upturned without losing any of the contents. If the evaporation be now continued on the water-bath, the bulky mass dwindles away, leaving a very slight residue. From boiling absolute alcohol it is deposited in granular waxy looking masses upon the side of the containing vessel. From boiling rectified spirit, if saturated, it is deposited in the gelatinous or bulky form, the whole becoming semi-solid, and resembling in appearance a strong solution of an aluminium salt to which ammonia has been added. Boiling glacial acetic acid takes up a small portion, and deposits it upon cooling or dilution in the gelatinous condition.

c. Resin δ. The wax-like appearance of the crude substance "*b*" is due to the presence of a hard brittle fusible resin, which I have not isolated in the pure state. It appears to be but slightly soluble in alcohol, but soluble in petroleum ether, benzol, carbon disulphide and turpentine. It is tasteless and odourless.

2. Red fatty matter. This portion of the ethereal extract was very pungent, but when treated with successive portions of 50 per cent. alcohol, the pungent principle passed into the alcohol, together with other substances which upon further examination proved to be identical with those contained in the alcoholic solution of the ethereal extract, which had been treated with petroleum ether. Besides these (gingerol, resins α and β) there was the red fat already described, and traces of resin, and of the white amorphous substance.

3. *Volatile Oil.*—This is the only constituent of the ginger root hitherto examined, and the statements concerning it are somewhat conflicting. Gmelin says that its colour is yellowish, Neumann that it is red, and Morin affirms that it is greenish-blue. Paponsek (*Wien. akad. Ber.* 9, 315), who submitted the oil to chemical examination, obtaining the formula $C_{10}H_{16}.H_2O$, states that it has a strong odour of ginger, and a burning aromatic taste, Bucholz on the contrary asserting that its taste is "rather mild at first but somewhat bitter and biting after." Time has only allowed me to note the following physical and other properties of the oil obtained in the manner previously described.

It is a limpid, straw coloured fluid, with a peculiar aromatic odour by no means recalling that of the rhizome from which it was prepared, and of an aromatic and somewhat camphoraceous taste. Sp. gr. ·853 at 15° C. (Hanbury and Flückiger in 'Pharmacographia,' ·878, Paponsek ·893) It is neutral in reaction, forms no compound with sodium bisulphite, and is very soluble in absolute alcohol, benzol, petroleum ether, ether and bisulphide of carbon.

One part of the oil dissolves in 25 of alcohol (sp. gr. ·815), in 50 parts of alcohol (sp. gr. ·834) but requires about 600 to 700 parts of alcohol of sp. gr. ·920. These approximations were obtained by adding with agitation alcohol of the above strengths, to 1 c.c. of the volatile oil contained in a flask, until a clear solution resulted. Dropped upon dry powdered iodine, instantaneous reaction takes place, accompanied by evolution of heat and effervescence. A few drops digested with a fragment of sodium produced a slight effervescence which continued for several days, the ultimate product being much darker in colour, and very viscid. The strange difference between the odour of the oil as it exists in the ginger and as obtained by distillation accounts for the statement made by Mr. Draper at the last Conference, that "an essence prepared from oil of ginger did not give the same results as that obtained from ginger itself." A sample of this oil, obtained from a London firm who import it from Germany, is identical in colour, odour and taste with that prepared by myself, but its specific gravity is ·907. A sample of oil obtained from an ethereal extract which had lost a great portion of its volatile oil from too long exposure to steam heat in the retort had a slightly darker colour and a specific gravity of ·874. Hence it appears most probable that the oil of ginger really contains two or more volatile oils differing in specific gravity, boiling point, etc.

4. *Neutral resin.*—This is the most abundant constituent of the ethereal extract, and, after treatment with 50 per cent. alcohol, remains as an odourless and tasteless brittle but somewhat soft resin, slowly taking the form of the vessel in which it is kept. Its colour by reflected light is nearly black, but by transmitted light, if viewed in thin layers, it appears transparent and of a dark red-brown colour. It dissolves readily in absolute alcohol, ether, benzol, carbon disulphide and turpentine. In rectified spirit it dissolves slowly but somewhat freely, but is almost totally unaffected by proof spirit and petroleum ether. Glacial acetic acid dissolves it, but it is only slightly acted upon by solutions of potash, soda or ammonia. The alcoholic solution is neutral to test paper.

5. *Acid resins.*—This portion of the original extract evidently contained, as before stated, at least two resins, besides traces of the active principle, and possibly also of an oxidation product of the essential oil. When treated with benzol or carbon disulphide it separated into two portions, the one taken up by the solvent, the other unaffected by it. This residue after being treated repeatedly with benzol and carbon disulphide until nothing further was dissolved I have called resin α.

Resin α.—As above obtained is a dark brown rather soft solid, breaking with a short resinous fracture, readily soluble in dilute alcohol, ether and chloroform, but almost entirely insoluble in benzol, carbon disulphide and turpentine. Glacial acetic acid dissolves it freely, as also does solution of potash, the fluid becoming of a dark brown colour. The alcoholic tincture gives a pale brown precipitate with both acetate and subacetate of lead. Does not dissolve in liquor ammoniæ, and is precipitated from its solution in potass by addition of ammonium chloride. The alcoholic solution is neutral to test paper.

Boiled with absolute alcohol and sodic carbonate the solution becomes of a dark brown colour, and sodium is readily detected in it. Hydrochloric acid does not affect the resin; sulphuric acid forms with it a brown solution which is decolorized by addition of potassium bichromate; nitric acid gives a brown solution which evolves nitrous fumes and becomes orange red.

The benzol solution of No. 5 was very pungent in taste, and when the benzol had been removed by evaporation and the semi-fluid residue dissolved in rectified spirit, addition of basic lead acetate gave a copious precipitate; but when the precipitant was added very gradually it was noted that the colour of the precipitate varied from an orange-brown to an orange-yellow. By fractional precipitation, decomposition of the orange-yellow lead salt, resolution of the resulting resin in alcohol, and re-precipitation (partial) by subacetate of lead, a compound of lead and resin was obtained, from which the resin was finally extracted.

Resin β.—In external appearance, consistency, etc., it closely resembles resin α; like it also it is readily soluble in dilute alcohol, ether, chloroform, glacial acetic acid and solution of potash; but it differs from resin α in being soluble in benzol, bisulphide of carbon and turpentine, and in giving an orange precipitate with subacetate of lead and a deep orange solution with liquor potassæ. It does not dissolve in ammonia, is tasteless and odourless, and in alcoholic solution has a barely perceptible acid reaction.

Dissolved in absolute alcohol and boiled with sodium carbonate, the solution assumes an orange-red colour and contains sodium. By action of hydrochloric, nitric and sulphuric acids it can scarcely be distinguished from resin α.

The alcoholic solution from which the resins α and β had been removed by lime yielded upon evaporation, etc., as before stated, a reddish, thick, oily-looking substance, which was intensely pungent in taste. This was dissolved in as small a quantity as possible of 50 per cent. alcohol, and shaken with a little lime, whereby more of the resins α and β were removed. When neutralized with sulphuric acid, filtered and evaporated, the residue was found to be much paler than before, but when dissolved in liquor potassæ it still gave a rich orange coloured solution. It undoubtedly contained traces of resin β, to remove which is an exceedingly difficult matter. It can, however, be accomplished by boiling the impure substance (which I have called gingerol) in petroleum ether and rapidly decanting. The ether as it cools deposits the gingerol in oily drops. By treating the crude substance several times with the same ether, collecting the still slightly impure principle, and subjecting it to a repetition of the above treatment, the pure or very approximately pure gingerol is obtained. Only the portions first taken up by the petroleum ether are employed (as by repetitions of the treatment the whole of the impure substance can be dissolved); hence the product of pure gingerol is small.

Gingerol.—This, which is the pungent or active principle of ginger, is a viscid fluid of about the consistency of treacle, of a pale straw colour, entirely devoid of odour and of an extremely pungent and slightly bitter taste. It is very soluble in alcohol (even when diluted to 50 per cent.), benzol, volatile oils, carbon bisulphide, solutions of potash and ammonia and glacial acetic acid. It is very slightly soluble in petroleum ether. The alcoholic solution is neutral in reaction and gives no precipitate with the acetates of lead nor with lime. It does not yield glucose when treated with dilute sulphuric acid; strong sulphuric acid dissolves it with production of a brown colour; hydrochloric acid does not affect it; nitric acid converts it into a blood red resinous substance. The specific gravity of a slightly impure specimen was 1·09 at 15° C.

Aqueous Solution of Ethereal Extract.—Upon evaporation this deposited a considerable amount of soft resinous matter; was acid in reaction and pungent in taste. It contained considerable traces of an alkaloid, malic acid and other substances, found in aqueous extract of the rhizome.

A second lot of ethereal extract was treated in a somewhat different manner. The whole was placed in a flask and the essential oil carried off by a current of steam. The residue was then treated first with petroleum ether and afterwards with proof spirit. What remained was completely soluble in benzol, but upon addition of a little petroleum ether the fluid separated into two distinct layers. The lower and darker coloured was removed and more benzol and petroleum ether added to it and the lower layer again removed. This residue was now found to consist almost entirely of resin α, and after treatment with successive portions of benzol to remove traces of gingerol and resin β, pure resin α remained. The benzol and petroleum ether solution when shaken with slightly diluted alcohol (about 75 per cent.) yielded up nearly all the gingerol, together with a part of the resins. Upon repeating this treatment the active principle contained still less of the resins and was further purified by treatment with petroleum ether as before described. The gingerol and resin α thus obtained are identical with those obtained by treatment with lime, decomposition of lime salt by acid, etc. Resin β can only be obtained by evaporating off the benzol and petroleum ether from solution which has been treated with spirit, dissolving residue in dilute alcohol, fractional precipitation with lime, etc.

Aqueous Extract of Ginger.—The ginger, or rather a portion of the ginger, which had been exhausted with ether, was macerated for a couple of days in sufficient cold water to cover it, then transferred to a percolator, and water passed through until the marc was exhausted. The first portion of the percolate had an acid reaction, was limpid, and of a pale brown colour. It was carefully evaporated upon the water-bath to a small bulk, a pellicle constantly forming upon the surface, which readily dissolved when the fluid was stirred. This solution gave with ammonia a copious crystalline precipitate, which when removed by filtration proved to be almost pure ammonio-magnesium phosphate. Both mineral and organic acids gave a flocculent, very voluminous flesh-coloured precipitate which only re-dissolved in large excess of mineral acid. Both acetates of lead gave bulky precipitates, as also did admixture with alcohol. The concentrated solution was mixed with 3 volumes of 85 per cent. alcohol, and after standing some time the precipitate was removed by filtration, and washed with a little alcohol. When now diffused in warm water, only part dissolved, a beautifully white crystalline powder remaining behind. This was separated and washed, and proved to be almost pure phosphate of magnesia, but contained traces of manganese, potassium, iron, calcium and oxalic acid. The aqueous solution derived from the alcoholic precipitate, when mixed with a little acetic acid, gave a voluminous precipitate, and the filtrate when mixed with alcohol gave a further precipitate (mucilage or gum). From the filtrate the alcohol was removed at a gentle heat, and to the solution acetate of lead was added. This gave a brownish coloured precipitate, a part of which dissolved in boiling water, and was redeposited in an indefinitely crystalline form upon cooling. The fawn-coloured crystalline mass was diffused through water and decomposed by sulphuretted hydrogen. The resulting acid when neutralized gave no precipitate with calcium chloride until alcohol was added, and was apparently malic acid associated with a little impurity. The lead salt when ignited left a residue of lead oxide somewhat under the normal amount. The portion of lead precipitate not dissolved by boiling water yielded but little to acetic acid, and the residue was phosphate of lead together with a little oxalate and brown humus-like matter. The aqueous infusion which had been treated with neutral lead acetate was rendered slightly alkaline by ammonia and excess of basic lead acetate added; the precipitate which fell was not further examined. The excess of lead was removed from the liquid by H_2S, and the excess of H_2S got rid of by warming the solution whilst exposed to a current of air. When rendered alkaline tannin produced a most abundant precipitate, and phosphomolybdate of ammonia, Nessler's reagent, and iodine gave indications of the presence of an alkaloid, but not in sufficient amount to warrant an attempt at its isolation. The tannin precipitate was collected, washed, dried, rubbed with lead oxide and rectified spirit, and digested at a gentle heat for several hours. The resulting solution when evaporated left a residue, which I will call "Indifferent substance precipitated by tannin."

The original infusion did not reduce Fehling's solution.

Acidified with acetic acid and filtered $CaCl_2$ gave a precipitate which readily dissolved in hydrochloric acid. Evaporated to a small bulk, traces of Ca and Mg removed, then acidified with hydrochloric acid and perchloride of platinum added, abundant evidence of the presence of potassium was obtained. These reactions together with the acid character of the infusion lead me to infer that the binoxalate of potash is a normal constituent of ginger rhizome. The substance precipitated by acids, mucilage, and indifferent principle precipitated by tannin were submitted to such further examination as my limited time allowed.

Substance Precipitated by Acids.—This substance, when obtained, together with mucilage, by precipitating an infusion of ginger with alcohol, easily dissolves in pure water; when obtained by addition of an acid it is not so readily soluble. Solutions of potash, soda, and ammonia dissolve it, and when an acid is added it is reprecipitated. When washed with a little water, and dried, the residue is transparent, reddish, very brittle, and readily reduced to a red-brown powder. It dissolves in strong hydrochloric, nitric, and sulphuric acids, the hydrochloric solution after some time acquiring a purplish yellow tint; the nitric solution is bright yellow; the sulphuric solution is similar in colour to that in hydrochloric acid. In each case dilution with water causes precipitation of the original substance. When burnt upon a platinum dish it swells up considerably, leaving a voluminous char, which burns away with difficulty, leaving a little slightly coloured ash, which appeared to be chiefly Mg_32PO_4.

·4200 gram yielded ·0105 ash or 2·5 per cent.

A little of the dried substance when fused with sodium in a test-tube and the resulting mass treated successively with solution of oxidized ferrous sulphate and hydrochloric acid, gave a copious precipitate of Prussian blue. ·651 gram when burnt with soda lime yielded ·135 gram of double chloride of platinum and ammonium, corresponding to 1·3 per cent. of nitrogen. (This substance is probably a mixture of albuminoid and arabinoid bodies.)

Mucilage.—This is precipitated by alcohol, after the nitrogenous substance has been removed by addition of acetic acid and filtration. When dried it is an amorphous gum-like mass. As precipitated from a strong aqueous infusion of the ginger it contained 25 per cent. of mineral salts (chiefly $Mg_3P_2O_8$ and KHC_2O_4); as obtained from a more dilute solution it yielded 13 per cent. of ash. It is soluble in water, forming a slightly mucilaginous solution, which is not affected by solution of borax, precipitates slightly with neutral lead acetates, ferric chloride, and mercuric chloride (probably only oxalate and phosphates), and solidifies (in concentrated solution) upon addition of basic lead acetate. After boiling some time with dilute sulphuric acid the product reduces Fehling's solution. No blue colour is exhibited when moistened with iodine and sulphuric acid.

Indifferent Substance precipitated by Tannin. — The matter precipitated by tannin was left as a pale brown amorphous residue upon evaporation of the tincture obtained by digesting the tannic precipitate with carbonate of lead. It did not reduce Fehling's solution after treatment with dilute acid. Its aqueous solution gave indications of the presence of an alkaloid with the phosphomolybic, metatungstic, iodine, and Nessler's reagents, but it was evident that this existed in it only in minute proportion. From its aqueous solution tannin only precipitated it after addition of an alkali.

Alcoholic Extract.—A portion of the powdered ginger which had been treated with ether and water was next percolated with 84 per cent. alcohol. The percolate was of a very pale red colour and when evaporated left an exceedingly small residue of a resinous character. It was insoluble in water or dilute acids, soluble in alkaline solutions, absolute and diluted alcohol. Did not affect Fehling's solution after treatment with acid. Not further examined.

The marc insoluble in ether, water and alcohol was digested in 1 per cent. soda solution for several days. The infusion was mucilaginous; it filtered with very great difficulty, the filtrate being opalescent. Neutralized with acid, only a very slight turbidity was produced, but upon addition of 3 volumes of 95 per cent. alcohol, a very voluminous, white, flocculent precipitate fell, which rapidly cohered into lumps, leaving the supernatant fluid perfectly clear.

Metarabin.—The substance, as above isolated, appeared to be an insoluble variety of gum, it was free from colour, and when dried left a brittle, slightly coloured residue. It contained a barely detectable trace of nitrogenous matter, and left upon ignition 5 per cent. of ash. It dissolved readily in alkalies, but very slightly, if at all, in strong hydrochloric acid.

The alkaline solution (together with the marc) was diluted, boiled (to dissolve and remove the starch), and the insoluble residue washed by subsidence and decantation, boiled and digested with a 1 per cent. hydrochloric acid. The infusion when filtered and neutralized became slightly turbid, and upon admixture of alcohol a flocculent precipitate was formed. This, which appeared to be pararabin or a closely allied body, yielded upon incineration nearly 20 per cent of ash, chiefly calcium oxide (but possibly also a little phosphate), derived from the calcium oxalate contained in the rhizome.

The quantitative analysis of the rhizome, the result of which will be found tabulated with those obtained upon examination of typical samples of commercial ginger, and given at end of part 2 of this paper, was made in a similar manner to that detailed in part 2, but not upon same quantities of ginger. The percentage of ethereal extract and of its constituents is calculated from amounts yielded by 28 pounds of powder, and the other constituents from 10 grams only. The total oxalates derived from analysis of a hydrochloric infusion, by precipitation with calcium chloride after addition of excess of an alkaline acetate correspond to 1·52 per cent. of oxalic acid. The phosphoric acid, as determined in solution from which the oxalate had been removed, equalled ·7 per cent.

Appended is a tabulated statement of the action of the various solvents, etc., upon the constituents of the ethereal extract:—

Name.	Alcohol.	Petroleum Ether.	CS_2.	Benzol.	Essential Oil.	KHO solution.	Glacial Acetic Acid.	Physical Properties.

(*To be continued.*)

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

The President's Address.

(*Concluded from page* 160.)

We have seen how little mere form has to do with the essential properties of protoplasm. This may shape itself into cells, and the cells may combine into organs in ever-increasing complexity, and protoplasm force may be thus intensified, and, by the mechanism of organization, turned to the best possible account; but we must still go back to protoplasm as a naked formless plasma if we would find—freed from all non-essential complications—the agent to which has been assigned the duty of building up structure and of transforming the energy of lifeless matter into that of living.

To suppose, however, that all protoplasm is identical where no difference cognizable by any means at our disposal can be detected would be an error. Of two particles of protoplasm, between which we may defy all the power of the microscope, all the resources of the laboratory, to detect a difference, one can develop only to a jelly-fish, the other only to a man, and one conclusion alone is here possible—that deep within them there must be a fundamental difference which thus determines their inevitable destiny, but of which we know nothing, and can assert nothing beyond the statement that it must depend on their hidden molecular constitution.

In the molecular condition of protoplasm there is probably as much complexity as in the disposition of organs in the most highly differentiated organisms; and between two masses of protoplasm indistinguishable from one another there may be as much molecular difference as there is between the form and arrangement of organs in the most widely separated animals or plants.

Herein lies the many-sidedness of protoplasm; herein lies its significance as the basis of all morphological expression, as the agent of all physiological work, while in all this there must be an adaptiveness to purpose as great as any claimed for the most complicated organism.

From the facts which have been now brought to your notice there is but one legitimate conclusion—that life is a property of protoplasm. In this assertion there is nothing that need startle us. The essential phenomena of living beings are not so widely separated from the phenomena of lifeless matter as to render it impossible to recognize an analogy between them: for even irritability, the one grand character of all living beings, is not more difficult to be conceived of as a property of matter than the physical phenomena of radial energy.

It is quite true that between lifeless and living matter there is a vast difference, a difference greater far than any which can be found between the most diverse manifestations of lifeless matter. Though the refined synthesis of modern chemistry may have succeeded in forming a few principles which until lately had been deemed the proper product of vitality, the fact still remains that no one has ever yet built up one particle of living matter out of lifeless elements—that every living creature, from the simplest dweller on the confines of organization up to the highest and most complex organism, has its origin in pre-existent living matter—that the protoplasm of to-day is but the continuation of the protoplasm of other ages, handed down to us through periods of indefinable and indeterminable time.

Yet with all this, vast as the differences may be, there is nothing which precludes a comparison of the properties of living matter with those of lifeless.

When, however, we say that life is a property of protoplasm, we assert as much as we are justified in doing. Here, we stand upon the boundary between life in its proper conception, as a group of phenomena having irritability as their common bond, and that other and higher group of phenomena which we designate as consciousness or thought, and which, however intimately connected with those of life, are yet essentially distinct from them.

When the heart of a recently killed frog is separated from its body and touched with the point of a needle, it begins to beat under the excitation of the stimulus, and we believe ourselves justified in referring the contraction of the cardiac fibres to the irritability of their protoplasm as its proper cause. We see in it a remarkable phenomenon, but one nevertheless in which we can see unmistakable analogies with phenomena purely physical. There is no greater difficulty in conceiving of contractility as a property of protoplasm than there is in conceiving of attraction as a property of the magnet.

When a thought passes through the mind, it is associated, as we have now abundant reason for believing, with some change in the protoplasm of the cerebral cells. Are we, therefore, justified in regarding thought as a property of the protoplasm of these cells in the sense in which we regard muscular contraction as a property of the protoplasm of muscle? or is it really a property residing in something far different, but which may yet need for its manifestation the activity of cerebral protoplasm?

If we could see any analogy between thought and any one of the admitted phenomena of matter, we should be bound to accept the first of these conclusions as the simplest, and as affording a hypothesis most in accordance with the comprehensiveness of natural laws; but between thought and the physical phenomena of matter there is not only no analogy, but there is no conceivable analogy; and the obvious and continuous path which we have hitherto followed up in our reasonings from the phenomena of lifeless matter through those of living matter here comes suddenly to an end. The chasm between unconscious life and thought is deep and impassable, and no transitional phenomena can be found by which as by a bridge we may span it over; for even from irritability, to which on a superficial view, consciousness may seem related, it is as absolutely distinct as it is from any of the ordinary phenomena of matter.

It has been argued that because physiological activity must be a property of every living cell, psychical activity must be equally so, and the language of the metaphysician has been carried into biology, and the "cell soul" spoken of as a conception inseparable from that of life.

That psychical phenomena, however, characterized as they essentially are by consciousness, are not necessarily coextensive with those of life there cannot be a doubt. How far back in the scale of life consciousness may exist we have as yet no means of determining, nor is it necessary for our argument that we should. Certain it is that many things, to all appearance the result of volition, are capable of being explained as absolutely unconscious acts; and when the swimming swarm-spore of an alga avoids collision, and by a reversal of the stroke of its cilia backs from an obstacle lying in its course, there is almost certainly in all this nothing but a purely unconscious act. It is but a case in which we find expressed the great law of the adaptation of living beings to the conditions which surround them. The irritability of the protoplasm of the ciliated spore responding to an external stimulus sets in motion a mechanism derived by inheritance from its ancestors, and whose parts are correlated to a common end—the preservation of the individual.

But even admitting that every living cell were a conscious and thinking being, are we therefore justified in asserting that its consciousness, like its irritability, is a property of the matter of which it is composed? The sole argument on which this view is made to rest is that from analogy. It is argued that because the life phenomena, which are invariably found in the cell, must be regarded as a property of the cell, the phenomena of consciousness by which they are accompanied must be also so regarded. The weak point in the argument is the absence of all analogy between the things compared, and as the conclusion rests solely on the argument from analogy, the two must fall to the ground together.

In a lecture to which I once had the pleasure of listening—a lecture characterized no less by lucid exposition than by the fascinating form in which its facts were presented to the hearers, Professor Huxley argues that no difference, however great, between the phenomena of living matter and those of the lifeless elements of which this matter is composed should militate against our attributing to protoplasm the phenomena of life as properties essentially inherent in it; since we know that the result of a chemical combination of physical elements may exhibit physical properties totally different from those of the elements combined; the physical phenomena presented by water, for example, having no resemblance to those of its combining elements, oxygen and hydrogen.

I believe that Professor Huxley intended to apply this argument only to the phenomena of life in the stricter sense of the word. As such it is conclusive. But if it be pushed further and extended to the phenomena of consciousness it loses all its force. The analogy, perfectly valid in the former case, here fails. The properties of the chemical compound are, like those of its components, still physical properties. They come within the wide category of the universally accepted properties of matter, while those of consciousness belong to a category absolutely distinct—one which presents not a trace of a connection with any of those which physicists have agreed in assigning to matter as its proper characteristics. The argument thus breaks down, for its force depends on analogy alone, and here all analogy vanishes.

That consciousness is never manifested except in the presence of cerebral matter or of something like it, there cannot be a question; but this is a very different thing from its being a property of such matter in the sense in which polarity is a property of the magnet, or irritability of protoplasm. The generation of the rays which lie invisible beyond the violet in the spectrum of the sun cannot be regarded as a property of the medium which by changing their refrangibility can alone render them apparent.

I know that there is a special charm in those broad generalizations which would refer many very different phenomena to a common source. But in this very charm there is undoubtedly a danger, and we must be all the more careful lest it should exert an influence in arresting the progress of truth, just as at an earlier period traditional beliefs exerted an authority from which the mind but slowly and with difficulty succeeded in emancipating itself.

But have we, it may be asked, made in all this one step forward towards an explanation of the phenomena of consciousness or the discovery of its source? Assuredly not. The power of conceiving of a substance different from that of matter is still beyond the limits of human intelligence, and the physical or objective conditions which are the concomitants of thought are the only ones of which it is possible to know anything, and the only ones whose study is of value.

We are not, however, on that account forced to the conclusion that there is nothing in the universe but matter and force. The simplest physical law absolutely inconceivable by the highest of the brutes, and no one would be justified in assuming that man had already attained the limit of his power. Whatever may be that mysterious bond which connects organization with psychical endowments, the one grand fact—a fact of inestimable importance—stands out clear and freed from all obscurity and doubt, that from the first dawn of intelligence there is with every advance in organization a corresponding advance in mind. Mind as well as body is thus travelling onwards through higher and still higher phases; the great law of Evolution is shaping the destiny of our race; and though now we may at most but indicate some weak point in the generalization which would refer consciousness as well as life to a common material source, who can say that in the far off future there may not yet be evolved other and higher faculties from which light may stream in upon the darkness, and reveal to man the great mystery of Thought?

Meetings of the Sections.

The various Sections commenced their meetings on Thursday morning, the 22nd inst., when the proceedings were opened by addresses from their respective presidents as follows:—

Section A.—*Mathematical and Physical Science.*—President: G. Johnstone Stoney, M.A., F.R.S.

Section B.—*Chemical Science.*—President: James Dewar, M.A., F.R.S.L. & E.

Section C.—*Geology.*—President: P. Martin Duncan, M.B., F.R.S., F.G.S.

Section D.—*Biology.*—President (Department of Zoology and Botany): St. George Mivart, F.R.S., F.L.S., F.Z.S. Vice-President (Department of Anthropology): E. B. Tylor, D.C.L., F.R.S. Vice-President (Department of Anatomy and Physiology): Dr. Pye Smith. This Department did not meet until Friday.

Section E.—*Geography.*—President: Clements R. Markham, C.B., F.R.S., F.L.S.

Section F.—*Economic Science and Statistics.*—President (in the absence of Mr. G. Shaw Lefevre, owing to the death of his father): Mr. Mundella, M.P.

Section G.—*Mechanical Science.*—President: J. Robinson, Pres. Inst. Mech. Eng.

Soirées, Lectures, etc.

On Thursday Evening a *Soirée* was given by the Master Cutler in the Cutlers' Hall, and on Tuesday the 26th a *Soirée* was given by the Local Committee in this same building.

On Friday Evening, the 22nd, Mr. William Crookes delivered a lecture on "Radiant Matter," to a large audience assembled in the Albert Hall. This lecture it is intended to print in an early number of this Journal. Another lecture was delivered in the Albert Hall on Monday evening, the 25th, the lecturer being Professor E. Ray Lankester and his subject "Degeneration." On Saturday, the 23rd, the lecture to the operative classes was delivered by Professor Ayrton, on "Electricity as a Motive Power."

Next Place of Meeting.

At a meeting of the General Committee on Monday, for the election of Officers, Professor A. C. Ramsay, LL.D., F.R.S., was chosen President of the Association for the meeting next year in Swansea. It was also finally decided to accept the invitation of the municipality of York to meet in that city in 1881.

At the concluding meeting on Wednesday it was announced that the total attendance had been 1404, against 2578 last year at Dublin, 1217 in 1878 at Plymouth, and 2652 in 1877 at Glasgow.

The following is a list of the papers read in the Chemical Section:—

Report of Committee on the Chemistry of some of the lesser known Alkaloids. Read by W. Chandler Roberts, F.R.S.

On some relations between the numbers expressing the Atomic Weights of the Elements. By Walter Weldon, F.R.S.E.

On the Synthesis of Diphenyl Propyl. By M. R. D. Silva.

Recent Researches in Explosive Agents. By F. A. Abel, F.R.S.

On Vapour Densities. By Professor Dewar, F.R.S.

To Describe a large Crystal of Mercury Sulphate. By P. Braham.

On the Manufacture of Crucible Steel. By Henry S. Bell, F.C.S.

On the Separation of Iron and Phosphorus especially with reference to the Manufacture of Steel. By Thomas Blair.

A new Process in Metallurgy. By John Hollway.

A Lecture Experiment in Illustration of the Hollway Process of Smelting Sulphide Ores. By A. H. Allen, F.C.S

On Lead Fume with a description of a New Process of Fume Condensing. By Andrew French.

On the constitution of Aluminic Compounds. By Professor Odling, F.R.S.

On the presence of Nitrogen in Steel. By A. H. Allen.

Colour tests for Phosphorus and Sulphur in Iron and Steel. By A. Vernon Harcourt, F.R.S.

To exhibit some experiments with Hughes' Voltaic Induction Balance. By W. Chandler Roberts, F.R.S.

Historical Sketch of the various Vapour Density Methods. By J. T. Brown.

Note on certain Vapour Densities. By Professor Wanklyn.

Note on Isocyan-propionic Acid. By Professor Wanklyn.

Physical Constants of Liquid Acetylene and Hydrochloric Acid. By G. Andsell.

The Action of Ammoniacal Salts on Metallic Sulphides By M. De Clermont.

On the Chemical Composition of a nodule of Ozokerite found at Kinghorn-ness. By W. Ivison Macadam.

On some curious Concretion Balls derived from a Colliery Mineral Water. By Thomas Andrews.

On some points in connection with Agricultural Chemistry. By Dr. Gilbert, F.R.S.

On the rare Metals of the Yttrium Group. By T. S. Humpidge, B.Sc.

On the Synthesis of Hydrocyanic Acid. By Professor Dewar, F.R.S.

On the amount of Nitrous Acid produced in Electric Illumination. By Professor Dewar, F.R.S.

On the Kinoline Bases. By Professor Dewar, F.R.S.

An account of some recent Experiments on Supersaturated Solutions. By John M. Thomson.

Notes of some recent Spectral Observation. By J. Norman Lockyer, F.R.S.

Notes on Petroleum Spirit or Benzoline. By A. H. Allen.

On the illuminative value of a mixture of Hydrogen. By A. Vernon Harcourt, F.R.S.

On a new form of Condenser. By G. T. Hazelhurst.

Notes on a sample of Fullers Earth found in an old Fullonica recently excavated at Pompeii. By W. Thomson, F.R.S.E.

On the detection of Milk Adulteration. By W. H. Watson.

Chemical researches on the Palmella cruenta. By Dr. Phipson.

Description of a glass burette for collecting, measuring, and discharging gas over mercury. By Philip Braham.

Parliamentary and Law Proceedings.

Prosecutions under the Pharmacy Act, Ireland.

In the Northern Division of the Dublin Police Courts, before Mr. J. W. O'Donnell, the chief magistrate, two summonses have been heard, brought under the Pharmacy Act, Ireland, by the Pharmaceutical Society of Ireland. The first case gone into was one against Messrs. George P. Beater and James North Hardy, trading under the name of Beater and Co., as druggists, of 17, Lower Sackville Street, the allegation being that they, "not being persons registered as a pharmaceutical chemist or chemist and druggist under the Pharmacy Act of 1875, did compound a certain prescription and sell same at Lower Sackville Street, in the Police District of Dublin Metropolis, on the 10th of July, 1879, between the hours of 10 and 11 o'clock, a.m., contrary to the form of the satute in such case made and provided."

Mr. Purcell, Q.C., instructed by Messrs. Ennis and Son, appeared on behalf of the Pharmaceutical Society of Ireland for the prosecution. Mr. Gerald Byrne appeared for the defendants.

Mr. Purcell said the Society were proceeding under the 30th section of the 57th chapter of the Pharmacy Act of 1875. That statute enacted that the Society should be a body corporate, and the 30th section was: "So much of the Act of 1791 as prohibits the keeping of open shops within the meaning of the said Act by any person other than a licentiate of Apothecaries' Hall shall be repealed; provided always, that it shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons within the meaning of the Act of the session of the thirty-third and thirty-fourth years of the reign of Her present Majesty, chapter twenty-six, or medical prescriptions, unless such person is registered as a pharmaceutical chemist or a chemist and druggist under this Act, or to assume or use the title of pharmaceutical chemist, or pharmaceutist, or pharmacist, or dispensing chemist, or the title of chemist and druggist in any part of Ireland, unless such person shall be registered as a pharmaceutical chemist or as a chemist and druggist respectively under this Act; and any person acting in contravention of this enactment, or compounding any medicines of the British Pharmacopœia, except according to the formularies of the said pharmacopœia, shall for every such offence be liable to pay a penalty of five pounds; but no such penalty shall exempt any person from being liable to any other penalty, damage, or punishment to which he would have been subject if this Act had not passed." On the 10th of July last, Messrs. Beater and Hardy, who carry on business as (chemists and) druggists in Lower Sackville Street, compounded a medical prescription and sold it to the party who presented it, and he (counsel) held a receipt given by the defendants for compounding. He did not think that the facts were disputed, but if they were the Society had their witnesses ready who would prove the offence alleged.

Mr. O'Donnell: What is the particular offence with which the defendants are here charged?

Mr. Ennis, solicitor: Selling and compounding medicines.

Mr. O'Donnell: Then it is for the sale and compounding of medicines, and not of poisons?

Mr. Purcell: Yes. On the 10th of July a medical prescription, which we have here, was presented at the establishment of Messrs. Beater and Hardy, who are not registered pharmaceutical chemists under the Act of Parliament, and in the presence of our witnesses it was made up. But I believe they do not dispute the facts.

Mr. Byrne, solicitor: I appear for Messrs. Beater and Hardy, and they admit that a breach of the law was committed in their establishment, but it was committed by one of the *employés* and not by themselves. Under the circumstances I hope the Society will not press the case.

Mr. Purcell: If they express regret that it occurred and promise that there shall be no repetition of it in future we will not press for the full penalty. It is not the object of the Society to do so under such circumstances——

Mr. O'Donnell: I am sure of that.

Mr. Purcell: But we are bound to vindicate the law.

Mr. O'Donnell: It is a very salutary Act. Mistakes occur every day in London in consequence of prescriptions being compounded by persons who are not properly qualified to do so, but, I am happy to say, there have been very few here.

Mr. Byrne: My clients will take every measure to prevent a similar occurrence in future, and as far as Messrs. Beater and Hardy are personally concerned they knew nothing of it.

Mr. Purcell: That is no justification.

Mr. O'Donnell: They would be both personally and pecuniarily responsible for any neglect that might occur in their establishment.

Mr. Purcell: On the undertaking of Messrs. Beater and Hardy that there will not be any repetition——

Mr. O'Donnell: I will impose a nominal penalty of ten shillings.

Mr. Purcell: I think that will do. And five guineas costs, your worship.

Mr. O'Donnell: This is the first case of the kind that has been heard, and it settles the law on the subject. Should a similar case be again brought the penalty inflicted will be very serious.

Mr. Purcell: That is the object of the Society.

Mr. O'Donnell: Of course, as a public body they act on public grounds and they will not prosecute in a mere squabble between different establishments. When they find anyone violating the law they should *chasser* him at once. The defendants are now fined 10*s.*, but if any person, with that conviction in his face, commits a similar offence he will be severely dealt with.

An order was made for the payment of 10*s.* and five guineas costs.

The second summons, which was brought against Mr. Joseph Brownrigg, of Talbot Street, trading as Brownrigg and Co., and was in respect of a similar offence alleged to have been committed by him on the 10th of July, was then heard.

Mr. Brownrigg, when the case was called, denied that the prescription had been compounded in his establishment, and asserted that he had sent it out to Messrs. Hamilton, Long and Co., where it was compounded.

Mr. Purcell: We will prove the facts.

Mr. Robert Cowan, 23, Geraldine Street, was examined by Mr. Purcell, and deposed: On the 10th of July I took this prescription (produced) into the establishment of the defendant. I was standing by all the time while it was being made up by Mr. Brownrigg himself.

By himself?—I saw him.

Did you see the stamp put on it?—I did.

Was it done by him in your presence?—It was.

Who wrote the directions?—He himself.

Is that the box of pills that you got with the bottle?—It is.

And who wrote the directions? — Mr. Brownrigg himself.

I ask a conviction in this case for the full amount.

Mr. Cowan, cross-examined by the defendant, who conducted his own case, stated: When I first went in you said it would require an hour to make up the prescription, and I went away for that time. On my return I stayed in the shop half an hour.

Did you see me send out?—No. I was looking at you all the time, and I saw you making it up.

To Mr. O'Donnell.—When I came back to the shop the defendant said he had not made up the prescription, and then he went and did it. He had nothing done when I came back, and he made it up before my face.

Mr. Brownrigg: I have a witness to prove that I sent to Hamilton, Long and Co.'s, and it was compounded there. I put on the labels myself.

Mr. Cowan: I saw Mr. Brownrigg filling the bottle from the bottles on the shelves in the shop.

Mr. Purcell: Not only is the label, as the witness swears, written in the handwriting of the defendant, but he actually has the audacity to have on it that he is a member of the Pharmaceutical Society—"Joseph Brownrigg, M.P.S."

Mr. Cowan: I saw him put his name to it.

Mr. Purcell (to witness): Did you go a second time to his shop?—I did, on the 16th of July.

Mr. O'Donnell: I will not take that as evidence. (To the witness.) Take the bottle in your hands. Did you see him write that on it?—I did.

Could any other person have written on the bottle?—No. There was a young man sitting on a chair, but Mr. Brownrigg wrote the label himself and put the wrapper on the bottle, and made up the prescription himself.

Mr. Purcell: Look at the stamp on the prescription. Do you see Brownrigg and Company on it? I do. The defendant wrote on it in my presence. The letters "M.P.S." are after his name.

That is "Member of the Pharmaceutical Society" of chemists and druggists and so forth, Talbot Street, Dublin, and he admits that he is not a member.

Witness, in reply to Mr. Purcell: The receipt produced is the one that Mr. Brownrigg wrote.

Cross-examined by Mr. Brownrigg: When I returned at the end of the hour you said the medicine was not ready, and that its preparation would take half an hour, but from the time you began to make it you were not twenty-five minutes. I saw you fill the bottle from bottles on your shelves.

Mr. Brownrigg (to Mr. O'Donnell): I admit he got it from me, but it was made up elsewhere.

Mr. Hugh James Fennell, Registrar of the Pharmaceutical Society of Ireland, was sworn, but before he was examined,

Mr. Brownrigg said: I admit I am not a member of the Pharmaceutical Society of Ireland.

Mr. Purcell (to witness): Do you see the letters "M.P.S."?—I do.

That is member of the Pharmaceutical Society?—That is the usual meaning of the letters.

Is it true or false?—It is not true that Mr. Brownrigg is a member of the Pharmaceutical Society of Ireland.

This closed the case for the prosecution.

Mr. William Coulson, defendant's assistant, was examined for the defence. He stated, in reply to Mr. Brownrigg: I remember the prescription perfectly well. I took it to Hamilton and Long's. Having some other things to get at the same time, I did not return at once with it. Mr. Cowan was kept near to an hour altogether.

Was the bottle corked and labelled when you brought it in?—It was. You then wrote a label yourself and put it on, taking off the other one. I saw the man (Mr. Cowan) when he came back. From where he was in the shop he could not possibly have seen you label the bottle. He was sitting down.

Cross-examined by Mr. Purcell: I am a chemist's assistant. I do not know the name of the assistant at Hamilton and Long's who made up the prescription. He would not put his number on it when it was for another chemist. I went out through the hall door of Mr. Brownrigg's.

What was your object?—Not to let the person in the shop know what we were doing. If we let every one see us go out for what we might be short of, people would say, "It is no good going there for they have nothing."

Did you hear the evidence sworn here to-day?—I did.

And was it false or true?—It is quite untrue that Mr. Brownrigg compounded the prescription himself.

Mr. O'Donnell: Suppose you brought the prescription to Hamilton and Long's would they not make an entry of it?—Not when it was for another druggist.

Mr. Purcell: Is it your evidence that they assist the druggists of Dublin in violating an Act of Parliament by making up prescriptions for them and letting them sell them?—It is no violation.

Mr. Purcell: Well, I think it is.

Mr. Coulson: That is the difference of opinion between us.—It is made up by a qualified apothecary.

Mr. O'Donnell: Are you in the habit of going to Hamilton and Long's?—When we have prescriptions, but we have very few.

Mr. Cowan: From the time I went in till when I came out, he (the witness) was not in the shop at all.

Witness: The shop is a divided shop.

Mr. O'Donnell (to Mr. Cowan): You said there was a young man on a chair in the shop?—But this is not the one, nor did I sit down. He has told a falsehood. I stood and looked at Mr. Brownrigg mixing the things.

Did any one bring in a bottle and hand it to him?—No one.

Mr. Purcell (to Mr. Coulson): Have you a receipt from Messrs. Hamilton and Long?—No. Receipts are only given when they are asked for. If you came to my shop I would not give you a receipt unless you asked for one. Mr. Cowan asked for the one he was given.

Mr. Purcell: Even if there were a shadow of foundation for this statement the Act covers it, for it is not only an offence against the 30th section to compound, but it is an offence to sell a medical prescription by a person who is not registered as a pharmaceutical chemist. The summons is not only for compounding, but selling.

(To Mr. Coulson): You brought the prescription to Messrs. Hamilton and Long's?—Yes.

Mr. O'Donnell: How long did that delay?—From ten or fifteen minutes.

Mr. Purcell: What did you pay at Messrs. Hamilton and Long's?—One shilling.

And got no receipt?—And got no receipt. There is not a day I am not in the habit of going there. They know who I am and give me things at trade prices.

Mr. Cowan, examined by Mr. Brownrigg, said: I did not see a glass counter dividing the shop.

To Mr. O'Donnell: I was quite close to the defendant all the time he was making up the prescription.

Mr. Brownrigg: Was not a little girl in the shop when I was called down first?—Yes, when I entered first.

And you said very well you are at your breakfast?—I said no such thing.

Mr. Purcell: Then it appears there was only a little girl in the shop.

Mr. Brownrigg: This was at nine o'clock in the morning.

Cross-examination of Mr. Coulson resumed by Mr. Purcell: This pill box (produced) is not the one we got from Messrs. Hamilton and Long's, as we could not wash the label off.

Is that the bottle you got from Messrs. Hamilton and Long?—I don't suppose they changed it. You don't imagine we pay twopence for a bottle when we can get them so much cheaper by the dozen.

Mr. O'Donnell (to Mr. Purcell): You say the section embraces selling and compounding?

Mr. Purcell (reading): "Provided always that it shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons . . . . or medical prescriptions." To sell or compound medical prescriptions, for that it is so intended is shown by the use of the disjunctive "or."—(To the witness): Were the pills made up at Messrs. Hamilton and Long's?—Yes.

How much did you pay?—I paid a shilling in all. We charged Mr. Cowan one shilling and sixpence.

Mr. O'Donnell (to the defendant): At all events by the sale that day you made a profit of sixpence. I fine you £5 and £3 10*s.* costs.

Mr. Brownrigg contended that the 31st section should be considered conjointly with the 30th, and in support of his argument quoted the following passage from the former, "Nothing in this Act contained shall extend to or interfere with the making or dealing in patent medicines, or with the business of wholesale dealers in supplying poisons in the course of wholesale dealing or of chemists and druggists who are practising as such in Ireland upon their own account at the time of the passing of this Act, save and except the provisions against the compounding of poisons or medical prescriptions, and against the preparing of any medicines of the British Pharmacopœia, except according to the formularies of the said Pharmacopœia."

Mr. O'Donnell held that the provisions of the 31st section did not alter the meaning of those of the 30th, and refused to change his ruling.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

MINOR.

THE PRESERVATION OF LEECHES.—Complaints are frequently heard of the inability of chemists to keep their leeches in health for any length of time. I have avoided the advertised leech aquariums and the like, and have for years kept leeches in perfect health by the following simple plan:—

I got a 7 lb. ointment jar, made of glazed white earthenware, and put my leeches into it. Then instead of replacing the top I covered the jar with white muslin, and tied it round tightly.

The water was never allowed to go unchanged more than a week, and by these simple means I have been able to keep all the leeches alive for months, even during the hottest weather, when the mortality amongst them is usually very great.

EDMUND F. CHERRY.

COURT PLASTER.—Soak isinglass in a little warm water for seventy-four hours, then evaporate nearly all the water by gentle heat, dissolve the residue in a little proof spirits of wine, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cool. Now stretch a piece of silk or sarsenet on a wooden frame, and fix it tight with tacks or pack-thread. Melt the jelly and apply it to the silk thinly and evenly, with a badger hair brush. A second coating must be applied when the first has dried. When both are dry, apply over the whole surface two or three coatings of balsam of Peru. Plaster thus made is very pliable and never breaks.

INDELIBLE ANILINE INK.—Triturate $1\frac{3}{4}$ grams of aniline-black with 60 drops of strong hydrochloric acid and 42 or 43 grams strongest alcohol; then add to it a hot solution of $2\frac{1}{2}$ grams gum-arabic in 170 grams of water.

This ink attacks steel-pens but little. It is not destroyed either by strong mineral acids or by strong lye.

If the first alcoholic solution of aniline black be diluted with a solution of $2\frac{1}{2}$ grams of shellac (instead of gum-arabic) in 170 grams of water, an ink is produced which may be employed for writing on wood, brass or leather, and which is remarkable for its deep black colour.

NOTES ON CINCHONA BARK.

BY DAVID HOWARD.

Recent importations of East Indian cinchona bark have thrown light on several points worthy of the notice of those interested in the subject.

The officinalis bark from the Government Plantation at Dodabetta gives us some valuable information as to the effect of age on the value of the bark. The date of the plantation from which each parcel was obtained was given, and we thus have a series of barks, classed as natural, mossed and renewed from trees planted each year from 1863 to 1867.

As "natural" bark from the lower stems is only obtained from trees not yet treated for "renewing," it is evident that in the older plantations the natural bark will be chiefly from the upper stem or from saplings and inferior trees, and thus, as Dr. De Vrij has shown, will be of inferior quality.

The result shows this to be the case, the best parcel of natural bark being from the plantation of 1867, that from the other plantations being of uneven quality showing no regular variation. The mossed bark on the other hand may fairly be taken to represent the oldest bark from the main stems in each plantation, and therefore is the best guide as to the influence of age on the quality of the bark.

The result is highly satisfactory, showing that as yet the bark from the oldest plantations, so far from deteriorating, continues to improve. Both the quinine and the total crystallizable alkaloid steadily increase from the bark of the 1867 plantation to that of 1864, that of the 1863 plantation yielding the same quinine as that of 1864, and slightly more cinchonidine and quinidine.

It is certainly more likely that so regular a progression is the result of greater maturity than that the difference should be caused by any variety in the *C. officinalis* cultivated.

This is a most important point, for recent importations of the bark of *C. succirubra* confirm the opinion so often expressed by my uncle, J. E. Howard, F.R.S., and by Mr. Broughton, the late Quinologist to the Indian Government ('Quinology of the East Indian Plantations,' p. 71), that in this species the bark deteriorates beyond a certain age. It is difficult to say exactly what that age may be, and it probably varies according to the growth of the tree, but some of the very finest of the red bark now coming from India, as far as appearance goes, certainly seems to have passed its maximum of richness in quinine.

As to the "renewed" officinalis bark, the time during which the different parcels have been forming is not given, nor is it stated whether it is from the first, second, or later crops, and therefore the comparison may not be accurate; but it is interesting to see that here also the older plantations show no deterioration, the best being from the 1863 plantation.

From a private plantation I have received a sample of root bark of *C. officinalis* from trees which were coppiced three years ago. It gives quinine 2·2 per cent., cinchonidine, ·2 per cent., quinidine, 1·5 per cent., and cinchonine, 3·3 per cent.

The stem bark from this plantation, at the time when the trees were cut down, gave: quinine, 2·6 per cent., cinchonidine, ·6 per cent., cinchonine, 1· per cent., and but a trace of quinidine.

We find, therefore, that in this sample the ordinary tendency of root bark to produce the dextrogyrate alkaloids is developed to a most unusual degree, the percentage of quinidine is a most extraordinary one for bark from *C. officinalis*.

I have also received from Darjeeling a very interesting sample of the bark of *C. succirubra* accidentally renewed. It is entirely the produce of accidental injuries to the trees (not deep enough to injure the cambium, and prevent the bark forming over the whole surface), no protection whatever having been given where the bark was removed.

The result is as successful as could have been expected from renewing under the most favourable conditions, the contained alkaloids being, quinine, 2·3 per cent., cinchonidine, 1·5 per cent , cinchonine, 1·2 per cent., quinidine, ·1 per cent.

Two parcels of the stem bark sent over at the same time from this plantation gave, first, quinine, ·8 per cent., cinchonidine, 1·2 per cent., cinchonine, 1·2 per cent., and secondly, quinine, ·9 per cent., cinchonidine, 1·1 per cent., cinchonine, 2·0 per cent.

The improvement in value in renewed bark is therefore not owing to the covering, but is found equally in this accidentally renewed bark, and it would seem that the mossing is valuable chiefly as enabling the tree to produce the renewed bark with as little injury to its health as possible. It will probably be found that a less perfect shelter than moss may in some circumstances be sufficient to preserve the health of the tree under this process.

It has been proposed by M. Moens to shave off the outer layers of bark without cutting quite through the bark. No doubt the cellular portion of the bark is richer in alkaloids than the inner fibrous layer (*vide* 'Quinology of the East Indian Plantations,' by J. E. Howard, F.R.S., pp. 23, 24 and 38), although the corky excrescences thrown out by the variety of *C. officinalis*, the "knotty bark of Jussieu," contain but little alkaloid (*Pharmaceutical Journal*, third series, No. 454, p. 769; 'Quinology of the East Indian Plantations,' p. 70). The inner and outer portions of a sample of the bark of *C. succirubra* gave the following results:—

	Quinine.	Cinchonidine.	Cinchonine.
Inner .	·6 per cent.	1·2 per cent.	1·4 per cent.
Outer .	1·2 "	1·4 "	1·7 "

It will be noted that not only is the total alkaloid more in the outer bark, but the quinine is in greater proportion, and therefore the outer bark would be of much greater value per pound to a manufacturer than the whole bark.

The practical value of the process chiefly depends on the effect on the tree. If when thus treated the tree throws out fresh bark of a similar quality to that produced in the old method of renewing without greater injury to its health, the process may be successful, but of course it is essential not to cut so deeply as to injure the cambium, and thus destroy the recuperative power of the bark.

AN IMPROVED METHOD OF MAKING PHOSPHORUS PILLS.

BY E. F. CHERRY.

Many have been the methods proposed for making phosphorus pills; most of them however, have something in the process to which objection may be made.

I believe the following process will be found free from all objections, and it has been in use now for years without a single instance of failure.

For the sake of example let it be supposed that 150 pil. phosphori are to be made, each to contain one-fiftieth of a grain of phosphorus. For this quantity we shall, of course, require 3 grains of phosphorus. This is to be put into a 1 ounce wide-mouth bottle: on it pour ½ ounce of chloroform, close the bottle, and allow it to stand until the phosphorus is completely dissolved. Carbonic disulphide has been recommended as a good menstruum in which to dissolve the phosphorus, but it is open to two objections: 1st. It is unpleasant to use on account of its disgusting odour; and 2ndly. It is not so volatile as chloroform, which is a disadvantage in the after part of the process.

When the process of solution is completed, pour the phosphorized chloroform into a mortar containing 150 grains of pulv. glycyrrhizæ. By stirring continuously for a few minutes, a dry powder is obtained consisting of liquorice combined with the phosphorus in a minute state of subdivision. This forms a good pill-mass by the addition of equal parts of syrup and mucilage of acacia.

These pills have been submitted to various eminent medical men, and have been found superior to those made by the B. P. process. In the latter it is often found that the presence of the wax prevents their solution in the stomach, and consequently their virtue is to a great extent lost.

Another recommendation is that the pills made as above are much less trouble to make than the B. P. ones; the latter process taking a long time to perform, while this new method only occupies a few minutes.

A NEW METHOD OF MAKING TINCTURE OF IODINE.

BY EDMUND F. CHERRY.

The ordinary method of making tinct. iodi often entails the dirtying of several measures, and not unfrequently stains on the skin. By the following method this is avoided; the tincture is made in a cleanly manner and can be allowed to proceed automatically, as it does not require any attention.

Suppose 2 pints are going to be made. Into a measure pour about 30 ounces of spirit, then take a funnel and loosely but completely plug the narrow part with cotton wool. On this bed place the pot. iodid. and the iodine. Then introduce this into the measure, taking care that the level of the spirit outside is *above* that of the solid ingredients in the funnel. It will be found that by a simple process of displacement the spirit will rise in the funnel and gradually dissolve the iodine and iodide of potash. This solution, by reason of its superior specific gravity, will sink to the bottom and fresh spirit will rise to continue the operation.

When the solids are completely dissolved, the remainder of the spirit may be added and the tincture is complete without any mess whatever.

MORPHIOMETRIC PROCESSES FOR OPIUM.*

BY ALBERT B. PRESCOTT, M.D.

(*Concluded from page* 130.)

B. *Process A, Modified by the Initiatory Treatment of the Opium with Hot Benzole.*—Each portion of the opium was digested, with heat, for one hour, with 35 c.c. of benzole, then washed on a filter with a little benzole, dried, and worked thereafter as directed in the process first given in this paper. The following results were obtained:—

Process B.

	Percentages. No. 1.	No. 2.	No. 3.	No. 4.	Mean.
a. Crystallized precipitate of crude morphia*	10·82	11·80	11·66	10·32	11·15
b. Ether-washed morphia	10·26	11·18	11·08	9·84	10·59
c. By estimating *b* with Mayer's solution	7·20	7·60	7·40	6·92	7·28
d. From filtrate, by amyl alcohol and Mayer's solution	3·08	2·72	3·60	3·72	3·28
e. Total morphia by Mayer's solution	10·28	10·32	11·00	10·64	10·56
f. Subtracting from *b* $\frac{1}{30}$ (Jacobsen)	9·92	10·81	10·71	9·51	10·28
g. Subtracting from *a* $\frac{1}{10}$ (Hager)	9·74	10·62	10·49	9·29	10·04

Comparison between Results of A and B.

	Percentages. Mean of A.	Mean of B.
a. Crude morphia	12·42	11·15
b. Ether-washed morphia	11·55	10·59
c. By estimating *b* with Mayer's solution	8·37	7·28
d. From filtrate, by amyl alcohol and Mayer's solution	2·50	3·28
e. Total morphia by Mayer's solution	10·87	10·56

It appears, then, that the use of hot benzole, instead of cold benzole, upon the opium, causes lower gravimetric results and lower results of the sum of the volumetric estimation. Result *b* is lower with each sample, as well as in the mean, from the use of hot benzole. The ether-washed morphia is purer in process A than in process B; the former giving of the mean 72·47 per cent. and the later only 68·84 per cent. of absolute morphia, by Mayer's volumetric estimation. Finally, the morphia precipitation is more nearly complete with process A than with process B; the former giving in the precipitate a mean of 77·00 per cent. and the latter a mean of 68·94 per cent. of the total morphia obtained by volumetric estimation. According to Cleaver (*Pharm. Jour. Trans.*, 1876, vii., 240), morphia is soluble in 2000 parts of benzole, at ordinary temperatures. The results of process B here seem to show that, when hot, benzole dissolves more morphia. The morphia volumetric yield is 0·0155 gram less after treatment with 35 c.c. hot benzole than after treatment with 50 to 100 c.c. cold benzole.

I will not venture to surmise why hot treatment, with benzole should make the precipitate less pure and less complete, but it was found, not only in the mean, as above stated, but in each of the four samples, the hot benzole treatment gave precipitates less pure and less nearly complete. Therefore, it appears inadvisable to use the benzole hot. And, because morphia is not without waste by cold benzole, the quantity to be used is limited, in the process recommended.

C. *Hager-Jacobsen's Process, as given by Hager, without Initiatory Treatment of the Opium with Benzole.*—(Hager's 'Untersuchungen,' ii., 176.) The materials and directions are essentially the same given in the proposed U. S. Pharmacopœia process, at the beginning of this paper, except that only eight drops of benzole are taken, and the initiatory treatment with benzole is omitted. The time of formation of the morphia precipitate was limited to three to three and a-half hours. As with processes A and B, the crude morphia was weighed, then ether-washed

* From the 'Proceedings of the American Pharmaceutical Association,' 1878.

* The weights of these precipitates were, in grams, for No. 1, 0·541; No. 2, 0·590; No. 3, 0·583; No. 4, 0·516.

and again weighed, and comparisons are given with crude morphia, minus $\frac{1}{10}$, and then ether-washed morphia, minus $\frac{1}{30}$. The precipitates were estimated volumetrically, and additional precipitates were obtained by twenty-four hours' standing, and volumetrically estimated, but, I regret to say, the final filtrates were not exhausted with amyl alcohol.

Process C.

	Percentages. No. 1.	No 2.	No. 3.	No. 4.	Mean.
a. Crystallized precipitate of crude morphia	9·96	14·14	12·80	10·28	11·79
b. Ether-washed morphia.	8·82	12·34	11·82	9·30	10·57
c. By estimating *b* with Mayer's solution	7·80	8·60	8·20	6·60	7·80
d. From additional precipitate by Mayer's solution	0·80	0·24	0·80	0·40	0·56
e. Total precipitates, by Mayer's solution	8·60	8·84	9·00	7·00	8·36
f. Subtracting from *b* $\frac{1}{30}$ (Jacobsen)	8·53	11·93	11·54	8·99	10·21
g. Subtracting from *a* $\frac{1}{10}$ (Hager)	8·96	12·72	11·52	9·25	10·61

Here the gravimetric mean result of ether-washed morphia is lower than in process A, and nearly the same as in process B. The additional precipitates contain, in the mean, 0·56 per cent. against 0·41 per cent. in process A. Of the morphia in the last mother liquor (filtrate) no estimation was made. By the volumetric estimation of the ether-washed precipitate it was, in the mean, 73·79 per cent. of morphia, a little purer than by process A (72·47 per cent.), and purer than B (68·84 per cent.). Judged by processes A and B (and D), the precipitation in C was deficient in No. 1, and notably impure in No. 2. Process C makes No. 2 to be 3·52 higher in per cent. than No. 1, A giving the difference 1·20, and B only 0·92 (for ether-washed morphia). The omission of the initiatory treatment with benzole leaves the opium-lime mixture loaded with the opium-wax and renders the filtrations more difficult and the entire operation less satisfactory. Indeed, one might say that the trouble of using the benzole was compensated for simply by the greater neatness of all the work afterwards.

D. *Procter's Staples's Process* ('Pro. Am. Pharm. Asso.,' 1870, p. 130; *Am. Jour. Pharm.*, 1871, p. 65; the first of the three methods tried by Procter).—The plan of the U. S. Pharmacopœia preparation of morphia modified by the washing of the opium with benzole.

The proportion of benzole used was 50 c.c. for the 100 grains of opium, the quantity taken by Procter. The benzole was applied by maceration in a filter and percolation, as directed for the proposed U. S. Pharmacopœia process. Following the proportions and directions used by Procter, the following results were obtained:—

Process D.

	Percentages. No. 1.	No. 2.	No. 3.	No. 4.	Mean.
a. Crystallized precipitate of crude morphia*	15·52	15·89	15·28	14·00	15·17
b. Ether-washed precipitate	14·91	14·87	14·54	13·28	14.40
c. By estimating *b* with Mayer's solution	11·20	11·11	11·60	10·40	11·08
d. From filtrates, by amyl alcohol and Mayer's solution	Results not satisfactory.				

The results with Staples's process were so evidently incorrect that I give them only as a confession of failure, the cause of which Mr. Stecher and myself had not time to investigate. In my own hands, and in the hands of those working under my instruction, Staples's process has usually given results rather lower than Hager-Jacobsen's. In this case the quantities of the samples were small, as given in the foot-note, but the balance was delicate and the work seemed satisfactory. The crude morphia was beautifully crystallized and of light colour, as is usual from Staples's process. I can only surmise that the "ether-washed morphia" contained something besides morphia, which can react with Mayer's solution. The results of working the filtrates were still less satisfactory. The filtrate from No. 1 was exhausted with amyl alcohol, this solution evaporated to dryness, the residue dissolved in sulphuric acidulated water, when it took 7·5 c.c. of Mayer's solution, indicating 6·00 per cent. of morphia. Then, with Nos. 3 and 4, the amyl alcohol residue was dissolved, as before, in acidulated water, this solution made barely alkaline with ammonia, and a bulky, light-coloured precipitate obtained. Filtered out and dried, the precipitate turned dark, coherent and waxy. Dissolved in acidulated water, the No. 3 solution took 3·5 c.c. of Mayer's solution (giving 2·80 per cent. morphia), and the No. 4 solution took 4·5 c.c. of Mayer's solution (indicating 3·60 per cent. morphia). The ammoniacal filtrates from these precipitates, last above named, were washed with benzole, then acidulated and titrated, when that of No. 3 took 3 c.c. of Mayer's solution (2·4 per cent. morphia), and that of No. 4 took 2·3 c.c. Mayer's solution (1·84 per cent. morphia). These benzole washings evaporated, and their residue dissolved in acidulated water and titrated, used for No. 3, 1·8 c.c. Mayer's solution (indicating of narcotina, 1·53 per cent.), and for No. 4, also 1·8 c.c. (same per cent. narcotina given by No. 3).

I would advise, in extracting filtrates from Staples's process with amyl alcohol, first to exhaust them with benzole, as was done for the estimations tabulated below. Narcotina, when free, is sufficiently insoluble in water, but narcotina, partially combined, may dissolve in the water solution of opium to a notable extent. If the crude morphia of process D, *a*, was loaded with narcotina, the ether washings have been insufficient to remove all narcotina, and the weights, *b*, may have represented this impurity.

May there be something beside alkaloids which precipitates Mayer's solution, obtained in the amyl alcohol extract from Staples's filtrates (though not so obtained from filtrates of Hager's process)? Dragendorff calls attention to the fact, that an aqueous extract of opium contains substances, aside from known alkaloids, which precipitate Mayer's solution, whatever those substances may be. Some results of the titration of water solutions of opium, acidulated with sulphuric acid, were found to correspond to 50 and 60 per cent. of morphia ('Werthbestimmung.,' p. 88). Again, titrating ammoniacal filtrates from opium, Dragendorff reports that when additions showing 19 per cent. and 21 per cent. of morphia had been made, the precipitates were still incomplete. Certainly no results so widely out of the way are obtained by titrating the amyl alcohol extract (a method used by Dragendorff himself), but it is desirable to know more positively whether amyl alcohol (always aqueous) takes up anything at all to precipitate Mayer's solution beside alkaloids. The work recorded in the next paragraph was entered upon before this question had defined itself in our investigation; but, although undertaken as a measure of the morphia left in Hager's filtrates and Staples's filtrates, and not as a test of the accuracy of amyl alcohol extraction, nevertheless it may be said that the results have such reasonable proportions as to do credit to the amyl alcohol extraction by which they were obtained.

Comparative Estimation of the Morphia remaining in a Set of the Final Filtrates of Hager's Process and of Staples's Process.—The estimation being done by Mayer's

* No. 1, from 2·5 grams opium, 0·388 crude morphia; No. 2, 3·24 of opium, 0·517 crude morphia; No. 3, 2·5 of opium, 0·382 crude morphia; No. 4, 2·5 of opium, 0·350 of crude morphia.

solution applied to amyl alcohol extracts, and the extraction with amyl alcohol, being preceded with benzole washing in case of the Staples's filtrates. These filtrates were obtained in a set of assays of tincture of opium, done by Mr. Henry Heim, in parallel operations by Hager's and Staples's process.* The work upon the filtrates, done by Mr. Stecher, was as follows:—The filtrates of Staples's process were first exhausted with two successive portions of benzole; those of Hager's process were treated directly with the amyl alcohol, the total alkaloid so obtained being estimated as morphia. In every case the amyl alcohol was used in three portions, successively, of 15 c.c., 10 c.c., and 5 c.c.—30 c.c. in all—each portion being shaken with the opium filtrate in a tube, the mixture left to separate, and the clear amyl alcohol layer drawn off. The united amyl solutions were evaporated to dryness on a steam-bath, the residue dissolved in sulphuric acidulated water, and this solution titrated with Mayer's solution. The results were as follows:—

* Valuation of tincture of opium, twelve samples, in parallel assays by Hager's process and Staples's process, reported by the writer from works by Henry Heim See.

The earlier process of Hager was used, differing from "Hager-Jacobsen's" in taking only 5 grams of opium (or the residue by evaporating an equivalent quantity of tincture), washing the residue into the lime opium solution, and concentrating the latter to about 25 grams before adding the ammonium chloride (and benzole and ether), then leaving twenty-four hours for precipitating the crude morphia. (Dragendorff's 'Werthbestimmung.,' 91.) For Staples's process, that given by Procter, 'Pro. Am. Phar. Asso.,' 1870, 131, was followed, evaporating tincture to one-half, and proceeding as directed, but leaving four days for the crude morphia to precipitate.

Mean morphia per c.c. for 8 Nos., omitting 2, 10, 11, 12; Hager's, 1·85 milligrams; Staples's 2·45 milligrams.

For the total 436 c.c. of 11 Nos. with Hager's process, the mean was 1·93 milligram morphia per c.c. of filtrate. The solubility of morphia in water, and to a greater extent in the mother liquor of morphiometric assays, even when no excess of ammonia is present, has been alluded to in a foot-note under process A. As the filtrate of Staples's is alcoholic, it ought to dissolve more morphia than the filtrate of Hager's process. Taking the solubility of morphia in pure water as 0·001 gram per c.c., it is indicated by this work that Hager's filtrates dissolve, in the average, 1·9 times more than water does (the extreme being 1·02 times, and 2·4 times); while Staples's filtrates dissolve, in the average, 2·45 times (in extremes, 1·77 times and 3·0 times) more than water dissolves.

As having a bearing on the comparison of Hager's process with Staples's it may be quoted here that Mr. Heim's gravimetric results, in valuation of tincture of opium give, as the average with the twelve samples, by Hager's process, 3·103 grains ether-washed morphia per fluid ounce of tincture; by Staples's process, 2·84 grains morphia per fluid ounce of tincture.

E. *Schachtrupp's Process for Estimation of Morphia and Narcotina.*—(*Zeitschrift für Analyt. Chemie*, 1868, vii., 509.) A weighed amount of opium (5 grams), is covered in an evaporating dish (porcelain), with a solution of sodium carbonate, heated on the water-bath, and when semi-fluid, evaporated to dryness. The dry mass is transferred to a perfectly dry beaker or flask, covered with benzole, agitated and heated moderately, then decanted on a filter, and the residue treated two or three times with portions of benzole and filtered. [The quantities of benzole were not stated by Schachtrupp. The solubility of morphia in benzole has been discussed under "Process B." It is advised to use, in all, about 40 c.c. for 5 grams opium, but a good deal more was used in our operations.] (The benzole solution is reserved for estimation of the narcotina). The dried filter with its contents is now added to the residue in the flask or beaker, and the whole warmed to expel the last trace of benzole. Amyl alcohol is now added to the dry residue, in the flask, the mixture stirred and heated to near boiling, and while hot decanted upon a filter, adding successively two more portions of amyl alcohol. [Schachtrupp does not specify how much amyl alcohol to use.] Set the mixed filtrates aside for a few hours. Decant from crystals of crude morphia; distil the solution to its one-third; add dilute hydrochloric acid, in the retort, and shake. Remove the amyl alcohol, the upper layer (from the water solution of morphia hydrochlorate, below); wash the decanted amyl alcohol with two or three additional portions of the dilute acid, and pour the united acid water solutions upon the crystals of crude morphia, previously separated, to dissolve them. [Schachtrupp does not give strength or qualities of the dilute hydrochloric acid. Mr. Stecher used four portions, and found the last to take up a notable proportion of morphia. Dragendorff states that all the morphia can hardly be obtained in this way. It would be better to evaporate the amyl solution to dryness, and then dissolve in acidulated water, as done by Mr. Stecher in extracting mother liquors with amyl alcohol described under process A.] The acidulated water solution of morphia is now evaporated on the water-bath, to a weight double to that of the opium taken, filtered, the filtrate treated with ammonia in slight excess, covered loosely, and set aside for twenty-four hours. The precipitate (at first bulky and afterwards growing crystalline) is collected on a filter, washed several times with distilled water, and dried and weighed. [The gravimetric morphia of this process retains considerable colour.] The reserved benzole solution is evaporated to dryness, the residue dissolved in sulphuric acidulated water, and the solution titrated for narcotina, with Mayer's solution. Each c.c. of the latter precipitates 0·0213 gram narcotina.

The following results were obtained by Schachtrupp's process:—

Process E.

	Percentages. No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	Mean.
a. Coloured morphia, precipitate . .	7·53	8·82	11·16	10·27		9·44
b. By estimating *a* with Mayer's solution . . .	4·80	5·60	10·20	10·00	7·00	7·52
c. Benzole alkaloids, by Mayer's solution, estimated as narcotina . . .	14·91	10·44	9·58	9·80	9·04	10·15

Flückiger and Hanbury mention percentages of narcotina, from 1·30 to 10·30. Dragendorff gives results for narcotina, from 8·8 to 14·7 per cent. ('Werthbestimmung.,' 83). As previously mentioned, Mr. Stecher used more benzole than should be used, and considerations of the benzole solubility of morphia make it certain that a notable proportion of morphia was obtained with the narcotina.* No work was done to separate morphia from the other alkaloids dissolved by the benzole, and it can only be declared that the results are untrustworthy, and the process of Schachtrupp an inexpedient one.

The trial of process E gives additional evidence that *the initiatory treatment of the opium with benzole* cannot be used to remove all the narcotina, while leaving all the morphia behind. To dissolve all the narcotina, which is partly held in feeble combination, alkali must be added,† as in Schachtrupp's process, and then the use of another benzole to take out the wax, etc., seriously diminishes the morphia. The office of the benzole is to free the opium of caoutchouc-like matter, colour, etc., and the additional service of making it unnecessary to purify the crude morphia crystals seems to be more than benzole can accomplish. The advantages of preliminary benzole treatment appear from the results of process C, wherewith they have been named. As to the results by the use of the benzole hot, see process B. It can hardly be said that the benzole treatment is very important; but as it is otherwise required in the Hager-Jacobsen process, the preliminary use of the agent does increase the number of materials to be taken.‡

The purification of the crude morphia crystals is best done, I believe, by the ether, non-alcoholic or water-washed. I suggest to put *water-washed ether* in the list of reagents, unless otherwise included, with direction to wash shortly before use, because any pharmacist can, from any grade in stock, in a few minutes, make a uniform quality of ether, free from those common impurities most objectionable for use as a solvent, alcohol and acetic acid, the latter derived in keeping.

With the Hager-Jacobsen process as proposed for the Pharmacopœia, I regret the unavoidable length of the directions, giving an appearance of complexity, perhaps forbidding to the pharmacist. In the execution of the process there is nothing difficult; all the operations define themselves sharply and satisfactorily, and there is little more weighing and much less waiting than in other processes. Some features of leading processes may be compared as follows:—

Process.	Quantity of Filtrate to 1 of Opium.	Time Required.
Hager-Jacobsen's .	1 to 10	5 to 6 hours.
" with benzole preliminary treatment	1 to 10	6 to 8 hours.
Staples-Procter's .	1 to 6 or 7 (alcoholic)	48 "
British Pharmacopœia	1 to $2\frac{1}{2}$	50 "

As to the purity of the morphia weighed, considered with the incompleteness of its extraction, and as to deducting a fraction for impurities, I would only add to what is given under "Process A," a remark of Dragendorff ('Werthbestimmung.,' 92), to the effect that, for ordinary purposes, the foreign substances left in the (chloroform-washed) crystals by Hager's process may be left to balance the loss in mother liquor and washings.

The reports made by careful analysts in different parts of the world render it evident that exact morphiometric methods for opium have not been attained, and the obstacles in the way towards exactness appear only the more apparent in the work I have undertaken. Indeed, absolute exactness is rarely if ever reached in human science. We must be patient with imperfection, always measuring our results by the truth beyond them, as nearly as we can, and we must work heartily for the uses of mankind with such approximate measures as we have.

University of Michigan.

* Benzole dissolves narcotina, codeina, papaverina and narceina (slightly).

† Obtaining, by Mayer's solution, from the benzole extract of a sample of dried opium (not made alkaline), 2·3 per cent. of narcotina, I found from the similar extract of another portion which was made alkaline, 3·3 per cent. of narcotina.

‡ I hardly need mention that Mr. William Procter recommended the adoption of the benzole treatment, referring to its use by Flückiger, and that the modification (of the Staples' process) very properly bears the cognomen due to Mr. Procter's important report on morphiometric methods.

CULTIVATION OF PERFUME PLANTS IN SOUTH AUSTRALIA.*

A recent report on the progress and condition of the botanic garden and Government plantations at Adelaide, South Australia, by the Director, Dr. Schomburgk, contains some interesting remarks on the cultivation of perfume plants in that colony.

A branch of cultivation that promises to become of very great importance in South Australia is the systematic growth of perfume plants. Of the magnitude of the commercial aspect of the perfumery trade, we are reminded that British India and Europe consume about 150,000 gallons of handkerchief perfume yearly, and the English revenue from eau-de-cologne alone is about £8000 a year; that the total revenue from imported perfumes is estimated at about £40,000, and that one great perfume distillery at Cannes uses yearly about 100,000 lbs. of acacia flowers (*Acacia farnesiana*), 140,000 lbs. of rose petals, 32,000 lbs. of jasmine blossoms, 20,000 lbs. of tuberose, besides a great many other fragrant plants. Dr. Schomburgk says:—"Most of the flowers which provide the material for perfumes grow most luxuriantly with us, viz.: mignonette, sweet verbena, jasmine, rose, lavender, *Acacia farnesiana*, heliotrope, rosemary, peppermint, violets, wallflower, laurel, orange, and the sweet scented geranium. I may say that these plants thrive probably in greater perfection here than in any other part of the world. No doubt South Australia should be a perfume-producing country. We see flourishing here some of the most valuable scent plants, and even some of our native plants will yield a valuable scent; but two things are needed to encourage the enterprise. First if the scent is manufactured in South Australia, freedom of the still, so as to license distilling in vessels of less than twenty-five gallons capacity, and, secondly, the *bonâ fide* advertisement of a capitalist manufacturer that he will buy any quantity of specified flowers, leaves, roots, or plants, at a marketable price, then some farmers might be tempted to plant a few acres of lavender or mint; another, geraniums or rosemary; another, jasmine; whilst plantations in hedgerows, or otherwise of roses, cassia, together with contributions of gardens, would lay the

* From the *Journal of the Society of Arts*, August 22, 1879.

foundation of an export trade. Then it must also be noted that whatever the value which plants yield in flowers, fruit, leaves, and stems, it is increased threefold under manufacture, and this manufacture again consumes other local produce called into existence by it, such as olive and other oils, fats, alkalies, wheaten flour, colouring matter, pottery, and glass ware, which combine to make the farmer and the manufacturer contribute largely to the maintenance of the population and the wealth of perfume-producing countries." Dr. Schomburgk further points out the profits likely to accrue from an extended cultivation of scent-bearing plants, as against the cost of land in England, acres of which in certain localities are under cultivation of peppermint, lavender, and other well-known plants of the same class. The failure of these crops, or more particularly those on the farms of Grasse, Cannes, and Nice, would be a serious disaster to this branch of commerce, the importance of which may be proved from the fact, that a member of a well-known perfumery house in Bond Street has thought it worth his while to visit Australia for the purpose of encouraging this branch of culture. Regarding the manufacture of the perfumes, an opinion is expressed which will no doubt be fully endorsed by practical men at home, that it is unadvisable to prepare them in the colony; this work would of course be much more effectually done in this country; at the same time, the plants might go through some manipulation or partial preparation, so as to reduce their bulk and consequent cost of freight. The outcome of this endeavour to open a new branch of commerce with Australia will be looked to with much interest.

The introduction and extended cultivation of the olive (*Olea europea*) in Australia is now *un fait accompli*; it is nevertheless satisfactory to find that a choice variety—that which produces the famous Lucca oil—has been successfully raised. This new introduction seems due to the energy and liberality of a private gentleman, by whom it is hoped the plants will be freely distributed.

VERATRUM VIRIDE—NOTES OF AN EXAMINATION.*

BY CHARLES BULLOCK.

When the root of *Veratrum viride* is digested in water acidulated with sulphuric acid at a temperature of 150° F., the mass becomes gelatinous and swells up to an increased bulk. When expressed and alcohol is added to the expressed liquor, a copious deposit of pectic acid is occasioned.

The presence of pectose and the large amount of resin and fatty matter contained in the root makes the use of alcohol necessary for its exhaustion.

Fifty-three pounds of *Veratrum viride*—rhizome with rootlets—from North Carolina, in powder, was exhausted with alcohol, the alcohol distilled off and the resulting extract exposed to a continued moderate heat until all of the alcohol was expelled. During this process the resin separated from the soft extract. It was removed and allowed to drain for several weeks during the warm weather of summer.

Weight of the soft extract .	6 lbs. $10\frac{1}{4}$ ozs.
Weight of the hard resin .	3 lbs. 4 ozs.
Total weight of extract from 53 lbs. of root	9 lbs. $14\frac{1}{4}$ ozs.

This extract furnished the material for examination.

In separating the alkaloids, advantage was taken of the previously-ascertained fact that *all* of the alkaloids were imperfectly precipitated from acid solutions by caustic alkalies or alkaline carbonates at ordinary temperatures, but if the solution is heated to 150° F., the precipitation is almost complete.

The Soft Extract.—86 per cent. of this extract is soluble in water. Petroleum benzin removes 4·3 per cent. of fatty matter. After removal of the alkaloids, the watery solution was treated in the usual manner with subacetate of lead, and after separating the excess of lead and neutralizing the free acid with carbonate of baryta, the filtered solution was evaporated to a syrup and thrown into alcohol. The filtered alcohol solution, evaporated and exposed to a temperature of 212° F. until it ceased to lose weight, gave a product representing 85·5 per cent. of the extract.

This product has a transparent red colour, a saccharine taste, with some bitterness, and acts energetically as a reducing agent with salts of copper and silver. In chemical character it appears to be almost entirely glucose.

The amount of alkaloids contained in this extract was determined for the portion soluble in water and for the resin separately.

880 grains of the extract, representing the yield from one pound of root, was exhausted with water, the washings were evaporated to reduce the volume and carbonate of soda added to alkaline reaction. After separating the precipitate, the solution was heated to 150° F. and a little caustic soda added. The precipitate occasioned was removed while the solution was warm.

The weight of the first precipitate by carbonate of soda was . .	16·7 grains.
The second, by caustic soda, was .	2·6 „
Total	19·3 „

These alkaloids contained a large amount of colouring matter, from which they were purified by re-solution in acetic acid, filtering and precipitation from a warm solution. The precipitate, when dry, weighed 10·7 grains.

All of the mother-waters were made acid and evaporated, then made alkaline and treated with ether. The ether product was dissolved in acetic acid, filtered and precipitated as before. Weight of product, 1·7 grain; total weight of mixed alkaloids, 12·4 grains.

The jervia was separated by precipitation, as a nitrate, from an acetic solution representing 3 grains in each fluidounce, by addition of an equal volume of a saturated solution of nitrate of potassium. After standing six hours, the nitrate of jervia was collected on a filter and washed with a solution of nitrate of potassium, pressed between folds of bibulous paper and dried. Weight of nitrate of jervia, 7·9 grains. After the separation of the jervia the solution was evaporated, heated to 150° F. and precipitated by soda. Weight of other alkaloids, 3·2 grains.

Resin from the Soft Extract.—To prevent any change which might be caused in saponifying the resin with lime, the following process was adopted with this as also, subsequently, with the hard resin:—

The fatty matter was removed by petroleum benzin. The resin, rubbed to a fine powder, was made into a smooth paste with water introduced into a bottle and a solution of carbonate of soda containing a little caustic soda added until the resin was dissolved. It was then agitated with ether and the ether removed. The washing with ether was then repeated. The product left on distillation of the ether was dissolved in acetic acid, filtered and precipitated by carbonate of soda, containing a little caustic soda. Weight of product, 9·3 grains.

The mother-water was made acid, evaporated, and after being made alkaline, treated with ether. The product, dissolved in acetic acid, filtered and precipitated, gave 0·7 grain more of alkaloids. Total weight of mixed alkaloids from the resin, 10 grains.

The alkaloids separated by nitrate of potassium gave—

Nitrate of Jervia	8·4 grains.
Other Alkaloids	1·6 „

Hard Resin.—429 grains, representing the yield from one pound of root, was powdered and digested in petro-

* From the *American Journal of Pharmacy*, July, 1879.

leum benzin. The loss of weight representing fatty matter, was 84·7 grains. After removal of the benzin by evaporation, the resin was reduced to a fine powder and treated as in the previous experiment, by dissolving it in an alkaline solution and treating the solution with ether. The weight of mixed alkaloids obtained was 22·5 grains. The mother-water was made acid, evaporated, and, after addition of caustic soda, treated with ether. The product obtained weighed 0·8 grain. The alkaloids, separated in the manner preceding, gave—

Nitrate of Jervia	14·1 grains.
Other Alkaloids	6·1 „

The resin from the soft extract and the hard resin were then precipitated from their alkaline solution by hydrochloric acid, and dried. The solution was made neutral with soda and evaporated to dryness. This product was added to the precipitated resin and the whole mixed with an equal weight of lime previously slaked, and the mixture boiled for a few minutes, then evaporated to dryness by steam heat. The dry mass was powdered and exhausted by hot alcohol. The product left on distillation of the alcohol was dissolved in diluted acetic acid, filtered and precipitated. Weight of mixed alkaloids obtained, 0·9 grain. The alkaloids, separated as before, gave—

Nitrate of Jervia	0·1 grain.
Other Alkaloids	0·8 „

The *total* amount of alkaloids obtained from the extract representing one pound of root, was—

From Soft Extract	12·4 grains.
Resin from Soft Extract . .	10 „
Hard Resin	24·2 „
Total yield of mixed Alkaloids,	46·6 „

When separated, the alkaloids represented—

	From soft extract.	Resin from soft extract.	Hard resin.
Nitrate of Jervia.	7·9 grs.	8·4 grs.	14·9 grs.
Other Alkaloids .	3·2 „	1·6 „	6·2 „
Total amount of Nitrate of Jervia . .			31·2 grains.
„ „ „ other Alkaloids . .			11·0 „
			42·2
Loss			4·4 „
			46·6

The loss of over 10 per cent. which occurred in separating the alkaloids is due both to separation of foreign matter and loss in manipulation.

An examination under the microscope of the alkaloids, after separation of the jervia, was made by allowing a drop of their alcoholic solution to evaporate on a glass slide. Crystalline forms were found, differing in form from jervia, indicating the probable presence of another alkaloid which crystallizes from its alcoholic solution. When further purified by solution in ether, dissolving the ether product in acetic acid and precipitating by nitrate of potassium until a solution containing 1 part in 200 of acetic solution was no longer disturbed by addition of the nitrate, then precipitating the solution at 150° F., by caustic soda, a product representing 5 per cent. of the mixed alkaloids was obtained.

Saponification of the Resin by Lime.—One pound avoirdupois of the hard resin was powdered and rubbed into a smooth paste with one pound of lime previously slaked. Sufficient water was added and the mixture boiled for a few minutes. After evaporation and drying on a steam-bath, the mass was powdered and exhausted with three gallons of hot alcohol. The product left on distillation of the alcohol was treated with warm diluted acetic acid,* filtered and precipitated while warm by caustic soda. The precipitate was purified by drying, re-solution and precipitation. The weight of mixed alkaloids obtained was 485 grains.

A better result was obtained from a second pound of the resin, by first removing the fatty matter with benzin and using two pounds of lime. The yield of alkaloids by the process of saponifying with lime was 20 per cent. greater than by the ether process.

Volatile Principles.—300 grains of the hard resin, deprived of fatty matter, was dissolved in water by addition of carbonate of soda mixed with a little caustic soda. The alkaline solution was submitted to distillation, collecting the product in a receiver containing water acidulated with acetic acid. The distillate was evaporated to reduce its volume, made alkaline and treated with ether. The result was negative.

Note.—After concluding the examination recited in this paper, I have seen the abstract of a paper read by Dr. Wright before the Chemical Society, London, May 15th, "On the Alkaloids of *Veratrum Viride*," in which the able and exhaustive examinations made by him contribute greatly to our knowledge of the constituents of this interesting drug. The name "rubijervine" has been given by him to the alkaloid which has claimed my attention, a name which is very appropriate to the reactions of the alkaloid. The alkaloid which I found to crystallize from solution in alcohol along with "rubijervine" is probably his "pseudojervine."

The large amount of alkaloids which are associated with the resin, and removed from it only by saponifying with lime, render it probable that by his process of obtaining the alkaloids a considerable amount escaped his notice.

The approximate yield of the bases which I obtained from 1 pound avoirdupois of the root by the ether process was 46·6 grains = 6·612 grams per kilo. The amount obtained by Dr. Wright was 0·80 gram per kilo.

The amount obtained from *the hard resin alone* by saponifying with lime represented 29·7 grains for one pound of root = 4·21 grams per kilo.

Philadelphia, June 6, 1879.

SOAP BARK IN THE TREATMENT OF SKIN DISEASES.†

The *Quillaia saponaria* is indigenous to Chili. Its bark is imported in flat pieces, which are usually several inches wide, and from 2 to 3 feet in length. These are hard and tough and of light grey colour. In the shops it is generally found in raspings and small woody fibres mixed with an acrid dust which readily provokes sneezing. It contains, among other ingredients, saponin, sulphate of calcium and a small quantity of starch.

A saturated alcoholic solution of saponin possesses the power of dissolving gums, resins and oils, and will form with them after being mixed with water, permanent emulsions. This same solution, when shaken with mercury, will keep it suspended. It will be seen that saponin in solution possesses all the chemical action of soap, and is often preferred to the latter. As a therapeutic agent this natural soap can be used in the form of infusion, tincture, or fluid extract.

An infusion of the bark can be easily made by tying some of it in a piece of white flannel, and allowing it to remain in a bowl of water for one or two hours, until the saponin is dissolved. I resort to this method of extracting the active principle in order to avoid the irritating effect of the minute fibres of the bark. If this solution is applied to any part of the body it will be found to

* Repeated treatment with hot water containing acetic acid until two gallons were used was necessary to exhaust the product.

† From the *Druggists' Circular and Chemical Gazette*, August, 1879.

fulfil all the requirements of a mild soap, and act in addition as a moderate stimulant and astringent on the skin. I have used it with marked benefit in dandruff of the scalp. It causes the enlarged glands of the part to contract, and often removes all infiltration of the skin. It has often been of great service in removing the scales in simple pityriasis, and in producing at the same time its moderately stimulant and astringent action. Similarly, I have had some excellent results from its use in chronic ulcers and eczema of the extremeties. I usually saturate a roller bandage with the infusion and bandage up the part. The cases in which I tried this means had previously used both the simple dry and wet roller bandage, but no success was attained until the above method was adopted.

The infusion is also a valuable remedy for aiding in arresting excessive secretion and fetid perspiration. The parts that are usually affected by these troubles are the face, armpits, hands and feet. In cases involving the face and armpits, I instruct the patient to dip a small piece of sponge in the infusion, and carefully mop over the surface once or twice daily. When the hands and feet are affected they should be bathed in the solution nightly, or on alternate nights, according to the condition.

When a more active stimulant and astringent effect is required, the tincture of saponin can be employed with much advantage. The tincture is prepared by extracting the bark, as already mentioned, by means of strong boiling alcohol. The solution thus formed is clear and of a deep wine colour, and a pungent taste. It is chiefly employed as an external remedy, and when applied to a part has a refrigerant effect. It is miscible with both water and oil, and has the power of dissolving, emulsifying, and removing fats and dirt from the skin. In many diseases, especially in *Seborrhœa sicca*, I have found it far preferable to the tincture of green soap. It has all the advantages that are claimed for the tincture of green soap, and at the same time is free from the high diffusive, penetrating, and destructive action on the tissues that the latter possesses.

I have used this tincture with great benefit, not only in the diseases to which the infusion is applicable, but also in general thinning and loss of hair in different parts of the body. It can be employed with great advantage as an addition to the internal treatment in that variety of the loss of hair in which the scalp is to all appearances healthy, but the surface is covered with short, fine, and downy hairs. In cases of this description it should be applied in full strength with a sponge, and should always be thoroughly rubbed into the scalp, and afterwards rinsed off with water.

NOTE ON HYRACEUM.*

BY WM. H. GREENE, M.D., AND A. J. PARKER, M.D.

Among the native remedies from the Cape of Good Hope, exhibited at the Centennial Exhibition, was a peculiar substance called hyraceum, which was supposed to be the inspissated urine of the Cape Hyrax (*Hyrax capensis*).

The material was obtained from Dr. Leidy, who, in the 'Proceedings of the Academy,' December, 1876, p. 325, gave a short account of it. According to this account "the hyrax is reputed to inhabit gregariously rocky places at the Cape of Good Hope, and the accumulated urine in the hollows of rocks, gradually evaporating, is supposed to give rise to the product in question. It is reported as having been employed in medicine with the same effect as castoreum."

Professor Cope remarked that "a material resembling the concretion made by the urine of the hyrax was found in the fissures of the rocks of New Mexico. It is probably the fecal and renal deposit of the wild rat, *Neotoma*."

About two years ago we made an exhaustive examination of this substance. It is a dark-brown, brittle and resinous material, having an aromatic odour and a bitter taste. About 56 per cent. of it is soluble in water, and nearly one-third of the residue from the aqueous extraction is soluble in alcohol, ether and chloroform.

The soluble material amounts in all to about 70 per cent., and the remainder is composed of 14 per cent. of woody fibre and insoluble organic material, and 16 per cent. of sand and other inorganic substances.

On ignition, hyraceum yields about 34 per cent. of ash, which is composed of chlorides, sulphates, phosphates and carbonates of the alkaline metals, and of lime and magnesia. It also contains nitrates in small proportion.

On precipitating the organic material contained in the aqueous extract with lead acetate, and afterwards decomposing the suspended precipitate by means of sulphuric acid, a substance was obtained which constitutes the greater portion of the organic material soluble in water. It was hard, horny and of a resinous character, transparent, and of a bright-brown tint. It probably consists of several substances, but we were unable to obtain a sufficient quantity for separation, and an ultimate organic analysis. It gives out a fecal odour, and seems to be derived from fecal matter.

The analysis, the details of which are subjoined, shows that the substance is a mixture of various salts and organic matter, the latter constituting about one-half, and containing traces of urea, together with uric, hippuric and benzoic acids. We also obtained from the material a small quantity of a substance having a sweet taste, and which is probably glycocol (?) derived from the breaking up of hippuric into benzoic acid and this substance.

Hyraceum is undoubtedly derived from the urine of some animal, but the large amount of lime (6 per cent.) in proportion to the other salts, and the character of the organic matter contained, indicates that it also contains fecal matter.

Analysis of Hyraceum.—Water, by desiccation, 7 per cent.

A microscopical examination revealed nothing of importance. Woody fibres, particles of sand and a general granular appearance were found.

Dried Material.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 6, 1879.

PROTECTION OF THE PRACTICE OF PHARMACY IN IRELAND.

The two cases of prosecution under the Pharmacy Act, Ireland, of which we published reports last week, serve to show that the Council of the Irish Pharmaceutical Society is resolved to maintain the character of the degree of pharmaceutical chemist, and we rejoice to be able to congratulate that body upon the manifestation of so laudable an intent.

At the time the Irish Act was passed there were some misgivings in this country that the adoption of only one grade of pharmaceutical practitioners and the application of the title of pharmaceutical chemist to that grade might have a prejudicial influence on the value—acquired and anticipated—of the same designation in this country.

The Irish Society was able to do what could not be done here in legislating for the pharmaceutical practitioners that were to succeed the old apothecaries. Here the practice of pharmacy was cast adrift to all comers, and in assuming new functions the English apothecaries abandoned the trust that was confided to them in the interest of the public. In Ireland, on the contrary, the right to compound physicians' prescriptions has always been zealously guarded by the apothecaries as their exclusive privilege in virtue of special preparation for the duty, and though they, like the apothecaries of England, are gradually developing into medical practitioners simply, the protection of the public and of the qualified pharmacist has been secured by the provisions of the Irish Pharmacy Act in a manner that could not be done here when our Pharmacy Act was passed in 1868, though the eventual realization of this object is thereby provided for.

As an incident of the first of these cases we find that the magistrate gave utterance to one of those expressions of opinion which are sometimes exceedingly damaging in their influence upon particular classes, but at the same time are totally destitute of any just foundation, and should therefore be studiously avoided by magistrates or other judicial functionaries. We refer to the comments of the magistrate upon the propriety of the action taken by the Pharmaceutical Society of Ireland. It was naturally urged by the counsel for the plaintiffs that the prosecution was not intended to be oppressive, but that it was merely the action incumbent on the representatives of the Irish pharmaceutical body for the purpose of vindicating the law and protecting the public. This view was at once accepted by the magistrate, who also proceeded to observe—in illustration, we presume, of the salutary nature of the Act—that "mistakes occur every day in London in "consequence of prescriptions being compounded by "persons who are not properly qualified to do so," and he then went on to say that happily there had been very few such cases in Ireland.

It is not our desire to open old wounds by following out the comparison thus instituted by the magistrate, though we think that if some members of the Council of the Irish Society had pointed out the total absence of any justification for the magistrate's remarks to the disadvantage of London he would not have done more than justice to his English colleagues nor would he have overdone that generous chivalry for which Irishmen are justly famous. But as this was not done it becomes our duty to give the most emphatic contradiction to the statement of the Dublin magistrate. Comparisons are always dangerous, no less than odious, and in this instance it would scarcely have been possible within so small a number of words to express a greater amount of inaccuracy. It is not the case that in London mistakes occur every day in the compounding of prescriptions; it is not the case that in London, or any other part of Great Britain, prescriptions are compounded by persons not properly qualified to do so. There is no contrast in these respects between Great Britain and Ireland which is to the disadvantage of the former. In the expression of a sense of what is necessary in the public interest as regards dispensing of medicines, Great Britain lies under the advantage of having led the way through the medium of the Pharmaceutical Society to establishing a regulation of the practice of pharmacy by which the competence and skill of pharmaceutists is ensured, and it is upon the model of the example thus afforded that pharmacists in Ireland have carried out the application of similar measures. In their labours to this end they have always had the cordial sympathy of their *confrères* in this country; we trust their efforts may always be united in the same direction, and that these amicable relations may never be interfered with by unwise comments in the spirit of the Pharisee, whether they be accidental or intentional.

THE FLOODS IN HUNGARY.

We have received a communication from Mr. Gustav Jarmay, the President of the Hungarian Pharmaceutical Society, acknowledging the receipt of £39 1s. in aid of the fund for the relief of the distressed pharmacists of Szegedin, and requesting us to express to those pharmacists of Great Britain whose contributions that sum represents the grateful thanks of himself and the other members of the Committee. We also will take this opportunity to express our hearty thanks to those who have supported our endeavour to obtain on the part of British pharmacists a fitting expression of sympathy with the misfortunes of their brethren in Hungary.

POISONOUS HONEY.

In a report by Mr. Vice-Consul Biliotti on the trade of the port and district of Trebizond, he refers to the poisonous effects produced by some of the honey obtained near the coast of that province. Those who partake of it suffer from giddiness, vomiting and intoxication, exactly as did Xenophon's soldiers in the same locality more than two thousand years ago. This poisonous quality has been on a former occasion attributed to the bees having collected the honey from the flowers of henbane and hemlock, which occur plentifully in the neighbourhood, but Mr. Biliotti appears to be inclined to refer the mischief rather to the *Datura Stramonium*, which grows in abundance on the coast. Although therefore bees are reared on a somewhat extensive scale in the province of Trebizond, in the neighbourhood of the coast, the hives are only remunerative in wax, but the honey produced in the high lands is innocuous, and is said to be of superior quality.

In the list of candidates who have passed the recent honours examinations of the London University the first name in the first B. Sc. and Preliminary Scientific Examinations is that of Mr. A. P. Luff, formerly a Bell Scholar, whilst bracketed with another gentleman in the second place is Mr. W. A. Gostling, a son, we believe, of Mr. Gostling, of Diss, a member of the Council of the Pharmaceutical Society.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, September 3, 1879.

Present—Mr. George Webb Sandford, President; Messrs. Atkins, Bottle, Churchill, Hills, Richardson, Robbins and Savage.

The minutes of the previous meeting were read and confirmed.

The Pharmaceutical Conference.

The President said he might state that he and several other members of the Council represented the Society at the Pharmaceutical Conference, and they were very warmly received. It was as good a meeting, he believed, as they had ever had, and the Sheffield chemists did everything to render their visit a pleasant one.

Weights and Measures.

The President read the following correspondence on the above matter:—

"Board of Trade,
"(Harbour Department),
"Whitehall Gardens, S.W.,
"August 21, 1879.

"Sir,—With reference to previous correspondence on the subject of providing proper standards of the weights and measures used in trade by apothecaries, I am directed by the Board of Trade to transmit to you, herewith, copy of the Order of Her Majesty in Council legalizing certain denominations of standards of apothecaries' weight and measure.

"I am, sir,
"Your obedient servant,
"Henry G. Calcraft.

"The President of
"The Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C."

[The Order in Council here referred to was published in the *Pharmaceutical Journal* of August 23, p. 145.]

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C.,
"August 27, 1879.

"Henry G. Calcraft, Esq.,
"Harbour Department,
"Board of Trade,
"Whitehall Gardens, S.W.

"Sir,—In reference to your letter of the 21th inst., enclosing a copy of the Order in Council 'legalizing certain denominations of Standards of Apothecaries' Weight and Measure,' may I venture to refer you to a memorandum sent to F. H. Farrer, Esq., by the then President of this Society, on the 30th January last, especially on the subject of verifying small weights and certain sub-divisions on glass measures, which are in daily use by chemists, and stamping them?

"If you will kindly favour me with the decision of the Board of Trade on these points or refer me for further information to the officer who has authority in the stamping department, I shall be greatly obliged.

"I am, sir,
"Your obedient servant,
(Signed) "G. W. Sandford,
"*President.*"

The President said he had not received any answer to the last communication, and on inquiry at a scale-maker's was informed that he had not at present received any instructions for stamping weights. It would be remembered that the question submitted was, whether the sub-divisions of glass measures would be verified.

Mr. Richardson asked if it was intended that glass measures should be stamped.

The President said no doubt they would be marked in some way—probably engraved.

Elections.

MEMBERS.

Pharmaceutical Chemist.

Hugh Odard Dutton, Rock Ferry, having passed the Major examination and having tendered his subscription for the current year, was elected a Member of the Society.

Chemists and Druggists.

The following, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected Members of the Society:—

Carr, Walter Paterson............Berwick-on-Tweed.
James, Joseph ....Cheltenham.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Jones, John ....Liverpool.
Scott, John ....Newcastle-on-Tyne.
Steele, John Cockburn ....Glasgow.

ASSOCIATE.

John Carter, London, having passed the Modified examination and tendered his subscription for the current year, was elected an Associate of the Society.

Mr. Richardson asked when the Modified examination would cease.

Mr. Bottle said when they got a new Act of Parliament.

The President said all who were on a certain register were entitled to come up for the Modified examination.

Mr. Robbins asked how many came up in the course of the year.

The Secretary said about 20 or 25 per annum. There were, he believed, about 1200 men still eligible to pass the Modified examination.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Allen, Ernest Edward	Winchester.
Bradley, Frederick William	Wisbeach.
Clarke, William Seth	Coventry.
Hall, Ernest Edward	Wednesbury.
Hepple, Thomas	North Shields.
Hill, Major	Sleaford.
Ingham, William Linnell	London.
Middleton, Burton	Ilkley.
Mitchell, Charles Edward	Bolton-le-Moor.
Newman, Alfred Pointon	Crewe.
Staley, Henry	Burton-on-Trent.
Skoulding, William George	Oakham.
Talbot, William Widdowson	Bulwell.
Thomas, William Morgan	Glamorgan.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons who have severally made the required declarations and paid a fine of one guinea were restored to the Register of Chemists and Druggists:—

John Brierley, Barrow-in-Furness.

Archibald James Millar, 2, Railway Terrace, York Road, Wandsworth, Surrey.

MINUTES OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£15 to a pharmaceutical chemist, formerly in business, but now out of employment. Applicant has had five previous grants.

£10 to the widow of a chemist and druggist, having three daughters dependent upon her.

£10 to the widow of a late annuitant on the Benevolent Fund.

£10 to a registered chemist and druggist, aged 67, suffering from partial paralysis.

The report and recommendations were received and adopted.

Mr. Savage said he was recently in the town where one of Isherwood's children was placed, and he thought it right to make some inquiry about her. He had not an opportunity of seeing the child, but he heard from an independent source a very nice character, both of the child and the gentleman with whom she was placed.

The Secretary said this information quite agreed with the letter received last month.

INFRINGEMENTS OF THE PHARMACY ACT.

A letter was read from the Solicitor enclosing correspondence with regard to certain cases of alleged infringement. The Council, according to the usual practice, went into Committee to consider the various matters referred to.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 175).

Proximate Analysis of the Rhizome (Dried and Decorticated) of Zingiber Officinalis, and Comparative Examination of Typical Specimens of Commercial Gingers.

BY J. C. THRESH, F.C.S.,

Pharmaceutical Chemist.

Part II.—Comparative Examination of the Gingers of Commerce.

For the above purpose Mr. Umney kindly selected for me a typical specimen of each of the varieties found in commerce, viz., Jamaica, Cochin and African.

No. 1. Jamaica ginger. A fine B.P. specimen. Irregular lobed decorticated pieces, three or four inches long, sub-compressed, yellowish-white, but not chalky on surface. Fracture short, mealy. Powder yellowish-white.

No 2. Cochin ginger. Irregularly lobed pieces, decorticated, two or three inches long, a little smaller than the Jamaica, and pale brown externally. Fracture, fibrous, short. Powder yellowish-white.

No. 3. African ginger. Short irregular coated lobes, of a brown colour. Fracture short, rather resinous. Powder brown.

Moisture and Volatile Oil.—A quantity of each of the above was reduced to powder, and small weighed portions placed in tared dishes on the water-bath, until they ceased to lose weight and no longer retained an odour of ginger.

No. 1. 1·652 grams lost ·234 or 14·17 per cent.
„ 2. 1·311 „ „ ·195 or 14·88 „
„ 3. 1·476 „ „ ·235 or 16·13 „

Ash.—The above quantities were burnt at a dull red heat, cooled in dry air, and rapidly weighed.

No. 1 yielded ash weighing ·059 or 3·57 per cent.
„ 2 „ „ ·063 or 4·80 „
„ 3 „ „ ·063 or 4·27 „

Ethereal Extract.—Twenty grams of each were packed in small percolators, and ether passed through to exhaustion. For this purpose the African required twice as much of the solvent as the Jamaica and Cochin. The ether was driven off at a low temperature, and the residue kept on water-bath until the loss of weight between consecutive weighings at short intervals was trifling.

No. 1 extract weighed ·658 grams.
„ 2 „ ·993 „
„ 3 „ 1·613 „

Volatile Oil.—The above residues were kept for eight to ten hours upon a chloride of calcium bath, until they no longer lost weight.

No. 1 extract lost ·150 = ·75 per cent. volatile oil.
„ 2 „ ·270 = 1·35 „ „
„ 3 „ ·323 = 1·61 „ „

A second determination of above was made by treating fresh portions of the powdered ginger with petroleum ether (boiling at 50° C.), removing ether by, first, a current of air, and, second, exposure for a few minutes to a temperature of 100° C. The extracts were then kept at about 115° C. until the weights were constant.

No. 1 gave results corresponding to ·830 per cent. volatile oil.

No 2 gave results corresponding to 1·14 per cent. volatile oil.

No. 3 gave results corresponding to 1·97 per cent. volatile oil.

No. 4 gave results corresponding to 1·38 per cent. volatile oil

No. 4 was the sample used in investigation of proximate constituents of ginger. The amount of volatile oil actually obtained from 28 lb. of this ginger was as before stated $5\frac{1}{2}$ ozs. or 1·23 per cent., and as this was undoubtedly not the whole of the oil contained in the ethereal extract, the above determinations may be taken as close approximations.

Deducting the volatile oil, from the moisture + volatile oil, we have—

Moisture in No. 1, 13·42 per cent.
„ „ 2, 13·53 „
„ „ 3, 14·515 „

Soft Fat, Resin δ and Wax (?). The ethereal extracts were next treated with small portions of petroleum ether to extract the fat, etc., the ether driven off, the residues washed with a little proof spirit, dried and weighed.

No. 1 yielded ·140 grams or ·7 per cent.
„ 2 „ ·241 „ 1·2 „
„ 3 „ ·245 „ 1·22 „

Neutral Resin.—The residues insoluble in petroleum ether were exhausted with proof spirit, and the washings of petroleum ether extracts added thereto. The portions insoluble in proof spirit consisted of the neutral resin, which was dried and weighed.

No. 1 weighed ·173 = ·865 per cent.
„ 2 „ ·190 = ·950 „
„ 3 „ ·461 = 2·305 „

Gingerol.—The above proof spirit solutions were precipitated with basic lead acetate, filtered, evaporated, and residue washed with dilute acetic acid, dried and weighed. This residue consisted of the active principle with traces of resins α and β. The lead precipitate retained traces of active principle, so that these determinations, gingerol and resins α and β are mere approximations.

No. 1 yielded ·132 or ·66 per cent.
„ 2 „ ·120 or ·60 „
„ 3 „ ·290 or 1·45 „

Resins α and β.—Calculated by difference we have from—

No. 1. ·063 gram or ·315 per cent.
„ 2. ·172 „ or ·860 „
„ 3. ·294 „ or 1·470 „

Aqueous Extract—The portions of the original gingers insoluble in ether were dried and mixed with water until each measured 400 c.c.'s. The mixtures were stirred at frequent intervals for several days, the insoluble portions then allowed to subside, 20 c.c. (= 1 gram ginger) of the clear supernatant fluid removed from each, evaporated to dryness and weighed, and the ash afterwards ascertained by ignition and re-weighing.

No. 1 gave ·143 extract less ·023 ash = 12·0 per cent.
„ 2 „ ·146 „ ·025 „ = 12·1 „
„ 3 „ ·105 „ ·030 „ = 7·5 „

Substance Precipitated by Acids.—Other portions of 100 c.c. each (= 5 grams ginger) were acidified with acetic acid, allowed to stand for a few hours, then warmed, and filtered through tared filters, the precipitates washed with a little dilute acid, dried and weighed.

No. 1 yielded ·266 less ash ·0035 = 5·25 per cent.
„ 2 „ ·262 „ ·0045 = 5·35 „
„ 3 „ ·235 „ ·005 = 4·60 „

Mucilage.—The acid filtrate and washings from above were evaporated to 20 c.c., and mixed with 60 c.c. of 95 per cent. alcohol. (In each case during the evaporation a little flocculent matter was deposited, but the amount was too small to materially affect the estimations.) The mixtures were set aside for a day, the precipitates then thrown upon tared filters, washed with a little alcohol, dried and weighed, and the ash afterwards determined and deducted.

No. 1 yielded ·1725, ash ·053 = 2·39 per cent.
„ 2 „ ·1155 „ ·043 = 1.45 „
„ 3 „ ·097 „ ·038 = 1·19 „

Organic Acids, etc.—The combustible portion of aqueous extract unaccounted for consisted of malic (?) and oxalic acids, an indifferent substance precipitated by tannin and possibly other bodies. These amount in

No. 1 to 4·36 per cent.
„ 2 to 6·80 „
„ 3 to 1·70 „

Alcoholic Extract.—The marcs insoluble in ether and water were drained upon filters, re-packed in the percolators, and 84 per cent. alcohol passed through so long as anything was dissolved. (200 c.c. in each case) The Jamaica and Cochin tinctures had a pale amber tint, the African a pale brown. 40 c.c. of each were evaporated to dryness and the residue weighed.

No. 1 gave ·016 or ·4 per cent.
„ 2 „ ·011 or ·28 „
„ 3 „ ·025 or ·625 „

The residues from treatment with ether, water and alcohol were next digested in sufficient 1 per cent. soda solution to measure 400 c.c. The Jamaica ginger yielded a mucilaginous solution, in which the insoluble matter settled very slowly; the Cochin ginger gave but a slightly mucilaginous solution, whereas the African variety yielded a perfectly limpid infusion. 50 c.c. (= $2\frac{1}{2}$ grams ginger) were neutralized with acetic acid mixed with 100 c.c. of 95 per cent. alcohol, and allowed to stand for a day. The precipitates were then collected on tared filters, washed, dried, weighed, then ignited and the ash estimated.

No. 1 yielded ·731, ash ·029 = 28·08 per cent.
„ 2 „ ·210, „ ·007 = 8·12 „
„ 3 „ ·049, „ ·0015 = 1·86 „

Starch.—The remainder of the alkaline infusions were in each case diluted to 1200 c.c., boiled for a few minutes, allowed to cool to 50° and digested at the latter temperature for forty-eight hours with a little diastase. 50 c.c. were then taken and boiled with 8 c.c. of dilute sulphuric acid (1 in 8) until the fluid ceased to react with iodine, or the volume was reduced to 50 c.c. After cooling the solutions were each run into 10 c.c. of Fehling's solution (= ·044 gram starch), until the blue tint disappeared.

No. 1. 14·9 c.c. = ·044 starch or 18·12 per cent.
„ 2. 17·1 „ = ·044 „ 15·79 „
„ 3. 20· „ = ·044 „ 13·50 „

Pararabin and Calcium Oxalate.—The residues insoluble in caustic soda and boiling water were slightly washed by subsidence and decantation, and mixed with sufficient 1 per cent. hydrochloric acid to measure each 400 c.c. After macerating twenty-four hours, they were boiled for a few minutes, and 50 c.c. (= $2\frac{1}{2}$ grams ginger) of each, filtered, neutralized with ammonia, and diluted with three volumes of 95 per cent. alcohol. The addition of ammonia to the Jamaica infusion caused a slight turbidity; the Cochin infusion was not affected, but a rather bulky brown gelatinous precipitate was produced in the African solution. The ammonia and alcohol precipitates were collected on tared filters, dried and weighed, then incinerated and the ashes weighed. The ashes from the Cochin and Jamaica gingers consisted of CaO derived from the calcium oxalate in acid solution; the African ash was of a brown colour, and contained manganese.

No. 1. Pararabin and calcium oxalate ·025 = 1·00 per cent.

No. 2. Pararabin and calcium oxalate ·374 = 14·96 per cent.

No. 3. Pararabin and calcium oxalate, etc., ·273 = 10·92 per cent.

The ash of No. 1 weighed ·010 = ·914 per cent. of calcium oxalate.

The ash of No. 2 weighed ·006 = ·580 per cent. of calcium oxalate.

The ash of No. 3 weighed ·085, but of this only ·022 was CaO, equivalent to 2·04 per cent. CaC_2O_4. Deducting the proportions of this salt from the result of last experiment, we have the yield of pararabin in

No. 1. ·086 per cent.
„ 2. 14·40 „
„ 3. 6·36 „

(the ash not CaO also being deducted).

Cellulose.—The marcs from treatment with dilute acid were digested for several days with constant agitation in nitric acid of sp. gr. 1·16, to which a little powdered potassium chlorate had been added. The insoluble portions, which were nearly colourless, were washed successively with water, dilute ammonia and alcohol, then dried and weighed.

No. 1 yielded ·7 cellulose = 3·5 per cent.
„ 2 „ ·75 „ = 3·7 „
„ 3 „ 1·25 „ = 6·25 „

Albuminoids.—Portions of the original gingers in powder were burnt with soda lime as in Will and Varentrap's method, and the ammonia estimated as double chloride of platinum and ammonium. As the precipitates were rather dark in colour, one of them was ignited, and the platinum weighed. The results were closely concordant.

1·069 gram No. 1 yielded ·245 pt. salt = 1·38 per cent. N.
1·360 „ „ 2 „ ·193 „ = ·891 „
1·130 „ „ 3 „ ·094 „ = ·522 „

In a second determination of the No. 1,

·833 grams yielded ·211 pt. salt = 1·44 per cent. N.

Taking one part of nitrogen as representing 6·25 parts of albuminoids, and neglecting to take into consideration the small percentage of nitrogen in the substance precipitated by acids, we obtain the following proportions:—

No. 1. 8·8 per cent. albuminoids.
„ 2. 5·57 „ „
„ 3. 3·27 „ „

Vasculose, Pectose, Loss, etc.—These have simply been calculated by difference. Thus, in No. 1, 91·908; in No. 2, 85·237; and in No. 3, 67·695 per cent. has been accounted for, leaving in

No. 1. 8·092 per cent.
„ 2. 14·763 „
„ 3. 32·305 „

to represent the fibrous and pectic matters, loss, etc.

Tabulated Results of Analyses.

	Original Sample.	No. 1.	No. 2.	No. 3.
Volatile Oil . . .	1·380	·750	1·350	1·615
Fat, Wax(?) and Resin (P. ether solution) .	·835	·700	1·205	1·225

Comparison of these results reveals the singular fact that the variety of ginger most esteemed contains only about half the quantity of essential oil found in the other varieties, and less of the active principle than either the African or common Jamaica, and about as much as good Cochin. It would be interesting to have prepared samples of the essential oils from these various sources, in order to ascertain their physical and chemical properties. But as possibly in all cases the aroma would be affected by distillation, it would be necessary to devise some other method of obtaining them. Undoubtedly the volatile oil in the finest Jamaica gingers possesses a finer bouquet than the others.

The very dark colour of tincture of ginger when made from the African rhizome is evidently due to the large percentage of the neutral, α and β, resins contained therein, and as these are tasteless and apparently inert, their presence only deteriorates the value of the ginger.

The most striking difference in the constitution of the varieties examined is the relative proportions of metarabin and pararabin which they contain. It is easy to distinguish between a sample of Jamaica and one of Cochin ginger, when in powder, by maceration for forty-eight hours in a 1 per cent. soda or potash solution. If, however, the fibrous portion of the rhizome has been removed by sifting, as is generally the case with the finer qualities of powder, the test does not give such decided indications, from which it may be inferred that the fibrous portion is the seat of this metarabinoid substance.

The same author also read a paper on—

Soluble Essence of Ginger.

BY J. C. THRESH, F.C.S.

Since the publication of my short paper on the above subject, which was read at the Conference last year, I have received a number of letters from chemists, and others interested, some containing suggestions, others queries. These chiefly referred to the essence becoming turbid after being kept some time, and to the evident loss of active principle, in the magnesia precipitate, this being exceedingly pungent.

To remedy these defects the following modification of the process was devised, by which almost all the active principle is removed from the precipitate, and the product does not become turbid by keeping, as is evidenced by the sample upon the table, which was made before last Christmas.

Take of strong tincture (1 to 1) of finest Jamaica ginger one pint, add in small portions at a time finely powdered slacked lime, shaking vigorously after each addition, until the tincture ceases to lose colour, throw the whole upon a filter, and pass through the residue proof spirit until the product measures two pints. Now add drop by drop dilute sulphuric acid until the rich yellow colour of the tincture suddenly disappears, let stand for twenty-four hours, filter, dilute with water to four pints, shake with a little powdered pumice or silica (by no means lime or magnesia), and filter at 0° C. if possible.

Rationale of the Process.—As may be gathered from a consideration of the constituents of ginger root, the alcoholic tincture will contain besides the extractive soluble in water, which need not further be considered, essential oil, neutral resin, α and β resins, gingerol, and small quantities of the red fat, wax (?) and peculiar extractive insoluble in ether. Upon agitating the tincture with lime the greater part of the α and β resins is removed, and by addition of the acid the lime which has entered into solution is precipitated. The addition of water precipitates the neutral resin, wax, fat, and peculiar extractive, and unless the ginger from which the original tincture was prepared was poor in oil, the excess of volatile oil also.

As in probably all cases the soluble essence is saturated with essential oil, the final filtration must be effected at a lower temperature than any to which the essence is likely to be exposed.

The product as thus obtained is very pale in colour, but if a darker essence is preferred it is only necessary to add one or two drops of solution of potash to give an alkaline reaction, when the rich orange tint due to the action of the alkali upon the β resin will be immediately produced.

The PRESIDENT congratulated Mr. Thresh upon his able report, and congratulated the Conference on being the means of inducing him to pursue his inquiries on this truly pharmaceutical subject.

Mr. UMNEY (London) said scientific chemists and pharmacists were greatly indebted to Mr. Thresh for having brought this subject forward. It had been a standing disgrace that a drug they daily handled in a variety of forms, such as African, Cochin and Jamaica ginger, was not thoroughly understood by them. Mr. Thresh had placed the subject before them very exhaustively, and from his paper they would be able to follow with certainty the pharmaceutical aspect of ginger. The soluble essence of ginger was a most elegant preparation, and useful for the manufacture of aërated water. The difference noticed in specific gravity of portions of the volatile oil was probably due in the main to the different processes by which the oils had been obtained. Those who had distilled essential oils knew that according to the heat used in their production they differed slightly in specific gravity. No doubt, according to whether this oil were made with petroleum spirit, or by distillation, the specific gravity would vary somewhat.

Mr. GREENISH remarked that he had examined microscopically sections of Jamaica and African ginger root, and found that a very large amount of starchy matter was developed in the Jamaica root as compared with the African ginger; but African ginger, if subjected for a series of years to the same amount of cultivation as Jamaica ginger, might possibly lose some of its pungent character, and develop starchy matter to an equivalent extent.

Mr. W. L. HOWIE (London) adverting to Mr. Thresh's statement that the oil of ginger odour did not recall that of ginger, said he was inclined to think that possibly the smell was masked by that of the petroleum spirit used in its extraction. The difference in the specific gravity of the oils was due to some extent to the method followed, but it might also be due to a change which he believed took place in the oil when it had been kept some time. A small quantity of oil of ginger, which he had had in his possession some years, and which had, he believed, been made by distillation, he found to be but sparingly soluble in rectified spirit—not more perhaps than one in ten, and even with one in fifty there were still left some small whitish globules, which, when separated and exposed to heat, dried into a clear glassy resin, with scarcely any odour or taste. After exposing a little of the oil, for some days, in a watch-glass to a temperature of 100° F., there remained a resinous residue like the other in appearance. He made these remarks in order that Mr. Thresh's attention might be directed to the further examination of the oil so as to discover whether or not it was a compound, and what was the character and extent of the change which occurred in it when kept for a long period.

Mr. MARTINDALE (London) observed that from a medical point of view and having before them the prospect of a new Pharmacopœia, it was doubtful whether it would be advisable to introduce soluble essence of ginger into it or not; although as a commercial article it might be very useful. The syrup of ginger was, in the present Pharmacopœia, prepared from the essence and did not make a very elegant preparation. It might be improved if it were not opaque, but prepared from a soluble essence. The old London syrup was made from an infusion, which contained the metarabin Mr. Thresh had mentioned and made it a mucilaginous, and not very satisfactory preparation.

Mr. F. B. BENGER (Manchester) remarked that the paper, which was by a pharmaceutical chemist actively engaged in their business, was of great practical value and might be taken as the type of the sort of papers it was desirable to bring before the Conference.

Mr. THRESH, in replying, said that he thought the essential oil exhibited did not smell of petroleum spirit. He had distilled a sample of the oil directly from an ethereal extract, and found that it had exactly the same odour as that distilled from petroleum extract; it was therefore quite impossible for it to have the odour of petroleum. He had observed (as also had Mr. Umney) that in distilling an ethereal or alcoholic essence of ginger a considerable quantity of oil came over at that low temperature, and he felt confident that this more volatile portion, which was lost, had the finest aroma. Again, he did not think it desirable to put the soluble essence of ginger into the Pharmacopœia for its own sake; but, as suggested by Mr. Martindale, it might be advisable to employ it for making the syrup of ginger, as the syrup thus prepared was really a much more elegant one than that made by the officinal process. The active principle was certainly very soluble in dilute spirit, but as the soluble essence must contain some essential oil also, it was impossible to make it of equal strength with the B.P. strong tincture; nevertheless by removing the inert resins they were enabled to make a stronger solution than would otherwise be possible.

The PRESIDENT asked if Mr. Thresh had made any special examination into the nature of the oil itself, as to its boiling point.

Mr. THRESH said he had not. His time was limited and the isolation of the active principle took so much time that he had not been able to pursue the subject further.

Professor ATTFIELD hoped Mr. Thresh would continue the investigation further, and examine the oil as well as the other principles, applying to the committee for a grant to cover any outlay.

The PRESIDENT was exceedingly glad so many able men had spoken of the value of the paper, and he hoped they would join him in passing a very hearty vote of thanks to Mr. Thresh for his able report.

The motion was carried unanimously.

The Conference then adjourned for luncheon.

After returning from luncheon the first paper read was on—

THE GROWTH AND DEVELOPMENT OF CLAVICEPS PURPUREA (Tulasne).

BY W. W. STODDART, F.C.S., F.G.S., ETC.,

Lecturer on Forensic Medicine at Univ. Coll., Bristol.

At the end of the year 1877, a farmer residing in the neighbourhood of Bristol requested me to investigate the death of some sheep which had taken place every autumn without any assignable cause, so much so that a heavy loss was annually incurred. Many visits were consequently paid to the farm for the purpose of finding out the cause of disease. I noticed that the sheep were fed only on the natural herbage grown on the spot. It consisted of two kinds of clover, the ordinary Dutch (*Trifolium repens*, L.), and the common purple (*T. pratense*, L.). With these were the ray grass (*Lolium perenne*, L.), or as it is commonly but erroneously spelled "rye" grass. A strict inquiry being made as to the symptoms, the farmer informed me that they were always the same and generally supervened in the month of August, when this very peculiar illness on the farm became prevalent. It took the form of dysentery, inflammation of the bowels, diarrhœa, the evacuations resembling coffee grounds, afterwards succeeded by exhaustion, collapse and death.

Analyses of water and the soil were made for the purpose of detecting any deleterious metal or other irritant poison. No satisfactory result followed and the cause of the illness seemed to be mysterious and inexplicable. At length I heard that the ewes sometimes slipped their young, which gave a remote suspicion that the cause of all might be due to ergotism. An inquiry was then made as to the presence of gangrene, when the unexpected but significant remark was made, that although the farm was on a dry, porous, sandy slope, yet the sheep always had the "foot rot," even in the summer, which defied all the remedies that usually proved effectual. With this idea in my mind and while watching the lambs feeding I noticed that they avoided the old mature plants, while they greedily devoured the young green ones.

On examining more minutely the former, I noticed several well formed, purplish, dark coloured ergots were projecting from the paleæ, but could not discover a single specimen on the younger fresh plants. Several of these ergots were then taken home for chemical and microscopic examination. I made a considerable number of sections which exactly coincided with the beautiful and truthful engravings in the paper by Tulasne, in the 'Annales Sc. Nat.' for 1853, Sur l'Ergot des Glumacées. While here, I must stop to express my admiration both at the accuracy of these microscopic delineations and the description of the metamorphoses of this curious fungus. I thought that this would be a good opportunity of studying the growth of this vegetable, and that the result of my observations during the following year may prove to be of some service in the cause of pharmacy.

During the next few months I had only the old and nearly dead stems of the *Lolium* on which I could work, but on the 12th of April I obtained some specimens of the *Lolium perenne* in which the commencement of the inflorescence was just to be observed. Soon afterwards I made several sections of caryopsides, on which were many thousands of conidia, which seemed rapidly to multiply and to completely fill some of the grains till they protruded far beyond the glumes. In two or three days the sclerotium stage of the mycelium began to change colour and assumed a purplish brown tinge. The sclerotium seemed now to have arrived at what was formerly termed the "sphacelia" condition, and was soft, while the upper portion was wrinkled. The exterior was white from the growth of the hyphæ, which seemed to grow with marvellous rapidity till at length only a small portion of the pistil remained free. Although the conidia were so numerous, I never noticed any on the andrœcium, even when examined with a one-sixth of-an-inch object glass, while close to them four or five of the caryopsides were completely filled with the little conidia, which are blunt and ellipsoid bodies about $\frac{5}{1000}$ mm. to $\frac{7}{1000}$ mm. in length, and from $\frac{3}{1000}$ mm. to $\frac{45}{10000}$ mm. in breadth. They are curved and divided into two parts, each part containing a nucleus. On touching them with a drop of diluted sulphuric acid, a cilium or minute flagellum was extruded, and when placed in water had a vibratile motion. On examining suspected flour, bread or pastry, the microscope would always show these conidia, especially with the addition of a little chromic acid.

In the third week of May several small drops of a syrupy substance made their appearance on the stem near the spikelet. If dissolved in a little distilled water and placed under the microscope, the solution would be seen to contain the conidia, and hence I suppose gave rise to the supposition that the honey-dew was intimately connected with the formation of ergot by aiding the growth of the mycelium. But it most probably only attracts and adheres to insects, who by this means convey the conidia to other spikelets and thus spread the infection to other grains. This saccharine mixture instantly reduces the copper solution of Trommer's test, thus showing the presence of sugar. When boiled, a slight milkiness is produced and not removed by nitric acid in excess, pointing out the presence of albumen. At this period the ergot attains its full development and gives no blue with iodine, because by the well-known metastatic power of fungi all starch is removed and an oil substituted. Of this oil, ergot sometimes contains about a third part of its weight.

At this period of its growth each sclerotium gives off the odour of trimethylamine when treated with potass, and produces a red colour. With spontaneous evaporation, after mixing the honey-dew with alcohol and a little ether, minute octahedra of mycose are formed and may be seen with the lens.

On July 18th I first gathered fully formed and mature ergots, which I now produce. They have a dark exterior with a white interior and give the ordinary red infusion.

On August 1st one of the lambs was taken ill with the usual inflammatory symptoms. The feet also in a few days had a gangrenous appearance, which did not seem to be alleviated by any of the usual applications of silver nitrate, carbolic or cresylic acids. The affection of the feet strongly reminded me of "clavellization," so destructive among the flocks of Italy, France and Moravia, and has frequently been supposed to have been a variety of variola.

The fungus has now reached the limit of its vegetative or myceloid growth, which plainly ends at the sclerotium stage as our medicinal agent called ergot, by means of which the embryo and most of the caryopsides have been destroyed.

The hyphæ are now ready to spread in every direction and thus extend the vegetative growth, from which only we derive the peculiar medical properties of the *Claviceps* in their greatest intensity and power on the animal economy, and it is now that the greatest effects are produced which are included under the name of "ergotism."

A *post mortem* examination of the sheep showed the presence of the conidia among the "coffee ground" looking fæces. The fungus having now arrived at this stage awaits for appropriate weather and other suitable conditions for the fructifying metamorphosis.

At the end of August one or two of the ergots that had fallen with the stems of the grass on the damp ground I placed, for more convenient observation, on the moist soil of a flower pot. In a few days I noticed on the dark cuticle of the sclerotium several minute excrescences from which gradually emanated some stalks about 11 to 18 millimetres in length, each supporting a minute round head about 4 millimetres in diameter, in fact furnishing good characteristic specimens of *Claviceps purpurea*.

It is not to be wondered at that these fungi should have received the names of sphœria or torrubia, because they so much resemble the growth so often described as being found on the heads of caterpillars or larvæ, and used as a medicine in China and Japan.

A very remarkable change now took place in the oil that was so noticeable as long as the condition of sclerotium continued, but directly the mature *Claviceps* appeared the oil oxidized, dried up and was found no longer. The round heads of the fungus now became covered with a large number of brown dots, which eventually became the openings of pear-shaped sacs or asci of the perithecium. If a section was made with a sharp scalpel each ascus was seen to be filled with a glutinous substance containing seven or eight spores. These last adhered to the ergot, looking like a powdery coating and causing the production of many thousands of conidia on each ergot and ready for the evolution of fresh mycelium.

This seems to me the true mode of development of *Claviceps*. It commences and proceeds with the vegetative growth till it reaches the sclerotium stage and at that period possesses in the greatest vigour the medicinal characteristics of ergot.

I have, I think, conclusively found that ergot has the greatest medicinal power in the month of August, and that the experience of six or seven years shows that the same changes take place in the plant at the same period of every year.

It has been known to medical men that the so-called essences of ergot are so uncertain in their efficacy that many, in order to ensure success, have determined to use the powder itself. Dr. Kluge, of Berlin, observed some years since, that for some reason or other the properties of ergot varied according to whether it was gathered *before or after the harvest*. In the former case it had an energetic action, while in the latter it was frequently powerless.

The sheep were distinctly seen to choose the young green grasses and to particularly avoid the older and ripe ones, probably directed by the odour of trimethylamine, for I found that I could not produce this odour till the sclerotium was fully developed and the starch completely gone.

I therefore think the following conclusions may be safely drawn—

1. That for all medicinal purposes, or pharmaceutical preparations, ergot ought to be gathered in the months of August or September.

2. That ergot always attains its greatest intensity at the end of the vegetative period.

3. That the medicinal powers of ergot diminish or disappear as soon as the fructifying period commences.

I have chemically and microscopically examined the ergots produced from the *Lolium perenne* while the plants have been living. The infusion was first treated by the ether process of Stas. On the evaporation of the ether an oily residuum was obtained containing a minute quantity of a resinous substance. The extract was then dissolved in alcohol, afterwards mixed with water and filtered. Chloriodide of mercury caused a precipitate reminding one of a vegetable alkaloid.

I did not detect any crystals of cholesterine that are said to exist in *Secale cornutum*, but phosphoric acid was clearly shown by using molybdate of ammonia and nitric acid.

In toxicological investigations the microscope is the most to be depended upon. The conidia are very abundant and may always be detected in bread, pastry or flour, especially if acetic or chromic acids be used to make their presence more evident. The one-sixth or one-eighth of an inch is a sufficiently high power. I always find that this mode of detection is preferable to the use of potass and distillation alone. The little conidia may be generally observed in the intestinal canal of a poisoned person or animal.

The PRESIDENT, in inviting discussion, remarked that the Conference had been favoured by Mr. Stoddart with an extremely suggestive and interesting paper.

Mr. LUFF said he should like to ask two questions of Mr. Stoddart. Some months ago a toxicological case was entrusted to him for investigation. It was that of a young woman's stomach in which ergot was found. He would ask Mr. Stoddart whether he noticed in the stomachs of the sheep during *post mortem* examinations very rapid decomposition. He was present at the *post mortem* examination of the young woman and very rapid decomposition set in during the course of twenty-four hours. At the inquest the medical witnesses wished to show that that proved the presence indirectly of ergot. He also wished to ask Mr. Stoddart whether he noticed the presence of the poison in the second or in the fourth stomach of the sheep.

Mr. THRESH said he should like to know definitely whether it was the same fungus that produced ergot in the rye grass as produced it in the rye.

Mr. GREENISH thought this an extremely interesting subject to pharmacists, because ergot was the only fungus in the Pharmacopœia. To investigate the subject properly it really required a knowledge of botany, of the microscope and of fungology. It was important to observe that the ergot just referred to was not ergot of rye, but an ergot from one of the grasses, and it appeared to have been exceedingly active and very poisonous. There had been lately presented to the Museum of the Pharmaceutical Society some of the ergot of Diss, also a grass ergot from Algeria which was longer and more slender than the ordinary ergot of rye. It was said to be a much more active ergot. There had not been sufficient opportunity yet to enable this point to be decided, but it would be possible to get any quantity from Algeria. There was one point he could not very well understand. Mr. Stoddart had said that the ergot on the young grass was very poisonous to sheep; and he (Mr. Greenish) assumed that on the young grass it would not be the fully developed ergot. At the same time Mr. Stoddart had stated that the ergot for pharmaceutical purposes would be best obtained fully developed, and the fully developed ergot could not be got until about the month of August. He asked how it was that the ergot was more active before it was fully developed on the young grass, and yet that it should not be obtained for pharmaceutical purposes until it was fully developed.

Mr. UMNEY said, with regard to the closing statement of Mr. Stoddart's remarks on the pharmacy of ergot, viz., "that the preparation of ergot must either be an ethereal or an ammoniacal one," he would say that he must take exception. The ether directed in the Pharmacopœia process was used to extract the fixed oil, and for the preparation of the extract the ether was driven off and the oily residue thrown away, the preparation therefore was an aqueous one.

Professor ATTFIELD said that probably many cases of poisoning which had hitherto puzzled analysts were explicable now with the facts which Mr. Stoddart had brought forward. A few weeks ago he had had one of these puzzling cases brought under his own notice; and he mentioned it because he thought a great deal of light had been thrown upon it by what he had heard from Mr. Stoddart, and because it to some extent supported Mr. Stoddart's conclusions. Some heifers which were turned into a particular pasture died. He examined the contents of the stomachs of these animals, but could find no trace whatever of any of the ordinary poisons or even of unusual poisons. He suggested that the farmer should instruct a botanist to examine the pasturage for poisonous plants or plants which would be likely to produce irritation enough to cause death; but he examined the contents of the stomach microscopically as well as chemically and found present crowds of minute bodies which he now thought must be the conidia to which Mr. Stoddart had referred. They were minute things seen very easily with a quarter inch power. They were somewhat sausage shaped, only thicker at one end than the other; and they afforded evidence of structure. He believed they were identical with those alluded to by Mr. Stoddart.

Mr. STODDART, in summing up the discussion, alluded first to the question put by Mr. Luff as to putrefaction taking place in the stomach. He generally found that blood was the first thing to putrefy; and he believed that what he had alluded to as being comparable to coffee grounds was simply coagulated blood. Whenever he got a stomach—and they were very frequently brought to him—and he saw there was much congestion—in other words, much blood—he assumed that probably strychnine had been used. So accustomed had he been to see the effects of strychnine that he was often able to say whether animals or men had been poisoned by that means, as decomposition would set in sooner than by the use of any other poison. He had usually found that to be the case. In answer to Mr. Greenish he repeated what he had previously stated, that the best time to gather ergot was in its maturity in the sclerotium condition. With regard to Mr. Umney's observation it only proved what he had said, that doctors differed considerably.

The President said the Conference was much obliged to Mr. Stoddart for his extremely interesting paper, and gave him a cordial vote of thanks for his labours in this direction. *(To be continued.)*

BRITISH ASSOCIATION.

The Process of Investigation in the Exact Sciences.*

BY G. JOHNSTONE STONEY, M.A., F.R.S.

The process of investigation in the exact sciences is fundamentally one in all cases. It has been well described by Mill in the third book of his 'Logic.' Nevertheless it is notorious that minds which are well fitted for some branches of physical inquiry find difficulty—sometimes insuperable difficulty—in pursuing others. It is not every eminent mathematican who would have made an equally good chemist, or *vice versâ*. This is because there exists a practical distinction separating the investigation of exact science into two well-marked classes when they are viewed, not as they are in themselves, but in their relation to the powers of us human beings. I refer to the distinction between the experimental method or the method of observation, on the one hand; and the deductive method, or the method of reasoning, on the other. All valid investigations in exact science appeal to what can be directly perceived, and all lead to a conclusion which can be reasoned out from it; but there are some of these investigations in which the main difficulty consists in making the appeal to the senses, and there are others in which the main difficulty lies in the process of reasoning.

To contend with these difficulties successfully requires very different qualities of mind and body. In experimental science the powers principally called into requisition are readiness and closeness of observation, dexterity in manipulation, skill in devising expedients, accuracy in making adjustments, and great patience. It also requires that the investigator should have an accurate memory of what else he has witnessed resembling the phenomenon under observation, that he should be quick to detect every point of agreement and difference that can be perceived, and be skilful to select those which are significant, and to employ them as materials for provision to guide his further proceedings. But the strain on the reasoning powers is generally less, often of trifling amount. The question is put to Nature, and it is Nature usually that gives the bulk of the answer. The most striking monument of splendid achievements by the experimental method of investigation unaided by the deductive method is to be found in the science of chemistry.

An equally typical instance of the power of the deductive method is the science of mechanics. This science, which has sunk deeper into the secrets of Nature than any other science, and which is the science towards whom all other physical sciences are at present more or less gravitating, is essentially deductive. There is little or no difficulty about its fundamental data. They are facts of Nature so patent to all men, and so indelibly implanted in human conception, that some persons have supposed that we have an intuitive perception of them. But, while the materials from which the mind is to work are thus easily obtained, it has taxed to the utmost the reasoning powers of understandings like Newton's to evolve the few consequences of them which are already known, and the investigator has to call to his assistance every aid to prolonged consecutive thought which mathematicians can devise.

In grappling with the problems of Nature we are seldom allowed the choice of the method of investigation we shall employ. This is commonly settled for us and not by us. Where we cannot advance without further information, we must make further observations, *i.e.*, we must employ the experimental method, the appeal *ad experientiam*: where we cannot advance without understanding better what the information we possess really amounts to, we must employ the deductive method.

No reach of intellect applied to the materials in existence before 1860 could have elicited the fact that iron exists upon the sun. This great discovery was made by Professor Kirchhoff, a scientific man who was equally versed in both methods of investigation. On the present occasion it was the experimental method he employed. He applied to the scrutiny of the sun's spectrum four prisms of the most homogeneous glass that could be procured, figured with the greatest accuracy that the eminent artist Steinheil could attain. He expended far more pains on their adjustment for each successive part of the spectrum than any of his predecessors had done, and he was rewarded by a more perfect vision of the sun's glorious spectrum than had met the human eye before. In a collateral inquiry, suggested by an observation made by Foucault, he and Bunsen placed a metallic vapour emitting bright rays in front of a still brighter incandescent body, so that the light from the brighter background had to pass through this vapour, and they found that this vapour now caused dark lines in the spectrum occupying the positions which its own bright lines had before filled. Professor Kirchhoff thereupon added an appliance to his spectroscope which enabled him to bring a metallic spectrum and the solar spectrum together into the field of view, alongside of one another. On accomplishing this he saw sixty of the brightest of the iron rays as continuations of sixty of the strongest of the dark lines in the sun's spectrum; and by an elaborate scrutiny, he satisfied himself that the observations had been pushed to a sufficient degree of exactness to make sure that a deviation would have been detected in any one of these sixty cases if it had amounted to as much as one-fourth of the average interval between consecutive lines of the solar spectrum. From this it was obvious that the sixty coincidences are not due to chance, but indicate that there is really iron vapour in the path of the rays. It will be observed that Kirchhoff's great merit and the real difficulty of his work lay in the scientific foresight and the industry which were required to frame hypotheses that were worth testing, to guide the investigation by these hypotheses, to contrive, construct, and adjust adequate apparatus, and to make with it the elaborate observations and the exact observations and maps which were necessary. But when by these means the new facts had been brought to light, the inference from them that there is iron in the atmosphere of the sun was an easy one. This example will better convey than a definition what are the characteristic features of an experimental inquiry.

On the other hand, no series of observations or experiments, however skilfully arranged, could have enabled anyone to understand the cause of that familiar but truly surprising phenomenon that a top stands upon its peg while it is spinning. But a full explanation of it is within the reach of any student who will train his mind to reason consecutively, and avail himself of the aids to prolonged consecutive thought which mathematicians have contrived. He will then see that the most obvious and familiar mechanical facts involve as necessary consequences all the phenomena which he finds in the

* Extract from a Presidential Address to the Mathematical and Physical Science Section, August 21, 1879.

schoolboy's top, in the physicist's gyroscope, and in the precision and nutation of the heavens. This then is a problem of Nature which falls within the province of the deductive method.

Wherever data are known exactly, these inferences from these data, however remote, may be depended upon as corresponding with what actually occurs in Nature. And if in such cases the mind of man has proved equal to the task of drawing inferences which can effectually grapple with the problems he finds around him in the Universe—which is, alas! as yet but too seldom—then will the deductive method, our plummet, explore depths in the great ocean of existence which our anchors of experiment could not have reached.

The distinction which is here made between deductive and experimental investigations would have no place in a logical system. But it has direct reference to human convenience, and derives its importance from this circumstance. It is obvious, too, that an investigation may partake of both characters—that it may require all the powers of the scientific observer to get at the facts, or even to appreciate them, and all the resources of the mathematician to elicit the consequences of them. For instance, on beginning his electrical studies, the student of Nature must master a mixed experimental and deductive inquiry to get at the elementary fact that free electricity resides either at or outside the surfaces of conductors; and he must engage in a further inquiry, and one only within the reach of a trained mind, to deduce from this the law of the inverse square. And, again, no full appreciation or even intelligent use of the common electrostatic and electrodynamic measures which he meets at the threshold of his electrical studies is within the reach of the mere experimentalist or the mere theorist. And if this treacherous ground lies before the immature student at his entrance, what shall we say of the bogs he struggles into as he advances? We are perpetually meeting with inquiries of this mixed character in electricity and some of the other physical sciences, but they are comparatively rare in either medicine or chemistry, and none that is difficult lies in the path of the beginner. How many students are there who are made to slur over the above and a multitude of similar difficulties, and who are told that they are learning science, when in fact what they are really learning is the pernicious habit of being content to see Nature through a fog or through other men's mental eyes?

In mechanics valuable progress can be made by the mere mathematician, the student of deductive science; and in chemistry similar progress can be made by the mere experimentalist. Of all the physical sciences these are the most purely deductive, and the most purely experimental. What I desire particularly to invite attention to is that the two great methods of investigation may best be acquired in these two sciences, and that for a really sound grasp of the remaining physical sciences, and especially with a view to further advance in physical science, a command of both methods of investigation is essential.

We must bear in mind, too, that either method of investigation may be misapplied, and that this is a risk carefully to be guarded against. The deductive method when misapplied lands us in speculation, the experimental method becomes empiricism; and it so happens that the sciences of mechanics and chemistry are not only monuments of the power of the two great methods of investigation, but instructive examples of their weakness also. For in chemistry, scarce any attempt at prolonged reasoning, carrying us by any lengthened flight to a distance from the experiments, can be relied on. The result has seldom risen to anything better than speculation. And on the other hand, in mechanics, conclusions which depend on experiments only are empirical; that is, they are deficient in accuracy, and their relation to the other phenomena of the science is left in darkness. Here, then, we find in these two sciences not only how strong these two methods of investigation are, but how weak they may become if misapplied.

Parliamentary and Law Proceedings.

An Act to Continue and Amend the Petroleum Act, 1871.

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may be cited as the Petroleum Act, 1879.

This Act shall be construed as one with the Petroleum Act, 1871, and together with that Act may be cited as the Petroleum Acts, 1871 and 1879.

2. Whereas by the Petroleum Act, 1871, it is enacted that the term "petroleum to which this Act applies" means such of the petroleum defined by that Act as, when tested in manner set forth in Schedule 1 to that Act, gives off an inflammable vapour at a temperature of less than 100° of Fahrenheit's thermometer, and it is expedient to alter the said test: Be it therefore enacted that—

In the Petroleum Act, 1871, the term "petroleum to which this Act applies" shall mean such of the petroleum defined by section 3 of that Act as, when tested in manner set forth in Schedule 1 to this Act, gives off an inflammable vapour at a temperature of less than 73° of Fahrenheit's thermometer.

Every reference in the Petroleum Act, 1871, to Schedule 1 to that Act shall be construed to refer to Schedule 1 to this Act.

3. A model of the apparatus for testing petroleum, as described in Schedule 1 to this Act, shall be deposited with the Board of Trade, and the Board of Trade shall, on payment of such fee, not exceeding five shillings, as they from time to time prescribe, cause to be compared with such model and verified every apparatus constructed in accordance with Schedule 1 to this Act which is submitted to them for the purpose, and if the same is found correct shall stamp the same with a mark approved of by the Board and notified in the *London Gazette.*

An apparatus for testing petroleum purporting to be stamped with the said mark shall, until the contrary is proved, be deemed to have been verified by the Board of Trade.

All fees under this section shall be paid into the Exchequer.

4. The Petroleum Act, 1871, shall continue in force until otherwise directed by Parliament.

5. This Act shall come into operation on the thirty-first day of December one thousand eight hundred and seventy nine, which day is in this Act referred to as the commencement of this Act.

6. The Petroleum Act, 1871, shall be repealed after the commencement of this Act to the extent in the third column of the Second Schedule to this Act mentioned.

Provided that any sample of petroleum taken before the commencement of this Act shall be tested in manner set forth in Schedule 1 to the Petroleum Act, 1871, and any offence committed before the commencement of this Act shall be prosecuted, and any investigation, legal proceeding, or remedy in relation to such offence, or to any act done before the commencement of this Act, shall be instituted, carried on, and have effect as if the provisions of this Act, other than those continuing the Petroleum Act, 1871, had not been passed.

First Schedule.

Mode of testing Petroleum so as to ascertain the Temperature at which it will give off Inflammable Vapour.

Specification of the Test Apparatus.

The following is a description of the details of the apparatus:—

The oil cup consists of a cylindrical vessel 2″ diameter, $2\frac{2}{10}$″ height (internal), with outward projecting rim $\frac{5}{10}$″

wide, $\frac{3}{8}$" from the top, and $1\frac{7}{8}$" from the bottom of the cup. It is made of gun metal or brass (17 B.W.G.) tinned inside. A bracket, consisting of a short stout piece of wire bent upwards and terminating in a point, is fixed to the inside of the cup to serve as a gauge. The distance of the point from the bottom of the cup is $1\frac{1}{2}$". The cup is provided with a close-fitting overlapping cover made of brass (22 B.W.G.), which carries the thermometer and test lamp. The latter is suspended from two supports from the side by means of trunnions upon which it may be made to oscillate, it is provided with a spout, the mouth of which is one-sixteenth of an inch in diameter. The socket which is to hold the thermometer is fixed at such an angle and its length is so adjusted that the bulb of the thermometer when inserted to its full depth shall be $1\frac{1}{2}$" below the centre of the lid.

The cover is provided with three square holes, one in the centre, $\frac{5}{10}$" by $\frac{4}{10}$", and two smaller ones, $\frac{3}{10}$" by $\frac{2}{10}$", close to the sides and opposite each other. These three holes may be closed and uncovered by means of a slide moving in grooves, and having perforations corresponding to those on the lid.

In moving the slide so as to uncover the holes, the oscillating lamp is caught by a pin fixed in the slide, and tilted in such a way as to bring the end of the spout just below the surface of the lid. Upon the slide being pushed back so as to cover the holes, the lamp returns to its original position.

Upon the cover, in front of and in line with the mouth of the lamp, is fixed a white bead, the dimensions of which represent the size of the test flame to be used.

The bath or heated vessel consists of two flat-bottomed copper cylinders (24 B.W.G.), an inner one of 3" diameter and $2\frac{1}{2}$" height, and an outer one of $5\frac{1}{2}$" diameter and $5\frac{3}{4}$" height; they are soldered to a circular copper plate (20 B.W.G.) perforated in the centre, which forms the top of the bath, in such a manner as to enclose the space between the two cylinders, but leaving access to the inner cylinder. The top of the bath projects both outwards and inwards about $\frac{3}{8}$"; that is, its diameter is about $\frac{6}{8}$" greater than that of the body of the bath, while the diameter of the circular opening in the centre is about the same amount less than that of the inner copper cylinder. To the inner projection of the top is fastened, by six small screws, a flat ring of ebonite, the screws being sunk below the surface of the ebonite, to avoid metallic contact between the bath and the oil cup. The exact distance between the sides and bottom of the bath and of the oil lamp is one-half of an inch. A split socket similar to that on the cover of the oil cup, but set at a right angle, allows a thermometer to be inserted into the space between the two cylinders. The bath is further provided with a funnel, an overflow pipe, and two loop handles.

The bath rests upon a cast-iron tripod stand, to the ring of which is attached a copper cylinder or jacket (24 B.W.G.) flanged at the top, and of such dimensions that the bath, while firmly resting on the iron ring, just touches with its projecting top the inward-turned flange. The diameter of this outer jacket is $6\frac{1}{2}$". One of the three legs of the stand serves as support for the spirit lamp attached to it by means of a small swing bracket. The distance of the wick holder from the bottom of the bath is 1".

Two thermometers are provided with the apparatus, the one for ascertaining the temperature of the bath, the other for determining the flashing point. The thermometer for ascertaining the temperature of the water has a long bulb and a space at the top. Its range is from about 90° to 190° Fahrenheit. The scale (in degrees of Fahrenheit) is marked on an ivory back fastened to the tube in the usual way. It is fitted with a metal collar, fitting the socket, and the part of the tube below the scale should have a length of about $3\frac{1}{2}$" measured from the lower end of the scale to the end of the bulb. The thermometer for ascertaining the temperature of the oil is fitted with collar and ivory scale in a similar manner to the one described. It has a round bulb, a space at the top, and ranges from about 55° F. to 150° F.; it measures from end of ivory back to bulb $2\frac{1}{4}$".

Note.—A model apparatus is deposited at the Weights and Measures Department of the Board of Trade.

Directions for applying the Flashing Test.

1. The test apparatus is to be placed for use in a position where it is not exposed to currents of air or draughts.

2. The heating vessel or water-bath is filled by pouring water into the funnel until it begins to flow out at the spout of the vessel. The temperature of the water at the commencement of the test is to be 130° Fahrenheit, and this is attained in the first instance either by mixing hot and cold water in the bath, or in a vessel from which the bath is filled, until the thermometer which is provided for testing the temperature of the water gives the proper indication, or by heating the water with the spirit lamp (which is attached to the stand of the apparatus) until the required temperature is indicated.

If the water has been heated too highly, it is easily reduced to 130° by pouring in cold water little by little (to replace a portion of the warm water) until the thermometer gives the proper reading.

When a test has been completed, this water-bath is again raised to 130° by placing the lamp underneath, and the result is readily obtained while the petroleum cup is being emptied, cooled, and refilled with a fresh sample to be tested. The lamp is then turned on its swivel from under the apparatus, and the next test is proceeded with.

3. The test lamp is prepared for use by fitting it with a piece of flat plaited candle wick and filling it with colza or rape oil up to the lower edge of the opening of the spout or wick tube. The lamp is trimmed so that when lighted it gives a flame of about 0·15 of an inch diameter, and this size of flame which is represented by the projecting white bead on the cover of the oil cup is readily maintained by simple manipulation from time to time with a small wire trimmer.

When gas is available it may be conveniently used in place of the little oil lamp, and for this purpose a test-flame arrangement for use with gas may be substituted for the lamp.

4. The bath having been raised to the proper temperature, the oil to be tested is introduced into the petroleum cup, being poured in slowly until the level of the liquid just reaches the point of the gauge which is fixed in the cup. In warm weather the temperature of the room in which the samples to be tested have been kept should be observed in the first instance, and if it exceeds 65° the samples to be tested should be cooled down (to about 60°) by immersing the bottles containing them in cold water, or by any other convenient method. The lid of the cup, with the slide closed, is then put on, and the cup is placed into the bath or heating vessel. The thermometer in the lid of the cup has been adjusted so as to have its bulb just immersed in the liquid, and its position is not under any circumstances to be altered. When the cup has been placed in the proper position, the scale of the thermometer faces the operator.

5. The test lamp is then placed in position upon the lid of the cup, the lead line or pendulum, which has been been fixed in a convenient position in front of the operator, is set in motion, and the rise of the thermometer in the petroleum cup is watched. When the temperature has reached about 66° the operation of testing is to be commenced, the test-flame being applied once for every rise of one degree, in the following manner:—

The slide is slowly drawn open while the pendulum performs three oscillations, and is closed during the fourth oscillation.

Note.—If it is desired to employ the test apparatus to determine the flashing points of oils of very low volatility, the mode of proceeding is to be modified as follows:—

The air-chamber which surrounds the cup is filled with cold water, to a depth of $1\frac{1}{2}$ inches, and the heating vessel or water-bath is filled as usual, but also with cold water. The lamp is then placed under the apparatus and kept there during the entire operation. If a very heavy oil is being dealt with, the operation may be commenced with water previously heated to 120°, instead of with cold water.

SECOND SCHEDULE.

Act repealed.

Year and Chapter.	Title.	Extent of Repeal.
34 and 35 Vict. c. 105.	The Petroleum Act, 1871.	Section three, from "and the term petroleum to which this Act applies" inclusive to the end of the section. Section eighteen.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[340]. Will any readers of the Journal kindly inform me if it would be right in making "ung. sulph. iodidi" to rub the iodide of sulphur with a little glycerine before mixing the lard, glycerine being a solvent for iodide of sulphur? INQUIRER.

[341]. The following prescription was presented to me to-day. Will some of your readers kindly inform me what the first ingredient is?—

℞ Ung. Calcis Hydr. Alb. . . . . . ʒij.
Ol. Amygd. Dulc,
Aq. Calcis . . . . āā ℥j.
M. ft. ung.
(Cream for the face). H. S. N.

[342]. Would some reader kindly inform me the cause of my failure in making ung. plumbi subacetatis compositum? I strictly followed the directions given in the B.P., but in the course of a week or so, the ointment began to change to a pale orange colour. The jar in which it is kept is free from lead, but it being standing next to the iodine ointment jar I thought that might be the cause. Having thrown the first lot out I began again, this time isolating the jar, but with no better results? AN APPRENTICE.

Correspondence.

THE INTRODUCTION OF CHLOROFORM.

Sir,—Referring to Mr. Brown's note on the introduction of chloroform, I subjoin the following extract from my laboratory book:—

154 lbs. chloride of lime,
$63\frac{1}{2}$ pints of wood naphtha.

The above mixed with a sufficient quantity of water was distilled in a large still heated with steam and the product distilled with strong sulphuric acid and again distilled with carbonate of baryta and dried chloride of calcium. The purified product weighed 13 lbs. 2 oz. and was supplied to Dr. Simpson, of Edinburgh, early in November, 1847, having been prepared by myself at the end of October and during the first few days of November in that year, and was, I believe, the first chloroform ever prepared as a commercial article in this country. Subsequently I prepared large quantities from pure spirit of wine which was found to yield a larger and purer product. At the time in question I was an apprentice to Mr. George Simpson, of Kennington, the head of the subsequently well-known firm of Simpson, Maule and Nicholson, manufacturers of aniline dyes.

13, *Curzon Street, W.* E. N. BUTT.

WEIGHTS AND MEASURES ACT.

Sir,—In the schedule of apothecaries' weights abstracted from the *London Gazette* of the 15th ult. and published in the Journal (Aug. 23), p. 145, I observe the largest single measure of weight is 10 ounces, equal to 4800 grains. I am at a loss to understand why this is the case when the troy pound contains 12 ounces and the sets of cup-weights in general use have always had this—the troy pound—as their largest weight. And will the 12 ounce weight now become illegal, or will it still be a lawful weight as being the silversmith's troy pound? I have not the late Act at hand, but I think the latter was legalized.

When the subject was before the Council, in your report I noticed the above peculiarity, but thought it was a misprint in the numerals 10 to 12, to which I had intended to draw attention. It had escaped my memory till now, when I again see the 10 ounce weight in print, with its equivalent in grains, which I think was not the case before.

This new weight will be a decimal blunder and a reproach on the originators of the Act for having discarded the metric decimal system.

Winchelsea. WM. MARTINDALE.

THE HEALTH OF THE DRUG TRADE.

Sir,—From frequent perusal of the Obituary in the *Pharmaceutical Journal*, and from other sources, my attention has been drawn to the peculiar fact that nearly 80 per cent. of chemists and druggists die at an age when men are generally supposed to be in their prime, both intellectually and physically, and a considerable number even under that age, while very few reach the allotted span of three score and ten years. The subject seems to me to be of sufficient importance to warrant a short discussion on the matter in the Journal. The question naturally arises, what are the causes of this lamentable fact? can that odour which is so characteristic of a chemist's shop be injurious to health? The atmosphere of our shops must frequently be vitiated by the escape of gases from many drugs and chemicals, whose injurious qualities, overloading the normal impure atmosphere which is generally found in large towns, cannot improve the condition of the respiratory organs.

In the absence of correct statistics as to the actual causes of death in each individual case, a just decision is impracticable, but I have been led to believe that consumption and cardiac affections are the two principal agents at work in our ranks. Do these insidious enemies find a footing amongst us through any fault of our own? Do the anxiety, the long hours, the constant deep attention which every druggist requires to devote to all the little minutiæ which go to make up his daily duties, and the want of that active exercise to the muscular system which is to be found in almost every other trade, induce towards an enervated nerve power?

This letter, I hope, will be the means of inclining some who are abler than I to give an explanation of the causes, so that those of our suffering brethren whose pale faces and degenerated nervous system may apply the remedy.

Edinburgh. J. K. NICOL.

"*Inquirer.*"—Under the circumstances you mention there may be a kind of acid fermentation set up, resembling lactic fermentation, but we are not aware that there would be any formation of valerianic acid.

"*Country Apprentice.*"—You are learning the business of a chemist and druggist as it is not unfrequently carried on in country districts. You are recommended to prepare for future eventualities by studying chemistry, botany and materia medica.

NOTES ON SOME JAPANESE DRUGS.

BY E. M. HOLMES, F.L.S.,
Curator of the Museum of the Pharmaceutical Society.

(*Continued from page* 103.)

HERBS AND LEAVES.

HAKKA (57):—*Mentha austriaca*, Jacq.? Fr. et Sav. vol. i. p. 366.

Syn. Mentha arvensis, L., var. *Javanica*, Bl.; Pharmacographia, p. 434, note 1; *Mentha arvensis*, var. *vulgaris*, Benth. MEGUSA, Sô mokou Zoussetz, vol. xi. fig. 27; Phonzou Zoufou, vol. xii. fol. 10.

This drug consists of the dried herb.

The leaves are lanceolate and nearly glabrous, with a tapering base and with few short but sharp serrations. The taste is powerfully pungent and strongly resembles that of *Mentha piperita*. The oil, however, of the two plants is not identical, as shown by Flückiger, since it does not give a fluorescence when treated with nitric acid.*

The leaves are probably used as tea by the Japanese. Mr. T. Christy informs me that he experienced great relief when in China, in an attack of sunstroke, by the application of the oil, which a Chinese doctor rubbed over his head. It produced a most profuse perspiration and tranquil sleep.

The Japanese peppermint plant has been attributed to *Mentha javanica*, Bl., by Flückiger and Hanbury; but all the specimens of that plant which I have seen have the taste of *Mentha viridis*, L., not of *Mentha piperita*, L. In the Sô Mokou Zoussetz the figure of the Japanese peppermint plant exactly corresponds to the drug; but is by mistake referred to *M. arvensis*, var. *vulgaris*, Benth., which is quite a different plant, with leaves widest below, like those of *M. arvensis*, and a similar taste. All the specimens of *M. Austriaca*, Jacq., including a type specimen, to which I have had access, have not the taste of peppermint. The plant yielding the Japanese peppermint oil must therefore be regarded as a yet unnamed form. In shape of the leaf and character of the calyx it seems to approach most nearly to *M. Canadensis*, but the leaves of that species, according to a living specimen of the hairy variety, kindly supplied by Professor Asa Gray, have a taste more approaching to pennyroyal.

KEI-NING-SOH (10):—*Digenea simplex*, Ag. (Algæ).

This seaweed is of a dull green colour, having lost its original purplish red tint by exposure to air and heat probably. It is well known that all seaweeds contain chlorophyll, the green colour of which in the case of red algæ is hidden by a red colouring matter, phycerythrine, and in the black or olive algæ by phycophæine and phycoxanthine.† By the action of fresh water and heat the colouring matter which conceals the chlorophyll is destroyed, and the presence of the latter becomes evident. From the quantity of sand and foreign matter present, the decoloration in this case would appear to be due to the action of the heat of the sun on a sandy shore, rather than to the effects of fresh water.

KING-KI-YO (15):—*Malva sylvestris*, Lin.

Syn. ZENI-AOI, Sô mokou Zoussetz, vol. xii. fig. 54.

This drug consists chiefly of the leaves of this well-known plant mixed occasionally with fragments of those of *Althæa rosea*, L. (Tachi-avi) and apparently also of *Malva pulchella*, Bernh. (Fuyu-avi). See Sô mokou Zouss., vol. xii. figs. 53, 55.

SHISSO (21):—*Perilla arguta*, Benth.; Fr. et Sav., vol. i. p. 365; Sô mokou Zouss., vol. xi. fig. 24; Phonzou Zoufou, vol. xii. p. 113 (calyx bad).

Syn. SISSOO, JAKOSJU, Miq. Prol., p. 36.

Shisso consists of the stems and leaves of the plant. The leaves are ovate, lanceolate, acuminate, the largest about two inches long by one inch broad, sharply serrate, and of a purplish tint underneath.

Shisso blossoms in September.

TO-YAK (17):—*Pleurogyne rotata*, Griseb. (Gentianaceæ); *Swertia rotata*, Thunb. Fl. Jap., p. 115.

Syn. SENBURI, TOYAKU; Sô mokou Zoussetz, vol. iv. f. 54.

This is a small plant, having a slight resemblance to centaury, but with pinkish-white flowers striped with purple, somewhat similar in size and shape to those of *Chlora perfoliata*; the leaves are linear-lanceolate, about one inch long and two or three lines broad in the middle. The taste is extremely bitter, like that of chiretta, and the odour hardly any. To-yak flowers in October. This plant is interesting botanically on account of the stigma being prolonged downwards over the edges of the valves of the ovary. The corolla has also at its base little glands terminating in hairs.

FLOWERS.

CHAU-TO-KO (13):—*Uncaria Gambir*, Roxb. (Cinchonaceæ).

Syn. TIAN-T'ANG, Porter Smith, Chinese Mat. Med. p. 224.

This drug consists of short portions of the slender stems half an inch to one inch in length and one to two lines broad, with one or two strongly recurved hooks. The whole is of a brown colour and has an astringent taste. These curious hooks do not consist, as described by Dr. Porter Smith, of the stipules, but of the stalk which bears the flower-heads. The flower stalks, as described in Bentley and Trimen's 'Medicinal Plants,' are furnished near the middle with a few bracts, beyond which the peduncle is more slender. After the fall of the fruit the portion of stem below the bracts elongates, hardens and forms a strong recurved hook by means of which the plant climbs. On some of the hooks the traces of the fall of the peduncle and bract may still be seen, on others, which have probably arisen from abortive inflorescences, there is no sign of them. It is probable that these hooks are also obtained from *U. acida*, Roxb., a plant which is used in the Malay Islands in the same manner.

The hooks possess astringent properties, and a wine is made from them used for infantile diseases, according to Dr. Porter Smith. Neither of these species are mentioned in Franchet and Savatier's work, and this drug may therefore be a Japanese importation from China.

BIAK-TAU KAH (52):—*Amygdalus persica*?

Syn. TOO, Thunb. Flor. Jap., p. 199; T'AU, Porter Smith, Chinese Mat. Med. p. 168.

These flowers evidently belong to some species of *Amygdalus*, and are called by Mr. Takemura "peach flowers." They are apparently derived from some cultivated species, since the majority of the blossoms

* *Pharm. Journ.* [3], vol. i., p. 682.

† Millardet, *Comptes Rendus*, Feb. 22, 1869.

are partially double. *Kah* means flowers, and *Tau* or *Too* is a sort of generic name both in Japanese and Chinese for fruits of the peach kind, and *Biak* means white, according to Mr. Takemura, so that some variety of *Amygdalus Persica* with white flowers may be the source of Biak-tau-kah. The dried flowers however have a slight pinkish tinge. Thunberg mentions a variety of peach with simple white flowers called "Sato Momu."

HOH-OH (32):—*Typha japonica*, Miq.

Syn. P'U HWANG, Porter Smith, Chinese Mat. Med., p. 224.

This yellow powder consists of the pollen. It is inflammable, like lycopodium, but shows a tendency to agglomerate into lumps. Dr. Porter Smith states that in China it is obtained from *Typha Bungeana*, and is used as a desiccant, astringent, styptic and sedative remedy, and also that it is made into a confection for external and internal use. It has neither taste nor odour.

The Chinese character, translated P'u hwang, is exactly the same as the Japanese character, Hoh-oh. P'u or Hoh being the name of the plant, and Hwang or Oh meaning yellow.

The spikes are said by Miquel to be used as a styptic.

The only species mentioned by Fr. and Savatier as a native of Japan is *T. japonica*, although the Phonzou Zoufou, vol. 33, figures two which are supposed to be (fig. 19 Kobo) *T. japonica*, Miq., and (fig. 20, Rindziakou) *T. angustifolia*, L.

IN T'YING (31):—*Artemisia capillaris*, Thunb.

Syn. INTSJIN; FKI IAMOGI and KAWARA IAMOGI; Kæmpf. Amœn., p. 897; IAMMA INTSJIN; Thunb. Fl. Jap., p. 309; KAWARA YOMOGI, Sô mokou Zouss. vol. xvi. fig. 27; Phonzou Zoufou, vol. xiv. fol. 2.

This consists of the flower heads, and bears some resemblance to Levant santonica, than which the flower heads are smaller. The paleæ are oval, obtuse and membranous, about six in number, and closely imbricated. The scales separate more readily than in santonica, and are mixed with the flower heads, as well as portions of the capillary leaflets. The taste is slightly pungent and aromatic, but not bitter.

The plant flowers in August, and is not an inland, but a littoral species.

SET-KOTZ-MO KAH (22):—*Sambucus nigra*, L.

Syn. NIWA TOKA, Tonga, Kæmpf. Amœn. fasc. v. p. 787; Thunb. Fl. Jap. p. 126.

This drug consists of the flowers freed from the stalks, and dried just before expansion. They are of a dark brown colour, and not to be compared in quality with those dried in this country. The species of *Sambucus* is given on Mr. Takemura's authority.

Thunberg states (p. 126) that neither this species nor *S. canadensis*, L., matures fruit in Japan, and are therefore evidently not natives. Probably for this reason *S. nigra* is omitted by Fr. and Savatier, in their Enum. Pl, Jap., p. 198.

SHIN-EE (4):—*Magnolia Yulan*, Desf.

Syn. SIN-Í; Porter Smith, Chinese Mat. Med., p. 142.

Shin-ee consists of the very young flower buds of this tree. The two outer scales are smooth, and the two inner are covered with a dense coat of silky hair; when these are removed the flower in a very rudimentary state may be traced. The taste is bitter and aromatic; of odour there is almost none.

According to Dr. Porter Smith, a kind of snuff made of the powdered drug was formerly used in China. It is probably imported from that country.

FRUITS AND SEEDS.

GOBO SEE (25):—*Arctium Lappa*, L. (Compositæ).

Syn. *Lappa Major*, Gaertn, Fr. et Sav. vol. i. p. 262; GOBO, UMMA BUSUKI; Kœmpf. Amœn. p. 828; Thunb. Fl. Jap. p. 304; KOUMA TORI BOKOUDSI, Phonzou Zoufou, vol. xv. fol. 23; GOBO, Sô mokou Zoussetz, vol. xv. fig. 33.

The small fruits of this plant are about a quarter of an inch long, linear, somewhat flattened, about one line wide at the apex, and tapering thence to the base. The taste is bitter and slightly pungent. They are of a greyish brown colour, speckled with minute black dots.

In Japan the burdock is cultivated as a vegetable under the name of gobo, and the root is used to put in soups. For this purpose it is taken up before the flowering stem appears (Kœmpfer). It is probably identical with the *Arctium edule* of Siebold. I have no information concerning the uses of this seed in Japan. Rather more than one hundred years ago they were used in this country in doses of one drachm as a diuretic and aperient, and the root is still used by herbalists in this country as an alterative in skin diseases and syphilis. The Japanese character for "see" is exactly the same as the Chinese for "tsze," and stands for "seed" in both cases.

GOME SEE (6):—*Schizandra nigra*, Max.

Syn. MADZI-SSA, Maximowicz, Diag. Pl. Nov. Jap. et Mandsh. Dec. x. p. 370.

This drug consists of reddish or black wrinkled fruits about the size of a pea, each containing two flattened kidney-shaped seeds. The seeds have a minutely tuberculated testa, and contain an oily albuminous nucleus. The berry is sweetish and mucilaginous, and the kernel of the seed has a slightly bitter oily taste, but no odour.

Gomichi is given by Franchet and Savatier as the Japanese name for *Schizandra Chinensis*, Baill. That plant, however, has smooth seeds. Maximowicz, in the work above quoted, states that *S. nigra* is at once distinguished from all the other species of this genus by the black berries with a glaucous bloom and the tuberculated seeds.

S. nigra is a climbing plant, clothing the pine and fir trees with its foliage in alpine woods, especially those of the Kundsho san chain of mountains in central Kiusiu. The fruit is ripe in October, and is considered edible.

The Chinese character Wu-wei-tsze, which, according to Dr. Porter Smith, is the Chinese name for the fruits of *Kadsura Chinensis* (*Schizandra Chinensis*, Baill.), is identical with the Japanese character above translated, gome-see, and means in both languages five-tasted seeds. The berries abound in a viscid mucus.*

GO-SIU-JU (50):—*Evodia rutæcarpa*, Benth.

Syn. *Boymia rutæcarpa*, Sieb. et Zucc, vol. i. p. 50; GO-SJU-JU; KAWA HASIKAMI, HABITE KOBURA,

* Porter Smith's 'Chinese Materia Medica,' p. 126.

Fr. et Sav. vol. i. pp. 71, 72; Phonzou Zoufou, vol. lxx. fol. 11.

This drug consists of the pedicels and very young fruits of the plant. The stalks are cylindrical, about one line in diameter, covered with down consisting of minute spreading hairs. The fruits are reddish brown, deeply pitted with oil glands, varying in size from a swan shot to a small pea, and divided half way down into five segments. The taste is decidedly rutaceous and pungent, although not exactly that of rue. The odour is very similar, but less powerful. Possibly the young fruits of *E. glauca*, Miq., are also used, since "koshiou you" is given as the Japanese name for this species in 'Phonzou Zoufou, vol. lxx., fol. 10.

Boymia rutæcarpa is a handsome shrub, six to ten feet high, and frequently cultivated in the south of Japan for its beauty. The flowers, which are diœcious, are produced in May and June. By the Japanese doctors of the Chinese school this drug is considered to be a most valuable remedy, and is used as a purgative, emmenagogue, sudorific and stimulant, and, in fact, seems to possess properties very similar to those accredited to the common rue.

KEE-KOCK (45):—*Citrus fusca*, Lour.

Syn. CHÍ-KOH, Porter Smith, Chin. Mat. Med. p. 66; CAY BAONG, CHI XAC, CHI KEN, Lour. Fl. Cochinchinensis, p. 467.

This drug consists of what appears to be fruits gathered when unripe, and then cut in half and dried. The rind is thick and externally of a dark or brownish black colour, internally whitish; the dried pulp is blackish. The taste is bitter and the odour very faintly that of orange. The drug is identical with that presented to the Museum of the Pharmaceutical Society by Dr. Porter Smith under the name of *Citrus fusca.*

The Japanese character is not, however, absolutely identical with the Chinese one given by Dr. Porter Smith.

The Japanese character translated "kee," and the Chinese "chí," is identical, but the one translated "kock" is not identical in appearance, although Mr. Takemura assures me it is identical in meaning with the Chinese character for "koh." Loureiro, however, gives as a synonym "chi xác," which more nearly approaches the Japanese name in sound.

Thunberg (Fl. Jap., p. 294) gives the very similar name "kikokf" as a synonym of *Citrus trifoliata*, L.

Citrus fusca is supposed by the Chinese to possess cooling, deobstruent and stomachic properties.

KETZ-MAY SEE (49):—*Cassia Tora*, L. (Leguminosæ). *Pharm. Journ.* [3], vol. vii. p. 350.

Syn. KIUEH-MING-TSZE, Porter Smith, Chinese Mat. Med. p. 54; KEUE-MING TSZE, Hanbury Science Papers, p. 231; TAGARAY-ELLEY, Ainslie Mat. Med. vol. ii. p. 405; KETSUMEI, Miq. Prol. p. 243; YEBISUGUSA, So mokou Zoussetz, vol. viii. fig. 1; Phonzou Zoufou, vol. xviii. fol. 12.

The seeds, which are to be seen in most collections of drugs from India or China, are of a dark brown colour and polished, about two lines long, quadrangular, oblique at both ends, but blunt at one end and pointed at the other, and having two very faint stripes on opposite sides.

Dr. Porter Smith states that in China they are used both externally and internally for sore eyes and for herpetic or furunculoid sores.

In India, according to Udoy Chand Dutt ('Hindu Mat. Med.,' p. 156), the seeds are dipped into the juice of *Euphorbia neriifolia* and made into a paste with cow's urine for keloid tumours; or equal parts of them mixed with the seeds of *Pongamia glabra* and a fourth part of the root of *Tinospora cordifolia* are made into a paste for ringworm.

Fr. et Savat. 'Fl. Jap.,' vol. i., express the opinion that neither this plant, nor *C. occidentalis*, nor *C. Sophora* grow spontaneously in Japan. The seeds of *C. Tora* are therefore probably imported into Japan. The Japanese and Chinese characters for *Cassia Tora* seed are identical, although in Chinese the word is pronounced, according to Dr. Porter Smith, Kiueh-ming-tsze.

KIEU-ESS (44):—*Allium senescens*, Thunb., Fl. Jap. p. 132.

Syn. YAMA-RAKKYO, Phonzou Zoufou, vol. xlv. fol. 13; Sô mokou Zouss. vol. vi. fig. 37; *Allium japonicum*, Regel., Fr. et Sav. vol. ii. pt. 1, p. 77.

These seeds have the appearance of ordinary onion seeds. They are black and angular, without odour, and have only a very slight alliaceous taste.

In China they are used for various fluxes and for hæmorrhages.

In 'Loureiro Fl. Cochin Chinensis' the term kieu is applied to three species, *A. triquetrum*, L., *A. odorum*, L., and *A. angulosum*, L.

(To be continued.)

LIQUID PREPARATIONS OF LACTUCARIUM.*

BY JOSEPH L. LEMBERGER.

In accepting the query to give a formula for a concentrated liquid preparation of lactucarium, from which can be made the syrup, tincture, or other preparations, the writer is fully aware of the difficulty usually met with in making the lactucarium preparations occasioned by the caoutchouc principle always present in this as well as most, if not all, the products from the lactescent plants; in order to overcome this difficulty petroleum benzin has been found the most practical, being efficient and cheaper than most of the solvents for caoutchouc. It was found that by beating the lactucarium in an iron mortar until it is well crushed it separates into layers, or plates, or very coarse granulation (according to its degree of dryness), as the nearest possible approach to comminution, it being impossible to powder it without the addition of sand or other foreign substance. Thus treated and macerated with benzin the caoutchouc principle is readily dissolved and the lactucarium is fitted for treatment with other menstruum. After numerous experiments the following is offered as a practical working formula for the—

Fluid Extract of Lactucarium.

Take of—

Lactucarium	16 troy ounces.
Petroleum benzin deodorized .	32 fluid ounces.
Diluted alcohol a sufficient quantity.	

Beat the lactucarium thoroughly in an iron mortar, then introduce it into a wide-mouth bottle of about three pints capacity, adding the benzin, corking tight, and allowing it to macerate, with frequent agitation, for twenty-four hours; then let it rest about twenty-four hours, or until the lactucarium subsides and the benzin solution becomes clear or nearly so; then, having decanted the benzin solution, transfer the lactucarium to a stone or glass slab or other similar vessel, spreading it as thin as possible, allowing it to remain in this situation until completely dry (at least twenty-four hours); then

* From the 'Proceedings of the American Pharmaceutical Association,' 1878.

rub it up in an iron mortar with an equal bulk of clean sand; next introduce it into a cylindrical percolator, first prepared with a disc of flannel and a thin layer of sand, pack lightly and add sufficient diluted alcohol to cover several inches, and after closing the outlet with a cork or otherwise allow it to macerate twenty-four hours; then percolate to exhaustion, reserving the first four fluid ounces. By means of a still reclaim the alcohol and evaporate the residue in a water-bath to ten (10) fluid ounces, mixing this with the reserved percolate and filter, adding sufficient diluted alcohol to wash the filter and remaining residue until the product weighs sixteen troy ounces.

With this fluid extract you can readily make—

Tincture of Lactucarium, as follows:—

Take of—

Fluid extract lactucarium . . 1 troy ounce (℥j).
Diluted alcohol. . . . . . q. s. for f℥viij.
A fluid drachm representing 7½ grains.

For—

Syrup of Lactucarium,

Take of—

Fluid extract of lactucarium . 1 troy ounce (℥j).
Simple syrup . . . . . . q. s. for f℥xvi.
A fluid drachm representing 3¾ grains.

SMILAX GLAUCA.*

BY JOHN BLANKENHORN, PH.G.

With the view of ascertaining the constituents of the long cylindrical light-coloured rhizome, a sample furnished by Professor Maisch was submitted to the following treatment:—Two pounds of the ground rhizome were exhausted by a mixture of two parts alcohol and seven parts water, and the percolate concentrated at a low temperature. After cooling, the whole was treated with acetate of lead until no further precipitate occurred, then filtered. The filtrate, thus deprived of nearly all colouring matter, was subjected to the action of sulphuretted hydrogen, in order to free it from lead, and again filtered. The sulphide of lead after thorough washing with water, was treated wlth boiling alcohol, filtered, the filtrate concentrated and spread on glass to scale; attempts were made at crystallization, but without success.

The precipitate with acetate of lead was thoroughly washed, suspended in water and decomposed by sulphuretted hydrogen, then filtered. The liquid was now evaporated; at first the colour was dark-red, and the colour of blue litmus was changed to red. Both characters became greatly augmented as the process of evaporation went on. A small quantity diluted with water gave the following reactions:—With alkalies, the colour was deepened; with ferric chloride, a greenish-black colour; with Mayer's test, a yellowish colour; with subacetate of lead, gelatinous precipitate; with solution of gelatin, gelatinous precipitate. These reactions showed the presence of tannin. After concentration to a small bulk, and setting aside for a few days, crystals of what appeared to be a magnesium compound were deposited. The filtrate from these crystals was now treated with twice its bulk of alcohol, filtered, and then found to be free from tartaric, citric and malic acids. After having been treated with ammonia and solution of alum, no precipitate was abtained with salts of iron, calcium, mercury and copper, but lead acetate occasioned a white precipitate.

The sulphide of lead remaining after the decomposition of the lead precipitate by H_2S was thoroughly washed and treated with boiling alcohol, filtered and allowed to evaporate spontaneously, then spread on glass to scale. The product was of a beautiful red colour, perfectly transparent, taste slightly bitter, wholly soluble in alcohol and partially so in water, but insoluble in ether and chloroform. Ammonia dissolved it, deepening the colour, and on the addition of an acid the colour was discharged. A small quantity dissolved in water with the aid of alcohol, and agitated, produced copious foaming, and was precipitated by acetate of lead. On digesting with water, a portion was dissolved, and on being evaporated was left behind as a red transparent mass; the portion insoluble in water dissolved in alcohol, and after evaporation left a brown transparent mass, both portions foaming on being agitated with water.

The filtrate, after precipitation by acetate of lead, left, on evaporation, an amorphous dark red-brown mass, with a tint of green, and perfectly transparent; the taste is very bitter and slightly acrid. It is freely soluble in alcohol and water, insoluble in ether and chloroform. With strong sulphuric acid it produces an orange-red coloration changing to brown.

The presence of starch, sugar, albumen, resin and pectic compounds was also incidentally noticed.

* From the *American Journal of Pharmacy*, June, 1879.

CHEMICAL NATURE OF PEPTONE.*

BY R. HERTH.

Peptone was prepared by digesting the finely powdered white of egg from 50 to 60 boiled eggs for 24 to 30 hours with a 1 per cent. solution of phosphoric acid, then treating with hot water, and digesting with 4 litres of a 0·65 per cent. solution of phosphoric acid and 40 c.c. of a clear pepsin solution which had been purified by dialysis, and was free from calcium and chlorine. When the liquid had become clear (after 5 or 6 hours) it was heated on a sand-bath, and freshly precipitated lead carbonate was added to neutral reaction. The small quantity of lead present in the filtrate was removed by means of sulphuretted hydrogen; the liquid was again filtered, concentrated on the water-bath, precipitated, and digested with concentrated alcohol, again dissolved, and the liquid reprecipitated. This process was repeated three times. The precipitated lead phosphate was quite white, showing the absence of sulphide. A concentrated solution of the peptone thus prepared gave a slight turbidity with potassium ferrocyanide and acetic acid. Various methods of purification were employed, but the reaction with ferrocyanide was invariably obtained. Whether this reaction is due to a trace of unchanged albumin in the peptone, is regarded by the author as a yet unsettled point.

In the original paper a number of analyses of the peptone are given, both of the substance prepared as described above and of the various precipitates obtained by fractionally precipitating with alcohol and with lead acetate and ammonia. These analyses show that peptone is not a mixture, but a distinct chemical compound. The percentage composition of peptone appears to be identical with that of albumin obtained from egg white. The author regards albumin as a polymeride of peptone, and the change brought about by the action of pepsin solution in albumin as analogous to the action of heat in effecting the change of paraldehyde into vapour of aldehyde.

A solution of peptone is not precipitated by many of the salts of heavy metals, by acids, or by boiling. Alcohol, mercuric chloride, and lead acetate, followed by ammonia, cause precipitates in solutions of peptone. The statement of Adamkiewicz (*Die Natur und Nährwerth des Peptons*, Berlin, 1877) that those reagents which precipitate egg albumin also precipitate peptone is regarded by the author as incorrect. Peptone forms compounds with metals analogous to those formed by albumin, but the compounds of peptone are generally soluble, while those of albumin are insoluble.

The author claims for his process of preparing peptone that it ensures a complete or almost complete conversion of the albumin into peptone, that it entirely removes syntonin, and that the absence of salts of the alkaline earths is also ensured. These salts are very difficult to remove from solutions of peptone.

The amount of ash in the peptone prepared by the author's process is not more than 1 per cent.

* From the *Journal of the Chemical Society*, August, 1879 (*Wien. Akad. Ber.* [ii], 76, 986—890).

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 13, 1879.

PROCEEDINGS UNDER THE PHARMACY ACT.

Although the present month is to a great extent devoted to holiday making by pharmacists, as well as others who have opportunity to do so, it has, as yet, not been altogether wanting in incidents of importance and interest to those engaged in this business. As will be seen from our report of legal proceedings this week, a step has been taken towards repressing the unlawful trade in scheduled poisons without the labels required by the Pharmacy Act, stating the name and address of the seller, and bearing the word "poison." The prosecution was instituted by direction of the Council of the Pharmaceutical Society in reference to the illegal sale of laudanum, a practice that has frequently been cause of complaint among chemists and druggists, besides being one that is extremely prejudicial to the wellbeing of the public. In some parts of the eastern counties, as many of our readers are aware, the habitual consumption of opium, in the crude state and in the form of laudanum, is carried on to a degree that is almost incredible, and the demand for the drug or preparations of it is so considerable that they are to be obtained at many of the small grocers' or other village shops throughout the district.

Of course the trade thus carried on by persons who are not registered in conformity with the provisions of the Pharmacy Act involves a breach of the 15th section of that Act, and renders the persons selling opium or any of its preparations, such as laudanum, liable to the penalty therein prescribed. It is therefore competent for the authorities of the Pharmaceutical Society, as charged with the execution of the law regulating the practice of pharmacy, to institute proceedings against offenders under this 15th section of the Act; but in the great majority of cases the persons so offending by the sale of laudanum or opium belong to the class of very small shopkeepers in villages, and owing to the difficulty as well as the expense of obtaining information and proceeding against offenders in distant parts of the country it has been found undesirable to have recourse to this mode of procedure as a general plan.

The illegal sale of opium and laudanum in the manner we now refer to is no doubt to some extent an interference with the privileges which are by law accorded to the legally qualified chemist and druggist in virtue of his conforming to those requirements as to education and examination which are held to be necessary for the interests of the public. The sale of these drugs by unqualified persons deprives those who have a right to deal in them of some business they might otherwise have, and of the profits arising from that trade. It may also be the case that the sale of these drugs will eventually lead to the usurpation of other parts of the business properly belonging to the chemist and druggist. In such cases, when clearly made out, it would undoubtedly be proper to enforce the provisions of the 15th section of the Pharmacy Act as a means of protecting the interests of the pharmaceutical body, and with that object to make use of the funds and resources of the Pharmaceutical Society. But this protective application of the Act being only incidentally a result of the provisions for securing the main object of protecting the public interests, and the petty sale of laudanum, etc., being more directly pernicious to the public health than to the trade interests of chemists and druggists, it is more fitting that its prosecution should be conducted under the 17th section of the Pharmacy Act. It is in that section declared to be unlawful to sell poison without a distinct label having the word "poison" and the name and address of the seller. This is a provision made for the safety of the public, to warn people against the dangerous character of certain drugs or preparations, and designed, in case of their criminal misuse or of accident, to furnish a clue to the discovery of the person by whom they have been misapplied. It is entirely a provision for the protection of the public; it is fully sufficient for that purpose, and as the capability of enforcing it is not confined to any particular body or set of individuals any person can be the prosecutor in a case of the kind now referred to.

One of the devices by which it has been sought to make this illegal sale of poison evade the provision of the Pharmacy Act has been to affix a label bearing the name of some registered person, but the present case at Horncastle serves to illustrate the insufficiency of this proceeding to protect the seller against conviction, and it is to be hoped the decision of the magistrates will be a timely warning to others engaged in similar ways.

It is also evident that the plea of selling with a patent medicine stamp will not avoid conviction, and that if some trouble be taken to obtain definite evidence of this mode of selling laudanum or other preparations, as suggested by Mr. Hampson, it may soon be demonstrated that unregistered persons adopting this plan are liable nevertheless as contravening the law.

THE WEIGHTS AND MEASURES ACT.

Among other matters that have attracted attention within the past few weeks is the new Act in reference to weights and measures. Some uneasiness is experienced in regard to the carrying out of the provisions of this Act, but we believe there is really no reason to fear vexatious interference.

We understand that no arrangements have yet been made for affixing a Government mark of verification to the glass measures used by chemists.

An idea seems to prevail that all weights and measures must have the stamp of the particular district in which they are used. This is clearly an error and should be corrected. The Act does not thus needlessly interfere with traders, but it specially provides that a weight or measure stamped by a duly appointed authority shall be deemed legally authorized for the whole kingdom irrespective of districts.

FORMATION OF A PHARMACEUTICAL SOCIETY IN CONSTANTINOPLE.

Although the regeneration of Turkey is not a very hopeful subject, the pharmaceutical portion of the Turkish community appear to be making an effort to raise themselves more nearly to the position occupied by followers of the same calling in other lands. Nor have they taken action a minute too soon, for never was pharmacy at a lower level in Turkey than now. It is true that the cumbrous alembic and pan of former times have disappeared, but they are not replaced by the glass retort or the porcelain capsule; neither is it to the delicate modern balance or graduated burette that the old weighing machine and rude measuring vessels have given way. The laboratory as a rule is absolutely wanting and the shelves are now filled with foreign specialties, drugs which were originally derived from the country now coming back to it in the shape of preparations from Paris, Vienna and other places. This appears to be attributed to a great extent to the law regulating the practice of pharmacy, which sets no limit on the number of pharmacies, and whilst pharmacists are placed by it under severe restrictions as to the sale of poisons and active medicines it is alleged that the sale of such articles by lower classes of traders is winked at.

On the 9th of June last a number of pharmacists met in the room of the Imperial Society of Medicine in Pera and agreed to form a "Société de Pharmacie de Constantinople," which should have for its objects to raise the level of pharmacy in Constantinople and other cities of the Ottoman empire, to assist the authorities in all scientific questions within its competence, and the defence of professional interests. After the election of officers,—C. Bonkowski Effendi being chosen the first President and J. Zanni the General Secretary,—the statutes of the Society were agreed to, and a copy ordered to be sent to Munif Effendi, Minister of Public Instruction, with a request for his approbation and protection of the Society as a work of public utility. The President was also requested to put himself in communication with other societies abroad asking for their advice and assistance.

The second meeting was attended by the Minister of Public Instruction, who assured the Society of the sympathy of the Imperial Government, and, what was quite as important, the Secretary was able to state that one hundred and forty pharmacists had expressed their desire to become foundation members. Several papers were read, and it was decided to make arrangements for the publication of the proceedings; the outcome has been the appearance of the first number of a journal, which is to be supplied free to the members. Steps have also been taken for the foundation of a library and museum, and in order to bring the literature of other countries within the reach of the members generally, committees of gentlemen acquainted with the respective languages have been appointed to prepare reports on the salient features of the journals and other books received, to be read at the weekly meetings.

It is a somewhat "far cry" from London to Constantinople, but we feel justified in assuring the members of the new Society that they have the hearty sympathy of British pharmacists in their efforts to improve the status of their common calling in the East.

THE METRIC SYSTEM.

Those of our readers who are interested in the progress of the metric system will be glad to learn that the subject came under the consideration of the British Medical Association during its recent meeting in Cork, and that, on the motion of Mr. Ernest Hart, a committee was appointed to consider and report whether it would be desirable to adopt the metric system in medicine in Great Britain and Ireland, and whether the British Medical Association should by any means, and if so by what, facilitate its introduction. The Committee consists of Dr. Clifford Allbutt, Dr. Lauder Brunton, Dr. A. Carpenter, Dr. Farquharson, Dr. T. Frazer, Dr. Harvey, Dr. Quain, Dr. Sieveking and Mr. Ernest Hart.

In introducing the subject Mr. Hart said the metric system had made great progress, and now the profession in Great Britain was to some extent isolated, since foreigners were cut off from following the results of work carried out by their English colleagues through not being able to follow the British system of notation, while the British medical man could not follow the system now adopted in foreign countries. Dr. Seguin, in supporting the motion, gave an account of the "brilliant metric campaign" in America, which has resulted in the adoption of the metric system in many public departments and by several medical societies, including the American Medical Association. In the new edition of the 'National Dispensatory,' by Stillé and Maisch, the metric weights are given second; but Professor Maisch states that had he not been hindered he would have given all the weights and measures of this book either preeminently or exclusively in the metric language.

EXEMPTION OF PHARMACEUTICAL CHEMISTS FROM JURY SERVICE.

As the lists of persons liable to serve on juries are now being exhibited at the doors of all places of public worship, we take the opportunity of suggesting to pharmaceutical chemists the advisability of examining them. If their names have been improperly included it is necessary, in order to secure exemption from service, to give proper notice to the parish authorities within the specified time.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

A lecture was delivered by Mr. S. F. Burford, on Thursday evening, August 14, before the above Association on "The History of Chemistry," being the opening lecture of a course on chemistry.

The lecturer said he thought it advisable in commencing a series of classes on chemistry to give the members a general view of the history of chemistry from the earliest times. Quoting from the works of Frankland and Fownes for a good definition of the term chemistry and what was embraced therein, and the various laws which governed it, he went on to say that as far as could be learnt the origin of chemistry was lost in antiquity. Tubal Cain has been considered its founder, as he was conversant with the art of working in metals, but it was more likely that it took its rise among the early Egyptians. Thoth or Æthotis is the first Egyptian of whom mention is made as having been a chemist. Siphoas, surnamed Hermes by the Greeks, 1900 B.C., wrote forty-two books on philosophy, and from him chemistry was entitled the Hermetic philosophy.

The priests of Egypt, though they studied chemistry with considerable success, veiled their discoveries in mystery and hieroglyphics, so that their studies were lost to others. Nevertheless they seemed to have been well acquainted with the arts of making imitations of precious stones, working metals, etc. They were also conversant with the uses of nitrate of silver, which they employed to write on linen, evidence of which is to be found on the linen bandages around mummies. From the Egyptians the Israelites gained some knowledge of chemistry, and Moses must have been acquainted with it to enable him to dissolve the Golden Calf, which Stahl states was rendered soluble in water by means of liver of sulphur.

During several centuries the study seemed to have been neglected till it appeared among the Arabians. In the ninth century Gebber, of Thus, in Persia, wrote three excellent books on chemistry; and so this study passed through the various stages of superstition and alchemy when men spent best part of their lives in the vain effort to transform the baser metals into gold and to discover the elixir of life. Even as late as 1825 the study of alchemy was pursued in England.

The lecturer then reviewed in detail the various studies of Lavoisier, Boyle, Locke, Brandt, Glauber, Roger Bacon, Leibnitz and Newton with their discoveries, going minutely into the studies of Priestley, Faraday, Davy, to our own time, passing to the statements of Lockyer and the announcement that Meyer had decomposed the element chlorine.

The lecturer concluded by remarking that it was impossible to glance around without seeing the benefits which every day accrue from the study of chemistry in the arts, manufactures, and in medicine, contributing to the health and happiness of the human race. The human mind cannot depict in its entirety the magnificent future of chemistry, but overwhelmed with the vastness which everywhere surrounds them, the noblest, purest minds return from contact with this awful infinity, and like the Angel in Jean Paul Richter's dream can only find relief in tears.

At the conclusion of the lecture, which was listened to with marked interest, a vote of thanks to the lecturer was proposed by Mr. J. J. Edwards, seconded by Mr. Brampton and carried.

MEETING OF CHEMISTS AND DRUGGISTS AT LIVERPOOL.

A general meeting of the chemists and druggists of Liverpool was held on September 1, at the Royal Institution, to resist the tendency to reduction of prices of proprietary articles. The chair was taken by Mr. A. Redford, President of the Registered Chemists' Association. The good attendance showed the interest generally taken in the subject of the meeting. Communications were received from Messrs. C. Jones, Birkenhead; Greenall, Flint; Stanton, Rock Ferry; Barton and Williams, approving the object of the meeting.

The Chairman, Messrs. Shaw, Symes, Edisbury, Marson, M. Hughes, Turner, T. F. Abraham, Peet, Woodcock, Warhurst, Wright, Hocken, Paddock, Wharrie, Mackinlay, Fletcher, Lloyd of Garston, and Messrs. Ball, Fore and Cooke, of Birkenhead, spoke with only one exception strongly against departing from makers' advertised prices. It would inevitably lead to reduction in other departments of the business, and the opinion was strongly expressed that its effects would be disastrous, and that no sufficient reason at present existed to justify its adoption. The meeting adopted resolutions affirming the determination of the trade generally to maintain the uniformity attainable by adhering to the makers' advertised retail prices.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 197).

The next paper read was on—

THE POLARIMETER AND ITS USE IN PHARMACY.

BY CHARLES SYMES, PH.D.

For the development and perfecting of the science and practice of pharmacy, various instruments and forms of apparatus have from time to time been introduced; it is not, however, to a new instrument that I am desirous of directing your attention, but to one which, although it came into existence some sixty years ago, has not in this country and in recent times received the amount of attention which it appears to me to merit, nor has it been applied to many purposes for which it seems calculated to be of use.

In its variously modified forms it is known as the polariscope, saccharimeter, polaristrobometer and polarimeter, men of science and manufacturers having progressively introduced such alterations as appeared desirable for the better accomplishment of the object aimed at, viz., polarizing a ray of light and accurately measuring the amount of rotation produced in that ray when it is passed through an optically active liquid or liquid possessing rotatory power. My chief aim in bringing this subject before the members of the Conference is to offer for their consideration some of my experience and to render familiar, as far as I am capable of so doing, this instrument which has hitherto been dealt with chiefly in works of a purely scientific character, and which has been regarded by the working pharmacist as outside his province and useful only in the prosecution of abstract science. That too little is known of its general application has long been my opinion, but this was brought more forcibly to my mind in June of last year, when (in company with Mr. Greenish) I paid a short visit to M. Petit, of Paris, and found him using the instrument of Laurent practically in his business for determining the purity of certain alkaloids, etc., and was assured by him that the results obtained were as trustworthy as those of the most accurate chemical analysis. To accomplish the object already mentioned and render the subject thoroughly clear to those who have not previously given any attention to it, I may be allowed to say a few words on polarized light.

A ray of common light, as you will be aware, is assumed to consist of vibrations in the ethereal medium or luminiferous ether occurring in two directions at right angles to each other, and by interference the primary planes are constantly shifting. If, however, these two vibrations are split up by the absorption, reflection or dispersion of one, or by refraction of both, the remaining portion, or one of the portions separated, constitutes a ray of polarized light and as the phenomenon of interference ceases it vibrates in one plane only. If now this is made to traverse certain media, the plane no longer remains in this direction, but is deviated either to the right or left, and is caused to rotate or assume a spiral form, and it is as already stated for the measurement of the amount of rotation caused by different fluids when so traversed that the polarimeter has been constructed.

The property possessed by quartz of circularly polarizing a ray of light was known to Sebeck and Arago, but it is to Biot in 1818, that we owe the discovery of the property possessed by many fluids of rotating a ray of plane polarized light. He states that this occurred to him accidentally whilst examining crystallized laminæ, placed in highly refractive media, such as oil of turpentine. He thoroughly investigated the phenomenon, and laid the foundation of a very important study, his early results being obtained by means of an instrument devised by himself, not unlike the polariscope attached to the microscope, except that the polarization was obtained by reflection from a blackened mirror and that the analyser was placed in the centre of a graduated disc. When the analysing prism was so placed as to obscure the polarized ray, on interposing a tube containing an active fluid the light was again found to pass until the analyser had been rotated through a certain number of degrees; that number being taken as the rotatory power of the fluid; but it was found difficult to determine the exact point of maximum darkness, and somewhat wide and inaccurate results were obtained. M. Soleil, an instrument maker of Paris, next constructed with considerable ingenuity and skill an improved form, by the use of which much greater accuracy could be obtained. In it the light first passes through a doubly refracting prism as analyser, then through a plate of quartz 3·75 mm. thick (subsequently replaced by a double plate); then through the fluid under examination, another plate of quartz, the compensator consisting of two wedges of quartz, and finally through the analyser. To this there was added what Soleil called a *produce of sensible tints*, consisting of a prism, Galileo telescope and quartz plate. On one occasion I spent a profitable hour or two in thoroughly examining this instrument, taking it to pieces and tracing the tortuous course of a ray of light through it; the study was interesting as showing what optical skill can accomplish and what complicated means had here been employed to surmount difficulties, which have since been overcome in a more simple manner. The special features in this instrument are first, that the ray of polarized light emerging in a vertical plane from the prism meets the double plate of quartz, one half of which rotates to the right, the other half to the left, the rotation being sufficiently great (90°) to decompose the ray and to produce a rose-violet tint uniformly over the whole field. This is known as the sensitive or transition tint, also the tint of passage. Secondly, the analyser is fixed with its axis corresponding to that of the polarizer, the amount of rotation produced being measured by compensation, effected by a plate of quartz, divided into two wedges and fitted with rack and pinion motion, by which they are moved over each other so as to increase or diminish the thickness; they are also attached to a vernier and scale. When the compensator is at zero, the whole of the disc is rose-violet, but the introduction of an active fluid causes one half to become red; the compensator is then moved through a sufficient number of degrees to restore uniformity and the amount of rotation is thus ascertained. Actual degrees are not marked in the scale, but the rotation produced by a plate of quartz 1 mm. thick, equal to that given by 200 mm. of solution of sucrose (16·19 grams in 100 c.c. of water), being marked on the scale and divided into 100 equal parts.

The instrument was specially constructed with a view to its use for sugar solutions and is best known as Soleil's saccharimeter, of which there are several modifications, such as the Soleil-Ventzke, Soleil-Scheibler, etc.

Accurate as were the results obtained by this means, there were some difficulties, such as the interference of coloured solutions with the sensitive tint, the shortness of the scale, etc., which have caused it to be superseded by more simple forms in which, as in Biot's instrument, the analyser is made to rotate, and these forms have been adopted by the two opticians Duboscq and Laurent, who may be regarded as the successors of Soleil.

In 1860, Professor Jellett, of Dublin, described to the British Association at Oxford, a new analysing prism, which he had invented, by which greater accuracy could be obtained than by any previous arrangement. The report is as follows:—"Professor Jellett described to the section a new analysing prism, by which the plane of polarization of polarized light may be determined with great precision. This instrument consists of a large prism of calc-spar, which is reduced to the form of a right prism by grinding off its ends, and sliced lengthwise by a plane, nearly, but not quite perpendicular to its principal plane. The parts into which the prism is thus divided are joined in reversed positions and a diaphragm with a circular opening is placed at each end. The light which passes through both diaphragms produces a circular field, divided by a diametrical slit into two parts, in which the planes of polarization are slightly inclined to each other. If then light, which has been previously polarized, be transmitted, it will be extinguished in the two parts of the field of view in positions which lie close together, and the light will become uniform in a position midway between these. This position determines the plane in which the incident light was polarized with a precision much greater than has been otherwise attained. Professor Jellett stated that the different observations did not differ from one another by an angle greater than a minute, and that the instrument was equally applicable to the case of homogeneous light."

The first practical application of this invention was in the construction of a polarimeter for the Professor by Bryson in that year, and the manufacture is continued by the same optician at the present time; it is the most simple form with which I am acquainted, efficient and inexpensive; it is the instrument now before you, the one with which my observations have been made, and which I have compared with those of Wild, Laurent and Duboscq, with very satisfactory results. The instrument of the last named maker still retains the double quartz plate of Soleil, but dispenses with the compensator, having been fitted with a Jellett's prism as analyser on a suggestion made by him in 1869.

That of Laurent has as its special feature the polarized ray passed through a diaphragm with circular opening, one half of which is covered by a plate of quartz, the division of the field by this means giving great precision to the readings; the analyser is an ordinary Nicol's prism. By this means the optical work is simplified as compared with the old form and the perfection of working is enhanced. Wild's polaristrobometer, manufactured by Hermann and Pfister, of Berne, is a special form of the instrument. It is somewhat elaborate in construction; the readings are taken at the disappearance from the centre of the field of certain lines or bands which cross it and which are produced by two plates of calx spar crossed at right angles to their principal faces. Those who work with this instrument speak of it as giving very satisfactory results. In 1872, Professor Jellett, in a paper read before the Royal Irish Academy, described a "new optical saccharometer," an ingenious arrangement by which the polarized ray is made to traverse a fluid, the rotatory power of which is previously determined and which is opposite in character to that of the fluid to be examined. In general terms it might be described as an instrument by means of which the relative rotatory power of any transparent fluid to that of a standard fluid may be accurately determined. Although delicate in its results it is somewhat troublesome in working and does not appear to have come into general use.

Originally, ordinary daylight, or that from an Argand lamp was used; but on discarding the more complicated instrument of Soleil, with its compensator, whereby the decomposition of the light due to the unequal refrangibility of the different rays was overcome, monochromatic light was adopted. Different operators, however, used different coloured rays with, as a matter of course, different results; hence it became necessary when stating the rotatory power of a body to indicate by what ray the reading was taken, and this still obtains to a large extent; thus, in the *Agenda du Chemiste* last year there are four tables giving the rotatory power of 76 bodies — 12 by the "*teinte du passago*," 7 by the red ray, 10 by the yellow, and 20 without any indication as to the ray, and the remainder indicated by letters corresponding to certain Fraunhofer lines, as used by the authorities from whom the results are quoted. It is true we have a factor, ·767, by which to multiply the values obtained by the yellow ray to convert them into those which could be obtained by the red, but it has been shown that this is not constant for all bodies. Further, one object of a table is to show at a glance without calculation the relative rotatory power of different bodies; now this clearly cannot be the case with such tables as those referred to. This chaotic state of things is to some extent in process of rectification, and modern instruments are all constructed with a special view to their use with the yellow flame, corresponding to the line D of the spectrum, or in other words, with a Bunsen flame containing a salt of sodium. This gives a grey field quite as sensitive as the transition tint, and where observations are continued for any length of time it is far less fatiguing to the eye of the observer.

Certain natural crystals possess high rotatory power. Thus a plate of quartz 3·75 mm. in thickness gives a rotation of 90°, whilst a column of English oil of turpentine, 100 mm. in length, gives only 14°·30. Some few salts, such as bromate and chlorate of sodium, acetourate of sodium, and hyposulphite of lead possess double rotatory power; but most inorganic salts, and some liquids, such as water, alcohol, ether and chloroform, are inactive. The activity in crystals and liquids depends on different causes, the former belongs to the domain of physics, the latter to that of chemistry, and it is this, viz., the molecular rotatory power, which we are more especially considering. The rotation produced by any given liquid (all else being equal) depends on the length of the column; it will be evident therefore that to have uniformly correct results the greatest accuracy must be observed in this respect, and that either the same length of tube must always be used or the readings must be brought to the same standard by calculation. The usual working length is 200 mm., but most operators supply themselves with tubes of 100, 50, and even 25 mm., as some of the fluids to be operated on possess so much colour that light will not pass through a larger column satisfactorily. It is desirable to use the larger tube whenever available, inasmuch as the error will be thereby diminished; but whatever be the dimensions of the tube used the results should be stated in terms corresponding to a column of fluid 100 mm. in length, this now being generally accepted, and $[\alpha]$ is used to indicate the molecularly rotatory power of such a column. Hesse, however (*Chem. Centr.*, 1875, 369; *Journ. Chem. Soc.*, 1876, 667), in referring to the results obtained by De Montgolfier, Weiss and Biot, points out the difference obtained by the ray D, the red and transition tints, and concludes that this symbol is equivocal, and suggests that it is better to use α_D for the rotatory power obtained by the yellow ray, as has indeed been the practice for some time in Germany.

When the transition tint was almost exclusively adopted the sign $[\alpha]$ was used to indicate the rotatory power read by it, otherwise it would have been more simple to have adopted this sign where the sodium ray was used, and to have used the qualifying letter only when other rays were employed, which is now rarely done.

Temperature influences the rotatory power to some extent, 15·5° C. (60° F.) being that at which readings are usually taken, and it has been found that the rotation decreases as the temperature increases, and *vice versâ*; but Landolt has shown that the diminution is not always uniform at all temperatures for the same body, or equal for all bodies. He gives as examples—

Oil of Turpentine $[\alpha]_D$ 36°·61: diminished rotatory power for an increase of 1° C. = ·004437.

Oil of Orange $[\alpha]_D$ 115°·31: diminished rotatory power for an increase of 1° C. = ·12371.

This diminution being represented graphically, not by a straight but by a slightly curved line. This, I think, would depend entirely on the expansion and rate of expansion of the liquid, inasmuch as an increase of temperature would necessarily increase the volume and reduce the number of molecules in a column of a given length; the slight expansion of the tube would tend in some degree to compensate for this, and in most fluids the difference for two or three degrees of temperature is so slight that it might be disregarded as being less than the probable error of observation.

Magnetism also influences rotation; indeed some bodies which are void of this property under ordinary circumstances will under its influence exercise it in a marked degree. The discovery of this phenomenon we owe to Faraday (*Phil. Trans.*, 1846, p. 1), and it has been further investigated by De La Rive (*Archives des Sciences, etc.*, vol. xxxii., p. 193; *Annales de Chimie*, 4th series, vol. xv., p. 57; *Phil. Mag.*, 4th series, vol. xl., p. 393); this is, however, a study in itself, and those who wish to prosecute it will find abundant matter of interest in the papers quoted; suffice it to say that under the influence of magnetism the same law holds good as regards decreased rotation for increased temperature.

The advantage of having certain commonly occurring liquids, such as those mentioned, void of activity, is obvious, as it enables us to make concentrated solutions of most solid substances, such as sugar, camphor, the alkaloids, etc., and to select a menstruum in which the body is most soluble, since *concentrated* solutions are most desirable, inasmuch as the calculation is made for the solid substance, and any error in observation will be increased in proportion to the dilution. Not only so, but it has been shown by Landolt (*Deut. Chem. Ges. Ber.* [9], 901—904) that to obtain accurate results, *saturated* solutions are absolutely necessary, for as in the case of temperature so in dilution, the effect cannot be represented graphically by a straight line. In concentrated solutions the divergence is only a few tenths of a degree, and the rotatory power of the body remains the same whatever be the (inactive) solvent employed, but observations taken with dilute solutions are utterly worthless. He further finds (Liebig's 'Analen,' clxxxix., 241—337) that some substances have an increased proportional rotation by dilution, whilst others are diminished; turpentine and ethyl tartrate always show increase, nicotine and camphor both show diminution, and these results are constant with all solvents.

Organic liquids and solutions are sometimes so much coloured that light will not pass through even 25 mm. sufficiently for our purpose. In such cases filtration through charcoal is usually resorted to; this under ordinary circumstances removes enough of the colour to admit of the observation being made, or indeed sometimes entirely decolorizes. But this procedure introduces a possible source of error, inasmuch as it has been shown by Dr. Stammer (*American Chemist, from the Sugar Cane*, *Pharm. Journ.* [3], vol. i., p. 926), that in the case of saccharine solutions the char absorbs sugar from the first portion of the liquid, which passes through and so reduces the strength and rotatory power. This would doubtless occur equally with solutions containing alkaloidal bodies and possibly some others; but as the char becomes saturated before it loses its decolorizing property, if a sufficient quantity be passed through, and the latter portion be taken for examination, the chance of error on this point is obviated.

The great commercial industry in which the polarimeter has been most useful is the sugar trade, and as the expenditure of large sums of money is not unfrequently dependent on the results so obtained, it is not surprising that the greatest perfection in construction and working has been sought for its special requirements.* There is, however, good reason to believe that of the other spheres of usefulness as yet unknown (in addition to those which are known) some are closely allied, whilst others belong to the domain of pharmacy. By its means (as already stated) the purity of the alkaloids can be readily determined; castor oil, croton oil, and doubtless some others of this class possess their specific rotatory powers, whilst the majority of essential oils do so in a high degree. Landolt, who has worked largely with bodies of a definite and constant chemical constitution, does not appear to have as much faith in its application to essential oils on account of some amount of variation dependent on soil, climate, etc., and in his recently published memoir he devotes but little space and consideration to them.

Oil of turpentine and other volatile oils were, however, amongst the first liquids examined in this way, and connected with which an interesting incident occurred. Biot, in announcing his discovery in 1818, called special attention to the fact that whilst in quartz or rock crystal there existed two opposite directions of rotation, in oil of turpentine the rotation was in one direction only, viz., from the right to the left of the observer, and this was the same in direction, although slightly different in degree for all samples examined. This statement remained unchallenged until 1843, when Dr. Leeson read a paper before the Chemical Society of London, entitled "Observations on the Circular Polarization of Light by transmission through Fluids." In this paper he stated that every sample of oil of turpentine which he had examined possessed a *right handed* rotation coinciding in direction with that produced by essence of lemon. These conclusions were so thoroughly opposed to those of Biot, that Dr. Pereira undertook to further investigate the subject, and by procuring reliable samples of French oil of turpentine from M. Guibourt, of Paris, he was enabled to demonstrate the fact that both observers were correct; that the French oil rotated to the left, the English or American to the right, and that a mixture of the two in proper proportions possessed no rotatory power whatever. (*Pharm. Journ.* [1], vol. v., p. 67.)

My first experience in the use of the polarimeter was in a direction not altogether pharmaceutical, but one which nevertheless merits attention from pharmacists, viz., in the examination of urine; it is a legitimate branch of our calling and one which medical men are usually willing to delegate to us; it possesses considerable interest and the remuneration is not influenced by unfair competition on the part of uneducated outside traders. It was diabetic urine containing in round numbers only 2 grains sugar per ounce; subsequently other experiments were made with samples containing larger quantities, but my experience led me to the conclusion that this method of determination is more troublesome and not more accurate than the copper test of Fehling or the recent one of Pavy, although its use has been recommended by Méhu and others. Passing on to essential oils, the work became interesting, although occasionally disappointing; for example, essential oil of bitter almonds distilled in this country, that from abroad which is often obtained from a mixture of peach kernels and almonds, and the artificial, or oil of mirbane, are all optically inactive, hence the polarimeter does not furnish us with a means of distinguishing between them. Other results were very satisfactory. Thus, finest imported otto of rose is levogyrate, giving a rotation of $-3{\cdot}52°$. A common quality was found to be dextrogyrate giving $+1{\cdot}50°$. Now the lower qualities of otto are known to contain varying proportions of oil of geranium; but on examining the only sample of this oil which was then at my disposal and which had been received from the south of France, it was found to give $-6{\cdot}73°$. This, then, could not have been the article used in adulterating the sample in question; but subsequently on examining the Turkey oil of geranium a solution of the problem was furnished, since it gave a rotation of $+1{\cdot}72°$ and indicated that it constituted the bulk of the so called common otto of rose. It was found too that otto of rose distilled in this country possessed an opposite rotatory power to that of the finest imported, as indicated in the table appended to this paper. On examining many samples of oil of lavender it was found that some of the commoner were adulterated with turpentine, and there was no difficulty in determining whether this had been done in France or England, on account of the different rotatory powers of the turpentines in the two countries. Whilst prosecuting this study my attention was directed to an excellent paper by Dr. J. H. Gladstone on essential oils (*Jour. Chem. Soc.*, new series, vol. ii., p. 1), in which he gives the specific gravity, rotatory power and refractive indices of a number of essential oils; also to a less important paper by Dr. Julius Maier, of New York, "Detection of the Adulteration of Essential Oils with Oil of Turpentine" (*Chemical News*, vol. xi., p. 301, from the *Amer. Journ. Science*, xxxix.; p. 273). Since the publication of these, some oils have come into use which were then less known than at the present time and some others are now supplied from different localities; it was therefore thought desirable to go over the ground anew and to compile a table giving the rotatory power and specific gravity of a somewhat larger number. Such a table is appended to this paper, the samples of oil operated on being the most reliable I could obtain, except where a second quality is mentioned for comparison, and all that were sufficiently colourless to be viewed through a column of 200 mm. were so examined. Some oils, such as those of hops, cassia, chamomiles, myrtle, etc., could only be read through 100 mm.; whilst some, such as patchouli and cajuput, admitted only sufficient light through 50 mm. All have been calculated to 100 mm. and at a temperature of $15{\cdot}5°$ C. Many results were obtained which being unimportant are not here recorded, but all tended to experience, and as deductions from which might be mentioned that turbidity even though very slight, materially interferes with the accuracy and sharpness of the readings; it is therefore necessary to filter any oils or solutions which are not perfectly bright. Age does not influence to any extent the optical activity of essential oils. Oil of cloves, new and colourless, and samples of a light sherry and dark sherry colour all registered very nearly the same, and samples of English oil of lavender less than a year, four years and five years old differed from each other less than one degree.

The *modus operandi* is exceedingly simple. A correct zero must be first obtained thus—one of the tubes being filled with distilled water, the glass disc is slid on so as to exclude air bubbles, and screwed firmly down. It is then placed in position and the instrument brought opposite to a sodium flame; the operation must be conducted in a dark room, or a black covering cloth be used. The analyser is then set so that the arrowhead on the vernier points to 0 on the scale when the whole of the disc is at a maximum of obscurity, *i.e.*, both halves equally obscure; it is necessary to take several readings of this and note down the results, taking the mean of the observations, and if, as sometimes happens, there is any difficulty in getting an exact zero it is convenient to make a note of the error and add or subtract this from the subsequent readings.

* Those who are interested in the various kinds of sugar will do well to peruse an excellent paper by Dr. O. Hesse, 'The Behaviour of Solutions of some Substances to Polarized Light' (*Pharm. Journ.*, 3rd series, vol. vii., pp. 191, 410 and 473).

If now the tube be replaced by one containing an optically active liquid, it will be found that the field is entirely illuminated, or that one half is so whilst the other is obscure. The analyser is then rotated until equal obscurity is regained and the number of degrees, minutes or decimal parts of a degree, through which it has been moved, as well as the direction, is noted. For each of the following results ten readings were taken; two of these (the highest and the lowest) were struck out, and the sum of the others divided by 8 gave the mean reading, or where the 200 mm. tube was used, division by 16 gave at once the correct mean for 100 mm. It is, of course, necessary from time to time to check the accuracy of the zero, just as a careful dispenser does the correctness of his scales.

With solid substances, a saturated solution being made in water or other suitable inactive liquid the specific rotatory power $[\alpha]$ is found by dividing the amount of observed rotation α, by the length of the column in decimetres l, by the weight of the active body in each unit of liquid w, and by the density of the solution d thus,—

$$[\alpha]=\frac{\alpha}{l\times w\times d}=$$

For the loan of authentic specimens of some of the following oils I have to thank Mr. E. M. Holmes, Curator of the Pharmaceutical Society's Museum.

Mr. Stoddart referred to the extensive use of the polarimeter in the examination of sugar, but said that the value was affected by the difficulty of determining the zero, as in Soleil's polarimeter, different people arriving at different conclusions respecting shades of colour.

Mr. Umney, adverting to the results Dr. Symes had obtained from the various oils, said he should expect to get a different result from the grass oil of India (Andropogon), than from the geranium oil obtained in the south of France.

Professor Attfield observed that the substances Dr. Symes had examined were nearly all mixtures of distinct things. The polariscope was extremely useful in examining a solution of a single substance, such as sugar, but it was not so useful in other cases unless the nature of the constituents of the mixture was known. Nevertheless, such observations as Dr. Symes's must be useful if they were multiplied, especially as a substance such as an essential oil, when properly obtained and pure, might give a fair average amount of rotation to a polarized ray of light. But he would suggest that many observations would be necessary on the same essential oil before they could well trust to the figures given to them. He hoped Dr. Symes would continue the subject. Perhaps, also, Dr. Symes with his intimate knowledge of the modes of construction of polariscopes would eventually be able to put pharmacists in the way of obtaining a cheap variety of the instrument.

The President said Dr. Symes had spoken of the use of the polarimeter in detecting sugar in urine, and it was a nice point for the physician to discover when the last trace of sugar disappeared from a patient's urine. Before the sugar was lost altogether it became a very difficult matter to estimate the exact percentage by the ordinary process, and he found when sugar existed in less than 1 per cent. in urine it was difficult to determine the exact percentage by the ordinary process. If this instrument, therefore, would detect more minutely the exact proportion when it arrived at such a degree of dilution it would be very useful. Although they might arrive at the exact figure as to the rotatory power of different essential oils, would not the figures have to be varied according to the age of each particular sample?

Dr. Symes, replying, said that most persons had no difficulty in getting the coloured zero with the Soliel instrument, but the maker finding that it did not suit the eyes of all observers introduced what he called *a producer of sensible tints*, whereby the flax flower tint could be changed for some other; it consisted of a Galileo telescope and quartz plate. He could scarcely understand any difference existing between the estimation of sugar by chemical means and by the polarimeter. Reading sugar solutions was almost a profession in itself, and the French who are sellers of sugar usually read higher than the English who are buyers. He regarded both Fehling's and Pavy's tests for diabetic urine as equally accurate with the results obtainable by the polarimeter; they were less troublesome, and the work could be with more confidence delegated to another person. He hoped to go on with the study and that others would take it up, so that ultimately the subject migh tassume a more definite and important position pharmaceutically. He then spoke of the desirability of obtaining cheaper instruments, and agreed with Professor Attfield that they ought to get them at half their present price.

A vote of thanks was then passed to Dr. Symes for his paper.

The next paper read was on—

The Application of Chloroform in the Testing of Drugs.

BY L. SIEBOLD.

In the 'Year-Book of Pharmacy' for 1877 there occurs an abstract of an article by Dr. C. Himly on the Detection of Mineral Adulterants in Flour by means of Chloroform. Having frequently tried this test and finding it extremely useful both as a qualitative and as a quantitative process, it appeared to me desirable to ascertain to what extent it might be advantageously employed in the testing of powdered vegetable drugs. As many of the latter are lighter than chloroform, and the usual mineral adulterants sink in that liquid, it was but reasonable to infer that this mode of separation might prove of value to the pharmacist.

I will not trouble the meeting with the details of my experiments, but confine myself to a brief summary of the results. In each experiment a small quantity of the dry powder was well shaken with about half a test-tubeful of chloroform, and the mixture allowed to stand at rest for twelve hours. The following drugs were found to rise so completely to the surface of the chloroform, that the observation and estimation of any mineral adulterant became a very simple and easy task:—Acacia, tragacanth, starches, myrrh, Barbadoes aloes, jalap, saffron, cinchonas, nux vomica, mustard, white pepper, capsicum and guarana. Known quantities of selenite and of chalk were added to these drugs, and subsequently determined by running the lower stratum of the chloroform with the sediment into a small dish, carefully pouring off the chloroform, drying the sediment at a gentle heat and weighing it. The result in each case was very satisfactory. No such accuracy could be attained by incineration, as in the presence of chalk there was always a loss of carbonic acid, and in that of selenite a loss of water and of oxygen, the sulphate being partly reduced to sulphide. An estimation of these adulterants by the usual analytical processess would, of course, give exact results, but prove much more tedious.

Both for qualitative and for quantitative purposes, the chloroform test therefore answers extremely well with the drugs named. In the case of the following substances no complete rise to the surface of the chloroform took place, but a portion was found to float and another portion to sink, though the absence of mineral adulterants was proved by analysis:—Gamboge, scammony, opium, soccotrine aloes, liquorice root, ginger, colocynth, cousso, ipecacuanha, cinnamon and cardamoms. Of the last two by far the greater portion was found to sink in chloroform. But even in these cases the test is not altogether without value, for a careful inspection of the sediment will show whether or not it is a mixture of various substances, differing in appearance, weight, etc. The mineral adulterant will generally, in such a case, form the lowest stratum of the sediment. A comparison with a genuine sample helps to arrive at a correct conclusion. Moreover, the chemical examination of the sediment gives results which cannot always be obtained by testing the ash. Take the case of cinnamon, for instance, which contains organic calcium salts. These upon incineration leave calcium carbonate, and a qualitative analysis of the ash would therefore fail to show whether this calcium carbonate was solely the result of ignition, or whether a part of it pre-existed in the cinnamon powder as an adulterant; while the addition of hydrochloric acid to the lowest stratum of the chloroform sediment would settle this point at once.

It is, however, in the case of the drug first named that I wish specially to recommend this mode of testing to pharmacists.

The next paper was by the same author on—

Note on the Behaviour of Iodine to Chloroform, and a New Test for the Detection of Alcohol in Chloroform.

Every chemist knows the beautiful purple colour of a solution of iodine in chloroform. It does not seem to be so generally known, however, that this colour varies with the degree of purity of the chloroform employed, and that this variation of colour is due to the presence or absence of alcohol.

A solution of iodine in pure chloroform is deep purple-violet, or if very weak it is purplish-pink, while a solution of the same substance in alcohol is brown, red or yellow, according to its strength. In solutions of iodine in mixtures of chloroform and alcohol, the colour of the alcohol solution so predominates over that of the chloroform solution, that the presence of even a small percentage of alcohol may be readily recognized in a sample of chloroform by comparing the colour of its iodine solution with that of a solution of iodine in perfectly pure chloroform. This mode of testing, however, would necessitate the use of exactly equal proportions of iodine, and of iodine of the same quality and purity, as otherwise the difference in the depth of coloration would materially interfere with the result. I therefore propose the following *modus operandi*, which on the strength of numerous trials I can recommend as a very simple, expeditious and reliable one:—

Introduce a small quantity of iodine into about 10 to 15 c.c. of the chloroform to be tested, shake until the solution has acquired a deep purple or purplish-red colour, not so deep, however, as to render it opaque, and decant the solution from the undissolved iodine. Divide the solution into two equal parts, which place in two separate test tubes of equal diameter, shake one with about four times its volume of water, and keep the other as it is, for comparison. The water will absorb the alcohol, and what settles down is a solution of iodine in pure chloroform, the colour of which will be exactly the same as that of the other portion if the chloroform was pure, but will distinctly differ from it if the sample contained alcohol. With 2 per cent. of alcohol or more, the difference of colour is very striking indeed; with 1 per cent. it is very distinct, and in the presence of only half a per cent. it is still clearly discernible. As little as half a per cent. of alcohol can therefore be readily detected in this manner. By resorting to distillation, a quarter of a per cent. and even less of this impurity may be detected by using the first portion of the distillate for the test. It is a curious fact, that, though chloroform boils at 62° C., and alcohol not under 78° C., the first portion of the distillate is richer in alcohol than the original sample, and that the distillation, if continued, finally leaves pure chloroform quite free from alcohol in the retort. The cause of this must be sought in the different densities of the vapours of alcohol and chloroform, that of the former being 23, while that of chloroform is nearly 60. I think, however, that the test as above described, without the trouble of a distillation, is sufficiently delicate for all practical purposes, and that it will commend itself in that form especially to pharmacists, on account of its simplicity and ease of application.

A third paper, by the same author, was a—

Note on the Specific Gravity of Liquids.

While the great usefulness of the hydrometer for the rapid determination of the specific gravity of all kinds of clear liquids is universally recognized, there appears to be anything but unanimity of opinion as to the value of this instrument as an indicator of the specific gravity of mixtures owing part of their weight to the presence of undissolved or suspended matter. I have therefore made a number of experiments with the object of deciding whether or not the indications of the hydrometer may be depended upon in the case of mixtures containing insoluble powders, oils, resins, etc., uniformly suspended. The results were as follows:—

Mixtures of Precipitated Chalk, Mucilage of Acacia, Syrup and Water—

	Specific gravity by hydrometer.	Specific gravity by balance.
No. 1.	1·106	1·1066
„ 2.	1·070	1·0710

Mixtures of Magnesia, Mucilage and Water—

	Specific gravity by hydrometer.	Specific gravity by balance.
No. 1.	1·059	1·0598
„ 2.	1·036	1·0359

Mixture of Precipitated Chalk and Water only—

Specific gravity by hydrometer.	Specific gravity by balance.
1·037	1·0396

The difference in this case arose from the fact that it wasi mpossible to read off the specific gravity quickly enough, for in the absence of mucilage or any other binding substance, the chalk began to subside immediately after shaking, thus causing a continual decrease in the specific gravity.

Mixtures containing subnitrate of bismuth, heavy spar and other mineral powders, each suspended by mucilage, were tested in the same manner and likewise gave concordant results.

Emulsions of Oil of Almonds, Gum Acacia and Water—

	Specific gravity by hydrometer.	Specific gravity by balance.
No. 1.	1·010	1·0110
„ 2.	1·007	1·0070

Emulsion of Copaiba, Mucilage and Water—

Specific gravity by hydrometer.	Specific gravity by balance.
1·014	1·0144

Various Samples of Milk—

	Specific gravity by hydrometer.	Specific gravity by balance.
No. 1.	1·030	1·0305
„ 2.	1·028	1·0278
„ 3.	1·032	1·0316
„ 4.	1·029	1·0300

Officinal Mucilage of Acacia—

	Specific gravity by hydrometer.	Specific gravity by balance.
	1·165	1·1670

The last determination was made in order to see whether the great viscosity of the liquid would have any notable effect on the indications of the hydrometer.

All the determinations were made at 62° F. The set of hydrometers used consisted of instruments specially made for very short ranges of specific gravities, the correctness of which I had frequently checked in previous determinations.

The foregoing experiments prove that carefully made hydrometers afford reliable indications of the specific gravities of liquids, no matter whether their gravity is due to dissolved or suspended substances.

The PRESIDENT having invited discussion on these three papers—

Mr. MARTINDALE asked a question as to the detection of chloroform in dichloride of ethidene.

Mr. C. UMNEY much admired as a chemist the simple test for detecting the presence of minute quantities of alcohol in chloroform. But the Pharmacopœia recognized the presence of 1 per cent. of alcohol in chloroform of trade, and they as pharmacists must not encourage the idea that chloroform was not medicinally pure because the specific gravity was 1·490. The accuracy of this statement could be checked by calculating the specific gravity of a mixture of 100 parts of chloroform at 1·500 and 1 part of alcohol at ·795.

Mr. E. C. C. STANFORD said in using chloroform he did not know whether the presence of alcohol did not very often give a disagreeable colour to the iodine solution. He had now discarded it for some years, and used nothing but bisulphide of carbon. That was an exceedingly good method of testing certain substances, such as kelp, where the actual amount of iodine was not more than 0·5 per cent.

Professor ATTFIELD asked Mr. Siebold whether there really was any adulteration in powdered drugs; his own experience was that there was little or none.

Mr. REYNOLDS referred to the use of chloroform for testing drugs, and mentioned that he had by this means easily ascertained that the active constituent of an anthelmintic lozenge was santonin.

Mr. SIEBOLD said he had observed adulterations of powdered drugs during his experiments, but not many, and in order to see to what extent the test might prove available, he had himself adulterated most of the drugs experimented with. With regard to the solubility of alkaloids and some other constituents of drugs, alluded to by one of the speakers, he said that in every case in which chloroform dissolved anything from the substance under examination, it was necessary of course to wash the sediment with chloroform before drying and weighing it. He thought this mode of separating mineral from light organic substances might also prove valuable in certain toxicological analyses. Respecting the purity of commercial chloroform, he stated that among the samples he had examined those manufactured in this country were, on the whole, very pure.

A vote of thanks to Mr. Siebold for his papers was passed.

The last paper read at this sitting was on—

THE EXTRACTION OF PILOCARPINE.

BY A. W. GERRARD, F.C.S.,

Demonstrator of Materia Medica at University College.

Having during the past year worked some large quantities of the leaves of jaborandi (*Pelocarpus pennatifolius*) for the alkaloid pilocarpine, I on three occasions varied my process with the view of obtaining the most economical results.

Exhaustion of the leaves with water instead of alcohol was tried and abandoned, as the volume of water required for a thorough exhaustion was so large as to necessitate the employment of much time and unnecessary heat in its evaporation; and moreover the large yield of extractive, most of which was albumenoid, required considerable and prolonged washing with alcohol to free it entirely from commingled alkaloids.

A process similar to that adopted by Wright for exhausting aconite root, viz., treating the root with alcohol acidified with tartaric acid, was tried with the jaborandi leaves; the presence of the acid did not in any way influence the process or result, neither to its advantage nor dis advantage, simple alcohol being equally efficient as a solvent.

In my first process for the preparation of pilocarpine (*vide Pharmaceutical Journal*), I found on treating the concentrated washings of the alcoholic extract with ammonia instead of potash, that much brownish black colouring matter subsided, freeing the mother liquor from a very objectionable accompaniment; this observation several times repeated led me to believe that ammoniated alcohol might be with advantage substituted for ordinary alcohol as the solvent of the pilocarpine. Another reason why I considered the use of ammonia might prove advantageous was that most salts of pilocarpine are only sparingly soluble in cold alcohol, but the hydrate is freely soluble, and in the percolation of the ammoniated spirit through the drug, the ammonia would liberate the alkaloid, which would be freely taken up by the alcohol. Tested on a small scale this process was successful, and the experiment was repeated upon 100 lbs. of jaborandi leaves as follows: 84 per cent. alcohol was treated with 1 per cent. of strong solution of ammonia, and the leaves percolated to exhaustion with this solvent, the alkaline alcoholic percolate was made neutral with tartaric acid, the alcohol distilled, and the residue treated with excess of ammonia and alcohol, again distilled and the pilocarpine dissolved out from the residue with chloroform converted into nitrate and crystallized to purity from boiling absolute alcohol.

The yield of alkaloid by the above process was greater than I had previously attained by other methods of working upon the same sample of leaf; the yield being ·7 per cent., and the ammonia (as I inferred it would) effectually liberated the pilocarpine, so that a comparatively small volume of alcohol was required for its solution, also leaving behind the brownish black colouring matter. The contact of free ammonia with the alkaloid during percolation might be objected to as likely to produce decomposition. This does not appear to be the case judging by the yield.

To purify the nitrate of pilocarpine, which is by far the best and most convenient salt for medicinal use, it is usual to boil the crude brown coloured salt of the first crystallization with absolute alcohol and set aside for a few hours, when the separated crystals may be thrown on a filter and washed with cold alcohol until colourless; the mixed washings will by further treatment yield a further supply of crystals, and the process may be carried on until at last will be obtained a viscous dark brown mass still containing alkaloid but no longer crystallizing. This residue is best worked up by treating with a large volume of water, and allowing to stand for twenty-four hours, when the larger part of the colour separates in flocks, falling to the bottom of the vessel; the solution now evaporated will again crystallize, and the crystals can be treated as beforementioned.

The percentage of pilocarpine in different samples of jaborandi is very variable, one specimen yielding me only ·03 per cent. whilst from others I have obtained ·3, ·5, ·7 per cent., the leaf giving the lowest percentage possessed the true characters of *Pilocarpus pennatifolius*, except that it was much thinner. I was unable to trace its source, but the differences I have alluded to lead one to think that it may be a second variety or grown in a different locality than that from whence we obtain our regular supplies of jaborandi. At any rate it is important to know that there are inferior qualities of the drug which if used in making tinctures, extracts, etc., would possess but little therapeutic value and this is an additional argument for the use of definite principles in medicine such as is found in the alkaloid pilocarpine, which is one of the most powerful and certain diaphoretics known in materia medica.

Mr. Martindale said that having worked at pilocarpine he thought he might have a prior claim to Mr. Gerrard for having first purified the crude crystals of nitrate of pilocarpine. Mr. Gerrard read a paper and showed specimens of nitrate of pilocarpine at the Bristol meeting. The crystals exhibited were contaminated with uncrystallizable matter. Towards the end of 1875, he (Mr. Martindale) worked some bark and stem of jaborandi, from which he got two drams of crude pilocarpine, and on January 18, 1876, experimenting with this, he dissolved it in one ounce of absolute alcohol, and added fifteen minims of nitric acid previously diluted with fifteen minims of distilled water. The small crystals separated readily and were purified by pouring off the spirit, by dissolving in boiling absolute alcohol, from which they separated free from colour. A quarter of a grain administered by the mouth produced the usual perspiration and salivation in forty minutes. The action was over in three hours. A physiologist who had worked a great deal at the subject had informed him lately that pilocarpine did not produce all the actions of jaborandi. It possessed the sialogogue and diaphoretic properties, but did not produce the same action on the heart as the extract of jaborandi. This was probably the effect of a second alkaloid. He should have liked to have asked Mr. Gerrard if he had sought for this in the uncrystallized residues in making this nitrate of pilocarpine.

Mr. Williams said Mr. Gerrard had suggested a new and very important process and they ought to thank him very much for his discovery by which they could get a better yield at a smaller expense of spirit. Not only was credit due to him for this discovery, but for the liberality with which he had made it known.

A vote of thanks was passed to Mr. Gerrard for his paper, and the first day's sitting of the Conference terminated.

The proceedings on Wednesday morning were commenced by the reading of a paper entitled—

Notes on Petroleum Spirit or "Benzoline."

BY ALFRED H. ALLEN.

Although it is well known to professional chemists that petroleum spirit is composed of hydrocarbons quite distinct from those constituting coal-tar naphtha, among the general public, and to a certain extent among people possessed of some knowledge of chemistry, great confusion has arisen as to the nature of the liquids known in commerce as "benzine," "benzene," "benzol," and "benzoline." Of these, the hydrocarbon *benzol* or *benzene*, C_6H_6, is the chief and characteristic constituent of coal-tar naphtha, while it is present in very insignificant amount in petroleum spirit or mineral naphtha. The terms *benzine* and *benzoline* have no scientific application, and are merely commercial names for petroleum spirit. It is owing, in a great measure, to the similarity of these names to those of the chief constituent of coal-tar naphtha that confusion has occurred, but it has been made far worse by the accidental or intentional substitution of one liquid for the other, until it is difficult to obtain the coal-tar product retail, even when it is asked for by its proper name. This would be of but little consequence if the two liquids were of exactly similar nature, but in certain cases they present decided differences of behaviour, although in general characters there are very close resemblances.

The following tabular statement of the characteristic differences between petroleum spirit and coal-tar naphtha has been compiled from various sources and includes a few original tests. All the characters given have been carefully verified by actual experiment on representative samples of commercial petroleum spirit and coal-tar benzol.

Petroleum Spirit, "benzoline," or "benzine."	*Coal-Tar Naphtha, or "benzol."*
1. Consists of *heptane*, C_7H_{16}, and its homologues.	1. Consists of *benzene*, C_6H_6, and its homologues.
2. Heptane contains 84·0 per cent. of carbon.	2. Benzene contains 92·3 per cent. of carbon.
3. Burns with a somewhat smoky flame.	3. Burns with a very smoky flame.
4. Commences to boil at 54° to 60° C.	4. Commences to boil at about 80° C.
5. Specific gravity about ·69 to ·72.	5. Specific gravity about ·88.
6. Smells of petroleum.	6. Smells of coal-tar.
7. Dissolves iodine, forming a solution of a raspberry red colour.	7. Dissolves iodine, forming a liquid having the colour of a solution of potassium permanganate.
8. Does not sensibly dissolve pitch, and is scarcely coloured by it, even on prolonged contact.	8. Readily dissolves pitch, forming a deep-brown solution.
9. When shaken in the cold with one-third of its volume of fused crystals of absolute carbolic acid, the latter remains undissolved.	9. Miscible with absolute carbolic acid in all proportions.
10. Requires two volumes of absolute alcohol, or four or five volumes of methylated spirit of ·828 specific gravity for complete solution at the ordinary temperature.	10. Miscible with absolute alcohol in all proportions. Forms a homogeneous liquid with an equal measure of methylated spirit of ·828 specific gravity.

Although the foregoing tests are abundantly sufficient for the distinction of petroleum spirit and benzol, when applied to mixtures of the two products they are of but little value even as qualitative indications, and in that case the density is the only one of the above characters which is capable of giving even an approximation to the quantities in which the constituent liquids are mixed.

The action of nitric acid on coal-tar naphtha is well known to result in the formation of nitrobenzene and its homologues, and has been employed by Schorlemmer for detecting traces of benzene, etc., in petroleum. On the other hand, the action of nitric acid on the hydrocarbons of the paraffin series, which constitute practically the whole of petroleum spirit, is almost *nil* in the cold, even if fuming acid be used, and is very limited in extent if hot acid be employed, provided that the very strongest be avoided. I found by experiment that the action of nitric acid on petroleum spirit was, under certain conditions, even more limited that I had supposed, and eventually I found that by employing the acid in a particular manner it was not only possible but easy to effect a tolerably perfect quantitative separation of coal-tar naphtha and petroleum spirit.

The following was the mode of treatment eventually employed, and, by adhering to it, it is possible to detect and approximately estimate the proportion of petroleum spirit existing in a mixture of it with benzol, in ten or fifteen minutes:—

A known measure of the sample (from 4 to 6 c.c.) was treated with four times its measure of yellow nitric acid of 1·45 specific gravity. The mixture was made in a flask, to which a condensing arrangement was attached. Slight heat was applied externally by means of a flame if the spontaneous action was not sufficiently vigorous. After about five minutes the contents of the flask were cooled, and then poured into a narrow graduated tube. Any oily layer was measured and removed with a pipette, and the remaining liquid poured into a large excess of water.

When ordinary petroleum spirit is thus treated the nitric acid becomes coloured more or less brown. Very little heat is evolved, but on applying moderate heat externally the production of red fumes proves the occurrence of a certain amount of action. The effect, however, is not so violent as I had anticipated from a perusal of Schorlemmer's description of the reaction, and, if the experiment be carefully made, the petroleum spirit employed forms a layer on the nitric acid, and on transferring the liquid to a graduated tube is found to occupy the original volume of the sample used. This is true whether petroleum spirit alone be operated on or whether it be previously mixed with various proportions of coal-tar naphtha. If the proportion of the latter be large, the quantity of nitrobenzene formed is larger than can be retained in permanent solution in the nitric acid. This fact causes no inconvenience, for the nitrobenzene forms a separate layer below the petroleum spirit, and in presence of nitric acid is not miscible with it. Nitrobenzene and petroleum spirit are perfectly miscible alone, but on shaking the mixture with strong nitric acid the nitrobenzene is dissolved out. It will be seen therefore that the reaction with nitric acid may be conveniently employed for the determination of petroleum spirit in admixture with benzene. Very fair approximate results are obtainable. If the layer of petroleum spirit be removed with a pipette and shaken with water to remove dissolved nitrous fumes, it is obtained in a suitable condition for further examination.

If, after removing the layer of unacted-on petroleum spirit, the nitric acid solution be poured into water, a very sensible turbidity is usually produced, even with petroleum spirit free from coal-tar products, and on filtering off the precipitate, or allowing it to settle, and decanting the liquid, distinct evidence of the formation of nitrobenzene is obtainable by the aniline test. When the more volatile portion of petroleum spirit is thus treated, the nitric acid is scarcely coloured at all, and hardly a trace of milkiness is produced when the acid is poured into water. The brown colour and turbidity on dilution increase with the boiling point of the sample of naphtha, and are strongest with kerosine oil; but in all cases in which petroleum products are treated with nitric acid, the quantity of precipitate on dilution is very insignificant. Although nitrobenzene is recognizable among the products of the action of nitric acid on petroleum spirit, as was shown long since by Schorlemmer, I do not think the turbidity produced on dilution is due solely to its formation. It is probably rather due to the production of various nitro-substitution products, as it is well known thet the higher numbers of the paraffin series are far more readily acted on by nitric acid than their lower homologues.

I have attempted to determine the proportion of benzene in a mixture with petroleum spirit, by measuring the nitrobenzene produced, but the results have not been satisfactory, partly in consequence of the solubility of nitrobenzene in water and acid liquids. By employing 250 c.c. of water for dilution, allowing the nitrobenzene to settle completely, decanting the greater part of the water, and pouring the "bottoms" into a graduated tube, the nitrobenzene may be readily measured. If an allowance of 1·5 c.c. be made for solubility in the one-quarter litre of acid liquid, the measure of benzene present in the sample taken may be roughly ascertained by multiplying the number of c.c. of nitrobenzene obtained by the factor 0·85. Thus if V be the volume in c.c. of nitrobenzene, then the benzene in the amount of sample taken was $(V+1·5)\times·85$. The method is not capable of giving accurate results, but may be useful in some cases as a check on the determination of petroleum spirit by measurement of the layer insoluble in nitric acid.

With a view of learning something respecting the proportion of heptane present in ordinary petroleum spirit, I made a mixture in equal measures of four samples of commercial "benzoline," such as is used for sponge lamps. This mixed specimen had a density of ·7001 at 15·5° C., and commenced to boil at about 54° C. It was distilled in the manner first described by Warren, in a flask furnished with an inverted condenser, filled with water, maintained at a temperature of 70° C., a second condenser being kept well cooled by a current of cold water. The distillation ceased when the temperature in the flask was 84° C., that is, 14° C. above that of the first condenser. The water in the first condenser was then raised to the boiling point, and the distillation continued till scarcely anything more came over, by which time the contents of the flask were at 114° C. The result of the distillation was as follows—for 100 measures of petroleum spirit taken:—

	Condensed below 70° C.	Condensed between 70° and 100° C.	Condensed above 100° C. (residue).
Percentage by measure . .	16	56	26
Density at 15·5° C., compared with water at same temperature	·667	·707	·742

The loss was about 2 per cent. of the original measure. Another specimen of petroleum spirit gave 22½ measures of distillate with the receiver at 70° C., 42 per cent. between 70° and 100° C., and 32 per cent. of residue; the loss being 3½ per cent. The densities of the three products were almost identical with those previously obtained.

The observed specific gravities of the first and second distillates correspond approximately with the recorded densities of hexane and heptane, and from this and the known boiling points of these liquids it is evident that the portion of petroleum spirit not condensed at 70° C. will consist chiefly of hexane and lower homologues, while the part condensed at 70° C., but distilling at 100° C., will be chiefly heptane and isoheptane. As, in the experiments described, this fraction measured from 42 to 56 per cent. of the entire spirit, it is evident that the proportion of heptane present equals if it does not exceed that of all the other constituents.*

The PRESIDENT said Mr. Allen's paper was an exceedingly useful and able one, and invited discussion of it by those who had knowledge of this particular class of chemicals.

Professor TICHBORNE (Dublin) said the paper they had just heard represented a class of papers exceedingly valuable to the analytical chemist, papers dealing with questions bearing on the reactions and detection of admixtures in articles met with in commerce. He should be glad if Mr. Allen would answer two questions. Mr. Allen mentioned that the solvent action of benzole and American light oils were different as regarded pitch. He presumed Mr. Allen meant coal-tar pitch. There were many pitches. One used in road making in Ireland was a pitch procured as a residue in distilling these American oils, and it was probable that that pitch would behave in the same way as regarded the heptane as the coal-tar pitch would behave as regarded benzole, that was, it would be soluble. He wished to know whether Mr. Allen had tried any experiments as regarded the action of these two solvent bodies upon creosote, and whether there was any difference. They knew already

* The physical properties of the benzoline examined by me are very different from those attributed to the liquid by Wiederhold, who on fractionally distilling benzoline of ·715 sp. gr., which commenced to boil at 60°, obtained—

48·6 per cent. of	·70 sp. gr.,	boiling at	100°.
45·7 ,,	·73 ,,	,,	200°.
5·7 ,,	·80 ,,	,,	above 200°.

that creosote was frequently adulterated with carbolic acid, and he desired to know if they had any means of distinguishing the adulteration by means of these solvents of creosote and carbolic acid.

Dr. SYMES said with regard to the odour of the two bodies in question, although they appeared to be somewhat similar, they smelt quite differently. If they were at all compared the odour was a very satisfactory test of the difference between the two, and if the admixture was agitated with water there always seemed to be quite sufficient evidence, not of the quantity, but of the presence of petroleum spirit. The difference in the solvent properties was very great. In separating chrysarobine from araroba the solvent powers of benzole were considerably greater than those of petroleum spirit, and a much larger yield was obtained. In exercising this great solvent property in this particular instance it perhaps produced a less pure product; but he had tried the solvent powers comparatively on some other bodies, and he thought it was exceedingly desirable to know thoroughly what they were using when they were supposed to use either petroleum spirit or benzole. A quantitative test which would readily determine the proportions in which the two had been mixed would doubtless prove valuable.

Professor ATTFIELD said some varieties of petroleums were so highly cleaned, that he questioned if they would be detected in benzole by their odour.

Mr. J. T. DOBB said Mr. Allen in his statement had referred to pitch. He should like to know if the kind of pitch that was used to ascertain the solubility was Swedish, Stockholm or mineral pitch. The gentleman who had previously addressed them spoke of pitch as a product of petroleum spirit from America, and used for roads only in Ireland. He found that in the distillation of tar the residue was pitch, commonly and commercially called mineral pitch. He had found himself that it was only partially soluble in petroleum spirit; but was perfectly soluble in coal-tar naphtha. He wished to ask Mr. Allen what kind of pitch he used to ascertain the solubility of petroleum spirit and the solubility of coal-tar naphtha.

Mr. ALLEN, in reply, said he was very glad gentlemen had called his attention to the kind of pitch he used. He certainly ought to have explained that he used coal-tar pitch. It seemed probable, as Professor Tichborne had suggested, that pitch from petroleum would dissolve in petroleum spirit better than the other. He might add that anthracene, one of the most characteristic constituents of coal-tar pitch, was much more soluble in benzol than in petroleum spirit. He had not made any experiments on wood pitch or petroleum pitch. He had never seen any petroleum pitch, and he would like to obtain a sample. In a paper, written by himself, that appeared in the 'Year-Book,' he had said, "Absolute carbolic acid dissolves half its volume of petroleum spirit, forming a clear liquid. On addition of a larger portion of petroleum spirit precipitation occurs. With one volume of carbolic acid and three of petroleum spirit, the layers have about the same measures as the original liquid. Each layer, however, contains both liquids, as may be proved by cooling the tube with a freezing mixture (or by wrapping filter paper round it, and dropping ether on the outside) when carbolic acid crystallizes out. Absolute carbolic acid is permanently soluble in about ten measures of petroleum spirit at 15·5° C. (=60° F.)." When carbolic acid was shaken with petroleum spirit it must not be supposed that the layers which separated consisted of the original liquors. Each was a solution of the one in the other. With ten measures of petroleum spirit to one of carbolic acid complete solution took place at ordinary temperatures. The solubility was enormously increased by rise of temperature, so that carbolic acid and hot petroleum spirit were miscible in all proportions.

Mr. Allen was thanked for his paper.

(*To be continued.*)

Parliamentary and Law Proceedings.

PROSECUTION UNDER THE PHARMACY ACT.

At the Horncastle Petty Sessions, held on Saturday, the 7th inst., before the Rev. Thomas Livesey (Chairman) and the Revs. Samuel Lodge and Arthur White, magistrates, a summons issued by Messrs. Clitherow and Elsey, of Horncastle, as agents for Messrs. Flux and Co., of London, solicitors of the Pharmaceutical Society of Great Britain, in respect of a sale of laudanum, by Robert Croft at his shop at Horsington on the 19th of July last, contained in a bottle not distinctly labelled with the name and address of the seller of the poison, was heard.

In the absence of the accused, a police constable proved due service of the summons.

Mr. Flux, addressing the Court, said that he appeared to support the case on the instructions of the Council of the Pharmaceutical Society of Great Britain, and as he understood that no prior case under the Pharmacy Act had been under the consideration of their Worships, he would shortly read the 17th section as being the one most especially applicable to the offence of the accused, and with the Court's permission would refer to earlier clauses as showing that in some respects the Pharmaceutical Society were specially charged with sundry duties concerning sales of poisons, and thus that the Council was justified in bringing this case before the Court in order to direct the attention of offenders and the public in the county to the law regulating the sale of poisons. He might mention that the consumption of laudanum in the county of Lincoln was excessive, that his clients had special means of information in regard to it, and had knowledge that the consumption of the dangerous and pernicious drug in and about the fen country had engaged the serious attention of the medical officers of the Privy Council. Laudanum was undoubtedly a poison, and Parliament had by the statute expressly enacted that opium and all preparations of opium should be deemed poisons, and that sales of them should be conducted by duly qualified persons known as chemists and druggists, and with certain formalities, which included labelling with the name and address of the seller. In respect of sales by unqualified persons, penalties were enacted, and in the instance under consideration, the sale had been made by a person not duly qualified, but with that class of penalties the Court had not to deal. The offence of the accused was that of having sold a poison without a label bearing the name and address of the seller so that on any improper use of the article there would not have existed, for the public protection, those traces concerning the sale which the law contemplated. He submitted that in thus bringing one case to the Court's attention and under public notice, his clients fulfilled their mission, and that it was now for the public and those generally charged with the administration of the law within the district to enforce the provisions of the statute. In regard to irregular sales any person might be the prosecutor in a case of the kind, whether the offender was or was not a duly qualified seller. Mr. Flux then read from the statute 31 and 32 Vict. c. cxxi, section 17, "It shall be unlawful to sell any poison, either by wholesale or retail, unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article and the word poison and with the name and address of the seller of the poison, and any person selling poison otherwise than is herein provided, shall upon a summary conviction before two Justices of the Peace, be liable to a penalty not exceeding five pounds for the first offence, and to a penalty not exceeding ten pounds for the second or any subsequent offence, and for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant, shall be deemed to be the seller."

Police Constable Samuel Kempston, examined by Mr. Flux, proved knowing Robert Croft, who keeps a grocer's shop at Horsington. The name of Robert Croft appears over the door. On the 19th July last witness went to the shop, and asked of a person in charge of it if they sold laudanum, and was supplied with the article in a bottle, for which he paid 8½*d*. The bottle bore a label which did not mention the name or the address of Robert Croft. He kept the bottle in the condition in which he had received it until Wednesday, the 3rd instant, when he handed it to Dr. George May-Lowe.

By the Court:—The label bore the words "Laudanum—poison," and also the name of J. H. Elmitt, chemist, Horncastle.

Dr. George May-Lowe, of Lincoln, lately public analyst for the county, examined by Mr. Flux, proved having received the bottle from the constable, and having analysed the contents, and that the contents consisted of a preparation of opium called laudanum.

As the magistrates were engaged in consultation, the accused arrived and made a statement not disputing the facts proved, but adding that the bottle was stamped with a patent medicine stamp.

The Bench fined the accused £2 10*s*., and ordered him to pay costs, £2 12*s*. 6*d*.

The accused expressed his inability to raise the amount.

The Court (on the suggestion of Mr. Flux) informed the accused of the clause in the Act of Parliament which would expose him to a penalty of £10 on a second or any subsequent offence.

Arbitration in a Plaster Dispute.

In the High Court of Justice, Queen's Bench Division, there has recently been decided a case which should be of interest to those engaged in pharmacy.

The parties to the suit were Leslie and Co., Limited, of Walbrook, plaster spreaders, plaintiffs, and Gale and Company, wholesale druggists, of Bouverie Street, defendants. The warehouses of both firms being within the city of London, the case was heard at the Guildhall, before Mr. Justice Field and a jury.

Scientific evidence was given in support of plaintiffs' case by Mr. Oxton, F.C.S., and for the defence by Professors Redwood and Attfield.

The plaintiffs' claim was one of damages arising, it was alleged, out of defects in the manufacture of resin and white soap plasters, which the defendants, as wholesale druggists, had supplied to them in the ordinary course of their business. The plaintiffs' practice was, it would seem, to purchase the crude plaister, and spread upon tapes and other material for which their firm had obtained a reputation. In addition, it was also alleged that on account of the rancidity of the plaster, after it had been spread but a short time only, they had sustained a considerable loss.

After the case had been fairly opened, the learned counsel contended that it was one of those disputes that should have been referred to an arbitrator, and that even at this stage it would be much better for a referee to be appointed under the authority of the Court. As both parties, seemed desirous that the case should be decided at the present hearing a mass of evidence extending into the second day was taken, when the foreman of the jury expressed his conviction that the case ought to be decided by reference to an expert, in which opinion Mr. Justice Field quite concurred, and directed that both parties should agree upon some one conversant with the subject.

Mr. C. Umney, (Wright, Layman and Umney), of Southwark, was accordingly elected as referee, and his appointment was confirmed by Mr. Justice Field, who gave him full liberty to examine the respective parties and their witnesses upon oath. Evidence was taken upon three days at the Cannon Street Hotel, in the City of London, supported on both sides by the same scientific evidence as at the first hearing at Guildhall, Mr. Courtenay appearing for the plaintiffs and Mr. St. John Wontner for the defendants. Mr. Umney's award was as under:—

1. That the plaintiffs in this action were a firm of plaster spreaders, who had, during a period of several years supplied the medical profession and the public with adhesive and other plasters in a novel and most convenient form, but that the plaintiffs did not in any way manufacture the crude plasters of which their spread plasters were composed, neither did they, either through their managing director, Mr. J. S. C. Renwick, or their foreman, Mr. Wallace Burnett, profess to have knowledge of such manufacture.

2. That one of the shareholders in the company of which the plaintiffs' firm was composed, viz., Frederick Henry Smith, doctor of medicine of St. Andrew's University, and Fellow of the Royal College of Surgeons of England, who lays some claim to a knowledge of manufacture of crude, as well as spread plasters was, and is, entirely ignorant of the former, and the composition of plaster as detailed in the specification of letters patent of himself for the manufacture of tape plasters or bandages, dated January 16, 1874, was not only impracticable, but that he himself did never prepare any plaster either of such composition, or from such recipe that was suitable for producing spread plasters.

3. That the plaintiffs not being possessed of that special knowledge of manufacture which is necessary in order that the business of a plaster spreader may be successfully conducted resorted for the purchase of such crude plasters as they manipulated, viz., resin and white soap plaster, to wholesale druggists and others, part of whose business it is to prepare crude plasters (either from formulæ tabulated in the British Pharmacopœia, or from recipes which they find are generally approved by medical practitioners and pharmacists to whom they generally supply them), and that such crude plasters are made of different proportions of ingredients (notably in litharge and oil), as compared with those designedly made for spreading purposes, a fact well known to those conversant with each branch of this industry.

4. That the defendants were in the habit of preparing various plasters, including those used by the plaintiffs, and that they did from time to time supply such from their private recipes in preference to those compounded from official formulæ.

5. That the complaint made by the plaintiffs against the defendants' plasters was in the main non-adhesiveness and rancidity.

6. That the formula given in evidence by the defendants through one of their firm, Mr. J. S. Walton, who regulated the manufactures of their laboratory, was although non-official, a recipe from which good plaster could be made, and that, when carefully prepared, such plaster, from the fact that it contained to 100 parts of oleaginous or fatty basis upwards of fifty (54) parts of litharge, would not either be rancid or likely to become so during such time in which plasters are generally expected to remain in a sound condition, neither could it have been non-adhesive made from the proportion of ingredients combined with the amount of resin prescribed in the formula.

7. That the plasters sold by the defendants were divided into two portions, the one comprised in the total supply from May to September 12, 1877, and the other that manufactured and supplied subsequently.

8. That the plaster supplied previous to September 12, 1877, was prepared from commercially pure ingredients and was of good average quality, and although it occasionally contained specks caused by slight defects in certain brands of litharge, these were not uncommon, and might in all probability have been removed by judicious melting, straining and subsidence (by no means an uncommon process in the manipulation of plasters)

had plaintiffs or their workmen been conversant with such treatment.

9. That the defendants' plasters were good and fairly uniform, but even if this were not so, as applied to that supplied subsequent to September 12, 1877, no claim should be made for any defect therein, inasmuch, as remelting had been resorted to, and this was opposed to a stipulation made by the defendants in a letter written on or about that date which contained conditions upon which the defendants would continue to do business with the plaintiffs and their accountability for their plaster being only so long as it remained in the state supplied, and not after its condition had been altered by melting, spreading or any other process; the defendants having had at this time a clear notion that the complaint of previous plaster was in the main due to and caused by, the unskilled treatment to which the same was subjected in plaintiffs' factory prior to spreading, and they, therefore, clearly thought it expedient thus to protect themselves.

10. That plaintiffs' factory men were in the habit of melting the plaister in pipkins and other vessels over gas burners (Bunsen's) constructed to give a maximum of heat, and that they did not exercise proper precautions in so doing, stirring of the plaster during the melting process being only *sometimes* resorted to, as stated by W. Metzner, when diligent stirring to prevent decomposition was necessary.

11. That a plaster prepared since hearing evidence, in accordance with defendants' recipe gave, when chemically examined, results corresponding to those obtained from plaister put in evidence and fully corroborated the statements of Professors Redwood and Attfield.

12. Finally, that for the reasons previously stated the plaintiffs have not proved their case, and judgment, therefore, should be entered for the defendants.

The above award being taken up by defendants was handed to Mr. Justice Field, the plaintiffs raising objections to the same upon finding that it was adverse to them. Mr. Justice Field, however, confirmed Mr. Umney's award, and gave judgment for the defendants with costs.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

---

[338]. Add the Liq. Ammon. Fort. drop by drop to the Arg. Nit. solution until the precipitate first formed is redissolved.

It is the formula for a dark brown hair dye, which I inserted in this Journal two or three years ago.

Hull. F. Staveley.

---

[338]. In this prescription it is evidently intended that the Liq. Ammon. Fort. is to be added to the nitrate of silver dissolved in the water, until the precipitate which is at first produced is redissolved. This is a common receipt for hair dye, and is used after an application of a solution of pyrogallic acid.

W. Fowler.

---

[340]. Iodide of sulphur should be triturated with a few drops of S. V. R. in making the B.P. ointment. It is less objectionable than glycerine, and it ensures the production of a faultless ointment.

In the next edition of the B.P. the form might, with advantage be altered to—

Take of

Iodide of Sulphur	30 grains.
Rectified Spirit	15 minims.
Prepared Lard	1 ounce.

Triturate the iodide of sulphur with the spirit in a porcelain mortar, and gradually add the lard, rubbing them together until the ointment is perfectly smooth.

R. H. Parker.

Review.

International Medical Pharmaceutical Dictionary, in three languages, French, English and German, compiled for the use of physicians and chemists in intercourse with foreigners, by George Herman Moeller, chemist, professor, etc. Munich: 1879. Jul. Grubert, publisher.

Perhaps a good dictionary may be considered one of the most valuable books in a library, and a library, however well chosen, must, without a dictionary, be considered incomplete; but there are dictionaries and dictionaries, and whilst there exists so great a variety and "still they come," it is necessary to use some discrimination as regards their choice.

The general principle in the arrangement of a dictionary should be that it contain the words or subjects of which it treats arranged in alphabetical order; but in modern times, to meet the extension in several branches of science, and the daily increasing desire for knowledge, works of very varied kinds have been prepared on the principle of alphabetical arrangement, and are termed dictionaries.

The title of the one before us is attractive; it professes to give the equivalent terms in three different languages necessary for mutual understanding of the medical man and the pharmacist in their intercourse with foreigners.

The book is divided into four parts; the first embraces materia medica, the second, man and his maladies, or the human body and its physiology, the third, pharmaceutics, the fourth, chemistry and physics, and these again are sub-divided; for instance, materia medica is subdivided into the therapeutic classification of medicaments, the pharmaceutic classification of the same, patent medicines with their prices, and finally the art of prescribing.

The materia medica proper embraces probably all the organic and inorganic materials that ever have formed a part of the materia medica of any European country, from "Ping-war-har-jamby" to "spirit of treacle." The second division, man and his maladies, is subdivided into physiology, including every part of the human body and diseases with all the "ills that flesh is heir to." The third, pharmaceutics, has in its subdivision every article required in pharmacy, from a bung to a thermometer, and every appliance found in the laboratory from a screw press to a gridiron. The fourth, chemistry, is so subdivided as to include the elements, simple combinations, and chemical analysis, from a simple element to a "compound atom," together with botany and zoology.

Every object in the several sciences named, with every term required to be used in their pursuit, are here given in three languages, followed by a complementary vocabulary, and a copious index in the German language, from which it may be inferred that the work is primarily intended for the German aerzte and apotheker. If it were reasonable to ask a person to employ his leisure time in learning a dictionary, doubtless much information would be acquired from this one, but life is too short to admit of such a luxury. The work may sometimes prove useful, but it is too diffuse to be readily available. Where there is a dictionary it can scarcely be said to supply a want, or where there is not one to compensate for the deficiency; and the labour bestowed upon it by the author will, we fear, be ill requited if its sale be dependent on its being used by physicians and chemists in Great Britain as an assistance in their intercourse with foreigners.

Correspondence.

A Request.

Sir,—With your permission, I wish to ask those who are in a position to give it, for tangible proof that the patent medicine stamp is used to cover the sale of scheduled poisons. As the sale of poisons under the guise of so-called patent medicines is likely to engage the attention of the Pharmaceutical Council, I am anxious to demonstrate by ample proof that the Act of Parliament is thus infringed.

May I ask therefore that members of the trade will kindly obtain for me, as soon as convenient, samples of poisons sold under cover of the medicine stamp, and that they may be sent to my address as annexed?

205, *St. John Street Road, E.C.* Robt. Hampson.

How can a Chemists' Assistant register Himself as a Dentist in bona fide Practice?

Sir,—The above question has been asked me during the last few months by numerous friends in both the dental and medical professions; in consequence I have been at considerable trouble to ascertain if any chemists' assistants really had registered as such, and I find that they have. I have also had chemists pointed out to me who have never done any dental operation beyond extracting a tooth, and have probably never seen inside a dental laboratory, and know absolutely nothing of "dentistry," who have registered as being in *bonâ fide* practice as dentists. Now the Act never contemplated registration by any persons other than those known as being engaged in the practice of dentistry, either separately or in conjunction with pharmacy or surgery.

It does not follow that because a chemist placed an engraved plate with the word dentist on it, upon his door, at the passing of the Act, that the law will recognize him as a dentist. A dentist in the eye of the law must have been a person engaged in every branch of the dental art, *i.e.*, able to undertake any operation and do any mechanical work that may be required for the mouth by the public.

The various dental associations, formed for the express purpose of sifting out fraudulent registrations, have an agent in every town now busily engaged in compiling a list of such registrations. Section xxxv. of the Dental Act, 1878, provides for such by fine and imprisonment.

Many think that because they have filled up the declaration paper sent by the Registrar, and received from him the "Dental Registration Certificate," that they are now safe; such, however, will not be the case without legal evidence of qualification and fitness, which will be demanded by the "British Dental Association." No chemist regularly engaged in "*bonâ fide* practice as a dentist" need fear any annoyance or subsequent trouble from the requirements of the Dental Act; such, however, as cannot bear the strictest investigation as being *bonâ fide* in practice at the passing of the Act had better at once, and previous to the publication of the register, apply to Mr. Miller, and have their names erased to prevent "Section xxxv." being carried into effect.

1, *St. Domingo Vale, Liverpool.* J. J. Musgrave.

Sp. Æther. Nitrosi.

Sir,—In your issue of August 2, there appeared a letter on this subject by Mr. W. Pollard in reference to the paper by me in the Journal of July 19. The usual derangement of business consequent upon holiday time must be my apology for the delay in replying.

Two questions appear to have suggested themselves to Mr. Pollard, and upon which he asks information.

1st. How is it that 2 per cent. of æther. is separated by the solution of calcic chloride, and only 1·72 is obtained by analysis?

In answer to this query, I must refer Mr. Pollard to the discussion that followed the reading of a paper at Bloomsbury Square, reported in the Journal, on page 377, vol. viii., 1877, and he will find it stated by some of the speakers that the ethereal fluid that rises in the tube is not all nitrite of ethyl, and the analysis I have given shows this to be true.

2nd. What becomes of two-thirds of the nitric acid used in the process?

Some of the nitric acid is decomposed by the alcohol, aldehyde and water being formed, a further portion remaining in the retort unused.

Bradford, Sept. 10, 1879. F. M. Rimmington.

Weights and Measures.

Sir,—Mr. Martindale in his note says that "the troy cup weights in general use have always had this, the troy pound of 12oz., as their largest weight." This is certainly not "always" the case, all the troy cup weights I have ever seen run thus—ʒij, ʒij, ʒiv, ℥j, ℥ij, ℥iv, ℥viij, going on to 16 and 32oz., the larger cup being always of the same weight as those fitting into it. I would give a hint to people having the larger cups of 16 and 32oz., that if the inspectors see them it may not be altogether pleasant, as these weights are not mentioned in the schedule and there is no standard for them; but in this as in some other matters connected with the Act, we can only hope the authorities will not ask too many questions.

Manchester. W. Wilkinson.

Liq. Kino ('Year-Book,' 1873).

Sir,—I take the opportunity now the subject is again before the members of the Conference and readers of your Journal to make a necessary correction. In the 'Year-Book' for 1873, in the paper on page 554, line 12, "four" should be "one and a half," which dilution would then bring the solution to the same strength as the tincture, *i.e.*, 2oz. Kino to Oj. I would ask those possessing the 'Year-Book' to make the necessary alteration. I did not observe the mistake till after the 'Year-Book' was published, and had not that paper been mentioned at the Sheffield Conference by Mr. Benger, I should not have thought it necessary to call attention to the error which was an oversight of mine at the time of writing the paper.

W., M. P. S., J. T., W. L., T. S. W.

NOTE ON GENTIAN ROOT.

BY O. CORDER.

Whilst walking through the Engadine, Switzerland, this summer, I found in some valleys, as in the Beveos Thal, great quantities of *Gentiana punctata*, and in one chalet saw several tons dug up for medicinal use; in others as in the Fex Thal, only *G. lutea* was noticed, and upon inquiry from a local botanist, M. Cavretzel of Pontresina, he informed me that I was correct in supposing that both are indiscriminately collected for pharmaceutical purposes. The two plants differ but little in the growing state, but when in flower would never be mistaken, *G. lutea*, having a yellow corolla and *G. punctata* a yellowish green one profusely spotted over with black dots.

THE PHARMACEUTICAL EXHIBITION IN HANOVER.

One of the most interesting features of the meetings of the Deutsche Apotheker-Verein consists in the exhibition of objects more or less closely associated with pharmacy, and the display in connection with the recent meeting in Hanover, although including many exhibits which have lost the charm of novelty, well recompensed the trouble of a careful examination. The larger portion of this exhibition was shown in the basement and gallery of a good sized hall in the "Odéon," adjoining the hall in which the meetings of the Association were held, but the machinery and larger pharmaceutical apparatus overflowed into the concert grounds, where they were placed under a long shed.

The number of exhibitors was considerable, the Catalogue containing 161 names. It was rather noticeable, however, that the manufacture of chemicals, as distinct from pharmaceutical preparations, was almost entirely unrepresented. On the other hand, several of the exhibits might be looked upon as being rather excrescences of pharmacy than pharmaceutical. Paper and labels, bottles and boxes, infants' foods and extracts of meat, condensed milk and soluble cocoa, aniline dyes and phosphorus paste, all had their exhibitors, and most of the cases were praiseworthy, but they presented in this direction little beyond what pharmacists are accustomed to see in this country.

Amongst the knickknackeries of elegant pharmacy one could hardly help being struck by the development in the preparation of gelatine capsules and perles. Some very fine and elastic specimens of these were exhibited by H. Kahle, of Konigsberg, and G. Pohl, of Schönbaum. In fact the gelatine capsule has developed in more ways than one, specimens being shown as containing 15 grams of oil. A remark as to the large size of these led to a practical demonstration with one by an obliging bystander, and the capsule was bolted without any indication of present difficulty or—what was quite as noticeable, perhaps—fear of subsequent inconvenience. Pastilles were also shown in considerable number, and of tempting appearance, one of sal ammoniac being frequently met with. Much nattiness was also evident in the getting up of plaster in small quantities, long strips of different widths being rolled up and enclosed in tin boxes for sale for a few pfennigs. Allied with these were also to be seen small rolls of linen, charged with plaster of paris, put up in air-tight cases, requiring only to be wetted to be ready for use as plaster bandages. It may be remarked here that some of the plasters appeared to be of admirable quality; especially may be mentioned an adhesive plaster on silk, exhibited by R. H. Paulcke, of Leipzig. This exhibitor also showed a fine specimen of glass wool, prepared from crystal glass and warranted to be free from lead, which metal has been alleged to be a source of impurity when glass wool is used as a filtering material.

Some very good specimens of drugs in powder, both coarse and fine, were shown by different exhibitors, notably by Dr. Brunnengräber, of Rostock, in whose case was also a fine cake of expressed oil of nutmeg. Many specimens of barks and roots cut small, but to a uniform size, for the convenience of pharmaceutical operations, were also to be seen, though perhaps the best show of these was made by W. Kathe, of Halle. Especially noticeable in this display were the fine specimens of rhizoma iridis, rhizoma galangæ, radix liquiritiæ, and radix rhei cut into small cubes. Some remarkably fine ergot was also shown by Mr. Kathe. It was stated to be the choice pickings of large parcels of ergot of rye collected in different parts of Germany, especially in Prussian Silesia, but the size was so enormous as to suggest the idea that it might have been parasitic on some other plant than rye.

A very fine case of pharmaceutical preparations was displayed by Dr. F. Witte, of Rostock. It contained a very large and handsome crystallization of caffein, but of not less interest was a series of preparations of pepsin and peptones. Amongst these was an "Eisen-pepton," prepared from a fibrin peptone. It is claimed that iron administered in combination with peptone is presented to the stomach in a form in which it does not cause irritation to the mucous membrane and is very easily assimilable. This preparation is in the form of powder, is said to be easily and perfectly soluble in water at a temperature of 28° C., and to contain 5 per cent. of iron oxide. A "tinctura episcopalis" gave rise to some speculations as to its possible origin, which were by no means allayed by the subsequent visit to the old cathedral at Hildesheim, where the remains of several bishops are supposed to lie at rest.

Attention has recently been directed to the subject of crystallization, and especially to the behaviour in this respect of solutions of isomorphous salts to each other. A case of crystals exhibited by F. Meyer, of Geestemünde, contained some very fine crystals, which well illustrated some principles laid down in two papers that have appeared in this Journal during the present year.* One very fine and perfect octahedron of chrome alum crystallized over ordinary alum weighed 1550 grams. From mixtures of solutions of the two alums the crystallization of chrome alum appears to take place most rapidly at starting, as indicated by the centre of the crystal being much darker than the outer portion. Judging from similar evidence, when a crystallization of magnesia sulphate is grown over nickelous sulphate the greater part of the deposit takes place at the ends of the prism as compared with the sides.

In the exhibit of Schmidt and Haensch, of Berlin, was an instrument that promises to respond to what was mentioned at the recent Conference meeting at Sheffield as a desideratum. This was a small polarimeter, which is described as a "half-shade Mitscherlich." From a cursory examination it appeared

* *Pharm. Journ.* [3], vol. ix., pp. 678 and 769.

to be a fairly good and delicate instrument,—the vernier being graduated to degrees representing each 1 per cent. of sugar,—and the price was five guineas. It is probable that an opportunity of examining this instrument, as well as a low-priced, but apparently very good, students' microscope, will be afforded at an evening meeting in the coming session. Some of the microscopes of this firm were fitted with an ingenious arrangement by which, after the traveller has carried the object glass from end to end horizontally across the field of vision, upon reversing the movement the object glass is, by a ratchet action, shifted vertically just sufficiently to expose a fresh field, and thus a systematic examination of an object can be attained.

In the machinery and apparatus shed were some very handsome and comprehensive pharmaceutical apparatus, aiming at the same objects as those described and illustrated in this Journal in the papers by Mr. Corder and Mr. Schacht.* A small vacuum apparatus, valued at £35, was also exhibited by F. H. Meyer, of Hanover. There were also several pharmaceutical presses. One consisted essentially of two vertical plates, with cavities to contain hot water, and was worked by a double screw (one to each plate). In another the pressure was effected by drawing four wedges placed above the pressure plate from an inclined into a perpendicular position. Mills, apparatus for filling, corking and washing bottles, etc., were also shown, but these call for no particular remark. There was also a small stove, adapted for the use of petroleum as a source of heat.

Different people have different tastes, and to some probably the small side room, devoted to the "Historisch-pharmaceutische Anstellung," was the most acceptable part of the whole. This was the first time in connection with this Association that an attempt had been made to gather together literary and other antiquities more or less belonging to pharmacy, and the committee at Hanover may be fairly congratulated upon the success that followed their effort. This is not the place for a catalogue, but it may be mentioned that the collection included some very curious old specimens of pharmaceutical utensils, including a brass mortar, which has just completed its five hundredth year, as would appear from the inscription, "GHEGOTE VAN IAN VERPIET. 1379." Some bezoar stones, mounted in gold filagree and formerly worn as charms, recalled a materia medica that has passed away. But this was done more vividly by a case of ancient remedies from the Altstaden Apotheke. It contained a large number of specimens in small bottles, and among those of which the labels could be deciphered were the following:—viperarum spinæ, viperarum exuviæ, dentes lupi, dentes hominis, pili cervi, pili leporis, pili hirci, calculus ex vess. fel. bovini, calc. ex vess. humanæ, priapus cervi, testiculi equi, testiculi cervi, testiculi cervis, testæ fluviatilis, succinum rubrum, succinum artificiale, stercus pavonis, stercus murium, stercus hirudinum, stercus equorum, stercus columbarum, and stercus anseris. There was a considerable collection of old documents, consisting of "privilegiums," indentures, certificates, and the like, most of them bearing a date in the latter half of the eighteenth century, but some much earlier. Many of these documents were elaborately emblazoned and otherwise ornamented, and most of them were written in the German language and characters. Amongst the books were several very old herbaria and herbals, a number of old pharmacopœias, mostly of German states, but some British, and several ancient works on alchemy and chemistry. Perhaps, as Victor Meyer has recently shown that it is not always safe to overlook as exploded the theories of these old masters, there may be a tendency just now to hunt up the literature of the past for hints. It will not therefore be out of place to conclude this notice with mention of the 'Zymotechnia Fundamentalis, or the General Principles of the Art of Fermentation,' published at Frankfort in 1734, a book which appears promising forage ground at a time when the nature of the "elements" is so much discussed, since it claims on the title-page to describe how a true sulphur may be artificially produced ("*wie ein wahrer Schwefel durch Kunst zum Vorschein zu bringen*").

CITRATES OF QUINIA.*

BY A. F. MANDELIN.

The author has made investigations in the pharmaceutical laboratory of the University of Dorpat, under Professor G. Dragendorff, on the composition of various citrates of quinia which may be obtained of a definite composition. He first gives an historical review of the labours of his predecessors.

Dr. Guleani, of Venice, was the first who proposed (in 1832) a method for preparing a citrate of quinia by double decomposition of sulphate of quinia and sodium citrate. The former salt may be either neutral or acid; according to its nature the proportions of the two salts required to react upon each other will somewhat vary, but they will yield in each case the same product, namely, a neutral salt.†

a.) $3(2Qu.H_2SO_4)$ + $2Na_3H_3(C_6H_5O_7)_2$‡ =
neutral quinia sulphate + "acid" sodium citrate =
$3Na_2SO_4$ + $2(3Qu.2Ci)$.
sodium sulphate + neutral quinia citrate.

b.) $3(Qu.H_2SO_4)$ + $2Na_3C_6H_5O_7$.
acid quinia sulphate + neutral sodium citrate.
$= 3Na_2SO_4$ + $3Qu.2Ci$.
sodium sulphate + neutral quinia citrate.

Wittstein analysed the crystallized salt and found it to correspond to a formula which in the new notation would be $2Qu.Ci.5\frac{1}{2}H_2O$.

Dr. Hager, in 1859, directed to prepare it from 10 parts of citric acid and 29 parts of pure quinia. Its composition was given as $3Qu.2Ci.10H_2O$. In 1875, the same author changed his directions to 1 part of citric acid to 3·5 parts of pure quinia. He called the resulting salt neutral citrate of quinia, and gave its composition as $2Qu.Ci.7H_2O$. In 1876, however, he reduced the proportion of quinia to 3 parts, and returned to the original formula, namely, $3Qu.2Ci.10H_2O$.

The Austrian Pharmacopœia directs to saturate citric acid with freshly precipitated quinia hydrate. Dœbereiner (1861) gives for this the following formula: $2Qu.Ci$.

Geiger, in 1845, directed the same method of preparation.

The Netherland Pharmacopœia (1871) directs 1 part of citric acid and 3 parts of quinia hydrate, which yield, according to Stœder (1878), a salt of the composition $3Qu.Ci.10H_2O$.

* From *New Remedies*, September, 1879. Abstract of a paper by K. F. Mandelin. *Chinincitrater: Undersökningar i farmaceutiska laboratoriet i Dorpat. Af K. F. Mandelin, fr. Jœnsuu i Finland.* 8vo. Dorpat, 1879.

† Throughout the above text we have abbreviated the formula for *quinia* ($C_{20}H_{24}N_2O_2$) by "*Qu.*," and the formula for *citric acid* ($C_6H_8O_7$) by "*Ci.*"

‡ This stands really for $2Na_3C_6H_5O_7 + 2H_3C_6H_5O_7$.

Wurtz gives the composition $2\,Qu.Ci.5\,H_2O$.

The author now proceeds to give an account of his own investigations. He brought together citric acid and quinia in four different proportions, and analysed the resulting crystallized salts with the following results:—

a. Three molecules of quinia and two molecules of citric acid. He obtained a salt containing 0·3963 per cent. of water, 72·99 per cent. of anhydrous quinia, and (28·14 per cent. corrected) 26·62 per cent. of citric acid, and corresponding to the formula 3 Qu.2 Ci.

b. One molecule of quinia and one molecule of citric acid. The resulting salt was anhydrous, and contained 64·55 per cent. of anhydrous quinia and (32·43 per cent., corrected) 35·45 per cent. citric acid. Composition: Qu.Ci.

c. One molecule of quinia and two molecules of citric acid gave a salt containing, when dried in the air, 0·60 per cent. of water, 63·79 per cent. of anhydrous quinia and 35·59 per cent. of citric acid (calculated by difference). The composition is, therefore, probably the same as that of the preceding salt. Hesse has already stated that by treating one molecule of quinia with a little more than one molecule of citric acid, a salt of the composition Qu.Ci. is obtained.

d. Two molecules of quinia and one molecule of citric acid. This salt contained 1·14 per cent. of water, 78·28 per cent. of anhydrous quinia, and 20·32 per cent. of citric acid. Composition: $2\,Qu.Ci.\frac{1}{2}H_2O$.

The solubilities of the three obtained citrates are the following in 100 parts of water:—

	Cold. Parts.	Boiling Parts.
Basic Quinia Citrate (2 Qu.Ci.)	0·1093	2·25.
Neutral „ „ (3 Qu.2 Ci.)	0·1133	2·39.
Acid „ „ (Qu.Ci)	0·1566	2·60

PETROLEUM FROM THE CASPIAN.*

A correspondent of the *Daily News*, writing from Baku, on the Caspian, gives an account of the petroleum springs existing there. All around Baku the ground is sodden with natural issues of naphtha. In some places the earth is converted into a natural asphalte, hard during cold weather, but into which the foot sinks a couple of inches at midday. Add to this that, owing to the scarcity of water, the streets are moistened with coarse black residual naphtha. It effectually lays the dust during fifteen days. After this period a thick brown dust lies four or five inches deep in the roadway, over which the numerous "phaetons" or street carriages glide so softly and noiselessly that the foot passenger is frequently in danger of being run over. When a north or west wind arises, the air is thick with impalpable marly earth, combined with bitumen. The least glow of sunshine fixes this indelibly in one's clothes. No amount of brushing or washing can remove it.

The shores of Baku bay north of the town trend towards the east, and some five or six miles distant are the petroleum, or, as they are termed, the naphtha springs. The surrounding district is almost entirely destitute of vegetation; and in its midst are some black-looking brick buildings, interspersed with curious wooden structures, twenty feet high, resembling Continental windmills. These latter are the pump or well-houses covering the borings for oil, and in which the crude liquid is brought to the surface. All around smells of petroleum, and the ground is black with waste liquid and natural infiltrations. Boring for naphtha is conducted much in the same manner as that for coal. An iron bit, gouge-shaped, is fitted to a boring bar, eight or ten feet in length, which is successively fitted to other lengths as the depth of the piercing increases. This depth varies from fifty to one hundred and fifty yards, this difference existing even at very short horizontal distances, sometimes not over forty yards. Layers of sand and rock have to be pierced. It is in the sand that often the greatest difficulties have been met with. A loose boulder will meet the boring tool, and displacing itself leave the passage free. But when the rods are withdrawn to allow the introduction of the tubes which form the lining of the well, the boulder falls back to its place, and baffles all attempts to continue the orifice. This boulder difficulty is the great terror of those commencing to bore. Sometimes, after a lengthened discharge of heavy carburetted hydrogen, the naphtha rises to the surface, and even flows over abundantly, as in the case of the artesian well. Under ordinary circumstances, it has to be fished up from a considerable depth. The boring is generally ten, or at most eighteen inches in diameter. A long bucket, or rather a tube stopped at bottom and fifteen feet in length is lowered into the well, and drawn up full of crude petroleum, fifty gallons at a time. This, which is a blue-pink transparent liquid, is poured into a rudely constructed, plank-lined trough at the door of the well-house, whence it flows by an equally rude channel to the distillery. The distillation is conducted at a temperature commencing with 140 degrees Centigrade, much lower, I am told, than the first boiling point for that from Pennsylvania. When no more oil comes over at this heat, the result is withdrawn and the temperature increased by ten degrees. This second result is also laid aside, and the heat being again increased a third distillation is carried on until no further easily evaporated liquid remains. This last is the best quality of petroleum for lamps. That which preceded it is the second quality; and the first, or highly volatile, liquid is either thrown away or mixed with the best and second best as an adulteration. The thick dark brown treacly fluid remaining after distillation is termed astalki, and is that used for the irrigation of the streets. The distilled petroleum, if used in lamps, would quickly clog the wick with a carbonaceous deposit. Previous to being offered for sale, it is placed in a large reservoir, within which revolves a large paddle-wheel. Sulphuric acid is first added, and after being allowed to settle, the clear top liquor is drawn off, and similarly treated with caustic potash. After this it is ready for sale. Up to the present, the residues, after the acid and potash treatments, have not been utilized. I have no doubt but that, later on, valuable products can be derived from them. With the astalki, or remnant after the first distillation, it is different. For years past it has been the only fuel used on board the war ships and the mercantile steamers of the Caspian. At Baku its price is only nominal, vast quantities being poured into the sea for lack of stowing space or demand. In cooking apparatus it is used, and for the production of gas for lighting purposes. In the latter case it is allowed to trickle slowly into retorts raised to a dull red heat, pure gas with little graphite being the result. Weight for weight this waste product gives four times as great a volume of gas as ordinary coal. By distillation at a high temperature and treatment with an alkaline substance, a product is obtained which is used as a substitute for oil in greasing machinery.

Apart from the local use of petroleum for lighting purposes, and its exportation for a similar use, comes its application to steam navigation. With the old-fashioned boilers in use, having a central opening running longitudinally, no modification is necessary for the application of the new fuel. A reservoir, containing some hundred pounds weight of the refuse (astalki), is furnished with a small tube, bearing another at its extremity, a few inches long, and at right angles with the conduit. From this latter it trickles slowly. Close by is the mouth of another tube, connected with the boiler. A pan containing tow or wood saturated with astalki is first introduced to heat the water, and once the slightest steam pressure is produced, a jet of vapour is thrown upon the dropping bituminous fluid, which is thus converted into spray. A ligh

* From the *Journal of the Society of Arts*, August 29, 1879.

is applied, and then a roaring deluge of fire inundates the central opening of the boiler. It is a kind of self-acting blow-pipe. This volume of fire can be controlled by one man by means of the two stop-cocks as easily as the flame in an ordinary gas jet. This I have repeatedly witnessed on board the Caspian steamers. As regards the expense, I give the following data on the authority of a merchant captain who has used naphtha fuel for years. His steamer is of four hundred and fifty tons, and of one hundred and twenty-horse power. He burns thirty poods per hour of astalki to obtain a speed of thirteen nautical miles in the same time. One pood is about thirty-three English pounds (16 kilogrammes), and costs on an average from five to six pence. Thus a twenty hours' voyage at full speed for such a vessel costs about twelve pounds sterling. The fuel is as safe and occupies much less space than the amount of coal necessary to produce a similar effect, not to speak of the enormous difference in price, and the saving of manual labour. Two engineers and two stokers suffice for a steamer of a thousand tons burden. With the immense supply of natural petroleum, as yet only very slightly developed, and its application to the already guaranteed railway from Tiflis to Baku, and to the inevitable future ones beyond the Caspian over the plains of the far East, I think this subject is worthy of every attention. Yet there are proprietors of large tracts of petroleum-bearing ground whose capital rests unproductive because of a want of demand. The island of Tchilican, not far from Krasnavodsk, teems with the precious liquid. The sea-ward cliffs are black with its streams flowing idly into the sea; and a natural paraffin, or "mineral wax," is found abundantly in the island and in the low hills a hundred versts west of Krasnavodsk. All round Baku the ground is full of naphtha. In hundreds of places it exhales from the ground and burns freely when a light is applied. Only a couple of months ago the volatile products produced a remarkable effect a couple of miles south of Baku. A large earth cliff fronting the sea was tumbled over as by an earthquake shock and, as I saw myself, hugh boulders and weighty ship's boilers were thrown a hundred yards. In some places I have seen fifty or sixty furnaces for burning lime, the flame used being solely that of the carburetted hydrogen issuing naturally from fissures in the earth.

OIL OF GAULTHERIA.*

BY JOSEPH BRAKELEY, PH.G.

The manufacturers of this oil are generally men of limited means and knowledge, and the apparatus used is very crude and simple in its arrangement, being easily taken down and removed to other parts when the supply of leaves is exhausted. This generally occurs in two or three years.

The first point in locating, after finding where the plant grows plentifully, is to secure a stream of water with enough fall to allow it to be carried to the top of the refrigerating tub. Under a rough shed the apparatus is erected, consisting generally of an ordinary copper whisky still with a capacity of from two to four hundred gallons, enclosed in brick work, and with the head only projecting. The still is connected with a copper worm, and a cask or tub to receive the distillate completes the arrangement. The process followed is the one generally used in distilling volatile oils. The leaves are placed in the still, covered with water, and heated by an open fire beneath. The steam carrying the volatile oil passes through the worm, is condensed, and the product is collected in the receiving vessel. The oil settling to the bottom, most of the water is dipped out and used again with the next lot of leaves, while the oil is collected by means of a tin separating funnel. The advantage of using the same water in each succeeding operation seems to be understood and is in general practice.

The above method is the one nearly always followed, and the amount of volatile oil obtained varies from ·66 per cent. to ·80 per cent. This is the percentage as given to me by a number of manufacturers. From their statements I believe the average yield to be about seven-tenths of one per cent. From certain facts given to me by one manufacturer I believe that were a close wooden cask or vessel substituted for the metallic still, and live steam introduced and passed through the leaves, a larger product would be obtained. This process was the only exception to that usually followed. He made his still of heavy tin plate in place of copper; this would be of the usual size and shape, and one would last five or six months. He always noticed that when the still was new and first used the amount of oil produced was very large, and gradually and steadily grew less as the still became older. Finally he would hardly get ·5 per cent of oil, and would be obliged to throw the still aside. On examining it then he would find it very much corroded and eaten away inside where the steam and oil came most in contact with the metal. He also noticed that a brown spongy mass would collect in the bottom of the receiving vessel, and that the amount of this deposit seemed to be inversely in proportion to the yield of oil. That is, when the still was new it would be almost wanting, and would gradually increase with the age of the still. This decrease in yield could hardly be ascribed to the plant giving a greater quantity of oil at one season of the year than at another, as the stills were renewed at different times in the year, and always with the same result. The most probable couclusion is that the oil acts on the metal at the temperature used in distilling, and forms the deposit referred to as collecting in the oil. I could not ascertain if other manufacturers using copper stills had noticed the same corroding effect, but as the average yield with all seemed to be about the same, I should think it very probable. This same party used also a false bottom in his still, supporting the leaves over a small quantity of water, merely the steam passing through the leaves. He found this arrangement to give better results. There was an arrangement by which the overflowing water from the receiving tub was returned directly and continuously to the still, thus retaining the water there at a constant level.

The oil as thus obtained has the specific gravity 1·17 and is of a pale red to a deep brown colour, and by most manufacturers is thus sent into the market, packed in tin cans of various shapes and sizes. One party uses animal charcoal, obtaining a product entirely colourless. He tried redistilling the oil with water and a small quantity of fixed oil, but did not get a satisfactory result; then he tried filtering through animal charcoal and was still unsatisfied. Then he adopted the plan of maceratiug the charcoal with the oil for several days and then filtering off the oil, which is thus well decolorized. The filter and charcoal are returned to the still with the next lot of leaves, thus losing no oil.

The leaves are gathered principally by woman and children. The price paid varies with the locality and abundance of the plants, seldom going below 1·00 dollars or over 1·75 dollars per one hundred pounds. To gather fifty pounds of leaves is considered a good day's work. The average is less, being nearer twenty-five or thirty pounds. The wages earned are small, but the entire family will turn out in the morning, so that by evening they will have collected a good quantity. The people, though, are apt to be indolent, and the manufacturer often finds himself without the material to operate on, and so earns rather a precarious living. None, so far as I know, have ever grown rich at the business, and the decline in the price of the oil in the market of late years has still further reduced their profit.

THE STATE OF PHARMACY IN GERMANY.

PHARMACEUTICAL affairs in Germany are at the present time in a state of agitation in reference to several important questions, the discussion of which will not be without some interest on this side of the Channel as throwing a light upon subjects which have here engaged the attention of pharmacists during the last few years. As our readers are probably aware, the practice of pharmacy in Germany has been for ages carried on under conditions especially favourable for the interests of those engaged in the business. The old established usage by which the possibility of competition was almost done away with is a condition so foreign to our experience at home that some will be inclined to envy the position of a German pharmacist under that *régime*, and almost to wish that something of the same kind could be established here.

Unquestionably the system of limitation of pharmacies in Germany has been productive of good, inasmuch as it has tended to make the business one eminently attractive for men of capital and scientific ability, and it has had the further effect of making the position of the pharmacist in Germany one very superior to that which must be taken as obtaining in regard to the general body in this country. But as in process of time it happens with most old institutions, their merits fall into disregard, so with the established system of limitation of pharmacies in Germany; there has grown up a feeling of dissatisfaction with it and a desire to replace it by a more free exercise of individual inclination.

Even among the proprietors of old-established German pharmacies the opinion is held that the restrictions which have been in force to prevent the opening of pharmaceutical establishments are out of date and not suited to the present requirements of society. Consequently there is an eager controversy going on as to the relative advantages of the protective system and that which is proposed as its substitute on the basis of absolute free trade principles.

Since Germany became one, the two pharmaceutical associations of North and South Germany have been united, but the official amalgamation has not obliterated either in the north or in the south the desire to hold a prominent, if not a preponderating, position in the regulation of pharmaceutical affairs. The union of Germany has in this respect, as in others, given additional force to the desire of Prussia to take the lead, and of Berlin to imitate the *rôle* of Paris in being Germany as Paris has been France. Those who know the character of the Germans who are not Prussians will be able to understand that this endeavour meets with strenuous opposition among those whom we may term provincial Germans, and hence it is possible to recognize in many of the proceedings of the German Pharmaceutical Association an expression of this contest between centralization and provincialism which gives marked animation to the discussions of various subjects.

The constitution of the German Association is especially representative, and the maintenance of active centres for the transaction of business relating to pharmaceutical affairs, is one of the best features of this body. It is one which, if properly used, scarcely admits of the complaint that the provinces are not adequately represented or that the ruling body can be insensible to the representations of its provincial members.

Among the subjects which commanded most attention at the late meeting in Hanover, the re-construction of the statutes of the Association is perhaps the most important to those immediately concerned, but as it would be unreasonable to expect that it would have the same interest here, it will suffice to say that most of the principal pharmacists in Germany are actively engaged in the consideration of this matter. Next in order and in import for the well being of the pharmaceutical body, comes the question as to the system of education to be adopted. On this point there is great diversity of opinion, some adhering to the old system of education in the pharmacy, while others lean to or advocate the adoption of a system of university education. For both views cogent arguments are adduced and equally cogent objections are brought forward on either side. A special committee has been appointed by the Association to consider and report upon this matter, and we shall take the opportunity, when this report appears, to place before our readers the substance of the views put forward on the subject.

The preparation of a new Pharmacopœia is another subject which engaged the members of the Association at the late meeting. At the meeting in Coblentz last year a committee was appointed to deal with this subject and some steps were taken to that end, but a number of difficulties have arisen to prevent the presentation of a report, and at the meeting in Hanover various questions connected with the subject were discussed. As the chief among these we may mention the following:—Whether the Pharmacopœia should be published in Latin or in German? Whether chemical formulæ should be used? Whether in naming metallic compounds the name of the metal should be placed first? Whether the use of synonyms should be limited?

The discussion of these and other questions occupied a considerable time, and from the interest manifested by the speakers it was evident that the pharmacists of Germany are determined to have some considerable voice in the construction of their new book of law.

In speaking of the Coblentz meeting last year we pointed out that one of the most striking impressions produced upon us as strangers was the amount of attention devoted to matters connected with "trade interests." The same tendency was this year equally manifest, and though running in a direction somewhat remote from the mere endeavour to monopolize the trade in patent medicines it served to show that if the material well-being of the pharmaceutical body is to be maintained, or if possible augmented, it is only by the active co-operation of those engaged in the business that this can be done. While looking over the records of the work done by the provincial branches of the German Pharmaceutical Association it was impossible to avoid drawing a comparison, or rather a contrast, between the general activity there displayed and the small extent to which this is the case throughout this country. The number of our provincial associations is also disproportionately small, and though some of them are well kept up there is too frequently an absence of any sustained effort to advance the interest of the business or even total quiescence except when some burning question is being agitated. In this respect there is much to be learnt with profit from the example of our German colleagues and we trust the opportunity may not be missed.

THE LOCAL GOVERNMENT BOARD ON THE WORKING OF THE SALE OF FOOD AND DRUGS ACT.

It is satisfactory to learn from the returns in the Report of the Local Government Board just issued that the proportion of the samples analysed under the provisions of the Sale of Food and Drugs Act in the year 1878 reported to have been adulterated is lower by 2 per cent. than in the preceding year. The total number of samples reported upon was 16,191, and of these 2,782, or 19·2 per cent., were returned as adulterated. Too much importance, however, must not be attached to these figures, for irrespective of the fact judiciously emphasized in the Report, that these percentages are based on the results of analyses as given in the quarterly reports of public analysts, and not upon the number of cases that have been tested in a law court, it needs only a glance at the abstract of returns to see that the figures may be affected seriously by local conditions and the number of samples examined, as well as the idiosyncrasy of the analyst. Thus in the column showing the percentage proportion of samples reported to be adulterated in the different counties we find Bucks returned as 0; Rutland, 0; Anglesey, 7·4; Bedford, 7·7; and Gloucester, 7·8; whilst Essex stands at 71·4 and Cumberland at 62·5 per cent. It can hardly be contended that these figures represent correctly the relative proportions in which trading in adulterated articles exists in these counties. Moreover, the whole returns would be affected to the extent of 2 per cent. if spirits were excluded from the calculation, and the diversity of opinion as to what constituted an adulteration of spirit, until the passing of the Act of last session, is notorious.

The number of samples of "drugs" reported to have been examined is 491, of which 125, or 25·4 per cent. have been returned as adulterated. Here again there is great diversity, Lancaster returning 22 adulterated out of 45, or nearly 50 per cent., whilst Lincoln reports none adulterated out of 25. The Board expresses regret that more samples of drugs are not submitted to analysis, "for it is obvious that prescriptions may have very different effects, according as they are made up with genuine or with adulterated medicines," and it then goes on to quote the report of the analyst for the West Riding of Yorkshire as to the evil results attending the dilution of sweet spirit of nitre with water. The aptness of the apposition is not, however, quite evident, in the face of the fact that in few, if any, recorded cases of a conviction for the sale of adulterated sweet spirit of nitre has the vendor been a registered chemist and druggist. Moreover, "sweet spirit of nitre" is not a preparation that would be used in dispensing.

On the 31st of December, 1878, the number of authorities who had appointed analysts was 196,—49 counties, 108 boroughs, and 39 district boards and vestries in the metropolis,—and 5 other boroughs had made arrangements with the county analyst or the analyst of a neighbouring borough.

THE LOCAL SECRETARY OF THE CONFERENCE AT SHEFFIELD.

Those who had the opportunity of taking part in the very successful gathering of the British Pharmaceutical Conference at Sheffield will be able to understand that very much of their enjoyment in various ways was due to the exertions of the Local Committee. Organizations of this kind sometimes fail to do what they should do, and then they are very difficult to get at for punishment by those who suffer for their shortcomings; but though in general they may be destitute of some of the usual attributes of humanity it is certain that when they do their work well they must possess a head to direct and a working hand to execute. In neither of these was the Sheffield Local Committee wanting, and it is with great pleasure we learn that the services of Mr. Maleham, the Local Secretary upon whom devolved the arduous labours of preparing for the meeting, have met with recognition from his colleagues, and that they have expressed their appreciation of his zealous exertions by presenting him with a handsome piece of silver plate as a token of their respect and admiration. We are sure that few who were present at the Sheffield meeting will fail to be gratified at hearing this.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

The next paper read was on—

The Valuation of Citrate of Iron and Quinine.

BY FREDERICK W. FLETCHER, F.C.S.

Notwithstanding the large number of papers which have been published during the last few years on the estimation of quinine in the Citrate of Iron and Quinine of the British Pharmacopœia, there still appears to be a lack of trustworthy information upon one point in the process which ought by no means to be overlooked. Recorded observations have hitherto been confined, with scarcely an exception, to the determination of the total alkaloid present in the citrate, without regard to its purity as quinine. That such should have been the case is not, however, surprising, when it is remembered that, until recently, the separation of quinine from some other cinchona alkaloids closely resembling it in their behaviour to certain solvents was a matter of extreme difficulty. But the process described by Dr. Paul, in the valuable paper which he communicated to the Pharmaceutical Society at an Evening Meeting in February, 1877,* may be said to have revolutionized the subject of quinine analysis. In that paper, it will be recollected, the author stated that a sample of sulphate of quinine, containing an admixture of no less than thirty per cent. of sulphate of cinchonidine might, if examined by the Pharmacopœia test, be passed as pure quinine. That this astonishing statement was well grounded, anyone who has since interested himself in quinine analysis can testify. Nor indeed was the possibility of such an extensive adulteration a matter of fancy. Not long since I met with a parcel of German quinine containing over twenty-five per cent. of sulphate of cinchonidine, and the opinions of those most competent to judge, confirm my own experience that from ten to fifteen per cent. of cinchonidine is invariably present in certain brands of foreign quinine.

The question now arises, whether if such sulphate is used in the manufacture of citrate of iron and quinine the Pharmacopœia test will detect the cinchonidine. The reply, as might have been expected, is in the negative. The alkaloid obtained from the citrate in the manner directed in the Pharmacopœia will dissolve in pure ether, even though 25 per cent. of its weight is cinchonidine. But this is not all. The process of extraction of the alkaloid by ether, which has now superseded the characteristically indefinite official test, will not eliminate cinchonidine for the same reason that it fails to do so when applied to sulphate of quinine. It is therefore necessary to have recourse to some other method. The process which I have devised for the purpose, and which I have found to succeed remarkably well, is simply an adaptation of Dr. Paul's plan of fractional crystallization. It is exceedingly easy of application, and although a considerable quantity of the citrate has to be operated upon, there is little or no loss of quinine, most of the alkaloid being recovered as sulphate. It has, moreover, the advantage of combining three operations in one, as the results indicate:—(1) The exact amount of anhydrous alkaloid; (2) The proportion of the latter which can be converted into crystallizable sulphate of quinine; and (3) The percentage of alkaloids other than quinine.

The operations involved are briefly as follows:—Place 20 grms. of the citrate in a 100 c.c. flask, dissolve in 50 c.c. of distilled water, and add gradually an excess of ammonia (·960), shaking well after each addition. This is important, in order that the quinine may separate in a state of fine division, as otherwise it is apt to be thrown out in tough lumps, difficult of subsequent solution. Pour in 25 c.c. of washed ether, and agitate with a rotatory motion till the alkaloid has completely dissolved. Transfer the mixture to a small glass separatory funnel, and having run the lower stratum of liquid back into the flask, pour the ethereal solution into a 100 c.c. platinum capsule. Treat the liquid in the flask with 20 c.c. more ether, and proceed as before. Repeat this operation a third time. The capsule containing the mixed ethereal solutions is then placed in a saucer of water, and the ether blown off by a current of air from a Fletcher's bellows. This immersion of the capsule in water obviates the tendency of the ether to creep up the sides. The platinum dish, which will now contain a pasty residue, is next placed in the air-bath, previously heated to 120°, and in fifteen minutes desiccation is complete. After cooling in an exsiccator, the capsule is covered and removed to the balance. The weight, minus that of the capsule and cover, multiplied by 5, is the percentage of total alkaloid. I may mention that having made many hundreds of analyses by this process, I can testify to the accuracy of the results obtained. In cases where a determination has been repeated, I have never found the results to vary more than 0·1 per cent. When an estimation of total alkaloid only is required, 2 grms. of citrate is a sufficient quantity to operate upon.

The anhydrous alkaloid is now to be converted into basic sulphate. Since a molecule of the latter salt contains 648 parts of quinia to 98 parts of sulphuric acid, and as decinormal sulphuric acid contains 4·9 grms. of H_2SO_4 per litre, it follows that one grm of anhydrous quinia will require 30·86 c.c. of decinormal sulphuric acid to effect its conversion into basic sulphate. The weight of anhydrous alkaloid in grms. is, therefore, multiplied by 30·86, and the number of c.c. of decinormal sulphuric acid thus indicated are run into the platinum capsule from a burette, and the former being placed on wire gauze over the flame of a rose burner, the contents are briskly stirred until the alkaloid is all taken up and a clear solution obtained. This is then transferred to a flask and allowed to cool spontaneously. The crystalline mass which will then have formed is thrown on to a small calico filter, about three inches square, stretched over a beaker, and, when drained, tightly squeezed to remove the last few drops of liquid. The latter is then filtered into a stoppered graduated tube of about 150 c.c. capacity, and its volume noted. 20 c.c. of washed ether and an excess of ammonia are then introduced, and the whole, after being well agitated, is set aside for six hours.

In the meantime the squeezed residue is detached from the calico filter, dried in the air-bath at a temperature of 100 degrees C. and weighed as anhydrous sulphate of quinine $\left\{ (C_{20}H_{24}N_2O_2)_2 \cdot H_2SO_4 = 746 \right\}$. To express the result in terms of ordinary crystallized sulphate $\left\{ (C_{20}H_{24}N_2O_2)_2\ H_2SO_4, 7\tfrac{1}{2}H_2O = 881 \right\}$ the weight found is multiplied by $\left(\frac{881}{746} = \right) 1{\cdot}18$. To this is added the amount of the latter contained in the mother liquor which has been separated (and which may be estimated to contain 1 part in 750), and the total will then represent the proportion of anhydrous alkaloid which can be converted into sulphate.

At the expiration of the time mentioned, the tube which has been set aside is examined, when the cinchonidine and quinidine present will be found to have crystallized out at the junction of the two liquids. The stratum of ether is removed by a small Nessler pipette; the crystals washed with two successive portions of 10 c.c. of ether, the last few drops of which can be absorbed by a little roll of filter paper. The crystals are then thrown upon a double-tared filter, made of two papers weighed one against the other, dried at 120°, and placed on the balance, the outside paper acting as a counterpoise. In practice I find that the weight of this first crop of crystals represents on an average two-thirds of the total cin-

* *Pharm. Journ.*, [3] vol. vii. (1877), p. 653.

chonidine or quinidine present. If, therefore, the amount does not exceed ·1 grm. the percentage of these alkaloids may be estimated to be below 5 per cent. Should the first weighing exceed this limit, the sulphate obtained from the first crystallization must be dissolved in 100 c.c. boiling water, and treated as before, the weight of alkaloid separated by ether being of course added to the amount first obtained.

As thus described the process may seem tedious, but in reality it is not so. Not counting the time which must be allowed for crystallizing, the entire estimation may be completed in something under two hours. The method, of course, does not distinguish between quinidine and cinchonidine, the usual tests for which must be applied to the solution of the mixed sulphates. This, however, is a point of minor importance, as the question of chief interest for the pharmacist is the determination of the exact amount of pure quinine present in the citrate. Two examples will be sufficient to illustrate the working of the process.

A. 20 grms. citrate taken. Yield of anhydrous alkaloid —extracted as above, by ether and dried at 120° C., = 2·67 grms., or 13·35 per cent. The number of c.c. of decinormal sulphuric acid required to convert it into sulphate was therefore (2·673 × 0·86 =) 82·5 c.c. This volume was run in from a burette and the alkaloid dissolved in the manner described. When cool, the filtered mother liquor, which measured 85 c.c., was treated with ether and ammonia. The first crop of crystals of cinchonidine weighed when dry ·113 grm., the second ·06 grm., therefore $\frac{(\cdot113+\cdot06)\times100}{2\cdot67}=6\cdot4$, which represents the percentage of cinchonidine in the total alkaloid. The sulphate obtained in the first crystallization weighed, when dried at 100°, 2·67 grm., or (2·67 × 1·18 =) 3·1 grms. of ordinary crystallized sulphate. On adding to this the amount present in the 85 c.c. mother liquor, which will equal $\frac{85}{750}=\cdot11$ grms., we get (3·1 + ·11 =) 3·21 grms. of sulphate of quinine. The weight of anhydrous alkaloid found by experiment being 2·67 grms. would be equivalent to 3·6 grms. of sulphate; the cinchonidine found represents ·15 grms., so that the crystallizable salt would stand as 3·4 grm. *found* against 3·6 grm. *calculated*, proving the absence of any appreciable amount of amorphous alkaloid.

B. 20 grms. of citrate taken. Yield of anhydrous alkaloid 3·06 grms., or 15·3 per cent. Weight of cinchonidine found, first crystallization, ·120; second, ·065 = $\left(\frac{(\cdot120+\cdot065)\times100}{3\cdot06}\right)$ 6·04 per cent. of the total alkaloid. The hot aqueous solution of the sulphate was sherry-coloured, and the sulphate which separated on cooling was very far from being white. It weighed when dry 2·46 grms., equal to (2·46 × 1·18 =) 2·9 grms. crystallized sulphate. This amount, *plus* ·113 grms., the quantity estimated to be present in 85 c.c. mother liquor, and ·15 grms. allowed for first crop of cinchonidine, gives a total of 3·16 of crystallizable salt. But the weight of anhydrous alkaloid found was 3·06 grms., equivalent to $(3\cdot06\times\frac{881}{648}=)$ 4·16 of crystallized sulphate; the difference of 1 grm. must therefore be considered to be amorphous alkaloid—which would thus constitute over 30 per cent. of the whole.

Whether the presence of 5, 10 or 20 per cent. of cinchonidine would bring a sample of citrate of iron and quinine, which nevertheless answered the B.P. test, within the reach of the Adulteration Act, is a point upon which I offer no opinion. An eminent analyst, with whom I was lately discussing the subject, took the negative view. If such is really the case, a revision of the Pharmacopœia will come none too soon. The plausible excuse which is sometimes set up, that manufacturers cannot perfectly separate the cinchonidine from the quinine except at a greatly enhanced cost, is utterly without foundation. The white sulphate manufactured both by Messrs. Howard and Mr. Whiffen I have never found to give the slightest reaction with Paul's test, and what is a still more striking fact, the so-called unbleached quinine of the latter maker is frequently quite free from cinchonidine. Certain of the foreign makes are also, as a rule, unimpeachable in this respect, whilst on the other hand, some others are systematically adulterated.

It may be worth noting, as a matter of practical interest, that the substitution of 1 per cent. of cinchonidine for quinine, in the manufacture of citrate of iron and quinine. reduces the value ½*d.* per ounce for each such addition; and when it is remembered that the Pharmacopœia test will easily pass 20 per cent. of cinchonidine, and that the consumption of the citrate is considerably over 100,000 ounces per annum, the valuation of this preparation resolves itself from a chemical into a question of commercial interest.

The PRESIDENT said this was one of those useful practical papers the importance of which appealed to them, and as there were practical manufacturers of the article present it would be interesting to hear what they had to say on the subject.

Mr. UMNEY said that the subject of citrate of iron and quinine had for some years been of interest to him. In a paper by himself in the *Pharmaceutical Journal*, August 30, 1873, he endeavoured to show that the Pharmacopœia directions and its test for this salt were written in somewhat of a haze. Those who remembered citrate of iron and quinine in its infancy would bear him out that it was customary for the labels to bear the words "this preparation contains an equivalent of 25 per cent. of sulphate of quinine." Even latterly the same labels have been affixed, but to some the statement "that this preparation contains 16 per cent. of quinia" has been added. The compilers of the Pharmacopœia presumed that from one part of quinine sulphate they would obtain by the formula indicated four parts only of citrate of iron and quinine. Now as a manufacturer he knew that from 100 ounces of sulphate of quinine he could produce 445 to 450 ounces of citrate of iron and quinine. The starting point, therefore, was wrong, and it was absolutely impossible to get a preparation working by that formula that would contain the equivalent of 25 per cent. of sulphate of quinine. This had been pointed out in the *Pharmaceutical Journal*, and he had no doubt some alteration would in the next Pharmacopœia be made in this respect. The Pharmacopœia in directing the precipitation of the alkaloid limited them to the quantity of water. It prescribed that 50 grains should be dissolved in one ounce of water, and that the precipitate when dried should weigh eight grains. They were therefore to infer that it contained 16 per cent. of anhydrous quinia. Now the experiments of Mr. Fletcher would show that citrate of quinine and iron would not give 16 per cent. of anhydrous quinia. To obtain the alkaloid anhydrous they must resort to a temperature of about 225° F., and such heat must be continued for four or five hours, for at 212° F. the precipitate would for hours continue to lose weight. He maintained that the tests in the British Pharmacopœia wanted revising, or one day pharmacists might find themselves landed in great difficulty with gentlemen known as public analysts. It had been given on the authority of a public analyst, in the case Mr. Fletcher had mentioned, that a prosecution would be with a negative result. Another point required modification. Mr. Fletcher had referred to the dissolving of cinchonidine by ether. Had the Pharmacopœia limited the quantity of ether used they might have prescribed the ether test with advantage. The question of the purity of the quinia precipitate was a very important one, for cinchonidine was now largely used, and was unquestionably a valuable remedy. He thought the paper was a most important one, and that the observations on the revision of the Pharmacopœia were not the least important part of it.

Mr. A. H. MASON (Liverpool) said that whilst it was universally admitted that the Pharmacopœia test was faulty, it was quite possible to guard against trouble from public analysts by adding such a quantity of quinine to the formula as shall yield the desired percentage to the Pharmacopœia test, and this plan was now adopted by some manufacturers.

Professor ATTFIELD said it was only fair to the editor of the British Pharmacopœia to say that at the meeting of the Conference in Glasgow that gentleman admitted that the quantitative test for quinine in citrate of iron and quinine was not all that could be desired, and thought that it was important to go a step further so that they might arrive at more accurate results.

Mr. SYMES said it had been shown in Mr. Fletcher's paper and the discussion—indeed, it had become a recognized fact—that the Pharmacopœia process strictly followed did not yield the product it described, and the tests given would not detect a considerable amount of impurity if present. Professor Attfield had stated that in justice to the editor of the work he should say that he was now aware of this. He (Mr. Symes) wished to remark that this being the state of things with regard to so important a preparation, it furnished further evidence of the necessity for a new edition of the Pharmacopœia, and he thought in justice to pharmacists this work ought to be proceeded with in a much more active manner than it appeared to be doing.

The PRESIDENT said he might be pardoned for the reflection that the discussion seemed to indicate how desirable it was that in the re-arrangement of the next Pharmacopœia pharmacists proper should be well represented. He hoped they would join him in a vote of thanks to Mr. Fletcher.

Mr. FLETCHER said he quite agreed with Mr. Umney that the B.P. test was most unsatisfactory, and as a manufacturer he could also endorse Mr. Umney's statement that citrate prepared strictly in accordance with the directions of the Pharmacopœia would not be found to contain 16 per cent. of quinine. With regard to what Mr. Mason had said respecting the 16 per cent. of alkaloid, it should be borne in mind that the Pharmacopœia method of weighing the alkaloid precipitated by ammonia was not intended to give anhydrous quinia. The precipitate was generally regarded as a tri-hydrate, 16 parts of which were equivalent to 13·7 parts of anhydrous quinia. He had verified this experimentally by adopting a slight modification of the process described in the *Pharmaceutical Journal* a few months since by Mr. W. Stevenson. Instead of dissolving the citrate in water he dissolved it in a saturated aqueous solution of quinine, containing a very small quantity of ammonia. The quinine, precipitated in the usual way, was then thrown upon a double tared filter, washed free from iron by a further quantity of the ammoniacal solution of quinine, and the precipitate dried without heat. Proceeding in this way, a sample of citrate which yielded to ether 13·7 per cent. of anhydrous quinia would afford very nearly 16 per cent. of air-dried alkaloid.

Mr. E. DAVIES, F.I.C., sent a paper on "The Estimation of Water in Iodine," which was read by Mr. Benger.

THE ESTIMATION OF WATER IN IODINE.

BY EDWARD DAVIES, F.C.S., F.I.C.

In endeavouring to discover a method for quantitatively determining the moisture in iodine several difficulties had to be overcome, owing to the conditions laid down in the blue list, namely, that the process should be "handy and direct." By the first requirement I understand that it should be performed with such ordinary apparatus as may usually be found in a chemist's shop, that the manipulation should be easy and simple, and that the time should not be very long. The second requirement, strictly construed, is that the water should be weighed, and, so far, I cannot claim to have complied with it. All attempts to retain the iodine whilst the water passed on into an absorption tube were failures. The best was to volatilize the iodine in a current of carbon dioxide over clean iron filings gently heated. The apparatus was troublesome to put together, and practically it was impossible to heat the iron sufficiently to make it absorb the iodine without decomposing some of the water.

I was therefore driven to adopt an indirect method and I think that the following process will answer the purpose satisfactorily:—

It consists in combining the iodine with mercury and weighing the resulting iodide. A small thin porcelain dish, about 2½ inches in diameter and weighing about 250 grains, is fitted with a small glass pestle, made from a piece of solid glass rod, 3 inches long and about $\frac{3}{16}$ thick, by heating one end in the blowpipe flame until soft, and then pressing it on the bottom of the dish so that it may have the same curvature. About 60 grains of dry mercury are put in the dish with the pestle, and the whole accurately weighed. Twenty grains of the iodine are then added and a few drops of absolute alcohol to moisten it. The iodine and mercury are rubbed together until complete combination takes place, which is shown by adding a few more drops of alcohol, and allowing them to flow upon the side of the dish. If there is no free iodine the alcohol remains colourless. The rubbing requires about five or six minutes if much water is present, but only about one minute with dry iodine. The dish and its contents are now dried in a desiccator over sulphuric acid for twelve hours and weighed. The loss of weight of the dish, mercury and iodine, represents the amount of water contained in the iodine.

The residue must be dried at ordinary temperature of the air, as mercury is far too volatile for a temperature of 212° F. to be used.

The iodine used in these experiments was resublimed and dried over sulphuric acid *in vacuo*. The mercury used was the commercial article not quite pure. The following are some of the results obtained, from 60 to 80 grains of mercury being used in each case:—

	1.	2.	3.	4.	5.
Mercury, pestle and dish ..	494·23	509·35	493·21	532·35	522·03
Resublimed Iodine........	20·00	20·00	20·00	30·00	30·00
Water added	5·87	6·86	6·59	7·77	6·29
Total	520·10	536·21	519·80	570·12	558·32
Residue after drying......	514·10	529·20	513·10	562·20	551·90
Water found	6·00	7·01	6·70	7·92	6·42
Excess	·13	·15	·11	·15	·13

As these results showed a constant excess of about ·13 grain, the iodine was examined with a view to ascertain if it contained water which was retained on drying *in vacuo* over sulphuric acid. Two results gave:—

Mercury, pestle and dish .	513·42	509·92
Iodine	20·00	20·00
Total	533·42	529·92
Residue after drying . . .	533·42	529·92

The iodine being thus found to be free from moisture and the mercury also by the same experiment, the only explanation of the excess of loss which I can suggest is, that as five or six times as long is required to bring about the combination when water equal to about 20 per cent. is present, some of the iodine escapes with the alcohol vapour.

The drying was continued for twenty-four hours and in some cases for forty-eight hours, but no perceptible loss was experienced after the first twelve hours.

The trifling excess which would amount at the outside to ½ per cent. in an excessively wet sample, and is absolutely nothing in dry iodine, cannot be considered a great objection to the process. A sample of resublimed iodine purchased in Liverpool contained 0·60 per cent. of moisture. A sample of commercial iodine contained 0·70 per cent.

Professor ATTFIELD remarked that he had made some experiments on the best means of estimating water in iodine, but he had not come to a very satisfactory conclusion. He believed the method adopted by those who used iodine tolerably largely was to expose a given weight of the iodine over sulphuric acid under a small bell-jar at as low a temperature as possible. No great amount of iodine escaped, and the loss suffered by the substance represented the amount of water present. That was a crude method, and he hoped they would arrive at a more exact one on the lines followed by Mr. Davies, namely, to endeavour to find some metal which would at, if necessary, a high temperature, and in large excess, absorb all the iodine, allowing the moisture to pass off in some way or other, and be collected and weighed. Hitherto he had found, that however large the excess of the metal might be, and whatever the amount of affinity of that metal for iodine, a little iodine did escape along with the moisture and gave an inaccurate result. With regard to Mr. Davies's suggested defect in the process followed, namely, that a little of the iodine itself escaped, and caused the percentage of water to appear too high, he thought many samples of iodine would give a loss due to another cause, namely, the presence of sulphuric acid in iodine. This would probably decompose iodide of mercury and form sulphate of mercury, an equivalent amount of iodine previously combined with the mercury passing off.

Mr. E. C. C. STANFORD was surprised to hear this spoken of as a new process. It was one he had adopted for several years; it was first suggested by Bolley, and would be found in Slater's 'Commercial Analysis.' His method was to use eight times the quantity of mercury and to use it dry; they used five times the quantity, and found the process correct to 0·1 per cent. It was also rapid and convenient. Mr. R. R. Talloch, of Glasgow, used zinc, and had kindly sent him the details of the process employed:—Place a weighed quantity of the iodine in a weighed platinum capsule or small basin, in which has been placed a weighed quantity (say twice that of the iodine) of zinc sheet clippings in size about one-eighth of an inch square, add a little water and move the capsule and contents gently about. Immediately the iodine acts upon the zinc, the first small portion of iodide of zinc produced dissolving the free iodine, which is thus presented to the zinc in a dissolved state. The fluid by-and-by becomes colourless, after which the contents are carefully evaporated to dryness, and the dry residue heated till it ceases to lose weight, taking care that no iodide of zinc is volatilized, which, however, is not easy. With the clippings the temperature does not rise beyond control. The dry residue which remains in the capsule is that of the zinc originally added, *plus* that of the dry iodine which has combined with a portion of it.

Professor TICHBORNE had used the process for many years, and he preferred that of drying over sulphuric acid. If a small bell jar was used practically the process became correct, or nearly so; the error in the loss of the iodine would depend in a great measure on the size of the vessel in which the iodine was dried. As regarded the old process in connection with mercury he might suggest that perhaps the best means of performing that would be to use a large excess of mercury, and to do it with a stopper bottle, shaking it up with the addition of alcohol. In that case there would be no loss from the volatilization of the iodine. In such a process as that detailed in the experiment they must make every allowance, and determine separately the presence of bromine, cyanogen, etc.

Mr. FOSTER observed that he had had some little experience in the estimation of iodine, and he had adopted the usual method, that was to expose a weighed quantity of iodine over sulphuric acid to which some iodine had been previously added, observing the precaution of having a very limited atmosphere in the way Professor Tichborne had pointed out. With these precautions he thought the ordinary process met the requirements of manufacturers, buyers and sellers. The other processes, ingenious as they were, scarcely met the requirements of the case.

Mr. DRAPER asked what was the objection to the use of hyposulphite of soda.

Professor ATTFIELD explained that the use of hyposulphite of soda was a very good process when there were no other substances to be estimated.

A vote of thanks was passed to Mr. Davies for his paper.

The next paper read was on—

THE PRESENCE OF TANNIN IN GENTIAN ROOT.

BY EDWARD DAVIES, F.C.S., F.I.C.

The paper on this subject by Professor J. M. Maisch, in the *American Journal of Pharmacy*, 1876, p. 117, would seem to have settled the question of the presence of tannin in gentian root in the negative. The researches of M. Ville, reported in the 'Year-Book of Pharmacy,' 1877, p. 217, on the other hand, are directly contradictory in their result. The subject thus presents some interest, both with regard to the fact itself, and to the reason of the discordant results obtained in such an apparently simple matter. My first experiments were made on a sample of ground gentian root. A hot infusion was first made, but as it was impossible to get this perfectly clear, an infusion was made with cold water. This solution gave negative results; gelatine gave a very faint precipitate after long standing, tartar emetic with chloride of ammonium gave no precipitate, and ferric chloride only produced a slight darkening of the colour.

This appeared decisive, but I thought it better to test some of the unground root. A piece, which probably had been kept some time, was thinly sliced and digested with cold water for two or three days. The solution had a bright yellow colour, and although considerably less material had been used than in the previous one, it gave a decided precipitate with gelatine. I then obtained a quantity of roots as fresh as possible, for which I am indebted to Messrs. Evans, Sons and Co., and made a cold infusion of the sliced root. In the liquid obtained gelatine gave a decided precipitate, acetate of chinchonine a strong precipitate, tartar emetic small precipitate, ferric chloride distinct darkening of colour.

This result was so decided that I made an attempt to obtain an approximate determination of the amount of tannin. Making use of an improvement in volumetric analysis made by Mr. A. Haddock (*Chemical News*, 1879, April 10), consisting in the use of a mirror instead of the usual black glass plate, by means of which the faintest turbidity is shown whilst the effect of colour is eliminated, a drop of the clear solution of the gentian root, 300 grains in 3000 of water, was put on a mirror, a drop of perfectly clear gelatine solution added, and a strong turbidity was produced. By the side of this a drop of a dilute solution of tannin was placed, and gelatine added to it. The tannin solution was diluted until the turbidity in the two drops was apparently identical. In this way the amount of tannin was estimated at 0·08 per cent, two tests agreeing very closely.

It is possible that this trace of tannin is liable to decomposition when the root is powdered and so exposed to oxidation; or that it is not a constant constituent of gentian root. Either of these suggestions, if correct, will explain the discrepancy in the results obtained by competent observers.

The small quantity contained in the root renders its isolation a matter of great difficulty, and until it can be so separated the proof that the tannin in the root is gallotannic acid is only partial. So far as the tests show, they indicate gallotannic acid.

A vote of thanks was accorded to the author.

The next paper was a note on—

Amylic Alcohol and Amylic Nitrite.

BY D. B. DOTT.

It was not my intention to write anything further on the subject of amylic nitrite, but a paper which has appeared in the *American Journal of Pharmacy*, by Dr. W. H. Greene, containing an adverse criticism of my contribution to the work of last year's Conference, almost necessitates some notice on my part. I think I ought to say at the outset that Dr. Greene seems somewhat to have mistaken the nature and scope of my paper. It was intended more as a contribution to pharmacy than as a research in pure chemistry. Be that as it may, however, I have carefully gone over the same ground as last year, with the general result of substantiating what was then said. Dr. Greene's vague allegation of inaccuracy resolves itself on examination into three points, that is to say, I stated erroneously:—

1st. That amylic alcohol may be obtained boiling at 128°—129°.

2nd. That nitrite of amyl does not distil at a constant temperature.

3rd. That nitrite of amyl decomposes when distilled.

As regards the first of these assertions I have now proved its accuracy by more rigorous experiment than was formerly applied. Fusel oil from a large Scotch distillery was rectified at first roughly in a capacious flask, the portion passing over at 125°—135° being retained. This was then distilled from chloride of calcium and repeatedly rectified. No distillate was obtained at so high a temperature as 132°. If any small quantity of that boiling point existed it must have been left behind in the syrupy solution of calcic chloride. It was soon found that the greater part of the above-mentioned fraction distilled at 128°—129°. The portion obtained at these temperatures was rectified at 129°, but even after many distillations it still yielded 2 or 3 per cent., passing over at 128°. This liquid was mixed with caustic baryta and agitated therewith from time to time. After forty-eight hours the alcohol was distilled from fresh portions of baryta, but without any alteration in the boiling point, the calcic chloride having doubtless completely removed the water originally present. The liquid obtained in this way had the characteristic odour of amylic alcohol and possessed the specific gravity of ·814 at 60° F. A quantity of it was oxidized by means of potassic dichromate and sulphuric acid, the alcohol being mixed with the acid and the mixture dropped into the strong aqueous solution of the dichromate. The flask containing the solution was attached to a reversed condenser and the solution gently boiled for two hours, after which the acid was distilled off. The distillate was neutralized with sodic carbonate and evaporated to dryness; the residue mixed with sulphuric acid and distilled. The valeric acid obtained was equal to about 20 per cent. of the alcohol used. The acid was converted into sodium salt, and the solution of the latter mixed with solution of argentic nitrate. The resulting valerate of silver was washed with cold water and dried in exsiccator. By ignition—

6·170 grs. gave	3·195 Ag.	= 51·78	per cent.	
9·035 „ „	4·685 „	= 51·85	„	
	$C_5H_9AgO_2$	= 51·67	„	Ag.

When we consider this result along with the circumstance that the alcohol in question yielded a product by the action of nitrous acid having the well-known properties of amylic nitrite, I think there can be no doubt that the liquid obtained from fusel oil at 129° was amylic alcohol. This is said with all the more confidence that my results agree exactly with those of Alexander Pedler, mentioned in his memoir on the valerianic acids (*Chem. Soc. Journ.* [2], vi., 74). It may be here mentioned that the apparatus used, both in distilling the alcohol and nitrite, was essentially the same as that of Le Bel and Henninger, described and figured in the *Comptes Rendus* (vol. lxxiv., p. 480). It consisted of an ordinary three-bulb condensing tube, with a contraction under each bulb, so that the ascending vapours had to pass through portions of liquid before reaching the condenser.

We come now to the second statement previously referred to, viz.: "That nitrite of amyl does not distil at a constant temperature." I never affirmed that it is impossible to prepare a nitrite of constant boiling point, but simply that I had found it impracticable to purify the medicinal nitrite to such an extent, and that therefore the Pharmacopœia test of a liquid boiling at 96° was one which the commercial nitrite could not reasonably be expected to answer. However, I think I am now in a position to state that even pure amylic nitrite does not distil at a constant temperature, in case it has been prepared from the 128°—129° alcohol. A quantity of the nitrite was prepared by passing the vapours obtained by the action of nitric acid on starch through amylic alcohol (B.P. 128°—129°). After saturation with the gas the liquid was of a bright green colour. It was agitated with water and after being separated therefrom was shaken up with anhydrous sodic carbonate. The product was now quite neutral to test paper and had a specific gravity of ·881. On being distilled it evolved dense red fumes and yielded 78 per cent. between 95° and 100°. This fraction was retained and shaken up thrice with solution of sodic carbonate in successive portions and then with dry carbonate before being rectified. At the commencement of the distillation red vapours were given off and the first portions of distillate were strongly acid. The fraction 95°—98° was retained and re-distilled, the portion coming over at 96°—97° being collected apart. Very little was obtained at 96°, the greater part distilling between 96° and 97°. Can it be that the nitrites corresponding to the 128° and 129° alcohols boil at 96° and at 97°? After twelve rectifications the nitrite had diminished to 20 per cent. of the original product and even then did not distil entirely at 96°—97°, the last three rectifications showing no increase in the percentage of the correct fraction. When this result is considered along with the fact that the amylic alcohol had been rectified sixteen times, it will surely be admitted that it is not easy to obtain an amylic nitrite of nearly constant boiling point, and that such a process is out of the question for a pharmaceutical preparation.

Regarding the third statement, "That nitrite of amyl decomposes when distilled," I certainly think that a very fair inference from the phenomena observed. If a liquid which has been washed with an alkaline solution until quite neutral to litmus be distilled, and the distillate is strongly acid, it is manifest that decomposition has occurred; and this is just what takes place with amylic nitrite, at least with as pure a preparation as I have examined. In the twelfth rectification red fumes were evolved as at first. Of course it is open to anyone to say that some impurity may persistently adhere to the nitrite, which former, by its decomposition under the influence of heat, may evolve nitrous vapours. That may be quite within the bounds of possibility, though I do not think it is probable; but even supposing it to be the case, it only confirms my original assertion, which obviously referred to medicinal nitrite of amyl obtained at 90°—100°, and not to a compound which (as then stated) I had never seen.

The President said the paper was a refutation of the charges brought against the author, and it struck him that Mr. Dott had succeeded in perfectly establishing his case.

Mr. Williams said he could to a great extent confirm the statements in the paper. In making nitrite of amy he had had considerable experience in one or two of the points, and the fact of its decomposition by constant distillation he could quite confirm. With respect, however, to the statement concerning amyl alcohol, he thought there could be no question that it had a constant boiling point. A paper read a year ago contained another point which he should like to refer to, and that was that nitrite of amyl might have a higher boiling point than that given in the Pharmacopœia and still be a justifiable and good pharmaceutical product for use; but he did not agree with that, and thought that as the higher boiling point might be due to the presence of other bodies like nitrite of caproyl, the nitrite of amyl used in medicine ought not to have a higher boiling point than that indicated in the Pharmacopœia.

Professor TICHBORNE also bore testimony to decomposition of nitrite of amyl in distillation.

Mr. ABRAHAM said in these experiments one or two degrees of boiling point were matter of considerable importance. Did the experimentalists take cognizance of the variation in barometric pressure, for half an inch would make about one degree variation in the boiling point?

Mr. MACKENZIE asked if nitrite of amyl became decomposed with keeping.

Mr. WILLIAMS thought perhaps it would keep any length of time if properly preserved; still it was questionable whether it was as good at the end of twelve months as at the end of one.

Mr. NAYLOR maintained that it could not be kept for any great length of time, and that he had known it turn acid when kept at a low temperature.

In reply to Mr. Williams, it was admitted by Mr. Naylor that the specimen spoken of had not been redistilled.

A vote of thanks was passed to Mr. Dott for his paper.

The following paper was then read on:—

THE GELATINIZATION OF TINCTURE OF KINO WITH A POSSIBLE REMEDY FOR ITS PREVENTION.

BY THOS. H. BAMFORD.

One of the very first subjects discussed at the evening meetings of the Pharmaceutical Society on its institution, was the gelatinization of tincture of kino, introduced by Dr. Redwood, and the general opinion expressed was, that this tincture kept best in small corked bottles in preference to large stoppered and partially filled bottles. However this may be, it has always been a source of trouble to the dispenser, which would be greatly aggravated if the tincture were a more popular one with prescribers.

In the majority of establishments, along with other seldom used preparations, it lies on a shelf in some out of the way place, and on the second or third occasion of its being required, it is usually found to have become consolidated into a stiffish, translucent, pinkish jelly, very elegant in appearance, bearing as it does a tolerable resemblance to red currant jelly, but altogether useless as a medicine. Then, if the dispenser be inexperienced and unaccustomed to this phenomenon, he begins a series of experiments in the hope of inducing the fickle tincture to resume its normal condition; the agency of heat and the addition of more spirit will sometimes induce it to leave the bottle, but hardly in a state of solution, and in this condition it should never be used by the conscientious pharmacist, since it would altogether fail in its action on the patient, as in passing into the gelatinous condition it likewise loses its astringency.

Pereira, in the article on kino in his 'Materia Medica,' dismisses the fact in a brief sentence, and accounts for it as follows:—"It is said that by keeping this tincture has, in some instances, become gelatinous and lost its astringency. Where this occurred, probably the Botany Bay kino (the inspissated juice of the *Eucalyptus resinfera*) had been employed."

It is doubtful whether the use of inferior specimens of kino will account for the deterioration of the tincture, as I have seen samples of all kinds, made expressly and kept under what were supposed to be the most auspicious circumstances, fail entirely as regards their keeping qualities, and the experience of any practical dispenser will bear out the statement that nine out of ten tinctures of this gum will pass into the gelatinous condition with more or less rapidity.

In the *Pharmaceutical Journal* for 1842, is the above named paper, entitled, "The Gelatinization of Tincture of Kino," and in this Dr. Redwood states as his opinion that the change is dependent on the conversion of the tannin into a partially insoluble substance, ulmic acid, and in the discussion which took place after the reading of the paper, a general opinion was expressed that this change was expedited by the contact of atmospheric air in partially filled bottles. Messrs. Bell, Morson, Ince, and other well-known pharmacists took part in the discussion, and the general opinion seemed to be that to its storage rather than preparation were we to look for the means of combating its unfortunate peculiarity. A somewhat protracted acquaintance with a sample kept in an unusual manner convinced me that I had at last seen a perfect panacea for this failing. The sample in question has now been kept in its present position (this is written from notes made in 1876), about twelve or fourteen years, and is to all appearances as good as on the day it was received into stock. It was placed in an ordinary quart stoppered round, in such a position that it was necessarily taken up and dusted every morning, and consequently was well shaken every twenty-four hours; the bottle was likewise covered with blue paper so as to perfectly exclude the light. The bottle was never full (possibly now there are 8 ounces in a 40 ounce bottle), so that it has always been in contact with air. When it is stated that it was procured from a London drug house, some time between 1862 and 1864, and has been in its present position since that time, all that is known of its history has been told. My advice to any druggist who has been troubled with this tincture is to remove his stock of it into a position where it must necessarily get a daily shaking (that is amongst the bottles which are dusted daily), and also coat the bottle with blue paper.

As during fifteen years' experience this is the only tincture of kino I have seen keep for twelve months, I am convinced that I have brought a remedy to the notice of the British pharmacist.

P.S. (1879).—The experience above recorded has received strong confirmation from the fact that a fresh supply was obtained three years ago from a local (Liverpool) house and turned into the same bottle, and remains to this present day in as good a condition as on the day of its reception into stock.

Mr. UMNEY thought before this question could be finally settled, experimenters must operate upon authentic specimens of kino. They had three distinct varieties that occasionally appeared in commerce. The official kino, the product of *Pterocarpus marsupium*, of the East Indies, the kino from *Pterocarpus erinaceus*, and the Australian or eucalyptus kino, from the *Eucalyptus resinifera*. (See Hanbury's 'Pharmacographia.') Anyone in the habit of visiting the drug warehouses of London where these imports were shown previous to sale was able, after a little practice, to distinguish one kino from another by tasting and observing the effect upon the palate and saliva.

Mr. MACKENZIE said he had had great experience in the use of kino, and he had no faith whatever in shaking it.

Mr. MARTINDALE was of opinion that much depended upon the age of the kino as to whether it was astringent or not.

Mr. COTTRELL paid the London houses a high compliment for great intelligence and probity, but expressed the opinion that some of the samples of kino sent out were not perfectly pure.

Mr. Benger referred to a paper read by Mr. George Ellinor at the Bradford meeting of the Conference in 1873, in which a liquor was recommended as a substitute for tincture of kino. If he remembered rightly Mr. Groves on that occasion expressed the opinion that old kino yielded a tincture liable to pectization, whilst that which was fresh did not.

Mr. Long thought the subject of tincture of kino a very interesting one. From the immense range of remedies they had to contend with, there were difficulties in keeping all their preparations in a proper state unless they had a very large practice, and he thought as new remedies were introduced that old and useless remedies should be knocked out.

Mr. Hasselby said he had been familiar with kino for twenty-five years and only recently had he seen a specimen of it gelatinized.

Mr. Greenish said in a paper on this subject introduced nearly forty years ago by Professor Redwood the same difficulties presented themselves as now had to be contended with. He hoped it would occupy a place upon the blue paper of the Conference, and that some pharmacist capable of undertaking the subject would ascertain whether gelatinization depended upon a particular kino or upon the age of the kino.

Mr. Chipperfield said he had never known any tincture of kino that had not gelatinized sooner or later, from the fact he supposed that it had been kept a somewhat unusually long time.

Mr. T. F. Abraham stated that he had known tincture of kino for fifteen years, and he had never seen it gelatinize. The only difficulty he had had with it was that it wedged the stoppers of the bottles. To provide for this in their establishment there were two bottles, one a standard bottle which was placed on the ordinary shelves and with the other bottles, dusted and consequently shaken once a week, and another a bottle which was kept in the back part of the shop and which was shaken perhaps not once in two months. The contents of both bottles were made at the same time from the same variety of kino and both kept equally well. The gentleman whose paper they had listened to, before he sugested remedies should have been quite sure that what he used was really B.P. tincture of kino.

Mr. Preston stated that their tincture of kino had gelatinized once in seventeen years, and he believed that was caused by the stopper of the bottle having become a little loose.

Mr. Robbins had known tincture of kino for some time and only once had he known it gelatinize.

Mr. Savage gave his experience with the tincture, which was to the effect that at one establishment it had gelatinized, and at the other it had not, but had kept exceedingly well. The little that had gelatinized had been put carefully away in a cupboard; the one that had kept well had been exposed to the light and dusted every day.

Mr. Ellinor said he had ordered kino from different houses and the tincture made from some of them would gelatinize, and that made from others would not. That which tinged saliva was the best kind and it never gelatinized as far as his experience went. He had, in a paper read at Bradford, recommended the substitution of a liquor containing glycerine in the place of the tincture, the object of which was, as far as possible, to avoid the use of spirit, but he had somewhat modified his opinion in consequence of Mr. Brady having then pointed out the extraordinary extent to which glycerine sometimes affected the characteristic property of astringents. He had observed in the Journal two recommendations for the use of glycerine in preparing the tincture, one preferring double the quantity of glycerine to be added to the other, but he thought they should be careful before altering a Pharmacopœia formula. If necessary at all to add glycerine the smallest possible quantity to effect the object should be ascertained.

Dr. Symes remarked that he had only met with tincture of kino that had gelatinized once, and he did not believe its gelatinization was so common as was generally supposed. Mr. Bamford had suggested a remedy in the keeping rather than in the preparation, but his own opinion was that the real remedy was in the preparation itself. The addition of a small quantity of glycerine appeared to be effectual, but it remained to be proved whether it affected prejudicially the astringency of the tincture.

Mr. Lee said he had known tincture of kino to keep for years in a fluid transparent condition when exposed to a strong light and frequently removed.

The President, in presenting the thanks of the Conference to Mr. Bamford for his paper, said it was his opinion that the remedy lay not so much in the management of the preparation as in the selection of the material of which it was composed.

The Conference then adjourned for luncheon and upon resuming the first paper read was—

Anhydrous Air as a Therapeutic Agent.

BY G. A. KEYWORTH, F.C.S.

Some time since my attention was drawn to the great pain and inconvenience caused by tension in various morbid conditions. It occurred to me that air artificially dried and heated and so made an energetic absorbent of moisture would give relief by causing shrinking of the parts. This I found to be the case. Frequent opportunities were presented of observing this effect upon a cancerous growth affecting the hand, with moist fetid surface. The jet was applied for an hour in the evening and caused cessation of pain for some eight hours, ensuring a good night's rest. After the application the surface presented a dried, shrivelled appearance. The loss of pain and stiffness was well marked and repeatedly verified. Anhydrous air as a mechanical anodyne may therefore prove a useful addition to the therapeutic armoury. The medical practitioner may see fit to apply it to gouty and edematous swellings, to inflamed surfaces, to indolent ulcers and intractable wounds with a view to promote healing by desiccation, and to various tumours and cancerous growths to relieve the pain and if possible check their increase. The apparatus I employed consisted of an eprouvette of glass, containing fragments of calcic chloride, through which large volumes of air were driven by means of a foot bellows of the Fletcher type. The exit end of the eprouvette was connected by india-rubber tubing with an iron tube 3 feet in length, with a diameter of ½ an inch, having a spirit lamp burning beneath the centre, and a piece of india-rubber tubing attached to the extremity for the purpose of applying the current. In this manner a stream of dried air heated to 100° F. could be maintained. A plug of cotton wool inserted within the entrance tube to the eprouvette acts as a filter when the jet is applied to unsound skin. The air might (if desirable) be impregnated with carbolic acid or other volatile substance by introducing a portion with the wool. Large volumes of air must be used and for a considerable time (sometimes several hours) in order to produce sensible effects. If the process should be found useful in medical practice dispensing chemists will probably be called upon to supply the apparatus on hire. An economical form of it will be supplied by the usual dealers in pharmaceutical apparatus. If used in hospitals on a large scale, a small gas engine or hydraulic motor could be adjusted in order to drive large bellows or a fan wheel, the eprouvette being of increased dimensions and the spirit lamp replaced by a Bunsen flame. The addition of india-rubber gas bags and pressure boards or other methods of compression can be made if increased force to the jet is required. It may be remembered that warm dry air has long been observed to promote, and cold air o retard the healing of wounds. Anhydrous air, though not a caustic in the usual sense, shares with such substances a certain power of disintegration by its affinity for moisture. The Michel process, introduced in Paris for removing tumours, consisted in the application of a paste of asbestos and sulphuric acid, the latter effecting destruction by absorbing moisture. Caustic potash, soda and lime act in the same manner.

The effect of nitric acid is due partly to this and to its power of oxidation. Anhydrous air is, however, free from the dangers and objections which attach to the use of these energetic chemical agents.

Mr. Keyworth's paper was read by Mr. Benger.

There was no discussion on this paper, and a vote of thanks was awarded to the writer.

The next paper was on—

Saponine from the Bark of Quillaia Saponaria.

BY H. COLLIER,

Teacher of Pharmacy at Guy's Hospital.

One of the subjects on the list of the Pharmaceutical Conference for investigation is Quillaia bark, its chemical composition, properties and uses. This bark had been under my notice for some time before the issue of this list, but as my chief aim has been to determine more precisely the nature of the saponaceous principle which it contains, I have adopted the above title for my paper. I have been assisted in my endeavours by my friend, Mr. Scard, F.C.S., chemical assistant to Dr. Pavy, F.R.S., Guy's Hospital, to whose practical chemical knowledge I am indebted for the various analyses of saponine which I am able to lay before you. I have by no means exhausted the subject; in fact, what I have to say must not be regarded as a complete investigation of saponine. I have obtained some results which may be looked upon as so many steps of progress towards the goal, but nevertheless there remain many points which are still obscure.

A principle which makes a froth with water, similar to that formed by ordinary soap, is very widely diffused throughout the vegetable kingdom. Although generally known as saponine, from its original source, *Saponaria officinalis*, it has other names according to the plant from which it is obtained. All these saponaceous principles may be one and the same substance modified perhaps by the impurities belonging to its extraction. Saponine has been the object of numerous investigations, but most discordant results have been published respecting it by different experimenters. Thus Bussy, Henry, Plisson and Overbeck state it to be a white non-crystalline friable powder. Rochleder and Schwartz that it is colourless, and Quevenne that it is yellowish white. Again, according to Henry and Plisson it is inodorous, whilst Quevenne asserts that it has a peculiar aromatic odour, and Sharling that the aqueous solution has a repulsive odour. There is also a great difference in the formulas assigned to saponine. According to Rochleder and Schwartz it is $C_{24}H_{40}O_{14}$, Overbeck $C_{42}H_{76}O_{30}$, and Bolley $C_{36}H_{56}O_{24}$. Before proceeding any further with the consideration of saponine, I think it will be well to say a few words respecting the source, character and microscopic appearance of quillaia bark. The following description is from the 'Treasury of Botany,' part ii., 952:—"Quillaia saponaria, quillaia or cullay of the Chilians, is a tree from 50 to 60 feet high, with smooth, shining, short stalked, oval leaves and usually terminal white flowers. Its bark, called quillaia or soap bark, is rough or dark coloured externally, but consisting of numerous regular whitish or yellowish layers, and contains a large quantity of carbonate of lime and other mineral matters. It is rich in saponine, a vegetable soap principle, and on this account it is commonly used as a substitute for washing clothes, two ounces of the bark being sufficient to wash a dress. It is also said to remove all spots or stains, and to impart a remarkable lustre to wool, and it is used to wash the hair, for which purpose it is powdered between stones, then rubbed with the hands in water, making a foam like soap." The cortex quillaiæ which I have examined consisted of heavy flat or slightly curved pieces varying in size from 1 to 4 feet in length, 4 to 8 inches in breadth, and from a ¼ to ½ an inch in thickness. The outer bark had been removed; there were, however, a few scattered pieces still remaining. Le Bœuf, who described the colour of the tincture he obtained as "d'une couleur orangée foncée," no doubt employed the bark without removing the remaining outside portions. Now this is an important matter, as this outer bark contains a colouring principle which contaminates the saponine. In all my experiments I have operated upon a bark from which every portion of outside layer had been removed by planing and the use of the chisel. The tincture from this is of a pale yellow colour. It is not difficult to reduce the bark to coarse powder, if it is thoroughly dry, but if exposed to the air it absorbs moisture, and although it may easily be separated into layers, it is not friable. It is rather an unpleasant substance to powder, the fine dust which arises causing a great amount of coughing and sneezing. Examined by the microscope an opaque longitudinal section of the bark with one inch object glass and oblique light gives a general view of the woody tissue, upon and among which lie large crystals of what are undoubtedly oxalate of calcium, as they are unaffected by acetic acid, but are dissolved without any effervescence by hydrochloric. A longitudinal transparent section, part of which is stained with aniline, shows principally the woody fibre with crystals lying about. In the coloured section some cellular tissue may be observed, and a few resinoid looking bodies of a brown colour. I have one section here which is made in a part where the resinoid bodies are chiefly deposited. These are somewhat of an oval form, and I have every reason to believe they consist of saponine with impurities, giving them a brown colour. The bark ignites very readily, and during combustion gives off an aromatic odour somewhat resembling cedar wood. It yields 11·8 per cent. of ash which consists chiefly of calcium carbonate; there is also a trace of iron.

Henry and Boutron-Charland were, I believe, the first who investigated quillaia bark and separated its saponaceous matter, which they described as an acrid principle. The method they adopted was to boil the aqueous extract with water, filter at the boiling heat, and the saponine which fell down on cooling and concentration was purified by solution in alcohol with aid of animal charcoal. I have prepared saponine by this method, but I was unable to obtain it pure; it would persistently remain brown after all treatment. The best process is that of Le Bœuf, which consists in boiling the bark with 84 per cent. alcohol, filtering at the boiling point, and upon cooling the saponine deposits. It is purified by washing with alcohol and ether. The principle of the above process is that saponine is more soluble in boiling rectified spirit than in cold, so that the excess deposits upon cooling, leaving above a saturated solution of saponine with colouring and other matters. This tincture upon evaporation yields 2·24 per cent. of solid residue. The first saponine I obtained by this process, after thorough washing with alcohol and ether and drying over a water-bath, was a white friable amorphous mass. There were some portions however which were not white but of a decided brown colour, and there appeared an oily stain upon the filter paper round the edge of the saponine. I found it to be very soluble in water, but ether, chloroform, benzol, carbon bisulphide appeared to have no effect in dissolving it. A portion heated on platinum foil burnt very easily, and a white ash remained. This was insoluble in water, but dissolved at once with considerable effervescence in hydrochloric acid. A platinum wire dipped into this solution and held in the flame of a Bunsen burner produced a very well marked red colour. The acid solution neutralized with liq. ammoniæ gave on the addition of ammonium oxalate a white precipitate insoluble in acetic but dissolved by hydrochloric acid. An examination for other bodies gave negative results so, that the ash of saponine is composed entirely of calcium carbonate. Now Bolley's saponine contained 1 per cent. of ash, and one sample examined by Rochleder and Schwartz contained 4·3 per cent. These investigators are I believe the only persons who mention anything about an ash. This discovery of the fact that my saponine contained an ash was the result of a preliminary examination before submitting it to analysis; it was therefore necessary to obtain the amount before proceeding. The plan adopted was to ignite the saponine in a platinum dish; when the carbonaceous residue had become quite white it was cooled and moistened with solution of ammonium carbonate, evaporated to dryness and again heated gently to expel excess of ammonia. The ash was thus weighed as carbonate: ·49 of saponine yielded ·0195 of ash carbonated as described, which gave 3·979 per cent. I could not regard this saponine as a pure substance. It had been most carefully prepared according to the process given by Le Bœuf, but the oily stain on the filter paper upon which the saponine had been dried, and the brownish tinge of some of it were so many indications of impurities. It was necessary for me, therefore, to endeavour to ascertain what was the nature of the impurities associated with saponine, and if possible to obtain a pure specimen in order to determine the formula of it.

I have worked upon three different lots of bark obtained at various periods, and the saponine prepared from all of them upon ignition left an ash consisting of calcium carbonate:—

Saponine from	1st bark	3·979	per cent.	of ash.
„	2nd „	3·904	„	„
„	3rd „	3·843	„	„

The saponine prepared by boiling watery extract of bark with rectified spirit and deposition on cooling contained 4·37 per cent. of ash.

It is a question in what state the calcium exists in saponine; from its mode of extraction and after treatment it is hardly possible to suppose that the calcium oxalate existing in the bark had been dissolved out with the saponine, and then appeared in the ash as carbonate. The fact that the saponine from different specimens of bark should yield such nearly equal amounts of ash is very strong evidence that saponine from quillaia bark is a calcium salt. I have endeavoured to obtain saponine free from calcium, but up to the present time I have failed to do so. It is stated by Rochleder and V. Payr that baryta water added to a strong watery solution of saponine precipitates saponine-baryta, and that the white precipitate washed with baryta water, dissolved in water and then CO_2 passed through the solution gives carbonate of baryta which separates out, and after its removal the saponine may be precipitated by ether-alcohol. My saponine threw down a brown gelatinous precipitate with the baryta; which did not appear to dissolve in water, and CO_2 produced no effect in the filtrate from the digestion of the barium precipitate. I next tried precipitating a watery solution of saponine with neutral acetate of lead; the precipitate, which was a very gelatinous one, after washing was dissolved in water and a current of sulphuretted hydrogen passed through the solution for several hours. No precipitate was produced but simply a black coloured liquid which upon dilution with water formed a clear dark brown solution. Afterwards to a similar solution of saponine in water I added oxalic acid until the liquid was distinctly acid. It was then laid aside for several days by which time the bottom of the beaker was covered with a white precipitate of calcium oxalate. The clear supernatant liquid was decanted and then neutralized with barium carbonate. It was impossible to filter quite bright and so it was allowed to remain for a week. At the end of that time the clear upper liquid, which I hoped was nothing but saponine in solution, was drawn off and carefully evaporated to dryness; the result was a brown amorphous mass, which upon ignition left some amount of ash in which barium was present. I next turned my attention to an examination of the tincture from which the saponine had been deposited upon cooling. I considered, that as this tincture was only a solution of impure saponine, a knowledge of its composition might suggest the purification of the saponine. The tincture evaporated over a water-bath left a soft reddish-brown sticky extract. This was digested with washed ether for some days; by this treatment it lost much of its colour but still retained its tenacious character. The ethereal solution was of a yellow colour, and when mixed with water became opaque, and after a short time a fatty matter appeared adhering to the sides of the tube. If hydrochloric acid instead of water were employed, the fatty substance at once separated in the form of distinct lumps floating on the surface of the liquid. These were not dissolved on the addition of alcohol, and no change of colour was produced by the application of heat to the alcoholic mixture. Upon evaporating the ethereal solution a soft oily substance remained, which imparted a permanent greasy stain to white paper; it was insoluble in water and alcohol, but readily dissolved by benzol. It was unaffected by alkalies or diluted acids. A similar oily matter may be obtained by adding tincture quillaia to water acidulated with hydrochloric acid. After standing for some time a yellowish precipitate separates which collected upon a filter and well washed with water dissolves entirely in ether and this solution upon evaporation gives this oily residue. If washed ether be added to the tincture this oily principle is also precipitated together with saponine. In this case the precipitate after being well washed with rectified spirit and then dried over a water-bath is resolved into an oily fluid which soaks through the filter. The extract after being treated with ether as above was then digested with absolute alcohol for a week; at the end of this time the alcohol had acquired a reddish-brown tint and the extract had become a grey amorphous powder entirely devoid of stickiness. The alcoholic solution acidified with hydrochloric acid and then heated became of a cherry-red colour, which was changed to a dark olive green by alkalies and restored again upon the addition of acid. The residual extract treated with water dissolved entirely and appeared to be only impure saponine. I had thus acquired two facts, that the impurities present in precipitated saponine were an oily matter soluble in ether, and a colouring principle soluble in alcohol. It would be necessary therefore only to treat with alcohol and ether in order to obtain pure saponine. But this had been the method of purification always adopted and I have never obtained saponine without a marked oily stain upon the filter paper and more or less brown colour. I tried digestion with alcohol and ether for several days, but the product was still impure. At last after numerous experiments I found that by boiling the saponine in rectified spirit, filtering at a boiling heat, allowing the precipitate to settle by cooling, and digesting this in absolute alcohol and ether, that a very much whiter product was the result: it still, however, gave a red colour when heated with rectified spirit and hydrochloric acid. The saponine of which the analysis is given was purified as above, but the solution, deposition, and digestion were repeated a second time. It was a white amorphous substance, and the filter upon which it had been dried presented no appearance of any oily stain, and dissolved in rectified spirit, and acidified with hydrochloric acid, upon heating no red colour was produced. I thus believed it to be a perfectly pure specimen of quillaia bark saponine. It contained 4·13 per cent. of ash, which is higher than that yielded by the other saponines prepared in a similar manner, but not subjected to so thorough a process of purification. Now the saponine obtained from the watery extract gave 4·37 per cent. of ash which corresponds more closely to the amount obtained from purified saponine. I can say in explanation of this that the last sample being free from oily matter would yield a higher percentage of ash, and that the product from the watery extract probably contained no oil, as this is not soluble in water, so that its ash approaches more closely that of pure saponine.

The absence of this oily impurity made a perceptible difference in the amount of carbon contained in the last sample of saponine compared with the first in which it was present. Now this has an important bearing, for the amount of carbon contained in the first saponine I prepared and submitted to analysis was 49·31 per cent. and this corresponds closely to the amount given in the published analyses: thus—

Rochleder and Schwartz . . .	52·17 per cent.
Overbeck	47·54 ,,
Bolley	49·54 ,,
Rochleder and V. Payr . . .	52·97 ,,
Bussy	50·00 ,,

It is therefore very probable that these saponines containing such a high amount of carbon were not pure and that the different results are owing to various degrees of purity of the sample examined.

The following is the result of the analysis of purified saponine.

	Calculated from formula $(C_9H_{22}O_7)_{10}CaO$.	Found.
C	43·63	43·51
H	8·88	8·88
O	45·23	45·30
CaO	2·26	2·31
	100·00	100·00

Deducting the CaO the percentage composition runs as follows:—

C	44·53
H	9·09
O	46·38
	100·00

Corresponding to the formula $C_9H_{22}O_7$ which requires—

C	44·62
H	9·09
O	46·29
	100·00

Considering the large number of atoms in combination with one of lime it may be inferred that the lime is simply united with the saponine and that it does not displace any hydrogen or compound radical, therefore, we should be justified in calculating the formula for saponine in deducting the lime found, and recalculating the percentage proportion. In fact, it may be assumed that saponine has a similar structure to that of arabine, which is said to be a calcium salt.

Another paper read by the same author was—

Tincture of Quillaia as an Emulsifying Agent.

BY HENRY COLLIER,

Teacher of Pharmacy at Guy's Hospital.

I now pass on to a consideration of the use of a tincture of the bark of *Quillaia saponaria* for the preparation of emulsions. The tincture which has been employed in the preparation of the various mixtures upon the table has been made according to the following formula, which is taken from Guy's Hospital Pharmacopœia:—

Quillaia Bark, in coarse powder .	4 oz.
Rectified Spirit of Wine	1 pint.

Digest for three days and then strain.

The bark before powdering is carefully freed from all remains of outside layer, and the tincture produced is of a pale yellow colour.

Into this bottle I have put some mercury and shaken it up with tincture of quillaia, the result is that the mercury has been reduced to a very fine state of division. It has very much the appearance of hyd. c. creta, and examined with a lens it is seen to be composed of distinct globules of mercury. So long as there is some tincture present this division of the metal remains; if it be dried, it at once runs together and appears in its ordinary liquid state. This is a remarkable power which tinct. quillaiæ possesses of destroying the cohesion between the globules of mercury, breaking them up and preventing them from uniting together, and it is this property which renders it so valuable an emulsifying agent.

A true emulsion consists, as is well known, of a number of oily or resinous particles floating about in a watery liquid by means of some agent which prevents them from cohering. To be perfect the emulsion should have a milky appearance, and the suspended particles should not subside or rise too rapidly. In the British Pharmacopœia there is a preparation containing mercury in a very fine state of division, and which is in fact an emulsion containing mercury finely divided. The preparation I mean is the *Linimentum Hydrargyri*, which Squire says "should be a lead-coloured cream, but is curds and whey." By using tinct. quillaiæ a lead-coloured cream may be formed which does not turn to curds and whey. The preparation here contains the same proportion of active ingredients as is ordered in the Pharmacopœia; if left undisturbed for some time the ung. hydrargyri settles to the bottom, but a vigorous shaking blends it again perfectly. The following is the formula:—

Lin. Camph.	℥j.
Tinct. Quillaiæ	℥iij.
(Liq. Amm. Fort. ℥ij, ♏ 40 Aq. ad).	℥v.
Ung. Hydrarg.	1 oz.

M.

Chloroform is made into an excellent emulsion by means of this tincture.

Chloroform	♏x.
Tinct. Quillaiæ	ʒj.
Aq. Destil. . . . . ad	ʒj.

Misce.

Although chloroform is such a heavy liquid, yet it remains suspended for some minutes after shaking. It finally settles as a creamy layer at the bottom of the bottle. A solution of saponine in water shaken with chloroform converts it into a thick creamy fluid; the water separates, but the chloroform permanently retains its creamy character.

Here is a mixture of castor oil made according to the following formula:—

Ol. Ricini	℥ss.
Tinct. Quillaiæ	ʒss.
Aq. . . . . ad	ʒj.

The tincture is first put into the bottle, afterwards the oil, and shaken together, then the water is added and again shaken. The emulsion thus formed resembles its prototype milk in appearance and like it separates after the lapse of some time into a cream at the top, which mixes again upon agitation. Emulsions prepared in a similar manner of oleum morrhuæ and oleum olivæ are of as perfect a character.

Ext. Filicis Liquid.	ʒj.
Tinct. Quillaiæ	ʒss.
Aq. Destil. . . . . ad	ʒj.

Misce.

This forms an excellent emulsion, and with the addition of syrup zingiberis ʒss constitutes the Mistura Filicis Maris of Guy's Hospital.

Copaibæ	ʒss.
Tinct. Quillaiæ	ʒss.
Aq. Destil. . . . . ad	ʒj.

Misce.

The copaiba in this mixture is perfectly emulsified.

Here is an example of an essential oil.

Ol. Terebinth.		♏xx.
Tinct. Quillaiæ		♏xx.
Aq. Destil.	ad	℥j.

Misce.

This formula, with the addition of tinct. limonis, is the mistura terebinthinæ (Guy's).

I have found that resinous tinctures require more than their bulk of tinct. quillaiæ to prevent any separation of resin.

Tinct. Tolut.		♏40.
Tinct. Quillaiæ		ʒj.
Aq. Destil.	ad	℥j.

Misce.

The resin deposits after some time, but upon shaking it is easily diffused.

This mixture contains the soluble matter of 12 grains of guaiacum resin in every fluid ounce, so that it is about the same strength as mist. guaiaci, B.P. The following is the formula:—

Resin Guaiaci		gr. xij.
Tinct. Quillaiæ		ʒj.
Aq. Destil.	ad	℥j.

Dissolve the guaiacum in the tincture, filter, and then mix with the water.

Resin of copaiba is largely used at Guy's Hospital where it is considered a valuable diuretic. It does not appear to me to make so perfect a mixture with tinct. quillaiæ as the hospital formula with pulv. tragacanth co. The liquid is not thick enough to prevent the resin separating too rapidly. Here are mixtures of copaiba resin made after the following formulas:—

Mist. Resinæ Copaibæ (*Guy's*).

Resin of Copaiba	15 grains
Rectified Spt. of Wine	20 minims
Compound Powder of Traganth.	15 grains.
Syrup of Ginger	1 fl. dr.
Distilled Water to	1 fl. oz.

Misce.

The resin and spirit are put into an evaporating dish and blended together by heating over a water-bath; then poured into a mortar containing the pulv. tragacanth co. previously made into a thick mucilage with a little of the water and well rubbed together, the syrup and the remainder of the water being gradually added.

Resinæ Copaibæ		gr. xv.
Tinct. Quillaiæ		ʒj.
Aq. Destilat.	ad	℥j.

The resin is dissolved in the tincture and the water gradually added with agitation.

Bals. Peru.		♏ xv.
Tinct. Quillaiæ		ʒj.
Aq. Distil.	ad	℥j.

This mixture is open to the same objection—the balsam subsides too rapidly. The above quantity of balsam with gr. xv. of pulv. tragacanth co. gives an excellent result.

I have now placed before you examples of emulsions of the various substances which are administered in that form, and I have no doubt but that you will agree with me that tincture of quillaia is worthy of a place in pharmacy for the preparation of this class of medicines.

Mr. Benger asked Mr. Collier if the taste of the tincture of quillaia was not sometimes objectionable.

Mr. Reynolds said he should like to extend the question put by Mr. Benger. The use of quillaia bark for these necessary purposes of pharmacy would divide itself into two sections:—Its use for external and its use for internal purposes. The question of physiological action and questionable taste might be taken as parts of the same subject. He would like to inquire if there were any other instances than the use of the male fern oil emulsion for which Guy's Hospital would reccommend the use of quillaia in an internal application, and if they were to understand that the half drachm dose containing 6 grains of bark was the maximum. Dr. Soullé had recommended an emulsion so as to bring carbolic acid into the form of a lotion and had written very highly of its effects in the treatment of wounds after certain operations.

Mr. Greenish observed that tincture of quillaia had been highly recommended by the Paris Pharmaceutical Society as an emulsifying agent. He had tried it in many instances, and had found it exceedingly useful. Dr. Vogl, of Vienna, had written most exhaustively on this bark; not only on its chemical composition, but its microscopical structure. There was also a valuable paper on its microscopical structure by Schlesinger in Wiesner's 'Untersuchungen.' He believed that tinct. quillaia would occupy a place in pharmacy.

Mr. A. H. Mason (Liverpool) remarked that the author spoke of quillaia bark in the natural state; his experience was that only the inner bark was offered for sale in this country; this was frequently stained, and he would like to ask if this was caused by exposure or if any decomposition took place likely to deteriorate the bark. He would like to know, moreover, if the frothing power of quillaia bark was due to the presence of saponine, and if so whether saponine obtained from other sources had the same properties. He would also ask whether the watery or the alcoholic extract yielded the greater percentage of frothing power and what the yield of extracts was.

Mr. Lee asked what strength of spirit was required to extract saponine from quillaia bark, and what temperature should be used.

Mr. Umney said he knew this bark was occasionally used medicinally, also that it was a most powerful drug applied externally. It entered into the composition of one well-known patent medicine, which had been before the public for years, and it was well known as a stimulant in certain skin diseases. Before it was recommended broadcast as an emulsifying body for all kinds of mixtures they ought really to ascertain if it was harmless in its nature when administered internally.

Dr. Symes referred to the use of quillaia bark in tooth powders and mouth washes as objectionable on account of its nauseous acrid taste, and asked if saponine in the purest form in which Mr. Collier had been able to obtain it still possessed this objectionable character.

Mr. Fletcher asked if the saponifying property was peculiar to the lime compound.

Mr. Hasselby asked how the author broke up the mercury, and said the process seemed so simple and effective that it might be used with advantage in sheep ointment.

Mr. Collier said as regarded the physiological action of quillaia bark he could only refer to Husemann's 'Pflanzenstoffe,' in which saponin was mentioned as being poisonous to the lower animals; but the fact of its being adopted by the Paris Society of Pharmacy induced him to think there could not be any harm in the substance. He had made a considerable quantity of emulsions with it, but more particularly of cod liver oil. The tincture of quillaia added to cod liver oil, and flavoured with cinnamon, made really a very palatable mixture, and he knew one person, who having an objection to oil, even liked it in this way. He explained the process of breaking up mercury, and showed that it would do well to make sheep ointment.

The thanks of the Conference were given to Mr. Collier for his paper.

(*To be continued.*)

Obituary.

Notice has been received of the death of the following:—

On the 10th of August, 1879, Mr. William Rowland, Chemist and Druggist, East Street, Chichester.

On the 15th of August, 1879, at Chelsea, Mr. William

Bartlett. Aged 75 years. Mr. Bartlett was one of the Founders of the Pharmaceutical Society, and served as a Member of the Council in the years 1845–46 and 1846–47.

On the 16th of August, 1879, Mr. Joseph Barnett, Chemist and Druggist, New Street, Burton-on-Trent. Aged 35 years.

On the 22nd of August, 1879, Mr. Thomas Rushworth, Chemist and Druggist, Wellington Street, Leeds. Aged 63 years.

On the 22nd of August, 1879, Mr. Joseph Pearce, Chemist and Druggist, Sheep Market Street, Crewkerne. Aged 67 years. Mr. Pearce had been a Member of the Pharmaceutical Society since 1869.

On the 22nd of August, 1879, Mr. Clement Dallas, Chemist and Druggist, Lavender Hill, Clapham, S.W. Aged 42 years.

On the 31st of August, 1879, Mr. Thomas Pass, Chemist and Druggist, Melbourne. Aged 72 years.

On the 1st of September, 1879, Mr. James Holiday, Chemist and Druggist, St. Dunstan's Street, Canterbury. Aged 76 years.

On the 6th of September, 1879, Mr. John Joseph Nicholson, Pharmaceutical Chemist, High Street West, Sunderland. Aged 42 years. Mr. Nicholson had been a Member of the Pharmaceutical Society since 1861.

On the 13th of September, 1879, Mr. Richard Flower Ellis Wilton, Chemist and Druggist, Bridgwater. Aged 33 years.

Correspondence.

Registered Dental Practitioners.

Sir,—I was utterly astonished upon reading Mr. J. J. Musgrave's letter in your last issue. Could anything be wider of the mark? The Act states "dentistry" or "dental surgery." That is "dentistry" (mechanical) or "dentistry" (surgical), either the one or the other, "separately" or in connection with medicine or pharmacy.

Our friend's lucid description of a dentist fails the further deduction, that "a dentist" (though eminently qualified or otherwise) shall not be compelled to do both if he chooses otherwise. If words mean anything at all, in the sentence dentistry or dental surgery, in the eyes of the law, common sense, or a dental surgeon, I think it must mean either the one or the other, or both. If it is not optional I am in the dark. A medical man may be a M.D., M.R.C.S., and L.S.A., I am not aware the eye of the law compels him to practise any one branch for which he is "registered" at the instigation of any person, whether he chooses or not.

Does not Mr. Musgrave's letter savour too much of what we call in Sheffield Broadheadism? By what authority can the British Dental Association or any other association, "demand legal evidence of fitness"? Who gave them that authority? The Dental Act does not. Intimidation, based upon such a foundation, can only find its reward in the treatment which doubtless such a communication will receive.

G. Ellinor, Ph.C., *Dental Surgeon, etc.*

Sheffield, Sept. 16, 1879.

Sir,—It is refreshing but not particularly instructive to read the letter of Mr. J. J. Musgrave under the above heading in your last issue. Mr. Musgrave evidently views with a jaundiced eye that portion of the Dentists' Act which permits chemists who were engaged in dentistry to register as such. Perhaps it may be well, however, to remind Mr. Musgrave that, however powerful a brief he may hold from his "numerous friends in both the dental and medical profession," it is—happily for those to whom he offers such disinterested advice—only a brief, and not the dictum of either judge or jury in the matter.

The new dental associations have a broad field of usefulness before them, and it will be to be regretted if they initiate their existence by stirring up strife between themselves as representing the dentist *pur et simple* and those associations who would represent the dentist "in conjunction with the practice of pharmacy."

Imperturbed.

Sir,—In your last issue there appeared a letter on this subject by Mr. J. J. Musgrave in which he states that a dentist in the eye of the law must have been a person engaged in every branch of the dental art, *i.e.*, able to undertake any operation and do any mechanical work that may be required for the mouth by the public.

He then goes on to say that any chemists who cannot show legal evidence of such qualification and fitness had better apply to Mr. Miller, to have their names erased from the register to prevent sect. xxxv. of the Act being carried into effect, as it provides for such fraudulent registrations by fine and imprisonment.

About the 27th of last December I wrote to Mr. Miller asking him if it was necessary for any person engaged in extracting teeth to be registered. I expected a plain answer to a plain question. On the 30th of December I received a letter containing a form of declaration and an intimation that December 31 was the last day on which I could be registered for the sum of £2. I sent the money and was registered as a dentist, as I concluded it was necessary to do so in order to continue to extract teeth. Now I wish to know if on applying to Mr. Miller to erase my name from the register, he will return the £2; if not, could an action stand for obtaining money under false pretences? Perhaps Mr. Musgrave can inform me; if not, I shall set the whole affair down as a big swindle.

September 16, 1879. Lower Molar.

Sir,—What is the object of your correspondent J. J. Musgrave in writing the letter which appeared in last week's Journal? Does he wish to prevent chemists' assistants from registering as dentists?

It is a well-known and indubitable fact, that there are hundreds of chemists, their managers and assistants, who practise dentistry, that is, who extract, scale, stop, etc., as ably as any professional dentist can do, who under the late state of the law could not be hindered or prevented from so practising; and I take it that the new Act has been passed to give such practitioners a legal status, and to prevent from so practising unqualified men, mere empirics and charlatans.

Another fact equally well known with the above, is that in country places throughout the length and breadth of the land, there are uneducated and vulgar men who take first to "cow-doctoring" and farriery, but who are equally ready at any time to bleed a horse or cow, or to cut a whitlow or extract a tooth for a human patient; and these are the men, I apprehend, who were intended to be, and who will be prevented by the new Registration Act from practising dentistry.

If a chemist's assistant were able to perform, in a proper manner, all the operations of dental surgery, he would not need a new Act of Parliament to enable him to register, and so give him a legal position; nor would he long stand, behind a chemist's counter. He would be, or soon could be, in a position to have his abilities fully recognized by the College of Dental Surgeons and to practise as a full-blown dentist.

Manager.

How can a Chemists' Assistant register Himself as a Dentist in bona fide Practice?

Sir,—Under the above heading, in your last week's issue, Mr. Musgrave says, "I have also had chemists pointed out to me who have never done any dental operation beyond extracting a tooth, etc., who have registered as being in *bonâ fide* practice as dentists." Now, sir, if extracting a tooth is not practising as a dentist, I should like to know what it is? Probably a great many chemists have registered whose business engagements will not permit them to do anything more than simple tooth extraction, and have thereby registered, as a precaution, against a possible prosecution for breaking the law. The registration of assistants, I should imagine, was illegal, because they are not actually practising surgery and pharmacy, only acting as assistants.

The Dental Act is like the Pharmacy Act; it must of necessity recognize a certain class of men, who have no right, so far as their qualifications are concerned, to be registered. As a natural consequence, it will be some years hence before these Acts have the beneficial effect intended.

Walworth, Sept. 15, 1879. F. W. S.

The Health of the Drug Trade.

Sir,—The subject which Mr. Nicol, of Edinburgh, has broached in a recent Journal is certainly of sufficient importance to claim discussion, and if some of our thoughtful members would give us the benefit of their opinions, it would prove instructive and interesting, for in these days of competition and restless anxiety to get our trade prices and honest due, this all important subject is, I fear, lost sight of.

Dr. Richardson, in his manual of 'Health and Life,' gives very interesting facts respecting the conditions and mortalities of all workers. He has collected tables of the death rate of males engaged in seventy occupations during three years, and perhaps it would surprise some of your readers, as it did me, that the lives of bakers, millers, tobacco manufacturers, and workers in metals, etc., stand higher in point of vitality than those of our own trade.

Dr. Richardson comments on the causes in a great number of cases, but with reference to chemists he says nothing. I suppose he thinks we are sufficiently competent to examine and trace the cause ourselves; but there is one circumstance he names with reference to grocers and drapers (both of which are better lives than chemists). He says, "that seventy-six grocers die to one hundred and eight drapers," and the explanation of the mortality given is that the grocer lives and works in an open shop, with doors rarely closed from morning to night. He deals in goods which give off little dust. He is rapid in his movements, and keeps himself warm by exercise without the aid of hot stoves. The draper, on the other hand, works in a close atmosphere. His shop door is on swing hinges. He is engaged handling goods which fill the air with dust and fluff, and the temperature is kept up by artificial means.

It has occurred to me this might be fitly applied to ourselves, for I have often noticed that chemists are very fond of keeping their doors closed, thereby retaining the vitiating gases the atmosphere of the shop is laden with, thus exerting their baneful influence on those employed in it.

Is it because it gives a mysterious air or professional appearance to the business? The most startling fact named by Dr. Richardson is that the lowest class in the vital scale are innkeepers and publicans.

His favourite theory then comes in to explain the reason, for he says, "the occupation is one that is most nearly allied to alcohol, for it tempts most rapidly into destruction those who are the dispensers of it."

Are we as chemists fond of the alcohol which kills, or is it the physic which kills too?

Sandford.

Sir,—Mr. Nicol has raised a very important question, and it is one to which I have given a great deal of attention during the last twenty years.

I believe I can supply him with the information which he requires. The obituary column of this Journal has for a long time had a horrible attraction for me. I should like to ask the contributors to it to endeavour in future to supply the name of the disease of which the person died.

There is no need to dwell upon this sad subject, but I will proceed to say that the result of my investigations goes to prove that if a pharmacist can avoid the practice of manufacturing chemistry, and confine himself to the ordinary retail or wholesale branches of our business, and conduct this business with ordinary prudence, and with a knowledge of the laws of health, he will live to a good old age, and enjoy his life as well or better than the tradesmen who live around him, and who are not possessed of the knowledge which I think he ought to have, and which I am not surprised to find that his neighbours are deficient of.

There are probably exceptional cases where the victim is placed in a very unhealthy part of a very large city, and where he is left with no assistance of any kind; my remarks do not apply to a slave like this, for I would say that his occupation is simply a living death, and that the sooner he is translated to another sphero, the better it will be for him.

Should this letter be read by any assistants in search of a business, let me implore them to shun "a snug little concern where the coming in is very low." The unlucky keeper of these shops is the most complete slave in the world; the negroes in America are quite happy people in comparison, for they work very little, eat a great deal, and find lying in the sun "berry pleasant."

I am much tempted to encroach upon your space in explaining the mode of life which a pharmacist should lead to enable him to be healthier than his neighbours, but I am also deeply impressed with the idea that very little will come of this discussion, for most of our brethren have drifted into a series of habits which have become part of themselves, and I fear that nothing can be said to warn them from the way which "seemeth good unto a man, and the end of these things is death." Upon the other hand, should any reader feel sufficient interest in this subject to challenge me in public, or to write to me in private, I shall be pleased to show how it is done.

Rochester. H. Barnaby.

Sir,—In taking up the subject of Mr. Nicol's letter o Saturday last, I would preface my remarks by saying that I do not write with the intention of trying to explain or give reasons for the alleged high percentage of mortality among chemists. Is it a fact proved and undisputed that our business is less healthy than any other indoor occupation of the shopkeeping species, even allowing for the few extra hours we are occupied, or that "nearly 80 per cent. of chemists and druggists die at an age when men are supposed to be in their prime?" I do not think it is possible to gather from the obituary notices of a scientific journal or two (which, it is unnecessary to say, do not obtain reports of all the deaths) a correct estimate of the average age at which chemists die, and for this reason, and looking to the source from which Mr. Nicol presumably draws his statement, I think he has been a little premature in his speculations. It has been said, not unfrequently, "How is it that chemists, as a rule, die young?" but has it occurred to one in a hundred to inquire if this assertion is really fact—that there is a greater mortality, and at an earlier age, among our class than among drapers, clerks, grocers, etc.?

I grant that in some large towns, where the system of keeping indoor assistants is for the most part the rule, and from the consequent night and day labour in the smaller establishments, where there are no relieving hands, many young men unconsciously, though slowly and surely, lay up the embryo seeds of future disease. In such cases the cause of the evil is obvious, and the remedy lies with themselves. It will be asked, of course, how the requirements of the trade and the medical profession are to be met in doing away with night attendance. I would ask too, "Is it not in the power of medical men to obviate, at least in a great measure, the necessity of night work by chemists, more especially in the case of those chemists and doctors who have almost exclusive dealings with each other?" By having at hand a few such remedies as chloroform, laudanum, etc., the majority of "emergency cases" could be dealt with by physicians with greater despatch, and therefore with gain both to themselves and their patients. And the loss to the chemist would be more than balanced by a well earned night's repose. This most desirable boon for the hard-worked assistant is certainly within the bounds of possibility, and for its acquisition it would only require a little friendly co-operation. Our sympathies in this respect with our English brother-assistants are genuine and sincere, but the hopes of better days in store for one and all of us will help to sustain us until we are eventually in possession of many such privileges, which we are at present deprived of. Although the gist of these remarks may appear in some measure to bear out Mr. Nicol's statements, yet with all respect to that gentleman, I hope that the publication of authentic statistics will refute the melancholy rate of mortality which, he alleges, exists in our midst.

Edinburgh. Alexander G. Laing.

Nitrate of Pilocarpine.

Sir,—My inability to be present at the Pharmaceutical Conference this year prevented me from replying to some remarks made upon my paper in discussion, I therefore ask you the favour of inserting the following reply.

The difference Mr. Martindale alludes to between the action of an extract of jaborandi and its alkaloid pilocarpine is a fact well known to me, as established by the physiological experiments of Professors Michael Foster and Sydney Ringer, and I intend shortly to commence some experiments on the secondary products of the manufacture of pilocarpine with the view, if possible, of settling the matter.

As to Mr. Martindale's discovery of the insolubility of nitrate of pilocarpine in cold alcohol, and its use for purifying the nitrate, I may say to such a trifle he is welcome; but he fails to point out what is of much more importance, viz., the solubility of the nitrate in boiling alcohol, from which it is deposited on cooling in colourless transparent crystals, much purer than can be obtained by any length of washing with cold alcohol.

University College Hospital, A. W. Gerrard.
September 16, 1879.

Soluble Essence of Ginger.

Sir,—We have failed to obtain a satisfactory result by Mr. Thresh's formula. Although cooled down to the freezing point the solution was quite opaque when filtered. Perhaps Mr. Thresh can explain this?

There is surely a misprint in the third paragraph ordering the tincture to be shaken with slacked lime "until it ceases to *lose* colour. . . Now add drop by drop dil. sulph. acid until the *rich yellow colour* of the tincture suddenly disappears." Shaking with the slacked lime *deepens* the colour.

Edinburgh. H. C. Baildon.

New and Improved Pharmaceutical Processes.

Sir,—In the "New Method for Making Tincture of Iodine," by Mr. E. F. Cherry, appearing in your issue of the 6th inst,, I fail to see improvement; there may be novelty, but it is of questionable advantage.

He must be a very clumsy manipulator who could not make a pint of tinct. iodi without "dirtying several measures" and "staining his skin."

The method of placing the ingredients in a bottle and occasionally agitating leaves nothing to be desired, and to say the least, avoids dirtying a measure and funnel, which unimportant consideration should not be thought of in compiling a pharmaceutical process.

Mr. Cherry's improved method for phosphorus pills differs only from one which has been long in use in the substitution of chloroform for carbon bisulphide as the phosphorus solvent.

On account of the extremely divided state of the phosphorus, I think it highly probable that considerable oxidation takes place in this method, the vapour of the $CHCl_3$ or CS_2 may retard it while the mass is in the mortar (the motion of the pestle, however, and atmospheric currents would, most likely, displace it), but during rolling and dividing oxidation would proceed rapidly (as instanced by "Greek Fire"). Finally, Mr. Cherry says nothing about coating or varnishing the pills, without which they would be valueless after having been kept a short time.

R. H. Parker.

Sir,—The only innovation in the paper entitled, "An Improved Method of Making Phosphorus Pills," seems to be the substitution of chloroform for bisulphide of carbon, and as no mention is made of the fact that this prevents the pill mass smoking, the only advantage of so doing is overlooked.

Of course no one likes the mephitic smell of bisulphide of carbon, but the mortar used can surely be placed in the open air for a couple of minutes.

Carbon bisulphide is preferable to chloroform for three reasons:—It costs much less; it is a better solvent, and it is much more volatile.

I am aware that on the last point I differ from Mr. Cherry. An experiment will at once settle the matter.

As to "The New Method of Making Tincture of Iodine," I fail to see how it improves on the old, in which the iodine and iodide of potassium were placed in a bottle, the spirit added, and the bottle gently shaken at intervals till complete solution had taken place, so rendering it unnecessary to dirty a funnel, and filter and waste a plug of cotton wool and a certain quantity of spirit by evaporation, as must be the case if the new method be adopted.

Greek Fire.

The Prosecutions by the Pharmaceutical Society of Ireland.

Sir,—Referring to your report of the proceedings in the case of the Pharmaceutical Society of Ireland *v.* Beater and Hardy, and the same *v.* Brownrigg, we beg to inform you that the rule of our establishments is to enter and number all prescriptions dispensed by us, and that this practice is invariably followed.

We may remark, at the same time, that we have frequently compounded prescriptions for Messrs. Beater and Hardy.

Dublin. Hamilton, Long and Co., Limited.

A. B.—The regulations respecting the appointment of Navy dispensers will be found in the 'Calendar of the Pharmaceutical Society.'

J. T. Fox.—(1) *Ranunculus arvensis.* (2) *Lamium purpureum.* (3) *Sanicula europœa.* (4) *Crepis virens,* probably; materials too meagre to determine. (5) *Vicia Sativa, β angustifolia.* (6) *Galium Aparine.* (7) *Vicia sepium.* (8) *Knautia arvensis.* (9 and 10) send better specimens. (11) *Lactuca muralis.* (12) *Carex glauca,* probably. Please limit the number of specimens to six in future.

A. B. C.—*Saponaria vaccaria.*

J. Shadwick.—Species of *Juniperus*; impossible to determine which in the absence of fruit.

J. H. Williams.—Garrod's 'Essentials of Materia Medica,' published by Longmans.

"*Aloe.*"—Snively's 'Manufacture of Perfumes and Toilet Articles,' published by Trübner.

J. Johnson.—The provisions of the 17th section as to the regulations to be observed in the sale of poisons do not apply to any medicine supplied by a legally qualified apothecary to his patient, nor apply to any article when forming part of the ingredients of any medicine dispensed by a person registered under the Pharmacy Act, provided such medicine be labelled with the name and address of the seller, and the ingredients thereof be entered, with the name of the person to whom it is sold or delivered, in a book to be kept by a seller for that purpose. But the regulations apply to all retail sales of scheduled poisons.

"*Rosicrucian.*"—A process for the deodorization of petroleum was described in the Journal for January 26, 1878, p. 582.

"*Associate.*"—Persons registered under the Dental Act are exempt from jury service.

"*Junior.*"—We do not possess sufficient information on the subject to warrant the expression of an opinion.

J. Gosling.—See the Journal for March 1 in the present year, p. 718; other recipes have also been given.

E. Robinson.—You will find an explanation in any good work on Physics. The action is primarily due to atmospheric pressure.

"*Wednesbury*" (who should have sent his name and address) will find several papers on pill coating by reference to the indexes of recent volumes of this Journal.

"*Eupatorium perfoliatum.*"—With reference to the paper on this subject that recently appeared in this Journal, before, p. 50, we are requested to add the following paragraph, which appeared in the original communication in the *American Journal of Pharmacy*:—"The analysis was made by Mr. Parsons [Department of Agriculture, Washington], who also submits this report."

R. W.—Sneezewort and evening primrose.

Communications, Letters, etc., have been received from Messrs. Attfield, J. H. Williams, Jackson, Wyborn, Davis, Mrs. Clarke, Euryowie, Dispenser, Alterative, Assistant, Quæro, Alchemist, Juvenis, T. S. W.

"THE MONTH."

Unusual seasons generally bring unusual phenomena, and abnormal conditions of plant life may therefore be naturally expected this year. Thus a Manchester correspondent writes that he recently came across a bed of hemlock with stems much above the average height, one of which, on being cut down, was found to measure 8 feet 9 inches in height, while the stem was $3\frac{1}{2}$ inches in circumference. A similar patch of the plant was recently noticed by the writer, near Dartford, quite an effort being required to reach the fruits with an outstretched arm, the plants, which were not measured, being probably close upon 9 feet high and much branched.

Fungi also, which might have been expected from the damp state of the ground and the recent warmth of atmosphere, at all events in the day, to have been abundant, are in fact unusually late and scarce. A recent search for *Amanita muscaria*, in a well known locality for it, near London, proved quite a failure. So great is the scarcity of fungi that it is feared that the fungus foray of the Woolhope Club at Hereford this year will prove less successful than usual, which would be rather an unfortunate occurrence, since several fungological celebrities from France are coming over to attend the meeting.

The unusual abundance of insects this year is another curious circumstance, and it would be interesting to ascertain how far it has affected the crops of medicinal plants. The writer recently observed a patch of peppermint completely stripped of leaves by one of the common garden caterpillars, *Mamestra persicariæ*. Most insects appear to dislike strong odours, but whether the moist weather has diminished the quantity of oil usually present in the leaves, or whether it is possible for insects to become habituated to unusual food, it is not possible to say. At all events, neither the elder nor the peppermint appears to be generally attacked by insects.

In damp meadows, in localities where it occurs, the colchicum may now be seen in full beauty, and almost reminds one of the early spring time when the crocus displays the same delicate hue. Many spring plants often blossom again in the autumn if the weather be damp and mild. This year there may be seen at the Botanical Gardens the bistort, *Actœa spicata*, crosswort, comfrey, and several others. The same thing often happens when flowers which naturally blossom in spring are transplanted at that season. Thus primroses transplanted in spring will sometimes flower in autumn for two or three years in succession.

Among the rarer wild plants to be seen in flower this month are, *Linosyris vulgaris, Artemisia campestris, Urtica pilulifera, Spiranthes autumnalis, Lactuca Scariola, L. saligna*, and *Bupleurum tenuissimum*. The first three may now be seen in blossom in the Herbaceous Ground at Kew, where several families are still well represented by plants in flower. Those which more especially afford abundant material for study are, Chenopodiaceæ, Polygonaceæ, Compositæ, Scrophulariaceæ, Labiatæ, Convolvulaceæ, Dipsacaceæ and Boraginaceæ. The Chenopodiaceæ are, even to advanced botanists, a very troublesome group, but a veritable *bête noir* to the tyro in botany, to whom it may be useful to know that although it is necessary to gather specimens in flower, as well as specimens having the lower leaves, it is best not to attempt to name the species until specimens with ripe fruit can be obtained.

Among medicinal plants at Kew a number which were recorded for last month still remain in blossom, such as lavender, peppermint, borage, camomile, hyssop, tansy, tobacco, melilot, wormwood, alkanet, and *Monarda didyma*.

Another species of *Monarda, M. fistulosa*, with pale pink flowers, presents a much less brilliant appearance than *M. didyma*, but its leaves give off a highly fragrant odour, like bergamot, when bruised. It is a curious coincidence that the odour both of lemon and bergamot should occur in more than one plant of the Labiatæ, while that of the orange does not seem to occur in that natural order.

A solitary flower of the cochineal cactus, *Opuntia vulgaris*, may be seen in the Herbaceous Ground, a sight of apparently rare occurrence in this country. Among the plants in the same ground worth a passing attention, at least, are several species of *Eryngium*, with their curious thistle-like habit. In the Compositæ may be noticed several plants of the genus *Echinops*, of which we have no indigenous representative, and which derive their name of globe thistle from their spherical capitulum, differing from ordinary composite flowers in each floret having an involucre of its own, while a general involucre is absent, or perhaps it would be more correct to say that what is apparently a flower-head consists of an aggregation of capitula, each of which contains only a single flower.

In the Onagraceæ bed may be observed a flower, *Lopezia coronata*, worthy of notice on account of its unusual structure. The parts of the flower in this family are usually four in number, or the stamens are sometimes reduced to two, but in this case there are apparently five petals, which gives an irregular appearance to the flower. This is due to one of the two stamens having no anther at its apex, but the filament developed instead in the form of a petal.

In hedgesides and damp waste places near old towns and villages, the soapwort, *Saponaria officinalis*, may be seen in blossom, its pretty pink flower frequently showing a tendency to become double. This plant has lately been spoken of as likely to be useful in carcinoma. Gerarde in his 'Herball' speaks of it as being used "for greene wounds, to hinder inflammation and speedily to heale them," and quotes from Ludovicus Septalius a remark which would have been doubtless much resented, had it been written in these democratic days. "I have sometimes used it with happy success in the most contumacious (venereal) disease, but it is of a somewhat ungrateful taste and *therefore must be reserved for the poorer sort*." It derives its name from the lather which may be made with water and the bruised leaves, and which is due to saponine, first obtained from this plant.

By the sides of streams may be seen the gipsywort (*Lycopus europæus*), remarkable for having only two stamens, the upper two being imperfect. This plant has the reputation of being one used by the gipsies to dye their skin.

The curious little plant *Samolus Valerandi*, may now be looked for in wet marshy or dripping places. Although the flowers are small and have an unattractive appearance, they are interesting on account of possessing, in the modified form of small scales, the second row of stamens, which is absent in most *Primulaceæ*, and by reason of which absence the stamens in this order are opposite to the petals, instead of alternate with them, as should, if the flowers were normal, be the case.

On damp sandy turfy heaths the Calathian violet, *Gentiana Pneumonanthe*, may now be found in flower. It is one of the prettiest of our native species, but is somewhat local and rare. The flowers differ from those of the commoner species, *G. Amarella*, in the stamens coming to maturity before the stigma, so that the pollen is carried by bees (which can only creep half way down the corolla) from the flowers in which the pollen is ripe to the older in which the anthers are withered and the stigma is viscid. As the stigma is higher up the tube than the stamens, self-fertilization is not possible.

In *Gentiana Amarella*, which is common on chalky hills at this time of year, although the anthers and stigma are mature at the same time, the stigma is above the stamens by reason of the style being longer than the stamens, so that cross-fertilization must also take place in this case. The *G. Amarella* is still sometimes gathered by herbalists under the name of English Gentian.

Most of those who have attended botanical lectures at Regent's Park Gardens are acquainted with the curious leaves of *Bryophyllum calycinum*, which when placed on damp earth in a warm place give rise to young plants from each notch at the margin of the leaves. Dr. W. Berge, of Zurich, has recently been examining the origin of these buds and their development into plants, and has found them to be of exogenous production and entirely developed from a meristem tissue in the base of the notches of the leaves.

Some interesting experiments on the action of anæsthetics on the sensitive plant have been made by M. Arloing. He found that chloral had not the same action on the plant as upon animals, while the contrary was the case with chloroform and ether. The anæsthetics were administered in the form of watery mixture to the roots, and the vessels containing the plants were then covered over so as to arrest evaporation, so that the anæsthetics must of necessity penetrate the plants either by the roots or leaves. The experiments showed that the rate of ascent of liquids in the plant increased from the base of the stem upwards, being one and a half to twice as great in the petioles as in the stem.

In the *Gardeners' Chronicle*, this month, Mr. W. G. Smith points out that a fungus very common at this time of the year possesses poisonous properties. A gentleman observing that it was eaten by slugs or snails most erroneously supposed it was therefore suitable for human beings and suffered severely for his theory. The fungus in question, known to fungologists as *Paxillus involutus*, is remarkable for the rim of the pileus or cap being distinctly curled under. The pileus is pale brownish and the gills run down the rather stout stem. The flesh when broken is dirty white, becoming brown, and the spores are reddish.

At the drug sales in London there has been noticed this month some spurious matico, with an aromatic odour between that of aniseed and sassafras, and another kind with leaves extremely similar to those of matico, but quite inodorous. A bag of the fruits of the doum palm, *Hyphæne thebaica* was also observed, but with what object they were imported it was not possible to ascertain. The fruit is said to be eaten by the lower classes in Egypt and to taste like gingerbread, whence it is sometimes called the gingerbread tree; its dry fibrous fruit, however, look so little like "gingerbread nuts" that there is not much temptation to try them. The seeds which are hard and horny are sometimes made into beads for rosaries. Goa powder of good quality was noticed and Calabar beans appeared to be more plentiful than of late.

Several inquiries concerning Alstonia bark have recently been made, and as some confusion appears to exist between *Alstonia scholaris* and *Alstonia constricta*, some readers may be glad to know that an account of the former may be found in Bentley and Trimen's 'Medicinal Plants,' No. 173. This bark is also called *Echites scholaris* and Dita bark. Attention was called to it so long ago as 1853, by Dr. Gibson. In his paper in the *Pharmaceutical Journal*, series 1, vol. xii., p. 422, a formula for the tincture (3 oz. of the coarsely bruised bark to a pint of proof spirit) is given, and some idea as to the dose and uses.

Alstonia constricta is an Australian bark used in Queensland as a substitute for quinine and is now coming into use in the United States. It is also known under the name of Queensland Fever Bark. It is quite different in appearance from Dita bark, which is used for dysentery rather than for fever.

At the meeting of the International Congress of Medical Science, at Amsterdam, among the papers read was one by Mr. Van Gorkom, on the culture of the different species of cinchona barks in Java. His experience, as superintendent of the quinine plantations in Java, naturally gives great value to his opinions. He considers that regular culture has done much to increase the value of the cinchonas for medical purposes, but that neither by outward nor by anatomical structure is it possible to determine the richness in active principles of any given sample of the bark and that chemical analysis alone can determine this point. He also finds that the properties of each species remain the same, although growing in foreign lands. Their tendency to hybridization, however, renders careful supervision of the plantations necessary, so as to secure seed of the best varieties only, or in other words, such as yield the largest amount of quinine. He believes that the growth of cinchonas in the East Indies is more influenced by the local condition of the climate and the soil than by a difference in the elevation of the land and that it is best not to attempt to grow them above 4500 or 5000 feet.

In the *Gardeners' Chronicle* an interesting extract from the *Colonies and India* is given concerning the collection of kauri gum. It is there stated that the districts in which the gum is found are generally covered with small mounds which indicate its presence. The gum hunter carries a steel-tipped spear with which he probes the mass, a little experience enabling him to ascertain the existence of the gum without further search. It is found in blocks from a few ounces to 50 or 60 pounds. The gum which is dug up is said to be used in this country for dressing calicoes, while the recent resin, or that from the existing tree, is employed principally in varnish making.

In the *Lancet* for September 6th attention is called to the fact that the use of sulphate of duboisine is liable to produce giddiness or even in some cases delirium. The writer says:—"When the supply of pure alkaloid becomes large enough to ensure uniformity of strength in the solution made by different chemists, it may be unsafe to prescribe a four grain solution of sulphate of duboisine, and the use of the drug for rapidly dilating the pupil or paralysing the accommodation in the out-patient or the consulting room may not be free from disadvantage."

On this subject Dr. J. Tweedy remarks in a subsequent paper, in the same journal, that "Duboisine, like many other remedies, has been and still is extravagantly abused. It is of immense power and value and necessary only in special cases, for which it should be reserved. Bulk for bulk, it is much stronger than atropine and should be employed with corresponding caution." From these remarks it is evident that duboisine is an unsafe drug to be used by patients themselves, and it behoves chemists, should they meet with prescriptions containing it, to tell the patient to be extremely careful not to exceed the quantity directed to be used. *Apropos* of the above remarks it is not quite evident in what way uniformity in strength of the solution made by different chemists depends upon the supply of the pure alkaloid. Does the writer mean to imply that chemists do not make solutions of the strength ordered, because duboisine is an expensive article? Solutions of alkaloids, etc., are usually made at the request of medical men, and such solutions naturally differ in strength according to the requirements of the prescriber; therefore it must rest with the prescriber alone to regulate the strength in the absence of a published formula.

This experience of duboisine does not appear to be universal with experimentalists, for in Dr. H. Macnaughten Jones's able summary, in the *British Medical Journal*, no mention is made of giddiness or delirium being induced by its application; on the contrary, he observes, "of the two (atropine and duboisine), so far as my experience teaches me, save for its expense, I prefer the sulphate of duboisine to the sulphate of atropine." The production of these symptoms may therefore be due to a peculiar intolerance of the drug similar to that which is well known to occur in some persons as regards atropine, and which is alluded to by Dr. Jones in the above paper.

Benzoate of sodium is said to be much used in Germany at present. It is stated that it reduces fever less rapidly than quinine and salicylate of sodium, but that the effect lasts longer. The dose given is 5 to 6 grams for children and 10 to 20 grams for adults.

In the *Medical and Surgical Reporter*, Dr. Mary J. Matlack calls attention to the value of asparagin as a diuretic. She considers it to be one of the best remedies in dropsy dependent on disease of the heart, and to be especially valuable in chronic gout. The dose given is 1 grain, three times a day, in conjunction with 12 grains of bromide of potassium.

Many of our readers have probably heard of the singular case of Alexis St. Martin, who had an opening into his stomach from a bullet wound which never closed, and who was the subject of experiments on gastric digestion, by Dr. Beaumont. The *Detroit Lancet*, for August, states that he is still alive and lives at Joliette county, Quebec province, Canada, and although seventy-nine years old, is strong and healthy. The hole in his stomach is an inch in diameter, yet his digestion has never failed. It should be added that he has been a hard worker all his life.

A new use for thymol has been discovered by Dr. Emil Stern, of Breslau, who states in the *Breslaue ärztliche Zeitschrift* (No. 8, 1879), that so far as he has been able to observe a mixture of a one per 1000 aqueous solution of thymol preserves vaccine lymph from decomposition, while it does not destroy its specific action and the mixture is not more irritating than ordinary vaccine matter. It does not appear, however, that thymolized lymph is infallible in its action, it seeming to vary in activity according to its age. The discovery, however, that thymol does not, like carbolic acid, destroy the power of the vaccine lymph is a remarkable one.

From the *Ammi Visnaga*, an umbelliferous plant common in Lower Egypt, and the rigid pedicels of whose umbels are used by the Arabs as toothpicks, Mr. Ibrahim Mustapha has extracted a glucoside to which he has given the name of kelline, from *kell*, the Arabic name of the plant. It is obtained by treating a mixture in equal parts of the powdered seeds of the plant and slacked lime with alcohol, evaporating to dryness in a water-bath, exhausting with ether, filtering and treating with boiling water the yellowish residue and filtering while warm. On cooling crystals are obtained which are purified by recrystallization first from hot acetic and then from boiling water. Kelline is described as a white very bitter substance, very slightly soluble in water, methylic, ethylic and amylic alcohols and chloroform when cold, but much more soluble in them when hot.

Pelletierine, the alkaloid isolated by Tanret from pomegranate root bark, and considered by him to be the active tænicide principle, appears to be making its way into favour on the Continent. The free alkaloid is a volatile oleaginous liquid, and the salts described by Tanret in his original paper (*Pharm. Journ.* [3], ix., 1023),—the sulphate, hydrochlorate and nitrate,—although obtainable in the crystalline form, are very hygroscopic and liable to undergo alteration through atmospheric influences, and are consequently not suitable for dispensing. For this purpose Messrs. Gehe recommend as most convenient the tannate, which forms a dirty white powder, stable when exposed to the air. In bringing the subject before the Paris Society at its August meeting M. Petit said that judging from the composition of the tannate of pelletierine the dose would vary from 1·50 to 2·0 grams, but as he admitted that the results of a polarimetric examination were absolutely different from those reported by M. Tanret it is not quite certain that the substances obtained by these two chemists were identical.

Aspidospermine, the alkaloid of the bark of *Aspidosperma Quebracho*, which has been recently recommended in the treatment of dyspnœa accompanying diseases of the lungs and other organs, has been the subject of a further examination by its discoverer, Herr Fraude (*Ber. d. deutsch. chem. Gesells*, xii., 1561). The author represents it by the formula $C_{22}H_{30}N_2O_2$, and states that at 14° C. one part of it is soluble in 48 parts of 99 per cent. alcohol, in 106 parts of ether free from alcohol and water, and in 6000 parts of water, the aqueous solution having a distinctly bitter taste. In many of its reactions it closely resembles strychnia, but its reaction with hypochlorous acid is characteristic. If a very small quantity be boiled for a few minutes in a few c.c. of aqueous solution of hypochlorous acid, sp. gr. 1·13 to 1·14, the liquid acquires an intense red colour, resembling that of a solution of fuchsin, which is persistent during a week's exposure to air and light. Brucine under similar conditions gives a dark Madeira colour, and strychnine a reddish yellow colour. The cinchona and opium alkaloids, veratrine, caffeine, atropine, nicotine and coniine give no colour reaction with the solution of hypochlorous acid.

Bromide of zinc having come recently into use in medicine M. Yvon recommends its preparation by double decomposition between zinc sulphate and potassium bromide. Upon triturating equivalent quantities of these in a mortar liquefaction quickly takes place, the water being afforded by the zinc sulphate. This product is left in contact about twenty minutes, then suspended in double its weight of perfectly rectified 95 per cent. alcohol and filtered. The solution of zinc bromide, which should pass through colourless, is evaporated to dryness first in a water-bath and then in a sand-bath. The product should be volatile, without residue and entirely soluble in water, alcohol and ether.

In the French Academy of Medicine, M. Vulpian has called attention to the fact that pepsines delivered from different pharmacies vary much in their digestive power, some of them modifying albumen so slowly as to make it doubtful what good effect they can have when administered to dyspeptics. He also confirmed a conclusion arrived at some time ago by Dr. Symes (*Pharm. Journ.* [3], iv., 1), that the action of pepsine is retarded by the presence of alcohol. Wines and elixirs of pepsine are very much used in France, and as M. Vulpian went on to say that some of the most renowned elixirs contained an extremely small quantity of pepsine, the rest intended to have been present having probably been precipitated by the alcohol during the manufacture of the preparations, the statement has caused some little sensation amongst the makers. M. Vulpian also described some experiments made by a pupil, M. Mourrut, which appeared to indicate that sufficient hydrochloric acid to correspond to the acidity of the gastric juice, added to a liquid containing diastase or pancreatine, retards the action of the diastase and stops that of the pancreatine, the former recovering its activity upon the neutralization of the liquid, but the latter remaining inert.

Some interesting experiments on the propagation of sponges, made by Dr. Schmidt, of the University of Gratz (Styria), have just been reported to the Paris Acclimatization Society (*Bulletin*, xxvi., 374). Dr. Schmidt has found that if a sponge be taken early in the spring, cut into small pieces, and immersed in water by attaching the pieces to wooden stakes, growth soon commences and eventually in about three years each piece may become a perfect sponge worth ten centimes. An estimate based upon what appears to be rather slender experience sets the probable profits from the investment of capital in this direction at about 60 per cent.

The disastrous consequences that might result from a person affected with colour blindness being placed in charge of a vessel induced the Board of Trade at the beginning of 1877 to issue instructions that persons presenting themselves for examination for masters' or mates' certificates should undergo a preliminary test as to their ability to distinguish the following colours, which enter largely into the combinations of signals used at sea:—black, white, red, green, yellow and blue. As a result, out of 5967 candidates 26—or rather less than half per cent. —were finally rejected as colour blind, and 13 others were only allowed to proceed to examination after a second trial. Green seems to have been the greatest stumbling block, it having been described wrongly by each of these 39 men, and in 25 cases referred to red. On the other hand, 12 referred red to green.

It may be remarked that some time since it was stated in *La France Médicale* that this infirmity could be overcome by looking through a layer of fuchsine in solution. A M. Javal has made a practical application of this observation by interposing between two glasses a thin layer of gelatine tinted with fuchsine, and it is claimed that by the use of such spectacles the errors caused by colour blindness are corrected. According to the *Medical and Surgical Reporter*, some experiments made in Philadelphia have confirmed this statement.

Still more additions to the "elements," and again the spectroscope has been the principal instrument used in the detection. M. Clève reports to the Academy of Sciences (*Compt. Rend.*, September 1) that he has distinguished in erbia two new elements, making four that have been separated from this substance, which was until recently looked upon as itself being the oxide of a single element, erbium. A writer in the *Chemical News* asks some pertinent questions as to the manner in which these strangers are to be treated in the text-books. Since June, 1877, the following new elements have been named—davyum, neptunium, lavœsium, mosandrum, phillipium, ytterbium, decipium, scandium, norwegium, uralium, and to these are now added, thullium and holmium. Whilst some workers are thus increasing the list of elements, others are steadily seeking to reduce it. In a short note read by Mr. Lockyer before the British Association he makes the following statement, leaving to others apparently to draw their own inferences:—"When carefully distilled metallic sodium was condensed in a capillary tube, placed in a retort, and heated in a Sprengel vacuum, it gave off twenty volumes of hydrogen. Phosphorus, carefully dried, and submitted to the same treatment, gave off seventy volumes of a gas which appeared to consist chiefly of hydrogen." Magnesium is said to have given off two volumes of hydrogen, and from sulphur sulphurous anhydride was always obtained. Iridium always gave off hydrogen *in vacuo* without heating, whilst lithium gave off as much as one hundred volumes.

Corresponding with the advance of science there must necessarily occur in national pharmacopœias successive changes in the names of many of the chemicals employed as therapeutic agents; with the lapse of time some of the earlier names have become quite obsolete. When, therefore, a prescription containing a well-known chemical, but with its more ancient name, is placed before a pharmacist whose acquaintance with drugs and chemicals dates no further back than the advent of the British Pharmacopœia, he is ignorant of the preparation when ordered by a name not found in that volume.

The library of everyone engaged in a business composed of the usual mixture of the retail of drugs and the dispensing of prescriptions may with advantage have on its shelves, in addition to the British Pharmacopœia, subsidiary works of reference, in which category may be named as specially useful Beasley's 'Pocket Formulary,' also Gray's 'Supplement,' a valuable work and one that well merits another edition, together with Jourdain's 'Pharmacopœia Universalis, or a complete encyclopædia of the materia medica contained in the pharmacopœias of London, Edinburgh and Dublin, as well as of all those of Europe and America, and of dispensaries formularies, etc.,' and, as hospital formulæ very frequently find their way into private practice, to the above may with advantage be added that valuable little work, Squire's 'Pharmacopœias of the London Hospitals.'

It must be obvious that the number can be greatly increased, but the few above named may be considered almost essential as works of reference in a well regulated pharmacy, and these should be so placed as to be readily accessible to the dispenser. Some of the questions asked and repeated in these pages may be taken to indicate that in many establishments no such facilities exist of easy reference when a difficulty occurs in the case of synonyms or formulæ which the British Pharmacopœia does not supply.

Correspondents would materially assist their less favoured brethren by naming works of reference which they have found valuable and could recommend to others similarly situated.

The first formula, No. 338, is evidently intended for a hair dye and the inquiry has been answered by several correspondents the answer of Mr. Staveley is definite. As regards the addition of liq. ammon. fort. to the solution of argent. nit., the ammonia should be added drop by drop with constant stirring and discontinued just before the disappearance of the last trace of precipitate. The addition of ammonia to a solution of argent. nit. precipitates the silver in the state of oxide, which is redissolved in excess of the precipitant, and care should be taken towards the end of the process that no more ammonia be added than is barely sufficient to dissolve the oxide precipitated.

The prescription No. 339 may be dispensed by rubbing the quinine to a fine powder, and then mixing it with one half the water ordered, and the ferri am. cit. being dissolved in the other half, they should be mixed. The result will be a turbid mixture, which will require being shaken before the administration of each dose. Probably the question refers merely as to whether the quinine should be dissolved by the addition of an acid, previously to its mixture with the ferri am. cit. The writer has not added an acid, its addition by the dispenser would consequently not be justifiable. The presence of an acid produces a more elegant result, and may with propriety be suggested to the prescriber, but should not be employed without his sanction, as he may have sufficiently satisfactory reasons of his own for the omission.

No. 340 contains the question whether it would be right in making ung. sulph. iodid. to rub the iodide with a little glycerine before adding the lard, "glycerine being a solvent of iodide of sulphur." In making the ointment it is very desirable that it should be smooth and without grit, and although any addition to a prescription must be adopted with great care, to either a few drops of glycerine or spirit in this case there can be no objection, and more especially as one correspondent says the addition of one of them "ensures the production of a faultless ointment."

Mr. R. H. Parker, in his reply to the question regarding the production of this ointment, states that in the next edition of the British Pharmacopœia the formula may with advantage have the addition of the rectified spirit. This remark points to another direction in which the discussions taking place in these columns may be of value, namely, in improving the formulæ for the next Pharmacopœia. It is well known that the accumulation of small but valuable facts with regard to the make of these and similar preparations, and their general application in practice, constitute that essential difference which is now and then observed in the same prescription dispensed at different establishments.

The prescription No. 341 contains an ingredient well known under its present name, hydrarg. ammon., but it is not so generally known by pharmacists of the present day under its former one, calx hydrargyri alba. It is one that in name has seen many changes, and probably the present one will not be final. A formula for the ointment occurred in the 'Pharmacopœia Londiniensis' of 1788, and is quoted by a correspondent in another column. An ointment of this preparation is frequently used as an external application in eruptions of the skin on the head or face.

No. 342 refers to a change of colour which takes place in ung. plumbi subacet. co. after being kept some time. This subject has been discussed on previous occasions, and it can only be necessary to refer "An Apprentice" to the remarks on this change in prescriptions Nos. 130 and 243, and some observations on the same in "The Month," Feb. 22, 1879, p. 698, and July 7, 1878, p. 65.

MELIA AZEDARACH, LIN.*

BY J. JACOBS, PH.G.

This beautiful tree is highly appreciated in the Southern United States for the beauty of its flowers, the elegance of its foliage and the medicinal uses to which it is applied; as a shade tree its popularity is equal to that of the maple in the North. It appears to be indigenous to Asia, but is planted as an ornamental tree in southern Europe, whence it was introduced into and naturalized in the United States at an early period, after the settlement of Carolina and Georgia. It is not found farther north than Virginia, as the severity of the climate of the more northern districts destroys it. The common names, *pride of China* and *pride of India*, undoubtedly originated from its rare beauty; *Indian lilac* from the resemblance of its flowers to those of the common syringa, and *bead tree* from the use of the nuts in rosaries, to which also, the German name Paternosterbaum (*paternostertree*) alludes. In the southern States it is known as *China-berry*, and to the young as *popgun tree*, in allusion to the use of its green fruit.

The tree attains a height of 30 to 40 feet, and from 15 to 20 inches in diameter; it grows rapidly, reaching the height of 12 or 15 feet in four years. The green fruit is very astringent, but when ripe it is a fleshy-yellow drupe, of a sweet taste, rather larger than a cherry, and containing a five-celled bony nut. The green fruit is used in Texas for making blacking.

The ripe berries were largely used in Georgia during the late war for the purpose of obtaining alcohol, by the usual process of fermentation and distillation; the whisky thus obtained was preferred by many to that produced from corn or rye. By expressing the fleshy part of the fruit, like the olive, a fixed oil is furnished from which a "Poor Man's Soap" is made.

Remarkable qualities are said to reside in the fruit, such as will intoxicate robins, which are particularly fond of and feed upon them during their annual migration southward; the seeds are widely dispersed by these birds, and hence trees are found in secluded places. Instances are known of the fruit being destructive to hogs, by what means it is not yet ascertained. A decoction of the berries sprinkled on plants prevents the depredations of

* From the *American Journal of Pharmacy*, September, 1879.

the grub-worm. The leaves and berries will preserve dried fruit from insects, and when packed with clothing will prevent the attack of moths.

The dried berries in whisky have been employed against ascarides, tape-worm and verminous maladies. The pulp of the berries stewed in lard has been used with success as an ointment in scald head. The decoction of the leaves has been employed in hysteria, and is astringent and stomachic. A decoction of the green bark, 4 ounces to the pint, is administered as an anthelmintic in doses of 1 or 2 fluid ounces, followed by a cathartic. When prepared in March or April, while the sap is ascending, unpleasant effects have been observed, such as stupor, dilation of the pupil, etc., which symptoms, however, pass off without perceptible injury to the system.

For the following experiments the bark of the root was employed, and as the liber is very easily separated, and this portion is the most effective in the Nim Bark (*Melia Azadirachta*, Lin.), this alone was used. The liber is of an extremely bitter taste, devoid of astringency, and its decoction gave no evidence of tannin; the outer portion, on the other hand, is very astringent, and its decoction gave abundant evidence of tannin by gelatin and ferric chloride. I may also mention that the inner bark is the portion used in making the decoction for administering.

After several preliminary experiments made with the view of determining the best course to pursue, one pound of the powdered bark was percolated with diluted alcohol until thoroughly exhausted. Upon distilling off the alcohol the aqueous residue held in suspension a considerable amount of insoluble matter. This residue was divided into two parts, one being filtered (*A*), the other evaporated (*B*).

The aqueous filtrate, *A*, was treated with solution of acetate of lead as long as a precipitate was produced; the precipitate was brought on a filter and washed well with water. The filtrate was treated with subacetate of lead, and this precipitate likewise collected and washed. The filtrate was freed from lead by sulphuretted hydrogen, separated from the sulphide of lead, and the sulphuretted hydrogen expelled by heating.

The sulphide of lead yielded nothing to hot water, but when treated with hot alcohol, a small amount of resinous or extractive matter was obtained. The filtrate from the sulphide of lead was concentrated to a syrupy consistence; alcohol produced a slight precipitate, and on the addition of ether a slight semi-fluid mass separated. Both precipitates occasioned by alcohol and ether redissolved in water and alcohol, respectively, and, evaporated spontaneously, left a dark amorphous residue, which was also obtained from the filtrate after ether and alcohol had been expelled; the ether precipitate proved to be sugar.

The examination of the lead precipitate did not lead to any decided results.

The evaporated portion, *B*, had a peculiar odour and bitter taste; it was treated with hot water, acidulated with hydrochloric acid and filtered from the residue, *C*. The filtrate was treated with magnesia and tested for an alkaloid, but none was found. The residue, *C*, was well washed with water, had a brownish-yellow colour and a strongly bitter taste, was not affected by hot or cold water, was slightly soluble in carbon bisulphide, insoluble in petroleum benzin and oil of turpentine, and soluble in alcohol, ether and chloroform, which solutions, on evaporation, refused to crystallize. The alcoholic solution was acid to test paper, but apparently did not combine with alkalies. On dissolving the substance repeatedly in alcohol, and precipitating it by water most of the colour was removed, the resinous principle remaining as a yellowish-white mass. It was given as an anthelmintic to a child aged four years, in the quantity of 3 grains, followed by a mercurial purgative, and proved to be at least as effectual as other vermifuges which had been previously given.

The results of his observations and experiments lead the author to the following conclusions:—

1. The activity of the bark resides in the liber, and this alone should be employed.
2. The active principle is a yellowish-white resin.
3. The drug is one of the best anthelmintics, and a fluid extract, prepared with diluted alcohol, or a tincture, would be a valuable preparation that would seem to deserve a place in the Pharmacopœia.

CHEMICAL NATURE OF THE ESSENCE OF LAUROCERASUS AND OF BITTER ALMONDS.*

BY M. FILETI.

The great difficulty of separating the whole of the hydrogen cyanide from essence of bitter almonds, and of the laurocerasus, renders it probably that it is present in some form of combination with the benzaldehyde; this compound would be the nitril, $C_6H_5.CH(OH).CN$, corresponding with mandelic acid. In order to test the truth of this supposition, the crude essences were treated with zinc and hydrochloric acid, in presence of alcohol and a platinum plate; twenty-four hours afterwards, the mixture was precipitated with water, and evaporated at 100° to remove alcohol. After filtration from the hydrobenzoïn, the liquid was supersaturated with potash, and agitated with ether, the ethereal solution being subsequently washed with water, and agitated with dilute hydrochloric acid. On evaporating the acid solution, the hydrochloride of a base was obtained, which was converted into the platinochloride and analysed, as was also the hydrochloride. The results correspond with the formula $C_6H_5.CH_2.CH_2NH_2$ for the base. From this it would appear that the nitril $C_6H_5.CH(OH).CN$ is present in the crude essences, and that by the action of nascent hydrogen it is not converted into the amide

$$C_6H_5.CH(OH).CH_2.NH_2,$$

as might have been expected, but that an atom of oxygen is eliminated in the process, so that the final product is the base $C_6H_5CH_2.CH_2.NH_2$. A mixture of *pure* benzaldehyde and hydrogen cyanide, when treated with zinc and hydrochloric acid in a similar manner, yields a base having the composition and properties of methylamine.

In a similar manner, both chlorine and fuming sulphuric acid act differently on the essences to what they do on a mixture of pure benzaldehyde with hydrogen cyanide. With the crude essence, a solid crystalline substance is formed, which Zinin has shown to be benzylideneformobenzamide, Ph.CH(OH).CO.N : CHPh; whilst the author finds that no solid substance is produced by the action of fuming sulphuric acid on the mixture, and with chlorine it yields ammonium chloride and monochlorobenzoic chloride.

The base above described is obtained in much larger quantity by the action of zinc and hydrochloric acid on amygdalin in aqueous solution. The hydrochloride of the base is more soluble in water than in alcohol, crystallizing from the latter in large plates, melting at 217°, and subliming near its fusing point. It would appear to be identical with that obtained by Colombo and Spica, by the action of nascent hydrogen on the compound of benzyl cyanide with hydrogen sulphide (*Gaz.*, 5, 124). On decomposing the solution of the hydrochloride with potash, agitating with ether, and leaving the ethereal solution to evaporate, the free base is obtained as a syrupy liquid, which after a time crystallizes in large plates (m. p. 101—104°). The author proposes to continue his examination of the more obscure reactions of the essences of bitter almonds and laurocerasus.

The Pharmaceutical Journal.

SATURDAY, SEPTEMBER 27, 1879.

QUESTIONABLE PROSECUTION UNDER THE SALE OF FOOD AND DRUGS ACT.

We have not unfrequently had occasion to comment upon the oppressive and vexatious mode in which the provisions of the Food and Drugs Act are brought to bear upon chemists and druggists without in any way serving the purposes for which that Act was passed, though at the same time tending to inflict serious personal inconvenience and injury. We regret especially that it has been necessary to make this complaint against the application of an Act which in its spirit harmonizes so thoroughly with the endeavours of the Pharmaceutical Society to expose and put a stop to the falsification of drugs.

Without going back to past instances we may refer to the case that has just been decided at the Chertsey Petty Sessions as affording a fair illustration of what is meant. According to the report of this case, which will be found at page 257, it will be seen that Police-constable Waters, acting upon the instructions of his superintendent, went to the shop of Mr. Boyce, an old-established pharmaceutical chemist at Chertsey, and purchased sundry articles, namely, quinine wine, citrate of iron and quinine, citric acid and cream of tartar. After having obtained and paid for these articles, he informed Mr. Boyce's assistant that they would be handed over to the county analyst for examination, and he offered to leave a portion of each article under seal. In due course these articles were passed through the hands of Superintendent Bungard to the county analyst, who examined them and reported the results he had obtained.

So far there is absolutely nothing to complain of in the manner of carrying out the provisions of the Act. The subsequent reports of the county analyst represented three out of the four articles in question to be genuine, as they might reasonably be expected to be when obtained from such a source. As regards the cream of tartar, however, the report of the analyst represented that it contained tartrate of lime to the extent of 11·7 per cent., and sulphate of baryta to the extent of 0·6 per cent. Both of these substances were spoken of in the analyst's report as being "foreign ingredients," and hence, we presume, the local authorities inferred that the analyst's report showed the cream of tartar not to be of the nature, substance and quality of the article demanded by the purchaser. It is true the analyst's report also stated that the "foreign ingredients" were insoluble, and not injurious to health, so that on this score, according to him, there was no ground for concluding that their presence would be to the prejudice of the purchaser, or the consumer, and it might have been expected that the vendor's freedom from liability to penalty under the provisions of the Act would have been apparent. But it cannot be expected that the local authorities of a town like Chertsey are always qualified to judge of such matters and they may well be excused for having, as it seems, put such an interpretation upon the analyst's report as to induce them to institute a prosecution under the sixth section of the Act against Mr. Boyce, for selling cream of tartar that was not of the nature, substance and quality, etc., demanded by the purchaser.

It is in this way that Mr. Boyce has found himself arraigned on a charge of having transgressed the law by selling an adulterated article and called upon to defend himself from the most damaging imputations that could be made against him in his business capacity. And now let us consider what are the data upon which this grave charge has been brought against him. Of the two so-called "foreign ingredients" reported to be present in the cream of tartar, the one that was in the largest proportion, and that, according to the analyst's report, would consequently have been chiefly to the prejudice of the purchaser, is the tartrate of lime, the other foreign ingredient, the sulphate of baryta, is of itself too small in amount to justify the inference that it was added as an adulteration. What then is the origin of the tartrate of lime? Is there any reason to suspect that it was added fraudulently to increase the weight of the cream of tartar, for that is the imputation conveyed by the charge preferred?

Upon referring to the British Pharmacopœia for information on this point, we find under the head of Potassæ tartras acida, a description of the substance commonly known as "cream of tartar." It is there stated to be an acid salt obtained from the crude tartar which is deposited during the fermentation of grape juice. Proceeding on this basis for further information from other sources, we find that crude tartar, the raw material from which the Pharmacopœia article, "cream of tartar," is prepared, generally if not invariably contains tartrate of lime; moreover, that grape juice itself contains tartrate of lime as well as tartrate of potash, and that in consequence of this association of these two tartrates in the primary source of crude tartar as well as of "cream of tartar," they continue to be associated in its products, so that tartrate of lime is not, as the analyst for the county of Surrey represents, "foreign" to cream of tartar, but a natural ingredient of it. And if we return now to the British Pharmacopœia we find this fact recognized by that authority. The solution of the charred substance in hydrochloric acid is described as becoming slightly turbid when neutralized with ammonia and mixed with oxalic acid and the presence of lime is thus indicated.

But this indication that acid tartrate of potash, in the sense referred to in the British Pharmacopœia, contains some proportion of tartrate of lime is totally ignored by the analyst for the county of Surrey. He like the peculiar people is above considerations which regulate the proceedings of more ordinary folk, and acting upon the esoteric conception that the term acid tartrate of potash is to be interpreted from an absolute chemical point of view, expects a policeman's request for "cream of tartar" to be responded to by a provincial druggist by the supply of perfectly pure bitartrate of potash. This and this alone is the basis upon which tartrate of lime has been treated as a "foreign ingredient" of cream of tartar, and it is only by allowing such superfine and unauthorized views to regulate his proceedings that the analyst has brought about the prosecution of Mr. BOYCE.

Nor is this the only point in which exception is to be taken to the report now in question. From an analyst it might be expected that in such a document, fraught with possible prejudice to another man's reputation, care would be taken not to state anything contrary to well-established chemical knowledge. Unless, indeed, it be unreasonable to expect a public analyst to respect chemical fact, we protest against the representation that tartrate of lime, as an ingredient of cream of tartar, is "insoluble." The assumption that it is an insoluble substance may induce the belief that it is also a "foreign ingredient," but certainly this belief has no better foundation.

It is scarcely to be wondered at that a very simple statement of facts relating to the presence of tartrate of lime in cream of tartar should have led the magistrates unanimously to dismiss this case. Provision had been made to support the defence of the case in this particular by reference to authorities, and by direction of the Council of the Pharmaceutical Society, Mr. FLUX attended to watch the case and assist the defence in case of need. At the same time, Mr. W. HODGKINSON, appeared on behalf of the firm from which Mr. BOYCE obtained the cream of tartar to testify that they had always been in the habit of supplying him with the very best drugs. While thus loyally supporting his customer he was also able, with the aid of Mr. ALLEN, to prove that the conditions under which cream of tartar passed into his hands and was supplied to retailers precluded the possibility of its being adulterated or in any way tampered with.

In these results there is a reason for satisfaction, but it certainly seems to be a somewhat superfluous thing that with the object of protecting the public against adulteration individuals should thus be put to the severest social torture that can be devised. The mere fact of having to appear before a bench of magistrates charged with an offence of the kind that Mr. BOYCE has been charged with is sufficient to furnish evil-disposed persons with opportunity for damaging a man in his reputation and in his business. In the present instance it has been satisfactorily proved that the charge was unfounded; it has also we think been made evident that the prosecution should never have been undertaken and Mr. BOYCE should never have been exposed to the possibility of being asked as he was on coming out of court how his "little job" had been settled?

This experience is one that may fall to the lot of any member of the trade who happens to become "*corpore vili*" upon which the public analyst chances to operate. Surely some arrangement could be devised by which this kind of human vivisection might be avoided without counteracting any beneficent influence that the Food and Drugs Act is calculated to exercise. While public analysts produce such certificates as that upon which the case in question was based, would it not be well to submit these documents to some competent central authority for decision whether prosecution is requisite or justifiable? At any rate, such proceedings as that above described are calculated to bring the Act into contempt, and to make the public analyst, for some sections of the community, a public nuisance.

THE NEW SESSION.

Two or three more days will bring the summer vacation of 1879 to an end, and during the coming week the medical and pharmaceutical schools of the metropolis will be alive with audiences who have assembled to hear the Introductories. On Wednesday the new session in Bloomsbury Square will as usual be inaugurated by an Evening Meeting of the Pharmaceutical Society, the special business of which will be the reception of the reports of the Professors of the School of Pharmacy, the Distribution of the Prizes awarded to the successful competitors of last session, and an Introductory Address to the Students of the present. The occasion promises to be of special interest, as the Address is to be delivered by a former Bell Scholar, Prizeman and Teacher in the School, Dr. W. A. TILDEN, of Clifton. It will not be out of place to point out that the invitation given to the Students and Friends extends to the ladies, and we hope that on this, as on former similar occasions, the meeting may be graced by the presence of many of the fair sex.

COUNTER PRACTICE IN NEW SOUTH WALES.

THE counter practice controversy appears to have spread to the antipodes, a Dr. BOWKER having introduced into the New South Wales Legislative Assembly a Medical Bill which the chemists and druggists of the colony condemn as ignoring the rights, customs, immunities and privileges secured to them by the Imperial legislation in the Apothecaries Act of 1815. At a recent Annual Meeting of the New South Wales Pharmaceutical Society, held in Sydney, a petition was adopted asking for the erasure of the obnoxious clause and the insertion of one repeating the saving clause of the Apothecaries Act; the construction of which has furnished so much food for argument in this country. It was also decided at the same meeting to take steps to draft a new Pharmacy Bill to be submitted to the Legislature.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

Meeting of the Law and Parliamentary Committee.

A meeting of the Law and Parliamentary Committee of this Association was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on September 19, 1879, at 1 p.m. Mr. Thomas Barclay, President, in the chair. Present—Messrs. Andrews, Churchill, Holdsworth, Jones, Southall and the Solicitor of the Association.

The President said the first question on the agenda paper related to the patent medicine question. The Executive at its last meeting passed a resolution directing the Law and Parliamentary Committee to take any steps which they may deem desirable to obtain information to enable them to bring about modifications in the Pharmacy Act, 1868, to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists, and to report to the next meeting of the Executive. The question they had to consider was what steps they should take to obtain information to bring about modifications in the Act. The necessity of dealing with that question was becoming greater every day, and it appeared to him to be the right thing that the Association should endeavour to procure such information as would enable the Executive to grapple with the subject.

Mr. Holdsworth said there were really two sides to the patent medicine question; one, that of prices at which they were sold, and the other the fact of unregistered men selling patent medicines containing scheduled poisons.

Mr. Jones said it was the law in France that all proprietors of patent medicines should make a declaration as to whether they contained poisonous ingredients.

The President said it would be damaging to the patent medicine trade in this country if it were made compulsory on the proprietors to make a declaration of the composition of their goods. On the other hand the Association would probably have the sympathy of medical men in asking the Legislature to pass an Act of that description.

Mr. Holdsworth said it would be necessary in the first instance to prove to the satisfaction of the Legislature that the present system of unregistered persons vending patent medicines containing scheduled poisons was dangerous.

Mr. Andrews concurred with Mr. Holdsworth's remarks. He said they would get very little sympathy from the Government unless they were in a position to show that an evil to the public existed in dangerous poisons being sold by unqualified persons under cover of the patent medicine stamp.

The President said he thought if that was proved they would have the medical men on their side and that the Legislature would be disposed to so modify the Act as to comply with their request. He added that he thought circulars might be issued from the office to influential members of the trade in various parts of the country inquiring for particulars of any serious accidents that had happened from the sale of patent medicines containing scheduled poisons.

After some further discussion it was moved by Mr. Andrews, seconded by Mr. Jones and unanimously resolved, "That a circular should be sent to members of the General Committee and others asking for well authenticated instances in which fatal results have followed from the sale of scheduled poisons under cover of the patent medicine stamp and for suggestions and information on the sale of patent medicines generally."

The President said the next question for the consideration of the committee had reference to jury service. A resolution was passed by the Executive at its last meeting, "That the Law and Parliamentary Committee be and are hereby empowered to take such steps as they deem advisable to obtain the exemption of all registered chemists and druggists from jury service."

The Solicitor said he feared nothing could be done by the Association in that matter at present.

The President said he knew from personal experience that it was a very sore point with the trade and one which they were very anxious should be taken up.

The Solicitor said no active steps could be taken until an amended Pharmacy Act or Jury Bill was before the House.

Mr. Holdsworth said it would be a mere waste of time and money to move in the matter just then.

Mr. Andrews said he was exceedingly anxious that all chemists and druggists should be exempt from jury service, but he thought they must wait for a favourable opportunity to accomplish their object.

The Secretary stated that in compliance with instructions received from the Executive at its last meeting, he had collected evidence in a number of cases of infringements of the Pharmacy Act, 1868, the particulars of which were laid on the table.

After a careful examination of the evidence collected, it was moved by Mr. Andrews, seconded by Mr. Southall and unanimously resolved, "That the Solicitor be instructed to take proceedings under the 17th section of the Pharmacy Act, 1868, against three illegal traders, and that particulars of these cases with the remaining cases of infringements of the Act, collected by the Secretary, be forwarded to the Secretary and Registrar of the Pharmaceutical Society."

The Secretary reported that, in accordance with a resolution passed by the Executive at its last meeting, he proceeded to Sunderland and investigated the case of a member of the Association, against whom proceedings had been taken by the Excise authorities for the sale of methylated spirit without a licence, and that the case was heard by the Sunderland borough magistrates on July 23rd, 1879, when the Solicitor of the Association defended. The defendant was fined a mitigated penalty of £12 10*s.*, with a recommendation from the bench to the Excise authorities to still further reduce the penalty to £5. A letter from the defendant was read, stating that he had received a notice from the Inland Revenue authorities, to pay the reduced penalty of £5, as recommended by the borough bench, and thanking the Executive for the way in which his case had been supported by the Association.

A number of letters were read from members of the Association, and instructions given to the Secretary as to the manner in which he should deal with the same.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from page 237.*)

The next paper read was—

Note on Aricine.

BY JOHN ELIOT HOWARD, F.R.S.

Aricine was discovered by Pelletier and Corriol* in a cinchona bark coming from Arica to Bordeaux. M. Pelletier thought that he had obtained a characteristic green colour by nitric acid, but as no one has been able (as I think) to verify this observation, it is probable that the colour, which he detected, was owing to the presence of some impurity in the nitric acid which he employed.†

* Pelletier et Corriol, 1829, *Journ. de Pharmacie*, xv., 595.

† Pelletier, *Ann. de Chimie et de Phys.*, li., 185.

Subsequent researches were less successful, and much obscurity was permitted to involve the question, increased by the supposed identification of *cinchovatine*, discovered by M. Manzini, with this alkaloid.

Recently the whole subject has been elucidated by the researches of Dr. Hesse, who has sent over specimens of various alkaloids to the Museum of the Pharmaceutical Society, together with the barks from which they were derived.

My attention has been directed by one of the officials of the Society to the apparent perfect identity of the *aricine* of Dr. Hesse, with a specimen of the same alkaloid which I deposited in the Museum of the Pharmaceutical Society, in December, 1852, attached to a portion of the bark from which it was obtained. In company with some of the authorities of the Society, I have compared the two specimens, and am satisfied they are the same substance.*

The bark of Dr. Hesse and mine are exactly alike. It is the *jaune de Cuzco* of Delondre and Bouchardat (of which I have an example from the collection of these gentlemen), figured in plate xix., and described in pages 38 and 39 of their 'Quinologie.' M. Delondre† met with it in the forests of Sta Ana, in his excursions in 1847 with Dr. Weddell; and I have a botanical specimen gathered in the same year by the latter, which he calls "*Cinchona Pubescens*, Vahl., var. *Pelletierana*, Peru, Province de Carabaya, June 18, 1847." The bark was imported and sought to be introduced as calisaya, with which it was mixed in 1829. This gave rise to the researches of M. Pelletier. The *jaune de Cuzco* I have referred to is perfectly identical with the bark from which both Dr. Hesse and I have obtained aricine; and I doubt much its having been obtained in a crystallized form from any other. I have never said that I had extracted it from the bark of *C. succirubra;* though in the strange medley of substances which the old red bark contains I indicated *aricine* (?) as possibly one of its contents. Probably this material was *paricine*, but it baffled my investigations.

M. A. C. Oudemans, junior, has been good enough to send me his 'Recherches sur la Quinamine,' which contains the analysis of 600 grams of the "mixed alkaloids" or quinetum from the bark of *C. succirubra* grown at Darjeeling.

It is as follows:—

Cinchonine	37·0	per cent.
Quinine	6·1	,,
Cinchonidine	22·9	,,
Quinamine	4·5	,,
Alcaloides amorphes	21·1	,,
Carbonate de sodium	2·9	,,
Eau	2·7	,,
Also in another experiment:—		
Quinidine	0·5	,,
Conquinamine	0·3	,,

I have been asked by the East Indian Government to give my opinion of the above as a medicament; and have objected to this mixture as containing so large a portion of alkaloid of uncertain description and of possibly injurious operation. Dr. Hesse‡ has found in the same compound "*Paricine* and two or three other amorphous basic substances." I myself found (in the product *first sent*) *copper* in so large a proportion as to coat the blade of a knife when introduced into a solution of the greenish powder. I have no doubt that the whole taken together would cure Indian fever, but should not like to subject myself to the treatment.

I have never put forward any claim to original discoveries as to *Aricine*; but having pretty frequently met with the bark in past years, I satisfied myself by many experiments of the substantial accuracy of the first published researches of Pelletier; and consequently have asserted the same at the time that the existence of *Aricine* was generally denied.

The first specimen of crystallized *Aricine* in my museum is dated October, 1849, and I have specimens of compounds of this alkaloid in 1853–'54 and '57. I have also some results from researches on the very peculiar colouring matter.

I am pleased that this subject is now again occupying the attention of chemists, and hope that the physiological effects of this singular substance, as well as those of *Paricine* will be investigated by some competent member of the medical profession.

This research possesses an interest beyond that which would at first appear, because it has relation to the classification of the different species of the genus *Cinchona*. It is obvious that the large production of quinine by the *C. Calisaya*; of cinchonine by the *C. Peruviana* and its congeners; of quinidine by the *C. Pitayensis*; of cinchonidine by varieties of *C. officinalis* and *C. lancifolia*; and of aricine by *C. Pelletierana*, point to real specific differences; and there is more even than this fact to be learned in the above connection.

In "Observations on the Present State of our Knowledge of the Genus Cinchona,"* published in the Report of the Botanical Congress of 1866, under the head "Jaen and Cusco barks," I have noticed that the *C. Pelletierana* is the true *Quina amarilla* or *yellow bark*, and that "around this are gathered other species of cinchona, which, viewed in this light, constitute a very exceptional and anomalous group of plants;† which most certainly belong to the genus cinchona, but in which the typical cinchonaceous elements are superseded by those corresponding to, and perhaps identical with, the products of other families of plants. I have shown under the heads *C. lutea* (*quod vide*) and *C. decurrentifolia*, in my illustrations of the 'Nueva Quinologia,' how botanical and microscopical researches illustrate and confirm each other; and how microscopical examination comes in to aid the diagnosis of the barks; all tending to show the *Ladenbergia-like* character which pervades them; and under the *C. lutea* it appears that Pavon's careful observation of the living plant brings out indirectly the same fact. He says that "a *milky juice* flows out when the tree is cut down or amputated;" that is to say, the milk cells are abundant and full of their peculiar product, in which respect the tree symbolizes specially with the kindred genus.

I refer to the "Report" itself for further observations on these yellow barks, and to my remarks‡ under *C. lutea* for the *yellow colour*. In conclusion I would briefly add that, the *red barks* are equally a *group of plants* of which the *C. succiruba* may be looked upon as the centre. (See my account of specimens of *C. succirubra* in my 'Nueva Quinologia, pp. 4, 5.) The *red bark* is only beginning to be fully investigated as to its alkaloids, and *even less so as to its other constituents*, as I have partly remarked in the work alluded to; but this much may be said with certainty, that the physiological effects must be considerably different from those of other barks. The Spanish physicians had an opinion about it, to which I cannot at the moment refer. I understand that a fluid extract of *C. succirubra* has recently obtained some celebrity, but have not yet had an opportunity of examining it. It is probable that its medicinal effects may vary from those of a tincture of *pale* bark, and still more widely from a tincture of *yellow* (cordifolia) or of *Calisaya* bark.

A vote of thanks to Mr. Howard was passed.

* The only perceptible difference is in the *colour*. Mine having been purposely crystallized in the first place from pure ether to distinguish it from cinchonine, retains some of the peculiar yellow colouring matter.

The author of the next paper not being present, an abstract of it was given by Mr. W. H. Naylor. The full text is as follows:—

The Chemistry of Chaulmoogra Oil.

BY JOHN MOSS, F.I.C., F.C.S. LOND. ET BER.

A body possessing well marked physical characters, and capable of producing effects interesting alike to the physiologist and the therapeutist is sure to excite that spirit of inquisitiveness which is the moving force in all scientific inquiry. The physiologist and the therapeutist both want to know what is the proximate cause of the phenomena noted by them, and the chemist busies himself to find it out; separating by his art the inert and diluting material. The members of this Conference sympathize most with the latter, and if each could be persuaded to tell the conclusion to which a scientific use of the imagination has led him in speculating as to the nature of the said proximate cause, nine times out of ten he would suggest an alkaloid. There is about an alkaloid something so definite, so tangible and real; it is so compact an expression of ideas and properties, is so representative and genuine, that to discover it is a desirable thing, and its presence is easily assumed where strongly marked properties exist. The thought is begot by a powerful desire, and is itself strong—so strong that all others relating to the same body are for the time subservient to it. That Chaulmoogra is a most powerful drug need not be insisted on here, seeing that the widely known favourable testimony of highly qualified observers in Europe and Hindoostan is concurrent with the position it occupies in the 'Pharmacopœia of India,' and the almost veneration with which it is regarded by the native Hindoos. That an alkaloid should be the first thing looked for when an examination of the oil was resolved upon, was a matter of course; had one been discovered further investigation had probably been stayed. As a guide and a warning to others who may be encouraged by this failure, the method adopted in searching for the possible alkaloid is here given.

§ 1. *Examination for Alkaloid.*

a. Volatile.—One pound of chaulmoogra was placed in a retort with twice its weight of water and boiled. The collected distillate, (4 ozs.), was perfectly clear, possessed the odour of the oil in a marked degree, and was neutral to test paper. With acetate of lead a precipitate was thrown down, as also with chloride of barium when made perfectly neutral with potash. With the usual alkaloidal reagents no change was produced in the liquid, which was accordingly precipitated with lead acetate, the precipitate collected, decomposed with hydrochloric acid and agitated with ether. Evaporation of the ethereal solution gave a fatty body, which was not further examined. The contents of the retort were now made alkaline with solution of soda and the distillation was continued; this time the distillate gave no indication with any of the reagents used in the first instance and was returned to the retort along with sufficient sulphuric acid to be in excess. Twelve ounces of distillate were collected and on the surface of it were floating aggregations of white, silky needles. The liquid was negative to reagents. The white needles were collected and found to weigh 2 grains. They possessed all the characters of cocinic acid, treated of afterwards.

b. Non-Volatile.—A pound of the oil was agitated with successive portions of warm water, acidulated with hydrochloric acid in a Winchester quart bottle. After each agitation the bottle was inverted and allowed to stand till cool, when the oil formed a solid cake, from which the liquid could be easily run away below. The united liquids were reduced in bulk over a water-bath and tested with the usual alkaloidal reagents, namely, phosphomolybdic acid, iodo-hydrargyrate of potassium, iodine in iodide of potassium, iodide of bismuth and potassium, and iodide of cadmium, each one of which produced a precipitate. The whole was now rendered alkaline by soda, filtered, and half the filtrate agitated with chloroform. The chloroform on evaporation to dryness gave a residue which was treated with very dilute sulphuric acid, and the acid solution was shaken with chloroform after addition of sufficient ammonia to make it alkaline. The chloroform solution was separated and divided, one portion being shaken with water containing sulphuric acid, and the other with hydrochloric acid. Very slightly coloured residues were obtained on allowing each of these solutions to evaporate spontaneously. The residues when microscopically examined exhibited after a time well defined isolated needles and prisms, few in number and widely scattered; the quantity of these crystals was so very minute that any attempt at a chemical examination was entirely precluded, even if its minuteness as compared with the original bulk of oil had not robbed them of all significance. The residues when dissolved in weak acid—they would not dissolve in water—gave a precipitate with ammonia which was found to agree in character with the ammonia salt of a fatty acid.

A like result attended the treatment of the second half of the filtrate with ether in place of chloroform. A further search for an alkaloid was made on the liquor produced when one pound of oil was saponified. The treatment was precisely as the foregoing after addition of soda. The precipitate formed by soda in the first instance, and already existing in the second, and which consisted of the hydrate and phosphate of calcium, vegetable tissue, etc., was digested in chloroform and further examined for alkaloid. Each attempt was rewarded with non-success.

Satisfied either that chaulmoogra contained no alkaloid at all, or that if it did the quantity was so very small that no share in the properties of the drug could be reasonably claimed for it, a fuller and more systematic examination than was at first contemplated seemed to be desirable. Such examination was accordingly instituted, and it grew in interest as fact after fact was slowly and laboriously laid bare. And here I would say that I know of no research drawing more frequently and more largely upon the patience and the resources both of mind and fingers of the chemist than the unravelling of the constitution of a complex fatty body, and my thanks are due and are cheerfully given to my friend and assistant, Mr. W. A. H. Naylor, for his unwearied and painstaking attention to my wishes and for his suggestive interest in the work, which was rendered more difficult by the exigencies of a busy laboratory where numerous and varied operations were proceeding at the same time.

§ 2. *General Examination.*

To make this account more complete it is necessary that I should refer to a previous paper published in the *Chemist and Druggist* for December, 1878.

To a general description there given of chaulmoogra were joined certain remarks having industrial and pharmaceutical interest; and besides these, the paper furnished results obtained in a preliminary examination undertaken as stated "with a view to obtain indications of the direction in which more particular investigation would lead to the most interesting and valuable results." A summary of these results will not be out of place here, inasmuch as it will assist in avoiding subsequent explanations.

a. Summary of results previously obtained.—Chaulmoogra oil has a decided acid reaction. The melting point is 42° C. and at that temperature the specific gravity is ·930. It froths freely when agitated with warm water and after standing separates over the surface of a milky emulsion. At the ordinary temperature alcohol (·807) dissolves a considerable proportion, including those constituents of higher melting point and acid reaction possessing the characteristic odour and acrid taste of the oil and giving Dymock's reaction (a rich olive-green colour with oil of vitriol) very readily. The portion not dissolved by cold alcohol exhibits a pale green colour with oil of vitriol and is completely dissolved by repeated treatment with warm alcohol of the same strength. Ether (·720), chloroform, carbon disulphide and benzine (·872) completely dissolve the oil, except (and the exception equally applies to alcohol) a minute proportion of flocculent dust consisting of oxalate and phosphate of calcium, sodium and potassium salts, vegetable tissue and albumenoid bodies. The albumenoid bodies are present in sufficient quantity to form a milky emulsion with a small proportion of whatever quantity of oil is agitated with water.

By saponification with potash and decomposition of the resulting soap by hydrochloric acid 81·11 per cent. of fatty acids are obtained, which after exposure assume a white bloom similiar to that observed on the surface of Japan wax. The fatty acids give a fine green colour on the application of Dymock's test.

b. The results which follow have been obtained since the publication of the paper above referred to, and though they still leave the chemical history of chaulmoogra oil in a somewhat incomplete state they form an interesting addition to our knowledge of this important drug.

The melting point of the fatty acids just as obtained from the oil in a mixed condition is 44°C. Numerous preliminary trials were made of processes for separating and identifying them which promised well on paper and were serviceable as illustrating the behaviour of the acids and their compounds under certain treatment, and which in addition to this, did indeed suggest the probable presence of acids afterwards found, but however interesting and instructive to the experimenter, the details would prove but tedious to others, and accordingly I shall confine myself to describing the processes finally adopted, by which the proximate principles to be described were actually separated.

c. Free fatty acids in the oil.—The strong acidity of the oil and its solutions indicates the presence of one or more free acids; to separate and identify these was the first part of the problem to be attacked. Half a fluid ounce of the oil was shaken with three fluid ounces of a saturated aqueous solution of hydrate of barium at 100° F. The watery liquid was removed and the oil washed with successive quantities of water at the same temperature as the solution originally used, until the washings came away neutral.

The united liquids were filtered, acidified with hydrochloric acid, and boiled. There was no separation. The oil therefore does not contain any compound of a fatty acid, and does not form with hydrate of barium any such compound, which is soluble in water or baryta water.

d. Oil treated as above will contain the fatty bodies originally present in it, and barium compounds of the free acids originally present. From this oil cold alcohol (·807) and ether (·735), used successively, dissolve away the former, leaving all the barium compounds; boiling alcohol dissolves a very few grains of the residue. The residue consisting of barium compounds was then fused by admixture with boiling water, hydrochloric acid added, and the fatty acids collected on a filter and washed with hot water till the washings were neutral and free from barium chloride. After this the fatty acids were kept melted on a water bath till dry, when they were treated with alcohol and the solution set aside. In a little while crystals appeared which when first tried melted at 55° C. By repeated crystallization from warm alcohol these were finally obtained of a pure white colour and having a constant melting point of 62° C. With the aid of a microscope and selenite plate this crystalline body was recognized as palmitic acid. The crystalline form and the arrangement of the crystals corresponded exactly with a beautifully executed photograph of palmitic acid forming one of a number in a pamphlet* published by Price's Patent Candle Company, and besides it corresponded in all characters to a specimen of chemically pure palmitic acid, for which as well as the pamphlet I am indebted to the kindness of the company.

On the first treatment with alcohol of the fatty acids separated as above a portion remained undissolved, which was subsequently found to go into solution when more alcohol was used, especially when warmed. This portion consisted of palmitic acid solely.

e. The alcoholic solution first obtained, from which crystals of impure palmitic acid separated as the alcohol slowly passed away into the air, yielded on evaporation to dryness a fatty acid, which when purified by repeated treatment with small quantities of cold alcohol had a fixed melting point of 29° C. This body is more fully described later on (*h*).

f. Turning now to the fatty acids obtained by decomposing the soap of chaulmoogra, 31·7 grams of the mixed acids were dissolved in just sufficient alcohol for the purpose and the solution was saturated by adding solution of ammonia (·959). This converted all the acids present into ammonia salts. Acid palmitate of ammonia is not freely soluble in spirit and separated out at once; the acid from this precipitate was prepared in the free state and identified. It was not pure but contained another acid not recognized at the time, which will be found freely described in *h*; this acid is also mentioned in *e*. The spirituous solution of the ammonium salts was now treated with chloride of ammonium and acetate of magnesium. These failed to produce any visible change in the solution, thus indicating the absence of more than traces of palmitic acid. On the further addition of an aqueous solution of chloride of barium a precipitate fell of a viscous character. This was collected and digested with cold alcohol, which dissolved a small portion, leaving a precipitate which was decomposed, washed, dried, dissolved in alcohol, and exposed to cold. The solution separated from the crystalline deposit of palmitic acid was now treated with lead acetate in presence of ammonia and warmed, and the precipitate resulting from this treatment was likewise set aside. The filtrate was kept warm until all the alcohol was expelled, and the liquid containing the lead salt thrown out of solution by the expulsion of the alcohol was treated with ether, by which it was completely cleared. Hydrochloric acid was now added, the chloride of lead produced removed by a filter, and the ethereal solution of fatty acid allowed to evaporate spontaneously. A crystalline substance separated in rosettes, which when subsequently crystallized from alcohol was quite colourless, but turned yellow in a few hours. It melted at 33° C. This is the melting point of hypogæic acid, which moreover possesses the characteristic of turning yellow a few hours after it is prepared. Hypogæate of lead is readily dissolved by ether; it also dissolves in warm alcohol, but the greater proportion separates out upon cooling. It is not precipitated by magnesium acetate in presence of alcohol. The barium compound also dissolves in hot alcohol but falls out of solution on cooling. The compounds of the acid under consideration possessed all these characters, and its identity with hypogæic acid was established by a combustion. 0·181 gramme was burned with chromate of lead and yielded ·1369 gramme of carbon and ·0217 gramme of hydrogen; side by side I give the numbers obtained, calculated into percentages, with those required by the formula for hypogæic acid, $C_{16}H_{30}O_2$.

	Numbers Obtained.	Theoretical Numbers.
Carbon . .	75·63.	75·59.
Hydrogen .	11·99.	11·81.

g. The precipitate produced by acetate of lead and not dissolved by warm alcohol was freed from adhering liquor by pressure between folds of bibulous paper and then digested in ether; hypogæate of lead was dissolved away. The insoluble portion was decomposed by hydrochloric acid and the free fatty acid crystallized from ether. It melted at 38·5° C. and crystallized in a form very closely resembling that assumed by palmitic acid, but when crystallized under the same conditions it is not so delicate as the latter. A further small quantity of this acid, as also of hypogæic acid, was obtained from the

* 'Examen der Acides Gras par la lumière olarisée.'

cold alcohol washings of the viscous barium precipitate. To examine it more particularly 660 grains of the mixed fatty acids were used for preparing some by a method slightly modified from the above. The acids were dissolved in alcohol and the solution was treated with ammonia and magnesium acetate. The precipitate, which will be considered later, was collected on a filter. Lead acetate was added to the filtrate and after two days standing the mixture was filtered. The precipitated lead salt was washed with cold alcohol, dried and digested in ether. The insoluble portion was again dried, fused on the surface of warm water, and decomposed by hydrochloric acid. The liberated fatty acid being removed by agitation with ether, was freed from the solvent and then dried over oil of vitriol. It weighed 18 grains, and by observation of the melting point was found to be still impure owing to the presence of palmitic acid. This was removed by fractionation from alcohol and th finael pure product, a white crystalline mass, weighed when perfectly dry 10 grains. The melting point was constant at 385° C.

0·171 gramme burned with chromate of lead gave ·184 gramme of water and ·446 gramme of carbonic acid, corresponding to ·0204 gramme of hydrogen and ·1216 gramme of carbon, or in 100 parts.

	Numbers Obtained.	Calculated from $C_{11}H_{22}O_2$.
Carbon . .	71·11.	70·97.
Hydrogen .	11·92.	11·82.

By the side of these numbers I have placed others with which they closely agree, calculated from the formula $C_{11}H_{22}O_2$, an acid not usually mentioned in the text-books, but which I find very fully described under the name of cocinic acid in a paper by M. Saint Evre—"Recherches sur les Acides Gras du Beurre de Coco."* He says "Il cristallise par le refroidissement de sa dissolution alcoolique en aiguilles incolores groupées en étoiles autour d'un centre commun. Il fond à la température de 34·70 et se dissout aisément dans l'éther et l'alcool à 36 degrés. Il est depourvu de toute espèce d'odeur, et lors qu'il a été maintenu en fusion pendant longtemps, puis soumis à l'action du vide, il se présente sous la forme d'un masse incolore, dure et cassante. Il se volatilise, mais seulement dans un courant de gaz." This desciiption applies perfectly to the acid separated from chaulmoogra with the single exception of the melting point. According to Dumas' theory a body having carbon atoms in the series $C_nH_{2n}O_2$ should melt at 36·5° C. Saint Evre's observation was as much below this point as that here recorded is above, and looking to the source whence his acid was obtained it was quite as likely to contain a minute trace of oleic acid as the cocinic acid from chaulmoogra is likely to have still held a trace of palmitic. Referring more particularly to the volatility of cocinic acid in a current of gas it will be seen in the section which describes the examination for alkaloid, that silky needles possessing all the properties of this acid were found in the distillate from chaulmoogra and water with sulphuric acid.

The position of cocinic acid is between rutic or capric acid and lauric acid in the series $C_nH_{2n}O_2$.

h. The magnesium acetate precipitate obtained in the last process was decomposed by hot dilute hydrochloric acid and the liberated fatty acids were washed till free from chlorides. Palmitic acid was separated from the mixture at first by dissolving in warm alcohol and cooling, but this method was altogether inadequate to its complete removal and a method of fractional precipitation was adopted; first, by the cautious addition of a concentrated aqueous solution of magnesium acetate to the simple alcoholic solution of the acid, and afterwards by similarly treating the solution when it had been made neutral by ammonia.

After the separation of the fractions the alcoholic strength and solvent power of the solution was reduced by the addition of water, and on standing a small quantity of magnesium salt separated out. That the last traces of palmitic acid were thus removed was shown by the following treatment of the filtrate. This was decomposed by hydrochloric acid, the fatty acid removed, washed and dissolved in alcohol. To the solution water was added till feebly opalescent and then the mixture was exposed to a temperature of 6° C. for some time without any further separation. The weak alcoholic solution was gently evaporated and allowed to crystallize. After repeated crystallizations a body was obtained of a feeble yellow tinge, which under the microscope shot out as it cooled into crystalline plates with a more or less deep thalloid fringe, polarizing at the margins only. The melting point was 29·5° C. Fractionated from alcohol the fractions were homogeneous, exhibiting precisely the same crystalline form and melting at exactly the same point.

0·348 of the acid burned with chromate of lead gave 0·3465 gramme of water, and 0·955 gramme of carbonic acid gas equivalent to 0·0385 gramme of hydrogen, and 0·2604 of carbon; or 11·06 per cent. of the former and 74·84 of the latter element.

In a second combustion 0·381 gramme gave 0·382 gramme of water and 1·048 of carbonic acid gas; equivalent to 11·13 per cent. of hydrogen and 75·01 of carbon.

In a third combustion 11·2 per cent. of hydrogen was obtained. The results placed side by side show as follows:—

	No. 1.	No. 2.	No. 3.
Carbon . . .	74·84	75·01	
Hydrogen . .	11·06	11·13	11·2

The numbers correspond to a member of the little known series $C_nH_{2n-4}O_2$, and the probable formula is $C_{14}H_{24}O_2$, which by calculation gives—

Carbon, 75; Hydrogen, 10·7.

Though additional data will be required to determine the formula I think it is certain that this body has not been previously examined and described, and accordingly, having reference to its source, I propose to name it *Gynocardic acid*, and trust shortly to be able to announce the correct formula.

This is the acid referred to in *e* and *f*, and as already stated has a pale yellow colour and a well marked crystalline form. Gynocardate of ammonium is soluble in water. The magnesium salt is insoluble in water, but dissolves in alcohol (·807) and falls out of solution on diluting. The lead and barium salts are insoluble in water, ether and cold alcohol.

§ 3. *Dymock's Test.*

Reference has been made in this paper to Dymock's test for chaulmoogra oil. Fuller reference will be found in the paper from which I have already quoted (*vide* p. 251), where the opinion was expressed that the reaction on which it is based was characteristic of the oil, and taken in connection with physical characters might be used as an indicator of genuineness. In the course of investigation I have been compelled to modify this opinion, and take the present opportunity of qualifying it. As progress was made in the work of separating the proximate parts of chaulmoogra, each was subjected to the test, with the result, at first, that the colour was invariably obtained. One of the first separated quantities of palmitic acid, gave the colour in so marked a degree that certain natural substances known to contain palmitic acid as well as the pure acid itself were submitted to the test. It was thus ascertained that pure palmitic acid does not present the reaction, nor do any of the bodies experimented with, including Japan wax and butter, except palm oil. This gives a splendid green colour with sulphuric acid when applied as Dymock directs, a colour of the same character as that afforded by chaulmoogra. The green coloration is therefore not peculiar to the oil, as was supposed by Dymock, but is a property which equally belongs to palm oil. As the working processes

* *Annales de Chimie et de Physique*, troisième série, 1847, xx., 91.

improved with additional knowledge of the material, the constituents of chaulmoogra which gave the green colour, were reduced and narrowed by purification till only the last, *gynocardic acid*, remained. It still remains. It has not been found possible by any means to deprive *gynocardic acid* of this colour-giving power. A quantity of it has been dissolved in alcohol and crystallized from it in successive small portions—each fraction has given the colour with equal intensity. It has been digested with animal charcoal, and after such treatment the colour has been verdant as before; it is inherent and a characteristic. *Gynocardic acid* also produces the acrid burning taste which is noticed when chaulmoogra is swallowed, and altogether appears to be a constituent of such importance as to deserve further attention, not only from a chemical point of view, but also in regard to its medicinal activity.

§ 4. *Constituents Separated and Recognized.*

Chaulmoogra oil then, so far as it is at present known, contains:—

Gynocardic Acid	11·7
Palmitic Acid	63·0
Hypogæic Acid	4·
Cocinic Acid	2·3

in combination with glyceryl as fats, and the two former in the free state as well. No attempt was made to determine accurately the proportion of each acid present, as the loss in purifying was necessarily considerable, but the figures against each represent fairly well the quantity of acid in 100 parts of oil.

The PRESIDENT said this paper was a very exhaustive and admirable one, and the members of the Conference owed their thanks not only to the writer, but to Mr. Naylor, whose clear and comprehensive condensation of its contents had placed the subject so lucidly before the Conference.

Mr. A. H. MASON said as some of the members present might be unacquainted with this oil, it would be well if information were given as to its origin and supposed properties.

Mr. NAYLOR said the oil was obtained from a plant known as the *Gynocardia odorata*, and had been used very successfully in cutaneous diseases. It was an oil much used in India, and had been sold in the bazaars there for a great number of years. It had also been used with considerable success in this country in cases of phthisis, but had not been previously studied chemically, except by Dr. Dymock.

Mr. WILLMOTT quoted a case in which it was found that the medical properties of chaulmoogra oil were not so great as those of gurjun oil.

Mr. BAXTER spoke of chaulmoogra oil as a cure for itch and mange in dogs.

Mr. GREENISH said that the green coloration produced by a drop of sulphuric acid brought into contact with the chaulmoogra oil, being considered by Dymock a test of the genuine oil, he would like to know from Mr. Naylor if he had tried it on oil extracted, for instance, by benzine, to ascertain if the coloration proceeded from the oil or from some organic matter which may have been pressed out into the oil.

Mr. NAYLOR, in reply, said chaulmoogra oil had been used for a variety of purposes, but it was never intended to be a panacea, and in some cases it had not been so successful as others. He had known it to be largely used in mange in dogs, and he had not heard of a case in which it had failed. With reference to the green colour produced with sulphuric acid, whatever solvent might be used, providing gynocardic acid was present, the fat from the solution would give a green colour. That test had been applied to the oil which had been extracted with benzol and oil obtained by pressure.

The next paper, which was read by Professor Attfield, the author not being present, was entitled—

THE CAPACITY OF DIFFERENT ORGANS TO ABSORB AND RETAIN ARSENIC IN CASES OF CHRONIC POISONING.

BY N. P. HAMBERG, M.D., H.M.P.S.

This paper called forth some adverse criticism, on the ground that the subject was foreign to pharmacy; and, as it did not contain anything which had not previously been established, its publication does not appear desirable.

The last paper read was—

NOTE ON THE ESTIMATION OF MORPHINE IN TURKEY OPIUM.

BY PROFESSOR FLÜCKIGER.

The estimation of morphine is the subject of many valuable papers which have been published in the various pharmaceutical periodicals. Numerous and elaborate as they are, these investigations have not, as far as I can see, arrived at a thoroughly satisfactory result. Without further discussing in this place the merits of these methods, I beg to submit to the Conference another process, of the utmost simplicity, yet of sufficient accuracy. How far this accuracy is attained by the method I now recommend remains for the profession at large to decide. It must be remembered that it is exclusively intended for the assay of official, *i.e.*, Turkey, opium. Valuable as may be the drug produced in other countries with regard to the industrial extraction of alkaloids, no modern pharmacopœia has ever admitted any other kind of opium than that of Asia Minor. My method will possibly prove less satisfactory if applied to Indian or Persian opium, although in my opinion, for a fair standard opium, it is a good and elegant process. It is as follows:—

Take of powdered opium 8 grammes (=123·5 grains), cold water 80 grammes; shake the mixture frequently; filter after twelve hours. The filter should have a diameter of five inches. The operation will afford on an average 65 to 70 grammes of clear liquid. No washing is to take place. 42·5 grammes of the liquid are collected in a little phial, the weight of which should have been marked on it. Then add to the solution 12 grammes of alcohol (sp. gr. 0·812 – 0·815), 10 grammes of ether and 1·5 gramme ammonia water of 0·960 sp. gr. The mixture after shaking will remain clear and allow a colourless layer of ether to make its appearance. The phial is corked and allowed to stay without further shaking it. After an hour or two, crystals of morphine begin to be formed, mostly at the border of the two layers. By and by they sink down to the bottom, and after a day or two the whole amount of whitish or white crystals of the alkaloid will be deposited. They are then to be collected by using two folded filters having a diameter of four inches. The phial is rinsed out with a mixture of 6 grammes of alcohol and 5 grammes of ether, and lastly with 10 grammes of ether, these liquids being gradually poured on to the crystals in order to wash them. The funnel in the meantime is carefully covered. The crystals are subsequently cautiously pressed between the folds of the two filters, which will almost completely absorb the mother liquor which the crystals of morphine may still retain. It will now be easy to remove the alkaloid very neatly from the filter; it must be weighed in the very phial in which some crystals may have remained obstinately attached to the walls. The phial lastly dried at 100° C. then contains the whole amount of morphine precipitated, that is to say its hydrate, viz., $C_{17}H_{19}NO_3 + OH_2$.

As to the mother liquor, it is to be observed for a day more in another corked phial; it does not usually afford a further crop of crystals. Yet in an open vessel amorphous matters are soon deposited.

A good Turkey opium being under examination will thus afford about 0·40 to 0·48 gramme of morphine, which are to be considered as deriving from half the weight of the sample, *i.e.*, from 4 grammes opium ; the percentage would then be 10 to 12.

The alkaloid must next be identified by resorting to the usual tests for morphine. Among them there is the official nitrate of bismuth, which I have pointed out some time ago* as one of the most characteristic tests for that alkaloid. If morphine is rubbed with concentrated sulphuric acid the liquid turns dark brown or black as soon as a little nitrate of bismuth is strewn on it. An excess of nitric acid present in the official nitrate of bismuth would at first produce rather a red hue. Lastly, there is also to be ascertained the purity of the crystals. To this effect take 1 decigramme of the morphine and dissolve it in 10 grammes of lime-water. If the lime-water is duly saturated, in the cold, the quantity mentioned will be a little more than sufficient. The morphine will then prove to leave a very trifling amount of colouring matter, quite insufficient to influence appreciably the percentage of the alkaloid. Should narcotine be present it would remain undissolved, and might be weighed if the whole quantity of morphine be treated with lime-water. But it would, in such a case, be much more advisable to get rid of the narcotine by repeating the experiment with another sample of opium. I would recommend then, as I have already urged in the 'Pharmacographia,' page 59, to dry the opium previously and to deprive it of narcotine by exhausting it with boiling ether. It must be borne in mind that we have to do now with perfectly dry opium, whereas in the beginning we started with air dry opium, the latter containing, possibly, as much as 7 or 8 per cent. of water.

If to the solution of morphine in lime-water a little chlorine water is added, a remarkable reaction is displayed: the mixture assumes a permanent bright red hue, which is highly characteristic ; this is, in fact, an excellent new test for morphine.

The assay as just described somewhat minutely is of the utmost practical simplicity; it must be granted that it claims no special rapidity, but it is by no means longer than any other process hitherto devised for the same purpose.

A few explanatory remarks must be still added. As a solvent for opium, cold water is by far the best, for the simple reason that it affords immediately a liquid ready for the precipitation of the alkaloid. It is true that the drug yields a less coloured solution by using alcohol, but this would require a distillation.

If opium is to be exhausted by means of water it is extremely difficult to point out how far the extraction must be carried on. Cold water on an average dissolves about 60 per cent. of standard Turkey opium if it is absolutely exhausted. By treating 8 grammes of opium with 80 grammes of water we should consequently obtain very nearly 85 grammes of solution. As it is practically almost impossible to get really as much as this, it will be safer to use just half the amount of the calculated liquid, namely, 42·5 grammes. The analyst who does not feel satisfied with this average number may ascertain exactly the amount of soluble constituents which his sample of the drug is able to yield ; he may then act accordingly.

I believe the morphine to be present in the opium as a sulphate, at least for the most part. This is evidenced by the fact that the alcoholic solution of opium is found to contain both the alkaloid and sulphuric acid. In the aqueous solution inorganic sulphates are also present chiefly sulphate of calcium, but in alcohol of all the sulphates only that of morphine (or other alkaloids) can be in solution. The sulphuric acid met with in the alcoholic solution of opium must therefore be due to sulphates of alkaloids. The solutions of opium display a slightly, yet undoubtedly acid reaction as the vegetable juices generally do. The acidity of opium becomes more distinctly manifest if its solutions are cautiously concentrated ; it is no doubt due to meconic acid.

It is important to precipitate the morphine from a solution containing alcohol and ether. By adding ammonia to an aqueous solution, a flocculent matter is precipitated. This abundant amorphous mass, either an alkaloid or not,—it is certainly far from being simply morphine,—remains in solution if the liquid contains a little alcohol ; one-third alcohol of the volume of the aqueous filtrate is quite sufficient for the purpose. Yet of no less importance is the action of the ether. It not only prevents the narcotine from being thrown down together with the morphine, but ether greatly promotes the formation of distinct and pure crystals of morphine. This alkaloid evidently separates very readily from a liquid saturated with ether.

No further mention is made in the above considerations of narcotine. Should its amount also be estimated in the official drug? I think not. The action assigned to narcotine by the physiological experiments appears to be not considerable at all. Should it, however, become desirable to estimate it, it would probably be a good plan to extract the opium first by water and then by acetic acid. The narcotine is present chiefly in the free state, as it is not really an alkaloid ; it is therefore not, or not entirely, removed by water. With acetic acid, as well as with other acids, narcotine forms not well defined salts ; the acids are simply solvents, from which it again separates as soon as the acid is neutralized. This is accomplished with carbonate of calcium. By shaking an acetic solution of narcotine and morphine with that carbonate, narcotine is precipitated ; not so the morphine. I have not, however, more exactly investigated this method, practical pharmacy, to which the present paper is devoted, being not strictly interested in the matter.

I believe that the above method for the estimation of morphine very well answers for pharmaceutical purposes. I shall be glad if the criticisms which it may meet with lead to some further progress in the question under notice.

Mr. Draper passed a warm eulogium on the paper which he said was characterized by great lucidity.

Mr. Naylor said it was not his experience that morphia existed in the form of sulphate of morphia, unless the paper referred to the Turkey opium. If morphia was dialysed the sulphate of morphia would undergo no decomposition whatever. If it was carefully examined by the microscope the sulphate of morphia could be readily seen, and so also could the crystals of the meconate of morphia if it was evaporated at a low heat. If meconate of morphia was heated at a high temperature it would split up. His objection to the process was that no very special provision in the process—as part of the process—was made for separating narcotine. The process to which they had just listened was identical with the beautiful process of Yvon published in the *Journal de Pharmacie et de Chimie*, only if his memory served him correctly the proportions of spirit and ether were a little different.

Mr. Williams viewed it as a slow process compared with others.

Professor Attfield admitted that it was a slow process, but easy.

The President said Professor Flückiger deserved their thanks for his paper, and the Conference accorded him that compliment.

Place of Meeting in 1880.

Mr. N. M. Grose (Swansea), introduced by the President, said he was deputed by the druggists of Swansea to convey to the British Pharmaceutical Conference a hearty invitation to visit the town in 1880, and if the association did them the honour to accept the invitation they would do all in their power to render their sojourn in Swansea agreeable.

---

* See my 'Pharmaceutical Chemistry,' Berlin, 1879, page 373.

Professor ATTFIELD moved that the best thanks of the meeting be accorded to the chemists of Swansea, so ably represented by Mr. Grose, and that their invitation be accepted.

Mr. REYNOLDS seconded the motion and, adverting to the admirable way in which Sheffield had received the pharmacists, said Yorkshire felt proud of Sheffield for the way in which it had entertained the Conference.

The motion was then carried.

ELECTION OF OFFICERS.

A ballot for the President and Officers for the ensuing year was then taken, with the following result:—

President.

W. SOUTHALL, F.L.S., Birmingham.

Vice-Presidents.

N. M. GROSE, Swansea.
R. REYNOLDS, F.C.S., Leeds.
G. W. SANDFORD, Pres. Ph. Soc. of G. B., London.
W. WARD, F.C.S., Sheffield.

Treasurer.

C. EKIN, F.C.S., Bath.

General Secretaries.

Professor ATTFIELD, F.C.S., London.
F. BADEN BENGER, F.C.S., Manchester.

Local Secretary.

J. HUGHES, Swansea.

Other Members of Executive Committee.

M. CARTEIGHE, F.C.S., London.
T. GREENISH, F.C.S., London.
H. W. MALEHAM, Sheffield.
A. H. MASON, F.C.S., Liverpool.
C. SYMES, Ph.D., Liverpool.
J. C. THRESH, F.C.S., Buxton.
W. A. TILDEN, D.Sc., F.C.S., Clifton.
C. UMNEY, F.C.S., London.
J. T. WILLIAMS, Swansea.

Auditors.

G. ELLINOR, Sheffield.
J. LLOYD, Swansea.

THANKS TO THE LOCAL COMMITTEE, ETC.

Mr. WILLIAMS moved—

"That the cordial thanks of the non-resident members of the British Pharmaceutical Conference be given to the Local Committee, and the other Sheffield members, and especially to Mr. Maleham, Mr. Ward, Mr. Ellinor, Mr. Learoyd and Mr. Cubley for the very successful manner in which they had conducted the arrangements of the meeting."

He said Mr. Reynolds had stated that Yorkshire felt proud of Sheffield for the way in which it had entertained the Conference, and if Sheffield had satisfied Yorkshire he felt that the rest of the country must be satisfied.

Mr. DRAPER seconded the motion and referred to their cordial reception and the pains the Local Committee had taken in showing the pharmacists the various manufactories for which the town was famous.

The motion was carried unanimously.

Mr. WARD, in acknowledging the compliment, said it had afforded him extreme pleasure to see the Conference in Sheffield, but he must in justice say that nearly the whole of the work had devolved upon Mr. Maleham. If the association were gratified the Local Committee were satisfied, and if they were gratified the Local Committee were satisfied.

Mr. MALEHAM said he was glad to have an opportunity of expressing his gratification at the kind manner in which the services of the Local Committee had been acknowledged by their guests. He deprecated the idea that he had done all the work, and said he had been ably supported by the Local Committee and Mr. Learoyd, the assistant secretary.

Mr. LEAROYD and Mr. ELLINOR also acknowledged the compliment on behalf of the Local Committee.

Professor TICHBORNE moved the following resolution:—

"That the members of the British Pharmaceutical Conference, assembled in Sheffield, desire to express their best thanks to Messrs. John Brown and Co., Limited, and Messrs. Brown, Bayley and Dixon, for having thrown open their most interesting works, and also to the managers of departments and others whose courtesy and attention so enhanced the pleasure of the visit."

Mr. T. F. ABRAHAM seconded the motion, which was carried.

Mr. FOSTER moved the following resolution:—

"That the best thanks of the Conference be conveyed to Messrs. John Round and Son, Messrs. Joseph Rodgers and Son, and Messrs. Walker and Hall, who have so kindly afforded members the privilege of visiting their works."

Mr. WALTER HILLS seconded the motion, which was carried.

THANKS TO THE PRESIDENT.

Mr. SUMNER moved—

"That the best thanks of the Conference be given to the President for the able manner in which he has conducted the business of the meeting."

He said he was delighted at the ability shown by the young members of the Conference, and that their papers showed that they were making progress beyond their predecessors. He did not see why such should not be the case, for they should live on the experience of the past, and the practice of the present.

Mr. RADLEY, as the senior member of the trade in Sheffield, seconded the resolution, and referred to the efforts of the President in the promotion of pharmacy.

The motion was carried with acclamation.

The PRESIDENT, in acknowledging the compliment, said he was afraid his friends sadly overrated his efforts as President. It must not be forgotten that he followed a long list of distinguished men, from whose example he had had large opportunities for learning his duties; moreover the kind consideration he had received from every individual who had attended the meeting had rendered his task so easy that his own share of the merit of having presided with some success was very small indeed. He confessed to some feeling of regret at relinquishing his highly honourable post, but had the satisfaction of knowing that it would pass into the hands of a very able man, one whose scientific qualifications would certainly very much exalt its dignity.

THE RESIGNATION OF PROFESSOR ATTFIELD.

The PRESIDENT said although the positive proceedings of the Conference had now concluded, there was just one matter he should like to introduce to their notice. The opinion had been expressed in the Executive Committee at its sitting that afternoon, that the members of the Conference generally would probably wish that some permanent record of their obligation to Professor Attfield should be presented to him, now that he found it necessary to resign the post of Honorary Secretary. The Committee had accordingly prepared a resolution, which would now be submitted for the approval of those present.

"1. That under the circumstance of Dr. Attfield's announced retirement from the post he now occupies, it is desirable to institute some permanent recognition of the invaluable services to the Conference rendered by Professor Attfield as its Senior General Honorary Secretary since its establishment sixteen years ago.

"2. That the gentlemen present form themselves into a Provisional Committee to give effect to this resolution, with power to add to their number.

"3. That Mr. Carteighe be appointed Honorary Secretary *pro tem.* to the above Committee."

The Conference then broke up.

Parliamentary and Law Proceedings.

Prosecution for Sale of Adulterated Cream of Tartar.

At the Chertsey Petty Sessions on Wednesday, September 24, before W. C. Scott, Esq., chairman, B. L. Lewis, Esq., W. F. Harrison, Esq., Baron G. de Worms, H. Yool, Esq., and T. W. Weeding, Esq., Mr. George Boyce was summoned for selling to one Frank Walters a certain drug, to wit, 2 ounces of cream of tartar, to his prejudice, on the 19th of August.

Mr. A. Haynes appeared for the defendant.

Police-constable Waters said: On the 19th of August he went to Mr. Boyce's shop under instructions from Superintendent Bungard and asked for 2 ounces of cream of tartar and was served by Mr. Clark, the assistant. He paid 4*d.* for it. After receiving the cream of tartar he told the assistant it would be handed over to Superintendent Bungard, who would take it next day to Guy's Hospital to be analysed. Witness asked him if he would like to keep a portion of it. The assistant said that he did not wish to do so. Witness then sealed it up in his presence and twenty minutes later handed it over to Superintendent Bungard.

Cross-examined by Mr. Haynes: He bought some quinine wine and other articles at the same time that he purchased the cream of tartar. He asked the assistant to take a portion of each of the articles that he purchased, but the assistant declined.

Superintendent Bungard said: On the 19th of August he received 2 ounces of cream of tartar from last witness and on the 21st took it to Guy's Hospital. He produced Dr. Stevenson's certificate, which stated the cream of tartar to contain 11·7 of tartrate of lime and ·6 of sulphate of baryta, and that the foreign ingredients were insoluble and not injurious to health.

Cross-examinined by Mr. Haynes: The other articles purchased were sent to the analyst and reported to be genuine. This was the case for the prosecution.

Mr. Haynes then addressed the Bench. He said that for the last sixty years Mr. Boyce and his father before him had been chemists in the town, and always had the very highest character for selling the best and choicest articles, and never before had they had the least word of complaint. The charge that he had to answer that day was that Mr. Boyce sold an article that was not of the required quality. He could only have wished that Dr. Stevenson had been present, because he could then have asked him questions that would have put a proper complexion on the case. However, he had practical and scientific witnesses present who would inform the Bench as to the manufacture of cream of tartar, and it would be shown that no adulteration in the sense of the word had taken place, and moreover Dr. Stevenson's certificate showed that it was not injurious to health, and was, therefore, not prejudicial to the purchaser. Cream of tartar was manufactured in France and Spain and other wine-growing countries, and he could prove that it could not possibly be made without tartrate of lime, as through the processes it underwent such was incidental to its manufacture, and was, in fact, part and parcel of the drug. Mr. Hodgkinson, of whom the articles were purchased, would produce some cream of tartar in its crude state and inform them how it was manufactured. He would also tell them that Mr. Boyce always bought drugs of the very best quality and paid the very best price for them, and, in fact, such evidence would be given as he thought would completely exonerate his client. He then called—

Mr. William Hodgkinson, of the firm of Hodgkinson and Co., Aldersgate Street, who said that defendant and his father before him had been customers of his firm for many years. Mr. Boyce was very particular, and was always supplied with the very best drugs. The cream of tartar which was the subject of the present case he had reasons to know came from Messrs. Hodgkinson's stores. Cream of tartar was sent to this country from Spain and France and came in a state that was known as argol, and was consigned from the brokers to the manufacturers. The argol was generally taken from the docks by the grinders. The cream of tartar in question came into the market in the usual way and was ground by Messrs. Stafford, Allen and Sons, who returned it to his firm and they sent it out as it was purchased. Messrs. Allen and Sons were the only grinders of the drug. The article sent to Mr. Boyce was the very finest that could be obtained. Argol, or cream of tartar, was the natural product of the fermentation of the juice of the grapes. It was impossible to have cream of tartar without tartrate of lime, and he was informed from the best authority that it was generally found in quantities of from 10 to 20 per cent., and the lowest he ever heard of was 7 per cent. He recognized the sample of cream of tartar produced from its very fine grinding. It could not be obtained finer. He could not account for the very small amount of baryta being with the drug, but had seen it with cream of tartar before.

Mr Edward Ransome Allen, of City Road, London, said his firm received a delivery order to obtain the cream of tartar in its crude state. It was then ground and sent to Messrs. Hodgkinson, and nothing was added to it.

Mr. George Boyce said he purchased the drug of Messrs. Hodgkinson and sold it as he received it. He believed it was the best quality that he could possibly buy.

Dr. Benjamin Horatio Paul, Ph.D., F.C.S., and Editor of the *Pharmaceutical Journal*, said the term "cream of tartar" was, according to the British Pharmacopœia, a synonym for acid tartrate of potash. The article referred to was the medicinal form of acid tartrate of potash and that met with in commerce. It consisted essentially of the compound of tartaric acid with potash, together with some varying proportion of tartrate of lime, which was incidental to the manufacture of cream of tartar in the usual way. The presence of tartrate of lime in cream of tartar was indicated by the British Pharmacopœia. Sulphate of baryta was an extraneous impurity, but it was scarcely conceivable that so small a proportion as that indicated by the analyst's certificate could have been intentionally added as an adulteration. The only other possible explanation of its presence was accidental admixture; but it was an inert substance not injurious to health, and the trifling amount present did not sensibly affect the medicinal efficacy of the cream of tartar or its intrinsic value.

The Chairman said the Bench were unanimous in dismissing the case.

Death from Opium Eating.

On Tuesday, September 23, Mr. D. Wightman held an inquest in Sheffield, on the body of Sydney Barnes, 50 years of age, painter. The evidence was to the effect that for the last two years the deceased had suffered from "painter's cholic," and in consequence had lost the use of one of his arms. Some time last week he fell from the top of a vine house at Sharrow, and broke his ribs. A year or two ago he was in the habit of taking quantities of opium, but he had not done so latterly as far as his wife knew. On Saturday night he went to Mr. Ward's shop, on Sheffield Moor, and bought two separate pennyworths of opium, stating that he wanted the drug to relieve the pains in his side, caused by broken ribs. He returned home, and shortly after dinner on the following day he took the opium, except a small quantity, which his wife destroyed. In the evening he went to bed and slept soundly until Monday morning, after which time he remained in a drowsy state up to his death. On Sunday he told his wife he intended to go to the Hospital next day to see what was amiss with his side. It was explained that the deceased had taken about one scruple and a half of opium, equal to 720 drops of ordinary laudanum.

Mr. F. A. Willington, surgeon, said he saw the deceased for the first time shortly before three o'clock on Monday afternoon. He was then insensible, and evidently dying. He applied the usual remedies, but death ensued, caused by an overdose of opium.

The Coroner remarked that the man, in his opinion, had died from an overdose of opium. It had transpired that he had been in the habit of taking it regularly on previous occasions, and all the symptoms explained by the surgeon indicated poisoning by opium. The deceased had taken much more opium than a surgeon would have advised him to take. The quantity was sufficient to have poisoned all the persons in the room.

The jury returned a verdict of "Death from taking an overdose of opium for the purpose of relieving pain, brought on by a recent accident."—*Sheffield Daily Times.*

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[339]. I think "Minor" ought to use Acid. Nitric. Dil.

[340]. In answer to "Inquirer's" note, I have used at times a little glycerine to rub down the sulph. iodid. when making ung. sulph. iodid.; by this means he will produce an ointment slightly lighter in appearance, but a much more satisfactory preparation.

THOMAS E. CHADWICK.

[341]. Calx Hydrarg. Alba is white precipitate.

Manchester. W. WILKINSON.

[341]. Calx Hydrargyri Alba was the term by which the present Hydrargyrum Ammoniatum was known in the old London Pharmacopœia (1788), and therefore Ung. Hyd. Ammon., B.P., should have been dispensed.

W. F. NORMAN.

[341]. Unguentum Calcis Hydrargyri Albæ, *vel* Unguentum Hydrargyri Ammonio-Chloridi (Pharmacopœia Londiniensis, 1788):—

Take of—

Ammonio-Chloride of Mercury	2 drachms.
Lard	3 ounces.

Add the ammonio-chloride of mercury to the lard, and rub them together.

Norwich. W. S. CORDER.

[342]. The official Ung. Plumbi Subacet. Co., invariably assumes a streaked orange colour soon after it is made, but it rapidly becomes rancid and the colour disappears.

The orange tint is probably due to the separation of an oxide of lead and the disappearance of the colour to decomposition of the oxide by the fatty acids present in the rancid ointment.

Neither coloration nor rancidity appears if vaseline be substituted for the oil and wax, which alteration will possibly be made in the formula when we have a new Pharmacopœia.

R. H. PARKER.

[342]. I should be glad if some reader would reply to the query of "An Apprentice" in the Journal of Sep. 6, with regard to ung. plumbi subacet. co. I made a little and found it turned the pale orange colour he describes, and attributed it to the fact that the liq. plumbi was an imperfect solvent, it having deposited a good deal of plumbi carb. in the bottle, and the camphor acting upon it turned the oxyacetate into litharge again, and hence the colour. Again I made some with a perfectly fresh solution and, as "An Apprentice" says, followed the instructions implicitly, and I find after four or five days that has turned the same.

I cannot find any allusion to the cause in any work that I have referred to. And as it is an ointment not unfrequently ordered in prescriptions, it is of great importance that it should be sent out so that the patient should not be surprised to find an orange coloured ointment after a few days.

ALCHEMIST.

[343].

℞ Acet. Scillæ	℥iss.
Spt. Chloroformi	q.s.
Sacc. Ust.	q.s.
Aqua	ad ℥ij.

A teaspoonful every two or three hours.

How should the above be dispensed? Was I right in putting in ʒss spt. chlorof., and 6 minims sac. ust.?

[344]. Will a reader of the Journal say how he would dispense, or of what strength he would make the following solution?—

Solutio Cheltenham Salts.		℥xij.
Tinct. Zingib.	ʒij.	
Tinct. Card. Co.	ʒij.	

A wineglassful every third morning in half a tumblerful of warm water.

DISPENSER.

Notes and Queries.

[624]. COLOUR OF CLOTH.—Pure nitric acid is used to test the durability of the colour in cloth. The test depends on the length of time it takes to destroy the colouring matter.

W. FOWLER.

[625]. ANILINE COPYING INK.—Could any reader oblige me with a formula for making copying ink (aniline) for the gelatine letter press? By so doing he would greatly oblige.

QUÆRO.

[626]. CLEANSING OF OLD COINS.—Will any reader of the Journal kindly furnish me with a formula of a solution for cleansing old coins by simply immersing them?

Correspondence.

REGISTRATION OF CHEMISTS' ASSISTANTS AS BONA FIDE DENTISTS.

Sir,—Having read four letters in reply to mine, I can see but one, F. W. S., who sees the question as regards the registration of assistants in the right light. The legislators of the Dental Act were perfectly willing to recognize existing rights, but not to bring to life rights that had never existed at all, or to induce any person to register himself as a matter of convenience with the view of taking up dentistry at some future time and thus save himself the necessary education and examination. Nothing was said about preventing chemists or their assistants from extracting teeth (which is the least important part of a dentist's business), and it was not necessary to register in order to continue to do so, and to say the least it is contrary to the laws of common morality for a person not a dentist to register as being in *bonâ fide* practice as such. "Lower Molar" says he wrote to Mr. Miller asking if it was necessary to register as a dentist in order to extract teeth, and that he received the declaration papers in reply, etc., etc. I must call his attention to the fact that it is not the duty of the registrar to answer inquiries or to determine who is legally entitled to register, and that everyone is allowed to fill up the papers as his conscience will allow him, and that on payment of the fee his name is placed on the register *conditionally*, *i.e.* that his claim will bear investigation. Of course on the publication of the register the Dental Association will take up the matter of illegal registrations, or why should section xxxv. be inserted at all? If *bonâ fide* chemists and dentists, or even chemists who without assuming the title of dentist merely performed the operation of extraction, have registered as being in *bonâ fide* practice as dentists, it must surely be allowed that that does not constitute a right for their apprentices and assistants to do the same; the Act was for the protection of the public, and not to raise up an army of ignorant impostors who have sprung into life as dental practitioners during the passing of the Act, to the detriment of the public and degradation of the legitimate profession.

"Manager" must have a very poor idea of dental operations when he asserts that they can be performed as ably by dabblers in the art as by any professional dentist who has devoted all his attention to the *spécialité*. I should like to to see very much the chemist's assistant who could put in really reliable gold and amalgam fillings, fill root canals, cap exposed pulps, etc. The old proverb that a "Jack of all trades is generally master of none" is very applicable to the above, and a Ph. C., dental surgeon, etc., must have as many irons in the fire as he can keep warm.

J. J. MUSGRAVE.

Sir,—The writers of the letters relating to the Dental Practitioners Bill in your last issue appear to have all taken up arms rather hastily against Mr. Musgrave.

"Lower Molar" certainly may be in the right in considering himself a dentist from the mere fact of extracting teeth, but the question is still an open one as to whether when the weeding out of the Dental Register takes place those whose only claim towards registering themselves consists in the fact of their extracting teeth will be considered dentists by the Medical Council, should information be made against them. The declaration may be made, the fee may be received, but the whole responsibility of such declaration rests upon the person who makes it. Evidently clause xxxv. was inserted from a certain foresight possessed by promoters of the Bill. The spirit of the law will be frustrated perhaps by many; anyhow, Mr. Musgrave gives a friendly warning, to the effect that should the spirit of the Act, which the words *bonâ fide* convey, be carried out, many who are now on the register may possibly find their names erased in future (even if not in the present) edition of the Dental Register. Holders of the certificate must remember that the register alone will be legal evidence. The spirit of the Act appears to have been to protect those men who before its passing had been *bonâ fide* engaged as dentists, and had called themselves such before the public.

My only object in writing is to uphold Mr. Musgrave's action in writing his letter, and to suggest that those who took up arms against him should wait until they see whether there were any cause for so doing. Mr. Musgrave's opponents appear to have spoken with the dictum of both judge and jury in the matter, so they have hardly a right to be so harsh on him, who as they say, holds simply a brief. After all the only thing to be done is to wait and see. It is said that "the wicked fleeth when no man pursueth."

GEORGE ERNEST CLARKE, *Surgeon-Dentist.*

Woodbridge.

THE HEALTH OF THE DRUG TRADE.

Sir,—Mr. J. K. Nicol, in the Journal of the 6th inst., calls attention to the circumstance that a large percentage of chemists die at a very early age, and speculates as to the cause.

To satisfy myself that the average age was less than it ought to be, I have gone over the Journal obituaries for three years, 1875-6, 1876-7, 1877-8, and I find that the average is fifty. This is certainly not very encouraging for the rising race of pharmacists.

And now, what are the causes of this early mortality? It seems to me that there are three things to be taken into consideration in accounting for it. These are:—(1) Confinement, on account of the length of business hours. (2) The strain upon the mind which is inseparable from the proper conduct of a chemist's business. (3) The highly polluted atmosphere of the shops.

A chemist's business is, I should say, the most confining business under the sun. In a small business, where the proprietor cannot afford to keep an assistant regularly, he is frequently several weeks at a time without being away from his shop. People do not always expect to find a physician or surgeon at home, but they never for a moment entertain the idea of not finding a chemist ready at any time to answer his bell, and supply sixpennyworth of physic. And take the case of assistants. In England, where the situations are indoor, an assistant's life partakes very much of the nature of that of a domestic servant; perhaps two hours twice a week, at night, are allowed for recreation.

In Scotland the situations are outdoor, and most of the places close at 8 p.m., and as few of the shops have night bells—perhaps one in each district of the town—the greater number of the assistants are free every night after that hour. This would seem better. In reality it is not so. In order, I suppose, that the outdoor assistants should have no advantage over their indoor fellows in their chance of longevity, it is generally the case that they have to get their tea after 8 o'clock. In a few humane places arrangements exist for the assistants either to get out for half an hour to tea, or to have it on the premises. These places, however, are very few. It is needless for me to do more than refer to the injurious effects upon the health of so long a fast between dinner and tea, and the taking of tea at so late an hour. In English situations the hours are longer, but meals are had regularly. In Scotch situations the hours are shorter, but meals are had irregularly. Which is the better? To my mind there is little to choose in either.

The practice of pharmacy requires great care and attention. The strain upon the mental faculties of those engaged in a busy shop is consequently very great, and when continued during such a length of time must of necessity be exhausting. There are other businesses in which a concentration of attention, equal to that in ours, is required; but I am not aware of any in which it has to be kept up for the same length of time.

And, finally, there is the polluted atmosphere. Chemists do not feel the smell of their shops, because they have become accustomed to it. There are few, however, of their customers who do not feel what they call the "physicky" smell always present. Hydrochloric acid vapour, free chlorine, fumes of nitric and sulphurous acids, ammonia, and carbonic acid gas, not to speak of an occasional whiff of bromine, make a nice addition to the already not over pure air of a town. To be confined for twelve hours a day in a compound atmosphere of this kind can scarcely be conducive to good health. People say we cannot readily catch infection, because the germs of contagious diseases find the atmosphere of our shops fatal to them. This may be true, but to escape contagion only to share the fate of the germs is not much for which to be thankful.

It is time that attention should be directed to the unhealthy nature of our business, apart from long hours.

Instead of having long hours we ought to have exceptionally short ones. No doubt the claims of the public must be attended to. I do not, however, think that the public, exacting though it be, desires that the members of one class should sacrifice their lives to save those of the members of another class.

A free discussion of the subject may initiate a disposition on the part of employers to favour shorter hours of business, or, at least, the concession of more time for inhaling fresh air to their assistants. I am strongly of opinion that a reduction in the hours of business would be a very effectual means of raising the standard of the drug trade. The present hours are in their effects very demoralizing.

Edinburgh. JUNIUS.

Sir,—Like your correspondent, Mr. Nicol, the undue mortality in our trade has been matter for reflection with me for years. I commenced at one time tabulating the deaths recorded in your own and other journals, with the view of instituting a comparison with the average general mortality, but finding that the ages were frequently omitted, I gave up the attempt. Speaking from an experience of twenty years, I do not for one moment think that (special manufactures apart) there is anything in the atmosphere of the ordinary chemist's shop prejudicial to health. The cause is to be found almost solely in our own individual habits. In a business full of constant anxieties, we voluntarily keep too long hours—we voluntarily allow ourselves too little outdoor recreation. If our aim is merely through this business to obtain a social competency, it is yet highly necessary, but if passing beyond this, we are also striving for mental cultivation, it is yet more imperative that we allow nothing to defraud us of our chances of re-oxygenation. We voluntarily keep too long hours—voluntarily I advisedly said—we are not bound to keep our shutters down until the last possible customer has appeared.

If medicine is really wanted there is not much fear of patients dying for lack of ringing the druggist's bell, while with the shop open unnecessarily late, for one application that is really pressing there may be dozens of the most trivial character.

From the nature of our calling the public justly expect us to cheerfully attend to their true wants at whatever hours they may arise; but for that very reason they should be considerate of us in not infringing upon our ordinary leisure times unnecessarily. The public require educating in this respect. It would be the dawn of a new era with us were we to arrive at a general understanding to adopt hours akin to those in other callings, and to levy a mild percentage upon all business effected after the shop was closed.

Let each pharmacist thus arrange for himself, and for those in his employ, some respite for breathing time, and we shall soon hear less of undue mortality in our ranks.

One of the greatest obstacles, often, to improvement in this direction is, singularly enough, the solitary chemist,—he who has neither assistant nor apprentice.

His neighbours are all willing to close, but "Why should I shut up?" argues he. "I shall have no peace, the bell will ring, and I may as well be in my shop as in my back room."

Such a one should remember that none of us liveth to himself, that although he may not feel himself at liberty to leave his premises, he should surely hesitate before in effect compelling everyone else in the trade in the town also to remain at home.

Now that there is such a call for educated pharmacists, it is more than ever necessary that for the production of the *mens sana in corpore sano* the requisite leisure should be afforded.

Cambridge. J. T.

Sir,—The letters of your correspondents on the health of the drug trade would have been of more value if they had supplied authentic figures, either from the Registrar-General's report, or other sources, from which the longevity in our trade might have been compared with that in others. No opinion on such a subject can be worth anything unless it is based upon deductions drawn from correct statistics.

Such statistics I am unable to supply, but the following figures, taken from obituaries printed in the *Pharmaceutical Journal* during the years 1877, 1878, and 1879, may interest your readers:—

Two hundred deaths gave an average length of life of 51·8 years. Four lives exceeded eighty, and were eighty-one, eighty-three, eighty-six, and eighty-seven respectively. The shortest life recorded was twenty-one years.

A percentage gave the following results:—

7·	per cent. died between	twenty and thirty.
18·	,, ,,	thirty and forty.
19·5	,, ,,	forty and fifty.
19·5	,, ,,	fifty and sixty.
22·5	,, ,,	sixty and seventy.
11·5	,, ,,	seventy and eighty.
2·	,, ,,	eighty and ninety.

My obituaries were all exhausted, or I should have extended these figures, and so made the statistics reliable. It should be mentioned that nearly all the deaths were of chemists in business for themselves.

Denmark Hill. THOS. HENRY POWELL.

ESSENCE OF GINGER.

Sir,—I think that if Mr. Baildon will be at the trouble of again agitating his essence of ginger with silica (in very fine powder) and filtering, that it will become clear. I recently prepared some and found that upon first filtration it was opalescent, but refiltration has made it perfectly bright.

With regard to the alleged misprint, there is no mistake, but perhaps it would have been better to have said "until nothing further is precipitated." Upon first addition of the lime the tincture becomes very dark coloured; when more is added a somewhat bulky precipitate speedily falls and the solution becomes of a "rich yellow colour," but is much paler than when the first portion of the lime has been added. The proportions of the various resins differ so much in different specimens of ginger, that a little judgment is required in addition of lime, etc.

JOHN C. THRESH.

NITRATE OF PILOCARPINE.

Sir,—From the misinterpretation of my remarks on the solubility of the above (p. 240 last week), Mr. Gerrard cannot have read my statement (p. 215, *Pharm. Journ.* 1879) carefully.

W. MARTINDALE.

Erratum.—In Mr. Fletcher's paper on "Citrate of Iron and Quinine," page 228, line 25 from top, *for* (2·673×0·86) *read* (2·673×30·86).

"*Bonus*" is recommended to make his wants known by means of an advertisement.

J. H. Dingler.—*Hypericum androsæmum.*

H. Cocks.—The effect of the addition of sodium hyposulphite is well known, but the resulting product can no longer be correctly designated a preparation of iodine.

F. A. Barrow.—*Syrup of Gentian* (Codex).—Gentian Root, 100 grams; Boiling Water, 1000 grams; White Sugar, q.s. Pour the boiling water on the gentian, infuse for six hours in a closed vessel, strain and press. Add the sugar in the proportion of 190 parts to 100 parts of the infusion, and make a syrup by simple solution in a covered water-bath.

A. H. Pope.—See the section on crystallography in Fownes's 'Manual of Chemistry,' vol. i., or the more extended treatise in Watt's 'Dictionary.'

"*Alterative*" is recommended to communicate the circumstances to the Secretary of the local Association.

"*Army Compounder.*"—The principle which should be followed in making up mixtures containing resinous tinctures has been explained on several occasions recently. See, for instance, vol. ix., pp. 528 and 529.

W. B. Southgate.—The following recipe for "Pick-me-up" has already been given in the present series of this Journal:—Cardamons, 5 parts; Caraways, 2; Cochineal, 2; Cinnamon, 10; Raisins, 80; Orange Peel, 56: Ginger, 14; Gentian Root, 3; Wormwood, 2; Quassia, 1; Alcohol, (·838) 750; Water, 750. Macerate for fourteen days, filter, and add syrup 200 parts.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Wetzel, Wilkinson, Clarke, Wershoven, Musgrave, Postans, J. Griffith, Mushens, Turner, Howe, Catechu, Verus, Student, Junior, Omnes Moriemur, Chemist, Gaul, An Emigrant, A Sawney, G. H. L.

NOTES ON SOME JAPANESE DRUGS.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

(*Concluded from page* 203.)

FRUITS AND SEEDS.

KOTREE SEE (18):—*Coriandrum sativum*, L.

The Japanese coriander seed does not differ in any respect from that of English commerce.

MAHNG DAH-RAH-GAY (19): — *Datura alba*, Nees.; Nees. in Linn. Tran. 17, p. 73; *D. Stramonium*, Thunb., Fl. Jap. p. 91.

Syn. MAN-TO-LO-HWA, Dr. Porter Smith, Mat. Med. Chin. p. 83; CHOSENASA-GAO, Sô mokou Zoussetz, vol. iii. fol. 55; MANDARA-REUGE, Phonzou Zoufou, vol. xxiii. fol. 20.

These fruits are rather smaller than those of *D. Stramonium*, more globular, with shorter spines, the base of the spines being markedly striated. The specimens have evidently been gathered and dried before ripe, the seeds not being mature.

Datura alba differs from *Stramonium* in its ovate downy leaves. It is used by the natives of India for poisoning, and professional poisons are often called dhatureas, on account of the use made of this drug. See 'Pharm. India,' pp. 175, 460.

MEH-NO-ME (60):—*Prunus Armeniaca*, L. (Apricot kernels).

Syn. KJOO, KARA MOMU, ANSU, Kæmpf. Amœn. p. 798, Thunb. Fl. Jap. p. 200.

These seeds correspond well with specimens of *P. Armeniaca* in the Indian collection. The endocarps, which are sparingly present, are quite smooth. The kernels are cordate, ovate, and about half an inch long and rather less in width, and two lines in thickness. The taste resembles that of a bitter almond.

Apricot kernels are known to yield an excellent oil, nearly, if not quite, equal to almond oil, but to what medicinal use the Japanese put these kernels, I have not been able to ascertain.

OO-BEI (35):—*Amygdalus nana*, L.

Syn. Prunus Mume, Sieb. et Zucc., Fl. Jap. I. p. 29; BAI, Thunberg, Fl. Jap. p. 199; UME AND UMEBOS, Kæmpf. Amœn, p. 799; MUME, MOMI, Fr. et Sav. vol. i. p. 117.

This drug consists of the dried unripe fruits. In appearance they resemble small prunes, but are very dry and hard. They have apparently been dried at a high temperature, since the kernels have a roasted taste and dark-brown colour internally. The endocarp or stone is half to three-quarters of an inch long and about half an inch wide, and one-third to half an inch thick. It is perforated with small holes like that of the almond. The taste of the sarcocarp, or fleshy part, is intensely sour.

The Japanese character, Bei, pronounced in Chinese Mei, is a generic term for any kind of plum, and is sometimes applied to other fruits. See Porter Smith, 'Mat. Med. Chin.' p. 174.

The fruits, preserved in dregs of Sacki or Japanese beer, are said by Kæmpfer to be exported to India and China.

According to Siebold and Zuccarini (*l. c.*, p. 30, 31) *Amygdalus nana* is much cultivated in Japan and was probably introduced from China. The same authors give a long and interesting account of the uses of this plant. It is a shrub or small tree from 12 to 20 feet feet in height, flowering early in February, and is one of the plants which the Japanese cultivate extensively in the form of miniature trees. The flowering branches are used to decorate the dwellings of the Japanese and the altars of their idols to indicate the approach of spring. The acid juice of the unripe fruits is used as a cooling drink in various fevers, for when ripe the taste is insipid. The acid juice is also used in the preparation of the delicate pink rouge from safflower.

REN-NIKH (51):—*Nelumbium speciosum*, Willd.

Syn. Nymphœa Nelumbo, L.; Thunb. Fl. Jap. p. 223; LIEN-GAU, Porter Smith, Chin. Mat. Med, p. 139, *sub* Lotus; REN, HATSIS; Kæmpf. Amœn. p. 880; HASU, Hachisu, Sô mokou Zoussetz, vol. x. fol. 9; Phonzou Zoufou, vol. xxxiv. fol 9.

This drug consists of the dark grey oval carpels, about five-eighths of an inch long, and one-third of an inch in diameter. The shell is moderately thin, but very hard, and encloses a sweet white starchy kernel. They are used in Cochin China, according to Loureiro (Fl. Cochin Chin. p. 341), both in food and medicine, in the latter for diarrhœa, etc. A long and interesting account of the uses of various parts of the plant is given by Dr. Porter Smith, in his 'Materia Medica of China.'

The Japanese character Ren is identical with the Chinese one for Lien, and means a river, the term nikh, meaning meat or food. The name "river-meat" is probably given on account of the kernels of the seeds being eaten.

SAI HEE (9):—*Citrus bigaradia*, var. trifolia, Thunb. Fl. Jap. 294.

Syn. SSI *vulgo* KARATATS BANNA GEES, Kæmpf. Amœn. p. 801 with *fig.*; KÔ KITS, Phonzou Zoufou, vol. lxxxvii. fol. 8.

This drug consists of the thin peel of a small orange about the size of the mandarin variety, which has the bitter flavour of the Seville orange. The peel has been removed entire by making four vertical slits in the peel nearly to the base of the orange and then pulling it off in one piece.

The Japanese characters above translated Sai-hee, are in Chinese pronounced Hiang-pi, Sai meaning green, and hee, peel or rind. This name is probably given on account of its being gathered before the fruit is ripe.

The rind, mixed with that of other species, is made, according to Kæmpfer, into a celebrated medicine called Ki-koku, a name also applied to the fruit.

SANG-SHIH SEE (36):—*Gardenia florida*, L.

Syn. SHAN-CHI-TSZE, Porter Smith, Chinese Mat. Med. p. 101; SAN CHE, Hanbury, Science Papers, p. 241, fig. 7; KUTSI JINASI, Fr. et Sav. vol. i. p. 207; SANSISI, MISUKTJINASI, Thunb. Fl. Jap. p. 109; KUTSJINAS, Kæmpf. Amœn. p. 808.

This fruit appears to belong to more than one species, but the larger proportion consists of the kind represented under fig. 7 in Hanbury's 'Science Papers,' p. 241. The fruits are about an inch or more long, three-eighths of an inch in diameter, bright brown colour, with six longitudinal narrow wings, and contain numerous seeds rather smaller and wider than linseed, bound together into a mass by a dried yellow pulp.

According to Mayer, the yellow colour of the pulp is due to a body named crocine, which appears to be identical with the polychroite of saffron. In China these fruits are supposed to possess emetic, stimulant and diuretic properties. A full account of the drug is given by Hanbury. The Japanese character for Sang-shih-see is identical with the Chinese one, although there is a slight difference in the pronunciation.

The Gardenia from which these fruits are probably obtained is a native of woody places in Japan, flowering in June and July, but is often used to form hedges in the gardens of the nobility. The fruits are also used as a dye.

SEKKEE-DOO HEE (24):—*Punica Granatum.* L.

Syn. SHIULI-P'I, Porter Smith, Chin. Mat. Med. p. 176; DSJAKURGO or SAKURO, Kæmpf. Amœn. p. 800; Thunb. Fl. Jap. p. 199.

This is the rind of the fruit dried. From its small size it would appear to be obtained from immature fruits. The pomegranate is stated by Kæmpfer to be rare in Japan and to produce an inferior fruit with a rather disagreeable taste, but Thunberg remarks that it is common about Kosedo.

SHO-EE-KOH (39):—*Fœniculum vulgare.*

Syn. SEN-RIO; KURE NO NOMO, Thunb. Fl. Jap. p. 120.

This is a small variety of fennel seed with a taste at first strongly resembling that of anise. The large vittæ, few in number, at once distinguish it from that fruit.

SHIKU-SHA (5): *Alpinia japonica*, Miq. Prol. p. 304.

Syn. Globba japonica, Thunb. Fl. Jap. p. 23; HANA-MIYO-GA, Sô mokou Zouss. vol. i. fig. 10; SAN DSJOKA, JAMMA MJOGO, Kæmpf. Amœn. p. 827; Phonzou Zoufou, vol. 10, fig. 5, Fr. et Sav. vol. ii. pt. 1, p. 20.

These are the seeds of a species of *Alpinia*, a few of the small fruits being mixed with it. The fruits, which are about the size of a large pea, but rather oval than spherical in outline, have a thin wrinkled pale-brown papery pericarp containing 3 to 8 triangular pyramidal seeds. The seeds are pale externally with a thin silvery coat, and have a faintly aromatic taste, but no pungency. These characters distinguish them from the fruits of *A. galanga* which are similar in appearance, but more oblong, and the seeds are remarkably pungent.

This plant grows in damp shady places near lakes, etc., and the fruit is ripe in December and January. It is often cultivated in Japan.

TAU NING (62):—*Amygdalus Persica.*

Syn. TOO, MOMU, Kæmpf. Amœn. p. 798, Thunb. Fl. Jap. p. 199, TAU-JIN, P. Smith, Chin. Mat. Med. 169.

These kernels are mixed with a few fragments of the endocarp, which is undoubtedly that of a small form of peach, Tau signifying a peach, and ning, kernels. In Chinese the last word is pronounced "jin."

Thunberg enumerates several varieties of the peach as follows: KE MOMU, with downy acute fruits; KATU ISI MOMU, with red glabrous, round fruits; KITO MOMU, with red double flower; SATO MOMU, with white simple flower.

In Japan the peach blossoms in March and April.

In China the kernels are used for coughs, blood diseases, amenorrhœa and worms.

From the list of Japanese drugs now concluded, it will be observed that there is a great similarity between the materia medica of China and Japan, an exchange of drugs evidently taking place between the two countries. Of the fifty-nine drugs here described, twenty-seven are apparently peculiar to Japan, and twenty-two others are common to China as well, while ten are well known in all civilized countries. The last include white hellebore root, zedoary root, mallow root, mallow leaves, elder flowers, burdock seed, pomegranate peel, orange peel, fennel seed, and coriander seed. Several in common use in this country are represented in Japan by analogous drugs, viz., Colchicum by the roots of *Fritillaria Thunbergii* and *Pinellia tuberifera*; *Triticum repens* by the root of *Eulalia japonica*; pulsatilla by *Anemone cernua* root; valerian by *Patrinia scabiosæfolia*; gentian root by *Gentiana Buergeri*; peppermint by Japanese peppermint; chirata by *Pleurogyne rotata*; and rue by *Evodia rutæcarpa*. Of Indian drugs *Datura alba* and *Cassia Tora* are used in Japan, while *Coptis Teeta* and *Datura alba* find a substitute in the roots of *C. anemonæfolia*. The influence of western civilization appears to have already had an effect on the materia medica of Japan; this is noticeable in the absence of any of the disgusting animal remedies used by the Chinese from the specimens sent over to this country. Hardly any of the Japanese drugs are altogether without sensible properties, either mucilaginous, tonic, astringent, aromatic or acrid, some of them being equal in power to analogous European remedies, and a few others, such as aconite root and valerian root, decidedly superior to the corresponding European drugs.

SUPPOSED IDENTITY OF COLUMBIN AND LIMONIN.*

BY E. PATTERNO AND A. OGLIALORO.

Schmidt (*Annalen*, 41, 338) considered that limonin was identical with the columbin extracted from colombo root by Wittstock (*ibid.*, 19, 298); and as the authors found much difficulty in preparing limonin in quantity from the seeds of the lemon and orange, whilst columbin could be obtained with comparative ease, they determined to examine into the question of the supposed identity of the two substances. The yield of limonin is but small, only 80 grams of the impure substance having been obtained from 15,000 grams of the seeds. It crystallizes in beautiful lustrous plates, and has the characters ascribed to it by Schmidt, except that it melts at 275° and not at 244°: moreover, it not only dissolves in potash without alteration, but also in baryta water, forming a kind of salt, which is not decomposed by carbonic anhydride. The formula which agrees best with the analytical results is $C_{26}H_{30}O_8$; this requires C = 66·38; H = 6·38.

When colombo root is extracted with ether and the solution is evaporated, a crystalline residue is obtained which, after being washed with a little cold ether to remove fatty matters, etc., is treated with boiling alcohol: on cooling, the solution deposits colourless prismatic crystals, which melt at 182°, and have all the properties of Wittstock's colombin. The results of the elementary analysis agree with the formula $C_{21}H_{22}O_7$, which requires C = 65·28; H = 5·69.

When the residue which is left after the separation of the columbin, and is almost insoluble in alcohol, is crystallized from boiling glacial acetic acid, it yields a second substance, having a melting point of 218—220°. Both this compound and Wittstock's columbin are therefore quite distinct from limonin.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 4, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ADMISSION OF WOMEN AS MEMBERS OF THE PHARMACEUTICAL SOCIETY.

IN the history of pharmaceutical affairs the first of October, 1879, will in future be memorable in that relation as the occasion when British pharmacists were relieved from the anomalous necessity of regarding their better halves as inferior to themselves. The persons most interested in this event have special reason to be thankful to the mover and seconder of the motion in their behalf for having at the earliest moment of the present session pressed forward the decision of the question whether women should be admitted to membership of the Society; for if it had been left for the following meeting of Council this achievement of petticoat emancipation would have been uncomfortably associated with the anniversary of another attempt to bring about social revolution. And considering how nearly opinions are balanced in regard to the desirability of admitting women into the Society it is, we think, at least fortunate for the *protégées* of Mr. HAMPSON and Mr. WOOLLEY that the advocacy of their case on the 5th of November has not afforded opponents an opportunity of instituting comparisons between their endeavours and those of GUY FAWKES and his colleagues.

For our own part we think that the movers of the resolution by which the petticoat has ceased to be a garb of disability for membership of the Pharmaceutical Society, and by which the admission of eligible persons into that body will no longer be regulated by circumstances over which the candidates have no control, may well be congratulated for having, by their success, done away with an obvious inconsistency.

From the time when the word "person" was, in point of law, decided to apply to women as well as men, the prosecution of the business of pharmacy under the terms of the Act of Parliament became by law as freely open to women as it had formerly been by usage, and although under the older *régime*, while submission to tests of qualification was voluntary, there might have been sound reason for declining to admit women as members of the Pharmaceutical Society, it is now very difficult, if not impossible, to say why women who have satisfied the requirements of the law in proving their eligibility to practise pharmacy should be refused participation in such benefits as appertain to membership of the Society. From a purely pharmaceutical point of view therefore, it may be regarded as matter for regret that any objection had ever been raised to the election of women as members, and we think that the very general support of Mr. HAMPSON's motion by the members of Council may be taken as expressing that view of the subject.

But the decision of the question from this point of view excluded from consideration most, if not all, of the arguments by which the election of female members of the Pharmaceutical Society was opposed. In the Council, at least, that opposition was not based upon narrow-minded feelings of jealousy, or of disrespect for women, any more than it was upon an assumption that they were incompetent to perform the duties of the pharmacist; but it was mainly out of consideration for what was held to be due to women in their social relations that the unfitness of some portions of the pharmacist's duty was urged as a reason for not admitting women as members of the Society. Their election into the body was held to be an encouragement for women to take up the business; it was opposed on the ground that it was an undesirable encouragement. This has always been the principle upon which Mr. SANDFORD has opposed the election of female members of the Society, and consistently with these views he has now, as President of the Society, recorded his vote against Mr. HAMPSON's proposition. There is, however, an absence of common ground upon which these opposite views respecting the election of female members can be considered together in such a manner that the acceptance of the one would involve the rejection of the other, and consequently we must infer that the altered direction of the votes given on the present occasion is due to the consideration of the question from a more special point of view than was formerly the case when Mr. SANDFORD's opinions were more generally supported. The desirability of putting an end to the agitation of this question also seems to have weighed with much effect in determining the votes of some members of the Council.

Incidentally the discussion of this matter suggests some important considerations as to the propriety of forcing to the issue of a vote a question upon which there are such opposite opinions. The fact that on two occasions the votes at general meetings of the Society were so evenly divided is scarcely a satisfactory ground for insisting upon the question being disposed of by the Council one way or the other. If those experiences pointed to anything they seem to favour the conservative course of keeping things as they were. Fortunately the admission of women as members of the Society is not calculated to affect very seriously the interests of other members, and there is consequently less reason for dissatisfaction with the settlement of the question by a narrow majority. But there are other subjects in regard to which we can conceive that either section of the equally divided pharmaceutical body would strenuously object to the decision of a question by so narrow a majority as that which has until the present occasion obtained in voting upon the female question either in the Council or at a general meeting.

However, it is far from being our desire to disparage on these or any other grounds the successful championship of the ladies by Mr. Hampson and Mr. Woolley, on the contrary, we congratulate Miss Clarke and Miss Minshull upon their election as members of the Society, and we congratulate the Society itself upon the removal of a restriction that was regarded as a grievance by those against whom it operated, with the result of stimulating an agitation which engaged more time and energy than the intrinsic merit of the question at issue really justified.

IRREGULAR SALE OF POISONS.

The intimation furnished by Mr. Flux at the hearing of the recent case of prosecution for illegal sale of poison, that any person might be the prosecutor in cases of irregular practice of this kind, has been very soon acted upon by the Chemists and Druggists' Trade Association. As will be seen from the report of legal proceedings at page 278, three such cases have been tried at Blackburn, Liverpool, and Birmingham, in all of which persons were charged, under the 17th section of the Pharmacy Act, 1868, with selling poison insufficiently labelled. In all of the cases the offence was virtually admitted by the defendants, and they were subjected to the payment of fines ranging from ten to twenty shillings and costs.

These cases will serve to bring before the minds of magistrates the fact that the provisions of the Pharmacy Act for the safety of the public are being systematically disregarded by a great number of persons throughout the county trading as oil and colour merchants, grocers, drysalters and patent medicine dealers. A great number of the poisons contained in the schedule to the Act are thus supplied to the public without bearing any of those precautionary protections against accident or misuse which the Legislature has indicated to be necessary. This fact has been emphatically pointed out by the jury in the late inquest at Newhaven (see p. 279), and the opinion had very properly been expressed by them that the preparation and sale of medicines containing dangerous ingredients should be restricted to duly qualified persons. The mere word "poison" written upon or placed as a printed label upon packets of such articles is not sufficient to satisfy the requirements of the Act, and hence persons selling poisons in this way are liable under the 17th section to a penalty of £5 and costs. Even if, in such cases as we have mentioned, the word poison, as well as the name of the poison, together with the name and address of the seller, were placed upon the packet or bottle containing the poison, and the provisions of the Act were complied with so far as the 17th section is concerned, persons selling poison in this way would be further liable to a penalty for breach of the law under the 15th section of the Pharmacy Act.

In the Horsington case the defendant pleaded as a defence that the laudanum he sold bore a patent medicine stamp, and it is well known that in some places the use of the stamp in this way is supposed to be a protection against liability under the Pharmacy Act. That it is not of such virtue to the unregistered vendors of poison is, however, beyond question, and we are glad to find action is being taken with the view of making these circumstances known to magistrates and the police as well as to the persons engaged in the irregular trade by which the public safety is imperilled and the business of the legally qualified chemist and druggist unfairly interfered with.

DEATH OF DR. MOHR AND M. POGGIALE.

With much regret we have to make known the death of Dr. Friederich Mohr at the age of 72. Originally a pharmacist at Coblentz, and since 1864 the Professor of Pharmacy at the University of Bonn, Dr. Mohr has established a world-wide reputation for his scientific acquirements and as author of several valuable works connected with chemistry, physics and geology. One of these, on practical pharmacy, is well known in this country in the form of a translation, edited by Professor Redwood; another, on volumetric analysis, has been made familiar to English chemists by the valuable labour bestowed upon it by Mr. Sutton, of Norwich. We hope shortly to be able to furnish our readers with some further account of the life of this remarkable man.

The October number of the *Journal de Pharmacie et de Chimie* also contains an announcement of the death of an active member of its editorial staff, M. Poggiale, and the discourses pronounced at his funeral by representatives from the various bodies to which he belonged. M. Antoine-Baudoin Poggiale was born in 1808, and his first memoir, published in 1834, was devoted to proving that the "parigline" of Palotta, the "smilacine" of Folchi, the "salseparine" of Tubeuf and the "parillinic acid" of Batka, were one and the same immediate principle. Amongst his subsequent works may be mentioned his treatise on Volumetric Analysis. M. Poggiale had filled the office of President of the Paris Society of Pharmacy and was a member of the Academy of Medicine.

Among the scientific works announced to be published during the coming season by Messrs. Macmillan and Co. is a "new and thoroughly revised edition" of Fluckiger and Hanbury's 'Pharmacographia.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, October 1, 1879.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Richardson, Rimmington, Robbins, Savage, Shaw, Squire, Symes, Williams and Woolley.

The minutes of the previous meeting were read and confirmed.

Weights and Measures.

The President stated that on the day following the last Council meeting he had received the following letter from the Privy Council office:—

"Board of Trade,
"(Standards Department),
"7, Old Palace Yard, S.W.,
"3rd September, 1879.

"Weights and Measures Act, 1878.

"Sir,—I am directed by the Board of Trade to acknowledge your letter of 27th ult. on the subject of verifying and stamping apothecaries' weights and measures.

"In reply, I am to point out that the local authorities named in the above Act are charged with the duty of inspecting, verifying, and stamping all weights and measures used in the trade, and that this Board are not authorized to interfere therein.

"I am also to add that, if the Pharmaceutical Society will depute someone to call on Mr. Chaney at the Standards Office, 7, Old Palace Yard, that officer will be glad to give him any information that may be in his power with reference to the above Act.

"I am, sir,
"Your obedient servant,
"Henry G. Calcraft.

"G. W. Sandford, Esq.,
"President of the
"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square, W.C."

In accordance with this communication he had waited on Mr. Chaney, and the result of the interview had been that he had received the following information:—No order had yet been issued as to the verifying of glass measures, and it had not yet been decided to issue any respecting them; if determined on it would probably only refer to the top line of graduation, and not to the subdivisions. For the present chemists need fear no interference from local inspectors, because they were not in possession of the standards, and would not be for three months to come. With regard to the idea which some persons entertained that weights or measures could only be used in the district in which they had been stamped, Mr. Chaney said this was altogether a mistake. A weight or measure stamped in one district was good in every district.

Mr. Rimmington said it was very desirable that what the President had stated should be generally known.

Mr. Richardson had always understood that the standards in each district were regulated by the standard in London. With reference to the glass measures, he did not quite understand whether they were to go on under the old system or to wait.

The President said that at present they must go on; they could not get them verified by the local inspectors.

Mr. Richardson said nothing varied more than glass measures. When could they have them stamped?

The President said certainly not for two or three months, because the inspectors would not have any standards by which to try them.

Mr. Shaw said he understood it was competent for any one to send his glass measures to the stamping office to be verified, and that Mr. Greenish had already sent three or four dozen, which had been verified and a mark placed upon them.

The President said he could only repeat that at present no inspector had in his possession the standards by which he could verify glass measures.

The Vice-President said it was very important that it should be generally known to chemists that any inspector who required a chemist to have his measures verified was for the present exceeding his authority.

The Chemists' Ball.

It was unanimously resolved that an application from Mr. Arthur L. Savory, asking permission to use a room on the Society's premises, for a meeting to make arrangements for the Chemists' Ball, be acceded to.

Local Secretary.

Mr. Sharp was unanimously elected Local Secretary for Sunderland in place of Mr Nicholson deceased.

Elections.

MEMBER.

Pharmaceutical Chemist.

The following, having passed the Major examination and having tendered his subscription for the current year, was elected a Member of the Society:—

Grimble, Alfred ....Boston.

ASSOCIATES.

The following, having passed the Minor examination and tendered or paid as Apprentices or Students their subscriptions for the current year, were elected "Associates" of the Society:—

Goodall, Thomas Torby ....Derby.
Wilks, Charles Frederick ......York.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Rowntree, Alfred Henry.........Manchester.
Timm, Edmund ....Goole.

It was proposed by Mr. Hampson, and seconded by Mr. Woolley—

"That the following Pharmaceutical Chemists, having tendered their subscriptions for the current year, be elected Members of the Society:—

Clarke, Isabella Skinner ....London.
Minshull, Rose Coombes.........London.

Mr. Hampson, in moving this resolution, said he was very glad to see that the ladies had again applied for membership. Two or three years ago, this question had been, he thought, unwisely relegated to the annual meeting, but since then there had been two or three elections of Council, and they were now, he contended, perfectly entitled to interpret the Act of Parliament according to the best of their ability. He believed the two ladies in question, having passed the requisite examinations and become registered, were without any doubt eligible according to the Act of Parliament to become members. They had conformed to everything which the Act required, and he thought the duty of the Council was to elect eligible persons irrespective of anything else. He had been told more than once that it was a matter of option with the Council, but he could not see it in that light. The duty of the Council was not to make the law, but to carry out the law; and it seemed to him somewhat impertinent to say, 'Because you are a woman, although you have gained admission to the rights of pharmacy under the Act of Parliament, when you apply under another portion of the Act of Parliament to become a member of the Society, you shall be refused.' This refusal had continued to take place for several years, but he took his stand on this point that the Council could not say that one portion of the Act of Parliament was a public matter, and another was a private matter. Some members had taken this ground, but he altogether refused to accept it, because the operations of the Society were carried on by the members of the Society, and the members were for the most part elected because they were pharmaceutical chemists or chemists and druggists before the passing of the Act, and it seemed to him that to put any stumbling block in the way of carrying out the Act of Parliament was illegal. If the members of the Council refused to admit eligible persons to membership of the Society because of their own private convictions or sentimental views, they were overriding the Act of Parliament and neglecting their duty as a Council. But apart from the legal aspect, he would say that it appeared somewhat ungenerous, he would almost say unmanly, to continue this persistent refusal. Surely there could be no harm in admitting as members those who had satisfied the examiners; on the contrary, they would do the Society honour by admitting to its ranks properly qualified lady members. Besides, by a refusal these ladies were also denied the privileges of using the library and museum, the title of membership, which in some parts of the kingdom was considered of great value, and the Journal. He did hope that this question would now be taken out of the hands of the annual meeting, where it ought never to have been placed. It was part of the executive duty of the Council to elect all eligible persons, irrespective of their sex. It would be as reasonable to ask what church they attended as to inquire as to the sex of eligible persons who applied for admission, and he hoped the matter would now be settled by carrying out the Act in its entirety.

Mr. Woolley seconded the motion, and endorsed everything which Mr. Hampson had said. He should be sorry for the Pharmaceutical Council to be the last to grant a request, the justice of which was obvious, and which must, ultimately, inevitably be granted. Body after body was granting to women what was their undoubted right, and he did trust the Pharmaceutical Council would not be left in the unenviable position of being the last to recognize it.

Mr Williams said he intended to support the motion. He had watched the proceedings of two general meetings in which this question had been agitated, and he should be very sorry that such a question should again be discussed by the general body. The necessity for such discussion no longer existed, for on two occasions the meetings were so evenly divided that it was a mere toss up which opinion should be followed. Taking it in its broader sense and seeing that these pharmaceutical chemists had applied for membership, he could see no reason why the fact of their being ladies should prevent their being elected. He thought the question had now come back to the Council for decision, and it was time it was finally set at rest. He should vote for the motion on that ground, and also because he agreed with Mr. Hampson that there was no real reason why they should not be elected.

Mr. Atkins intended to support the motion, though he demurred to the remark that the question ought never to have been referred to the annual meeting. He was very glad it had been so referred, for he did not think it would have been well to attempt an organic change without feeling the pulse of the constituency. He was, however, quite convinced that it was undesirable to remit it still further. Having tested the opinion of the members twice, the Council had done all it was bound to do, and he believed its constituents would be thankful to have the question taken out of the arena of unprofitable discussion. It was unnecessary to go over again the abstract arguments, and he hoped the question had now been removed from the ground of controversy altogether.

Mr. Savage was very glad to have so far a unanimous expression of opinion as to the desirability of admitting these ladies to the Society. He had always held that they had a right to be admitted, and he felt more than ever the importance of saving any further discussion of the question. The admission of all who had distinguished themselves in the examinations was, he thought, desirable, and he thought it was very much to the credit of these ladies that they had had the moral courage and perseverance to go successfully through the ordeal.

The President said as he still adhered to the view he had always held, he must correct Mr. Savage as to the opinion of the Council being unanimous. He had always voted against the admission of ladies and should continue to do so. Mr. Hampson said the Council ought to carry out the laws, but if it were to carry them out without judgment, they would be utterly useless. Then again, Mr. Hampson said that the members carried on the business; but if so, they had the vote of the members against the admission of ladies.

Mr. Hampson: By a majority of one or two.

The President said never mind what the majority was, it was a majority, and having sent this question to the members for decision, he held that the Council was to a great extent bound by their decision. Mr. Hampson had said the members of the Council had withheld from ladies certain privileges, but they were only privileges which belonged to members of the Society, not privileges which conferred any rights in respect of trading. He need not say anything further, because his views were well known.

Mr. Mackay said that in these days of wars and rumours of wars, he felt disposed to be a man of peace. Although he had his own ideas with regard to the admission of ladies to membership, he could not hide from himself that there had been an immense deal of agitation about it, and unless it were settled to-day there would probably be a great deal more; he was therefore disposed to settle the matter by voting for the admission of ladies.

Mr. Frazer said he rejoiced at the conversion of some of the members, and he trusted the matter would now be settled.

Mr. Richardson heartily supported the motion. He looked upon pharmacy as a suitable occupation for women, especially in villages and small towns, and their reception as members would give an impetus to women to become pharmacists. He hoped the President would withdraw his opposition, and that the vote would be unanimous.

Mr. Bottle said he should vote for the motion, not with a view of conceding to ladies what Mr. Hampson asserted was their right, but as a matter of courtesy, which he thought they had well earned by passing the examinations, and also with a view of bringing about a peaceful termination to a question which had formed a bone of contention for some years. A prolonged agitation would be infinitely worse than admitting even a dozen women into the Society.

Mr. Shaw said he had always supported the admission of ladies, and he was delighted to find such a large number of conversions to the proposition now made. He regretted that the matter had ever been remitted to the annual meeting, and he would remind gentlemen that during the discussions on the Pharmacy Act it was distinctly stated that all persons passing the examination, or persons who became pharmaceutical chemists, should be eligible to become members of the Society. That was held out to everyone, and as ladies were not excepted, they had certainly a right to be admitted.

Mr. Greenish said he should vote for the motion as a simple act of justice to those who had qualified themselves by passing the examination and who had been left out in the cold for a long time.

Mr. Hills said he also intended to record his vote in favour of the motion.

Mr. Robbins said he had brought forward a motion last year to endeavour to settle this question by an appeal to the members, on which he had been outvoted. The matter had come before the Council several times and he thought the members were all getting tired of it. To avoid further agitation, and to settle the question, he thought the Council were now prepared to give an almost unanimous vote in favour of the admission of ladies.

The motion was then put and carried, the President being the only dissentient.

Mr. Bottle asked what would be the position of these ladies in case they changed their names.

The President thought the Married Women's Property Act would reserve to the ladies their right of membership.

Two persons were restored to their former status in the Society, upon payment of the current year's subscription and a fine.

Additions to the Register.

The Secretary reported that—

John Cammack, Benington, near Boston;
William Clarke Edmonds, Rawmarsh, Yorks;
Frederick Ellis, 25, Cleveland Road, Downham Road, Islington, N.;
Frederick John Sicre, 33, Molyneaux Road, Farnworth Street, Everton, Liverpool; and
William Henry Thomas, 94, Victoria Street, Dowlais;

having made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and their declarations having been duly supported by medical practitioners, their names have been placed on the register.

Reports of Committees.

The President said that the Solicitor had been requested to attend at half past twelve, and he would therefore ask the Council to take the General Purposes Committee's report first, as it was on matters arising out of that report the Solicitor's opinion was required. The Council would of course go into committee to discuss these matters.

Mr. Symes said, in case a resolution was passed in regard to reporting the proceedings in committee, he could fancy it quite possible the Council might be in a dilemma as to what might be reported. He would suggest that the best mode of carrying out the resolution which was carried at his suggestion at the last meeting but one, would be, that the Council when in committee should frame a report which should be presented to the Council on resuming, and published. That was a parliamentary method of proceeding, and he merely rose to call general attention to that fact, so that when the Council went into committee the members should know what they were going into committee upon and should be in a position to frame a report of the proceedings to be presented to the Council on resuming.

Mr. Shaw said he was not present when the resolution referred to was passed, but he had read the report with interest. It struck him that the resolution would not amount to anything, and he found that, in answer to an inquiry, Mr. Symes explained that what had been optional in former times would now become compulsory. If he understood Mr. Symes's present proposal aright, it was this, that when the Council went into committee notes were to be taken, and when the discussion came to a close it was to be put to the members, and a decision come to as to what report should be published. This would be a most difficult thing to carry out, for immediately the Committee had closed one discussion it would have to open another as to what should be reported. Such a system would entirely destroy freedom of discussion. It had hitherto been left to the discretion of the professional reporter, who was constantly called upon to exercise his judgment in such matters, and he should recommend that the same course be followed in future, it being, of course, understood that the reporter would omit all personal matters and details of pending legal proceedings.

Mr. Hampson supported Mr. Symes's view. The resolution he brought forward some time ago was for the purpose of having a report of what took place in committee which would give satisfaction to the outsiders, and do no harm to the interests of the Society. It appeared to him that the best person to take the report would be the reporter himself; but it would necessarily be brief, and he thought it should be handed to the Committee, who should decide whether it was a faithful report and suitable for publication.

The President having read the resolution referred to,

Mr. Richardson said he feared that if Mr. Symes's proposal were adopted the members of Council would be there for a week. He thought the matter might safely be left to the President, the Secretary, and the reporter. He had been connected with a public body for nearly nine years, and he thought it would be much better if every report from a Committee were rendered in a form in which it could be published in the Journal and discussed in open Council.

The President said the Council had a good deal of business to do, and he must ask Mr. Symes to give notice of a motion if he had anything definite to propose, otherwise they must proceed with the report of the Committee.

GENERAL PURPOSES.

The report of this Committee was then read.

It consisted principally of correspondence with the Solicitor, with regard to sundry legal matters in which he had been instructed to take proceedings. There was also correspondence with the Secretary relating to alleged infringements of the Pharmacy Act, in regard to some of which the Committee recommended that proceedings should be taken. It also recommended that a grant of £35 be made to the Manchester Chemists and Druggists' Association, to partly defray the expenses of lectures on Chemistry, Materia Medica and Qualitative Analysis at the Manchester School of Pharmacy.

The Council then went into committee to consider the report and to confer with the Solicitor on certain points therein contained.

In the course of the conversation the Solicitor stated that he had just received a communication saying that—

Daniel Tudor Williams, of Aberdare,

who had been sued in the county court for a penalty for infringement of the Pharmacy Act, 1868, had paid the amount claimed, with costs, into court.*

On resuming, the report and recommendations of the Committee were unanimously received and adopted.

Mr. Churchill stated that he had just received a telegram from the Secretary of the Chemists and Druggists' Trade Association saying that in one of the cases which had been before the Committee, the Trade Association had prosecuted, and the defendent had been fined £1 and costs.

Mr. Richardson thought it would lead to confusion if both bodies undertook the prosecution of offenders.

The President said that anyone could institute proceedings under the 17th section; the Society did not generally prosecute under that section, which constituted a police offence.

The Council again went into committee to consider the opinion just given by the Solicitor with regard to a certain case which had been submitted to him, but after some discussion it was ordered to stand over to next month, the Secretary in the meantime to obtain fuller information.

The Council then resumed.

FINANCE.

The report of this Committee included a recommendation that sundry accounts be paid. It also stated that the Committee had considered the question referred to it by the Council, with regard to the payment of annual subscriptions to local secretaries, and was of opinion that

* It will be remembered that Mr. Williams's name was removed from the Register some time ago.

it would not be wise to alter the existing regulations, excepting in the form of letter sent to members who had not paid by March 31st, an amended form being submitted.

The report and recommendations were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

This Committee reported that a prosecution having been instituted against a member of the Society for the sale of cream of tartar alleged to be adulterated, the case had been under its consideration, and that as cream of tartar of commerce invariably contained a portion of tartrate of lime, it was deemed desirable that the Solicitor of the Society should watch the case at the time of the hearing. That he had been instructed to do so, and the magistrates had dismissed the summons.*

Mr. Woolley asked if the defendant received his costs.

The President said he could not answer that question.

Mr. Woolley said there was a case near Manchester, in which the analyst gave an opinion that proved to be totally erroneous with regard to a certain drug, and there costs were awarded against him. Honest tradesmen ought not to be subjected to this kind of persecution and have to bear the costs into the bargain.

The President said there had been another prosecution for the sale of cream of tartar in the same county, and no doubt by the same analyst, which the magistrates had dismissed without calling for any defence.

The report was received and adopted.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£15 to the widow of a registered chemist and druggist, aged 60. Applicant had a grant of £10 in February, 1877.

£15 to a member, aged 59, suffering from ill-health. He had a grant of £20 in August, 1878.

£10 to a former member, unable to work from sickness, who has had three previous grants.

£10 to a registered chemist and druggist, formerly in business, who has had two previous grants.

£10 to a registered chemist and druggist, who has also had two previous grants.

£5 to another registered chemist and druggist, aged 61, an unsuccessful candidate for an annuity last year, and who has had two previous grants.

£10 to a female registered chemist and druggist, who has had three previous grants.

One other application was ordered to stand over for further inquiries.

The Secretary had reported that there are now twenty-nine annuitants on the Fund, and given particulars of the age and date of election of each.

The Committee having considered the financial position of the fund, was of opinion that it was expedient to elect three pensioners, and recommended that the election be held on Friday, December 19.

Mr. Williams said the Committee only proposed to elect three annuitants, but there were nine candidates, and several other worthy objects could easily have been added to the list, but the Committee was really aground for want of funds. In fact it was running some risk in proposing to elect three, for in all probability the means would be exhausted by the end of the year. If the subscriptions were more general from those who now did not subscribe at all, there would be abundance of funds not only for three, but for the whole nine. He trusted that their friends in the country would see this, and recognizing that it was not a matter of disputed politics, but of genuine benevolence, would endeavour to give something, however small, to assist the fund.

Mr. Rimmington drew attention to the case of one of the annuitants whose conduct had on a former occasion been the subject of inquiry, and suggested that it would be well to remove him and put a better man in his place.

Mr. Williams said this could hardly be done offhand without due notice and consideration.

Mr. Bottle hoped the Council would feel that it was in a position to elect three annuitants, and he was sorry it could not be more. But he had felt on the previous evening when the Committee considered the matter that he could not go to the extent of proposing four, since the balance sheet showed that it was doubtful on which side the balance would be at the end of the year; but there would certainly be no surplus for investment. It was true that in the coming year some deaths might occur, but, on the other hand, as the annuitants became older they were entitled to larger pensions, and there were constantly more claims for casual relief. He therefore hoped that all who were able to contribute to the fund would assist in doing the large amount of good which the Benevolent Fund was calculated and he hoped for many years would continue to do.

The report and recomendations were unanimously adopted.

Mr. Shaw gave notice that he should next month bring forward a motion for the purpose of preventing canvassing cards and circulars being issued by candidates.

The Pharmaceutical Conference at Hanover.

Mr. Greenish stated that, with Dr. Paul and Mr Passmore he had attended the meeting of the German Pharmaceutical Association held in Hanover the first week in September. As on the former occasion in Coblentz, they were very cordially welcomed, and at the dinner the toast of the Foreign Guests had been received with considerable enthusiasm. There had also been placed at the disposal of each of them a guide to Hanover and its surroundings, also tickets of admission to the Pharmaceutical Exhibition and other places of interest in and about Hanover. Some specimens of new preparations shown in the exhibition had been promised for the Society's Museum. The apparatus, which formed an important part of the exhibition, was mainly composed of modifications of that of Beindorff, so well known in German pharmacies. There was also exhibited by a firm in Berlin a polarimeter very efficient, and at a moderate price, and a microscope of a construction that possessed some advantages over those in general use in this country; both of these there was some probability of being able show at one of the Evening Meetings of this Society. He should be glad to see some of their colleagues in Germany return the visit on one of our festive occasions in England. He had much pleasure in moving—

"That a vote of thanks be presented to the President of the German Pharmaceutical Association and the Local Committee at Hanover for their cordial reception of English visitors at the meeting of their Association."

The motion was seconded and carried unanimously.

PHARMACEUTICAL MEETING.

Wednesday, October 1, 1879.

The first evening meeting of the session took place on Wednesday, October 1, the chair being taken by the President of the Society at half-past eight.

The minutes of the last meeting were read and confirmed.

The President, having expressed his pleasure at seeing so large a gathering on the opening night of the session, called on Professor Redwood to present his—

Report on the Chemistry and Pharmacy Class.

Professor Redwood said the business of the evening being of a somewhat varied character, and the actors who were to take part in the proceedings

* This case was reported in the Journal of September 27.

being numerous, it was necessary, or at least desirable, that those who had merely formal duties to perform should be as brief as was consistent with setting forth the merits of those whom they had to introduce to the notice of the meeting. In reference to the examinations he might state that in his class and also in that of his colleague, Professor Bentley, who he regretted to say was unable to be present that evening, there had been three separate examinations. In the first place there were two examinations for those students who had studied five months, namely, one at the end of March, and one at the end of July. On these examinations a bronze medal was awarded and certificates of merit, the latter being only given to those students who obtained an equal number of marks to those who at the ten months' examination obtained a certificate of honour. The certificate of merit therefore in this case was really of greater value than the certificate of merit in the ten months' examination. As the result of the examination in March he found that there were five gentlemen in his class who received certain indications of merit; at the head of these was a gentlemen who would be found to figure also in subsequent examinations, one whose name could not fail to be familiar to them, namely, Mr. Mackay, of Edinburgh,—not a member of the family of Mackay's which they were most familiar with, but still it was satisfactory to know that talent was not confined to that one family. There were four other gentlemen, whose names appear below, all of whom obtained 75 per cent. of the highest number of marks which could be given, and they were all entitled to certificates of merit. In the July examination some of these gentlemen again appeared. Those who had previously obtained honours as five months' students could not compete on that occasion in the five months' examination; but there were again five gentlemen who obtained distinction, the bronze medal being awarded to Thomas Horton. In July also there was the examination for those who had been studying ten months, and those who had not been studying so long were eligible to compete, and occasionally did so, but it could not be expected that they would often succeed in competition with those who had been studying for double the length of time. Here again the silver medal was awarded to Mr. Mackay. As he mentioned the names of the other successful competitors, Professor Redwood said he desired to add one remark, namely, that it was a feature in these examinations of late years that a larger number of students had competed than was formerly the case, and further, that a larger proportion of those who had competed had proved successful in the competition. This was a highly satisfactory feature, inasmuch as it seemed to indicate that the students now obtained a more thorough preliminary education before they came to that school; they were better prepared, and were therefore more generally successful than was the case several years ago.

The following is a list of the students in this class to whom prizes have been awarded:—

FIVE MONTHS' COURSES.

FIRST COURSE.

Bronze Medal........................James B. Lillie Mackay.

Certificates of Merit ....
- Frank Harris Alcock.
- Beresford Fred. Harold Maudson.
- Edward Jarrett Eaton.
- James Henry Allan.

SECOND COURSE.

Bronze Medal........................Thomas Horton.

Certificates of Merit ....
- Henry William Drew.
- William Herbert Hyatt.
- George Wale.
- William Inchle Gulliver.

TEN MONTHS' SESSION.

Silver Medal........................James B. Lillie Mackay.

Certificates of Honour ....
- Thomas Horton.
- Edward Jarrett Eaton.
- James Henry Allan.

Certificates of Merit ....
- Frank Harris Alcock.
- Henry William Drew.

The following were the questions for the examinations:—

FIRST COURSE. BRONZE MEDAL.

Hours 10 till 2.

1. Define the meaning of the terms matter, force and inertia.
2. What is the meaning of the term weight?
3. What is the weight of a pint of rectified spirit, B.P.?
4. What marked distinctions are there between gaseous diffusion and liquid diffusion?
5. Briefly explain the undulatory or wave theory of light.
6. Describe the normal composition and characters of crystallized carbonate of potassium, and also of the carbonate of potash of the Pharmacopœia.
7. Give the composition of oxide of zinc, and describe the methods by which it may be produced.
8. In what state is bismuth principally found in nature? What is its melting point, and what appearance does the metal present when a mass of it, after being melted, and then cooled, is broken?
9. Give the respective compositions of the lowest and highest oxides of antimony, and describe the processes by which they may be obtained.
10. Give the respective compositions of glucose, alcohol, aldehyde, acetic acid, and acetone, and explain how these are or may be related to each other.

SECOND COURSE. BRONZE MEDAL.

Hours 10 till 2.

1. Describe the method of taking the specific gravity of calomel and also that of wax.
2. Explain the meaning of the term "allotropy."
3. What is the meaning of the terms "specific heat" and "latent heat?"
4. Describe the essential characters of an emulsion.
5. Describe ozone and peroxide of hydrogen, their properties and the method of producing them.
6. Describe phosphorus, its production from natural sources, its allotropic conditions, and its properties.
7. What is the natural source of cadmium, how is it isolated, and what are its properties?
8. Describe acetic acid, its production in various ways, and the relation it bears to alcohol.

SESSIONAL COURSE. SILVER MEDAL.

Hours—10 till 1, and from 2 till 5.

1. What is the weight of a pint of distilled water, and what is the specific gravity of a liquid, a pint of which weighs 9625 grains?
2. What are respectively the specific heats of water, oil, and mercury?
3. What is the velocity with which a body falls to the earth through a vacuum, at the latitude of London, in the first, second, and third second of time?
4. Describe the principle of the action of the siphon.
5. What is the law relating to the rate of diffusion among gases?
6. In what way does the density of a gas into which diffusion takes place affect the result?
7. Describe the production of chloride of magnesium and also of chloride of aluminium.

8. What is the composition, and the assumed constitution of borax, and how is the borax of commerce usually prepared?

9. What are the chemical charges that occur in the conversion of barley into malt?

10. Describe the production of lactic and butyric acid.

11. Describe the production of artificial urea, and point out the relation it bears to cyanogen.

Report on the Practical Chemistry Class.

Professor Attfield being next called upon, said he was much pleased to see such a large number of old students present, and no doubt his colleagues who lectured in that hall would be very glad if they could see such a muster every day in the session. He appeared there in two capacities, as professor and as examiner. As professor he had given in his report to the Council in the usual way at the end of the session, and that report he now held in his hand. He would not read the whole of it, but might say formally that the number of students was 75, the average period of work by each was six months, and the number of hours occupied in work daily during that period was three and a half. As compared with the previous session the number of pupils was the same, the average number of months' work was rather greater, but the number of hours worked daily was decidedly less, hence neither this nor, indeed, the previous one compared favourably with former sessions. Out of the 75 pupils only 5 attended for purposes other than those connected with pharmacy, whilst there were three ladies working at practical chemistry for the requirements of the medical profession. He might add with regard to the lady students that he saw no reason whatever why ladies should not work at practical chemistry in the Pharmaceutical Society's laboratories. With regard to the general work of the session, he had only to say that they had had what might be called a quiet session. They had got on remarkably well together throughout. The class consisted of gentlemen, and without exception they were men who had come to be prepared not so much for examination as for the general work of life. He trusted they were not disappointed. As examiner, he had to report that at the end of the session he held an examination for the Council prizes, when the student who obtained the highest number of marks was Mr. Frank Harris Alcock. He obtained 81 out of 100 marks, and hence took the silver medal. The second, Mr. F. W. Warrick, and third, Mr. R. J. Price, obtained 76 and 75 per cent. of marks respectively, and were awarded bronze medals, and then came five gentlemen whose numbers carried Council certificates. Nine other competitors obtained less than 60 marks, so that there were 17 in all, a good proportion of the whole number of students. This was the result of his examination, extending over two days, but he had also been teacher of these men, and had one way or other examined them for more than two hundred days during the session. He had thus gained so good a knowledge of the relative positions of these seventeen men that he was able to say that two who did not even obtain the minimum number of marks qualifying for a certificate of merit were as good men as those who had obtained marks qualifying them for medals. The sound, and he thought safe deduction, was that even a two days' examination conducted by a professor in the subject was an inefficient test of competency, but he would not be so disloyal to the School or the Society, to say nothing of himself, as thus to criticize his own action as an examiner, unless he were prepared with a remedy. The remedy he suggested was to let the professors' periodical examinations throughout the session count in the adjudication of position at the end of the session. It would be scarcely right, having said thus much about the two gentlemen who did not succeed, if he were not to add that in one of the two cases he knew why the competitor did not obtain a higher place, and in the other case he believed he knew the reason. In the one case the man was ill, and in the other case he thought he had good evidence that instead of analysing a certain solution which had been given to him, the man took up the wrong vessel and analysed something which had not been given to him. It was well known that he had great sympathy with men who failed at all kinds of examinations, because he knew it was not always their fault. Whether they failed because of such an accident as he had described or because they did not happen to be very well, or because they happened to have been educated at a school like his own, where the students were not so much prepared for examination as for the battle of life, and consequently, he was sorry to say, sometimes did not do very well at examinations; whatever the causes were, he had great sympathy with disappointed candidates, and he hoped this little suggestion with regard to his own work would have attention. The method might be carried further and deeper if the Council thought fit; if so, he was sure that a large number of good men would cease to suffer from failure at examinations.

The following is a list of students in this class to whom prizes have been awarded :—

Silver Medal	Frank Harris Alcock.
Bronze Medals	Fredk. Walmsley Warrick Robert John Price.
Certificates of Merit	Edward Jarrett Eaton. James B. Lillie Mackay. William Inchle Gulliver. Beresford F. H. Maudson. Thomas Horton.

The following were the questions for the examination :—

July 21st and 22nd, 1879.

Hours 10 to 5 each day.

(*Books and Memoranda permitted.*)

Standard number of Marks, 100.

FIRST DAY.

1. The "solution" given to you may contain any of the ordinary metallic salts used in medicine; analyse it, and state the result.

2. Is there any common poison in the "vomit" placed before you?

SECOND DAY.

3. Examine the specimens of epsom salt, iodide of potassium, sulphate of quinia and distilled water supplied to you, and report on their quality.

4. How much nitrate of silver is present in one fluid ounce of the "lotion" given to you?

Note.—Manipulation as well as results will be scrutinized.

Report upon the Botany and Materia Medica Class.

The President then, in the absence of Professor Bentley, presented the report which that gentleman had sent in. He first read a letter which Professor Bentley had addressed to him, explaining that his official duties at King's College, as Dean of the Medical Faculty, would prevent his being present that evening, and saying how deeply he regretted being deprived of the pleasure of meeting his old students on that occasion as he had been accustomed to do for so many years. The Professor's report stated that in the first course examination he had 19 candidates, the average marks being exceedingly good, some exceptionally so; the three first obtained respectively 90, 80 and 77 per cent., and 2 more 76 and 75. In the second course there were 6 candidates, 3 being specially worthy of distinction, who obtained respectively 92, 82 and 75 marks. At the terminal sessional examination there were 14 candidates, the majority of whom passed through it very creditably, and the first three obtained exceptionally high marks.

The following is a list of the students in this class to whom prizes have been awarded:—

Five Months' Courses.

FIRST COURSE.

Bronze Medal........................James B. Lillie Mackay.

Certificates of Merit .... Fred. Wm. Ed. Shrivell. / Frank Harris Alcock. / James Edward Williams. / Edward Jarrett Eaton.

SECOND COURSE.

Bronze Medal........................Thomas Horton.

Certificates of Merit .... Henry William Drew. / William Inchle Gulliver.

Ten Months' Session.

Silver Medal........................James B. Lillie Mackay.

Certificates of Honour .... Thomas Horton. / Frank Harris Alcock. / Henry William Drew. / Edward Jarrett Eaton.

Certificates of Merit .... James Edward Williams. / William Inchle Gulliver. / Fred. Wm. Ed. Shrivell. / James Henry Allan. / Percival C. Powrie. / Isaac Leach.

The following were the questions for the examinations:—

FIRST COURSE. BRONZE MEDAL.

Hours from 10 till 1.

1. Describe the structure of a seed; and define the terms dicotyledonous, monocotyledonous, and acotyledonous.

2. Describe the characters of (*a*) ordinary woody tissue; (*b*) disc-bearing woody tissue; (*c*) liber tissue; and mention the plants and parts of plants where they are respectively found.

3. Describe the structure of a leaf-bud. Define the following:—Herb, spine, runner, rhizome, corm, bulb, tubercule and tuber.

4. What are the botanical and geographical sources of Alexandrian and East Indian sennas? Describe their general and chemical characters and enumerate their official preparations.

5. What are the botanical and geographical sources of the official ipecacuanha? Describe its general and chemical characters, and show how it may be distinguished from the varieties of ipecacuanha known as striated and undulated.

6. What are the botanical and geographical sources of asafœtida. How may it be distinguished from the other official gum resins of the Umbelliferæ, and what are its official preparations?

SECOND COURSE. BRONZE MEDAL.

Hours from 10 till 1.

1. Describe the internal structure of an acrogenous or acotyledonous stem.

2. Define the following terms as applied to leaves:—Primordial, connate, decussate, equitant, crenate, serrate, lanceolate, obcordate, pinnate, and pinnatifid.

3. Describe the parts of a carpel; and explain the terms simple and compound pistil, apocarpous and syncarpous.

4. What are the botanical and geographical sources of sumbul? Describe its general and chemical characters, and mention its official preparations.

5. What are the common adulterants of scammony, and how may they be detected?

6. What do you understand by a balsam? Describe the botanical source, collection, preparation and general and chemical characters of balsam of Peru, and mention any official preparation into which it enters as a constituent.

TEN MONTHS' SESSION. SILVER MEDAL.

Hours from 10 till 1.

Botany.

1. Describe the structure of epidermal tissue.

2. Define the following:—Amentum, capitulum, cyme, thalamus, receptacle, disk, involucre, cupule, spathe, monœcious, diœcious, and corona.

3. Describe the several kinds of placentation, and give illustrations of natural orders in which they may respectively be found.

4. What is the nature of the fruit? Explain the composition of the following fruits:—Apple, strawberry, rose, acorn, fig, and pine-apple.

5. Distinguish the Compositæ from the Dipsacaceæ; and the Labiatæ from the Scrophulariaceæ and Boraginaceæ.

6. Give the essential characters of the following natural orders:—Ranunculaceæ, Leguminosæ, Umbelliferæ, Orchidaceæ, Iridaceæ, and Liliaceæ.

Materia Medica.

Hours from 2 till 5.

1. Describe the general and chemical characters of Senega root. Mention the roots which have been found mixed with it, and the means of distinguishing them.

2. What are the botanical and geographical sources of Ammoniacum? Describe its general characters, the mode in which it is obtained, and its composition; and mention its official preparations.

3. How would you distinguish the official jalap resin from the resins of Tampico Jalap, Scammony, and Guaiacum.

4. What are the supposed botanical sources of the official Rhubarb root? Describe its general and chemical characters, and show how it may be distinguished from English Rhubarb root.

5. Describe the characters of the flowers of *Anthemis nobilis*; and state how they may be distinguished from those of *Matricaria Parthenium.*

6. Describe the physical and chemical characters of Croton Seeds. Mention the differences between East Indian and English Croton oil, and give the dose and official preparations of Croton oil.

Report on the Botanical Prize.

The President read Professor Bentley's report on the Herbarium competition. There were four collections submitted, the first of which was admirable in every respect and included 800 specimens. For this he recommended that a silver medal should be awarded to Mr. Thos. F. Perkins. The second, by Mr. Walker, which contained 600 specimens, was also highly to be commended, and eminently deserved the bronze medal; and the third by Mr. Norman deserved a certificate of merit.

The following were the awards:—

Silver Medal ....Thos. Frampton Perkins.
Bronze Medal........................Charles Walker.
Certificate of Merit ....William Francis Norman.

THE COUNCIL EXAMINATION PRIZES.

Mr. SOUTHALL, being next called upon to report on the examination for the Pereira medal and other Council examination prizes, said he appeared in a position very different from that of the gentlemen who had already addressed the meeting, inasmuch as he and his colleague, Mr. Moss, had had no opportunity of seeing and conversing with the students whose work they had examined, as the Professors had, but simply knew them by the mottoes attached to their papers. The examinations had been gone through in a satisfactory manner, showing that the competitors had paid great attention to their studies.

The following are the names of the persons to whom the prizes have been awarded:—

Pereira Medal (silver); and Books value £5, presented by Mr. T. H. Hills.

Frank Harris Alcock.

Pharmaceutical Society's Medal (silver); and Books value £3, presented by Mr. T. H. Hills.

Marshall Leigh.

Pharmaceutical Society's Medal (bronze); and books value £2, presented by Mr. T. H. Hills.

Henry Allen.

The following were the questions for this examination:—

CHEMISTRY.

Time 10 to 1.

Five only of the following questions must be attempted:—

1. *Catalysis, Eremacausis, Fermentation, Putrefaction.* Define these terms and give an instance in which each is correctly applied.
2. How would you perform the analysis of glass?
3. What is a graphic formula? Give such formulas of Phosphoric Anhydride and Acetic Acid.
4. Give reasons for representing Ferric Chloride as $Fe_2 Cl_6$, and not $Fe Cl_3$, and Tartaric Acid as $H_2 C_4 H_4 O_6$, and not $HC_2 H_2 O_3$.
5. What is an *Alcohol*, an *Olefine*, a *Ketone*, a *Glycol*, a *Chlorhydrin*, a *Nitrile*? Give an example of each with formula.
6. What is the construction of Nicol's prism? Describe the effect produced upon a ray of light directed through its length. State also how light transmitted by one prism is affected by a second according to the relative positions of the two.

BOTANY.

Time allowed: Three hours.

In framing answers Candidates should not enlarge upon the questions, but should confine themselves to giving, as briefly and clearly as they can, the information required.

1. Expain the processes of assimilation and metastasis in the living plant.
2. Describe the organs termed elaters and their function, and mention the natural orders in which they occur.
3. Describe any special provisions you may be acquainted with for the fertilization of Orchids.
4. What are proliferous flowers, and what organs of plants are occasionally viviparous, giving examples of each?

MATERIA MEDICA.

1. Describe Myrrh, its chemical composition, the localities whence it is imported, and the history of its use.
2. Give any information you may possess respecting the cultivation of Cinchona in India, and name the most valuable species and varieties.
3. What are Hermodactyls?
4. What is Gurjun Balsam, and what is it remarkable for?

The PRESIDENT then presented the various prizes and certificates to the successful competitors, after which he called upon Mr. Taylor to state the result of the examination for

THE JACOB BELL MEMORIAL SCHOLARSHIP.

Mr. TAYLOR said he had now for four years shared the duty of conducting this examination and he must again express, as he did last year, his surprise and disappointment that these prizes received so little attention and attracted so few competitors. Last year Mr. Williams, the then President, drew forcible attention to the value of these scholarships, in the hope that more would be induced to compete for them, but this year the number was one less than last. When it was considered that these scholarships were worth nearly all the other prizes put together, and that there were only eleven competitors, it could not but occasion a feeling of surprise as well as regret. Of these eleven, eight were from London and one each from Nottingham, Brighton and Manchester. The successful candidates were Mr. Wm. Elborne and Mr. John Thomas. These gentlemen acquitted themselves so well, and their testimonials from previous employers were so good, that his colleague and himself had no difficulty in submitting their names to the Council. He trusted they would avail themselves of the privileges they had obtained, and if they made as good use of them as previous Bell Scholars had done, they would become accomplished and useful members of society and reflect credit not only on the Society but on the name of the distinguished man in whose name these scholarships were founded. He could not sit down without saying that the third candidate, who took the motto *Labor omina vincit*, did his work so well, that he hoped, if eligible, he would try again. But no doubt there were dozens of young men now engaged in pharmacy, who could pass an equally good, if not better examination than those who had now succeeded, and considering that the scholarships were worth £30 each in money, together with free education and all the privileges the Society could afford, it was really astonishing that so few should compete for them.

The PRESIDENT, after presenting the Bell Scholars with the books given by Mr. Hills, said he hoped that both the successful and unsuccessful competitors for the prizes which had just been distributed would be encouraged to renew their studies with zeal, and so prepare themselves, as Professor Attfield had expressed it, for the battle of life. They must remember that their education did not end here, and he hoped they would so extend it as to become ornaments both to society in general and to that Society in particular. They would be looked to for the future prosperity and honour of the Society. Those who had obtained the scholarships he would earnestly exhort to look at the bright example of their predecessors, and a very bright example was now before them in Dr. Tilden, one of the earliest Bell Scholars, who had already greatly distinguished himself, and promised to distinguish himself still more. Let them as far as lay in their power follow in such footsteps.

The successful candidates for these scholarships were:—

William Elborne
and
John Thomas.

The questions set for this examination were as follows:—

Time allowed: Three hours (12 to 3).

LATIN.

Translate into English:—

1. Tum vero omne mihi visum considere in ignis
Ilium, et ex imo verti Neptunia Troja:
Ac veluti, summis antiquam in montibus ornum
Quum, ferro accisam crebisque bipennibus, instant
Eruere agricolæ certatim; illa usque minatur,
Et, tremefacta comam concusso vertice, nutat;
Volneribus donec paullatim evicta supremum
Congemuit, traxitque, jugis avolsa, ruinam.
Descendo, ac, ducente deo, flammam inter et hostis
Expedior: dant tela locum, flammæque recedunt.

2. In Extractis præparandis, nisi aliter indicatum sit, humorem balneo aquoso in patinâ quamprimum consume, sub finem assidue spathâ movens, donec crassitudo sit ad pilulas fingendas idonea.

Grammatical questions on the above:—

3. Parse *visum, verti, veluti, ornum, accisam, instant, tremefacta, concusso.*

4. Explain the cases of *ignis, ferro, agricolæ, volneribus.*

ENGLISH.

1. Parse fully:—

The real strength and security of governments in these days lie in public opinion formed and enlightened by free discussion.

2. Write a short essay on Peace.

ARITHMETIC.

1. Simplify $2\frac{1}{3}+72\frac{5}{8}+316\frac{1}{6}+2\cdot875$.

2. A person sold ·15 of an estate to one person and then $\frac{5}{17}$ of the remainder to another person. What part of the estate did he still retain?

3. If 9 men or 15 women, working 10 hours a day could reap a field in 8 days 6 hours, in how many days of $10\frac{1}{2}$ hours each could 10 men and 12 women reap a field one-fourth larger?

4. Express a gallon in litres, and a kilometre in yards.

FRENCH AND GERMAN.*

Translate into English:—

Plusieurs furent pris, blessés, ou tués, ou entraînés loin du roi par la foule qui se jetait sur eux: il ne restait que cinq hommes auprès de Charles: il avait tué plus de douze ennemis de sa main, sans avoir reçu une seule blessure par ce bonheur inexprimable qui jusqu'alors l'avait accompagné partout, et sur lequel il compta toujours. Enfin un colonel nommé Dardof se fait jour à travers des Calmouks avec seulement une compagnie de son régiment: il arrive à temps pour dégager le roi.

And:—

Il s'est efforcé de connaître Dieu, que par sa grandeur est inconnu aux hommes, et de connaître l'homme, qui par sa vanité, est inconnu à lui-même.

Or:—

Er starb endlich auf einer italienischen Reise in der Stadt Mantua, im drei und siebenzigsten Jahre seines Lebens, und im Vollgenuss seines Ruhms, nachdem er hatte besessen das Vertrauen seines Königs vierzig Jahre ununterbrochen.

And:—

Nach Frankreich zogen zwei Grenadier,
Die waren in Russland gefangen,
Und als sie kamen ins deutsche Quartier,
Sie liessen die Köpfe hangen.

CHEMISTRY, PHARMACY, AND BOTANY.

Time allowed: Two hours (4 to 6).

1. Describe the process for the manufacture of commercial oil of vitriol. What is Nordhausen sulphuric acid, and how can it be prepared?

2. Acidum hydrochloricum, B.P., has a specific gravity 1·16, and contains 31·8 per cent. by weight, of hydrochloric acid gas. How many fluid ounces of the B.P. acid can theoretically be prepared by the decomposition of one pound of pure chloride of sodium by means of sulphuric acid?

3. Give the official process for making ferri phosphas, with any remarks you may consider suitable.

4. State what you know concerning rectified spirit and proof spirit. How can a spirit 60° over proof be reduced to proof spirit? Name a few tinctures made with rectified spirit, and give reasons for its employment in those tinctures.

5. Give the Pharmacopœial process for making injectio morphiæ hypodermica, suppositoria morphiæ, tinctura opii and syrupus papaveris.

6. What is thistledown? Describe the inflorescence of the oat.

7. Give an account of the germination of an almond, and describe the tissues of which the bark of an exogenous stem is composed.

The President then called upon Dr. Tilden to deliver the—

Inaugural Sessional Address.

Ladies and Gentlemen,—

The Council of the Pharmaceutical Society of Great Britain has done me the honour to request that I would address a few words to the assembled students on this interesting anniversary. Those who have preceded me in this position upon corresponding occasions have been, every one of them, men older in years than myself, of wider knowledge and experience, and above all distinguished practitioners of pharmacy; but, I think the Council did wisely to engage, once in a way, the services of one who, whilst retaining distinct and pleasurable recollections of his association with pharmaceutical students, has in the course of events so far severed connection with the pharmaceutical body that he can look upon their proceedings from the standpoint of an outsider. Notwithstanding misgivings as to my individual fitness for the post, I did not hesitate to accept the invitation of the Council, because I was anxious to testify to all my good friends here my reciprocation of the kind feelings which led to the proposal. I had no better way of expressing my thanks than to accede to the request.

We are met together, as every one present is aware, for the express purpose of doing honour to the students attending the courses of instruction in this institution. In the name of the Council, the Professors and Officers of the Society, I have first of all to express to those students who have just received their prizes at the hands of the President, most hearty congratulations upon the success with which their labours have been crowned, and to wish them prosperity in the career upon which they are now about to enter. Gentlemen, you are justly proud of the honours which are the reward of your industry. You are justly gratified at the approbation of your friends. You have listened, I doubt not, with

* The candidate is at liberty to choose either French or German, and is not required to show a knowledge of both.

quickened pulse to the praises pronounced by your professors. You have received the applause of this great meeting. I am sure that the memory of these things will abide by you, and when, in future years, some of you may appear as spectators at a renewal of this scene to celebrate the successes of those who will come after you, you will all feel stirred, as we do to night, with a sympathetic triumph.

There is another class of students, for the moment less distinguished, but in general equally deserving of respect. I mean the students who have not received prizes—to whom, I feel also, every one present will desire that I should say a few words of encouragement.

Do not despair, my friends, because you have no trophies to carry away with you. If you have worked steadily, with an honest desire to learn, you have gained that which will serve you more usefully in the battle of life than prize-books or certificates. You carry with you the recollection of conflicts with self, of struggles against difficulties apparently insuperable, of encounters with temptation in which you have come off victorious, and these experiences, added to even a moderate amount of professional knowledge, will make good and useful citizens of you. But my belief is that we may anticipate something even better than this. When I look back through the prize-lists of past years, I see there many names that have since become distinguished in the ranks of pharmacy, and when I remember that in the competition for prizes there is often but a small, and sometimes a scarcely discernible difference between the merits of the best man, who gets the prize, and the second best man, who does not get it, I feel satisfied that of the majority of the students of this institution we have not heard the last when they take their leave of the place.

But I must not forget, gentlemen, to urge upon you all, whether prize-takers or not, the importance of seriously and systematically continuing your studies. I do not mean to say that I would advise everyone to go on working away at the whole range of subjects to which your attention has been directed in your progress through this school. It is now the time when each of you may follow the bent of his own inclination. I do not say I hope you will choose chemistry or botany or therapeutics, or any other branch of science in particular, but I am myself deeply impressed with the necessity for a reasonable interest, call it a "hobby" if you like, to every reasonable man. And I ask you to take my word for it there is no prophylactic so potent, no remedy so sure, against the inevitable weariness which sooner or later overtakes the mere idler or seeker after pleasure.

Some of you probably think you have learnt a great deal since you came here. Relatively to your former state of ignorance that is no doubt true, but after all what you now know by comparison with what you have yet learn is a mole-hill to a mountain. Do not suppose I wish to disparage. This is merely the condition of everyone in this room, professors (if they will forgive my saying so) and all, and the wisest man is he who recognizes this somewhat humiliating fact the soonest, and does his best to add to his little heap.

What is the use of all this? I will tell you presently some of the so-called practical uses, but in the meantime I want just to remind you that increased knowledge will give you a treasure which, in one way at least, is better even than a good balance at the bank. It will give you self-respect. I do not mean conceit, that peculiar and special vice of half-educated people. I mean by self-respect that kind of self-knowledge which enables a man to estimate his own powers at their true value, avoiding, on the one hand, exaggerated distrust on the score of defects perceived and, on the other hand, undue exaltation by reason of conscious ability.

But I would impress upon you young pharmacists the importance of finding your "hobby," if possible, in your business. If you make your business the real occupation of your life it will certainly yield you a harvest not merely of internal satisfaction, a reward rich enough in itself, but tangible advantages such as commend themselves to the commercial mind are equally certain to accrue. This is true of every calling in life. It is almost a truism. But in its special application to pharmacy I want to speak a few words. The old-fashioned pharmacist, represented in my memory by the late Henry Deane, was a man with a soul, but not above his business. I know that, happily, some of the race remain. Such a man knows the contents of every bottle and drawer in his shop, not merely in regard to cost and retail price, but the entire history and precise quality of each particular sample. He buys no concentrated abominations whilst the roses, long innocent of any tint but brown, moulder in their dusty corner. His aromatic waters are distilled and have no acquaintance with calcined magnesia. He has his own views on the proper season for the preparation of liquor taraxaci and makes it with his own hands. He knows what medicinal plants grow in his own neighbourhood, and he prefers to make his own extracts of henbane and conium. I spare you the rest. You know how much more I might say, but if you have any doubt whether this kind of thing pays look round at any such men you can find and judge for yourselves of their prosperity.

But there is another aspect of the same question. Some years ago a remarkable paper was read at the Pharmaceutical Conference by Mr. Joseph Ince. Everyone present will understand that I refer to the essay on "Pharmaceutical Ethics." In that paper Mr. Ince did not hesitate to declare unreservedly that "pharmacy is a trade," and in a meeting which included many of the most able, and not a few of the most influential of living pharmacists, there was no dissentient from that view of the matter. So far as I am able to judge, and in spite of Acts of Parliament since devised to regulate the practice of pharmacy, the occupation of the pharmacist is not materially changed since 1866. But it appears to my humble judgment that this dictum of Mr. Ince's, whilst absolutely and literally true, does not cover the whole of the facts of the case. The pharmacist is a tradesman, but interwoven with his trade is a multifarious system of transactions involving the employment of knowledge and skill, gathered through the somewhat prolonged course of training, which at present culminates in the examinations of this Society. And it is a question in my mind whether the ideal pharmacist ought to be purely a tradesman.

When the time comes, as I believe it will come, and perhaps very soon, the pharmacist who desires to do so will be in a position to make his election between a kind of business represented by the shop on the one hand, the mere drug store bringing according to the accounts of the grumblers neither honour nor profit; and on the other hand a calling in which he will have due exercise for what professional skill he may possess and gather his income somewhat in accordance with the customs prevailing in other professions. But this will not be done by railing at the law, the public, or the doctors. A young man having passed his examination, whether it is the Minor or the Major, is not entitled on that account to regard himself as an unrecognized and unrewarded benefactor of the human race. He has suffered all this toil and expense, not I apprehend for the good of mankind, but because he knows there is at the end of it a monopoly, such as it is, of a certain calling reserved for him by the law. I know the reply which is almost upon the lips of some of my hearers. Look at the state of trade, look at the cheap drapers and grocers, who destroy all one's profit, and then the co-operative stores!

Let us look at this calmly for a few minutes. So far and so long as the pharmacist is a trader, he must take with other traders the chances of competition and the stores, and he must submit to the neglect of what is called "society." I know not what may be the end of all this, and I question whether in this room there is a prophet who is qualified so far to prophesy. But it is perfectly clear to my mind that no amount of remonstrance, be it never so reasonable, no amount of reproach, be it never so vehement, will prevent the public from supplying themselves in any way which the fashion of the moment renders the most acceptable.

It appears to me that the pharmacist will be more likely to improve his position by stedfastly promoting the cause of higher education, and by maintaining an attitude of dignity in that professional citadel in which he cannot be assailed, and into which, sooner or later, I believe he will not only be obliged to retreat, but will find it his best interest to do so. In plain English what does all this mean? I figure to myself a time when the pharmacist will leave to his neighbour, the grocer, the sale of such commodities as starch, mustard, pepper, cigars, British wines, aerated waters, quack medicines, and all such trumpery; when he will no longer dispute with the hairdresser the trade in toothbrushes, pomade, and shaving soap, and will no longer think it necessary to deck his pharmacy with glittering smelling bottles or chest protectors in bright array; when the plate glass front shall disappear from without, and the counter with at least half the mysterious, and often meaningless, gold labels from within.

But I know that all this sounds unpractical, if not impossible. I admit that it is very largely so at the present moment, but not, I venture to think, in the immediate future. I am aware that after taking away from the pharmacist the whole or nearly the whole of his trade, the residue of pure pharmacy and dispensing practice remaining over would, in too many cases, be sadly unproductive of income. Although these should undoubtedly constitute the chief avocation of the pharmacist, yet I may be permitted to remind you that the chemist and druggist and the pharmaceutical chemist have contrived to secure to themselves the patent of a title which Sir Humphry Davy himself, unless he happened to be on the pharmaceutical register, would not now be suffered to use unchallenged. Does not this suggest something? It points, I think, unmistakably to a development which the pharmacist, with due qualifications, has within his reach. Who so well fitted as he, by his special training, to become the public adviser upon all questions connected with sanitary affairs, to investigate cases of poisoning or adulteration? What is there to prevent him from in time supplanting the half-informed medical officer of health, and the too often incompetent public analyst? If he wishes to get a further stamp put upon his qualifications, either for his own gratification or for the satisfaction of his clients, there is the Institute of Chemistry ready to examine him. I should be taxing your patience too severely if I were to attempt to enter into further detail upon this topic which, however, appears to me to be worthy the deliberate and serious consideration of all pharmacists, but more especially of you students who are about to commence your professional career. I do not say you are driven to anything of the kind I have endeavoured feebly to picture. If you prefer it, or find it advantageous in the pursuit of that indispensable commodity, a sufficient income, or for other reasons find no escape from the prevalent form of general business, no one can question your right to do as you think fit; but I ask you as reasonable men whether you can be justly surprised that a generally ignorant, always unreasoning and careless public, should fail to appreciate at their due value professional services performed, and professional opinions pronounced behind a barricade of little articles that would find their appropriate place in an Italian warehouse or a fancy bazaar.

But my task is only half accomplished. I should be neglecting a most important part of my duty if I omitted to address myself to those who are about to commence or to continue their studies to-morrow. There is but one golden rule for the student, and that is, learn all you can and learn it thoroughly. Some there may be here who feel disposed to question the utility of all this chemistry and botany that the pharmaceutical student is now expected to learn. I can only assure you that if you will but wait patiently you will discover in time a practical application for every scrap that you can gather of this seemingly superfluous knowledge, and wish you had more. When it was my fortune to have to do with pharmaceutical students they were invariably most earnest, painstaking and industrious, and I have no doubt that these qualities still form their most prominent characteristics. They were, however, liable to one or two little weaknesses which I dare scarcely hope have since disappeared. My attention was very frequently drawn in those days to a disposition to regard every question from the so-called practical point of view, a certain degree of restlessness being too often manifest when anything like general theoretical questions came to be discussed, unless they happened to bear in the most direct and unmistakable manner upon some subject of every day life. I do not mean to imply that this is a peculiarity of pharmacists or of pharmaceutical students, but merely that they are not free from this which is the characteristic error of most practical men. I remember a speaker upon some occasion, I cannot now remember the who, when or where, took upon himself to declare that there was no such thing as *pharmaceutical* chemistry. Such an expression sounds a little startling, but the meaning of the speaker was probably this, that the broad principles of science remain the same no matter what application you propose to make of them, and that without a knowledge of these principles you may know the whole of materia medica from beginning to end and yet be absolutely ignorant of chemistry; you may be familiar with the name and even with the aspect of every flower of the field and have no claim to be considered a botanist. Science does not consist in mere manual dexterity, neither does it consist in a knowledge of any number of hard names. One of the most serious consequences of neglecting all but what lies close at hand is this, that whilst you may learn to perform with the most punctilious accuracy all kinds of individual operations, you remain almost as incapable as ever of coping with any unexpected difficulty, and you are quite unable to assist in making the advances which pharmacy, in common with every other human art, must continue to make if it is to survive?

There is just one other topic, in conclusion, to which I must advert. We have all heard a great deal in this room and elsewhere about that ugly word "cram." Now whilst I sympathize with nearly all that has been said and written upon the subject, and whilst I deplore the existence of a system so destructive, I think there has been just sufficient ambiguity in the use of the term to make some students feel the denunciations rather too wholesale and somewhat indiscriminate. There are two sorts of "cram." The one is both foolish and dishonest. But although, I suppose, we must admit that it is sometimes practised by candidates for pharmaceutical examinations, I have so much confidence in the skill and experience of our Board of Examiners, that I do not believe the system meets with greater success here than at other institutions, or even so great. I need not enter now into details because the subject has been discussed over and over again *ad nauseam*. But I would just suggest to those young men who propose to devote that portion of their time which should be spent in the acquisition of knowledge to the invention of schemes for cheating the examiners, that it will be to their own interest to credit the examiners with just a little common sense as well as knowledge of their business, or they may find out to their disappointment that the Board is not made up, as they fondly suppose, of a pack of idiots like themselves. The legitimate process, on the other hand, is that kind of cramming to which every student must resort if he wishes to pass a given examination safely and honourably. This process consists in nothing less than learning very thoroughly the subjects in which he is to be examined, and for the time, no others. It seems to me unreasonable to complain of a student because he declines to make the attempt to study the whole of a text-book, of botany for example, when the board before whom he is to present himself for examination has previously announced that it intends to examine him in a portion only of that subject. It may fairly be assumed that the limit has not been fixed without due deliberation, and if the student honestly sets to work at the task assigned, that is all that can be expected of him. One cannot be said to know a subject well unless he is prepared to answer clearly and intelligently any reasonable questions that may be put to him in that subject, and therefore the most important thing to aim at is precision, without which a great deal of knowledge may become worse than useless for the purposes of examination, and let me add of practical life. From all which you will perceive that I am one of those persons who, whilst recognizing the possible harm that may befall that rare phenomenon, the extraordinary genius, by reason of the existence of the examination system, yet hold the opinion that in the influence of the system upon the cause of education the good decidedly predominates.

To candidates for examination let me add one hint. Supposing the student to have attained to an accurate knowledge of the subject, or that part of it in which he is to be examined, what reasonable grounds ca there be for that excessive nervousness displayed by some candidates? If I were an examiner, a candidate in this condition would excite my suspicions at once. I should either suppose the nervousness assumed, with the object of deceiving me, or I should credit him with a knowledge of defects apparent to his own consciousness, though hidden from mine.

And now, Gentlemen, I need not detain you any longer. You are about to enter upon a period in your career, at once the most interesting and the most delightful. One word of caution. You all start off, I know, with a great stock of resolutions and good intentions. Take care they are not all wasted at the outset. In commencing an ascent the experienced mountaineer will start soberly, and pursue, at a steady pace, the path previously determined upon. The unskilful only tries short cuts, exhausts himself by spurts, or loiters, with the notion that it will be time enough to make up lost ground later in the day. Be advised in time. You have in your professors experienced and able guides. Follow them, act upon their instructions as to your journey, and do not be lured from the open path by people who tempt you with vain promises to relieve you of your labour. We who have climbed the same heights will watch your progress with unfailing interest. We know what are the difficulties you are likely to encounter and how they are to be surmounted. But we know, also, that the labour must be your own.

The PRESIDENT proposed a vote of thanks to Dr. Tilden for the admirable and practical address which he had just given. While it contained excellent advice to the younger members of the meeting, he was quite sure there was no one present, even as old as himself, who would not be benefited by a careful consideration of it.

The VICE-PRESIDENT said such a resolution really required no seconder, but he hoped he might be excused if he added a word or two, for two reasons. In the first place, they would wish to express in the most emphatic way their appreciation of Dr. Tilden's kindness, and therefore, perhaps, it would be appropriate that he, in his official position as Vice-President, should second the vote of thanks. Secondly, he was probably better acquainted than many present with Dr. Tilden's claims to their gratitude. Dr. Tilden had for several years occupied a very important scientific position in the locality with which he was himself connected, and consequently he knew the work Dr. Tilden had been doing there, and the high position he had taken. Under such circumstances it might not unreasonably have happened that Dr. Tilden might have forsaken pharmacy altogether; but that was not so. In his own endeavours to advance scientific tific pharmacy he had constantly received the greatest possible assistance from Dr. Tilden, who had helped forward the work with his large knowledge and high scientific attainments in a manner which no other gentleman could possibly have done. Therefore, when that gentleman now came forward to deliver his address to the students who were aiming to sustain pharmacy in its highest *rôle* they must not regard it as a spasmodic effort on his part, but as the last of a long series of acts all tending in the same direction.

The motion having been carried by acclamation—

Dr. TILDEN said it had given him great pleasure to appear there on that occasion, and he esteemed it an honour to receive the invitation of the Council. They would easily understand that he might have acquitted himself better if he had been called upon at a somewhat earlier date, because, coming tenth or twelfth in a succession of men who had occupied a similar position, it became increasingly difficult every year to say anything worthy the acceptance of the meeting. And when it was remembered that the best men were always selected first, it would be seen that those who came later had an additional difficulty to contend with. There were probably many parts of his address which might require further elaboration and explanation than he had been able to give, in order to make his meaning acceptable to members of the Society, and he felt that he had to some extent taken a liberty in attempting to express himself on some of the topics on which he had touched, but he hoped that any imperfections of that kind would be excused, for his intentions certainly were of the best.

The meeting then adjourned to Wednesday, November 5.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Annual Meeting of the thirtieth session of this Association was held in the Royal Institution, September 25, 1879. The president, Mr. T. Fell Abraham, in the chair. The minutes of the last general meeting were read and confirmed. The donations to the library were duly acknowledged. The following annual report of the council and the treasurer's financial statement, which showed a balance in hand of £13 15*s.* 3*d.*, were read.

ANNUAL REPORT.

"In presenting the Annual Report of the Thirtieth Session of the Liverpool Chemists' Association, your Council has pleasure in observing the renewed energy and increased scope of usefulness which characterize the proceedings of the session now closing.

"Twenty-four new members and thirteen associates were elected during the past session, fourteen members and four associates have retired from various causes, leaving the number at present on the list 172—consisting of 17 honorary members, 130 members, and 25 associates.

"There were eleven general meetings held during the session, the time of each being fully occupied with papers of chemical, pharmaceutical, or general scientific interest, whilst many important subjects were discussed under the head of miscellaneous communications.

"There has been a marked improvement in the attendance of members and associates at the meetings. This, comibned with a more general activity, appears to your Council a very encouraging sign. The Council is glad also to report that your fourteenth Conversazione proved itself a very successful and enjoyable entertainment, whilst financially it yielded a credit balance to the general fund. The Association is indebted to the several members who rendered their services, to the exhibitors of the numerous objects of interest, and in particular to Mr. Edward Davies, F.C.S., F.I.C., for his exceedingly interesting lecture on 'Phosphorescence and Fluorescence.'

"The Association, as in the previous year, took part in the holding of the Second Associated Soirée of the Literary, Scientific, and Art Societies of Liverpool, and is indebted to Mr. Davies on that occasion also for the delivery of an entertaining and appreciated lecture.

"The School of Pharmacy was provided with courses of lectures on Chemistry by Mr. Thomas Williams, F.C.S.; Botany, by Dr. Shearer; and Materia Medica, by Dr. Carter. Eight pharmaceutical students attended the Chemistry Class, and, at the close, an examination was held, under the superintendence of the President. The questions were kindly supplied by Professor Attfield, who also adjudicated the answers, deciding in favour of Mr. John Albert Jones, who will this evening be awarded the President's prize.

"The syllabus for the forthcoming Chemistry Classes has been already issued. The lectures on Materia Medica and Botany will be announced in due course.

"Several donations of books and pamphlets have been added to the Library during the session, and some periodicals and journals have been bound. Various specimens have also been contributed to the Museum, including a complete series illustrative of sugar refining, from Mr. J. T. Armstrong, F.C.S. The re-arrangement of the contents of the Museum has made some progress. The issue of books from the Library amounted to 445 volumes, in addition to references.

"Invitation having been received to send delegates to the British Pharmaceutical Conference, held at Sheffield, the President, Vice-President, Treasurer, and Mr. A. H. Mason, F.C.S., were appointed and attended.

"The ballot at the concluding general meeting for the appointment of President for the thirty-first session resulted in the election of Mr. Charles Symes, Ph.D.

"Mr. Armstrong having resigned his seat on the Council in consequence of removal from the neighbourhood, Mr. Thomas Garside, F.C.S., was elected in his place.

"The following members of Council retire by rotation, and are eligible for re-election:—Messrs. T. F. Abraham, E. Davies, T. Garside, and T. Williams."

It was moved by the president, seconded by Mr. E. F. Morton, and carried unanimously, that "The reports as read be adopted and together with the list of members and abstract of proceedings of the past session be printed and circulated among the members."

It was proposed by Mr. Joseph Hallawell seconded by Mr. A. Watt, F.C.S., F.I.C., and carried unanimously, that "The best thanks of the meeting be given to the donors to the Library and Museum, to the authors of papers and to the exhibitors of apparatus, etc., during the past session."

It was proposed by Mr. T. H. Johnson, F.C.S., F.I.C., seconded by Mr. Henry Burroughs, and carried unanimously, that "The best thanks of this meeting be given to the officers and council for their services during the past session."

The president's prize of books offered to the student in the chemistry class who should pass the best written examination was produced, having been awarded on Professor Attfield's adjudication to Mr. John Albert Jones. The meeting then proceeded to the election of four members of council. Messrs. Edward Davies, F.C.S., F.I.C., Thomas Garside, F.C.S., Alexander Watt, F.C.S., F.I.C., and Thomas Williams, F.C.S., were declared duly elceted.

Parliamentary and Law Proceedings.

PROSECUTIONS UNDER THE 17TH SECTION OF THE PHARMACY ACT, 1868.

At the Blackburn Borough Police Court, on Friday, September 26, 1879, before Messrs. E. Wharton (chairman) and W. Hopwood, Stephen Green, drysalter and patent medicine vendor, appeared in answer to a summons charging him with unlawfully selling poison.

Mr. Henry Glaisyer, solicitor, Birmingham, appeared in support of the summons, being instructed by the Chemists and Druggists' Trade Association of Great Britain. He said the summons was issued by Mr. William Frederic Haydon, the Secretary of the Association, under the provisions of the 17th section of the Pharmacy Act, 1868, which said—"It shall be unlawful to sell any poison either by wholesale or by retail unless the box, bottle, parcel, wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and the word 'poison,' and with the name and address of the seller of the poison; and any person selling poison otherwise than is herein provided shall upon a summary conviction before two justices of the peace in England be liable to a penalty not exceeding £5 for the first offence, and for the purposes of this section the person on whose behalf any sale is made out, an apprentice or servant, shall be deemed the seller." Mr. Haydon came to Blackburn on the 30th of July last, and visited the defendant's shop in Bolton Road and purchased a pennyworth of oxalic acid, a pennyworth of white precipitate powder, or ammoniated mercury, and a packet of rat poison, containing strychnine, all of them being poisons mentioned in the schedule to the Act and subject to its provisions. It was proposed to proceed only in one of these cases, that of the oxalic acid. The label on the packet contained only the word "poison," and therefore there were two particulars in which the statute had not been complied with. The name of the poison was not mentioned, and the name and address of the seller of the poison was not stated. The defendant was not a chemist, and was therefore unqualified to sell poison at all. A penalty is provided by the statute for selling poisons by unauthorized persons. but such penalty was not recoverable before the magistrates, and the defendant was charged on that occasion with having infringed the statute by not having labelled the packet in accordance with the provisions of the 17th section. Mr. Glaisyer, in continuation, drew attention to the fact that the business belonged to the defendant beyond a doubt, for his name appeared on a board over the door, and he had also paid rates in respect of the premises. The provisions of this statute were necessary in order to protect the public and afford a ready means of tracing where poison was obtained in cases where it was subsequently improperly used.

The defendant pleaded guilty, and said he was sorry for doing wrong. He had been in the trade twelve years.

The Chairman: You must have known you were doing wrong.

Mr. Glaisyer: I may state for the information of the Bench that in consequence of the sale of poison being made in this way so frequently, the present proceedings have been instituted in order to make known the provisions of the statute.

The Chairman (to the defendant): This is the first case of this description that we have had in this court, and we shall be content if you pay a fine of 20*s.* and the costs. You are liable to a fine of £5 and costs.

At the Liverpool Borough Police Court on Saturday, September 27, 1879, before Messrs. Henry Hugh Hornby and Edward Browne, justices of the peace, Mr. Richard Rowland Minton and others, trading as R. R. Minton and Co., appeared in answer to a summons charging them that they did on the 6th day of August last, at the borough of Liverpool, unlawfully sell to William Frederic Haydon, at 135, St. James's Street, certain poison, to wit, oxalic acid, in a certain packet, the cover of which packet did not set forth the name of the article or the name or address of the sellers of the same, contrary to the provisions of the 17th section of the Act, 31 and 32 Vict., cap. 121.

Mr. Henry Glaisyer, solicitor, of Birmingham, instructed by the Chemists aud Druggists' Trade Association, appeared in support of the summons. The defendant appeared in person.

Mr. Glaisyer, in opening the case, said that the defendants were the partners in the firm of Messrs. R. R. Minton and Co. They carried on an extensive business in this town, at Cheapside, and other establishments, as oil and colour merchants. The summons, as in the previous case, was issued under the provisions of the Pharmacy Act, 1868, 31 and 32 Vict., cap. 121, sec. 17, which he read. The facts of the case were shortly these:—Mr. Haydon, the secretary of the Chemists and Druggists' Trade Association, came to Liverpool on the 5th of August, and visited the defendant's shop, 135, St. James's Street, and there he purchased a pennyworth of oxalic acid, which is one of the poisons mentioned in the schedule to the statute. There was no label placed on the packet, but the word "poison" was written on it. There were therefore two particulars in which the section of the Act had not been complied with. There was no doubt the business belonged to Messrs. Minton and Company. Their name appeared on brass plates attached to the windows of the shop, and also on many articles in the shop, and in addition they were rated for the premises and had paid rates due in respect of them.

Mr. Hornby: You say the word "poison" was written on the packet?

Mr. Glaisyer: The word "poison" was written on the packet, but not the other particulars.

Mr. Goodwin, who appeared for defendant, said he did not dispute that defendant sold this article; but it was a long time ago.

Mr. Stubbs: What you have to say is in mitigation.

Mr. Goodwin: We only wish to say it is not an article we generally keep; we did not know in fact that it was in the shop. A young man got it to oblige a few customers. It is used by dyers principally, and is sold in very small quantities. It is quite an omission that the young man has not put a proper label on the wrapper.

William Frederic Haydon, called, sworn, and examined, gave evidence bearing out the opening statement by Mr. Glaisyer.

Mr. Goodwin: As one of the principals I might as well say we admit we are guilty in this matter. But really we were not aware the acid was being sold. We leave ourselves entirely in your hands. We will take care that in future nothing of the kind shall occur. I have no doubt we have transgressed the law.

Mr. Hornby: The defendants are fined 10*s.* and costs.

At the Birmingham Police Court, on Wednesday, October 1, 1879, before Messrs. Ralph Heaton and Henry Wiggin, Joseph Guest Earp, oil and colour merchant, 22, Cheapside, Birmingham, was summoned by the Chemists and Druggists' Trade Association of Great Britain, for a contravention of the 17th section of the Pharmacy Act, 1868, "by selling certain poison, to wit, oxalic acid, in a certain packet, the cover of which packet did not set forth the name of the article, or the name or address of the seller of the same, contrary to the statute in such case made and provided."

Mr. Glaisyer appeared in this case, instructed by the Chemists and Druggists' Trade Association of Great Britain, the information being laid by the secretary, Mr. W. F. Haydon.

Mr. Glaisyer said the summons was issued under the provisions of the Pharmacy Act, 1868, 31 and 32 Vict., cap. 121, sec. 17 (as in the previous cases). The facts of the case were shortly these:—Mr. Haydon visited the defendant's shop, 22, Cheapside, Birmingham, on the 8th of August last, and there he purchased a pennyworth of oxalic acid, which is one of the poisons mentioned in the schedule to the statute. The label placed on the packet contained the word "poison" only. There were therefore two particulars in which the section of the Act has not been complied with. There was no doubt the business belonged to Mr. Earp. His name appeared over the shop door, and in addition he was rated for the premises.

The defendant: No doubt about it.

Mr. Glaisyer: I am instructed to press for a heavy penalty, Mr. Haydon having in June, 1877, two years since, purchased poisons from the defendant, who was at that time warned that he was acting illegally. A month after that purchase, Mr. Haydon was told by an assistant of the defendant that Mr. Earp only sold poisons to persons he knew. In August last defendant sold the poison with which he was now charged.

William Frederic Haydon, called and sworn, deposed to the above facts.

In reply to a question, Mr. Haydon said that in June, 1877, he purchased from the defendant oxalic acid and red oxide of mercury, both poisons scheduled under the Pharmacy Act, and this being so far as he was aware, the defendant's first offence he reported the purchases to the Secretary and Registrar of the Pharmaceutical Society of Great Britain. He now produced a letter, dated July 5, 1877, which he received from the Secretary and Registrar of that Society, stating that he had written to the defendant giving him notice that if he continued to infringe the provisions of the Pharmacy Act, legal proceedings would be taken against him without further notice. In July of the same year, witness went to the defendant's shop and again endeavoured to purchase oxalic acid, but was told by the assistant that they had ceased to sell poisons except to persons they knew as customers.

The defendant: I have never been warned.

The magistrates' clerk to Mr. Haydon: The letter you have produced is not admissible as evidence that the defendant has been previously cautioned.

The defendant: My foreman has omitted to put the name of the article and my name and address on the packet. We sell oxalic acid to boot makers, and for cleaning brass.

The magistrates' clerk to Mr. Haydon: Have you cautioned the defendant yourself?

Mr. Haydon: I have not.

Mr. Heaton, addressing defendant: You have not conformed to the Act of Parliament. It requires that you should put the name of the poison upon the packet, also your own name and address. Had it been clearly proved that you had been cautioned previously, we should have inflicted the full fine. You must, however, pay 20*s.* and costs.

The Sale of "Fever Powders."

On Tuesday, September 30, the Deputy Coroner for East Sussex (Mr. J. E. Fullagar) held an adjourned inquest at the Bridge Hotel, Newhaven, on the body of Elizabeth Ellen Young, a little girl aged four years and eleven months, who was supposed to have died under suspicious circumstances.

Mr. Edward Henry Moore deposed that he was the public analyst for the county of Sussex. He received from P. S. Renville a packet containing twelve powders. They bore a label, indicating that they were "Welch's Fever Powders," and professing to be prepared by Henry Moon, Trafalgar Street, Brighton. They were in six sets of two powders each, professing to be suitable for different ages of children, and there was a blank space on the labels for the age to be filled in. The different sets were for cases of children from six to eight years of age, four to six years, three to four years, two to three years, one to two years, and four to seven months. He had made an analysis of the powder, and had found that the composition was entirely sugar and calomel. He had further assured himself of the absence of those mineral poisons which, from their appearance, would be likely to be mistaken for calomel, viz., antimony, arsenic, a possible impurity of calomel, and bichloride of mercury. Taking the powders generally, the proportion of calomel was 1 to 3 grains. The difference in the weight of the powders, as presumably for the same age, was in eight cases out of ten exceedingly marked. In the two powders for children from three to four years of age there was a difference of weight of three-quarters of a grain, representing a variation of one-quarter of a grain of calomel. The variation averaged in the eight powders from 12 to 25 per cent. In all cases of variation the proportion of calomel to sugar was fairly sustained. In the two powders for four to six years there was a variation of half a grain, one weighing $4\frac{1}{2}$ grains ($1\frac{1}{2}$ grain calomel), and the other 5 grains ($1\frac{1}{6}$ grain calomel). The greatest difference was noticeable in the powders for children of from six to eight years, where there was a variation of 1 grain in weight. The two powders, one to two years, and the two from four to seven months were identical in weight. The first representing 4 grains to each powder, consequently containing $1\frac{3}{4}$ grain of calomel, and the latter containing $2\frac{2}{10}$ grains of calomel. The powders from three to four contained $1\frac{3}{4}$ grain of calomel. Calomel was a difficult powder to mix with nice accuracy owing to its extreme weight as compared with its usual excipient. The difference of the weight of some of the powders was to such extent as to be suggestive to measuring rather than weighing. In his opinion the powders were imperfectly described as "Fever Powders," and the use of calomel would be prejudicial in a case like the present.

Police Sergeant Renville stated that he purchased twelve powders at Mr. Samuel Sargeant's shop, on Tuesday evening last. Mr. Sargeant served him himself. The six sets, for different ages of children, were kept in six different boxes, which bore a label outside stating the age of the child for which the powder was intended. The packets containing the powder were all alike, and there was a blank space for the age to be filled in. Mr. Sargeant filled in the ages on the twelve packets in witness's presence. He sent them to Mr. Moore.

Mr. T. M. Cann stated that he had made a *post-mortem* examination of the deceased, and found that death was due to inflammation of the bowels. A powder containing one and three quarter grains of calomel would tend to aggravate the symptoms instead of relieving them. That amount of calomel would not necessarily be too much for a child if it was administered by a medical man for certain diseases, but it was a highly injurious medicine for general distribution. In cases like the present it would increase the inflammation, but it would not be possible to ascertain where the natural inflammation left off, and the inflammation caused by calomel commenced. The powders were very improperly described as fever powders, for although calomel might be useful in certain special instances, it would be injurious in the great majority of fevers.

This concluded the evidence, and the Deputy-Coroner then summed up, remarking that one good result of the inquest would be that parents would be warned against buying a powder which they might imagine to be a cooling or aperient medicine, but which in reality contained a very dangerous ingredient. In this case it had not been proved that death was caused through the taking the powder, especially as evidence had been given showing that a portion of the medicine was vomited, but at the same time these so-called fever powders were being extensively used, and might produce very injurious effects. Apart from the dangerous nature of the powder itself, he considered that the packets were sold in a manner which might very easily lead to a serious blunder. The envelopes containing powder of different strengths were precisely alike, and it would be a very easy mistake to sell them out of the wrong box, or to get the packets in the different boxes confused. If the jury were of opinion that death could not be traced to anything else but natural causes, it would rest with them, if they thought fit to do so, to append a rider expressing their opinion concerning the indiscriminate sale of dangerous medicines.

After some consideration, the jury returned a verdict of "Death from natural causes," and added the following rider:—"The evidence discloses that a medicine fit only for skilled application is being indiscriminately sold and administered by incompetent persons, and the jury are of opinion that the sale and preparation of medicines containing dangerous ingredients should be restricted to duly qualified persons, and the active ingredient of such medicines should be stated on the wrapper in which the medicine is contained."—*Brighton Gazette.*

Correspondence.

Trading by Government Clerks.

Sir,—I am sorry to see that the retail traders in London have again been making themselves ridiculous by holding a meeting in Exeter Hall. They seem to have attempted to make capital out of the presence of a provincial mayor, who expressed disappointment at the smallness of the number of representatives. I know nothing of that gentleman's social status at home, but I suspect that he felt anything but flattered with the society in which he found himself in Exeter Hall.

From the small number who attended it seemed to be inferred that retail traders are lukewarm as to the effect upon their businesses by competition with trading establishments conducted by the clerks in the service of the government. The fact is they feel the grievance very keenly, but they have no power at the present to grapple with it. As a body they are men of sense and judgment and bear their grievance quietly rather than mix themselves up with such as gave evidence before the Royal Commission or those who constituted the conference at Exeter Hall.

I have watched the progress of the stores with some interest and I have observed with regret the ill-judged action taken by a certain class of retailers to counteract their progress. I admit the perfect freedom of every one to purchase his requirements in any market which may be most to his fancy and I think no one denies the right of fair and legitimate competition in business which gives stimulus to enterprise, and at the same time offers every facility for enabling the public to spend their money to the best advantage.

As regards the establishment of trading concerns conducted by the clerks in the employ of the government I maintain without fear of contradiction that the system is an illegitimate and dishonorable innovation upon the vested interests of a very large and important section of the taxpaying community, a system altogether uncalled for by the requirements of the public and utterly unjustifiable, as it aims to subvert interests which are national and to set up no compensating interests in their stead. Government clerks, whether active or pensioned, are in every sense of the word the servants and dependents of the public; although they are not under the immediate control of the public, their salaries and pensions are paid out of the earnings of the public through those whom the latter entrust with the custody of their welfare. As such the clerks in the employ of the government have neither legal nor moral right to do anything detrimental to the interests of any portion of the community. What would be thought of an individual taking service under another and taking advantage of some hitch in his contract to use the advantages of his position for his own benefit and to the detriment of his employer. Yet the government clerks now engaged upon the stores are in exactly the same position. They may be under no contract prohibiting them from such proceedings, but that arises only from the fact of such restrictions not having been previously required. Circumstances alter cases and what would be considered actionable at, if not punishable by law in an individual, seems to be justified in this case by the social status of those engaged in it.

I cannot but feel surprised at the keen patronage bestowed upon the stores by many landed proprietors and clergymen of the Church of England, although I must admit there are many exceptions. I see landed proprietors and clergymen whose rents and tithes are realized in the neighbouring market towns spend as little of their money as possible in those towns, but supply their establishments from the stores, although their predecessors and even they themselves at one time seemed to have no idea of spending their money except in their own neighbourhood. Of course every one is perfectly at liberty to spend his money where he thinks proper, but I would ask such if that is an equitable application of the principle "live and let live." I have also been surprised at the favourable attention bestowed upon the stores by professional men such as lawyers and doctors. Now these gentlemen as a rule are dependent for their incomes upon the personal feeling of the community around them, and yet I know several who are stealthily keeping their household from the stores. It is not difficult to bring such gentlemen to their bearings, as tradesmen clients have only to transfer their patronage to such as spend their money at home. I have seen the principle applied in two cases with electrical effect; one had the chagrin of seeing a younger rival pocket an account of close upon fifty pounds which he would have received himself, but for the careful housekeeping of his good lady, and I saw another visibly cringe under the same process from a like cause; few can afford to lose practice any more than traders can afford to lose business.

In my day the best feeling existed amongst the town tradesmen towards the county families and the feeling was reciprocated; now I am sorry to see that a stand-off feeling is gaining ground and that owing to nothing which has taken place between them, but from the habit of the latter to take advantage of the illegitimate system of trading inaugurated by the clerks in the government offices. Now, sir, it is admitted that the antagonism of class against class in the case of capital and labour is a national misfortune. Is it desirable then that division should be still further increased by setting the middle and upper classes against each other, and that at the instigation of a small body who were unknown and possessed no influence until they commenced their system of trading and gave it influence by combining with it a state title?

The clerks in the government offices have a perfect right to co-operate in supplying themselves with the necessaries of life, but they have no right whatever to extend their operations beyond their own immediate class as they are now doing. They are not only supplying their own wants, but they are increasing their salaries by taking advantage of facilities which were never intended for such a purpose and at the expense of a class who are heavily taxed to support the expenses of the state, part of which, no matter what proportion, are the salaries and pensions of active and retired clerks in the employ of the state. Promoters of stores may say what they like about the small percentage of the business of the country which they do, but that is not the point. The question to be decided is, Are the clerks in the government offices to be allowed to receive salaries at the expense of the public and at the same time to be allowed to embark in business to the detriment of those out of whose earnings their salaries are paid? I think that the subject only requires to be brought fairly before the government and the system can admit of no defence. To those who are already so engaged I would give a certain time, say three years, either to withdraw their connection or to resign the service of the state, although they have no claim to consideration on account of vested interests. The remedy is in the hands of the retail traders; a general election is close at hand and they have sufficient influence to demand the support of a measure for such a purpose.

A Looker-on.

Communications, Letters, etc., have been received from Messrs. Leslie, Moscrop, Rogers, Siebold, Brayshay, Hall, Need, Shillcock, Tanner, Evans, Burrell, Rusticus, Elevator, Ph. Chemist and Dentist, Nostrum, Ink, Chemist and Dentist, Analyst for the County of Surrey, Student, Eboracum, Potassium, X. Y. Z., A. B., F. W. S. G., J. S., R. W., H. P.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 123.)

OPHIOXYLON SERPENTINUM, *Linn.*, APOCYNEÆ.—*The root. Vernacular*: CHOTA-CHAND (Hind.); CHANDRÁ (Beng.); HARKAI (Bomb.); PATALAGANDHI (Tel.).

History, Uses, etc.—This shrub is mentioned in Sanskrit works under the name of sarpagandha. The Hindus use the root as a febrifuge and as an antidote to the bites of poisonous reptiles; also in dysentery and other painful affections of the intestinal canal. By some it is supposed to cause uterine contraction, and promote the expulsion of the fœtus. Ainslie gives the following account of it: "Tsjovanna amelpodi is the name given on the Malabar coast ('Rheede Mal.,' vi., 81, t. 47) to a plant the bitter root of which is supposed to have sovereign virtues in cases of snake bites and scorpion stings; it is ordered in decoction to the extent of a pint in twenty-four hours, and the powder is applied, externally, to the injured part. The plant is the radix mustela of Rumphius ('Amb.' vii., 29, t. 16). The Javanese class it among their anthelmintics, and give it the name of puli pandak. It may be found noticed both by Burman, in his 'Thesaur. Zeylan.' (t. 64), and Garcia ab Horto ('Hist. Aromat.'); the latter recommends it as stomachic. Rumphius speaks of it as an antidote to poisons, and Bontius, in his 'Hist. Mat. Med. Ind.' tells us that it cures fever" ('Mat. Ind.' ii., 441).

In the Pharmacopœia of India its use in labours to increase uterine contraction is noticed, upon the authority of Dr. Pulney Andy, but we have no evidence of its efficacy in such cases. In Bombay most of the labourers who come from the Southern Concon keep a small supply of the root, which they value as a remedy in dysentery and other painful affections of the intestines.

Description.—Root crooked, tapering from half an inch in diameter downwards. Bark soft, corky, marked by longitudinal fissures, light brown; wood brittle, showing rings and medullary rays, visible to the naked eye. Taste very bitter; odour of the fresh root acrid.

Microscopic structure.—The suber upon transverse section presents the appearance of a piece of honeycomb, viz., alternate rows of long tubular cells and compressed scales. The inner portion of the bark consists of a delicate parenchyma, loaded with starch, and traversed by indistinct medullary rays. The wood is remarkably starchy.

The root is not an article of commerce.

The ALLAMANDA AUBLETII (*Cathartica*, Linn.), APOCYNEÆ, is said to have been introduced into India from Brazil by the Portuguese. It has become quite naturalized, and in some places has run wild. Though not used in India, it has a medicinal reputation, the leaves being considered a valuable cathartic in moderate doses, especially in the cure of painter's colic; in overdoses it is said to be violently emetic and purgative. Ainslie has a short notice of the plant, and mentions its use at Surinam by the Dutch as a cathartic. It is a beautiful climbing shrub, very common in Bombay gardens. The leaves are elliptic, lanceolate, and arranged in fours round the stem on very short petioles. The flowers are large, yellow,

and funnel shaped, and are borne at the ends of the branches. It has no native name, but the gardeners call it peula, which simply means yellow.

CARISSA CORUNDAS, *Linn.*, APOCYNEÆ. *The root. Vernacular*: KARONDA, KARAUNDA (Hind); KARWAND KARINDA (Bomb); KARAMCHA (Beng.); KALAKA (Tam.).

History, Uses, etc.—This very common shrub, called in Sanskrit, karamardaka, is remarkable for its white jasmine-like flowers, which have a powerful odour, and for its purple-black fruit, which, unripe, is so much used by Europeans for preserving. The natives also use the unripe fruit for pickling. It is described in native works on materia medica as astringent, and the ripe fruit as cooling, acid, and useful in bilious conditions.

The root has a reputation as a bitter stomachic, but I have no experience of its use.

Description.—Roots long, brown and scabrous; wood very close grained and tough. The greater part of the bark consists of enormous stony cells, often more than an inch in length, flat, and closely packed together, forming a network round the wood, through the interstices of which the soft parenchyma comes in contact with the cambium layer.

The odour of the root is disagreeable, and the taste acrid and slightly bitter.

The fruit in size, shape, colour, and taste is not unlike a damson.

STRYCHNOS POTATORUM, *Linn. fil.*, LOGANIACEÆ. *The seeds. Vernacular:* NIRMALI (Hind., Beng., Bomb.); TETRAN-KOTTAI (Tam.).

History, Uses, etc.—This seed, in Sanskrit kataka or ambuprasada, has been in use in India from the earliest ages for the purpose of clearing muddy water. It is mentioned by Susruta in his chapter on water. One of the seeds is usually rubbed hard for a short time round the inside of the earthen pot, into which the water is afterwards poured and left to settle; the impurities subside and the water remains clear and tasteless. Medicinally nirmali rubbed down with honey and camphor is applied to the eyes to strengthen the sight and prevent lacrymation, it is also used in ulceration of the cornea and purulent discharge from the conjunctiva (Confer. Chakradatta). Mahometan writers tell us that it is cold and dry and that when applied externally to the abdomen it relieves colic; they also notice its use to strengthen the sight, and as a remedy in snake-bite. The author of the 'Taleef-i-shareefee' recommends it in irritation of the urinary organs and gonorrhœa. He directs four of the seeds to be powdered and mixed with a little curd of milk, to be tied up in a piece of cloth and steeped in water during the night. The infusion is to be taken in the morning. Ainslie says, "The fruit, though when very young it is made into a preserve and eaten, is reckoned, in its mature state, amongst the emetics of the Tamool doctors in Southern India; given in powder in the quantity of about half a teaspoonful." The *clearing nut* has a place in the secondary list of the Pharmacopœia of India, and is there said to be used as a remedy in diabetes on the authority of Kirkpatrick A suggestion is also made that the nut would be of use if supplied to troops marching in the rainy season, when little but muddy water can be procured.

Dr. Pereira (*Pharmaceutical Journal*, 1850, vol. ix., p. 478) suggests that the property of clearing water possessed by these seeds depends upon the albumen and casein which they contain. If the seeds be sliced and digested in water, they yield a thick mucilaginous liquid, which when boiled, yields a coagulum (albumen), and by subsequent addition of acetic acid, it furnishes a further coagulum (casein) (Confer. 'Phar. of India,' p. 146).

Description.—The seed is nearly orbicular button-shaped, about ½ an inch in diameter and ¼ inch thick; round the border is a slightly prominent ridge, which makes the junction of the two portions of albumen constituting the bulk of the seed. At one point a slight irregularity of the ridge marks the situation of the radicle; from this runs a faintly projecting line to the umbelicus, which is central and well marked; a hardly perceptible depression marks the opposite side of the seed. The integuments are yellowish grey and covered with fine silky hairs. The albumen horny but not quite so hard as that of nux vomica. The embryo consists of a club-shaped radicle and two delicate heart-shaped cotyledons. The albumen is tasteless.

Microscopic structure.—The hairs have a similar structure to those of nux vomica, and show the same play of colours with polarized light.

STRYCHNOS COLUBRINA, *Linn.*, LOGANIACEÆ. *The root and wood. Vernacular:* NAGA-MUSADI (Tel.); MODIRA-CONIRAM (Mal.); KUCHILA-LATA (Hind., Beng.); GOAGARI-LAKRI (Bomb.).

History, Uses, etc.—This scandent strychnos is supposed to be the arbor ligni colubrini of Rumphius, who states that it is used in Java as a febrifuge and anthelmintic and also externally in certain skin diseases. Horsfield notices its use in cutaneous affections and to alleviate the pain and swelling from confluent smallpox. Ainslie says that it is the dund-ul-sini of Avicenna; but this I think must be incorrect, as dund is the name given in Arabic works for *Croton tiglium.*

Virey, in his 'Histoire Naturelle des Médicaments,' p. 191, informs us that bois de coulenore in an overdose occasions tremors and vomiting, but mentions at the same time, that in smaller doses it may be considered as a useful vermifuge, and be given also with advantage in obstinate quartan agues. Guibourt considers that *S. colubrina* yields the true lignum colubrinum, or pao de cobra of the Portugnese, but he is unable to decide whether the wood usually found in commerce is produced by this tree or by *S. nux vomica.* (Confer. Guibourt, 'Hist. Nat.' ed 1869, vol. ii., p. 527.) Its claims as an antiperiodic have been examined by Dr. Berdenis Van Berkelow (Schmidt's 'Jahrbucher,' May 24, 1866, and 'Brit. and For. Med. Chir. Rev.,' April, 1867, p. 527.); and after a trial with it in twenty-two cases, quartan and tertian, he reports favourably of its action, and considers that from its cheapness it may advantageously be used as a febrifuge. In Bombay shops, two kinds of lignum colubrinum (goagurree-lakri) are met with; the genuine and least common is the wood of *S. colubrina* the other that of *S. nux vomica*; both are much used by the Hindus on account of their tonic properties in dyspepsia and malarious affections. In the dyspepsia of vegetarians preparations containing strychnia are particularly efficacious. I usually prescribe the extract of nux vomica in half grain doses and find that it has all the virtues of the lignum colubrinum.

Description.—The smaller branches with the bark on, form the goagurree-lakri of the shops. The general structure of the bark resembles that of nux vomica, but it is of a rusty colour, and the small warts upon it instead of being pale are of a bright rusty brown. The pieces of wood vary in size and length, and are much more knotty and crooked than those of nux vomica. The texture of the wood is also closer, harder, and of a deeper colour; when touched with nitric acid it turns of a reddish orange.

Microscopic structure.—The bark is thicker than that of nux vomica, but resembles it in structure, with the exception that the zone of stone-cells is wider and more irregular, and the cells themselves are bright yellow, and larger. (See microscopic structure of nux vomica bark).

PHYLLANTHUS NIRURI, *Linn.*, PHYLLANTHUS URINARIA, *Linn*, EUPHORBIACEÆ. *The plants. Vernacular:*—(P. NIRURI), JARÁMLA (Hind.), BHUI-ÁMLA, (Beng.), BHUI-AUNLA (Bomb.), KIZHKÁY-NELLI (Tam.), P. URINARIA bears the same names with the addition of the adjective *red.*

History, Uses, etc.—These plants are common weeds which appear in the rainy season. The name bhumyámlaki, which occurs in Sanskrit works, is probably applicable to both. Hindu physicians consider *P. niruri* to be deobstruent, diuretic and healing; they prescribe the dried plant in powder or decoction in jaundice. The dose of the powder is about a teaspoonful. Meer Muhammad Husain in his 'Makhzan' tells us that the milky juice of *P. niruri* is a good application to offensive sores and that a poultice of the leaves with salt cures scabby affections of the skin; without salt it may be applied to bruises, etc. From Ainslie we learn that these two plants are the *Herbæ mœroris alba* and *rubra* of Rumphius, and that an infusion of the leaves of *P. niruri* with fenugreek seed is considered a valuable remedy in chronic dysentery; also that the leaves are a good stomachic bitter. In Bombay *P. niruri* is used as a diuretic in gonorrhœa and acidity of the urine.

Description.—*P. niruri*, annual, erect-branched; branches herbaceous, ascending, floriferous; branchlets filiform; leaves elliptic, mucronate, entire, glabrous; male and female flowers in separate axils, male on the lower ones; dehiscence of anthers transverse, glands in the female bifid and trifid; capsule globose, smooth, two seeds in each cell; seeds triangular ('Bombay Flora').

P. urinaria.—Root generally annual, though in some soils bi- and even perennial. Stem erect, striated, of a pale reddish colour. Branches several, ascending, striated from the insertions of the stipules. Leaves scattered, spreading, pinnate, from one to two inches long, flower bearing. Leaflets alternate, linear, oblong, entire, smooth, three-fourths of an inch long, and one-fourth broad. Petioles compressed, somewhat triangular. Stipules of the petioles three-fold, acute, membranaceous; those of the leaflets two, lateral. Male flowers, exterior leaflets axillary, two to three, subsessile. Calyx, nectary and stamens as in *P. niruri.* Female flowers, lower leaflet axillary, solitary, sessile. Calyx and nectary as in the male. Capsule scabrous, three-celled, six-valved. Seeds two in each cell, transversely striated on the outside. It is immediately distinguished from *P. niruri* by its sessile flowers and scabrous capsules (Roxb.).

(*To be continued*).

THE DIGESTIVE FERMENT OF CARICA PAPAYA.*

BY A. WURTZ AND E. BOUCHUT.

The analyses of Vauquelin and the observations of Cossigny, Bajon, Endlicher, Peckholt, Roy, and Moncorvo, concerning the digestive action of the juice of the papaya, induced one of the authors to obtain some of this product from America, and submit it to a number of experiments which have been carried out during two years in the Hôpital des Enfants Malades. These have been recently completed from a chemical point of view in the laboratory of the Faculty of Medicine.

The liquid juice which flows from incisions made in the tree is neutral and milky. It coagulates immediately and separates into two parts, a kind of insoluble or slightly soluble pulp, and a colourless and limpid serum.

Juice which had been sent to the authors had undergone alteration which was manifested by a putrid odour. In this the butyric ferment was discovered. In order to protect the juice from this change some was sent mixed with sugared water or glycerine and aromatized with some drops of oil of peppermint. In this state it appeared as a thick milky liquid, without any odour suggesting fermentation. Put into contact with raw meat, fibrin, boiled white of egg or gluten it attacked and softened them after a few minutes, and eventually dissolved them after a digestion of some hours at 40° C. Milk is coagulated at first and the precipitated casein is afterwards dissolved. The false membranes of croup, removed by tracheotomy, and worms, such as ascarides and tæniæ, are attacked and digested in a few hours. Without doubt this juice contains a digestive ferment analogous to that which is secreted by the carnivorous plants, *Nepenthes*, *Drosera*, and *Darlingtonia*, to which Messrs. Darwin and Hooker have called attention. It is known that Messrs. Gorup-Besanez and Will have separated from this juice a kind of vegetable pepsin.

The following is a description of the experiments made to recognize the nature and mode of action of the digestive ferment which exists in the *Carica Papaya*, and which appears to be more active than that secreted by the above-mentioned plants:—

(1). The milky liquid described above was thrown upon a filter and the gelatinous precipitate washed several times with distilled water. The solution, with the wash waters added to it, was reduced to a small volume in a vacuum, then mixed with ten times its volume of absolute alcohol. A white precipitate was formed which was left in contact with the alcohol during twenty-four hours, then collected on a filter and dried in a vacuum. There was thus obtained a white amorphous matter that was entirely and easily soluble in water. The aqueous solution was again precipitated with alcohol, and the new precipitate, washed with absolute alcohol, was dried in a vacuum. In this state, the product obtained appeared under the form of a white amorphous powder, completely soluble in water, a property that indicates the absence of vegetable albumen, coagulable by alcohol.

According to a preliminary analysis, this body, which is a ferment, contains 10·6 per cent. of nitrogen. Its concentrated aqueous solution possesses a slightly astringent taste, becomes slightly turbid upon boiling, gives with alcohol an abundant precipitate and is precipitated by nitric acid, an excess of which dissolves the precipitate, forming a yellow liquid. Acetate of lead and tannin form with it abundant precipitates.

0·1 gram of ferment, precipitated once by alcohol, was dissolved in 50 c.c. of distilled water, and the neutral solution digested at 40° C. with 10 grams of moist fibrin. At the end of ten hours the fibrin was dissolved except a residue weighing 1·5 gram in the moist state.

0·1 gram of ferment precipitated once by alcohol, was dissolved in 50 c.c. of water, and the solution, rendered slightly alkaline by caustic potash, was digested at 40° C. with 10 grams of moist fibrin. At the end of ten hours the fibrin was dissolved, except a residue of dyspeptone. The filtered liquid, slightly alkaline, gave a precipitate with acetic acid; it was also precipitated by nitric acid and became turbid upon boiling. The conversion into peptone was not complete.

0·15 gram of ferment, precipitated once by alcohol, was added to 10 grams of moist fibrin reduced to a thick jelly with 75 c.c. of water acidulated by $\frac{2}{1000}$ of hydrochloric acid. This jelly, heated in a stove to 40° C., liquefied in a quarter of an hour. At the end of two hours the whole was reduced to a turbid liquid. The finely divided precipitate remained in suspension in the liquor and presented the appearance of dyspeptone of fibrin. Its weight was 1·8 gram in the moist state and 0·48 gram when dry. The filtered liquid gave a precipitate with nitric acid.

0·1 gram of ferment, precipitated twice by alcohol, was added to 20 grams of moist fibrin and 150 c.c. of water and the whole heated in a stove to 40° C. during twenty-four hours. At the end of that time the fibrin was dissolved, except a residue weighing 2·5 grams in the moist state. The digestion was not prolonged because the liquor manifested signs of putrefaction. The filtered solution was coagulable by heat and precipitable by nitric acid.

In this experiment, made with a neutral liquid, as in that which was made with one slightly alkaline, the fibrin dissolved without swelling. The flocks at first softened, preserving their form and volume, and were disintegrated by dissolving; there remained a residue of dyspeptone.

It results from the preceding experiments that the nitrogenous matter precipitable by alcohol from the aqueous juice of the papaya possesses the property of dissolving large quantities of fibrin, and is distinguished from pepsine by the character that it dissolves fibrin, not only in the presence of a small quantity of acid, but even in a neutral or slightly alkaline medium. This ferment the authors designate under the name of "papaïne."

(2). The carefully washed pulp from which the aqueous liquid containing the papaïne had been separated was submitted to long washings with distilled water. These wash waters, having been evaporated in a stove at 40° C. and reduced to a small volume, gave with alcohol a precipitate that dissolved fibrin under the same conditions as the papaïne precipitated directly from the aqueous juice. This experience gave rise to the thought that the soluble ferment might have its origin in the action of water upon the pulp, which itself has very decided digestive properties, and which possesses, even after long washing, a slightly acid reaction. However, this point is reserved, for the pulp to which it refers is difficult to wash and only yields to water very slowly the soluble ferment it retains. It is besides very aqueous: 54 grams of this pulp left upon evaporation only 2·5 grams of a solid residue having a gummy appearance.

20 grams of this pulp, well washed with water and containing 0·9 gram of dry substance, were put to digest, at 40° C., with 56 grams of moist fibrin and 200 c.c. of water. The digestion was prolonged during forty-eight hours, some drops of prussic acid being added to prevent putrefaction. The fibrin was completely dissolved: the weight of insoluble residue was inferior to that of the pulp introduced.

10 grams of well washed pulp (leaving after drying 0·43 gram of solid matter) were digested at 40° C. with 17 grams of moist fibrin and 50 c.c. of water, with the addition of one drop of hydrocyanic acid. The whole was dissolved at the end of twenty hours, save a residue weighing 3 grams in the moist state, or 0·71 gram after desiccation. The filtered liquid gave no precipitate with nitric acid.

In these last experiments there was not only solution of the fibrin but transformation into peptone, *i.e.*, complete digestion. The filtered liquid, having been con-

* Read before the French Academy of Sciences, Aug. 25, 1879 (*Comptes Rendus*, vol. lxxxix., p. 425).

centrated in a stove, gave with alcohol an abundant precipitate, which collected at the bottom of the vessel in clots of gummy appearance and presenting all the characters of peptone of fibrin. It was entirely dissolved in water, and the aqueous solution was not coagulated by heat; it gave no precipitate either with nitric acid or with ferrocyanide of potassium added to acetic acid. Heated with an excess of nitric acid, it gave a yellow liquor (xanthoproteic acid). With acetate of lead it gave a slight turbidity, with tannin an abundant precipitate. Diluted with water it gave with picric acid a yellow precipitate soluble in an excess of peptone and in a great excess of water or picric acid. This is, according to M. Henninger, a very delicate reaction of fibrin peptone.

The alcoholic liquors from which the papaïne had been precipitated were distilled *in vacuo* at a low temperature and put into contact with fibiin and water. The fibrin was not dissolved; the ferment had been entirely precipitated by the alcohol.

It results from these experiments that *Carica Papaya* contains an energetic digestive ferment that can be easily isolated.

THE ACTION OF HEAT IN VACUO ON METALS.*

BY T. A. EDISON.

In the course of my experiments on electric lighting I have developed some striking phenomena arising from the heating of metals by flames and by the electric current, especially wires of platinum, and platinum alloyed with iridium. These experiments are in progress.

The first fact observed was that platinum lost weight when heated in a flame of hydrogen, that the metal coloured the flame green, and that these two results continued until the whole of the platinum in contact with the flame had disappeared. A platinum wire four-thousandths of a inch in diameter, and weighing 306 mgrms., was bunched together and suspended in a hydrogen flame. It lost weight at the rate of a fraction less than 1 mgrm. per hour as long as it was suspended in the flame. When a platinum wire is stretched between two clamping posts, and arranged to pass through a hydrogen flame, it is coloured a light green; but when the temperature of the wire is raised above that of the flame, by passing a current through it, the flame is coloured a deep green. To ascertain the diminution in the weight of a platinum wire when heated by the electric current, I placed between two clamping posts a wire five-thousandths of an inch in diameter, and weighing 266 mgrms. This wire, after it was brought to incandescence for twenty minutes by the current, lost 1 mgrm. The same wire was then raised to incandescence; for twenty minutes it gave a loss of 3 mgrms. Afterwards it was kept incandescent for one hour and ten minutes, at which time it weighed 258 mgrms.—a total loss of 8 mgrms. Another wire, weighing 343 mgrms., was kept moderately incandescent for nine consecutive hours, after which it weighed 301 mgrms., showing a total loss of 42 mgrms. A platinum wire twenty-thousandths of an inch in diameter was wound in the form of a spiral one-eighth of an inch in diameter and one-half an inch in length. The two ends of the spiral were secured to clamping posts, and the whole apparatus was covered with a glass shade 2½ inches in diameter and 3 inches high. Upon bringing the spiral to incandescence for twenty minutes that part of the globe in line with the sides of the spiral became slightly darkened; in five hours the deposit became so thick that the incandescent spiral could not be seen through the deposit. This film, which was most perfect, consisted of platinum, and I have no doubt but that large plates of glass might be coated economically by placing them on each side of a large sheet of platinum, kept incandescent by the electric current. This loss in weight, together with the deposit upon the glass, presented a very serious obstacle to the use of metallic wires for giving light by incandescence, but this was easily surmounted after the cause was ascertained. I coated the wire forming the spiral with the oxide of magnesium, by dusting upon it finely powdered acetate of magnesium: while incandescent the salt was decomposed by the heat, and there remained a strongly adherent coating of the oxide. This spiral so coated was covered with a glass shade, and brought to incandescence for several minutes; but instead of a deposit of platinum upon the glass, there was a deposit of the oxide of magnesia. From this and other experiments I became convinced that this effect was due to the washing action of the air upon the spiral; that the loss of weight in and the coloration of the hydrogen flame were also due to the wearing away of the surface of the platinum by the attrition produced by the impact of the stream of gases upon the highly incandescent surface, and not to volatilization, as commonly understood; and I venture to say, although I have not tried the expeiiment, that metallic sodium cannot be volatilized in high vacua by the heat derived from incandescent platinum; any effect that may be produced will be due to the washing actiou of the residual air. After the experiment last described I placed the spiral of platinum in the receiver of a common air-pump, and arranged it in such a manner that the current could pass through it, while the receiver was exhausted. At a pressure of 2 millimetres the spiral was kept at incandescence for two hours before the deposit was sufficient to become visible. In another experiment, at a higher exhaustion, it required five hours befoie a deposit became visible. In a sealed glass bulb, exhausted by a Sprengel pump to a point where a quarter of an inch spark from an induction-coil would not pass between points 1 millimetre apart, was placed a spiral, the connecting wires passing through the glass. This spiral has been kept at the most dazzling incandescence for hours without the slightest deposit becoming visible.

I will now describe other and far more important phenomena observed in my experiments. If a short length of platinum wire one-thousandth of a inch in diameter be held in the flame of a Bunsen burner, at some part it will fuse, and a piece of the wire will be bent at an angle by the action of the globule of melted platinum; in some cases there are several globules formed simultaneously, and the wire assumes a zigzag shape. With a wire four-thousandths of an inch in diameter this effect does not take place, as the temperature cannot be raised to equal that of the smaller wire, owing to the increased radiating surface and mass. After heating, if the wire be examined under a microscope, that part of the surface which has been incandescent will be found covered with innumerable cracks. If the wire be placed between clamping posts, and heated to incandescence for twenty minutes, by the passage of an electric current, the cracks will be so enlarged as to be seen with the naked eye; the wire, under the microscope, presents a shrunken appearance, and is full of deep cracks. If the current is continued for several hours these effects will so increase that the wire will fall to peices. This disintegration has been noticed in platina long subjected to the action of a flame by Prof. John W. Draper. The failure of the process of lighting invented by the French chemist, Tessie du Motay, who raised sheets of platinum to incandescence by introducing them into a hydrogen flame, was due to the rapid disintegration of the metal. I have ascertained the cause of this phenomenon, and have succeeded in eliminating that which produces it, and in doing so have produced a metal in a state hitherto unknown, and which is absolutely stable at a temperature where nearly all substances melt or are consumed; a metal which, although originally soft and pliable, becomes as homogeneous as glass and as rigid as steel. When wound in the form of a spiral it is as springy and elastic when at the most dazzling incandescence as when cold, and cannot be annealed by any process now commonly known, for the

* Paper read before the American Association for the Advancement of Science; Saratoga Meeting.

cause of this shrinking and cracking of the wire is due entirely to the expansion of the air in the mechanical and physical pores of the platinum, and the contraction upon the escape of the air. Platinum as sold in commerce may be compared to sandstone, in which the whole is made of a great number of particles with many air spaces. The sandstone upon melting becomes homogeneous and no air spaces exist.

With platinum or any metal the air spaces may be eliminated and the metal made homogeneous by a very simple process. This process I will now describe. I had made a large number of platinum spirals, all of the same size and from the same quality of wire; each spiral presented to the air a radiating surface of three-sixteenths of an inch; five of these were brought by the electric current up to the melting-point, the light was measured by a photometer, and the average light was equal to four standard candles for each spiral just at the melting-point. One of the same kind of spirals was placed in the receiver of an air-pump, and the air exhausted to 2 millimetres; a weak current was then passed through the wire, to slightly warm it for the purpose of assisting the passage of the air from the pores of the metal into the vacuum. The temperature of the wire was gradually augmented, at intervals of ten minutes, until it became red. The object of slowly increasing the temperature was to allow the air to pass out gradually and not explosively. Afterward the current was increased at intervals of fifteen minutes. Before each increase in the current the wire was allowed to cool, and the contraction and expansion at these high temperatures caused the wire to weld together at the points previously containing air. In one hour and forty minutes this spiral had reached such a temperature without melting that it was giving a light of twenty-five standard candles, whereas it would undoubtedly have melted before it gave a light of five candles had it not been put through the above process. Several more spirals were afterwards tried, with the same result. One spiral, which had been brought to these high temperatures more slowly, gave a light equal to thirty standard candles. In the open air this spiral gave nearly the same light, although it required more current to keep it at the same temperature. Upon examination of these spirals, which had passed through the vacuum process, by the aid of a microscope, no cracks were visible; the wire had become as white as silver, and had a polish which could not be given it by any other means. The wire had a less diameter than before treatment, and it was exceedingly difficult to melt in the oxy-hydrogen flame. As compared with untreated platinum, it was found that it was as hard as the steel wire used in pianos, and that it could not be annealed at any temperature.

My experiments with many metals treated by this process have proved to my satisfaction, and I have no hesitation in stating that what is known as annealing of metals to make them soft and pliable is nothing more than the cracking of the metal. In every case where a hard drawn wire had been annealed a powerful microscope revealed myriads of cracks in the metal. Since the experiments of which I have just spoken I have, by the aid of Sprengel mercury pumps, produced higher exhaustion, and have, by consuming five hours in excluding the air from the wire and intermitting the current a great number of times, succeeded in obtaining a light of eight standard candles from a spiral of wire with a total radiating surface of 1-32nd of an inch, or a surface about equal to one grain of buckwheat. With spirals of this small size which have not passed through the process, the average amount of light given out before melting is less that one standard candle. Thus I am enabled, by the increased capacity of platinum, to withstand high temperatures, to employ small radiating surfaces, and thus reduce the energy required for candle light. I can now obtain eight separate jets, each giving out an absolutely steady light, and each equal to sixteen standard candles, or a total of 128 candles, by the expenditure of 30,000 foot-pounds of energy, or less than one horse-power. As a matter of curiosity I have made spirals of other metals, and excluded the air from them in the manner stated. Common iron wire may be made to give a light greater than platinum not heated. The iron becomes as hard as steel, and just as elastic. Nickel is far more refractory than iron. Steel wire used in pianos becomes decarbonized, but remains hard, and becomes the colour of silver. Aluminium melts only at a white heat.

In conclusion, it may be interesting to state that the melting-point of many oxides is dependent on the manner of applying the heat; for instance, pure oxide of zirconium does not fuse in the flame of the oxy-hydrogen blow-pipe, while it melts like wax and conducts electricity when on an incandescent platinum spiral which is at a far lower temperature; on the other hand oxide of aluminum easily melts in the oxy-hydrogen flame, while it only vitrifies on the platinum spiral.

PILL COATING.*

BY ROBERT H. DIMOCK.

Pills without coat are, when freshly made, undoubtedly most active, but if kept for any length of time, grow hard and more or less insoluble. Mr. H. M. Wilder's recommendation to keep them in mass and make them as required (as in the case of blue mass, and directed by the British Pharmacopœia) is a good suggestion, but some inconveniences are connected with it which interfere with its general adoption. Inclosing or coating the mass, when freshly made in the form in which the pills are to be taken, and thus preventing drying and hardening, is an improvement; and when we not only preserve the pills from deterioration through atmospheric influences, but also improve the appearance and conceal the taste, it would seem as though we had reached perfection. Still, there remains an opportunity for experiment to fill a want felt at the prescription counter; we need a coating which can be applied to the fresh pill as soon as formed, and which will dry sufficiently in a few minutes to permit the pill being placed in a box. I hope to supply that need, in this paper, and think the process will enable any pharmacist to coat all the pills he dispenses with a permanent soluble coating.

Sugar, as a coating, is very beautiful in appearance, and pills so coated are fairly active, when well made; but the use of sugar-coated pills compels the druggist to depend upon the wholesale manufacturer, as with no means or machines can he coat, on a small scale, pills with sugar to compare in appearance with those in the market. The necessity for drying the pills, to prevent the discoloration of the sugar and allow perfect adherence of coating, and the time required to bake on the coating, removes sugar, when used alone, from those materials which may be employed at the prescription counter with economy of time.

It seems hardly necessary to speak of resinous coatings, as apart from the insolubility of the resin the same dry, hard pill is needed as in the case of sugar. Dipping in gum, or sugar solution, and then rolling in either powdered starch, slippery elm, French chalk, etc., fails to produce a coating which I would take much pride in; the pill dries slowly, and when dispensed in an excess of powder without drying, complaints are raised that the coating adheres to the fingers or to the patient's mouth, and that the pill tastes very bad. When thoroughly dry, I find these coatings very insoluble, more so than at first I would have thought possible.

A mass for coating, composed of flaxseed, Irish moss and sugar (as recommended in the *Druggists' Circular*) was tried, but was found to harden slowly and to mould easily, but to be very soluble. Gelatin has given me

* From the *American Journal of Pharmacy*, September, 1879.

the best satisfaction, and more closely approaches, I think, what we want in a quick yet efficient coating, as pills can be coated while soft, the coating hardens quickly, is elegant in appearance and does not require much skill in applying. Among the disadvantages in its use should be mentioned insolubility of coating, if the gelatin has not been carefully selected; moulding, if the coating is too thick; stickiness of coating, from carelessness about concentration of solution; the time required and the trouble in handling the pills on needles; inability to keep the mass ready for use, owing to decomposition, and the injury caused by successive heatings.

Moulding of the gelatin, both in solution and on the pill, will be, to a certain extent, remedied by the addition of 10 grains salicylic acid in solution with 8 grains borax to 1 ounce gelatin and ½ ounce water. If the water-bath is made properly shallow, time will be saved in melting; but the injury caused by heating the mass many times can only be obviated, I think, by using the solution described below. The time occupied in the hardening of the coat sufficiently for placing the pills in a box is not under fifteen minutes in the most favourable dry and cool weather, while in mine it will average ten minutes.

Of the different kinds of coatings having gelatins for their base, Garod's consists of gelatin, 5 oz; gum arabic, 3 oz.; sugar, 2 oz.; water, q. s.; it does not harden as quickly as gelatin alone, and has not as bright and fine an appearance, but is very soluble. It has probably been suggested by the composition used for capsules.

The coating most satisfactory to me, perhaps because originating with me, is made as follows:—

Take of—

Gelatin	ʒvj
Acid Acetic, No. 8	f℥i ʒvj
Spirit of Nitrous Ether	f℥j
Granulated Gum Arabic	ʒj
Oil of Gaultheria	♏v
