Your certificate refers to tartrate of lime and sulphate of barium only. How did you ascertain there was any cream of tartar in the drug you analysed if you did not try to find out what was properly present?—Because upon ignition I could see it was a tartrate; we are not supposed to search all through the organic acids in an analysis of this description.

But how did you know it was cream of tartar at all?—From its appearance and flavour.

I want to know how you knew it was cream of tartar?—I think I have said I found it was a soluble tartrate.

That is not sufficient.—I knew by its flavour that it was acid tartrate of potash.

Did you judge solely by flavour what it was?—You have a chemist there, and——

Answer my question if you please.—I tested for acid and found that it was acid to test paper.

Then you consider that was enough to prove the presence of cream of tartar?—That and other tests.

What other tests? Tell me how you ascertained it was cream of tartar at all?—There were no special tests put directly for cream of tartar.

Then you did not apply any special test for cream of tartar?—There is no test for cream of tartar.

You say you found 6 per cent. of tartrate of lime present?—Yes.

How did you arrive at that result?—By the usual process of analysis.

Give details, please.—The substance was weighed out in the usual way, dissolved in hydrochloric acid, the solution filtered, separated from a trace of barium sulphate, neutralized, precipitated with oxalate of ammonia, filtered, ignited, weighed as oxalate of calcium, the precipitate dissolved and converted into sulphate, and weighed as such, the mean of the two taken.

Now you say you found traces of barium. How did you find that?—In the ordinary way, by decomposition and precipitation with sulphuric acid.

Can you give me details both as to tests and quantities found?—I employed no special test, except that of microscopical examination. I should not like to swear it was barium sulphate.

That is very important, because in your certificate you charge this man with having sold sulphate of barium mixed with his cream of tartar. How did you test for this barium?—Its insolubility in acids and its granular and opaque appearance under the microscope; it was only a very slight trace.

Is that the only substance insoluble in acids which might be present in cream of tartar?—No; but it is the only substance which would pass examination under the microscope as well.

You say in your certificate that neither the lime nor the barium are injurious.—Not in the quantity the sample contains.

Is cream of tartar used as medicine, do you know?—Yes; I do know, but simply from reading in books and so forth. I have no real knowledge on that point.

How is it obtained?—From argol.

What is argol?—Argol is the crude precipitate from wine during fermentation.

What is the chemical name for that precipitate?—It is not a chemical, it is not chemically pure, it is acid tartrate of potash with lime, and sometimes barium; at least, all samples of argol I have ever tested contain some lime.

Where does the tartrate of lime come from that is present in cream of tartar?—I have no knowledge; but I presume it is mixed in to affect fermentation.

Where does the barium come from?—I do not know.

The lime may be in the juice of the grape I suppose?—Not to the extent of the percentage in this sample.

What quantity might be there then?—Well, I should think not more than 1 per cent.

Then how is cream of tartar made from argol?—Commercially, do you mean?

How is cream of tartar made?—Argol is crude cream of tartar: this is cleansed by crystallization. I am not conversant with the process of manufacture.

Let me have it as far as you can.—As far as I can recollect the argol is boiled in water and concentrated, probably filtered, the colouring matter precipitated in some way, and the ordinary process of crystallization brought about by concentration.

Have you tested many samples of cream of tartar?—Yes; perhaps fifteen or sixteen.

Have you met with one that did not contain tartrate of lime?—Certainly not.

Tartrate of lime in variable quantities?—Yes.

Have you ever looked for lime in wine?—I have, and found it there.

How did it come there do you suppose?—It is a common practice with makers of wines to lime them.

Have you ever tested grape juice?—No; but I have sufficient knowledge of such natural products to know that no great quantity of lime could be present in the natural juice of the grape. Might I be allowed to make a statement which will justify me in giving the certificate I have given? I have no means whatever of putting before the bench a justification of my position. I am in a most invidious position, almost that of a public prosecutor, and I do not like to leave the box without making a statement.

Magistrates' Clerk: I think you may make any statement you like.

Mr. Glaisyer: Any statement by the analyst should have been made before his cross-examination.

Mr. Angell: I do not consider I have been giving evidence on behalf of the prosecution.

Mr. Glaisyer: Then please say no more on my behalf, I want nothing further from you.

Chairman of the Bench: You are brought here by the defendant.

Mr. Glaisyer: I want nothing further from him. This case is brought under the 6th section of the Sale of Food and Drugs Act.

Magistrates' Clerk: Under the 4th.

Mr. Glaisyer: Under the 4th I am told, that section states "No person shall, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder, or order or permit any other person to mix, colour, stain, or powder any drug with any ingredient or material so as to affect injuriously the quality or potency of such drug, with intent that the same may be sold in that state, and no person shall sell any such drug so mixed, coloured, stained, or powdered, under the same penalty in each case respectively as in the preceding section for a first and subsequent offence." Therefore you see that the defendant is charged with having sold a certain drug, to wit, cream of tartar, which was mixed with a certain material, to wit, sulphate of barium and tartrate of lime, so as to affect injuriously its potency. I am prepared to prove if necessary that no barium was present, and also that the tartrate of lime found in the sample is an essential constituent of cream of tartar, and that cream of tartar, as such, does necessarily contain uncertain proportions of tartrate of lime—but necessarily some—and the public analyst has stated in his own evidence that no sample of cream of tartar which has been submitted to him has been free from tartrate of lime. The process which he has described as that for the production of cream of tartar is substantially correct. The crystals are deposited from the must of the wine when the aqueous liquid changes to spirituous liquid; that deposit is dissolved in water by boiling, and the scum on this boiling liquid, "the cream" is skimmed off, and that when it is crystallized is cream of tartar, and that cream of tartar contains as a necessary constituent a certain quantity of tartrate of lime varying according to the countries from which it is imported—varying very considerably. The defendant, whom I shall call before you, will state that he purchased the cream of tartar, from which the sample supplied to Superintendent Kellaway was taken, from a most respectable house, indeed one of the leading firms of wholesale druggists in the country—Messrs. Hearon, Squire and Francis. Mr. Squire, who is in attendance here, will tell you that the cream of tartar was imported by his firm, and by them it was simply ground and sent out, and

Professor Attfield, whom I shall call—Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain—analysed a sealed sample of this cream of tartar, and he will tell you that the tartrate of lime which he found in that sample is a natural constituent of all cream of tartar, and further that no traces of barium were present. While I am upon this subject I may say that the public analyst states that the very slight traces of barium which he said were found by him in this sample were wholly innocuous. Upon these facts being proved, I shall ask you to dismiss the case, if you even think now it is necessary for me to go further.

Chairman of the Bench: Have you many witnesses to call?

Mr. Glaisyer: Three.

Chairman of the Bench: I think you had better proceed.

Mr. William Blissett, called, sworn, and examined by Mr. Glaisyer.

You are a chemist residing in this town, I believe?—Yes; I have carried on business here for two years.

You have heard the evidence of Superintendent Kellaway, and it is substantially correct?—Yes.

From whom did you buy this cream of tartar?—From Messrs. Hearon, Squire and Francis, on October 1, last.

Did you sell it in the same state in which you bought it?—I placed it in stock and sold it in precisely the same state in which it reached me.

Have you ever met with cream of tartar that did not contain tartrate of lime?—Never.

Mr. William Squire, called, sworn, and examined by Mr. Glaisyer.

You are a member of the firm of Messrs. Hearon, Squire and Francis, I believe?—Yes.

Of 5, Coleman Street, London?—Yes.

In what state do you buy cream of tartar?—We either import it or buy it on the market. Generally we import it from Bordeaux; it is also imported from other places. We buy very little on the market.

Do you always analyse it when you buy it?—Yes; we invariably subject each parcel to analysis.

Is tartrate of lime invariably present?—Invariably, in greater or smaller proportions.

The certificate of the analyst charges the defendant with having sold cream of tartar containing 6 per cent. of tartrate of lime and a trace of sulphate of barium. The article in question was supplied to the defendant by your firm, I believe?—We supplied Mr. Blissett with the cream of tartar before the bench; this cream of tartar contains 6 per cent. of sulphate of lime, but no trace of barium. I have known cream of tartar to contain as much as 11 or 12 per cent. of tartrate of lime, but I have never sold any containing so large a proportion.

Do you know of your own knowledge that tartrate of lime is always present?—Yes.

Why is it present?—It is one of the natural constituents of the juice of the grape, and it is not in any way added to the cream of tartar as an adulterant. I have never yet seen a sample of cream of tartar without tartrate of lime.

Mr. Dyett: You say you have never seen cream of tartar without tartrate of lime?—I will go further than that, it is utterly impossible to obtain the ordinary cream of tartar without it. You may go to any shop in the kingdom and you will not find one sample of commercial cream of tartar that does not contain some proportion of tartrate of lime.

Professor Attfield, called, sworn, and examined by Mr. Glaisyer.

You are Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain?—I am.

Author of a manual of chemistry?—Yes.

Member of the Council of the Institute of Chemistry?—Yes.

Have you frequently analysed cream of tartar?—Yes; many times for the past twenty-five years.

I have already told the bench what cream of tartar is, but you can no doubt describe it more clearly—please do so?—Cream of tartar is made from tartar. Tartar is the name of a substance deposited naturally from wine. Tartar is contained in the crust of port wine bottles; it is chiefly deposited in the manufacture of the wine. The tartar is a natural constituent of the juice of the grapes from which the wine is made.

Have you examined pure grape juice?—I have examined pure grape juice, pressed by myself from grapes, and I have found lime in that juice; moreover books by standard authors state that tartrate of lime is contained in grape juice. For instance in a book on chemistry by Gmelin, English translation, vol. x. (there are eighteen volumes of this work), page 287, under the head of tartrate of lime appears this sentence.—"Tartrate of lime occurs in many plants, especially in grapes, and mixes with the tartar."

Now please proceed with the process of manufacture for cream of tartar?—Tartar is dissolved in the juice of the grape, but it is deposited as a solid from the wine; that is because it is insoluble in the spirit of the wine produced in the course of fermentation. From that crude tartar cream of tarter is made. The crude tartar is boiled with water and the cream of tartar separates out from the clear hot liquor. That cream of tartar still contains the tartrate of lime of the grape juice. I have analysed hundreds of samples of cream of tartar. They all contain tartrate of lime. Books by standard authors also state that cream of tartar contains tartrate of lime, as for instance in the book already quoted (page 276), it states that the crude tartar contains tartrate of lime, the purified tartar constantly containing tartrate of lime to the amount, according to Vauquelin, of 5 to 7 per cent., sometimes, according to Duflos, even of 16 per cent. Therefore I say that cream of tartar is essentially and naturally a mixture of acid tartrate of potash and tartrate of lime. Pure acid of tartrate of potash is sometimes called cream of tartar, but on the other hand cream of tartar is not necessarily acid tartrate of potash, nor even, according to the British Pharmacopœia, is cream of tartar pure acid tartrate of potash.

Have you examined a sealed sample of the cream of tartar before the bench?—On January 6, last, I received a sealed portion of the cream of tartar in question which I analysed.

With what result?—As regards the presence of tartrate of lime in the cream of tartar I confirm what is stated on the public analyst's certificate.

Magistrates' Clerk: Of course your evidence is not evidence as against the certificate of the borough analyst.

Mr. Glaisyer: I beg your pardon; it is not only equally good, but it is better. It is *vivâ-voce* evidence on an analysis of the same article; it is better than any certificate. Kindly proceed, Professor Attfield.

Professor Attfield: As regards the presence of tartrate of lime I confirm what has been stated by the public analyst. I also confirm him in the proportion, but I differ from him entirely as to the conclusion he draws from the analysis. I say from my knowledge of the subject that the presence of this 6 per cent. of tartrate of lime shows that the article analysed is cream of tartar—pure cream of tartar. As to sulphate of barium I say there is no trace present, and I further say, that having heard the evidence of the public analyst, that his tests do not prove the presence of any trace of sulphate of barium. I tested for the barium——

Magistrates' Clerk: We shall take your evidence for what it is worth of course.

Mr. Glaisyer: Certainly you will, and it is worth a great deal.

Professor Attfield (continuing): I tested for the barium chemically, and also by the microscope, and also by the spectroscope, and I thus proved the entire absence of barium.

Cross-examined by Superintendent Kellaway.

What is the standard book by which you prove the purity of drugs?—There is no book that is a standard for the purity of all drugs.

Do you admit that the Pharmacopœia is an authority? —It is one of the best authorities, but only one of many.

Mr. Angell: May I cross-examine the witness?

Chairman of the Bench: I think you may. You see, Mr. Glaisyer, Mr. Kellaway is only superintendent of the police.

Mr. Glaisyer: I will raise no objection, but really the prosecution should have instructed a competent advocate to conduct their case.

Mr. Angell: In the characters and tests for the purity of cream of tartar given in the British Pharmacopœia, there occurs this paragraph, "And when neutralized by ammonia is rendered slightly turbid by oxalic acid"?—That statement does occur in the British Pharmacopœia.

Does not a slight turbidity indicate a slight contamination with lime?—That depends on the quantity you employ, and what you understand by the word "slight."

What would you understand on reading this paragraph by "slight turbidity"?—As a chemist, from that I can only infer that lime is an admitted constituent of cream of tartar.

I want your opinion, and value it very much, on this point, as to whether on reading "slight turbidity" in the British Pharmacopœia, you do not understand that the contamination with lime is also slight, independent of the quantity operated upon. Do you, or do you not, understand that the words "slight turbidity" mean that the contamination is slight?—I read the word "slight" in that paragraph in connection with the quantity taken.

Then the quantity taken is of no importance?—I say that all I am told there is this, that lime in a slight quantity is an officially recognized constituent of cream of tartar.

And do you consider that 6 per cent. of dry tartrate of lime would produce a slight turbidity only?—The test relates to lime and not to tartrate of lime. I repeat that my reading of that test is this only, that lime is a natural constituent of cream of tartar——

I agree with you that lime is a natural constituent in cream of tartar. You are Professor of Practical Chemistry, you have told us, to the Pharmaceutical Society? —I am.

Does not the Pharmaceutical Society issue the British Pharmacopœia?—Certainly not. That Pharmacopœia is written to guide medical men.

I have been misinformed on that point, then. We, as public analysts, want to know where we are to go for our standard, and I am simply trying to substantiate something that may be useful to public analysts. Did you find an insoluble residue when you examined the cream of tartar in question?—Which process do you refer to?

Did you by any process find any insoluble residue?—When boiling it with strong acid there was a very slight residue.

What did you do with that residue?—I examined it by the spectroscope and I found that it was not barium. It was silica. I am of opinion that what the public analyst thought was sulphate of barium was silica.

Did you rely entirely on the spectroscope, then?—No; I relied on chemical evidence and microscopical evidence combined with the spectroscopical evidence.

What was your chemical test which proved to you that it was silica and not barium?—That the residue was soluble in hydrofluoric acid.

That would prove it was silica, undoubtedly. You have told the bench that you found lime in grape juice? —I have.

In natural grape juice?—Yes.

When you expressed the juice from the grapes did you crush the seeds with it?—I did not.

How much lime did you find?—I did not examine it quantitatively.

Was there enough there to weigh?—Yes, but I did not trouble to weigh it; I could have ascertained very easily.

Then it does not by any means prove that in cream of tartar there might be as much as 6 per cent. of tartrate of lime?—It neither proves as much, more or less.

Mr. Glaisyer: The examination of the grape juice was not for the purpose of this particular case?

Professor Attfield: No; it was made months ago.

Mr. Glaisyer: Do the bench think it necessary for me to address them.

Chairman of the Bench: I think not.

The magistrates retired, and after a short interval re-entered the court, when the Chairman said: The magistrates have carefully considered this case and have decided to dismiss the summons, but without costs.

Mr. Glaisyer: I really must appeal to you to reconsider your decision as to costs, and I submit there are several reasons for doing so. In the first place, the charge against the defendant has not been maintained, but is proved to have been utterly groundless and frivolous. Again, this is the second time he has been brought before you within the last eighteen months on a frivolous charge which the prosecution could not maintain. The defence in these cases involves a heavy expense, which under the circumstances should be borne by the prosecution, and I may remark that the costs would not have to be paid by Superintendent Kellaway, but would be paid by the county fund. And yet again, the same question has quite lately been tried in your county, and the summons was then dismissed, in a case where the drug contained still more tartrate of lime than is found in the present instance, and since that decision the prosecution has had ample time to retire from the present proceedings. Under all these circumstances I must press for some costs to be awarded.

Chairman of the Bench: We have fully considered the matter and cannot alter our decision.

Alum in Norfolk Baking Powder.—The Conviction Quashed with Costs.

At the Cambridge Quarter Sessions, January 9 (before the Recorder, J. R. Bulwer, Esq., Q.C., M.P.), the appeal of G. and E. Warren, grocers, Cambridge, *v.* Henry Phillips, inspector of provisions for the borough, came on for hearing. It was an appeal against a decision of the magistrates who, on November 20, convicted the Messrs Warren of selling a certain article of food, to wit, baking powder, which contained a certain ingredient, to wit, alum, the same being injurious to health. The penalty imposed by the justices was a fine of 40*s.* and costs.

The appellants were represented by Mr. T. C. Blofeld and Mr. Horace Browne; Mr. Cockerell and Mr. Turner appeared for the respondent.

The notices of appeal, the sale of the powder in question, and the fact that it contained alum were all admitted, and

Mr. Cockerell at once proceeded to open the case for the respondent. He said that the proceedings before the magistrates were taken under the 3rd section of the Sale of Food and Drugs Act, 1875, for selling an article of food, namely, baking powder, mixed with an ingredient that rendered it injurious to health. The interpretation clause described "food" as every article used for food or drink by man other than drugs or water. In a case recently heard at Malton a question arose upon the words "injurious to health" under the Public Health Act, 1875, with respect to certain nuisances caused by manure works there, and it was held that it was unnecessary to make out that the said nuisances were injurious to the health of everybody, but sufficient to show that the alleged nuisance was injurious to the health of children or invalids. The case referred to was that of the Malton Local Board against the Malton Manure Company. The facts under which the conviction in the baking powder case took place were these:—Some proceedings having been taken against a baker for the adulteration of certain buns sold by him, and it being alleged by him in defence or mitigation that the adulteration was caused by the use of this Norfolk baking powder, it was thought desirable and necessary to test the validity of the sale of that powder by having an analysis made of it as sold by the dealers in Cambridge, and that analysis led to these proceedings being taken; the real defendants then and the real appellants now were the manfacturers of this powder, Messrs. Smith and Sons, of Norwich. A quantity of the powder was purchased, and it was put before the public analyst, whose certificate he handed in to the Recorder.

Mr. Blofeld said the appellants would not dispute the analysis being approximately correct, but he would hand up to the Recorder the actual analysis. There was only one thing omitted. Learned counsel then handed up the analysis to the Recorder, observing that he did not wish it to be made public.

Mr. Cockerell said, speaking roughly the quantity of alum contained in the powder was about one-third of the whole, and the question for the Recorder to decide was whether that quantity made the powder injurious to health.

The Recorder pointed out that in one of the analyses the alum was described as crystallized potash alum, and in the other as burnt alum.

The Recorder said the conviction set forth that the appellants, "did sell a certain article of food, to wit, baking powder, mixed with a certain ingredient, to wit, alum, so as to render such article injurious to health." Therefore they had first to ascertain what was the food that was mixed with the alum? The charge was "food, to wit, baking powder, mixed with a certain ingredient, to wit, alum." Therefore the "article of food" was the baking powder.

Mr. Cockerell: That is my contention.

The Recorder: But the baking powder, from the analysis you have handed to me, is not complete without the alum. The alum is a part of the baking powder. First of all before you get the thing that is mixed you must get the food.

Mr. Cockerell: The food is the baking powder. I say alum is no part of the baking powder necessarily. Baking powder ought to contain no alum.

The Recorder: But you have got the powder that the man sells.

Mr. Cockerell: It is sold as baking powder.

The Recorder: What of that? Suppose for argument that I sell chalk and arsenic mixed together and advertise it as baking powder, is it to be said that I adulterate an "article of food," chalk by the arsenic, or the arsenic by the chalk? Let us go by steps. Where is your article of food that is adulterated? The article of food becomes extinct by the adulteration. Where is your article of food without the alum? Bicarbonate of soda and other matters. Is bicarbonate of soda an article of food?

Mr. Cockerell: I say that baking powder is an article of food, commonly sold by these people and by various others; but alum is not a necessary part of that powder, which ought not to contain any.

The Recorder: Is there anything known as baking powder?

Mr. Cockerell: Oh, yes.

The Recorder: If you will give me evidence of that I will be glad. I never heard of baking powder beyond what chemists advertise as such, any more than I know of aperient draughts which may contain no one knows what. Is there such a thing known as baking powder?

Mr. Cockerell: Yes, known to the public.

The Recorder: I mean as an article of food.

Mr. Cockerell: Of course people do not eat baking powder. Everybody knows what it ought to be.

The Recorder: You can only know what baking powder is by analysing it. Suppose A sells a particular compound and calls it baking powder, which is to produce certain effects if used in cookery; B makes up a certain other mixture and calls that baking powder; while C, D, and so on, proceed in like manner. They are all called baking powder.

Mr. Cockerell asked if the word "mix" did not bring the baking powder under the section.

The Recorder: The Act says "No person shall mix any article of food." You must first of all get your food.

Mr. Cockerell: I say the alum ought not to be there, and that the powder is mixed improperly.

The Recorder: Then you are driven to the other alternative, that the bicarbonate of soda and the rest of the ingredients are an article of food.

Mr. Cockerell: When compounded as baking powder.

The Recorder: Suppose I go to a druggist's shop and ask for an aperient draught, and it is composed of rhubarb and magnesia. Is the chemist to be convicted for adulterating rhubarb with magnesia, or magnesia with rhubarb?

Mr. Cockerell: You get what you want.

The Recorder: No, I do not; I ask for an aperient draught.

Mr. Cockerell: Suppose you went and asked for a particular drug?

The Recorder: If the inspector had gone and asked for bicarbonate of soda, and they had given him the soda mingled with crystallized potash alum, there would have been a case directly.

Mr. Cockerell said the effect of the learned Recorder's construction of the Act would make it inoperative altogether.

The Recorder: No, if a baker chooses to mix some noxious compound,—mind I do not say this is,—with his bread and sells it he is liable. I am only calling attention to the matter just to have my mind clear upon it.

Mr. Cockerell said no question of this kind had ever been raised. We treat baking powder as an article of food.

The Recorder: Then I shall want you to tell me what baking powder is.

Mr. Cockerell: My medical witness will tell you what this particular baking powder is, and what baking powder ought to be without alum, but that is put in because it is cheaper. It is admitted that the powder is to be put into articles of food.

In the course of further argument the Recorder said even if the powder became injurious to health when put into food it was not an article of food.

Mr. Cockerell also said that the rice flour was an article of food.

The Recorder: I do not know know what evidence will be given upon it, but I should have thought the rice was only a medium or padding.

Mr. J. W. Knights, public analyst for the borough and county of Cambridge, F.C.S., etc., deposed that he was of opinion that when mixed with the flour the baking powder rendered the gluten of the flour and the soluble phosphate contained in the flour insoluble. When a teaspoonful of the powder was mixed with a pound of flour and water added, it would liberate the carbonic acid gas and render the soluble phosphates contained in the flour insoluble, by forming phosphate of alumina, which is insoluble. It would render the phosphoric acid insoluble. He believed an adult in health required 50 grains of phosphoric acid per day. Phosphoric acid was derived from bread and other articles of consumption; in some cases chiefly from bread. Bread made with this powder, as directed, would give less soluble phosphoric acid than there should be by 7-10ths. 7-10ths of the phosphoric acid would be rendered unavailable and he should presume the bread would be less nutritious. With children the effect would be the same, but to a greater degree. It would impair digestion.

Cross-examined by Mr. Blofeld: As to rendering the phosphoric acid insoluble, what authority have you for stating that a man in health requires 50 grains of phosphoric acid in the twenty-four hours?—I saw it so stated in a medical work. Parkes's 'Treatise on Practical Hygiene.'

Are you aware that the body rejects as much as from 75 to 100 grains of phosphoric acid per day?—A very large quantity.

May I take it that which the body rejects is what the body does not require to assimilate?—Certainly not, but I am not a medical man. When the bicarbonate of soda and alum are mixed with water effervescence takes place and carbonic acid gas is given off. The residuum from the alum is hydrate of alumina, that from the soda is sodic sulphate or sulphate of soda.

So that when the bread is made with this powder there is no alum in it and no bicarbonate of soda; they both cease to exist?—Yes.

By the Recorder: This change takes place when water is added. In the presence of flour the case is somewhat different. The bicarbonate of soda and the alum effervesce in the dough, and there is a residuum from each, but the hydrate would become phosphate.

By Mr. Blofeld: When mixed with the flour and moisture I should say the phosphate of alumina is formed immediately, and not hydrate first, but I cannot say that positively. It is necessary, to change the hydrate of alumina into phosphate, that there should be actual contact between the hydrate and the phosphoric acid in the flour.

How is the little hydrate of alumina there would be in a 1-pound loaf to come into contact with all the grains of phosphoric acid to be found in the dough, so as to form it into phosphate of alumina?—Because it is mixed in a dry state. Phosphate of alumina is perfectly well known to be insoluble in water. I believe phosphate of alumina is not soluble in the gastric juices, but that is a question for a physiologist and not a chemist. It is perfectly insoluble in acetic acid. It is soluble in hydrochloric acid, and the gastric juice is supposed to contain that. I do not believe the gastric juice is practically a weak solution of hydrochloric acid. I have heard that no hydrochloric acid exists in the gastric juice in a free state. I forget where I read that, but it was not in a newspaper. I have no authority for the assertion that the gastric juice is not equivalent to hydrochloric acid. The injurious effect of this baking powder does not depend upon the assertion that phosphate of alumina is insoluble in the stomach.

If it is soluble in the stomach what harm could it do?—It would probably have an astringent effect.

The Recorder: Does a minute quantity of alum in bread make it injurious to health—I have heard that it rather improves it?—I think it is no improvement. However small the quantity there is a corresponding quantity of phosphoric acid rendered insoluble.

By Mr. Blofeld: Cannot cite any case where injury has been done to health by the use of a small quantity of alum.

By the Recorder: Alum is very little prescribed except for use externally and as a gargle.

The Recorder: How long would it take to kill a man if he ate an ordinary quantity of bread daily made with this baking powder?—A man in health and with good digestion would possibly live some time.

The Recorder: He would live for ever? Have you ever heard an instance of anybody having a fit of indigestion from eating bread made with this powder and clearly traceable to it?—No. I have come into contact with no case, but I should judge, from my chemical knowledge, that indigestion would follow. The effect of either hydrate or phosphate of alumina would be to harden the gluten. Baking powder can be made with many other ingredients besides bicarbonate of soda and alum.

As a chemist, in how many ways could you make baking powder?—Four or five ways probably. By combining an alkali with an acid, baking powder is formed. Only three or four ways would be unobjectionable.

There is no such thing as baking powder, is there, beyond the fact that a man fancies the name and gives it to what he makes?—There is no recognized formula for making baking powder.

You might make it as you would make an aperient draught?—Yes; it is not known in the British Pharmacopœia. It is what men choose to call it. It might be termed "Substitute for yeast powder," or "Norfolk dumpling powder."

Mr. Matthew Moncrieff Patteson Muir, prælector of chemistry in Caius College, Cambridge, then gave the effect of an experiment that he had made with a mixture like that contained in the baking powder with phosphate of soda instead of flour, and said he found insoluble phosphate of alumina. He also made an experiment with half a pound of flour free from alum, treated it with water, and found the water contained a large quantity of phosphoric acid. He also mixed half a teaspoonful of the baking powder with half a pound of flour, treated it as before, and found the water contained very small quantities of phosphoric acid. Witness was about to give the result of experiments made with bread in which was mixed the Norfolk baking powder and bread made with another baking powder, but Mr. Blofeld objected to a comparison between baking powders. Witness then described an experiment he had made with the Norfolk baking powder when made into bread according to directions, and said he found about $1\frac{1}{2}$ grains of soluble phosphoric acid to the pound of flour used in the bread. In an experiment he had made with yeast bread he found about 3 grains of soluble phosphoric acid to the half-pound of flour, or, in round numbers, four times the quantity. He tested the bread with hydrochloric acid of $\frac{2}{10}$ths per cent. strength at a temperature of 100° F., with the results he had given. The reason for taking that particular kind of hydrochloric acid was because that was taken as the average strength of the hydrochloric acid in the gastric juice. He then stated that he composed a mixture like the baking powder prepared, a quantity of gluten from flour, digested it with half a litre of $\frac{2}{10}$ths per cent. strength hydrochloric acid for fifty hours, and found that there was 20 per cent. less of the gluten dissolved than there was in a similar quantity heated without alum, soda, etc. Then he made a further solution with a mixture of dextrine—a modified form of starch which might be taken to represent the starchy matter in flour—with water, and added a solution of alum and a solution of phosphate of soda. The phosphate of alumina which was precipitated carried with it the greater portion of the previously soluble dextrine. In experimenting with a loaf made of the same powder he determined the quantity of phosphate of alumina existing was 25 grains per 4-pound loaf; that was about 5 grains to the $\frac{1}{2}$-pound loaf. Witness then corrected himself, and said he made a mistake in his calculation, he should have said about 3·03 in the $\frac{1}{2}$-pound loaf. From these experiments he should say the effect of this baking powder made into bread was that the alum in powder was wholly decomposed, with the production of phosphate of alumina and sulphate of soda. This phosphate of alumina, he added, rendered the gluten and the dextrine less soft.

By the Recorder: I could form no idea of the effect of a man eating an ordinary quantity of bread for a year made with this baking powder because I have no medical knowledge.

Dr. J. B. Bradbury, Linacre lecturer in physic at St. John's College, F.R.C.P., and one of the physicians at Addenbrooke's Hospital, deposed that from what he had heard from the experiments of the last two witnesses, he should say the effect of the powder used in bread would be to rob the dietary of a certain amount of soluble phosphate which was essentially necessary to nutrition. He agreed with the other witnesses as to the amount of phosphoric acid required for a healthy adult every twenty-four hours, and as to the amount contained in a pound of flour. In answer to the Recorder, the witness said that people suffered from indigestion who did not eat bread. They got their phosphoric acid from meat, milk, etc. Baking powder produced the same effect as aerating the bread, which was done by forcing carbonic acid into the dough by machinery.

Bread made with yeast disagrees with some people. Practically speaking, is there any fault to be found with bread made with this baking powder?—I should say people might partake of it occasionally with impunity, but if they were to eat it constantly, and especially if they were to live upon it, it would have a deleterious effect. It would produce indigestion even in a man who led a regular life.

How long has this baking powder been in use?

Mr. Blofeld: Thirty-nine years, and many millions must have eaten bread, etc., made with it.

Dr. Bradbury: It leaves no record how many people have died. There are many diseases one cannot fathom. Stone is very common in Norfolk, and it is not very easy to fathom the cause of it.

The Recorder: Baking powder does not produce stone, does it?—Indigestion does.

The Recorder: I should have thought the water of Cambridge would have produced more.

Cross-examination continued: A man eating bread made with this baking powder would be the worse for it at the end of five years.

Is bread made with this baking powder anything like so indigestible as new cheese?—New cheese would suit one person who would not suffer at all, while others would suffer.

Your evidence with respect to this baking powder is founded on the assumption that the phosphate of alumina is insoluble in the stomach?—Not altogether, but chiefly.

And if I satisfy you that the phosphates are not insoluble in the stomach your opinion would be altered or modified?—It would.

In answer to questions by the Recorder, witness said that 50 grains of phosphoric acid were excreted by a healthy man in twenty-four hours, and these had to be supplied, and that if a man were deprived of the component parts of the phosphoric acid he would be injured to that extent.

Dr. Paget, Regius Professor of Physic in the University of Cambridge, F.R.S., F.R.C.P., etc., deposed that having heard the evidence of Messrs. Knights and Muir, and assuming that their experiments were correct, the effect of a person in ordinary health eating an ordinary quantity of bread made with this baking powder would be that in the course of time digestion would be impaired. Going on the experiments of Mr. Muir, that it has the effect of rendering less soluble the dextrine and the gluten of the bread, he should certainly be of opinion that it would render them less digestible, and so far injurious to health. In children the effect would be more marked, and with persons who had weak stomachs and were troubled with dyspepsia or feeble digestion it would be positively injurious. Questioned on the amount of phosphoric acid required to be taken into the system by a person in good health every twenty-four hours, the professor stated that to keep a person in health he must take as much of an ingredient, if it were a constituent of the body, as went out of him, and assuming it to be correct that 50 grains of phosphoric acid went out daily, he required to have a like amount introduced.

Mr. Blofeld: Do you imagine that the loss of $2\frac{1}{2}$ grains of phosphoric acid through eating $1\frac{1}{2}$ pound of bread would be injurious to any man's health?—Not if a man got other food. If a man were to get $2\frac{1}{2}$ grains of phosphoric acid less every day than passed out of him it would very soon be a serious matter.

If I neutralize $2\frac{1}{2}$ grains of phosphoric acid which I should otherwise get should I be one whit the worse off than before?—Probably not; probably you take more phosphoric acid every day than is good for you.

Mr. Blofeld: I hope you confine your remarks to phosphoric acid. But take anyone else in this court; would any man eating this bread be sensibly injured?—I hope not, because I should hope everybody gets as much food as would compensate him for the loss of the phosphoric acid he requires. If he gets meat, cheese, eggs, milk and other things in fair quantities the loss of that small amount of phosphoric acid would be of very small moment indeed. The articles I have mentioned contain phosphoric acid, as do fish and cheese in very large quantities, and vegetables in less quantities. At this moment I cannot think of any article of food that does not contain phosphoric acid. My opinion that bread made with this baking powder is injurious is based upon the fact spoken to by Mr. Muir that it renders less soluble the gluten and dextrine of the flour.

The Recorder: Would you say in the words of the Act of Parliament that bread made with this baking powder was an article of food injurious to health?—I would not venture to say it except in the case of persons of weak digestion. We have not sufficient exact experience I think in regard to persons in ordinarily good health to give an opinion on the matter. There is experience of alum in bread being injurious to health.

Is alum always injurious?—Taken repeatedly I should say it would be. I should say if any practical physician were asked if he would allow any person to take even a few grains every day of his life for a time he would not only advise to the contrary, but would say probably it would cause some disorder of the stomach before long. It is scarcely ever prescribed except externally.

Mr. Blofeld then addressed the Court on behalf of the appellants, and called—

Mr. Fras. Sutton, F.C.S., F.C.I., public analyst for Norfolk and other places. He deposed that when the baking powder was mixed with the alum it became hydrate of alumina. He did not believe that in bread made of this baking powder phosphate of alumina was found, and it was a very difficult thing to prove that it was. If it were so formed it was believed that it would be soluble in the gastric juice. Alumina found in bread might neutralize a certain amount of phosphoric acid in the bread; but the fluids of the stomach decomposed that phosphate of alumina, and the result would be that the person would be none the worse for it. He had made two 4-pound loaves, one with yeast and the other with the Norfolk baking powder. The yeast bread on treatment with cold distilled water gave 3·04 grains of phosphoric acid dissolved by the water. The bread made with baking powder gave 2·32 grains, being a difference of 72-100ths of a grain in a 4-pound loaf, or $17\frac{1}{2}$-100ths of a grain in a 1-pound loaf.

It is said that the use of baking powder hardens the gluten and the dextrine?—My opinion is that it has no such effect in bread. I have tried an experiment to see if it did by mixing phosphate of alumina with gluten, but I have made no experiment with dextrine. I do not agree that phosphate of alumina renders the gluten less soluble from the experiments I have made. My experiments was to mix the phosphate with the gluten in a very large excess. In one of the boxes produced I have got gluten without phosphate, and in the other the same quantity of gluten with phosphate added in five times the proportion that would be found in the baking powder, and the condition is not altered in the least.

The Recorder: Have you tested its solubility?—No, I did not think it was fair to make such a test with hydrochloric acid. It is not soluble in water, but it is soluble in the juices of the stomach.

By Mr. Blofeld: Hydrochloric acid has not got the salivary fluids or the pepsine in it. Hydrochloric acid is only one of the ingredients, and is but a feeble reproduction of the gastric juice. It is like the gastric juice, leaving out the most important parts. The salivary fluids are particularly necessary for the digestion of all kinds of food, like bread and so on.

You would not be surprised to find that Mr. Muir's experiments were correct, and yet that if the phosphate got into the gastric juice it would do no harm?—Not at all. I may also say that a very high authority, Mitscherlich, of Berlin, states that compounds of gluten with alumina are perfectly soluble in the juices of the stomach.

Will you tell us the result of the experiment you have recently made with two pigs?—Two healthy pigs, of about five stone weight each, were purchased and placed in a pen with a boarded floor to prevent them getting earth, which contains alumina. For eight clear days they were fed upon bread made with this Norfolk baking powder in proper proportions mixed up with warm water to a very soft, sloppy consistence, so as to give the best chance for the formation of phosphate of alumina. They consumed in the eight days 91 pounds of flour, and at the end of twenty-eight days I went and saw them killed. The pigs had thriven well during that time, and their internal appearances were perfectly healthy. I had the stomach removed and the whole of the bowels, and had them tied up and sent to my laboratory, where I examined them. I opened one stomach where the pigs were killed, and they had the mixture of the powder then in a sloppy condition. I removed separately the contents of the upper portion of the bowels, the second stomach, and also the contents of the lower bowels, or rectum. I took equal portions from the two sets of bowels for each pig, keeping the two uppers separate and the two lowers separate. I then dried down these separate portions of fæces in platinum vessels, and then burned off the organic matter, with the addition of small quantities of nitrate of potash to prevent the reduction of the phosphoric acid; the result would be the ash, in fact, of the fæces, and would contain the whole of the phosphoric acid and other mineral matters present. I then made an analysis of the ash to find the ratio between the alumina and the phosphoric acid. The analysis of the upper bowels showed, phosphoric acid, 7·24 per cent., oxide of iron, 1·08, alumina, 3·68, lime, 0 9, magnesia, 0·4, sulphuric acid, 0·274, the remainder was unconsumed carbon, alkalies, etc. In the case of the lower bowels the proportions were, phosphoric acid, 2·43, oxide of iron, 1·18, alumina, 4·91, lime, 1·13, magnesia, 0·54, sulphuric acid, ·343. On the assumption that the whole of the phosphoric acid is combined with the alumina, the excess of alumina in the upper portion of the bowel was 2·07 per cent., and in the case of the lower bowel 3·15 per cent. But it is an open question whether the whole of the phosphoric acid is combined with the alumina, because the other things present, which are stronger bases, keep it entirely to itself. The inference to be drawn from the experiment is that the gastric juice in the stomach takes all the phosphoric acid it requires, and if the phosphate of alumina is there at all the gastric juices absorb the phosphoric acid out of it if it is required, leaving the hydrate of alumina in the bowel to be rejected with the fæces.

By the Recorder: That experiment is a guide to what goes on in the human stomach, and I look upon it as an analogous case.

By Mr. Cockerell: Is alum in bread injurious?—*Per se*, I do not think it should be allowed, because it opens up a way for fraud. Apart from that, I do not think a little of it used would be injurious. I do not think 40 grains in a 4-pound loaf would be injurious. That is my private opinion; I am not giving a medical opinion on that point. Chloride of alumina would be objectionable in a large quantity.

The Recorder: I suppose you might evolve poisonous things out of a mutton chop?—Oh, yes.

By Mr. Cockerell: Mr. Muir produced his phosphate of alumina in conjunction with the gluten; mine was produced the same way as it would be in the bread. I extracted the gluten from the flour in a pure state. The effect of hardening the gluten in any way would be to make it tough like leather. It is of no use my making experiments that do not go on in the stomach. Those made by Mr. Muir were merely a waste of time and nothing more.

By the Recorder: I do not dispute the accuracy of Mr. Muir's experiments as he made them. My opinion of Mr. Muir's experiments as a chemist is a very high one, and I think he is a very admirable experimenter.

Re-examined: I have used this baking powder for years for all kinds of pastry, cakes, etc.

By the Recorder: I have had no reason to complain of its having given dyspepsia, indigestion, or anything of the kind, nor have my wife or family.

The Recorder asked if there was any need to go further after what this gentleman had said. This was a penal enactment, in which the first offence rendered a person liable to a penalty of £50, and the second to imprisonment, with hard labour, for a period not exceeding six calendar months. Could he be expected to confirm this conviction when a skilled witness like Mr. Sutton (for whose opinion he had the highest esteem) declared upon his oath that there was nothing injurious to health in the use of this baking powder, raising the question even upon the merits, without the question as to whether the case came within the statute?

Mr. Blofeld said he should like to call Dr. Thudicum and Dr. Tidy in fairness to Messrs. Smith and Sons.

The Recorder assented, and

Dr. J. L. W. Thudicum, F.C.P. Lond., F.C.S., and Fellow of several other learned societies, deposed: I have been frequently consulted on these questions by the Government and by Boards of Health.

Mr. Blofeld: You have been present throughout this trial, and, having heard all the evidence that has been given, and the experiments that have been made by Mr. Muir and those of Mr. Sutton, and his experience of this baking powder, is there in it in your opinion anything that is injurious to health?—In my opinion there is nothing injurious in the use of this baking powder.

Assuming that phosphate of alumina is formed in the stomach, would it or would it not be decomposed in the gastric juices in the stomach?—It would be entirely decomposed by the gastric juices in the stomach.

Do you admit that there is phosphate of alumina there?—I merely assume that there is for the purpose of this argument.

Is it your opinion that there is or is not?—It is not proved that there is.

By the Recorder: The decomposition would take place without any extra effort of the gastric juice. The difference it would make by its presence would be inappreciable.

By Mr. Blofeld: The hydrate of alumina in the bottle produced is perfectly harmless.

The Recorder (to Mr. Sutton): How much do you say you produced from a 2-pound loaf?—6 grains.

Dr. Thudicum: That rests upon the evidence of Mr. Sutton, and I coincide with it. It is perfectly harmless.

Mr. Blofeld: Dr. Beverley may have taken 20 grains?—He might.

You have heard a good deal said about the diminution of the phosphoric acid absorbed into the system by the use of this baking powder, will you give us your opinion?—The diminution of phosphoric acid in the human body by the use of this baking powder would be quite inappreciable, and would be of no consequence whatever to the body.

You heard Mr. Sutton give his evidence as to the experiment he made with the two pigs and the conclusion he came to. Do you agree with the conclusions he drew?

—I agree with them, and think they are physiologically stronger than he put them.

The Recorder: You think the experiment was a satisfactory one?—Very so.

Mr. Cockerell, addressing the Recorder, said he took it that he had decided the case, and as he (Mr. Cockerell) did not apprehend he should be able to alter the Recorder's view of the matter it would be absurd for him to take up more time.

The Recorder said it was satisfactory to find that there was not so much difference between the gentlemen on the one side and on the other. No one disputed the accuracy of the experiments made, but upon the one side hydrochloric acid was used, and on the other side it was said by a very able gentleman that this acid was only one of the component parts of the gastric juice, and the experiment he made was strictly analogous to what took place in the human system.

Dr. Charles Meymott Tidy, M.B., F.C.S. (Professor of Chemistry and of Forensic Medicine at the London Hospital, Medical Officer of Health for Islington, and late Deputy-Medical Officer of Health for the City of London, etc.), was next sworn and examined by Mr. Blofeld.

The first question is as to phosphate of alumina being formed. Do you agree that it is formed in bread by the use of this baking powder, or is it an open question or not?—I think it is very improbable that the phosphate of alumina is formed at all, because in order to form phosphate of alumina you must have actual contact between the phosphoric acid and the alumina, and I cannot see how that can be brought about under the ordinary conditions of digestion, and even granting that it occurs—and I do not think it makes the slightest difference in the case—even supposing that it does occur, I know, as a matter of fact, that the phosphate of alumina is soluble in the gastric juices in weak acid solutions, and I know that when phosphate of alumina is in solution of that nature with the membrane between and the alkaline blood on the other side the whole of the phosphoric acid filters through into the blood. I know that as a laboratory experiment, and I know if that occurs as a laboratory experiment it occurs much more rapidly in the living tissue.

Can you see anything in the use of this baking powder which can be injurious to health?—No; most certainly not. I should like to say, in giving my opinion with respect to this powder, that I do not wish to express any opinion about alum in bread as a means of fraud. I conceive alum ought not to be used in large quantities, as it is not on the question of injury to the health, but for the reason that bread holds a larger quantity of water and bakers can use a very inferior quality of flour. I am only giving my opinion of this baking powder and not of the alum in bread-making.

Mr. Cockerell: Nor of the use of alum at all?—I do not give it, but simply as alum leads to fraud.

The Recorder: You think there is nothing injurious in this powder?—No, in the proportions in which it is possible to use it. It might be said, "Couldn't you put in a large quantity of this powder?" but this could not be done, as it would spoil the bread entirely. Therefore, it is utterly impossible, to my mind, that this powder could be used for the purpose of fraud from the point of view from which I put alum forward and from which alum is occasionally used.

Mr. Blofeld said he had Dr. Beverley here, but he did not think, after the evidence that had been given, it was necessary to call him. That was his case.

The Recorder, in giving judgment, said: It is unnecessary for me to express any opinion upon the legal point as to whether this case falls within the Act of Parliament; but if my opinion is worth anything to anybody, I still adhere to the opinion I have already expressed, that it does not come within the Act for reasons some of which I have already given. I decide this case upon its merits and upon the evidence. After the evidence we have just heard I do not think this baking powder is an article of food, or that bread made with it becomes an article of food injurious to health, and, as a matter of fact, I find in favour of the appellants.

Mr. Blofeld: I have to ask for costs.

Mr. Cockerell: I never heard of any costs being given against the magistrates. We come here to uphold the decision of the magistrates.

The Recorder: Who is the respondent?

Mr. Cockerell: Mr. Phillips, the provision inspector.

The Recorder: Who put the law in force?

Mr. Cockerell said proceedings were taken against the sellers of this powder in Cambridge in consequence of a conviction that took place there of a man for selling buns made with this powder. The magistrate threw out a hint that proceedings should be taken against the sellers of the powder.

Mr. Blofeld said the buns in question could not have been made with this baking powder.

The Recorder also said that they could not have found alum in the buns if they were made with this powder.

Mr. Cockerell: They did not say it was alum.

Mr. Blofeld: They did say so, and here is the conviction to prove it. (Conviction handed in.) The persons who started these proceedings were a committee connected with the corporation, and not the magistrates.

The Recorder: I should be loth to make an order for costs, and especially against Mr. Phillips, a public officer put forward by the corporation to look after the health of the town, but if the conviction were sustained I see that the costs Mr. Phillips would have received from Messrs. Warren would have been £10 1*s*. Ordinarily speaking, I should not think of giving costs against the magistrates nor against a public officer, but I should like to know the circumstances under which this prosecution was instituted.

Mr. Cockerell said he had stated the circumstances.

The Recorder: Where will the costs come from?

Mr. Cockerell did not know.

Mr. Horace Browne said they would come out of the corporation. His learned friend, Mr. Cockerell, was being instructed by the Town Clerk.

After further opposition on the part of Mr. Cockerell,

The Recorder said: I do not see why the usual results should not follow upon a successful appeal. I quash the conviction, with costs.

The costs allowed amounted to £100.—*Norwich Argus.*

Review.

THE ART OF PERFUMERY, and the Methods of Obtaining the Odours of Plants; the Growth and General Flower Farm System of Raising Fragrant Herbs; with Instructions for the Manufacture of Perfumes for the Handkerchief, Scented Powders, Odorous Vinegars and Salts, Snuff, Dentrifices, Cosmetics, Perfumed Soap, etc. To which is added an Appendix on Preparing Artificial Fruit Essences, etc. By SEPTIMUS PIESSE, Ph.D., F.C.S. Fourth Edition, rewritten and enlarged. London: Longmans and Co.

The great development of this art within comparatively few years renders it necessary to manufacturers, to chemists and druggists, and others commercially interested in this industry, that from time to time a comprehensive *résumé* of the improvements and discoveries relative thereto should be published in the form of a manual of reference. Such works hitherto published in England have been written in a vein rather too "popular," and although general processes have been briefly described, and the formulæ of many fashionable compounds given, yet both these and the American works by Christiani and Snively fail to give to the manufacturer a summary of all the facts relating to improved processes, the detection of adulterations, the botanical nature and culture of the plants used, and the researches in organic chemistry which have an important bearing on the subject. Undoubtedly such a work would be voluminous, but not more so than those relating to other industries, and if historical chapters (already most ably worked out by another author), quotations from Scripture and from the poets were omitted, there would be more space for extracting, from such useful works as Guibourt, Gerhardt, Gmelin and others, the essence of all that relates to the subject, and in fact, render the book more suitable to practical men than to antiquarians and young ladies. Still, the treatise now under notice is a great improvement over the old editions. It contains additional illustrations and a few useful cultural notes, etc. (mostly reprinted from a series of papers contributed by Mr. Piesse to the *Garden* during the last half of 1877), but improvements in the main processes are unnoticed. To take, for instance, the process of maceration. It is described precisely as in the French edition of 1865, *i.e.*. the employment of a pan suspended *en bain-marie*. No mention is made of Piver's plan of dividing a long macerating tank into about seven compartments, connected by pipes leading from the top of one to the base of the next. In this system a metallic basket containing the vegetable substance to be extracted is suspended in each compartment, a kettle on the left supplies the fat, heated to the proper temperature, which circulates from left to right through the tank, in which a constant temperature of 65° C. is maintained by means of a steam pipe. The basket at the left contains the substance which has passed through all the compartments, it is raised from time to time, filled with fresh substance and then attached to the right, the other baskets being moved to the next compartment to the left. In this way the fresh substance has to traverse each compartment from right to left, while the fat flows slowly from left to right, and, saturated with the perfume of the substance, collects in the tank on the extreme right.* This process enables the operator to effect complete exhaustion of the substance operated upon. (It was described by Turgau in 'Grandes Usines de France,' iv., p. 132.)

Neither is any mention made of Piver's enfluerage process. This consists of two upright chambers fitted with shelves of perforated metal, or trays, upon which the flowers and grease are placed; these two chambers, otherwise air-tight, communicate by a pipe at the base, and a bellows on the top of each chamber, worked by a lever, causes the air to circulate to and fro from one chamber to the other, and the grease absorbs the odour much more rapidly and with less liability to become rancid than by the old method of piling up the frames or *châssis*: this process was, however, described in Mr. Piesse's French edition of 1865. In a few lines Piver's other invention, termed the "pneumatic" process, and Millon's process of extraction by ether are briefly described. Whilst on the subject of processes, why should Mr. Rimmel's "myrogène" be omitted? It at least created some interest at the Paris Exhibition, and now promises to become of great practical value.

Not a word is said of the artificial formation of vanilline by Haarmann from coniferin (patented in 1874) and by Tiemann from oil of cloves (patented in 1876); neither is mention made of the equally interesting papers by Tiemann and Herzfeld on the artificial formation of coumarin.†

Mr. Piesse gives the formulæ of several of the specialities prepared by his firm, such as lignaloe, and opopanax bouquets, but it is remarkable that psidium is overlooked; this is said to be prepared from the flower of the pomegranate, although that flower is odourless. With regard to opopanax, the odour of the gum-resin is compared by eminent writers on drugs to that of bruised ivy leaves, ashweed (*Ægopodium Podagraria*) and garlic,—in Christiani's formula for his bouquet there is no opopanax whatever—either the gum-resin or the oil. The section devoted to soaps, hair-washes, preparations for the skin, etc., contains much valuable information, in fact appears to be the best written portion of the book, which, although it lacks in many points, is superior in some respects to the American works above quoted.

In conclusion we may remark that throughout the book the personal and possessive pronouns recur with unpleasant frequency and keep the name of the author continually in the mind of the reader,—an inelegant fault which a good writer should never be guilty of (except for advertising purposes).

Notes and Queries.

[638]. CLEANING OF PAINTINGS.—H. W. asks the method, mode of application, and the manner in which peroxide of hydrogen acts in cleaning oil paintings.

The picture had better first be sponged with cold water and allowed to dry, then apply the solution of peroxide of hydrogen with a clean sponge in successive lines, not going over the same surface twice, and again allow to dry. If the solution is sufficiently strong the painting is now tolerably clean; if not, a second or third application is necessary.

Peroxide of hydrogen (hydroxyl or hydrogen di-oxide (H_2O_2)), owing to the readiness to part with half its combining weight of oxygen, is a powerful bleaching agent; but the way in which it serves to clean oil paintings is accounted for thus:—Sulphuretted hydrogen, which is present in the atmosphere, especially in the neighbourhood of towns, attacks the lead in the paint and forms lead sulphide, which is readily soluble in peroxide of hydrogen, water and lead sulphate being the result.

$$PbS + 4H_2O_2 = PbSO_4 + 4H_2O_4$$

J. T. C. WILLIAMS.

[638]. CLEANING OF PAINTINGS.—In reply to H. W.'s query, the discoloration of paintings is due to the carbonate of lead contained in the paint becoming converted into black sulphide of lead (PbS) by the H_2S present in the atmosphere.

When the peroxide of hydrogen is applied, the black sulphide is oxidized to the white sulphate and so the colour of the painting is restored. J. T. LLOYD.

RUSA GRASS OIL.

Sir,—Permit me to correct a mistake which occurred at the Pharmaceutical Meeting on November 7. The Rusa grass oil which I presented to the museum was not distilled from the grass which I sent for identification, but from undoubted *A. schœnanthus*, Lin., obtained from the grass distilling districts. The grass sent, which really has an odour of fresh ginger, is a rather rare grass found about old wells near Bombay, and not at all like *A. schœnanthus*, which I consider has no claim to the name of ginger grass.

Bombay. W. DYMOCK.

PETROLEUM ACT, 1879.

Sir,—It will be noted that the schedule of the Petroleum Act, 1879, which you recently published in your columns, contains no description of the "lead-line or pendulum" referred to in the directions for applying the flashing test.

Professor Abel has, however, informed me, in reply to a letter pointing out the oversight, that "a pattern pendulum or lead-line, as a guide for the length of pendulum to be used in connection with the petroleum test, has been deposited at the Standards Office, Old Palace Yard, with a label upon which is specified that the pendulum is two feet in length, from the point of suspension to the centre of gravity of the weight."

Where a large number of samples have to be tested I would recommend the use of a metronome, such as is used in teaching music, adjusted to beat synchronously with the pattern pendulum, the distinct sound emitted at each oscillation forming, in my experience, a better guide than the noiseless swing of the lead-line.

Boverton Redwood,
Chemist of the Petroleum Association.

Fewness of Candidates for the "Bell Scholarship."

Sir,—As wonder has been expressed more than once at the small (1) number of candidates who compete for the "Bell Scholarships," and as no answer has yet been recorded, I beg to offer the following thoughts towards the solution of this problem.

It is improbable that a boy gains the knowledge of French and Latin requisite for that examination during the three years that he is engaged in the profession of pharmacy; but he rather acquires a knowledge of pharmacy, chemistry and botany, and forgets most of what he knew in classics, mathematics and modern languages.

Now a boy, having—at the close of his school days—a little better knowledge of classics, mathematics and modern languages than is requisite for the Bell Scholarship would not feel greatly tempted by the prospect of being allowed to compete—after a three years' apprenticeship—for a scholarship worth £30 and instruction for one year, if he knew that there lay within reach scholarships of greater pecuniary value, and leading to more lucrative professions than that of pharmacy. Thus the average value of the six hundred scholarships at the colleges in Cambridge is £240 each; whilst from the statements of my friends in the University of Oxford, I gather that the scholarships there are of greater value; and in both universities a man may hold more than one scholarship.

Therefore a boy, whose education was of this standard, would not enter the profession of pharmacy unless that—(1) he had a father in the profession; or (2) he had a dislike to further study; or (3) he was ignorant of other openings, and over-estimated the value of this; or (4) he had a decided liking for pharmacy; all of which causes may combine with others that are unknown to

Manchester. A. H. Jackson.

Late Hours and Sunday Trading.

Sir,—I have with interest perused all letters regarding late hours which have appeared in your Journal since September 6, when the subject was first raised by Mr. J. K. Nicol. The discussion certainly must have done good since it has been clearly proved by the statistics given by Mr. T. H. Powell and statements by other gentlemen that the root of ill-health is long hours of business.

Now that we have hit upon the evil we must try to remedy it. Several methods have been suggested and among others one is prominent and perhaps pugilistic, that is, for assistants to hunt in couples and bully the employers, to overawe if possible, and make them give their signature to the early closing movement. This will not do; it has been too often tried without success. The secret lies entirely with the assistants themselves; they must either adopt the plan of mechanics who, when they require more pay or shorter hours, simply go out on strike, or make up their minds to take a good round salary from those over zealous employers who try to usher two days' work into one. Regarding Sunday trading, I think it a most degrading thing of men holding a position in society as chemists, as a rule, are expected to do, to try and make gain on that day which above all others is set aside as a day of rest. Is it not possible that chemists living at a distance from their shops could allow their brethren in trade who live next door to their shops the power of dispensing any prescriptions which may be urgently required on the Sunday?

This surely might be done quietly without throwing the shop open for regular trade. I would consider a business not worth having if it did not pay after getting due attention for six days in the week. Employers generally say in defence of Sunday closing that they get a large number of prescriptions on that day and should they close their shops customers would go elsewhere and probably not return; but let them take into consideration the large number of those prescriptions which could have been got on Saturday or remained till Monday, because invariably a great many are old prescriptions requiring to be repeated; and most assuredly chemists instead of being deserted by the public merely for closing their shops on Sunday would be countenanced and admired for their stability. W. S. T.

Patent Medicines and the Sale of Narcotics.

Sir,—Your articles on "patent medicines" and the sale of narcotics have greatly interested me. An experience of fifty years induces me to offer a few remarks thereon.

I think it will be admitted by the public and the medical profession, that those who have had a special education and a practical examination as to their knowledge of the properties, doses, mode of preparation, and action of medicines on the human frame, are best qualified to vend them, and are thereby able to answer any questions respecting them and their adaptability to the case for which they are wanted.

I need not say how often the chemist prevents a serious result by inquiring for what purpose the article asked for is required. Although a patent medicine is a secret remedy, the chemist generally knows the basis of it, *e.g.*, he knows that most rheumatic and gout medicines contain colchicum, and cough medicines opium or its salts or chloral. I consider the trade has acted unwisely in aiding the proprietors of patent medicines by circulating counter bills, but it is the bold and continuous advertisements backed by house to house circulation of almanacs and pamphlets which has brought them so prominently before the public.

My suggestions are—

Let every chemist keep prepared a simple remedy for ordinary ailments, and retail it as required, giving only a few doses in each bottle, and recommending the applicant, if not relieved to apply to his medical man or go to parish doctor, dispensary or hospital.

Sell patents at full prices; but give no encouragement to their sale, and cease to circulate their counter bills. And, as you justly observe, medical men are equally interested in bringing about some regulations for restricting the sale of nostrums, many of them containing scheduled poisons; they should cease when practicable to act as apothecaries, and thus let the chemist have the dispensing of their prescriptions. By so acting they would do away with a good deal of counter prescribing, which many of us cultivate, simply because we are deprived of our legitimate business. Now I think if this were brought before medical men by the principal chemists of a locality, the higher class of them would soon fall in with the suggestion, thus placing each section of the profession in its right position and producing that unity and co-operation which is so desirable.

Senex

H.—An unregistered person is not liable, as such, to a penalty for selling sweet spirit of nitre of any strength. The pill mentioned would contain a scheduled poison, and would therefore come under the provisions of the Pharmacy Act with respect to the dispensing of poisons.

B. T. Kimber.—The article on gelatine will be found on p. 148, of vol iv., 3rd series.

J. H. Aldridge.—The information is given in Payen's 'Industrial Chemistry,' art. Coal Gas.

"*Sigma.*"—We are not acquainted with a work devoted to the manufacture of cocoa and chocolate, but a lecture on the subject delivered before the Society of Arts, by Mr. J. Holm, was reported in vol. iv. of the present series of this Journal, pp. 804, 843, 885.

E. W. Hurley.—The insertion of queries as to price, similar to yours, always fail to evoke useful information, so much being dependent upon the nature of the business and neighbourhood in which the dispenser is engaged.

T. W. L.—Respecting the making of suppositories containing green extracts see the Dispensing Memorandum on p. 949 of vol. ix. (1879).

Communications, Letters, etc., have been received from Messrs. Wallis, Mee, Martin, Summers, Deck, Evans, Sons and Co., Sanklan J. H.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 463.)

SOLANUM NIGRUM, *Linn.*, SOLANACEÆ. *The plant. Vernacular.* — MAKOI (Hind.), KAMUNI, GHATI (Bomb.), MANATTAK-KALI (Tam.), KÁKMÁCHI (Beng.).

History, Uses, etc.—The plant is called Kakamáchi in Sanskrit works and is described as having tonic, alterative and diuretic properties. Mahometan writers, under the name of Anab-us-thalib, describe several kinds of *Solanum*, of which *S. nigrum* is probably one, but the fruit imported into Bombay from Persia under the name of Anab-us-thalib appears to be that of *Solanum dulcamara*. In India the juice of *S. nigrum* is given in doses of from 6—8 ozs. in the treatment of chronic enlargements of the liver, and is considered a valuable alterative and diuretic. The juice after expression is warmed in an earthen vessel until it loses its green colour and becomes reddish-brown; when cool it is strained and administered in the morning. It acts as a hydrogogue, cathartic and diuretic. Mr. M. Sherriff, in his Supplement to the 'Pharmacopœia of India,' speaks very favourably of it when used in this way.

Description.—An erect annual or biennial plant, with spreading or diffuse branches, 1—3 feet high, glabrous or pubescent with simple hairs, without prickles, but the angles of the stem sometimes raised and smooth or rough with prominent tubercles. Leaves petiolate, ovate, oblong, attenuated at both ends, 1—3 inches long, entire or repandly toothed. Flowers small and white, in little cymes contracted into umbels on a common peduncle from very short to nearly an inch long. Calyx 5-toothed or lobed to the middle. Corolla deeply lobed, 3—4 lines in diameter. Anthers very obtuse and short, opening in terminal slits often, at length continued down the sides. Berry small, globular, usually nearly black, but sometimes yellow or dingy red.

Chemical Composition.—The alkaloid solanine was first obtained in 1820 by Desfosses, of Besançon, from the berries of this plant. The same alkaloid was afterwards found in *S. dulcamara*. Winckler in 1841 observed that this alkaloid could only be obtained in an amorphous condition from the latter plant, and that it differed from the solanine of the potato. In 1858–59 Zwenger and Kind discovered that solanine, $C_{43}H_{69}NO_{16}$, was a compound of sugar and a crystallizable alkaloid, solanidine, $C_{25}H_{39}NO$. The latter under the action of strong hydrochloric acid parts with water and becomes converted into an amorphous basic compound, solanicine, $C_{50}H_{76}N_2O$.

Commerce.—The dried fruit known as Anab-us-salib in Bombay comes from Persia. Value Re. ¼ per pound.

S. nigrum is a common weed everywhere in cultivated ground.

GEN.? Sp.? SOLANACEÆ. *Local name*, SANIPÁT.

The drug consists of the plant in fruit broken up into small pieces. The fruit is a globular dry papery mucronate capsule, firmly attached to the calyx; the upper part of the capsule to which the placenta is attached is double. The placenta, which is large and oblong, is supported upon a thick peduncle and occupies the centre of the capsule; to it are attached numerous straight six-angled wedge-shaped seeds, which are packed closely together and fill the remaining space. The calyx is 5-partite, the upper segment very large and extending over the fruit like a hood. Leaves ovate, leathery, about 1 inch long, with short blunt hairs, margin much lighter in colour than the rest of the leaf. Seed straight, wedge-shaped, with six prominent longitudinal ridges. Testa tubercular, each tubercle minutely granular. The stems, which are numerous, are woody and covered by a thin grey bark; the central pith is very large. The drug has a slightly bitter somewhat tea-like taste, and is prescribed in the condition known in Sanskrit as Sanipát (typhoid symptoms). It is said to come from Northern India.

EMEX, Sp.? POLYGONACEÆ. *The herb. Vernacular.*— SHUKÁI (Hind., Bomb.).

History, Uses, etc.—This drug is described in Mahometan works as the Akraniki or Afsharniki of the Greeks. Other Arabic names given are Shaukat-ul-baida, Shaukat-ul-Arabiya and Kathir-ul-rakab. The Latin name is said to be Atrakias. Some say it is the same as the Bádaward of the Persians. Muhammad Husain very truly denies this, but admits that it is somewhat like it. He says the Persian names are Charchah and Kangar-khár, and describes two varieties: one with a white flower and more slender stems than the other, which has purple flowers and is the kind generally used. "The latter," he says, "has triangular stems the size of a man's finger or less, and thick small triangular downy leaves, terminating in thorns; the seeds are small, triangular and of a greyish colour. The whole drug is of a yellowish-white colour and sweetish taste. The root and fruit are generally used, but the root is to be preferred. Shukái is more drying and astringent than Bádaward; it is attenuant and deobstruent," etc. ('Makhzan-ul-adwiya,' article "Shukái.")

Description.—The drug, as met with in Bombay, consists of all parts of the plant broken up; but very little of the root is present. The portions of the stem are of a greenish-yellow colour, round, crooked, channelled, with numerous branches springing from the axils of the leaves; the external surface of the stem is silicious, hard and pubescent, internally it is full of soft pith. The petioles of the leaves are stem-clasping, the lower ones completely so. The lower leaves are of considerable size, with a triangular midrib, channelled on the upper surface, and short thick spinous lobes, which vary much in shape. The plant has a gummy, rather disagreeable taste. The fruit is occasionally found mixed with the drug in considerable quantity. It is a woody nut, ¼ of an inch long, formed by the fusing together of the different parts of the perianth and ovary, somewhat triangular in form; at the base are spines formed by the calycine segments; at the apex the perianth forms a number of tooth-like processes, which surround the top of the ovary. The seed is ovoid, horny, and has a terebinthinate odour.

Commerce. — Shukái is imported from Persia. Value Re. ¼ per pound.

RUMEX VESICARIUS, *Linn.* CHUKA (Hind., Beng., Bomb.), CHUKRA (Sans.).

This is cultivated all over Asia and is used just as sorrel is in Europe; excellent *potage à l'oseille* may be made with it. The plant is doubtless one of the kind of Hamáz mentioned in Arabic works, and is much esteemed for its medicinal properties. The juice is said to allay the pain of toothache, and by its astringent properties to check nausea, promote the appetite and allay morbid craving for unwholesome substances. The herb also is considered very cooling and of use in heat of stomach, and externally as an epithem to allay pain, especially that caused by the bites or stings of reptiles and insects. The seeds are said to have similar properties and are prescribed roasted in dysentery, and as an antidote to scorpion stings. The root is also medicinal.

Description.—The fruit sold in the shops as Gulhamáz is reddish-brown, about $\frac{2}{10}$ of an inch long, and consists of three fringed leaf-like expansions, each furnished with an oblong glandular body and attached at the base to a short thick pedicel; they enclose a triangular polished dark brown seed.

ACALYPHA INDICA, *Linn.*, EUPHORBIACEÆ. *The plant. Vernacular.*—KUPPI, KOKLI (Bomb.); KUPPAI-MENI (Tam.).

History, Uses, etc.—I have not met with any description of this plant in native works on materia medica, although it appears to be well known to the herbalists. Ainslie gives "arittamunjayrie" as the Sanskrit name and "shwet-basanta" as the Bengali; he has the following notice of the plant. "The root, leaves and tender shoots are all used in medicine by the Hindoos. The powder of the dry leaves is given to children in worm cases, also a decoction of them with the addition of a little garlic. The juice of the same part of the plant, together with that of the tender shoots, is occasionally mixed with a small portion of margosa oil, and rubbed on the tongues of infants for the purpose of sickening them and clearing their stomachs of viscid phlegm."

The Hakeems prescribe the koopamaynee in consumption. It would appear from Rheede's account of this plant, that on the Malabar coast the root is supposed to have a purgative quality; his words are, "Radix trita, et cum aqua calida assumpta, cathartica est; folia trita et cum aqua epota ventrem laxant; illorum decoctum auribus immissum mitigat dolorem." He calls it "cupameni" ('Mat. Indica,' vol. ii., p. 161). In the 'Phar. of India' (p. 205) the following reference to this plant by Dr. G. Bidie, of Madras, will be found. "The expressed juice of the leaves is in great repute, wherever the plant grows, as an emetic for children, and is safe, certain, and speedy in its action. Like ipecacuanha it seems to have little tendency to act on the bowels or depress the vital powers, and it decidedly increases the secretion of the pulmonary organs. The dose of the expressed juice for an infant is a teaspoonful." Dr. Æ. Ross speaks highly of its use as an expectorant, ranking it in this respect with senega; he found it specially useful in the bronchitis of children. The purgative action of the root noticed by Rheede ('Hort. Mal.' x., p. 161, t. 81) is confirmed by Dr. H. E. Busteed, who has used it as a laxative for children. In Bombay the plant has a reputation as an expectorant, hence the native name Kokli (cough).

Description.—Stem erect, from 1–2 feet high, branchy, round, smooth; leaves scattered, petioled, ovate-cordate, three-nerved, serrate, smooth, about two inches long and one and a-half broad. Petioles as long as the leaves. Stipules small, subulate. Spikes axillary, generally single, peduncled, erect, as long as the leaves, many flowered, crowned with a body in the form of a cross, the base of which is surrounded with a three-leaved calyx; the arms of the cross are tubular, with their mouths fringed; from the base of the cross on one side issues a style-like thread, with a fringed stigma. The body of the cross contains an ovate seed-like substance. Male flowers numerous, crowded round the upper part of the spike. Calyx four-leaved, leaflets cordate. Filaments minute, numerous. Female flowers below the male, remote. Involucre cup-formed, with an opening on the inner side, striated, smooth, toothed, from 2–4 flowered. Calyx three-leaved (Roxb).

In Bombay *A. Indica* is not nearly so abundant as *A. ciliata*, Willd., which is one of the commonest roadside weeds towards the end of the moonson.

POKLI-MIRI. PIPERACEÆ.

These are abortive pepper-corns and have long held a place in the Hindu materia medica. Garcia d'Orta notices the drug under the name of Canarese pepper, and observes that it never finds its way to Portugal, but that it is valued as a medicine by the natives to purge the brain of phlegm, to relieve toothache and as a remedy for cholera. I am inclined to think that this drug must be the aborted produce of the female vines of *P. trisicum* mentioned by Roxburgh ('Flora Indica,' i. 153).

MYRICA SAPIDA, *Wall.*, MYRICEÆ. *The bark. Vernacular.*—KAIPHAL (Hind., Bomb., Beng.); MARUDAM-PATTAI (Tam.).

History, Uses, etc.—This is the Katphala of Sanskrit writers, who describe it as hot and stimulant, and recommend it in catarrh and affections of the chest. It is also used by the Hindus as an external stimulant application in cholera, etc.

Under the names of Dar-shishaán, Kandool, and Aod-ul-bark, Mahometan writers tell us that the bark is resolvent, astringent, carminative and tonic; that it cures catarrh and headaches. With cinnamon they prescribe it for chronic cough, fever, piles, etc.; compounded with vinegar it strengthens the gums and cures toothache; an oil prepared from it is dropped into the ears in earache. A decoction is a valuable remedy in asthma, diarrhœa and diuresis; powdered or in the form of lotion, the bark is applied to putrid sores; pessaries made of it promote uterine action. The usual dose for internal administration is about 60 grains. Duhn-ul-kandool, an oil prepared from the flowers, is said to have much the same properties as the bark.

Description.—Bark half an inch thick, externally scabrous, pitted from the separation of pieces of suber, of a mottled rusty-brown and dirty-white colour; suber warty; substance of bark and inner surface of a deep dull red colour; when soaked in water it produces a deep red solution. Taste strongly astringent.

Microscopic Structure.—Within the suberous layer is a remarkable stratum of stony cells; the parenchyma is loaded throughout with red colouring matter, and permeated by large laticiferous vessels, from which a gummy latex exudes when the bark is soaked in water.

Chemical Composition.—The bark yields its colouring matter freely to water and alcohol. Water also extracts the gum. The watery extract evaporated to dryness yields a brittle highly astringent substance of the colour and taste of kino. No chemical examination of these substances has been made.

Commerce.—The bark comes from the hilly districts of Northern India. Value, Rs. 1-2 per maund of 41 pounds.

(*To be continued.*)

THE TESTING OF PEPSINE.*

BY A. PETIT.

Recent investigation having directed attention to the ferments which preside over the transformation of the various alimentary matters, it appeared to me that it would be useful to define the present state of this interesting question, and particularly to state the method of testing most convenient to be adopted for these ferments, of which the medical employment is becoming more and more common.

In commencing this study I would recall that all the facts relative to the action of pepsine and diastase have been explained with the greatest clearness by M. Mialhe. Upon reperusing the memoirs of 1845 and 1846 it will be seen that his opinions, sharply discussed at the time when they appeared, are now accepted by all investigators occupied with the phenomena of digestion. On the present occasion I will deal only with certain facts connected with the transformation of nitrogenous foods by pepsine.

These substances,—albumen, fibrin, casein, etc.,—submitted to the combined action of pepsine and an acid, are transformed at first into a compound, named caseiform albumen by M. Mialhe and more recently syntonine; then into another substance,—the ultimate product of the stomachic digestion of albuminoid matters, —the albuminose of Mialhe, or the peptone of Lehmann. According to their source, these peptones, although they are very probably isomers, differ from one another by their action upon polarized light.

M. Henninger thinks that the peptones are formed by the hydration of albumenoid matters, and as they combine indifferently with acids and bases he considers them as weak acid amides. M. Meissner divided the products of transformation of albuminoid matters into parapeptones, metapeptones, dyspeptones and peptones α, β, and γ; but these divisions can no longer be accepted in the present state of science.

The essential characters of peptones are those of not being precipitated by saturation of the acid liquids holding them in solution, or by nitric acid, or by ferrocyanide of potassium added to acetic acid. They are mostly soluble in water, even after having been precipitated from their aqueous solution by excess of alcohol.

The test by nitric acid has a prime importance, as will appear subsequently. It permits, in fact, of ascertaining rapidly whether the transformation is more or less advanced. When nitric acid added drop by drop to a peptic solution of albumen no longer gives a precipitate it may be concluded that all the albumen is transformed into peptones.

The report upon pepsine presented in 1865 by M. Guibourt to the Société de Pharmacie did not sufficiently bring out the importance of this reaction. M. Guibourt thought that the solution of the fibrin was sufficient, and it appears (p. 102) that 1 gram of pepsine prepared by the Commission, in presence of 8·40 grams of lactic acid and 20 grams of water, very incompletely modified 12 grams of fibrin after heating for twelve hours at 40 to 45° C. The solution was in fact semigelatinous and was strongly precipitated by nitric acid. Certainly, at the present time, such a pepsine would be considered to be of mediocre quality.

Rapid solution indicates that the pepsine is of good quality, but between this phenomenon and that of transformation the difference is essential.

Let us now examine the various methods of testing that have been proposed for pepsine and see which is most suitable for adoption.

1. *Test by coagulation of milk.*—This process ought to be rejected. M. Guibourt had, in 1865, come to the conclusion from experiments made on rennet, that the principle in rennet which produces the coagulation of milk is not that which dissolves and transforms fibrin. I have observed also that a pepsine, twelve times more active than another prepared from calves' rennet, was much less active than the latter in respect to the coagulation of milk. It is probable that this special action is due to a particular ferment.

2. *Test by coagulated white of egg.*—This test is universally adopted in England and in Germany. I have made some experiments to determine—

(*a*) The temperature most favourable to solution;
(*b*) The action of various acids;
(*c*) The acidimetric strength which it is advisable to give to the liquors.

With respect to temperature, experiments were made at from 30° to 80° C. Even at elevated temperatures the action of acidified pepsine is produced, but the maximum occurs at 50°.

With liquors containing 2 to 15 per mille of acetic or butyric acid, I have been able to convince myself that in the presence of these acids pepsine is without action upon coagulated white of egg. Tartaric, lactic, and especially hydrochloric acids, on the contrary, facilitate the action of pepsine.

The solution of tartaric acid ought to be of the strength of about 10 grams, and that of lactic acid from 8 to 12 grams per litre. With hydrochloric acid, the digestion of white of egg takes place very well in liquors containing from 1 to 3 parts per 1000 of real acid, the most favourable acidity being $1\frac{1}{2}$ parts per 1000.

In the study of similar phenomena it ought never to be forgotten that the digestion in the stomach goes on at a temperature of about 40° C. It is therefore especially at this temperature that the test of artificial digestions should be made. It might happen, in fact, that an acid solution, acting on albumen at 50° or 60° C., would be less active at 40° C. This is what takes place with lactic acid, which at a concentration corresponding to 2 or even 3 per 1000 of real hydrochloric acid leaves white of egg in great part undissolved at a temperature of 40° C., whilst hydrochloric acid of 1 per 1000, in the same conditions of time and temperature, dissolves and transforms all the albumen.

In these facts is found the experimental demonstration that the free acid of the gastric juice is hydrochloric acid. This is a fact, moreover, gained to science by the remarkable researches of M. Richet, who has proved that the acidity of the gastric juice is about 2 per 1000; that it is due solely to hydrochloric acid, and that if lactic acid is found there it is the product of a special fermentation which the food has undergone in the stomach.

The more that artificial digestions are studied the more evident becomes the similarity which exists between these phenomena and those of the stomachal digestion. No doubt, the stomach absorbs during the digestive period a portion of the liquids and of the peptones they contain, and this, according to Schiff, favours digestion considerably. The movements in the food which this initiates facilitate the action of the gastric juice, the secretion of which is uninterrupted; but it is no less true that in experiments *in vitro it is easy to equal and even to surpass the digestive power of the stomach.*

We know that the activity of the gastric juice is always maintained within certain limits, the secretions of the stomach rapidly re-establishing an equilibrium when this is more or less destroyed. The specific action recognized in hydrochloric acid throws light on the rationale of certain medicines and the troublesome influence exercised by some substances upon the act of digestion. As has been justly remarked by M. Richet, in the case of abnormal fermentations there is produced a great excess of lactic, acetic and butyric acids. Hydrochloric acid is no longer secreted, but instead, a less active acid, lactic acid, or inactive acids, acetic and butyric. The utility will hence be understood of employing in such a case alkalies, which in saturating the free acids induce a fresh secretion of hydrochloric acid and thus restore to the gastric juice all its digestive power. It

* *Journ. de Pharm. et de Chimie,* 5th ser., vol. i., p. 82.

will be understood also that to attain the same object sometimes solutions of hydrochloric acid and sometimes of the alkaline bicarbonates have been given with success. It is necessary, besides, in this case, that the acetates and butyrates should be eliminated by stomachal absorption; otherwise they would be decomposed and the inactive acids again set free by the hydrochloric acid secreted normally or administered as medicine.

To return to the testing of pepsine by coagulated white of egg, one objection that may be brought against it is that it does not establish a sufficient gradation in the transformations. However this may be, the method of operating is as follows:—

An egg is kept in boiling water during half an hour, and the very coherent white is then passed through a moderately fine strainer. 5 grams of this coagulated albumen, put into contact at 40° C. with 25 grams of hydrochloric acid containing 1·50 of HCl per litre, ought to be dissolved in four to five hours by 0·10 gram of pepsine of good quality. It is necessary to agitate the flask every half-hour.

Test by fibrin.—This appears to me to present great advantages over the preceding. The phenomena are very distinct and very comparable. Whatever may be the origin of a ferment, in the same conditions of time, temperature and acidity of the menstruum, its exact equivalence can be determined by relation to other specimens. The following are the conclusions I have arrived at with respect to the best conditions for the transformation of fibrin.

The temperature of 50° C. is that of the maximum. The same pepsine is about four times less active at 40° than at 50° C.

The acid most favourable to the transformation is hydrochloric acid. In order to approach the action of this acid it is necessary to employ relatively large quantities of lactic or tartaric acids, about 25 to 30 grams per litre. With lactic acid in the proportion of 20 grams per litre the action is five times less than that which corresponds to a 3 per 1000 solution of hydrochloric acid. With hydrochloric acid the most favourable action is obtained with a solution containing between 2 and 5 grams of real HCl per litre.

To recapitulate, it appears that the acidity of the gastric juice does not exceed 2 to 3 grams per litre of acid expressed as HCl, which would give 5 to 7·5 grams of acid expressed as lactic acid, whilst the action would be much weaker in the presence of the latter solvent.

I would also remark that the acidity of the 1 per 1000 in HCl, which is favourable to the solution of coagulated albumen, is not sufficient for the easy transformation of fibrin. In order to approach physiological conditions I would propose therefore to employ 1·50 gram of real HCl per litre in the testing with coagulated white of egg and 3 grams per 1000 for testing with fibrin.

It may be asked whether it is not possible to render the testing of pepsine more practical by diminishing the time of operating. Nothing is more easy. In heating during six hours instead of twelve about twice as much pepsine is required for the transformation. Again, in heating during six hours at 40° C. instead of twelve hours at 50° C., nearly eight times the quantity of pepsine is required to obtain the same result.

This great influence exercised by temperature renders it necessary that a standard for operating should be fixed in an exact manner. The Commission of 1865, in recommending to heat to from 40° to 45°, was not sufficiently precise upon this important point.

I have stated that there is an essential difference between the solution of fibrin and its transformation; the following experiments demonstrate this very clearly:—

A pepsine prepared in my laboratory, which dissolved and transformed in twelve hours at a temperature of 50° C. six hundred times its weight of fibrin in a liquor containing 4 per 1000 of real HCl. dissolved in the same conditions:—

1,200	times its weight of fibrin in	1 hour.
2,400	” ” ”	1 hour 10 minutes.
4,800	” ” ”	1 hour 15 minutes.
9,600	” ” ”	1 hour 45 minutes.
19,200	” ” ”	2 hours 10 minutes.

It was not thought necessary to carry the experiment further.

An identical experiment was made with lactic acid in the proportion of 0·40 gram to 25 c.c. or 16 grams per litre. Although the same pepsine transformed in these conditions only one hundred times its weight of fibrin, instead of six hundred times, as in the preceding experiment, it was found that it dissolved—

1,200	times its weight in	30 minutes.
2,400	” ”	1 hour 15 minutes.
4,800	” ”	1 hour 30 minutes.
9,600	” ”	4 hours.
19,200	” ”	5 hours.

It is necessary to add that in flasks differing from the others only in the absence of pepsine no liquefaction took place.

To test a pepsine, therefore, I should take of hydrochloric acid of the strength of 3 grams of HCl per litre 25 c.c.; then 5 grams of moist fibrin strongly dried, and add to several flasks so prepared quantities of pepsine ranging from 0·10 to 0·60 gram. These should be heated to 50° C., for it has been seen that four times as much pepsine would be required at 40° C., which would be an useless waste. Agitate every half-hour until the complete solution of the fibrin, and then every hour.

A good pepsine ought not to give a precipitate with nitric acid after twelve hours' heating in flasks containing 25 to 30 centigrams, and after six hours in those containing 50 to 60 centigrams. The nitric acid should be added drop by drop to 10 c.c., for example, of the solution, and not the slightest turbidity should be produced in the liquor at the moment of adding it.

In these experiments I have for some time used a fibrin of mutton washed until it has become white and preserved in pure glycerine. When required for use it is washed with plenty of water.

In subsequent communications I shall show the action which a number of bodies exercise upon the peptic and diastasic ferments.

THE ALKALOID OF THE BAPTISIA TINCTORIA.*

BY FRANCIS V. GREENE, M.D., U.S. NAVY.

In the volume of the *Amer. Jour. Phar.* for the year 1862, there appears at page 310 an article on the "*Baptisia tinctoria*," by B. L. Smedley, in which he claims to have isolated the alkaloid of this plant. The process given is as follows:—The root was boiled with water acidulated with hydrochloric acid, and to the strained decoction milk of lime added in slight excess. The copious precipitate produced was collected, washed with distilled water, dried and treated with boiling alcohol. On evaporating the alcohol from the filtered solution there remained an extract of a light yellow colour, which was treated with hot water slightly acidulated with sulphuric acid. The solution thus obtained was agitated with animal charcoal, filtered and set aside to crystallize; it yielded perfectly transparent crystals, in plates, similar to those of potassic chlorate. It was further stated that by adding ammonia in slight excess to the above liquid a white, feathery precipitate of the alkaloid was obtained.

A later investigator, Mr. J. A. Warner, (*op. cit. supra*, 1871, p. 251), after repeating the above process, and ascertaining that the crystalline salt of the first writer was composed entirely of calcium sulphate, announced the following method, by which he had separated what he supposed to be the chloride of the alkaloid of this

* From the *American Journal of Pharmacy*, December, 1879.

plant. A concentrated tincture of the root, after being rendered slightly acid by the addition of sulphuric acid, was evaporated to a small bulk, a large quantity of water added and the precipitated resin separated by filtration. To the clear filtrate solution of potassio-mercuric iodide was added in slight excess, the precipitate collected, suspended in water, decomposed by sulphuretted hydrogen and the sulphide of mercury removed by filtration. The filtrate, which was supposed to contain the alkaloid in solution in the form of an iodide, was then concentrated, carbonate of ammonia added in slight excess and the syrupy liquid shaken with chloroform. On separating and evaporating the chloroform solution there remained an amorphous mass, which was dissolved in water acidulated with hydrochloric acid. This solution was treated with animal charcoal, filtered and concentrated to one-third its bulk, when it yielded long, needle-like crystals.

It will be seen from the above process that the opinion in regard to the presence of an alkaloid in this plant was based solely upon the formation of a precipitate when Mayer's test solution was added to an acidified aqueous solution of its root, and consequently, as the crystals obtained in the above manner were not afterwards so treated as to yield the uncombined alkaloid, the results of this examination have not been accepted ('Prac. Pharm.,' Parrish, 1874, p. 475) as conclusively establishing the existence of such principle in this root. The following experiments, while rendering it doubtful whether the base of the salt obtained as above was really an alkaloid, prove conclusively that the root of the *Baptisia tinctoria* does contain such a substance.

A few ounces of the powdered root were exhausted by percolation with distilled water, the percolate filtered, calcined magnesia added and the mixture evaporated to dryness. The magnesia mass was then extracted with absolute alcohol. On evaporating the alcohol from this solution there remained a light yellow amorphous mass, a small portion of which was placed on a piece of reddened litmus paper, and moistened with a drop of distilled water, when a deep blue coloration was produced. A small quantity of the mass was then dissolved in a little distilled water, and the filtered solution placed under a bell-glass over sulphuric acid. On the evaporation of the liquid no crystals could be discovered in the residue. It was therefore re-dissolved in slightly acidulated water, and again evaporated over sulphuric acid, when the mass was still found to be amorphous. It was finally dissolved in distilled water, and the acid solution tested with the various reagents for alkaloids, with the result of giving very decided precipitates with potassio-mercuric iodide, iodine in iodide of potassium solution, potassio-cadmic iodide, phosphomolybdic acid, phosphotungstate of soda, and tannic and picric acids. The whole of the light yellow amorphous mass was then dissolved in a small quantity of distilled water, a little calcined magnesia added, the mixture evaporated to dryness, when it was successively agitated with the different simple solvents with the following results. On evaporating the benzol that had been shaken with the mass, and adding a little distilled water to the small amount of residue, no blue colour was communicated to reddened litmus paper, and no precipitates were formed by the acidified solution with the above-mentioned tests. Absence of the blue colour and of the precipitates was also noticed when benzin and chloroform, that had been agitated with the mass, were treated in a similar manner. Ether, on the contrary, dissolved the alkaloid from the magnesia mass; the residue therefrom, when moistened with distilled water, staining the reddened litmus paper a deep blue, and when dissolved in acidulated water affording precipitates with the above-named reagents. Hence, it will be seen that we have for this alkaloid solubility in water, alcohol and ether, and insolubility in benzol, benzin and chloroform. From the insolubility of this alkaloid in chloroform it will be evident that the crystals obtained in the process used by the last-mentioned experimenter could not have been those of the chloride of this alkaloid, which, although undoubtedly present in an uncombined state in the concentrated solution, after treatment with carbonate of ammonia was not removed from it by the use of chloroform.

A larger quantity (8 troy ounces) of the powdered root of the *Baptisia tinctoria* was subsequently percolated as before, and the filtered solution evaporated to dryness with calcined magnesia. The dried mass was extracted with 95 per cent. alcohol, and this solution evaporated to a small bulk. Distilled water was added in large quantity, and the liquid filtered to remove the deposited resin. A solution of tannic acid was then added to the clear filtrate as long as a precipitate was formed. When the precipitated tannate had subsided it was transferred to a filter, washed with distilled water, and while still moist removed to a mortar, intimately mixed with finely pulverized oxide of lead, and the mass thoroughly dried in a capsule, after which it was extracted with ether. On evaporating the ether there remained a considerable quantity of the same yellowish, semi-transparent, gummy mass that had been obtained in the first experiment. A small portion of this mass, ignited on platinum foil, left no inorganic residue.

In order to separate the alkaloid from the foreign matter contained in this mass it was determined to resort to the use of oleic acid, in the manner lately recommended by L. Wolff (*Am. Jour. Phar.*, January, 1878, p. 8). A small quantity of the pure acid was added to the mass contained in a capsule, the contents heated over a water-bath, the oleic acid, containing the alkaloid in the form of an oleate, poured off, and benzin, which dissolves both the acid and the oleate, added to it. The benzin solution was then agitated with distilled water slightly acidulated with hydrochloric acid, and, after the complete separation of the two liquids, the aqueous solution was drawn off. After concentrating this solution it was placed aside to crystallize, and in a few days acicular crystals were formed. The amount of the chloride obtained in this manner proved merely sufficient to establish that this alkaloid is soluble in ammonia, and to determine its character by the precipitates afforded by it with the usual reagents for this class of substances.

Lastly, about 2 troy ounces of the finely powdered root were thoroughly moistened with a solution of bicarbonate of soda, the mass placed in a porcelain capsule, heated to dryness on a water-bath, then powdered, transferred to a small percolator and extracted with ether. After evaporating the ether from the percolate, which was of a light yellow colour, distilled water was added to the residue and the liquid filtered to separate a yellowish-white resin that had subsided. This aqueous solution of the alkaloid, which was still of a pale yellow colour, was then concentrated, carefully neutralized with very dilute hydrochloric acid, repeatedly agitated with successive portions of ether as long as this menstruum removed any colouring matter, and then placed aside, when, after a few days, it yielded crystals, some of which presented the form of perfect octahedra.

APIOL.*

BY H. C. WHITNEY.

The seed of *Apium Petroselinum* has variously been made the subject of research and analysis by different parties; prominent amongst them Messrs. Joret and Homolle, of Paris, who claim to have found therein, besides a crystallizable fatty matter, pectine (the apiin of Braconnot), chlorophyll, tannin, colouring and extractive matters, lignin, various salts, volatile oil, and a peculiar oily substance for which they proposed the name of apiol.

* From *New Remedies*, January, 1880.

This is said to be a yellowish oily liquid, non-volatile, heavier than water, of a peculiar and tenacious odour, distinct from that of the plant, and of an acrid, pungent taste. They also claim it to be inflammable, insoluble in hot or cold water, very soluble in alcohol, and entirely dissolved by ether or chloroform. It is analogous to the fixed oils, but is not chemically changed by the alkalies.

The process given by them for obtaining the so-called apiol is as follows:—They exhaust the seed with alcohol, treat the tincture with purified animal charcoal, distil off three-fourths of the alcohol, treat the residue with ether or chloroform, evaporate the solution thus formed, mix the residuary liquid with an eighth of its weight of litharge, allow the mixture to rest twenty-four hours, and then filter through a thin layer of charcoal.

I found, in reviewing this process, that the alcohol dissolves from the seed the apiin, essential oil, resin, and the supposed apiol.

After the treatment with ether or chloroform, the oil, resin, and apiol are separated from the pectine, and being mixed with an eighth of its weight of litharge for the purpose of removing what fat oil it may yet contain, besides the saponifiable resin, it is allowed to stand for a certain length of time and filtered, and the product thus obtained is what they named apiol. After the apiin is separated by ether or chloroform and the fatty oil and resin by litharge, the mere act of filtering through charcoal certainly cannot separate the essential oil from the peculiar oily substance which they want to obtain, but must pass through the filter with it, so that what they obtain as pure apiol can only be an impure essential oil obtained by the absorption process as lately proposed.

To substantiate this idea, I took freshly powdered parsley seed, subjected it to repeated distillations with water until the latter passed entirely clear, obtaining thereby water strongly impregnated with the volatile oil of parsley seed. The oil at the bottom thereof being separated therefrom, the water was subjected to cohobation from a solution of sodium chloride, yielding the entire quantity of oil contained in the seed; which in this instance amounted to 4·27 per cent. The oil so derived corresponded closely to the so-called apiol of Joret and Homolle, with the exception of its being lighter in colour and evidently purer than theirs.

The residue of the distillation was strained while hot, separating the (by distillation) exhausted seed; the liquid yielding upon being filtered, a large quantity of apiin on cooling. The residuary seed, being treated with petroleum benzine, gave 9·114 per cent. of a green fatty oil and liquid resin. Being subsequently subjected to the action of ether, gave 2·734 per cent. additionally of fatty oil and resin; the latter being separated, as in the former case, by shaking it with alcohol. The fatty oil, being entirely freed from resin, amounted to 7·239 per cent. The different portions of alcohol containing the resin, dissolved from the fatty oil, gave upon evaporation a greenish-brown oily liquid, lighter than water and readily saponified by the fixed alkalies, with a peculiar odour distinct from that of the essential oil, which in all but the latter respect differs from the apiol of Messrs. Joret and Homolle.

Of late, Mr. E. V. Gerichten (*Berichte der Deutschen Chemischen Gesellschaft*, Nos. 16—17)* claims to have found during his researches and investigations in parsley seed a body for which he proposed the name of apiol, or parsley-camphor, and asserts that it is the only substance which is entitled to that name.

He finds that it is obtained during the distillation of the oil of parsley seed from the seed with water; which would be at a temperature not much above 212° F., whereas he subsequently claims for it a boiling point of 300° C.

How this occurs is to me not exactly comprehensible, since I failed, during a number of experiments therewith, to discover any separation of the fine needles of the parsley-camphor which he claims to have found. He further gives a method for obtaining the same by a direct process, which, after all, does not materially differ from that of Messrs. Joret and Homolle, and which certainly, as I have conclusively proven above, does not yield anything else than the impure essential oil as obtained by the absorption process.

The apiol or parsley-camphor of Mr. E. V. Gerichten must have been derived by a different process than described by him in his paper. It makes but little difference, however, for the apiol of Mr. E. V. Gerichten can be of little more than chemical interest, while the article of that name by Messrs. Joret and Homolle is that which is so much valued for its emmenagogue properties and which alone finds therapeutical application. As the latter article is certainly nothing but a complex body, not saponifiable by fixed alkalies, which does not congeal at a temperature of 32° F., and, contrary to the statement of Messrs. Joret and Homolle, comes over almost entirely at a temperature of 212° F., I am safe to say that it is principally composed of the essential oil of parsley seed intermixed with small quantities of a soft resin, which latter is in such minute quantities that I can readily infer the emmenagogue properties to be contained in the volatile oil, and would suggest, therefore, that the apiol of the present be superseded by the term, oil of parsley seed, from which the medical profession no doubt will receive the same emmenagogue effect; or, if such is not the case, that the soft resin, which is one of the constituents of the apiol of old, be separated by the process I have above indicated, and employed for the purposes which apiol has been used for until now.

* *Pharm. Journ.*, [3], vii., 693.

"PUNCH" ON POISONING BY PATENT.

(*A Little Tragedy of the Statute Book.*)

SCENE.—*A Chemist's Shop—Legally Disposed Proprietor and three suffering Customers discovered discussing the "Sale of Poisonous Drugs Act."*

Legally Disposed Proprietor. Well, you can't have it. There!

First Suffering Customer. There—indeed! Why the child has kep me up, without a blessed wink of sleep, these five nights! You might make us up a 'aporth of laudanum? Come, now.

Legally Disposed Proprietor. Can't do it, my good lady. Law is law.

Second Suffering Customer. Just so. But my case is very different. I want something just to quiet this neuralgia. Now, I'm told that a little opium——

Legally Disposed Proprietor. No use, sir; we daren't let you have it. Get a doctor's order.

Third Suffering Customer. But, really, it is preposterous. Here, I come for something to allay violent symptoms of incipient coma, and do you mean to tell me you can give me nothing calming of any kind?

Legally Disposed Proprietor. Oh, yes, I can do something for you in the patent way. Have you ever tried Deadman's Somnolent Elixir?

Suffering Customers (*all together*). No! Is it strong?

Legally Disposed Proprietor. Strong? Why, it would send an elephant off like a top (*produces it*), and it's only one-and-three-ha'pence. We sell a good deal of it.

First Suffering Customer. Give me a bottle.

Second Suffering Customer. Here, I'll have one.

Third Suffering Customer. So will I.

Legally Disposed Proprietor. That is the article (*hands small packet bearing Government Label to each*). But mind the directions, because it *is* strong. (*Smiling.*) It is what we call *a powerful narcotic.*

[*Exeunt three Suffering Customers, with three bottles of powerful narcotic, to make arrangements for three Coroner's inquests, as Curtain falls.*

The Pharmaceutical Journal.

SATURDAY, JANUARY 24, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

MISREPRESENTATION OF THE PHARMACY ACT.

THE position of chemists and druggists in regard to the popular abuse of narcotics, which has been lately commented upon by medical journals and the daily press, is one which does not appear to be generally understood, and even those who have written upon this subject manifest defective acquaintance with the provisions of the Pharmacy Act that are intended to serve for the protection of the public against accidental poisoning. In like manner the functions of the Pharmaceutical Society in respect to the carrying out of that Act have been incorrectly construed, and a letter recently written by the coroner for Doncaster furnishes a striking illustration of this fact.

In that letter reference is made to a fatal case of the misuse of "soothing syrup," in which an infant, three months old, was "doctored" by its mother with two teaspoonfuls of a syrup stated to contain opium and purchased from a person who is described as an "unregistered druggist." The coroner justly remarked that it was clear the Pharmacy Act had been infringed in this case, and he adds that there was reason to expect an example would be made by the punishment of the offender. So far there is no exception to be taken to the remarks of the Doncaster coroner; but he goes on to say that shortly afterwards a paragraph appeared in a local newspaper stating that the seller of the syrup of poppies had paid to the Solicitor of the Pharmaceutical Society the sum of five pounds as a penalty for breach of the Pharmacy Act, and then he comments upon this fact as indicating that an offence of a grave nature had been privately condoned, arguing at the same time that such a proceeding showed the Pharmacy Act was defective and required amendment.

If there were any kind of justification for the inference that a breach of the Pharmacy Act had been "condoned" by the Pharmaceutical Society, the argument of the Doncaster coroner would have had some weight. In such a case there would have been some reason also for the objection raised by the *Daily News* to the Pharmacy Act "allowing chemists to compound with the Pharmaceutical Society," and for the statement made in the London letters of various provincial papers that an infringement of the Pharmacy Act had been "squared" for five pounds paid to that institution.

But there is no foundation for any of these suggestions, which have originated solely from ignorance of the Pharmacy Act and its provisions, and as pointed out by the President of the Pharmaceutical Society in the *Times* of the 21st inst., the Doncaster coroner, as well as those who wrote under his inspiration, have failed to make themselves acquainted with the powers conferred upon the Society by the Pharmacy Act. It is thus that they have failed to perceive that in the Pharmacy Act provision is made for dealing with two distinct offences, one of which, viz., the selling of poisons otherwise than in conformity with the Act and with regulations made in pursuance of it, the Pharmaceutical Society is specially empowered to take cognizance of by suing for penalties. This it does as a public duty, and any penalties recovered are under the control of the Commissioners of Her Majesty's Treasury. The other offence of selling poisons without proper labels is one that renders the sellers liable to prosecution by any person before justices of the peace in England or the sheriff in Scotland, and upon summary conviction renders them liable to a penalty.

As pointed out in the *Times* of last Thursday, by Messrs FLUX, SLADE and Co., the Solicitors to the Pharmaceutical Society, there is no trace in the Pharmacy Act of legislative intention that the Society should become public prosecutor for carrying out the provisions of the seventeenth section of the Act, under which a policeman or any other person could prosecute an offender against it. The prosecution referred to by the Doncaster coroner was not instituted under that section of the Act, but under the fifteenth section, above referred to as relating to the special duty of the Society according to the Act, and, as the Solicitors point out in their letter to the *Times*, defendants are at liberty to exercise their undoubted right to pay the penalty before judgment so as to avoid a trial of the action.

Under such circumstances there is no foundation for the charge that the Pharmaceutical Society or its Solicitors have privately condoned offences of grave nature involving the destruction of human life, and the strictures of the Doncaster coroner, as well as the comments in the newspaper press to which they gave rise, are devoid of any meaning. The fact that the seller of the soothing syrup had been subjected to a penalty under the fifteenth section of the Pharmacy Act did not in any degree relieve him from liability to a further penalty under the seventeenth section, and if, as Messrs. FLUX and SLADE point out, there was, in the fatal case referred to by the Doncastor coroner, an offence of so grave a nature as to involve the destruction of human life, it still remains to be explained why a verdict of manslaughter was not found.

The circumstances above narrated serve to show very forcibly the ignorance that prevails concerning the Pharmacy Act and the powers that it confers, and the facilities with which it may be used for repressing irregular sales of poison. If, for instance, the Doncaster coroner had taken the trouble to communicate with the Secretary, or the Solicitors of the Society, or if he had referred to the Pharmacy Act itself, there is every reason for believing that his accusation would never have been made.

THE NEW WEIGHTS AND MEASURES ACT.

In other trades besides that of the chemist and druggist the new Act appears to be causing inconvenience, and one of the most recent illustrations of the fact is mentioned in the *Daily News* of last Thursday. The trade in oil has hitherto been carried on with the aid of a measure recognized as the five gallon measure, and oil is exported to a very large extent in five gallon tins. Some few wholesale firms in London are alone said to export no fewer than a million gallons of oil annually in such tins, independently of the Liverpool trade and that of other places. This five gallon measure, however, is not comprised among the secondary standards sanctioned by the Board of Trade, and as a consequence two well-known wholesale firms have been proceeded against under the new Act for using in their trade a measure of which there is no recognized Board of Trade standard, although it is the measure which by common usage of the trade has always been adopted.

A letter from Messrs. McIntyre and Sons, the manufacturers of graduated glass measures, which appears at page 600, will give some idea of the trouble and perplexity that chemists and druggists may have to encounter from the local inspectors' varied interpretation of the new Act. We think that it will not require much sagacity to perceive in the statements made by Messrs. McIntyre ample grounds for regarding this subject of weights and measures as one of special importance to chemists and druggists. It would, we think, be very unwise to look upon the Act in its bearing upon apothecaries' weights and measures as being likely to remain a dead letter, though we are aware this is believed by some persons to be possible. For this reason we have deemed it our duty to mention the subject from time to time so as not to lie open to the charge of having failed to furnish desirable information.

At the last meeting of the Council the preponderance of opinion was in favour of memorializing the Board of Trade in regard to the practical working of the Act as it relates to chemists and druggists' weights and measures, and we have reason to believe that a definite understanding is likely to be arrived at.

THE CHEMISTS' BALL.

The Fourteenth Annual Ball, held at Willis's Rooms on Wednesday last, far from showing any signs of flagging interest, surpassed nearly all its predecessors in the number attending it, three hundred and seventy having been present. Although the company was so large, the excellent arrangements of the Committee were so admirably carried out by the Honorary Secretary, Mr. Arthur L. Savory, and his colleagues, as to secure the comfort of all. As on previous similar occasions only one toast was given, "Success to the Chemists' Ball," coupled with the Health of the Ladies. In proposing it, Mr. G. F. Schacht, Vice-President of the Pharmaceutical Society, remarked that it might add to the pleasure already experienced by those present to know that, in consequence of the success of the gathering, their attendance on that evening would probably provide the means of alleviating to some extent the distress of other members of the craft who had not been so fortunate as themselves.

THE CONSUMPTION OF CHLORAL.

Some of our readers probably have observed in the medical journals a disposition to ascribe the misuse to which it is believed chloral is very largely put to undue facilities offered by chemists and druggists for its purchase. We would therefore suggest that a useful purpose would be served by the communication of observed facts as to the demand for chloral and the conditions under which it is procured by purchasers, as well as information of any cases in which its use has been attended with fatal results. The Committee of the Clinical Society of London has already taken some steps in this direction.

FIRE AT NEWCASTLE.

A very destructive fire broke out, on Saturday last, in the warehouse of Messrs. Mawson and Swan, as the consequence of breaking a bottle containing some volatile inflammable liquid. The whole block of buildings, extending back from Mosely Street, has been destroyed, together with the contents, and the damage done is estimated at something like fifteen thousand pounds.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The Annual Dinner of this Association will be held at the Holborn Restaurant on Wednesday evening, January 28, at 8·30 p.m. precisely; Professor Redwood in the chair.

We observe that Mr. Robert Gibson, medicated lozenge manufacturer, entertained over two hundred and forty friends and workpeople to dinner, in the Hulme Town Hall, Manchester, on the evening of January 15, in celebration of his silver wedding.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Wednesday, January 1, 1880, the report of the College of Preceptors on the examination held on January 6, was received.

Three hundred and three candidates had presented themselves for examination, of whom *one hundred and seventy-one* had failed. The following *one hundred and thirty-two* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically).

Ansell, Alfred ....Birkdale.

Hull	6	2	4	Worcester	2	1	1
Inverness	2	1	1	York	5	3	2

The questions for examination were as follows:—

Time allowed: Three hours for the three subjects.

I. LATIN.

1. Translate the following passages into English:—

A. Id ne accideret magno opere sibi præcavendum Cæsar existimabat. Namque omnium *rerum quæ* ad bellum usui erant summa erat in eo oppido facultas, idque natura loci sic muniebatur ut magnam ad ducendum bellum daret facultatem, propterea quod flumen Alduasdubis ut circino circumductum pæne totum oppidum cingit; reliquum *spatium*, quod est non amplius pedum DC qua flumen intermittit, mons continet magna *altitudine*, ita ut radices montis ex utraque parte *ripæ* fluminis contingant.

B. Multo denique *die* per exploratores Cæsar cognovit et montem a suis teneri et Helvetios castra movisse, et Considium *timore* perterritum quod non vidisset pro viso sibi renuntiasse. Eo die quo consuerat intervallo hostes sequitur, et *milia* passuum tria ab eorum castris castra ponit.

2. Parse the words in Italics in the above extracts.

3. Decline the nouns *res*, *flumen* and *opus*, and give the first person singular of the present and perfect indicative, the present infinitive, and the supine of the verbs *sequitur*, *daret*, *contingant* and *moveri*.

4. Translate the following sentences into Latin:—
   (i.) The town is surrounded by a broad river.
   (ii.) The mountain is held by the forces of the enemy.
   (iii.) The scouts report to Cæsar that there is great abundance of everything in the town.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

5. A gentleman's income last year was £685, out of which he saved £274 7*s*. 6*d*. What was his average daily expenditure?

6. Multiply the sum of $\frac{3}{5}$ and $\frac{5}{6}$ by their difference, and divide the product by $8\frac{3}{5}$.

7. Reduce $6\frac{1}{2}$ guineas to the decimal of £5.

8. If the carriage of 60 cwt. for 20 miles cost £14 10*s*., hat weight can be carried 30 miles for £5 8*s*. 9*d*.?

9. What is a *metre*,. a *litre*, and a *gramme*? What is the proportion between a litre and a gallon? Reduce 2 *miles* 3 *furlongs* 15 *yards* to metres, etc.

III. ENGLISH.

10. Define what is meant by an Adjective, a Verb, an Adverb, and a Preposition.

11. The words *after* and *before* may be used as *adverbs*, as *prepositions*, and as *conjunctions*. Give sentences illustrating each of these uses.

12. Correct the following sentences, giving your reason in each case:—"I do not know who to blame." "He is older than her." "Nor want nor cold his course delay." "John as well as Thomas are to blame."

13. Parse fully each word in the following sentence:—
"Words are like leaves, and where they most abound,
Much fruit of sense beneath is rarely found."

14. Write a short composition on one of the following subjects:—"Intemperance," "Fashion," "The Drama," "Great Cities," "The Endowment of Research," "Universities."

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifteenth conversazione of the Liverpool Chemists' Association was held at the Royal Institution on Thursday evening, January 15.

The proceedings opened with a very excellent musical entertainment, kindly undertaken by Mr. Charles Sharp, after which the meeting adjourned to the museums, where microscopic and other objects of scientific and general interest were exhibited, manufacturing processes conducted, and scientific demonstrations given.

The following members of the Microscopical Society of Liverpool and other gentlemen exhibited objects of interest by the aid of powerful microscopes:—

T. F. Abraham, Animal Sections, etc.; H. C. Beasley, Sections of Igneous Rocks; G. F. Chantrell, Low Forms of Animal Life; M. Conroy, F.C.S., Arrowroot and other Starches; J. H. Day, Sections of Wood, Coal and Fossil Wood; E. Davies, F.C.S., Vegetable Sections and Coal; A. E. Fletcher, F.C.S., Crystals under Polarized Light; I. Fisher, Volvox Globator; Dr. Hicks, the Circulation in a Frog's Foot; A. H. Mason, F.C.S., Physiological Specimen of Human Eye, Lung of Snake, Microphotographs, etc.; Dr. Symes, Acari in Powdered Cantharides; J. Vicars, Diaptomus Castor (alive).

The following exhibits and demonstrations were held in the various spacious rooms of the building at intervals during the evening:—

The Manufacture of Artificial Fruit Essences practically illustrated, by Michael Conroy, F.C.S., Hon. Sec.; Process for Continuous Extraction, in Operation, Dr. Symes; Works of Art, in Repousse Silver and Bronze, and also of Cloisonné Enamel of their own and Japanese Manufacture, Messrs. Elkington and Co.; a collection of Cinchona Barks, and a series of Alkaloids and Salts prepared therefrom, Mr. Thos. Whiffen, London; a "Dehne" Laboratory Filter Press in Action, Messrs. Van Gelder and Apsimon; a New Illuminating Apparatus, Messrs. Chadburn and Son; Photographic Transparencies, Mr. Jas. A. Forrest; a collection of Artificial Fruit Essences, Messrs. Evans, Sons and Co.; Complete Set of the Elementary Bodies, Dr. J. Campbell Brown; a series of Food Products, illustrating their different constituents, etc., Messrs. Southall, Brothers and Barclay; Views of Ancient Liverpool and Novelties in Photographic Art, Messrs. Brown, Barnes and Bell; Engraving and Lithographic Printing, etc., Messrs. Blake and Mackenzie; Glass Blowing, practically illustrated, Mr. Topham; the Manufacture of Cardboard Boxes, practically illustrated, Messrs. Ayrton and Saunders; Exhibition of a series of Tubes illustrating some of Mr. Crookes's researches on Radiant Matter, Dr. Symes, President; Exhibition of Geissler's Vacuum Tubes, illuminated, Mr. Alfred H. Mason, F.C.S., Vice-President; Melde and Lissagon's

Pendulum Curves, Mr. Alfred E. Fletcher, F.C.S.; Graphoscopes, Stereoscopes, etc., Messrs. Chadburn and Son; Graphoscopes, Stereoscopes, etc., Messrs. Knott and Co.; Graphoscopes, Stereoscopes, etc., Mr. Marr; Transformagoria, Mr. Boulding; Jewel Kaleidoscopes, Mr. J. Hallawell, jun. The Edison Loud Speaking Telephone was exhibited by the Edison Telephone Company and worked in connection with different parts of the town. Mr. Edison's representative was in attendance.

At 8·30 the chair was taken in the lecture theatre by the President, Dr. Symes, when Mr. Edward Davies, F.C.S., F.I.C., etc., delivered a popular lecture on "Gases and Vapours."

Mr. Davis delivered the lecture in his usually lucid and instructive manner, and delighted his hearers by many beautiful and rare experiments; those bearing upon the influence of pressure on vaporization, the spheroidal state of water, and freezing water in a red hot crucible, being very successfully shown.

After the lecture,

Mr. James Birchall exhibited, by means of the oxyhydrogen light, nearly fifty photographic views of town halls, churches, and other buildings of historical interest, in the chief cities of Belgium, including Liége, Ghent, Bruges, Louvaine, Ypres, Courtrai, etc., accompanying each with an interesting brief description.

During the evening the band of the First Lancashire Artillery Volunteers, by permission of Major Grayson, attended and played several selections.

Refreshments were served in the library and the committee-room.

The whole of the proceedings passed off in a very satisfactory manner, and the meeting broke up at half-past ten.

NORTHAMPTON PHARMACEUTICAL ASSOCIATION.

A supper in connection with the above Association was held on Wednesday evening, January 14, at Franklin's Restaurant, Guildhall Road. The Chairman of the Society, Mr. J. Lewis; the Vice-Chairman, Mr. G. C. Osborne, and all the members with some friends were present.

After supper, the first toast the Chairman proposed was, "The Health, Happiness and Prosperity of the late Chairman, Mr. G. C. Druce," who had during the past year left the town. This was drunk with enthusiasm, all present feeling that they had lost, not only an able chairman, but an efficient and willing conductor of various classes. The next toast was "The Prosperity of the Northampton Pharmaceutical Association," to which the Vice-Chairman responded. In the course of his remarks he stated that the attendance at, and the interest taken in, the Botany Class which he himself conducted, had been fairly good, and he expressed the hope that the classes would be kept up in full vigour till the end of the session. The Chairman then proposed "The Healths of the Conductors of the Chemistry and Materia Medica Classes, namely, Messrs. Hayllar and Slater, both of whom briefly responded. Various other toasts, songs and recitations followed and an enjoyable evening was spent.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, January 15, Mr. Warren De La Rue, President, in the chair. The following certificates were read for the first time:—A. Lloyd, P. Mathews, G. H. Morris, H. F. Pasley, A. G. Salamon, E. Wilcock, W. H. Wood.

The following papers were read on—

The Effects of the Growth of Plants on the Amount of Matter removed from the Soil by Rain. By J. H. Prevost. —The soil used was taken from a plot of ground which had been richly manured with stable manure and ashes in October, 1878. It was placed in two glazed earthenware pans, the depth of soil being 3 inches; the surface exposed was 17 inches in diameter. The drainage water was collected and muslin covers tied over the pans. Each pan contained 4300 grms. of soil. In one was sown 4 grms. of white clover seed, the other was left blank. The seed was sown on July 21, and the two pans exposed till October 4. The clover plants had grown up, but had not flowered. The drainage from the clover soil contained 48·125 grains per gallon; that from the blank pan amounted to 220 grains per gallon. These residues were analysed. The author states that it is impossible from the meagre data in hand to draw any definite conclusions except that the results do not very widely differ from those Dr. Voelcker obtained with the drainage from a wheat crop; the principal points of interest being that rain removes much more matter from a soil containing no plants than from one which is cropped, and that the proportions in which the salts are removed do not greatly differ. Further researches are promised.

Mr. Warington said that the method of investigation just described was at one time much used in Germany. It was, what might have been anticipated, that the loss on a cropped soil would be much less than on an uncropped soil. This had been abundantly proved by the experiments of Rothampstead. Many striking results had been obtained during the past wet season. The best advice to give to farmers was that if they wished to prevent loss of the constituents of the soil, they should always keep a crop on it. He had noticed that Dr. Prevost had found phosphoric acid in the drainage. This was exceedingly unusual, as in most cases all was retained. It might be accounted for by the small depth of soil. The soluble organic matter required much investigation.

Mr. Wynter Blyth then described a simple apparatus for the treatment of substances in open dishes by volatile solvents. It consisted of a circular cast-iron pan of suitable size, open at the top; the bottom was not flat, but pushed up in a dimple like the bottom of a wine bottle. The evaporating dish was placed inside and covered by a glass bell jar, the edge of which rested in the circular trough formed by the projecting dimple. Mercury is poured in until the edge of bell jar is covered and thus an air-tight mercury joint formed. To the upper end of the bell jar is fitted a condenser, which may be vertical and return the condensed liquid to the dish or horizontal if evaporation is desired. The author had used such an apparatus with great convenience for more than twelve months, the escape of vapour being thus completely prevented. The apparatus was exhibited.

The next paper was read by Mr. W. H. Perkin on—

Dibromanthraquinones.—Graebe and Liebermann give two processes for the preparation of dibromanthraquinone; one by brominating anthraquinone; the other by oxidizing tetrabromanthracene. These processes yield, however, two different products, which are isomeric; they are named by the author α and β dibromanthraquinone. The α body is prepared by heating bromine with anthraquinone; it crystallizes from naphtha in flat needles; it is nearly insoluble in alcohol and fuses at 245° C. The β isomer is prepared by boiling tetrabromanthracene with chromic acid, dissolved in a large excess of glacial acetic acid, for some time. On recrystallizing six or seven times from naphtha, the body was obtained in needles fusing at 275° C., quite different from the crystals of the isomeric α substance. The substance is soluble with difficulty in alcohol. The author then studied the action of caustic alkalies on these two substances. In both cases alizarin (identified by its dyeing properties, its spectrum and by analysis) was obtained. The decomposition of the α body furnished, besides alizarin, a colouring matter somewhat resembling alizarin; it dissolves in alkalies with a blue-violet colour, and its alkaline solution is precipitated by lead acetate. It has, however, no dyeing properties. Its absorption spectrum gives two weak bands. It is not quinizarin nor anthrapurpurin, and may be a dioxyanthraquinone with the hydroxyls in the same position as the bromine in the dibromanthraquinone. A small amount of another colouring matter seems to be present, dyeing mordants. The author is at present engaged in the study of these substances, the quantity prepared in the present research being too small for a complete investigation. The author then discusses the formation of the same dioxyanthraquinone from the two isomeric dibromanthraquinones. In the case of the β compound, as no secondary colouring matter seems formed, the reaction is:—

$$C_6H_6\genfrac{<}{}{0pt}{}{CO}{CO}\!>C_6H_2\genfrac{<}{}{0pt}{}{Br}{Br}+2KHO=$$

$$C_6H_6\genfrac{<}{}{0pt}{}{CO}{CO}\!>C_6H_2\genfrac{<}{}{0pt}{}{HO}{HO}+2KBr.$$

In the case of the β isomer, probably bromomonoxyanthraquinone is first formed, the further action of potash produces bromalizarin with the liberation of hydrogen, which attacks the bromine and removes it as hydrobromic acid, and thus alizarin is formed. Probably, too, a certain amount of destruction takes place between the potash and the alizarin, some hydroanthraquinone being formed. At the end of the paper the author states that he has recently examined Auerbach's original paper on isopurpurin, and concludes that that substance, from the properties given, is a mixture of flavopurpurin and anthrapurpurin; the former substance preponderating. Isopurpurin is not, therefore, identical with anthrapurpurin as has been stated by the author of the present paper.

The Secretary then read a paper on—

The Melting and Boiling Points of Certain Inorganic Substances. By T. CARNELLY and W. CARLETON WILLIAMS.—The authors have determined the melting points of various substances by the specific heat method (*Chem. Soc. Jour.*, 1876, i., 489). The list includes tellurium, with its chlorides and bromides, cuprous bromide, etc. The boiling points were determined by the method described in *Chem. Soc. Jour.*, 1878, Trans. 281. The melting points of silver and copper have been recently re-determined by Violle, and in consequence, some corrections have been necessitated in the last paper of the authors (*Chem. Soc. Jour.*, 1879). The authors point out that in the mercuric compounds the melting point sinks and the boiling point rises with an increased molecular weight, the reverse is the case with cuprous compounds, thus:—

		Chlorides.	Bromides.	Iodides.
Mercuric	melting point	287	244	241
	boiling point	303	319	349
Cuprous	melting point	434	504	601
	boiling point	954	861	760

Mr. WARINGTON then contributed some notes on—

Some Practical Points connected with his Laboratory Experience.—The first point considered was the modification proposed by Dr. Frankland, some time since, as a substitute for the steel blocks which form the air-tight connectors between the laboratory and the measuring tubes in the gas apparatus. It will be remembered that Dr. Frankland causes the measuring tube to end in an upright funnel in which fits roughly a conical stopper, which terminates the laboratory tube. The joint was made tight by a piece of sheet indiarubber tied on the lower end of this conical stopper, the indiarubber being turned back, applied to the sides of the funnel and the joint covered with mercury. This modification the author has found extremely convenient; one difficulty was the constant wearing out of the indiarubber. This was traced to its rubbing up and down, as it was not absolutely fixed on the stopper. By tying the indiarubber above as well as below the stopper, this difficulty has been obviated and the rubber lasts many months instead of a week. The author strongly recommends the coating of laboratory benches, mercury troughs, etc., with paraffin. The wood is made quite hot by a Bunsen flame or in an oven and the paraffin rubbed in. Thus the wood is completely protected from the action of acids. In the determination of nitric acid by Frankland's process, the author has observed that the action is often incomplete when the attack on the mercury is feeble; by adding a drop of dilute hydrochloric acid the reaction is always vigorous and the results good. Diphenylamine solution in strong sulphuric acid forms a magnificent blue coloration in the presence of a trace of a nitrate. The author has thus detected $\frac{1}{1000}$ of a milligram of nitrogen as nitric acid. The absence of other oxidizing agents must be secured.

The Society then adjourned to February 5.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, the 8th inst., Mr. H. Allen, Vice-President, in the chair.

The Secretary read the following paper on—

THE ANALYSIS OF STEEL.

BY WYNDHAM R. DUNSTAN, F.C.S.,

Assistant Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

Steel differs from pig iron in its percentage of carbon, its property of welding and its higher melting point, steel melting at a temperature of 1800° C. and pig iron from 1400 to 1600° C. It is distinguished from wrought iron by its fusibility and larger proportion of carbon. Steel is further characterized by its softening at a red heat and its property of becoming hard and brittle by sudden cooling. These properties depend upon the proportion of carbon present and on the presence or absence of other substances. It is not my intention, this evening, to treat of the manufacture of steel, but of its analysis; I may say, however, that most of the steel in commerce is produced by one of the three following processes: (1) The cementation method, consisting in the addition of carbon to malleable iron; (2) the Siemens-Martin method, by the solution of malleable scrap iron in molten pig iron; (3) the Bessemer process, as improved by Mushet, consisting in the oxidation of the carbon and silicon of the pig iron by blowing air through the molten metal and the subsequent addition of an iron containing a large proportion of carbon to bring the iron back to the composition of the steel required.

The steel made by any of these processes should contain from 98 to 99 per cent. of iron. Carbon might exist in it in two forms, (1) as uncombined carbon or graphite, of which a good steel should contain a very small proportion, the best steel containing none; (2) the carbon existing as carbide of iron, generally known as combined carbon, the proportion of which determines in a great measure the quality of the steel. A small amount of carbon, from 0·8 to 0·05 per cent., renders the steel more difficult to fuse, and a larger amount, from 1·0 to 2·0 per cent., facilitates the fusibility but decreases its tenacity and weldability. Phosphorus is an important element in steel; the proportion should be as small as possible, as little as 0·1 per cent. rendering it "cold short" or unworkable at ordinary temperatures. From this will be seen the importance of the recent discovery of Messrs. Thomas and Gilchrist, that by substituting a lining of magnesian limestone instead of a silicious lining for the Bessemer converter the phosphorus is almost entirely eliminated. Silicon is an ingredient which should not exist in large quantities in the steel; 0·5 per cent. renders the steel "red short" or unworkable at a red heat. Silicon is considered a necessary constituent of hard steel to the extent of from 0·03 to 0·04 per cent. Krupp's cast steel contains 0·3 per cent. Sulphur is an element which exists in the best steel only to the extent of from 0·00 to 0·01 per cent.; 0·1 per cent. renders it red short, weldable at lower temperatures, but brittle. Copper should be entirely absent from good steel, as a very small amount renders it red short. Manganese is now universally considered a necessary constituent of steel; its probable virtue consists in its presence during the manufacture by combining with the silicon and sulphur, thus removing them. This view is confirmed by the fact that nearly all the manganese passes into the slag; 0·3 to 0·5 per cent. generally exists in the steel.

It will be seen that the determination of the amount of carbon, phosphorus, sulphur, silicon, manganese and copper is very important, and from the small amount of the substances present the accurate analysis of steel is one of the most difficult and delicate processes in chemical analysis. The steel must be reduced to a fine state of division before analysis, either by means of a hard file or by crushing in a steel mortar. The graphite is most easily and accurately determined by the method proposed by Tosh: 5 grams of the steel are dissolved in pure hydrochloric acid and warmed; the solution is filtered, the insoluble matter washed with dilute hydrochloric acid until the filtrate ceases to give any coloration with potassium ferrocyanide, then with a hot solution of sodium hydrate to remove silica, with boiling water, and finally with a mixture of alcohol and ether, as this residue often contains hydrocarbons. The insoluble matter is dried at 100° C., weighed, then ignited and weighed again, the loss is pure graphite, the residue may contain titanium and a mere trace of silica. This method gives results which compare very well. The total carbon is best estimated by Bromeis' modification of Regnault's method. The steel must be in very fine powder. A piece of combustion tube drawn out in the usual manner for organic combustions is first filled to about three inches with a mixture of equal parts of lead chromate and previously fused potassium chlorate. Three grams of the steel are mixed with lead chromate, previously incorporated with 16 per cent. of fused potassium chlorate, and the mixture introduced into the tube, then finally some pure lead chromate. A calcium chloride tube and previously weighed potash bulbs are then attached. The lead chromate is first heated to redness, then the mixture containing the steel, which when it is at a red heat burns with incandescence, all the carbon being oxidized to carbonic anhydride; finally, the mixture at the end of the tube is heated, which drives forward any remaining carbonic anhydride. I have obtained accurate results with this process; two combustions of the same steel gave respectively 1·5 and 1·6 per cent. of total carbon. Fresenius recommends that a weighed portion of the steel be dissolved in dilute sulphuric acid and the gases evolved passed over red hot cupric oxide; the carbonic anhydride produced, after drying through calcium chloride, is absorbed by solution of potassium hydrate and weighed. This only gives the combined carbon, as when steel is dissolved in hydrochloric or sulphuric acid the formerly combined carbon unites with the nascent hydrogen and forms hydrocarbons, the graphitic carbon remaining behind; this is either treated as I have described under graphite or burned in a stream of oxygen, the resulting carbonic anhydride being absorbed by potassium hydrate solution. This amount added to the former gives the amount of total carbon in the steel. The presence of hydrocarbons in the residue of graphite, as I have before noticed, renders the process untrustworthy for the estimation of the combined carbon only. The process for the estimation of combined carbon which is most commonly employed in commercial analysis is that proposed by Eggertz. It depends upon the fact that when steel containing combined carbon is dissolved in nitric acid a soluble brown colouring matter is produced, the intensity of which varies with the amount of combined carbon present. By dissolving the same weight of two different kinds of steel in nitric acid and diluting till both colours are alike, the steel containing the largest amount of combined carbon will yield the largest amount of liquid, the proportion of the volumes indicating the relative proportion of carbon in the two steels. If then the amount of carbon in one sample of steel be known the amount in another sample can be determined by this process. An ordinary piece of bar steel is obtained and the amount of total carbon determined by combustion, several combustions being made and the mean taken; the graphite is then determined by the method of Tosh and deducted from the amount of total carbon; this gives the amount of combined carbon present in the steel. This sample, the carbon in which has been determined thus, is kept as a standard steel, portions of which must be filed off from time to time as required. A tube sealed at one end and of the same bore as a graduated tube, so that a given quantity of liquid stands at the same height in both tubes, must be obtained, and some pure nitric acid having a specific gravity of 1·20. Nitric acid of this strength and at the temperature followed in the experiments yields with iron containing no combined carbon a solution of ferrous nitrate of a greenish colour. A decigram of the standard steel and the same quantity of the steel under examination is weighed out and placed in two test tubes with from 1·5 to 3 cubic centimetres of the nitric acid, and after a short time both are placed in a water-bath at a temperature of 80° C. for about two or three hours; if any residue is then left the supernatant liquid is poured off and the residue treated with more nitric acid until nothing more is dissolved. The solution of the standard steel should be poured into the graduated tube and diluted so that every cubic centimetre corresponds to 0·0001 gram of carbon, thus if the standard steel contains 1·55 per cent. of carbon the solution must be diluted to 15·5 cubic centimetres and then poured into the ungraduated tube; a mark should be made on this tube indicating 15·5 cubic centimetres. The solution of the other steel is then poured into the graduated tube and diluted with water until the colour appears the same as that of the standard upon placing them in front of a piece of wet blotting paper and holding in front of a window; by this means the changes in colour can be viewed without difficulty. The number of cubic centimetres the solution of the steel occupies when the colours are the same indicates, after division by ten, the percentage of combined carbon in the steel. If, for instance, the solution stood at 9·5 cubic centimetres the steel contains ·95 per cent. of combined carbon. This process is quick and, provided the necessary materials are at hand, easy of manipulation, so that twenty analyses of combined carbon per diem may be made with ease. To facilitate the working of the process it has been proposed to imitate the colour produced by the standard steel by various substances having a similar colour, as a solution of coffee in alcohol, caramel, etc., but the most satisfactory way is to take 0·1 gram of the standard steel for each analysis.

Phosphorus being present only in small quantities in steel, and as a small difference in the percentage makes an appreciable difference in the quality of the steel, its estimation must be conducted with great care. Tosh's process is to dissolve three grams of steel in aqua regia, evaporate the solution to dryness, dissolve in hydrochloric acid and filter off insoluble matter. The iron, which is now in the ferric state, is reduced to the ferrous state by heating with excess of sodium sulphite; sulphurous acid is driven off by heating, a little ferric chloride added and then solution of ammonium carbonate until a permanent precipitate is produced. This precipitate, which is small, contains all the phosphorus as ferric phosphate; it is filtered off and, after washing, dissolved in a small quantity of hydrochloric acid, citric acid added and the phosphorus precipitated as ammonio-magnesium phosphate. This process is quite accurate and generally reliable. Abel dissolves the steel in warm nitrohydrochloric acid, evaporates to dryness, expels the nitric acid by excess of hydrochloric acid and again evaporates to dryness. The residue is dissolved in hydrochloric acid, diluted and filtered, nearly neutralized with ammonium carbonate, the iron reduced as in Tosh's process by ammonium sulphite and subsequent expulsion of the sulphurous acid by heat after acidifying the solution with dilute sulphuric acid. Amonium acetate and a small quantity of ferric chloride are added and the solution boiled; all the phosphorus is precipitated as basic phosphate and acetate. The liquid is quickly filtered, washed once with boiling water, dissolved in hydrochloric acid, neutralized with ammonium carbonate, a mixture of ammonium hydrate and sulphide added and the solution warmed. By this means the phosphate of iron is decomposed, the iron remaining as a precipitate of sulphide, which is filtered off and washed with dilute ammonium sulphide solution, all the phosphorus passing into the filtrate, which is precipitated in the usual manner with magnesia mixture. The process which I have been in the habit of employing is to empty two grams of the steel into a capacious beaker containing about one ounce of hot nitric acid. When all action has ceased the solution is evaporated to a low bulk, hydrochloric acid added to expel all the nitric acid and the solution evaporated to dryness, dissolved in hydrochloric acid, filtered to remove silica, and evaporated to low bulk with nitric acid; twenty cubic centimetres of ammonium molybdate solution prepared by Eggertz's method are then added and the solution allowed to stand in a warm place for twenty-four hours. The precipitate is filtered off, washed with a mixture of the ammonium molybdate solution and water, dissolved in ammonium hydrate, tartaric acid added (in case any traces of iron should be left in the precipitate), then magnesia mixture. This process gives results which compare very well and eliminates most sources of error.

Sulphur is estimated by taking ten grams of the steel, which is emptied into a hot mixture of two parts of hydrochloric acid and one part of nitric acid. When all action has ceased the liquid is evaporated to dryness, dissolved in hydrochloric acid, filtered, the filtrate diluted with water and nearly neutralized with ammonium hydrate, barium chloride added, the solution warmed, and allowed to stand twelve hours. The barium sulphate is filtered off and washed with dilute hydrochloric acid and hot water. Eggertz estimates sulphur by dissolving the steel in sulphuric acid and exposing a silver plate to the action of the gases evolved, the colour produced being compared with standard coloured plates. Sulphur may also be estimated by dissolving ten grams of steel in concentrated hydrochloric acid and passing the gases evolved through a solution of lead acetate acidified with acetic acid. The lead sulphide is washed, heated with nitric acid, and when cool sulphuric acid added, the solution evaporated until fumes of sulphuric anhydride appear, diluted with water, and the lead sulphate collected and weighed.

Silicon is estimated in the filtrate from the graphite estimation by evaporation and dissolving the residue in hydrochloric acid and treating it in the usual manner. Sometimes it occurs that slag has become incorporated with the metal and therefore the silicon results would come out too high. Eggertz dissolves the steel in bromine which does not attack the slag, but separates, of course, the silicon from the iron. Sodium carbonate dissolves this latter variety of silicon but has no effect on the former. Slag in English iron rails was found by Eggertz to be often from 4 to 5 per cent. In finished steel and cast steel, however, it rarely occurs.

Manganese is estimated by dissolving two grams of iron in hydrochloric acid, a small quantity of nitric acid is added, the solution warmed, so as to convert the iron into the ferric state, and neutralized with ammonium hydrate so that it shall be cloudy. A saturated solution of ammonium acetate is then added and the solution boiled, when the iron is completely precipitated as basic iron acetate, which is collected on a filter and washed. The washings and filtrate are rendered alkaline with ammonium hydrate and a few drops of bromine added, the solution kept at a temperature of 50° C., and being allowed to remain at that temperature for twelve hours; the hydrated oxide of manganese is collected on a filter, dried, ignited and weighed as Mn_3O_4. Formerly sodium or potassium salts were used throughout the above process, but it was found that after ignition the oxide of manganese had an alkaline reaction due to the presence of sodium hydrate. Wright and Menke* have shown that the oxide of manganese precipitated by bromine in presence of potassium acetate, after drying, contained 11·87 per cent. of K_2O.

Copper is estimated by dissolving thirty grams of steel in hydrochloric acid, partially neutralizing with sodium carbonate, evaporating to low bulk, passing sulphuretted hydrogen, dissolving the precipitate and estimating the copper by the colorimetric method, if only a small quantity is present.

After a discussion on the above, paper the Chairman called upon Mr. Arnold to deliver his Report on Pharmacy.

Suppositories.

BY H. R. ARNOLD.

The manufacture of these preparations is somewhat troublesome to the pharmacist, often involving much time and ending unsatisfactorily. This report will best be classed under three heads:—1st. A reference to the machines generally used; 2nd. The excipients, and 3rd. The manner of manipulating green extract suppositories.

The general way of making these preparations is to melt the excipients together at a gentle heat, then to add the active ingredients, and constantly to stir until the mixture is of the consistence of thick cream, then to pour it into metal moulds, previously cooled (more especially is this necessary if the mould be made of block tin).

These moulds are made in two pieces, the conical hollows occupying the junction, so that when the mass is cold they are easily opened and the suppositories turned out. Another form of mould has been devised and used by Mr. Gerrard, the mould opening as it were transversely, instead of longitudinally, as is the case with the other. Lastly, machines have been invented, but I believe not generally adopted, for making suppositories by pressure. Whether this method will ever supersede the old way of melting I would not venture to predict, though at present I fail to see the superiority of this new method over the old; at any rate with the excipients that are now in general use for suppositories. Suppose, for instance, we wish to make some opium suppositories:—First the ol. theobromæ has to be grated, and obtained in as fine a state of division as possible; then the powder or extract must be well mixed with it; and by the time this is done I think you will have come to the conclusion that it would have been better had the ol. theobromæ been melted and constantly stirred till cold; by this means a more homogeneous mass is obtained. The mass is now subjected to pressure. Regarding the appearance of suppositories made by pressure (using only ol. theobromæ as the excipient), they do not compare at all favourably with those obtained by the old process, the surface presenting several veins or patches of a lighter colour than the rest of the mass. This defect is not noticed so much with morphia and other light coloured suppositories, as with the darker ones, such as opium; if, however, the basis be altered by the substitution of wax and lard, so as to nearly resemble the B.P., these defects are remedied.

The excipients that have been proposed form time to time are vaseline, stearic and oleic acids, ol. theobromæ and 10 per cent. of cetaceum, and gelatine.

The B.P. basis is too soft, and I think the lard and wax might be left out with advantage.

---

* *Jour. Chem. Soc.*, Jan., 1880.

The following method answers well in making green extract suppositories. Rub the extract in a mortar with a little water to a thin paste, then having previously melted the ol. theobromæ, add it gradually to the extract, stirring well until it begins to thicken. Should the extract separate through the ol. theobromæ being too hot, the addition of a few drops of water will completely suspend it. The advantage of the method will be more evident in making suppositories containing morphia in combination with an extract, as the extract invariably separates upon the first addition of the oil, but the water easily solves this difficulty.

In making suppositories containing tannin, too much heat must be carefully avoided, or the tannin coagulates in a resin-like mass.

Lastly, of the many solutions that have been proposed from time to time for moistening the mould, none seem to answer so well as a solution composed of equal parts of sapo mollis and glycerine.

Mr. W. H. Symons, F.C.S., at the commencement of the discussion, exhibited several varieties of pessaries and suppositories prepared with various bases, cacao butter, gelatine, oleic acid and stearic acid, vaseline and paraffin, and by the various official formulæ, including those made in accordance with the 1874 Additions to the British Pharmacopœia. The suppositories had first been fashioned with the fingers, and then pressed into the ordinary mould. They exhibited the same appearance as those made by fusion, all had been kept for over two years and had undergone very little change, with the exception of a 5 grain socotrina aloes suppository three months old, prepared with the gelatine basis, which had become covered with a buff coloured incrustation. The advisability of using a small quantity of oleic acid as a solvent for alkaloids when prescribed in minute quantities, as in the case of atropin, was maintained. The advantage of using a thermometer marked at 130° F. for a stirring rod in the preparation of tannin suppositories as a means of preventing the agglomeration of the tannin, which takes place above the temperature indicated, was suggested. The speaker also explained an easy method of making suppositories and pessaries of extraordinary sizes. A cone of tin foil is made on a moderator lamp with wick-stick, or other suitable cone, the tin foil is strengthened by a paper cone, to which its apex is attached by sealing wax. The mould so made is then placed in any support, such as the mouth of a bottle, or in moist sand, and a proper quantity of the melted mass poured into it; the whole can then be floated on cold water until set, when the tin foil is stripped off. Specimens made by this method were handed round for inspection.

Mr. R. H. Parker thought that the best form of mould was that made of gun-metal, and opening on hinges from the suppositories in longitudinal section and fitted with a screw clamp. He thought that when tannin was used in suppositories a gelatine basis was inadmissible, although prescribed in the Skin Hospital Pharmacopœia. When melted with cacao butter it sometimes aggregated into pasty lumps; this was due to the access of water, either from the water-bath or from using an imperfectly dried specimen of tannin. In the latter case the difficulty was surmounted by avoiding a high temperature. The speaker had found that dry powdered tannin stirred into melted cacao butter at 212° F. for ten minutes, showed no sign of aggregation. He objected to extemporaneous drying of extracts. Many extracts, if not all, suffered more or less deterioration by continued exposure to a temperature of 180° to 212° F. Powdered extracts were perhaps unobjectionable if dried very slowly, in which case of course the heat was not extemporaneously applied. A much more homogeneous appearance was obtained by reducing the extract to thin creamy consistence with water and then rubbing down with the melted fat, which must be kept at a temperature of 100° F. The combination of tannin with aqueous extracts and cacao butter was easily managed by mixing the powdered tannins with one part of the fat and the extract *secundum artem* with the other, then stirring the two together. When atropin was ordered in pessaries the alkaloid should be carefully triturated with nineteen parts or other convenient quantity of very finely powdered sugar of milk in order to weigh small quantities conveniently. It was less objectionable than oleic acid, because it answered for both the theobroma and gelatine bases; in the former case the fat should be stirred till nearly cold, while in the latter it of course dissolved. Moreover, oleic acid unless present in an objectionably large quantity would not facilitate the measurement of small quantities of the alkaloid. When extracts were prescribed for bases, Mr. Parker thought that they were best manipulated as a pill mass, being divided by pressure on the pill machine; this produced cylinders that might be inserted into the ordinary mould, which should be dusted over with starch, the mass being finally pressed into shape.

The meeting then adjourned.

Parliamentary and Law Proceedings.

Prosecutions under the 17th Section of the Pharmacy Act.

At the Newcastle-on-Tyne Borough Police Court, on Thursday, January 15, 1880, before B. B. Blackwell, Esq. (Chairman), Alderman Robinson and J. Burrell, Esq., Mr. William Wright Brewis, grocer and patent medicine vendor, of 1, New Street, Newcastle, was summoned by the Secretary of the Chemists and Druggists' Trade Association of Great Britain, for contravention of the Pharmacy Act, 1868. He was charged, "That he did on January 12 last, at Newcastle-on-Tyne, unlawfully sell to Mr. W. F. Haydon, certain poison, to wit, 'Battle's Vermin Killer,' being a preparation of strychnine, in a certain packet, the cover of which packet did not set forth the name or address of the seller of the same. That the said sale was effected, the purchaser being unknown to the seller and not introduced to the seller. That the date of the sale, the name and address of the purchaser, and the name and quantity of the article sold were not entered by the seller in a book kept by him for that purpose, contrary to the statute in such case made and provided."

Mr. Henry Glaisyer, solicitor, Birmingham, appeared in support of the summonses. Mr. George Rowell, solicitor, Newcastle, appeared for the defence.

Mr. Rowell said he should advise his client to plead guilty, and simply address the bench in mitigation of the offence.

Mr. Glaisyer said he was instructed by Mr. Haydon, Secretary of the Chemists and Druggists' Trade Association of Great Britain, who laid the information, to prosecute the defendant for three offences under the 17th section of that Act. Three summonses had been issued, but as the defendant pleaded guilty, one statement of the facts would be sufficient. On the 12th of this month, Mr. Haydon purchased at the shop of the defendant, No. 1, New Street, in that borough, a packet of Battle's vermin killer. The packet in which this vermin killer was contained did not set forth the name or address of the seller, the purchaser was unknown to the seller, and was not introduced to the seller, and the formalities required by the Act as to the registration of the sale were not complied with by the seller. The article had since been analysed by Mr. Haydon and found to be a preparation of strychnine. Preparations of strychnine were added to part 1, schedule A, of the Pharmacy Act in December, 1869, as appeared by a notice published in the *London Gazette* of December 21, 1869.

Mr. Rowell said in this case he should ask the bench to impose a merely nominal penalty. His client was a grocer carrying on an extensive business in the town. Some little time before he had taken out a licence to sell patent medicines. By accident one of the articles, of which he then took into stock a very small quantity, was Battle's vermin killer. This was a well-known article sold hundreds of times every day in the way his client had sold it for domestic purposes, and not at all for medical purposes.

Chairman of the Bench: Your remarks as to this poison being sold in hundreds of cases in the same manner in which it has been sold by your client is not only no reason why your client should not be punished, but rather the contrary, and we must say that we are sorry to find from your statement that there are numerous instances in which the law has been broken and the public safety endangered. Every week, almost, there are persons poisoned by taking this vermin killer, and if your client reads the papers he must have seen these cases and he ought, therefore, to have been much more cautious as to its sale.

Magistrates' Clerk: Will you be satisfied with a conviction on one summons, Mr. Glaisyer?

Mr. Glaisyer: Yes; with the costs in all the summonses.

Mr. Rowell: One summons would have covered the whole charge.

Magistrates' Clerk: I am responsible for the summonses having been issued. I advised Mr. Haydon to take out three summonses as there were three distinct offences.

The magistrates conferred.

Chairman of the Bench: We have carefully considered this matter, Mr. Rowell. Your client is convicted upon the selling, that is, for having unlawfully sold this poison to a person a perfect stranger to him, and not introduced to him, without making any inquiries; that we consider the most important charge, and we convict upon that, and we fine your client 40*s.* and costs in that summons, but he must pay also the costs in the other two summonses.

At the Leeds Borough Police Court, on Friday, January 16, 1880, before W. Brace, Esq., Stipendiary, Hubert Murray, trading as a chemist and druggist, at 110, Kirkgate, Leeds, was charged: "That he did on the 29th day of October, 1879, at the said borough, unlawfully sell to W. F. Haydon, Secretary to the Chemists and Druggists' Trade Association of Great Britain, certain poison, to wit, oxalic acid, in a certain packet, the cover of which packet did not set forth the name of the seller of the same, contrary to the statute in such case made and provided."

The defendant pleaded guilty so far as selling the packet.

Mr. Glaisyer, who was instructed by the Secretary of the Chemists and Druggists' Trade Association of Great Britain, by whom the information was laid, said that on the 29th day of October last, Mr. Haydon went to the defendant's shop, No. 110, Kirkgate, Leeds, and purchased from an assistant, who gave the name of Backhouse, two pennyworth of oxalic acid. The packet was labelled "Oxalic Acid. Poison. Edward Boothman, Druggist, 110, Kirkgate, Leeds." The parcel was subsequently analysed by Mr. Haydon and found to contain oxalic acid. Oxalic acid was a poison enumerated in part 2, schedule A, of the Pharmacy Act. The defendant was wholly unqualified to sell poisons scheduled under the Act, not being a registered chemist and druggist; but he attempted to do so under cover of Boothman's name. Edward Boothman, a registered chemist and druggist, who formerly owned the business now being carried on by the defendant, had been dead some years. The defendant was the tenant of the premises at 110, Kirkgate, and he had been regularly rated for those premises and has paid rates for many years.

Mr. Haydon, Secretary of the Chemists and Druggists' Trade Association of Great Britain, deposed that on October 29, last, he went to the defendant's shop, No. 110, Kirkgate, when he purchased from the assistant of the defendant, who gave the name of Backhouse, two-pennyworth of oxalic acid, which he now produced, labelled, "Oxalic Acid. Poison. Edward Boothman, Druggist, 110, Kirkgate, Leeds." He subsequently analysed the contents of the packet and found it to be commercial oxalic acid. Hubert Murray, the defendant, was not qualified to sell such poisons, his name not appearing in the last published register of pharmaceutical chemists and chemists and druggists.

The Defendant: I am not a chemist, I admit that, but I thought I had done all that was necessary in carrying on my business by means of a qualified man.

The Stipendiary: Do you say your assistant is a qualified person?

The Defendant: He is not a registered chemist and druggist, but he has had a great deal of experience. We sell very little indeed of this oxalic acid.

The Stipendiary: In this case the defendant is charged with selling poison which is not labelled with the name of the seller.

The Defendant: It is labelled with Boothman's name and I am carrying on the business in Boothman's name.

The Stipendiary: That is so; but that is just what the law says you must not do. The full amount of the penalty appears to be £5; I shall order in this case that you pay a penalty of 50*s.* and costs.

The Defendant: Cannot you mitigate the penalty, your worship?

The Stipendiary: You do not appear to understand me. The full penalty is £5, and I have reduced it to half that amount. You must understand that every day you carry on this business you are trading in an illegal manner, and are liable to be sued for penalties for trading as a chemist without qualification.

The Defendant: Then what am I to do with my business?

The Stipendiary: You must obey the law or you will have the Pharmaceutical Society or some other body suing you for further penalties.

Poisoning by Morphia.

An inquest was opened at the Guildhall, Doncaster, on Wednesday, January 14, respecting the death of a woman named Leonora Hattersley, aged 30 years, which happened the previous night.

The Coroner (A. J. Shirley, Esq.) in opening the inquest said it appeared to him to be a very singular case, and he was sure would receive at the hands of the jury the attention it deserved. Deceased had lived at Brierley, near Burnsley. About sixteen years ago she went out of her mind, but recovered, remaining very weak, both bodily and mentally. About four years ago she suffered from melancholia, but recovered in about fifteen months, and ever since then she had been liable to fits and remaining prostrate. On Saturday and Sunday week she had two fits, Dr. Leak, of Hemsworth, being the attendant. Deceased had an uncle living at 32, Bridge Terrace, Doncaster, and on Monday afternoon she came with her sister on a visit. It appeared ever since her first illness deceased had been in the habit of taking morphia—sometimes he believed six draughts in one week, and sometimes as many as three draughts in one night, without medical advice. She had also had injections of morphia into different parts of her body, but not recently. On the same afternoon she arrived at Doncaster her sister went to Mr. Hopper's shop in Cleveland Street and obtained a sleeping draught, telling the man who supplied her that her sister was used to taking them, and she wanted a strong one. The deceased went to bed at 10.30 and had a tablespoonful of Hopper's mixture at 11. She, however, did not sleep until four o'clock in the morning, when upon her saying she thought she had had, or was going to have a fit, another dose of mixture was given to her, and in about two hours she dozed off and never awoke again, dying about eight o'clock the same evening.

Dr. Wilson was sent for, he arriving about seven o'clock in the morning, and he at once thought the case was one of morphia poisoning, and not a case of a person being in a fit. Mr. Walker, the house surgeon at the Infirmary, also saw the deceased, and would be able to give his opinion. He (the Coroner) mentioned the above facts thus carefully because they would have to inquire whether death was caused by fits or by an overdose of morphia. He must also mention that that was the second time within three months he had had to inquire into cases of that kind, and his predecessor held a similar inquiry shortly before his death. Not only was the question of the use of morphia and other narcotics local, but it was a matter which had been discussed in the *Times*, both by correspondence and an article which appeared on Monday. The Coroner here read extracts from the *Times* article, which deprecated the free use of morphia.

Caroline Hattersley, mother of deceased, said that during the last twelve years her daughter had suffered from epileptic fits. Three weeks before her death she was suddenly taking ill, but Dr. Leak did not express alarm, calling it hysterical croup. She had had sleepless nights, not being able to rest anyway. To facilitate her having rest draughts were brought which caused sleep for three hours at a time. She had morphia injected several times, but it was never used without the doctor's attendance. She had also suffered from neuralgia. The reason she came to Doncaster was to give her change of air and scenery. Witness was not with her when she died. They had got everything for her that could do her any good.

Sophy Hattersley, sister to deceased, stated that the doctor said the mental illness contributed to the bodily, but deceased always thought differently. Brandy was given as a stimulant, and chloral and morphia made into draughts for her. Morphia was injected into her arms about twelve grains (*sic*) at a time. The draughts she generally took previous to her death did not make her sleep very long. The last time morphia was injected was a year and a half ago, while at Scarborough. On Monday witness and her sister reached Doncaster about half-past two in the afternoon, and deceased then seemed rather excited. They did not bring any sleeping draughts with them. Dr. Leak had attended her twice during last year, a week ago being the last time. He then changed the medicine. Witness thought the first medicine contained iron. She was unable to continue the last medicine, as she became ill after taking a dose of it. On the night of Monday, January 12, witness went to Mr. Hopper's, Cleveland Street, and asked for a sleeping draught, saying "Let it be a strong one, as she has taken ten grains of morphia."

The Coroner here reminded witness that she must have misled the attendant, as the ten grains were injected, not inwardly consumed.

Witness resumed: The attendant said he would give her five grains, and told a little boy who was in the shop to hand him a bottle. Witness now said she told the chemist's assistant the ten grains of morphia were taken when the deceased had the neuralgia. The bottle was produced, and bore a label "Solution of Morphia. To be used with great care." There was also a notice underneath saying according to the Act of Parliament the mixture had to be labelled "Poison," although its composition remained unaltered. Deceased measured the dose herself by marks on the bottle. Nothing was said at the chemist's shop about the dose, and witness did not ask, as the bottle was the same one used previously. The sale was entered in a book, and witness signed her name. She never signed one before. When deceased went to bed she was restless and tossed about till four in the morning. The first dose was given at eleven, and another at four in the morning, but part of it was left in the glass, and she also spilled a little of the first one. After eleven deceased said either she had had a fit or was going to have one. She also vomited. The dose was not diluted with water. After the second dose she did not sleep for two hours, and was again sick. Witness persuaded her to try and sleep, and in a few minutes she seemed to go into a fit in her sleep, the same as witness had seen her do while at Scarborough. It was then between six and seven, and from that time till seven at night she seemed to be asleep. She had never been in a fit of such a length before, but during the past few weeks she had grown weaker. Her hands and lips were blue. Dr. Wilson was sent for about half-past seven in the morning. Deceased turned cold almost directly after going into the fit. Mr. Walker, of the Infirmary, was with Dr. Wilson.

William James McChesney, manager and assistant at Mr. Hopper's shop, Cleveland Street, said he remembered a female going to the shop about seven o'clock for a sleeping draught, and stipulating for ten grains of morphia. Witness told her he thought it was a great deal. In answer to the Coroner, he said he should think half a grain would kill a man. He asked her if she was sure she wanted morphia, or was it chloral hydrate. She replied she was sure it was morphia, as a medical man had told her so. Witness made her some up, saying it contained five grains each draught. He also explained to her that one draught would be ten times in excess of the maximum dose, and enough to kill several people. He did not tell her when to repeat it, as he thought it would not be used above once. He once made up a draught containing ten grains of morphia for a man, but he was since dead.

The Coroner: I should think so.

Witness: The sum of 1*s.* 6*d.* was paid for the bottle, which was a 6-ounce one. Morphia was extracted from opium. Witness was not himself registered. He put both labels on the bottle. Did not think the label saying its composition remained unaltered was liable to mislead people, by making them believe it was harmless. He particularly explained that not more than a teaspoonful was to be taken by an ordinary person. Witness produced the book, fully showing the sale and signed by the purchaser.

The Coroner here read the section of the Act, which said that no poison was allowed to be sold to any unknown person, or, if so, without being introduced by someone known to the seller, and their name also signed in the book.

Witness said he saw a young man, cousin of deceased, whom he knew, outside, but he did not go into the shop.

By the Foreman: I told the woman if she gave more than a teaspoonful it would be at a risk.

By the Coroner: The next morning Miss Hattersley went down to the shop and said they had had to call in two doctors. Witness told her he was very sorry, but he had used every precaution in his power by telling her how to use the medicine. She replied, "There must be some mistake. I believe I wanted chloral hydrate. I am entirely to blame myself."

Robert Tong, an errand boy in the employ of Mr. Hopper, who was in the shop when Miss Hattersley was supplied with the medicine, detailed the circumstances, and said that when Miss Hattersley went into the shop she said two doses had been given. No blame was laid on either party. Witness was in the shop all the time. He did not hear Miss Hattersley say, "It is my own fault."

Miss Hattersley, recalled, said she did not remember being cautioned, except by Mr. McChesney saying it was a large dose, and she said in answer she had been used to taking large doses. She did not remember any conversation about a spoonful. When she went on Tuesday morning to ask how many grains had been given she told the assistant Dr. Wilson's opinion was it was an overdose of morphia. The assistant said it was a strong dose, and seemed troubled, and witness told him he was not to blame.

Cross-examined by Mr. McChesney: I did not say I was entirely to blame. I said I did not think I wanted morphia, it must have been chloral.

In answer to a juror Mr. McChesney said there was no limit to the quantity of morphia which could be supplied.

The case was then adjourned to Monday, the 19th, the bottles meanwhile to be analysed by Mr. Allen, the borough analyst.

At the adjourned inquest on Monday afternoon, the following additional evidence was taken:—

Thomas Mallone Leak, physician and surgeon, of Hemsworth, said he had known the deceased, Leonora Hattersley, since she was born. Sixteen years ago he attended her for a bad attack of kleptomania. It was some time before she recovered, in fact it was in doubt whether she should not be sent to an asylum. In a few weeks, however, she recovered somewhat, but was always weak and ailing, mentally and bodily. Later on she suffered from neuralgia, dyspepsia, hysteria, and epileptic fits. She had continued in a like state up to the present time. He did not think he had attended her more than three times during the past year, once it was for neuralgia, and the last time for croup. He had an attendant named Hunter, who left eighteen months ago. He was quite certain that neither he nor his attendant had ordered her 10 grains of morphia. She had taken very little of it. He never recommended her to take morphia; if she wanted any, he gave it to her, but never told her to buy it. On looking into his books, he found she had not taken morphia more than three times, and not more than ½ a grain. If he was giving a dose, he should give from ⅛ to ½ a grain. It would be dangerous to give as much as 3 grains. When he supplied morphia, it was given in an ounce draught, but the strongest deceased ever took was ½ a grain. It was several years since she had morphia injected, about ⅛ of a grain, increased to a ¼ of a grain, not more. Neither by injection nor draughts had he or his assistant ever given her as much as 10 grains of morphia. He had given her hydrate of chloral, from June to July, 1878, in 15 grain doses. That was the ordinary dose, and would not be dangerous. He did not know she ever got any morphia or chloral at any chemist's shop. The last time he attended her was on Sunday, December 28, being called in for an attack of croup. He mixed some medicine for her, which he thought was consumed. He attended her after, and changed the medicine, as she had ceased to be feverish, and had had two epileptic fits. She was a person liable to go off at any time. Mr. Coleman recommended her coming to Doncaster. He (witness) knew the family, who were exceedingly respectable. He never saw anyone waited on before, as deceased had been.

By the Foreman: He did not remember anyone being able to take morphia in grains, but had known them take a quantity of laudanum tantamount to 5 grains of morphia.

By the Coroner: He did not know of bottles marked for teaspoons. The bottle produced was a 6-oz. bottle, and if he had sent it out he should have put on so much for a dose. It was impossible to say how much morphia anyone could take that had been used to it. 3 grains was dangerous for anyone to take at first, but one accustomed to it might take 5 grains.

By the Foreman: If he sent morphia he should put it in a bottle as a dose.

By the Coroner: Not on any account would he supply a bottle containing 30 grains. He did not know that a female was more susceptible to it than a male, but this woman would be very likely to suffer from it unless she had been in the habit of taking it unknown to him.

Dr. Wilson, physician and surgeon, said he was called to deceased. He was told she was subject to epilepsy, and that during the night she had had a fit. She was in a profound state of insensibility, and he could elicit no signs of consciousness whatever. He ordered various applications likely to rouse her and left. He was again summoned, and found his directions had been carried out, but still she had not recovered. Finding she was in a state of stupor deeper than she ought to be, he made inquiries. The sister went into the room and showed him a bottle, asking if it had anything to do with it, and he replied everything. Witness sent to the Infirmary for the galvanic battery and Dr. Walker. She died at 8 o'clock that night. He thought death was caused by morphia poisoning. He afterwards made a *post-mortem* examination. They found she was suffering from heart disease in a form not at all unlikely to cause sudden death. Epileptic fits sometimes cause death, but deceased did not show any symptoms.

William Walker, house surgeon at the Infirmary, was called in to see deceased. He had heard Dr. Wilson's evidence, and confirmed it. The body was well nourished, and was not at all emaciated,

By Mr. Claybourn: When he went it was too late to apply the stomach pump.

Sergeant John Thompson proved receiving two bottles, marked A and B, from the coroner. He took them to the public analyst, Mr. Allen, at Sheffield, with instructions to analyse them.

Mr. Allen, public analyst, said he received two bottles from Sergeant Thompson, and was told by him to search for narcotic poison. It was necessary to direct his attention to the point in question. He analysed the bottle marked A. It smelt of chloroform. He also found a preparation of iron, iodine, and a small quantity of morphia, but not more than ½ a grain to the fluid ounce. He did not examine that further, but analysed the bottle marked B, which he found to be a solution of morphia, containing about 5 grains of hydrochlorate of morphia to the fluid ounce. The bottle was divided into twelve parts, so that an ounce would be two divisions. When he received it, rather more than four divisions, or 2 ounces, had been used by someone. There was a little acid in the bottle. In the official authority, the Pharmacopœia, the maximum dose to be taken was ½ a grain, reckoning 4 grains to the ounce. There are 4 grains of hydrochlorate of morphia in a fluid ounce. He had analysed a bottle before containing 4 grains to the ounce, but never one so strong as that one. 1 grain of morphia was considered dangerous, and not more than ½ a grain should be given as a dose.

The Coroner, in summing up, said it was one of the most important cases they had had to consider for some time. It was only some months ago that a similar inquiry was held, and the jury then recommended that more care should be taken in dispensing medicines. The three things they had to consider, were, a case of poisoning; if it was by morphia poisoning; was there any negligence, and if so, on whose side. The Coroner concluded by saying that supposing the jury agreed that there had been negligence on the part of the druggist, was it so gross as to amount to criminal negligence; and if there had been criminal misconduct, it would be their duty to say so; if, on the other hand, they believed due care had been exercised, and that death had been caused by misadventure, it would be their duty to say so.

The jury then retired for about twenty minutes, when they returned the verdict that deceased died of morphia poison, by misadventure on the part of the sister, and gross negligence on the part of the druggist, but not so gross as to amount to criminality.

The Coroner said the verdict was an exceedingly proper one. The recommendation which was given at the last inquest had not acted in a salutary manner, and he was satisfied the druggist had not used the care he should have done.

The Coroner then reprimanded McChesney, telling him it might have been a much more serious affair. It was perfectly clear either that he did not give instructions to the sister, or she did not understand him. He hoped that in future McChesney would be more careful, as if again before a jury that fact would go hard against him. To the sister the coroner said he had no doubt she had been very kind and attentive to the deceased, but he would recommend her when she went again to a druggist's shop not to make a rash statement, and also to take care the druggist put full directions on the bottle.—*Doncaster Free Press.*

THE USE OF PATENT MEDICINES CONTAINING POISONS.

Last week Mr. St. Clair Bedford held an inquiry at the Westminster Sessions house, as to the death of Mr. Henry MacFarlane, aged 53 years, of 21, Coburg Row, Westminster, who died on Monday under somewhat mysterious circumstances.

Henry MacFarlane, the son, said his father was a horse dealer, and had been a sufferer from rheumatic gout for the past ten or twelve years. He had been in the habit of taking different patent medicines. He would always take a larger dose than was prescribed on the bottle. Witness got home at two o'clock on Wednesday, the 7th inst., and found his father had had a severe attack of the gout. The deceased told witness that "he had taken a jolly good dose of the tincture," but did not say the quantity. He then held up a 1-ounce phial labelled "Gout and rheumatic tincture." On Sunday morning the deceased complained of shortness of breath, and witness fetched Dr. Sylvester, who prescribed some other medicine. He did not get any better, and when Dr. Sylvester called on Monday morning the deceased was unconscious. The doctor then told the witness that his father was suffering from an effusion on the brain. The deceased remained insensible until his death, which occurred on Monday night.

Dr. Sylvester said he had no knowledge of the deceased previous to his being called to his residence. Witness made a *post-mortem* examination, and found excessive inflammation of the pericardium, with effusion of serum. The left ventricle of the heart was very much thickened, the aorta was diseased, and both lungs were full of serum. The abdomen and kidneys were very much contracted, and the latter were afflicted with Bright's disease of some years' standing. Death was due to Bright's disease and peritonitis.

The Coroner: Do you know the contents of the phial?

Witness: No; I do not know the contents, but if the tincture contains morphia or opium it would accelerate the death. He (witness) could certify the cause of death, but he would not like to swear that the tincture did not accelerate the death, because he thought it more probable that it had.

The jury, after some discussion, returned a verdict in accordance with the medical testimony.

POISONING BY LAUDANUM.

On Thursday, Jan. 15, Dr. Hardwicke held an inquiry at 2, Ingestre Road, Highgate New Town, as to the death of James Charles Mills, 24, who committed suicide on the previous Saturday. He was a salesman at Messrs. Ward and Crawley's, house furnishers, of Camden Town. In consequence of toothache he had been in the habit of taking laudanum for the purpose of procuring sleep. On Saturday morning he returned home, complaining of being very tired. After drinking a large quantity of laudanum, which, however, was supposed to be sherry, he went to bed, where a few hours afterwards he was found in an insensible condition. He gradually got worse, and died from poisoning by laudanum. The jury returned a verdict that the deceased committed suicide while of unsound mind.—*Times.*

WRONGFUL USE OF MERCURIAL POWDERS.

An inquiry has been held at Okehampton into the circumstances attending the death of Lilian Drew. It appeared from the evidence that the child while being treated for measles by a regular medical practitioner had had some powders administered to her by the advice of a nurse. Symptoms of salivation were manifested, and the child eventually died, and in the opinion of Dr. Walters death resulted from exhaustion produced by mercurial poisoning. It was admitted, however, by the medical witnesses that the powders might not have caused death, although they aggravated the symptoms. The jury returned a verdict that the death resulted from measles and other disorders, and requested the coroner to caution all persons not duly qualified to abstain from administering any drugs without medical advice.

Obituary.

Notice has been received of the death of the following:—

On the 5th of December, 1879, Mr. Henry Clairmont Lea, Chemist and Druggist, Hastings. Aged 76 years.

On the 15th of December, 1879, Mr. James Tennant, Chemist and Druggist, John Street, Pentonville, N. Aged 69 years.

On the 15th of December, 1879, Mr. Henry Huggins, Chemist and Druggist, Stansted. Aged 40 years.

On the 3rd of January, 1880, Mr. John Hartley Jennings, Chemist and Druggist, Burley Lawn, Leeds. Aged 52 years.

On the 6th of January, 1880, Mr. Edward James Evans, Chemist and Druggist, Llanybyther, Carmarthenshire. Aged 36 years.

On the 7th of January, 1880, at his residence, Rose Hill, Derby, Mr. Arthur Elijah Hughes, Chemist and Druggist. Aged 32 years.

On the 9th of January, 1880, at Malta, Mr. John Reginald Evans (of the firm of Evans, Sons and Co., Liverpool), of Wallace Bank, St. Michael's Hamlet, Liverpool.

On the 10th of January, 1880, Mr. Henry Limon, Pharmaceutical Chemist, Burgh-le-Marsh, Lincolnshire. Aged 48 years. Mr. Limon had been a Member of the Pharmaceutical Society since 1857.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[381]. I had the following prescription handed me last week to prepare. How should it be dispensed the second, third and fourth weeks? State quantity of iodide for those weeks:—

℞ Iodid. Potass	grs. 100.
Spirit. Ammon. Aromat. . . .	℥j.
Aq.	ad ℥xx.

℥j ter die sd.

The iodide to be increased ij per dose every week until 80 grains are taken each day.

Two chemists' assistants I have asked say the ij means double. For myself I think the physician means ij grains per dose. Which is right? J. H.

[382]. I should like to have the opinions of any of your readers as to what should have been given for last-mentioned article in the following prescription. The powders were for a child two years of age.

Scammony	24 grains.
Jalap	24 "
Grey Powder.	18 "
Powdered Antimony	18 "

Mix. Divide into six powders. JUNIOR.

[383]. What should be used when alum. sulph. is ordered in a prescription?

W. S.

---

[384]. Will some reader kindly say if the following prescription can be dispensed without separation? My customer informs me that it has frequently been dispensed in town without any separation:—

Tr. Valerian. Am. . . . . ʒij.
Ferri et Quin. Cit. . . . . ʒj.
Aquæ . . . . ad ℥viij.

Is the separation not due to the ammonia in the tincture?

Beta.

Correspondence.

Weights and Measures Act, 1878.

Sir,—As manufacturers of graduated glass measures, we have carefully read the reports of your meetings to learn all that was possible respecting the above Act.

We found that at the Evening Meeting of the Pharmaceutical Society on December 3, 1879, Mr. Greenish stated that he had four dozen and eight measures verified, for which the inspector charged halfpenny each. We have applied to the inspector for our district and he states his fees are *halfpenny* for *each line* on the measure. The President stated at the same meeting that he had been confirmed at the Standards Office in the idea that an 8 oz. measure might be graduated in ounces, half ounces and drachms, and that it was fully provided for in the Act that a 6 oz. measure should have graduations from half drachm up to full measure. We have been informed by our inspector that he will not verify either 6, 8, 12 or 16 oz., and no size above 20 oz. measures. The sizes that he will verify must be graduated quite different to the present method. A 4 oz. measure on the drachm side must have a line only at ½, 1, 2, 3, 4, 8 and 16 drachms, and no lines above the 16. On the ounce side the graduation would be the same as at present, excepting that the 1½ oz. line would be removed. According to his opinion also the 1 oz. and 2 oz. measures are to be treated similarly, no measure showing a line for 6 drachms—whilst the 20 oz. measure must have lines only at 1, 2, 3, 4, 5, 10 and 20 ounces, "only seven lines on each."

Can any of your numerous readers kindly inform us if our inspector is correct in his interpretation of the Act, as it seems very hard on all the chemists and druggists throughout the United Kingdom that their measures, although quite correct, should not pass the inspector through not being graduated as above? Can they also inform us if the use of "fl. oz." and "fl. dr." on each measure in place of the present symbols for fluid ounces and drachms is compulsory, also if it is a correct rendering of the Act to charge a halfpenny per line for testing, as, if so, it will cost fourpence halfpenny to verify a 4 oz. measure, there being nine lines on each? We also consider it very hard that all the grosses of graduated measures we have in stock should be rendered quite useless for home trade, through not being graduated in what we venture to call, as practical graduators, an awkward way. Dispensers, too, will frequently have to use two measures to get one quantity, say for instance, six drachms, besides hampering trade by so greatly increasing the cost. Finally, the present inspector only attends his office twice a week for three hours a day. How is he to verify the grosses of measures that we alone would require verifying?

J. H. McIntyre and Sons.

The Electric Light and Paper Carbons.

Sir,—The appearance in your issue of 17th inst. of the long letter on Edison's recent doings in electric lighting, prompts me to send you a note on this subject. It will interest many of your readers to know that as regards the use of paper carbons, the point now made most important by Mr. Edison or his friends, this versatile American has been forestalled by an English electrician and pharmacist. More than twenty years ago my friend and neighbour, Mr. Joseph W. Swan, expressed to me his conviction that incandescence lamps would ultimately prove better than the electric arc, and that carbon would probably be the best material to be rendered incandescent by the current. He worked for some time upon this subject, producing his carbons from paper and card, and I remember many years ago taking up one of his paper carbons under the impression that it was a piece of watch spring. It was of a steel grey colour, sonorous, and sufficiently elastic to bear slight flexure if carefully handled. With these carbons he obtained a beautiful and steady light, though not a durable lamp. They were used, as Edison has recently used them, enclosed in an exhausted vessel, and included in the voltaic circuit, but Mr. Swan's difficulties, like those which Mr. Edison is now experiencing, showed that to obtain and maintain a satisfactory vacuum was more important and more difficult than to produce carbon ribbons from paper and card. I am glad to add that Mr. Swan's recent experiments give promise of ultimate success, and that not far distant.

Grey Street, Newcastle. Barnard Proctor.

"Unknown to the Seller."

Sir,—The opinion expressed by the Wigan coroner, reported in the Journal recently, introduces another difficulty in connection with the retail trade and induces me to ask what is understood by the words used in the 17th section of the Pharmacy Act, 1868, "unknown to the seller," and "known to the seller." In large towns, where there is a class of operatives, these are so constantly removing that it is almost impossible to say more than you know them by sight, and this term can with great propriety be applied to others who have been occasional customers for years, when they required a simple medicine; and although I know that they do reside somewhere in the neighbourhood (perhaps under some officers in charge of the building), yet if they asked for Battle's vermin killer and took it with the intention of committing suicide, and did accomplish their purpose, according to Mr. Rowbottom I should have acted "carelessly" in supplying it.

Whilst admitting the necessity for due care in the sale of poisons, I cannot suppose that it was intended to fetter our business with such stringent restrictions as to make it almost impossible to carry on a retail trade.

Observer.

Errata.—On p. 572, col. i., line 22 from bottom, *for* "sulphate of lime" *read* "tartrate of lime." On p. 579, col. ii., at the end of the equation in Mr. Williams's reply to query 633, *for* "$4\,H_2O_4$" *read* "$4\,H_2O$."

H. B. L. B. (who should have sent his name and address). —It is not compulsory to pass an examination before practising as an analyst. The answers to your other questions would be so dependent upon circumstances of which we are ignorant that we cannot give them satisfactorily.

H. S. S.—See the article on Syrup of Lactophosphate of Lime in the number for the 10th inst., p. 544. For the preparation of ipecacuanha see the paper by Dr. Duckworth, on the "Pharmacy of Ipecacuanha," in vol. ii. of the present series of this Journal, p. 721.

"*An Apprentice.*"—A recipe for "inseparable lime juice and glycerine" has been given in the Journal for June 14 last, p. 1032, as well as in other places.

"*Quæro.*"—(1) Royle's or Garrod's 'Materia Medica and Therapeutics' would possibly suit you. (2) Proctor's 'Lectures on Pharmacy' or Parrish's 'Practical Pharmacy.'

"*French.*"—(1) *Petit Moniteur de la Pharmacie*, the office of which is at 6, Rue Gît-le-Cœur, Paris. (2) We cannot say, but possibly your object might be attained by the cautious use of a depilatory.

T. O. Owen.—See the communication on "Distilled Essence of Lemon," by Mr. J. Moss, published in the Journal for March 29 last, p. 798.

C. L. H.—Species laxantes St. Germain (Gray's Suppl.). —Senna leaves exhausted with spirit, ℥iv; elder flowers, ʒiiss; fennel seeds, anise seeds, āā ʒx. Weil cut and bruise them and mix together, and when dispensing add purified cream of tartar powdered, ʒvj.

Communications, Letters, etc., have been received from Dr. Downes, Messrs. G. Cormack, Macnaught Bros., Howie, Reynolds, Flynn, Eyre, Mallen, Williams, Umney, Miller, Junior, Mot Rekla, W. R.

"THE MONTH."

Cold frosty air and biting north-easterly winds are still the order of the day, and the ground seems too hard and dry to allow even the earliest flowers to burst through its frozen crust. Even the winter heliotrope is far behind in its appearance, and the christmas rose is rarely to be seen. At the time of writing, however, a specimen in bud of the *Helleborus fœtidus* has been forwarded by a Kentish correspondent. The small number of flower buds and the frost-bitten appearance of the leaves of this specimen show that winter has dealt hardly with it even in that favoured "garden of England."

In the Botanical Gardens at Regent's Park, the boldo tree is now in blossom; also, the winter's bark tree, whose handsome clusters of snow-white flowers contrast admirably with the dark green foliage. A species of eucalyptus and one of the cardamom plants, *Amomum angustifolium*, are also in blossom in the Economic House, but the Herbaceous Ground presents so blank an appearance that skating rather than botanizing appears to be the most attractive pursuit to those pharmaceutical visitors who have the good fortune to obtain admission.

The subject of the dormant vitality of seeds must always possess some interest for pharmaceutical readers, since it has a bearing upon the cultivation of henbane. In a recent number of the *Garden* a correspondent gives an instance which came under his notice, in which the seeds of several species of *Solidago* apparently remained dormant for twenty years. The ground had been covered with shrubs and carefully kept free from weeds during that time; at its expiration the ground was cleared, and two years afterwards it was covered with specimens of *Solidago* three or four feet in height.

In the *Gardeners' Chronicle* a correspondent calls attention to the poisonous properties of the berries of *Solanum Dulcamara*. Eight animals out of a flock of healthy (?) sheep pined away and died after eating the plant, and there was found in their stomachs only dulcamara besides the turnips; on removal from the field no more died.

In the same paper, Mr. C. U. Dod remarks that he recollects a boy of twelve, at a boarding school, whose life was but just saved by emetics within an hour of eating nightshade berries. On the other hand, the editors of that journal say that the berries of *S. nigrum* have been eaten as tomatoes with impunity.

Bentley and Trimen in their 'Medicinal Plants' state that "the action of dulcamara is unknown, and that several physicians have given the preparations of dulcamara in very large doses without any obvious effects." In Gerarde's time it was evidently used in medicine as a resolvent; the celebrated Boerhave considered the young shoots superior to sarsaparilla; while Linnæus recommended it as a remedy for inflammatory diseases, fever and rheumatism, and does not appear to have regarded it as poisonous.

The black nightshade, *Solanum nigrum*, however, has had a bad reputation, Floyer having stated that thirty of the berries killed a dog in three hours. Dr. Swain Taylor also observes that the berries of the *Solanum nigrum* have in one instance, at least, produced very serious effects on children who have eaten them. The children complained of headache, nausea, vertigo, colic and tenesmus. One child died in the acute stage, and two others, apparently from secondary consequences, during treatment. He denies, however, that the effects of the plant on the system are as dangerous as they are generally supposed to be. On the other hand, one hundred and eighty ripe berries of the plant have been given by Duval to a dog, and in another experiment six ounces of a watery extract, without any ill effects resulting. Orfila also relates that he found the extract of the plant to have a very feeble effect as a poison.

Amidst these conflicting statements it is difficult to arrive at the truth, and it seems a blot on the escutcheon of the medical profession that the knowledge of the medical properties of two of our commonest wild plants should still remain undefined. It would be interesting to determine whether a poisonous property is contained in the seeds and not in the pulp of the fruit, whether it is more powerful in certain seasons than in others, whether the poisonous effects occasionally produced are due to idiosyncrasy, or whether other plants have been mistaken for *Solanum*. In the case of sheep poisoning above mentioned, it is within the limits of possibility that belladonna, or other herbs poisonous to sheep, might have grown in the same field, and that death might have been due to their eating such plants. In a case of sheep poisoning which occurred in a particular meadow on a farm in one of the southern counties, the plants by which the sheep were poisoned were found to be *Ranunculus Flammula* and *Hydrocotyle vulgaris*, plants which are almost sure to be abundant in damp pastures in the hedges of which *Solanum Dulcamara* loves to grow. Woody nightshade is such a common plant that it must very frequently be within the reach of both sheep and children, and it is certainly remarkable that cases of poisoning by it are excesssively rare. Observers in the country might possibly be able to find out whether the berries of these plants are eaten by birds.

A correspondent of the *Garden* points out that although the plants of *Cotoneaster microphylla* and other bushes in the neighbourhood are quite cleared of berries, those of *Cotoneaster Simmondsii* remain untouched by them, another illustration of the fact that different species of the same genus may, like those of the genus *Aconitum*, possess very different properties.

More than twenty years ago Professor Bentley pointed out the differences between aconite root and horseradish,* in consequence of the former having been mistaken for the latter with a fatal result. The two roots are so totally unlike in almost every respect that it is difficult to comprehend how even a cook could mistake the one for the other. Nevertheless on Christmas day last, a farmer and his family, at Malmesbury, partook of the scraped root of aconite, and the wife succumbed, in spite of medical aid, to its deadly properties.

Under proper treatment, however, aconite is by no means one of the most fatal poisons. In the *British Medical Journal* for December 27, an account is given of recovery after taking a teaspoonful of linimentum aconiti, a quantity nearly equal in strength to an ounce of the B.P. tincture. It cannot be too widely known that after an emetic has been given, or the stomach pump used, the antidotes to aconite poisoning which have been found most effectual are strong stimulants, such as ether, brandy, ammonia, etc.

* *Pharm. Journ.*, [1], vol. xv., p. 449.

The economical, but dangerous custom of putting the sprouting top of the horseradish root back into the ground after it has been used, when, from the scraping it has been subjected to, it would have the conical shape and little more than the size of aconite root, has probably led to the sad mistake which has recently occurred. In connection with this subject it may be interesting to note that an Indian species of aconite root, called "wakhma,"* and supposed to be obtained from *Aconitum palmatum*, has a peculiar odour slightly resembling horseradish when dried, and probably in the fresh state also. This odour Dr. Dymock, in his paper, likens to that of the garden nasturtium which, as is well known, smells like plants of the cruciferous order. It would be worthy of inquiry if any of the species of aconite cultivated in gardens in this country have roots possessing a similar odour to that of horseradish.

The interesting researches of Dr. Pringsheim on the function of chlorophyll were briefly referred to in the last "Month," and subsequently a fuller abstract was given in this Journal.† In reference to these notices a letter has been received from Dr. A. Downes, of Chelmsford, claiming that, in a paper by himself and Mr. T. P. Blunt,† communicated to the Royal Society in October, 1878, on the Influence of Light upon Protoplasm, which was a continuation of their research upon the effect of light upon bacteria and other organisms associated with putrefaction and decay,‡ Dr. Pringsheim has been anticipated in the observation that chlorophyll acts as a protective substance to the protoplasm against the injurious influence of the light by diminishing the amount of combustion. In that paper it was recorded that sunlight in the presence of free oxygen destroyed bacterial life by effecting the gradual oxidation of the constituent protoplasm of these organisms, and it was argued that it would be unreasonable to suppose that this protoplasm is so essentially different in its fundamental composition from other protoplasm that this special action of light should be found in connection with it only. But it is pointed out that, nevertheless, protoplasm may be very differently circumstanced in its relations to light and oxygen, in that it may be protected, and among the forms of protection mentioned is that of "special colouring matters, which filter out the more injurious rays." Dr. Downes says that when this sentence was written the protective function of chlorophyll was very prominently in the authors' minds.

Professor Planchon has recently contributed an interesting communication to the *Journal de Pharmacie*, in which he shows that great similarity of structure exists in the stem and bark of several species of *Strychnos*, including the hoang-nan of China, the m'boundou poison of West Africa, *Strychnos Nux-vomica*, *S. Castelnæ* and *S. Colubrina*. The bark consists of an outer corky layer of rectangular cells; next a zone, consisting of elongated cells filled with reddish matter, then a zone of sclerogenous or stony cells, and, lastly, the liber tissue. In the bark of the species yielding curari this stony layer is more developed than in others. The wood is marked by the presence of large lacunæ, which at first sight might be mistaken for vessels. In one species, *S. Colubrina*, the lacunæ do not at first appear to be present; but upon microscopical examination they are found to exist, and to be filled with what seem to be white silky fibres, though really consisting of matter secreted by the plant in the interior of the lacunæ, as may be seen from the resinous deposit which is found in a rudimentary state in several other species. It may be hoped that M. Planchon will continue his researches, and endeavour to show in which part of the bark the curarine is more especially developed.

According to the *Journal de Pharmacie* one of our common weeds, *Arenaria rubra*, L., perhaps better known in this country under the name of *Lepigonium rubrum*, Fries, has recently been brought into notice in France by Dr. Boureau, of St. Lazare, as a remedy for cystitis, vesical catarrh, hæmaturia and gravel. The results obtained from its use have led him to the conclusion that its diuretic properties will cause it to become an important agent in therapeutics. It has been known for some time in Malta and Sicily, and was introduced by a Maltese into Algeria about twelve years ago; it was there experimented upon by Dr. E. Bertherane, whose paper in the *Bulletin de la Société des Sciences d'Algérie*, 1878, appears to have attracted attention in France. It has been analysed by M. F. Vigier, a Parisian pharmacien, who attributes its action to the large proportion of alkali and the resinous aromatic principles it contains; but as the distillate was decidedly ammoniacal there seems to be a possibility of its containing also an easily decomposable alkaloid. M. Vigier considers the best pharmaceutical preparations to be a decoction and an aqueous extract. Inquiries as to the probability of a demand arising for it in this country having recently been made, it may be well to mention that the plant is a common littoral weed in England, and that if gathered on our southern shores it is likely to be scarcely, if at all, inferior to that obtained from Algeria.

Another new Californian drug has been introduced to notice in the United States. It is called "yerba mansi," and is the root of *Anemopsis californica*, Hook., a plant belonging to the natural order Saururaceæ. It is used as a remedy for venereal sores and swellings. As might be expected in a plant so nearly allied to the pepper family, the root possesses an aromatic pungent taste. Its properties have been found by Mr. J. U. Lloyd to be due to a volatile oil heavier than water and to an astringent substance. He could find no trace of alkaloid or resin. The active principles of the plant are yielded to alcohol.

In the *American Journal of Pharmacy*, Professor Maisch gives an account of experiments performed in the laboratory of the Philadelphia College of Pharmacy, which he believes to furnish confirmation of his former statement in February, 1876, that gentian root does not contain tannin. Further experiments upon the fresh root are to be undertaken and it is hoped that by aid of the results obtained this moot point may be definitely settled.

Dr. T. Peckolt has examined the volatile oil of *Myroxylon peruiferum* and finds that its sp. gr. is 0·892 at +13° C., and 0·852 at +15° R. and that it has a pleasant aromatic odour resembling sassafras. The action of combined nitric and sulphuric acid on it produces a resinous mass of a brown colour and a mild aromatic musky odour, a gramme of oil yielding 0·60 of the resin, which is said to be well adapted as a substitute for musk. The *Myroxylon peruiferum*, L.f., must not be confounded with *M. Pereiræ*, Klotsch.

* *Pharm. Journ.*, [3], vol. viii., p. 23.
† See before, pp. 501 and 561.
‡ See *Pharm. Journ.*, [3], vol. viii., p. 512.

which yields balsam of peru. The former is a native of South, not Central, America, and yields a resin resembling balsam of tolu, but not containing any crystals of cinnamic acid. It is known at Buenos Ayres under the name of "albahaca."

In the *Pharm. Central.*, Oct. 30, a mixture of Siam benzoin, pitch, salicylic acid, gurjun balsam and absolute alcohol is recommended as a cheap substitute for balsam of peru, which it much resembles. It is especially adapted for healing wounds, and for use in veterinary practice; it goes under the name of "balsamum salicylico-benzoinatum."

To a limited number of persons sneezing appears to be a pleasant operation, but those who find it excessively disagreeable will be glad to learn of a simple and cheap remedy, made known in the *British Medical Journal* by Mr. S. M. Bradley, surgeon to the Royal Infirmary at Manchester. It consists in placing a loose plug of cotton wool in the nostrils. In hay fever, in a dusty atmosphere, or in those stages of catarrh in which a cold atmosphere is irritating to the mucous membrane of the nose, this simple application is said to give immediate relief.

An Italian correspondent of the *Lancet* calls attention to an insidious and frightfully fatal disease called "pellaga," of which no less than 97,000 Italians are said to be dying at the present time, the number of victims representing 3·62 per 1000 of the whole population, and in the infected departments, especially in Lombardy and Venice, a higher proportion than ever occurred during the worst cholera epidemic in France. The disease usually runs a slow course, like consumption. Its cause is believed to be the exclusive consumption as food of maize in a deteriorated condition and the unhealthy state of the hovels in which the rustics live.

Another case of fungus poisoning has recently occurred at Lynn, in Norfolk, in which the patient died. The case is a very interesting one from a botanical point of view, since the fungus eaten, *Amanita phalloides*, is nearly allied to the *Amanita muscaria*. It seems to have acted as an irritant poison, and not in a similar manner to the *A. muscaria*. Fortunately for the advancement of scientific knowledge, the case fell into the hands of an accomplished fungologist, Dr. C. B. Plowright, so that the symptoms produced can be traced to a known fungus. The species eaten in this case is an especially dangerous one, as it has a pleasant taste resembling that of the mushroom. Only half an ounce appears to have been eaten on an empty stomach, but no symptoms were produced until after a lapse of twelve and a half hours.

In a paper on the destruction of obnoxious insects, by Dr. Hagan, professor of entomology at Harvard University, he states that the application of yeast on insects produces in them a fungus which proves fatal to the insects. In an experiment made by Mr. J. H. Burns,* all potato beetles sprinkled with diluted yeast died on from the eighth to the twelfth day and the fungus was found in the vessels of the wings. Most persons must have noticed dead flies stuck to the window panes in the autumn by a fungus or mould which has caused the death of the insect. In proposing, as Dr. Hagan does, to use yeast as an insecticide, he has struck on a new plan of destroying enemies that are intangible by ordinary means. A great deal more is required to be known, however, of the relations between various microscopic bacteria and fungi, such as mucor, before it will be wise to fill the atmosphere of our houses with fungoid germs, lest the remedy be worse than the disease. It has been remarked by many people that in years when cholera was prevalent in this country there were very few house flies to be seen.

* *Nature*, December 25, p. 188.

At the drug sales recently, a fine specimen of the leaves of *Cassia obovata* was offered, probably from Barcelona. Calabar beans and jaborandi of good quality were more abundant than usual, and condurango bark, which appears to have no sale in this country was again offered. A small variety of cardamoms, bleached perfectly white, the roots of *Cyperus esculentus*, senega containing vincetoxicum root, and aricine bark (*C. pubescens*), were also noticed. Siam benzoin in the tear was offered in unusually large quantities.

Within the last few weeks, also, a very fine sample of pale bark in quills was offered at the drug sales under the name of Loxa bark, but the price bid for it upon the basis of experience as to the usual composition of this bark was small, and as it had been ascertained that this particular parcel contained an unusually large amount of quinine it was withdrawn from the sale, and when put up afterwards at the bark sale it realized four shillings a pound.

The fate of this bark in the drug sales serves to illustrate how much need there is for revising the Pharmacopœia standard of officinal bark. At present external appearance is thought more of than anything else; bark presenting the characters of flat calisaya or yellow bark will always sell, whether it contains quinine or not, and, generally speaking, the bark of this kind now met with in the market does not contain anything like the amount of quinine indicated in the Pharmacopœia as proper, while a great deal more contains none at all. The Loxa bark above referred to, contained 1·75 per cent. of quinine, with 0·61 per cent. cinchonidine and was therefore well calculated for pharmaceutical use.

Lately there have been several parcels of bark containing aricine offered, and although they all agreed in being totally destitute of any of the usual cinchona alkaloids, they have been sold at good prices. It is somewhat difficult to conjecture what use such bark as this can be put to, for it is not only without even cinchonidine or cinchonine, but is also without the bitterness characteristic of the poor kinds of bark that are useful in making liqueurs, although they may not have much medicinal value.

A communication from Mr. Murrell on the use of nitroglycerine in angina pectoris, which appeared a few months since in the *Lancet*, has created some demand for medicinal preparations of this compound. The appearance, therefore, in the *Practitioner* for the present month, of an article by Mr. Martindale on the difficult subject of its pharmacy is very timely. Mr. Martindale has made the important observation that nitroglycerine is readily soluble to the extent of 15 per cent. in almond or olive oil, and he is of opinion that a 1 per cent. oily solution would in many cases be preferable for medicinal use to the alcoholic solution of the same strength, it being stable, non-volatile, uninflammable and perfectly inexplosive. Nitroglycerine is also readily soluble in melted cacao butter, but care is necessary to prevent, by frequently shaking the solution, a separation during the cooling of the fat. To such a medicated fat of definite strength sugar may be added, and the mass may then be rolled into pills, and varnished.

It being usually desirable, however, to obtain the effects of the nitroglycerine as quickly as possible after administration, a more convenient plan is to add the cacao butter mass to chocolate paste, mix well with the aid of heat, and then roll out and cut into lozenges, which may be made to contain each one-hundredth of a grain, or more if required.

In *New Remedies* for this month a new suppository mould is described and figured, which has the advantage of compressing the suppositories while the mould is opened and thus preventing their breakage when made of cacao butter or other material of a friable character.

In the same journal is described a new tincture press, of a different character to any hitherto in use, which has recently been patented by Mr. J. G. Baker of Philadelphia. Professor Remington considers it to be well adapted to expressing tinctures of bulky drugs, such as arnica flowers, hops, etc.; "the only class of drugs for which it cannot be successfully used are those in very fine powder and such as are of a sticky or tenacious character." The materials are supplied to the press through a funnel, and fall on a screw which works in a horizontal direction in a tapering tube, at the end of which they are delivered quite dry, while the liquid passes through a perforated false bottom in the tube. By this means the use of press cloths is avoided, and the residue is not dry on the surface only and moist in the interior, but is uniformly dry throughout.

In a note upon vanillin, in the *Chemiker-Zeitung* (Dec. 18 and 25), by Messrs. Haarmann and Reimer, regret is expressed that consumers of vanilla have been so slow in adopting the use of the vanillin prepared artificially by the oxidation of coniferin. On more than one occasion, however, statements have been quoted in this Journal which, if correct, would fully explain this, to the effect that the artificial vanillin does not truly represent all the aromatic principle of vanilla. Nevertheless, in the present article the authors maintain that the artificial vanillin is not to be distinguished from the natural principle for which vanilla is valued, it being identical in melting point, crystalline form, smell, taste, and chemical reactions, whilst it can be produced much more cheaply. The amount of vanillin in vanilla varies from ½ to 2 per cent., and it is estimated that the annual consumption of vanilla amounts to at least 50,000 kilograms yearly, at a cost of £150,000. This the authors claim would be fully represented by 1000 kilograms of vanillin, costing £70,000.

At the meeting of the Chemical Society on the 23rd inst. Dr. Pavy brought forward a modification in connection with the test for sugar by the reduction of cupric oxide, which promises to be of service where the test is only occasionally used. In order to obviate the inconveniences accompanying the keeping of the usual test solution for any considerable time, he has sought for a method of bringing a mixture of the dry ingredients into a coherent mass so that they might be kept in solid form. This has now been effected under his directions by means of pressure, and the product is a sort of pellet, which when placed in about 3 c.c. of water and heat applied yields the clear deep blue liquid constituting the ordinary cupric test solution.

In a paper read before the Royal Society on the 13th inst., Dr. E. J. Mills claims to have observed a new order of chemical phenomena, which he has provisionally designated "chemical repulsion." If a thin layer of solution of baric chloride be evenly distributed between two plates of glass, placed horizontally, excess being removed by pressing the plates together, and then dilute sulphuric acid be brought into contact with it through a perforation made in the upper plate, precipitation takes place and continues progessively and uniformly from the perforation as a centre; forming an increasing circle, for instance, if the perforation be circular. If the sulphuric acid be introduced through two perforations in the upper plate, two circles are formed, but as their circumferences approach each other development is retarded between the perforations, the figure of advance being no longer circular but oval, and however long the experiment may be continued there always remains a line of demarcation of "no chemical action" between the two figures. When there are perforations at the four points of a square and one in the centre, the centre circle, having as it develops no way of escape from the surrounding four, eventually forms a square figure bounded by repulsion lines. Dr. Mills considers that the phenomena observed afford proof of two propositions—(1) that chemical action can take place at a distance, and (2) that two or more chemical actions, identical except in position, completely exclude one another.

The public has been so surfeited during recent years with the wonders of science that even the announcement simultaneously from both sides of the Atlantic that the track has been struck which might lead to the artificial crystallization of carbon in the diamond form fails to excite an exuberance of surprise. One of these claims, and the one most worthy of notice, has been put forward by Mr. Mactear, of the St. Rollox Chemical Works, who announced at a meeting of the Philosophical Society of Glasgow, in December, that he had produced artificially what he believed to be diamonds, but which, until further tested, he preferred to describe as a pure crystalline form of carbon. These crystals were said to have the crystalline form and possess the refractive power of diamonds, also to resist the action of acids and alkalies and the intense heat of the blow-pipe. This claim was at first somewhat summarily dealt with by Professor Maskelyne, in a characteristic letter addressed to the *Times* and *Nature*. That gentleman, having had "a few microscopic crystalline particles" handed to him as representing the product, submitted them to examination and found that when rubbed between topaz and sapphire they were crushed without producing abrasion; that they behaved towards polarized light in the manner of a birefrangent crystal; and finally, that the particles resisted all attempts to burn them. From these and other experiments Professor Maskelyne had no hesitation in declaring that Mr. Mactear's "diamonds" were not diamonds, but consisted of some crystallized silicate, possibly one resembling augite.

Mr. Mactear, however, was not so easily put down, and replied, affirming in the most positive manner that he had been able to produce carbon in the diamond modification, and that of this he did not despair of convincing Professor Maskelyne; meanwhile, he asked the scientific world to suspend its judgment. In addition, Mr. Crookes, in the *Chemical News* of the 9th inst., stated that some of Mr. Mactear's particles when submitted to the molecular discharge in a high vacuum showed phosphorescence similar to that manifested by Brazilian diamonds under similar conditions. Almost simultaneously, on the 8th inst., appeared another letter from Professor Maskelyne, in which he acknowledges, after working during several hours with Mr. Mactear, that without altering his opinion with respect to that part of the product he had previously examined, he had now seen other portions, differing in properties and worthy of further investigation, which he believed bore out the claim that topaz and sapphire had been scratched with them. In fact this letter was followed by a certificate signed by four experts, testifying that a diamond had been scratched, and rubies, sapphires, an amethyst and a cairngorm had been engraved with Mr. Mactear's "crystallized carbon sand." However, eventually, in a letter published on the 16th, Mr. Mactear admits that the substance he had looked upon as crystallized carbon was not so, but consisted almost entirely of silica, alumina, magnesia and a residue insoluble in hydrofluoric acid, which when fused with caustic soda still contained minute crystalline forms and particles of what was assumed to be carbon in some graphitic form; in fact, that it was probably a mixture of substances of the nature of sapphire, spinel, and possibly corundrum, with graphitic carbon. But notwithstanding his present failure, Mr. Mactear believes he is on the right track, and is encouraged by Professor Maskelyne to pursue his research. Meanwhile, he claims that the production of such a hard crystalline substance is likely to be successful from a commercial point of view, as it might replace diamond dust in many of its uses in the arts, it being producible at a moderate cost.

Incidentally, this result appears to have thrown some doubt over the trustworthy nature of the inferences drawn from phosphorescent phenomena in a high "vacuum," inasmuch as the crystalline particles ascertained to consist of silica, alumina, magnesia, etc., manifested a behaviour similar to Brazilian diamonds. Chemical inferences from physical phenomena, as in this case and in spectroscopic observations, appear therefore to be questionable, just as the inferences drawn from certain phenomena of a pretended supernatural order have been shown to be untrustworthy by the recent "capture of a spirit," called up by a young lady upon whom a distinguished philosopher is said to have been experimenting for years without being able to detect any deception.

The other claim has somewhat of pathetic interest attached to it. A frog, impatient of confinement in a frogarium, threw off restraint, and, like his brother of nursery fame, went on his travels, but only like him to come to grief, being found some time after starved to death and shrunk to half his original proportions. Froggie's former jailor, a Dr. W. B. Fletcher, being of an inquiring turn of mind, submitted the body to dissection, and coming to the lungs found these organs clogged with thousands of black crystals which looked like coarse gunpowder, but under the microscope presented facets with smooth surfaces, presenting the same angle of crystallization as the diamond. On burning they gave off carbonic acid gas and are represented to have been pure crystals of carbon, in fact, it may be supposed, black diamonds. Theorizing upon these results Dr. Fletcher suggests that in the lungs of huge reptiles of the antediluvian period dying under similar conditions there may have been formed large crystals of carbon which afterwards became transformed into lustrous diamonds. Remembering the very severe rebuke referred to in these columns last month, it is perhaps rather venturesome to ask whether this is a specimen of "quiz."

The announcement respecting Mr. Edison's alleged success in solving the problem of the general application of the electric light, which was included in these columns last month, has since been supplemented by some very interesting—though rather highly coloured—information respecting the work done in this direction at Menlo Park and in other parts of the States. But it turns out that the success at present is one that has rather been attained than maintained. It is found that in many of the lamps the carbons, after a time, become destroyed, though whether by the oxygen in the residual millionth of an atmosphere, to which degree the exhaustion of the globes is said to be effected, or by the impairment of the vacuum by the access of air through minute imperceptible fissures formed during variations of temperature in the glass, is yet a subject of dispute. Moreover by the substitution of incandescent carbon for incandescent platinum the number of lights maintainable per horse power is considerably reduced and the expense thereby increased. In fact, Mr. Edison seems to be at present foiled by difficulties that have hitherto baffled other investigators, and amongst them, as appears from the letter of Mr. Proctor in last week's Journal, is Mr. J. W. Swan, of Newcastle, one of our own craft.

That a residual atmosphere in an exhausted globe is capable of manifesting considerable activity is shown by the result of an investigation recently reported by Mr. Swan to the Newcastle Chemical Society, as to the nature and cause of the deposit which takes place on the sides of the vessel when carbon is heated to incandescence by the electric current. Such a deposit was examined a short time since by Mr. B. S. Proctor, and pronounced to be chiefly carbon, and the question arose whether the carbon had been volatilized and deposited from a gaseous form. Experiments are now said to have conclusively proved that this is not the case, but that the deposit is due to the mechanical transport of carbon particles, the residual air contained within the globe being the medium.

With the opening year the Institute of Chemistry has shown signs of life in the announcement of an examination in practical chemistry to be held towards the end of next month, and in the offer of two prizes in encouragement of original research. One prize of the value of £50, provided by the President, is for the "best original investigations involving gas analysis;" the other, of the value of £25, is provided by Dr. C. Meymott Tidy, and is for the "best original investigation on the special reactions of the alkaloids and their separation from mixtures." These prizes will be open to Associates of the Institute and to all persons (except Fellows) who shall, before the 31st of December next, have qualified for the associateship in all respects short of passing the prescribed practical examination, for which examination success in this competition will be accepted as a substitute.

This month, one of the oldest and most important of pharmaceutical journals commences its seventy-second year and one hundred and eighth volume with a new series. Its first series of six volumes appeared in the years 1809 to 1815, under the title of the *Bulletin de Pharmacie.* Then came the second series of twenty-seven volumes, published under the title of the *Journal de Pharmacie et des Sciences Accessoires.* With the third series of forty-six volumes, commencing in 1841, the present title of *Journal de Pharmacie et de Chimie* was adopted, and the fourth series, just concluded and numbering thirty volumes, was commenced in 1864.

Apropos of scientific journals, a very interesting Catalogue of Scientific Serials of all countries that has been compiled under the auspices of Harvard University by Mr. S. H. Scudder includes the names of 4390 scientific serials. Of these 1128, or more than one-fourth, are published in Germany. Next comes France with 715; then follow Great Britain and Ireland with 550, the United States with 427, Italy with 333, Austria and Hungary with 308, Holland with 218, Russia with 107, etc. Judged by this standard of numbers, the preponderance of scientific periodical literature published in the German language is very marked, as it exceeds that published in Great Britain and her colonies and in the United States added together.

Not long since a remark was attributed to the German government to the effect that Germany being a civilized country regulations controlling the sale of proprietary medicines in it were not required. There would therefore appear to be a sad retrogression towards barbarism if it be true, as currently reported, that the suppression of secret and proprietary medicines is now under consideration by the German Imperial Health Department. It is said also that in Switzerland the sale of secret and patent remedies is about to be submitted to very stringent regulations.

Salicylate of soda is of comparatively recent introduction as a remedial agent, but is at the present time very extensively prescribed. It must be expected that some of its combinations in prescriptions will present difficulties such as that experienced in No. 380, where salicylate of soda is added to a mixture with quinine. If a solution of sulphate of quinine be poured into a solution of salicylate of soda, the quinine will separate, and some of it will float on the surface of the liquid and the remainder will adhere to the sides of the bottle; but a very satisfactory mixture may be made from this prescription by dissolving the salicylate of soda in a part of the orange flower water and mixing with it from two to four drachms of mucilage of acacia. The dissolved quinine being then poured in becomes thoroughly diffused through the mixture, and continues so without any tendency to agglomerate.

The dispenser should always direct his efforts to carrying out the intentions of the prescriber, and this cannot effectually be accomplished unless the active ingredients are so combined in the medicine that the patient will experience no difficulty in taking a definite quantity of each ingredient in the measured dose. Most of the difficulties that present themselves with combinations of quinine may be overcome by the addition of a little mucilage.

In the prescription No. 381, there appears to be an omission, on the part of the prescriber, of the word "grains" after "ij;" the directions as regards increase of dose would then read, an increase of two grains per dose every week until 80 grains are taken per day. As the prescription stands, each dose will contain 5 grains of iodide of potassium to be taken three times a day; this proportion, it is intended, should be that of the first week; the second week, by increasing the dose two grains, each dose would be 7 grains, and so on until it reaches 27 grains, which would be equivalent to 81 grains in the day, the closest approach to the maximum dose indicated. There does not appear to be any valid reason for the rendering of these two figures into double the dose.

No. 382 is one of those recipes, frequently met with by dispensers, which are generally considered to be copied from a family medical guide, or written by a person who has not received a medical education. Perhaps none of the recipes which come under the notice of the dispenser give more trouble than some of these. He has in these prescriptions to use great care, the names of the drugs are sometimes very puzzling, and the dose is also approaching the dangerous. Such a dose as is here ordered may be given in cases demanding prompt treatment, but the dispenser, in the exercise of his judgment, would do well to make some inquiry previously to the dispensing of the one in question. As regards the preparation intended by "powdered antimony," the antimonial powder, B.P., being an official preparation, would be the safest to use.

When alum. sulph. is ordered in a prescription, it is usual to use the alum of the B.P. It is more generally ordered as alum. sulph. than alumen. The prescribers of medicine direct their attention to therapeutics and do not always follow closely the alterations required by the progress of chemical science. There is a sulphate of alumina, made by dissolving a precipitated hydrate of alumina in sulphuric acid, which is official in the United States Pharmacopœia.

The prescription, No. 384, contains ferri et quinæ cit. with tr. valer. ammon., and necessarily the quinine will be thrown out of solution, for the most part adhering to the sides of the bottle. A little mucilage added to the water in which the salt has been dissolved previously to the addition of the tincture will obviate this inconvenience and form a satisfactory mixture. This combination of ingredients has already been commented on in the pages of this Journal; the prescription will be found September 21, 1878, p. 238, and referred to in "The Month," following p. 246, and at the same time reference is made to "The Month," June 29, 1878, p. 1045. It may again be stated here that when ammonia is prescribed with a solution of sulphate of quinine, or those combinations of quinine used in dispensing and having a place in the B.P., the quinine will be thrown out of solution in the solid form, unless diffused by means of mucilage previously added to the vehicle.

GURJUN BALSAM.

A letter received from Professor Dragendorff informs us that Mr. Hirschsohn was in error in stating in his recent paper on this subject (see before, p. 561) that one of the samples described in it as having been examined by him had been received from Professor Flückiger, it having been presented to the Dorpat Museum by Professor Hamberg, of Stockholm.

PICROTOXIN AND ITS PROPERTIES.

The recent introduction of picrotoxin as a remedy for the night-sweating which accompanies phthisis has led to some inquiry respecting the nature and properties of this drug. The following information is taken from an article appearing in the *British Medical Journal* for the 17th inst., under the title of "Recent Studies on Therapeutics:—"

Picroxtin is the active principle of cocculus indicus (*Anamirta cocculus*, the *Menispermum cocculus* of Linnæus), a plant which has been recognized as a medicine since the days of the Arabian physicians, by whom it was described under the name of "*maheradsch*." This cocculus was probably first known in Europe as a poison for taking fish, which it first throws into violent irregular motion and then stupefies. All kinds of fish are killed by it; the barbel, it is said, taking the longest to die. Fish are inordinately fond of the berries, and, when rendered helpless by the dose they have taken, are readily caught. They should be removed from the water as soon as they appear on the surface, and their bellies emptied, or their flesh may become poisonous and cause irritation if eaten. In nearly all civilized countries, the use of cocculus for this purpose is illegal. Cocculus has also been used from an early peroid by unprincipled brewers, partly for giving beer a due degree of bitterness without the employment of hops, partly to give it "bottom" and render it more intoxicating. In an old treatise on brewing, we find the following instructions:—"Three pounds of cocculus indicus to be added to ten quarters of malt, it giving an inebriating quality which passes for strength of liquor; it also prevents the second fermentation of beer, and the bursting of the bottles in warm climates." It is said to be used by thieves and bad characters for the purpose of drugging their victims.

It is a curious circumstance that, although cocculus indicus possesses such powerful and valuable properties, it has in modern times found little favour as a medicinal agent; and we cannot help thinking that its general abandonment as a remedy was a singularly unwise step. It is a valuable local application for certain forms of skin-disease. In the east, it has been long used applied externally in the form of a powder for the destruction of vermin on the skin, as well as for the cure of scabies; and, in the form of ointment, it is said by Christison to be one of the best applications for the treatment of ringworm of the scalp. Speaking of the ointment of the old Edinburgh Pharmacopœia, he said that, although it may occasionally fail to cure the eruption, it always does good by relieving the accompanying irritation. Undoubtedly a picrotoxin ointment, made with vaseline or some similar substance, would prove a welcome addition to the armament of the dermatologist. Cocculus indicus also possesses considerable value as a medicine for internal administration. A few years ago, M. Felix Planat recommended it as a remedy for epilepsy—not as a specific, but as a truly useful drug. The sole exceptions recognized by him to its curative powers in this affection are inveterate cases, whether idiopathic or symptomatic. He employs a tincture made by macerating for three weeks two hundred grammes of cocculus indicus in one thousand grammes of alcohol. Of this, he begins by giving two drops twice-a-day, and then each successive day increases each dose by one drop until thirty drops a-day are being taken. He then gradually reduces the quantity a drop at a time until the original dose is reached, when the treatment is suspended for a fortnight; after which it is renewed, and again intermitted alternately during six months. For chorea, picrotoxin is recommended by no less an authority than Gubler; and, according to Tschudi and others, it is especially useful in paralysis of the sphincters. It is also employed in various forms of dyspepsia, notably when there is severe epigastric pain aggravated by pressure or by taking food. Dr. Phillips speaks of it as being of singular service when the colon is distended with flatus, and when the bowels are constipated and the motions hard and lumpy. He also recommends it for certain symptoms associated with irregular menstruation. The administration of two or three drops of a saturated tincture of cocculus three or four times a day prior to the expected flow, and continued during the first two or three days of its progress, will frequently ward off the pains and render the discharge more natural.

Picrotoxin, or cocculin as it is sometimes called, was discovered by Bouillay in 1812; and its composition is represented by the formula $C_{12}H_{14}O_5$. It may be obtained in several different ways, details of which will be found in Watt's 'Dictionary' and other works on chemistry. It is colourless, inordorous, has an intensely bitter taste, and is neutral to test-paper. It is soluble in water, alcohol, ether, and fixed oils, and it crystallizes out from aqueous solutions in the form of beautiful stellate groups of colourless needles. In its physiological action it is most peculiar. In some respects its effects on the living organism resemble those of strychnia. Tonic and clonic spasms of great severity and violence culminating speedily in death are induced by large doses, and opisthotonos and gasping are frequent concomitants. It induces spasmodic contractions, involving first a single group of muscles, and finally almost every muscle in the body. The tetanic cramps of picrotoxin differ from those of strychnia in that the latter affect chiefly the extensors. It has been well said that the convulsions of picrotoxin more resemble the choreic, those of strychnia, the tetanic; in other words, picrotoxin exerts its influence chiefly on the cerebral contres, whilst strychnia affects the spinal.

Quite recently, Dr. Murrell has introduced picrotoxin as a remedy for the night-sweating of phthisis. He uses a 1 in 240 solution in water, and of this he gives from one to four minims three times a day, the last dose being taken at bedtime, or immediately before the time at which the perspiration usually commences. He has employed this mode of treatment at the Royal Hospital for Diseases of the Chest in twenty cases, with only one failure. The sweating is usually arrested in two or three days, and there is no return for a fortnight or more. The picrotoxin is best give alone, and not in a mixture, and it has been found to succeed after oxide of zinc, belladonna, Dover's powder, and other remedies have failed. A great advantage of the treatment is that it does not make the skin too dry, but leaves it comfortably moist, whilst not unfrequently atropia seems to parch it up. The aqueous solution is apt to deposit crystals in winter, but it soon clears up on warming.

JAPAN WAX.*

It is only about twenty-five years since Japan wax has found its way to Europe. From small insignificant samples which reached the London market about the year 1854, the quantity exported has reached very large figures at the present time. Japan as well as China produces this article, but the manner of production and even the true source of the Chinese article are still so much enveloped in doubt that no reliable data can be given. The author of the present paper, therefore, confined his investigations to the Japanese article.

Before entering upon a description of the latter, the author gives a list of such other vegetable tallows or fats as have been actually used, or might possibly be employed, as substitutes of Japan wax. The most important of these are the following:—

Carnauba Wax, also called Ceará or Brazil wax, found upon the leaves of *Copernicia cerifera*, Mart. Native of Brazil. Forms a hard brittle mass, melting at 83·5°—84° C.

Pela Wax, or Chinese wax, is produced upon the young shoots of *Fraxinus chinensis*, Roxb., by the agency of an insect, viz., coccus pe-la, Westwood. It does not reach the European market. Melts at 82·5° C.

---

* Abstract of a paper by Arthur Meyer, of the Pharmaceutical Institute of the University of Strassburg. From *Archiv der Pharm.*, Aug. Reprinted from *New Remedies*, November, 1879.

Koga Wax, without doubt obtained from *Cinnamomum pedunculatum*, N. ab E., in Japan. Softer than Japan wax.

Ibota Wax, produced by an insect upon *Ligustrum Ibota*, Sieb. Very firm and white. Neither of the two latter reach Europe.

Chinese Vegetable Tallow, Stillingia tallow, prepared from the seed-kernels, or more likely fruit-capsules of *Stillingia sebifera*, Mart., in China. A rather soft, white, granular mass, chiefly used in China for making candles. Melts at 37° C.; according to the author, however, it does not melt completely, until 45° C. is reached.

Palm Wax from the trunk of *Ceroxylon andicola*, Humb., of tropical America. When crude, melts at over 100° C.

Myrica Wax, or myrtle wax, from the fruit of *Myrica cerifera*, L. Melts at 47·5°—49° C.

Japan wax may be distinguished from all of these by its physical and other properties. Formerly it was only imported in round cakes, of about 12 cm. ($4\frac{7}{8}$ inches) in diameter, and 2·5—3 cm. ($1-1\frac{3}{16}$ inch) in thickness; but at present it occurs also in square cakes, and in square blocks, the latter of about 65 kilos (143 pounds) each. When freshly broken, the fractured surface is almost white, sometimes slightly yellowish-green. At the surface they have a hoary appearance, owing to a shining, crystalline, white down. When freshly broken, the odour is tallow-like and disagreeable. Occasionally dark yellow lots occur in the market. These fetch a lower price, and have the peculiarity that they turn darker relatively much more rapidly than the white variety. After being preserved for some time in a solid condition, the melting point of the fat is at 52—53° C.; but a recently solidified sample melts at exactly 42° C. The specific gravity of the bleached substance is somewhat above that of water. Boiling alcohol of 97 per cent. dissolves it easily, but deposits it nearly all again on cooling, retaining only 3 per cent in solution. Warm ether likewise dissolves it readily, but deposits it in flakes or granular masses on cooling.

There are three principal sources of this fat or tallow in Japan, namely, *Rhus succedanea*, L., *Rhus vernicifera*, DC., and *Rhus sylvestris*, Sieb. et Zucc. The latter, however, furnishes none of the commercial product, being only cultivated in some districts of Japan for domestic use.

Rhus succedanea, L., when fully developed, attains a height of about 9 metres ($29\frac{1}{2}$ feet), and has a short trunk, reaching a circumference of about 1 metre (39·4 in.). The stem or trunk is covered with a uniform grey bark, and has a yellow wood, which contains a bright sap turning dark or black on exposure to air. The ramification is not profuse, and the leaves are placed close together at the ends of the branches. The colour of the leaves is a handsome green, turning to red in the autumn. They are about 15—20 cm. ($5\frac{3}{4}$—$7\frac{3}{4}$ inches) long, imparipinnate, and have a round, naked petiole. The leaflets, from four to six pairs, are opposite, naked, rather tender and entire. Some samples are stated to have more or less serrated leaflets. The size of these is about 5—7 cm. in length, and 1·5—2·5 cm. in width. The flowers are mostly situated in the axis of the leaves, and form broad, multiflorous panicles, which are, however, much shorter than the leaves. The flowers are diœcious, small, greenish-yellow and have a short peduncle.*

Rhus vernicifera, DC. attains a height of 8 to 12·5 metres (26 to 41 feet), and a girth of 1 m. (39·4 inch.). The bark of the trunk is grey and becomes fissured by age; the wood is greenish-yellow. The leaves make their appearance in May, and fall off about the end of October, without first turning red. Their length is up to 30 cm. (12 inch.). The leaflets are in pairs of 4 or 5, entire, and mostly opposite. The upper ones are elliptical, the lowest pair oval and somewhat smaller; all have a short pointed apex and generally an uneven base.

Neither *Rhus succedanea* nor *R. vernicifera* appear to be natives of Japan. Professor J. Rein, of Marburg, who has resided for some time in the country, thinks they are introduced from the Loochoo Islands. *R. sylvestris*, however, is a true native of Japan and does not occur elsewhere.

The fruits of the above, and of many other species of *Rhus*, have a great similarity, being a drupe or stone-fruit, which in the case of *R. succedanea* is about 7 mm. long, 5 mm. broad, and 5 mm. high. The colour of its smooth, shining epidermis, when dry, varies from a dirty bright yellow to a light brown; when fresh, it is yellowish-green. The vegetable fat or tallow is contained in firmly closed cells which are loosely coherent, and are completely filled with the fat. For this reason the fat resists, while inclosed by the epidermis, the action of solvents, such as hot alcohol or ether, and even hot water. The shell incloses the embryo very tightly, and the whole fruit may be boiled with water for a long time before any fat is extracted from it. Mr. Meyer assayed ten fruits, which together weighed 1·51 grams. They consisted of 46·45 per cent. mesocarp, 42·35 per cent. epidermis and putamen, and 8·85 per cent. embryo (with 2·35 per cent. loss). The quantity of fat extracted from the ground mesocarp by ether amounted to 20·9 per cent. of the whole weight of the fruit. The properties of the fat, whether obtained from the one or the other species of *Rhus*, are identical. It is brittle, bright yellowish-green, and has the specific gravity 0·916. It melts at 52—53° C. when old, and at 42° C. when recently solidified.* At 30° C. it is soluble in about 700 parts of 97 per cent. alcohol.

From the various statements of eye-witnesses and existing reports on the process employed by the Japanese to extract the fat, Mr. Meyer concludes that the most usual plan is the following:—

The fruits are previously well dried,† and then ground by means of mill-stones, or in mortars, with wooden pestles, or by bamboo flails. They are then freed by sifting and winnowing from shells and epidermis; sometimes, however, these latter are not separated. The mass is then heated over boiling water, in order to melt the fat in the cells, which is then expressed by means of different presses. During the second pressing, a little fatty oil is occasionally added to the mass, in order to retard the congelation of the fat. The crude tallow thus obtained is now boiled with dilute lye, whereby it becomes granular and more susceptible to the bleaching process; then exposed to the sun, and several times melted with water. The bleaching and melting is repeated until the product is pure and white.

Japan wax is chiefly used in Europe (and in the U. S.) as an admixture to beeswax in the manufacture of candles, as it facilitates the removal of the latter from the moulds; it is also used in the manufacture of wax-matches. Shoe and furniture manufacturers likewise use it in considerable quantity as an ingredient in polishing materials. For pharmaceutical purposes (ointments) it is not well adapted, since it is, like bleached beeswax, already a rancid substance, and promotes the rapid deterioration of fats mixed with it. Perfumers, however, make use of it for preparing a castor oil pomade; a mixture of castor oil and Japan wax having the peculiar property of becoming entirely transparent by repeated melting.

* For a further description of this and the following as well as for the details of the microscopical examination of the seeds, see the original, which is illustrated by two excellent coloured plates. In *New Remedies* there is an illustration of a flowering branch of *Rh. succedanea* constructed after the plate accompanying the author's paper.

* The fat obtained from the fruits of *Rhus Toxicodendron*, L., melts always at 42° C., whether old or new.

† Complete drying is supposed to be necessary for this reason, that the milk-sap of the mesocarp becomes insoluble in water, etc., only after drying in the air.

The Pharmaceutical Journal.

SATURDAY, JANUARY 31, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF POISONS.

In pointing out last week the misconception under which the coroner for Doncaster laboured in respect to the Pharmacy Act, and by which he was induced to make an entirely unfounded charge against the Pharmaceutical Society, we anticipated that this correction of his error and especially the very clear exposition of the matter by Messrs. Flux and Slade, the Solicitors of the Pharmaceutical Society, would have sufficed to convince him that he was wrong in his opinion that the Society had privately condoned offences of a grave nature, involving the destruction of human life. We were also disposed to believe that as a natural result of this demonstration of error on the part of the coroner for Doncaster, that gentleman would have lost no time in rescinding his unjust charge. Such a proceeding seemed to be not only proper in common fairness, but also to be one consistent with the official position of the accuser and requisite under the circumstances of the case.

But Mr. Shirley has not followed this course. On the contrary, he has again written a letter on the subject, which appeared in the *Times* of last Tuesday, without manifesting any sign of having been convinced of his erroneous interpretation of the Pharmacy Act. We can therefore only infer that he has not recognized his mistake and express our regret that this circumstance compels us again to refer to the subject for the purpose of exposing his errors, and if possible, making them apparent to himself. In the letter just mentioned, Mr. Shirley takes the trouble to point out that the person who incurred the forfeiture of five pounds was besides that liable under the seventeenth section of the Act for selling poison unless he did so in accordance with the regulations specified in the Act. Why he should take this trouble and thus occupy the columns of the *Times* it is not so easy to comprehend, because the statement is merely a reiteration of the information given by Messrs. Flux and Slade in the explanatory letter by which they sought to enlighten Mr. Shirley concerning the Pharmacy Act.

But though Mr. Shirley has somehow arrived at a perception of the fact that in respect to the sale of poisons there are two distinct offences contemplated by the Act, and two distinct penalties provided for their commission, he has apparently failed to perceive that there is a wide difference between the two offences so far as the powers and action of the Pharmaceutical Society are concerned. The provisions of the fifteenth section of the Act are to be regarded as mainly directed to the promotion of the objects for which a Royal Charter of Incorporation was granted to the Society, and—out of regard for the public benefit to be derived from their promotion —the Pharmacy Acts of 1862 and 1868 were passed to confirm that charter and furnish a protection to persons competent to carry on the business of pharmacy. Though the provisions of that section operate in a manner conducive to the public interest, they are at the same time principally protective of a class and the duty of proceeding against offenders under this section was therefore made the especial business of the Pharmaceutical Society. That duty was to be exercised in accordance with the objects of the charter, "for the protection of those who carry on the business of chemists and druggists." And while the funds of the Society were to be applicable for the purpose of defraying the cost of prosecuting offenders in such manner as the Council of the Society might direct, all penalties recovered by convictions under the fifteenth section were to be subject to the disposal of the Commissioners of Her Majesty's Treasury.

If there were in the Pharmacy Act no other provision for restricting the sale of poison than that above referred to, it might reasonably have been made incumbent upon the Pharmaceutical Society to exercise its powers under the fifteenth section of the Act, not specially for the protection of the class it represents, but also in all cases where the interest of the public was prejudiced. Such an extension of the Society's duties as a public guardian would have necessarily entailed its endowment with public funds adequate for the purpose. Even if such had been the duty of the Pharmaceutical Society it would have been impossible to prevent persons sued for penalties from paying the penalty incurred so as to avoid trial of the action, and in such a case there would not have been a shadow of justification for saying that an offence had been condoned without due regard to public interest, or "squared" by the payment of money.

But the important point is that in the Pharmacy Act there is other provision for restricting the sale of poison in regard to the interests of the public, and by the seventeenth section it is made unlawful to sell any poison unless certain specified conditions are fulfilled by the seller. A person committing an offence under this section is liable to prosecution at the instance of anyone who chooses to take action, and upon summary conviction is liable to a penalty of five pounds. This is altogether irrespective of the liability incurred under the fifteenth section, and the provisions thus made by the Pharmacy Act, give the public generally full power to punish offenders. The case which has called forth the strictures of the coroner for Doncaster was precisely one of a nature to be dealt with, under the seventeenth section now referred to, by those persons who were in the exercise of their official duties cognizant of the offence. If there be any blame attributable for the failure to prosecute it lies at the door of those who, knowing the facts, did not avail themselves of the power given by the Pharmacy Act, and it is not to be cast upon the Pharmaceutical Society.

But Mr. Shirley so represents the circumstances of this case in his last letter to the *Times* as in some degree to make it appear that the further prosecution of the offender was the duty of the Pharmaceutical Society. He says "that a druggist who sells poison "to a child in an unlabelled bottle asking no "questions and causing death should be punished "as the law directs." We do not demur to the justice of this proposition as it reads, but it contains a fatal fallacy which renders the inference intended to be drawn from it invalid. The assumption that the seller of the poison was a druggist is no doubt intended to suggest that his punishment was a duty appertaining to the Pharmaceutical Society; but that assumption was altogether gratuitous; he was not a druggist at all, but as was proved before Mr. Shirley, acting as coroner at the inquest, he was a grocer, and in no way qualified to deal in poisons.

It is only by means of such confusion of the two kinds of offences punishable by the Pharmacy Act that it is possible for Mr. Shirley to suggest that "the public will learn with surprise that having ex-"tracted for its own benefit five pieces of the "current gold coin of the realm called sovereigns, the "Society's functions ceased." It might more correctly be said that the Pharmaceutical Society having performed its duty of prosecuting under the fifteenth section of the Act, some other persons had failed to perform their duty by prosecuting under the seventeenth section. It is true this fact may be a ground for satisfaction in knowing that a public prosecutor is now appointed, and that in future there will be a special functionary to deal with such cases; but it affords no real ground for the conclusion that the utility of the Pharmaceutical Society is less than it is properly supposed to be, or than it it ought to be. Neither is it any reason for concluding that the action taken by the Pharmaceutical Society in the case Mr. Shirley refers to was a half measure, or anything less than it should have been according to the law both in the interests of the public and in the interests of the class it represents.

Therefore the whole of the conclusions to the disparagement of the Pharmaceutical Society and the Pharmacy Act, which Mr. Shirley considers irresistible, and has been enabled to make known by the publication of his letter in the *Times*, are in reality mere unsubstantiated fancies. Just in the same way, his assumption that the five pounds paid to the Pharmaceutical Society as the penalty for a breach of the fifteenth section of the Act was money obtained for and applied to the benefit of the Society, can only be supposed to rest upon defective acquaintance with the Pharmacy Act. Nothing therefore seems to remain for Mr. Shirley but to ponder over the provisions of that Act, and to confess with a good grace he has been mistaken. In that way he may yet prove that his zealous activity in this matter has been well intentioned, and he may serviceably contribute towards the realization of objects which others besides himself are desirous of bringing about, for lessening the liability to accidental poisoning arising either from the sale of poisons by unqualified persons or from their sale without due precaution.

THE NEXT EVENING MEETING.

An Evening Meeting of the Pharmaceutical Society will be held on Wednesday next, when the following papers will be read:—"Tincture of Senega as an Emulsifying Agent," by Mr. H. Collier; and "On the Diffusive Properties of Some Preparations of Iron in Relation to Dialysed Iron," by Professor Redwood. Some Specimens of Drugs, etc., from the late Indian Museum, which have been presented to the Pharmaceutical Society by the Government, will be placed upon the table.

CHEMISTS' ASSISTANTS' ASSOCIATION.

On Wednesday evening, the Annual Dinner of this Association took place at the Holborn Restaurant, the chair being taken by Professor Redwood. Among the guests were Professor Bentley, Dr. Muter, and Mr. Luff, and in all, the party numbered ninety-three. After dinner, several toasts were proposed and responded to, and some good songs and music were given by members of the Association. In all respects the vitality manifested by the ordinary meetings of the Association was recognizable on this occasion, and there was little reason to doubt that its members were as good at recreation and refreshments as they have proved themselves to be at work. Such Associations are calculated to be of great service in promoting the interests of pharmacy, and we cordially hope that this one may continue to maintain the prosperity and success it has already attained.

SEIZURE OF COCCULUS INDICUS.

At Revel, one of the Russian ports in the Baltic, a large quantity of cocculus indicus, imported as laurel berries, has been seized and confiscated. The chemist who detected the fraud will get half the value of the seizure, in this case amounting to several hundred roubles. With the exception of a portion retained for scientific purposes, the whole of the cocculus indicus will be destroyed.

At the next meeting of the Chemical Society, which will be held on Thursday, February 5, the papers read will be:—"Communications from the Laboratory of the Tokio University, Japan: On Persulphocyanate of Silver," by W. Atkinson; and "On Methylated Dioxethylenamines," by H. F. Morley.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Wednesday, January 21, 1880.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificate of the University of Oxford.

Rogers, Francis Alfred ....Stamford.

Certificates of the University of Cambridge.

Keeling, Arthur Gadsby ....Walthamstow.
Daintree, Ernest ....Cardiff.

Certificate of the University of Edinburgh.

Dodds, Nicholas ....Kelso.

Certificates of the College of Preceptors.

Bacon, Edward...... ....
Benson, Colin ....Chelmsford.
Hall, William Joseph ....Belper.
Roberts, Richard Ellis............Penmaenmawr.

MEETING OF THE NORTH BRITISH BRANCH.

The third evening meeting was held in the Society's rooms, 119A, George Street, Edinburgh, on Thursday, January 22, Mr. J. B. Stephenson, in the chair. The minutes of previous meeting having been read and confirmed, the Honorary Secretary announced the following donations:—

To the Museum:—Thirty-three specimens from the Society in London, mostly drugs from North British America, per Mr. Holmes. These will be exhibited at the next meeting.

To the Library:—*The Canadian Pharmaceutical Journal* for December, from the Ontario College of Pharmacy; *The Pharmacist and Chemist* for December, from the Chicago College of Pharmacy; *The Australian Supplement to the Chemist and Druggist*, from the Pharmaceutical Society of Victoria; the *Journal of the Chemical Society* for December and January, and Balfour on the Ipecacuanha Plant, from Mr. Mackay.

Dr. Stevenson Macadam then read the following paper on—

The Presence of Arsenic in Common Things.

BY DR. STEVENSON MACADAM,

Lecturer on Chemistry, Edinburgh.

Fully eighteen years ago I drew special public attention to the extensive employment of arsenical green colouring matter in ordinary wall paper-hangings, which contained from 1 to 40 grains of arsenic in each square foot of paper. Taking 20 grains of arsenic as an average proportion, an ordinary large-sized room with 1000 square feet of wall surface would thus have 20,000 grains of arsenic, and an ordinary small-sized room with 500 square feet of wall surface would have 10,000 grains of arsenic covering the walls. Such arsenical colouring matter is in most cases more or less loosely adhering to the surface of the paper, and the dusting and rubbing down of the walls are liable to detach the pigment as a fine powder, which becomes diffused through the atmosphere of the room, and temporarily settles on the carpet, bedclothes, bed and window hangings, cornices, etc., liable to be disturbed again by the next dusting operation, any alteration of the bedclothes or hangings, or even during the airing of the room. The arsenical dust might thus be inhaled in every breath. Possibly, also, the alternate damping and drying of the wall paper in such a room, which always takes place from time to time during occupancy and non-occupancy, and even during fluctuations in the humid condition of the atmosphere, may tend to vaporize the arsenic into the atmosphere of the room. I have repeatedly tested the dust from the cornices, etc., of rooms papered with the arsenical paper-hangings, and have always found more or less arsenic in the dust.

During the last year my attention has been specially directed to the great prevalence of green colour in textile fabrics, paper for labels and boxes, artificial flowers, children's books and toys, and other common articles, and I resolved to investigate how far the green colour was of an arsenical nature. In a very large proportion of the articles examined arsenic was found more or less present, often in small quantity, but occasionally in very large proportion. The preliminary trials were made by Reinsch's process, taking care to have a blank experiment throughout, and, thereafter, various articles were selected for the purpose of the determination of the quantity of arsenic present in such. The quantitative analysis was carried on by treating the article with a dilute solution of hydrochloric acid, containing one part by volume of the acid to eight parts of water. After heating and filtration, the arsenic and copper were precipitated by a stream of hydrosulphuric acid, and the liquid filtered and the precipitate washed. Thereafter the mixed sulphides were treated with dilute ammonia, the solution evaporated to dryness, the residue acted upon by nitric acid, again evaporated, dissolved in water, and the resulting arsenic acid treated with ammonia and ammoniacal sulphate of magnesia solution. The precipitate thus obtained of the arseniate of magnesia and ammonia—

$$2(MgNH_4AsO_4)H_2O$$

was dried on a weighed filter, and the arsenic calculated therefrom into arsenious oxide.

Working in this way, I examined three samples of thin gauze cloth which were coloured of a light green tint. These cloths gave me the following results, calculated to the square foot of each of the cloths:—

	Arsenious Oxide obtained from the square foot.
No. 1 Cloth	31·72 grains.
No. 2 „	11·60 „
No. 3 „	26·60 „
Average of three samples . . .	23·31 grains.

These cloths are sold for cheap ball dresses, and for trimming dresses, and are often used for covering gasaliers, mirrors, etc., during summer weather. The price was sixpence to a shilling a yard, and consequently for a few pence, a large amount of deadly material could readily be purchased. Indeed, taking ten yards of cloth of 36 inches wide as a reasonable amount in a dress, there would be present in such a dress 90 square feet, each containing on the average 23 grains of arsenic, or in all fully 2000 grains of arsenic. Such an amount is enough to startle any one, not only in the fact of its being present in the cloth, but also in the readiness with which the poison can be so procured.

Again, I examined a large number of green coloured papers, more or less glazed, and used in covering pasteboard boxes, and in making printed and other labels for articles of food, drink and general merchandise. Indeed, a large proportion of band-boxes sent out by milliners, hatters, etc., of toy boxes, and of shop labels and tickets are more or less covered with this green paper. Three samples were taken for quantitative analyses, and they yielded as follows:—

	Arsenious Oxide obtained from the square foot.
No. 1 paper	45·40 grains.
No. 2 „	35·98 „
No. 3 „	16·22 „
Average of three samples . .	32·53 grains.

Taking the average amount of 32 grains of arsenic in the square foot, a small sized band-box with three square feet of green surface, will have about 100 grains of arsenic. An ordinary sized cracker-box with one and a half square feet of green surface will have 48 grains, whilst the small cracker-boxes, specially fitted up for children, have a square foot of green paper and 32 grains of arsenic. Even the papers of the crackers themselves are often green and arsenical, and yield 2 to 3 grains of arsenic each. The labels on tinned meats are often green and arsenical, and yield from 6 to 20 grains of arsenic each. Indeed you can scarcely purchase a bottle of any liquid or solid article of food, delicacy or stimulant, at the present time, without running the risk of getting at least one poisonous dose of arsenic on the label affixed to the bottle or package, or even on the paper in which the article is wrapped up.

I have likewise found the same poisonous green pigment on envelope wrapping bands, each containing 1 to 2 grains of arsenic; in children's picture and story books containing at least 50 grains of arsenic; in concert and ball-room cards and tickets, in artificial flowers, water colour paints, children's toys, etc. Indeed, the present rage for green colour seems so general that it is a rare thing to find a shop window where arsenical green is not present on the paper of the shelves or walls, the labels and tickets on the articles, and the wrappers or boxes containing the wares.

In domestic use also, the green colour has lately invaded the size tinting of kitchens, presses, and rooms which are size painted. Emerald green, which is sold in every painter's shop to all and sundry at a few pence per lb. contains, as analysed by me, fully 50 per cent. of arsenic; and size green, which is also sold to every one at as cheap a rate, contains from 2 to 14 per cent. of arsenic, according to the depth of the shade of green. I have tested the size colour as supplied and put on by painters on the walls of kitchens and other rooms, and have calculated that from 7 to 36 grains of arsenic are present in every square foot of wall surface.

In this communication I have limited my analyses and observations to those cases in which the arsenic was present as arsenical green in large quantity. I am aware that the same poison is present in other colours and in other states of combination than as the arsenite of copper (Scheele's green), and the aceto-arsenite of copper (Schweinfurt green), and it is probable then I may return to the subject again. But in the meantime, enough has been said to show the great prevalence of the poisonous arsenical green in common things. It scarcely admits of question that such ready means of acquiring deadly material should not be allowed in any country. Independently of the question of accidents occurring from children sucking or even eating articles containing the poison, or of parties being affected by the arsenical wall papers, or wall size paint, there is the facility for carrying out murderous designs, which ought not to be placed in the hands of a community, or be left to chance for malicious people not to take advantage of. There seems little use in a Poison Act to restrict the sale of comparatively small doses of poison, when every one can purchase in any painter's or drysalter's shop about half a pound of arsenic in the form of emerald green for sixpence, and at least a quarter of a pound of arsenic in green paper hangings for the same money; and where, without making any direct purchase at all, anyone can obtain from an old meat can, a bottle label, a grocer's wrapper, a child's picture book, a worn-out artificial flower, or a piece of an old band-box, as much arsenic as will enable him to inflict deadly injury upon himself or his neighbours.

Noxious trades cannot be carried on where the atmosphere or the water supply of a community are affected injuriously thereby, and it would seem reasonable that the wholesale trade of disseminating over the country vast quantities of arsenic should be equally amenable to and be suppressed by the strong arm of the law.

Dr. Macadam illustrated his lecture by tests, and exhibited a large number of articles in common use containing arsenic.

Mr. D. B. Dott, Edinburgh, afterwards read the following notes on "Beberia":—

Beberia.

BY D. B. DOTT.

Beberia is the principal alkaloid of the bark of the greenheart tree (*Nectandra Rodiœi*), and was discovered therein by Dr. Rodie, of Demerara, in 1834. Professor Maclagan, in 1843, showed that Rodie's beberia was a mixture of two alkaloids—beberia and siperia. In 1845, Maclagan and Tilley assigned to beberia the formula $C_{35}H_{20}NO_6$ (old notation); but it was first obtained in approximate purity by V. Planta, who gave the formula $C_{19}H_{21}NO_3$. In 1860, Walz made experiments on buxine, the alkaloid of *Buxus sempervirens*, and found it to be identical with beberia; his analysis agreeing with the formula of V. Planta. A valuable paper on the subject was contributed by Professor Flückiger to the *Neues Jahrbuch für Pharmacie* (xxxi., p. 257), of which an abstract appears in *Pharmaceutical Journal* (2nd ser., vol. xi.). He prepared his purified base by exhausting the crude alkaloid with ether, dissolving the base so obtained in dilute acetic acid, and precipitating with potash. This treatment was repeated several times until the precipitate produced was free from colour. The alkaloid prepared in this way was analysed by Dr. Kraushaar (Flückiger's assistant), and gave of carbon, 71·61 per cent., and of hydrogen, 6·73 per cent. The platinum compound gave 19·22 per cent. of platinum. The chief point of interest in Flückiger's paper is, however, his identification of the alkaloid pelosine with beberia.

Pelosine was discovered by Wiggers in 1838, and found by Bödeker to answer to the formula $C_{18}H_{21}NO_3$. Flückiger prepared pelosine from the bark of *Cissampelos Pareira*, L., and found that its reactions were in all respects the same as those of beberia, and he was quite unable to detect any difference between the two bases. An analysis gave 72·09 per cent. of carbon, and 6·80 per cent. of hydrogen. The platinum compound yielded 19·13 per cent. of metal, and the hydrochloride, 12·68 per cent. of hydrochloric acid. Referring to these results, Fluckiger remarks, "Perhaps Bödeker's formula is the more correct. It would be desirable to examine crystalline derivatives of the alkaloid in order to ascertain whether $C_{18}H_{21}NO_3$ or $C_{19}H_{21}NO_3$ is the true expression of its constitution; but I tried in vain to obtain, for instance, a bromated compound, or any product of the decomposition of the alkaloid in a crystallized state."

From what has been said it may be held as proved that beberia, pelosine, and buxine are one and the same alkaloid, and Flückiger maintains that the name buxine must be applied to them all as it was given as early as 1830 to the alkaloid of *Buxus* by Faurè. I do not admit, however, that this rule of priority of name must be considered as invariably binding, and would rather be inclined to say that if an alkaloid or other substance had become well known under a certain name, that name ought to be retained, even although the substance had been called something else at an earlier time.

As I mentioned in a note read before the British Pharmaceutical Conference at Dublin, I some time ago obtained the hydrochloride of beberia in the crystalline form, which enables me to say that the alkaloid I worked with was really pure beberia. The hydrochloride was recrystallized several times, and the base precipitated from its solution by ammonia. Thus obtained and dried at the ordinary temperature, beberia is a white amorphous substance which loses water by exposure to the heat of a water-bath. It is a monacid base of well-marked alkaline character, being capable of decomposing ammonic salts when warmed with their solutions. This property is only possessed by the stronger alkaloids such as codeia and morphia, and not by the weaker members of the class such as papaverine and narcotine. Beberia combines to form readily soluble salts with hydrochloric, nitric, sulphuric, acetic, tartaric, citric and oxalic acids.

The hydrochloride crystallizes in minute four-sided prisms from an aqueous solution. If the solution is neutral it is apt to assume the form of a transparent jelly. The only other salt I have obtained in the crystalline form is the nitrate. It is almost characterestic of the salts of beberia that their solutions yield precipitates with such a variety of reagents. These include hydrochloric, hydriodic and nitric acids, potassic ferricyanide and ferrocyanide, sodic phosphate, nitrate and iodide, and mercuric chloride. Beberia forms a deep red solution with strong nitric acid, which on dilution with water gives a bulky precipitate; but I hardly think this reaction can be considered characteristic of the alkaloid, and I have tried in vain to devise some colour-test which should be conclusive evidence of its presence.

It only remains now to give the results of my analysis of the crystallized hydrochloride. The alkaloid was estimated in the air-dry salt by precipitation with ammonia, the precipitate being dried at 120° C.

6·125 grs. gave 5·105 grs. = 83·34 per cent.
3·520 „ „ 2·970 „ = 84·37 „ „
Mean = 83·85 per cent.

I need hardly say that no great accuracy could be expected in this determination, as the alkaloid is by no means insoluble in solution of ammonic chloride.

The chlorine was estimated by precipitating with argentic nitrate in the presence of nitric acid.

6·225 grs. gave 2·540 grs. Ag Cl = 10·37 per cent. HCl.
7·380 „ „ 3·010 „ „ „ = 10·36 „ „ „
8·220 „ „ 3·338 „ „ „ = 10·32 „ „ „
Mean = 10·35 per cent.

Various portions of the hydrochloride prepared at different times were dried by exposure to the air and then under a bell-glass over sulphuric acid.

10·040 grs. lost 1·470 grs. = 14·64 per cent.
6·755 „ „ 0·900 „ = 13·32 „
7·695 „ „ 1·025 „ = 13·32 „
8·620 „ „ 1·240 „ = 14·38 „
Mean = 13·91 per cent.
$C_{18}H_{21}NO_3H_2O$. $3H_2O$ = 13·25 „ H_2O.

The last molecule of water is not lost in the exsiccator or in the water-bath, but requires a temperature approaching 120° C. for its elimination. At the same time, however, there is evidently some decomposition, as the anhydrous hydrochloride obtained at that temperature invariably yielded a smaller percentage of chlorine than was afforded by the same salt dried over sulphuric acid.

The beberia-hydrochloride platinic-chloride was prepared by adding solution of muriate of beberia to solution of platinic chloride, the former being in excess. The precipitate was well washed with warm water and dried at 120° C. The temperature must not be allowed to rise above that, on account of the liability of the salt to decomposition under the influence of heat.

4·290 grs. gave 0·840 gr. pt. = 19·55 per cent.
3·955 „ „ 0·770 „ „ = 19·46 „
6·065 „ „ 1·180 „ „ = 19·45 „
2·535 „ „ 0·495 „ „ = 19 52 „
5·190 „ „ 1·015 „ „ = 19·55 „
Mean = 19·50 per cent.

It was not considered necessary to make a combustion of the alkaloid, as the afore-mentioned results, considered along with those of previous experimenters, are sufficient to determine the composition of the base.

Appended are the percentages of Kraushaar's and Flückiger's analyses. The numbers under the name of he last-mentioned chemist relate to pelosine.

	Found. F.	Found. K.	Calculated for $C_{18}H_{21}NO_3$.
C	72·09	71·61	72·24
H	6·80	6·73	7·02

The Platinochloride.

F.	K.		Calculated for $(C_{18}H_{21}NO_3.HCl)_2PtCl_4$
19·13	19·22	19·50	19·54

The Hydrochloride.

	Found.	Calculated for $C_{18}H_{21}NO_3.HCl.H_2O$.
$C_{18}H_{19}NO_3$	83·85	84·58
HCl	10·35	10·32

These results leave little room for doubt that the composition of beberia is represented by the formula $C_{18}H_{21}NO_3$.

Mr. Dott gave practical illustrations of the tests for beberia and kindly presented to the Society specimens of bebeeru nuts, beberia and hydrochlorate of beberia.

Essential Oil of Aloes.

Dr. Wm. Craig, Edinburgh, exhibited to the meeting a curiosity in the shape of a specimen of the essential oil of aloes, on which he made the following remarks:—

This oil is a pale yellow mobile liquid, sp. gr. 0·863, and boils at from 266° to 271° C. It is to the presence of this oil that the odour of aloes is due. It exists in very small quantity in aloes, only about two fluid drachms being obtained from five hundred pounds of aloes. This oil has a resemblance in taste and smell to the oil of peppermint. The boiling point, however, of the oil of peppermint is only 190° C. Although aloes has been used in medicine for upwards of two thousand years, its volatile oil was first discovered in 1873 by Messrs. T. and H. Smith and Co., the well-known chemists of this city, and the discoverers of aloin, the active principle of aloes. In that year they succeeded in isolating a small quantity of the "oleum aloes," and exhibited it that same year at the Vienna exhibition. That specimen was afterwards presented to the Pharmaceutical Society, London, and unfortunately the bottle containing it was broken, and the oil was lost. Last year they again succeeded in obtaining a small quantity of the oil from five hundred pounds of Barbadoes aloes. When it is remembered that to obtain two fluid drachms of this oil, it is necessary to distil about 500 gallons of fluid, the members of the Society will have some idea of the difficulty of obtaining this substance. In the specimen exhibited the oil is floating on the surface of a colourless, mobile, ethereal liquid, of a sp. gr. 0·95, being the liquid from which the oil of aloes was finally distilled. The specimen exhibited is interesting on account of its extreme rarity, being in all likelihood the only specimen of this oil in the world. Through the kindness of the Messrs. Smith, I am enabled to exhibit it to the members of this Society. Of course there has been no opportunity of investigating its therapeutic qualities, but from its nature it is likely to be an aromatic and antispasmodic.

Dr. Craig also exhibited some very beautiful and perfect crystals of citric acid.

The usual vote of thanks to the gentlemen who furnished the evening's programme brought the meeting to a close.

Provincial Transactions.

GRIMSBY CHEMISTS' ASSOCIATION.

The annual dinner of the above institution took place at the Royal Hotel, on the evening of Tuesday, the 20th inst. After dinner the usual loyal and patriotic toasts were given and responded to, and were followed by those of "The Trade Association of Great Britain," "The Pharmaceutical Society of Great Britain," and the toast of the evening, "Success to the Grimsby Chemists' Association."

The President (Mr. G. Croft) explained the chief objects of the society. He said the Association was formed for the mutual protection of the trade in Grimsby and district; to promote friendly relations of chemists and druggists towards each other; and to create a better understanding amongst the community than had previously existed. He was convinced that the chemists of Grimsby, as well as chemists generally, were an intellectual class of society, and he sincerely hoped they would individually and collectively try to elevate their professional status rather than degrade it. If a trade grievance occurred let it be brought before the Association and all would be made right. He felt that these annual dinners would be productive of good fellowship and trusted they would be more successful each succeeding year. Several of the gentlemen present enlivened the proceedings during the evening with songs and pianoforte music.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The assistants' section of this society met in Anderson's College, George Street, on Wednesday evening, the 14th inst., to hear a paper by Mr. David Lees, President.

Mr. Lees took for his subject "The Constituents of the Atmosphere," and spoke of the more important of them at some length, explaining the functions of the elements which go to compose the air, their properties collectively and in an isolated condition, the effect of continued breathing on the air, and its relation to the animal and vegetable worlds generally.

The paper was attentively listened to throughout, and after a few remarks by members a hearty vote of thanks was awarded to the reader.

It was intimated that Mr. William Simpson, Vice-President, would read an essay at the next meeting.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The annual meeting was held on Wednesday evening, January 23. Mr. W. Ward, F.C.S., etc., in the chair. The following officers were elected for the ensuing year:—President, Mr. G. Ellinor, Ph.C., etc.; Vice-Presidents, Mr. J. Preston and Mr. Turner; Joint Hon. Secs., Mr. E. Radley Learoyd and Mr. G. W. Newsholme; Treasurer, Mr. W. Jervis; Council, Messrs. Ward, Carr, Burnell, Ottley, Maleham, Cubley, Watts and Hall.

The President delivered his inaugural address, in the course of which he said, the past year had been eventful in the assembling, for the first time in Sheffield, of the British Pharmaceutical Conference, and expressed the great satisfaction it gave to local members. Referring to the subject of prosecutions under the Sale of Food and Drugs Act, he thought it was high time a determined effort was made to protest against the manner in which money is unjustly taken out of the pockets of chemists in various parts of the country, through the incompetence or want of correct knowledge of drugs by the majority of borough or county analysts. The question that should be asked was, Is it right that defendants should have to pay the costs when there is no adulteration? He further noticed some of the amusing and variable interpretations of the Pharmacy Act and the instructions given by some coroners. In conclusion, he expressed a hope that he would be able to conduct the business of the Society with that care and diligence which had characterized his predecessors.

Votes of thanks for past services concluded the business of the meeting.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held at the rooms of the Association, George Street, Hanover Square, on Wednesday evening, January 14, the President in the chair, when a paper was read by Mr. G. W. Bullen on "Benzene and its Derivatives."

After a few preliminary remarks with reference to the important position occupied by the benzene, or aromatic group, both chemically and commercially, the author commenced by giving a somewhat detailed account of the discovery, manufacture, and uses of benzene, passing notice also being given to the other hydrocarbons of this group, viz., toluene, xylene, cumene, etc.

The nitro-derivatives of the benzene series were then considered, special reference being made to nitro-benzene, or artificial oil of almonds, including the best methods for distinguishing it from the natural oil; reference was also made to two other kinds of nitro-benzene differing from that ordinarily known in having higher boiling points, the differences in the boiling points being due to the presence of the nitro-derivatives of the higher hydrocarbons, toluene, xylene, etc., in greater or less proportions. These two heavy nitro-benzenes are used solely in the commercial world for the manufacture of aniline.

The amido-derivatives, or those bodies which are derived from benzene and its homologues by substitution of amidogen (NH_2) for hydrogen, were then described, attention being principally confined to the discovery and manufacture of aniline, the amido-derivative of benzene, processes for the manufacture of the principal dyes on the large scale being mentioned.

The two kinds of alcohols belonging to the series were next brought under notice:—1. The phenols, or those alcohols which are incapable of being converted into aldehydes and acids by oxidation. 2. The normal, or aromatic alcohols, which contain the group CH_2OH, and are capable of forming aldehydes and acids by oxidation in the same manner as the ordinary primary alcohols, such as methyl and ethyl alcohols.

The difference in the formation of these two kinds of alcohols having been explained, the most important of the phenols and their derivatives were then described, viz., carbolic acid, cresol, thymol, pyrocatechin, guaiacol, resorcin, orcin, and trinitrophenol, or picric acid. It was also noticed, as being of some interest, that carbolic acid and thymol, possessing such great similarities in their antiseptic and caustic properties, are so closely allied chemically. The normal alcohols and their aldehydes were then submitted to consideration, benzol alcohol being regarded as the most important, yielding as it does benzaldehyde, or bitter almond oil, and benzoic acid by oxidation. Saligenin was mentioned as partaking both of the nature of a phenol and a normal alcohol, the hydroxyl radical being substituted for hydrogen, both in the principal and lateral chains of the molecule. Among the aldehydes benzoic aldehyde, or bitter almond oil, salicyl aldehyde, the aldehyde of salicylic acid, and vanillin were noticed, mention being made of the fact that vanillin prepared artificially from coniferin was a complete failure from a commercial point of view, as it loses its aromatic odour in a very short time. Among the acids of the aromatic group, benzoic acid was regarded as occupying a position analogous to that of aniline among the aniline dyes, or in other words, as being the keystone of the series, there being a vast number of acids derived from it by addition, substitution, etc.,—salicylic, or oxybenzoic, and gallic, or trioxybenzoic acids, being mentioned among other examples. In conclusion, the principal processes for the manufacture of benzoic acid, both from natural and artificial sources, were described.

After the reading of the paper a discussion took place, at the termination of which a cordial vote of thanks to Mr. Bullen for his interesting paper was passed.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Buffon.*

BY PROFESSOR ST. GEORGE MIVART, F.R.S., SEC.L.S., V.P.Z.S.

(*Continued from page* 517).

I next desire to direct your attention to another matter treated of by Buffon—I mean THE RESEMBLANCES AND DIFFERENCES WHICH EXIST BETWEEN THE MIND OF MAN AND THE HIGHER PSYCHICAL FACULTIES OF ANIMALS.

This question is eminently a question of our own day, and one which I feel cannot but excite interest in this Section.

But its accurate investigation is attended with special difficulties, and amongst them are two temptations, which are apt to beset the inquirer:

(1). The first of these arises from the wide-spread love for the marvellous of whatsoever kind, and the tendency to inverted anthropomorphism.

(2). The other is the temptation to strain or ignore facts to serve a favourite theory.

As to the former of these dangers, I may perhaps be permitted to quote some remarks made by Mr. Chambers, approvingly cited by Professor Bain: "There are two subjects where the love of the marvellous has especially retarded the progress of correct knowledge—the manners of foreign countries, and the instincts of the brute creation . . . . It is extremely difficult to obtain true observations" as to the latter "from the disposition to make them subjects of marvel and astonishment." . . . . "It is nearly as impossible to acquire a knowledge of animals from anecdotes as it would be to obtain a knowledge of human nature from the narratives of parental fondness and friendly partiality." This I believe to be most true, and that here the danger of mistaking inference for observation is exceptionally great. The inquirer ought not to accept as facts marvellous tales without criticism and a careful endeavour to ascertain whether the alleged facts are facts and not unconscious fictions.

As to the second danger, the lamented George Henry Lewes, whom no one can suspect of any hostility to Evolution in its most extreme form, remarks (in his posthumous work† just published) that the researches of various eminent writers on animal psychology have been "biassed by a secret desire to establish the *identity* of animal and human nature," and certainly no one can deny that those who do assert that identity are necessarily exposed to the temptation referred to. Of course persons who desire to disprove this identity are exposed to the opposite temptation; but it cannot be maintained that there is evidence of Buffon having been influenced by any such desire.

The obvious difference between the highest powers of man and animals has led the common sense of mankind to consider them to be of radically distinct kinds, and the question which naturalists now profess to investigate is whether this is so or no.

But we may doubt whether many who enter upon this inquiry do not enter upon it with their minds already made up that no such radical difference can by any possibility exist. To admit it, they think, would be tantamount to admitting some non-natural origin of man, to accepting as a fact something not harmonizing with our views as to nature generally, leading to we know not what results—possibly even to lending some support to Christianity. To admit it, would be to deny the principle of continuity. There cannot, therefore, be any essential difference between man and brute, and their mental powers must be the same in kind. This, I think, is no unfair representation of the state of mind in which this question is very likely to be entered upon at the present time. Surely, however, if we profess to investigate a question, we ought in honesty to believe that there *is* a question to investigate, or else leave the matter to others; and if evidence should seem to show that "intellect" *cannot* be analysed into sense, but is an ultimate, it ought to be accepted, at the least provisionally, as such, even at the cost of having to regard its origin as at present inexplicable. Can we explain the origin of "motion?" But what rational man thinks of denying it on that account? Let us not reject anything, then, which may be evident, on account of certain supposed speculative consequences.

But that no such consequences as those referred to need follow from the admission of the radical distinctness of human reason, seems evident from the views of Aristotle. He certainly was free from theological prejudices or predispositions, and yet to his clear intellect the difference between the merely sentient and the rational natures was an evident difference, and the facts which are open to our observation are the same as those which presented themselves to his.

To enter on this inquiry with any fair prospect of success, it is not only necessary to guard against such temptations as these, but it is also necessary to be provided with a certain amount of knowledge of a special kind: namely, with a clear knowledge of what our own intellectual powers are. I conceive that, great as is the danger of exaggeration and false inference as to the faculties of animals, the danger of misapprehending and underrating our own powers is far greater.

Buffon held very decided views as to the distinctness of the mind of man from the so-called minds of animals. But an ingenious and gifted writer,* who has recently done good service in supporting Buffon's claims to greater consideration than he commonly receives, has, nevertheless, done him what I believe to be strange injustice in attributing to his great work an ironical character, and this in spite of Buffon's protest† against irony in such a work as his. I cannot venture to take up your time with controversy on this subject; but apart from Buffon's protest against "équivoque," it is incredible to me that he should have carried on a sustained irony through so voluminous a work—thus making its whole teaching absolutely mendacious. One remark of Buffon's, which has been strangely misinterpreted by this writer, I shall have occasion to notice directly; but I think it may suffice to clear Buffon's character from the aspersion of his admiring assailant, to point out that in the table of contents in the final volume of his 'History of Mammals,'‡ (which table gives the pith and gist of his several treatises), he distinctly affirms the distinctions maintained in the body of his work.

The following were Buffon's views. In his "Discourse on the Nature of Animals,"§ he says, "Far from denying feelings to animals, I concede to them everything, except thought and reflection" . . . . "they have sensations, but no faculty of comparing them one with another, that is to say, they have not the power which produces ideas." He is full of scorn|| for that gratuitous admiration for the moral and intellectual faculties of bees, which Sir John Lubbock's excellent observations and experiments have shown to be indeed gratuitous. Speaking of the ape, most man-like (and *so* man-like) as to brain, he says:¶ "Il ne pense pas: y a-t-il une preuve plus évidente que la matière seule, quoique parfaitement organisée, ne peut produire ni la pensée, ni la parole qui en est le signe, à moins qu'elle ne soit animée par un principe supérieur?"**

|| *Op. cit.*, tome iv., p. 91.

¶ *Op. cit.*, tome xiv., p. 61.

** Mr. Butler cites objections brought forward in a certain passage (from pp. 30 and 31, vol. xiv.), as if they were Buffon's own. But they are the objections of an imagined opponent whose views Buffon himself combats. It is worthy

Buffon has been accused of vacillation with respect to his doctrine concerning animal variation, but no one has accused him of vacillation with respect to his views concerning reason and instinct.

I come now to the passage which I said has been so strangely misunderstood. It is that in which he expresses his conviction that "animals have no knowledge of the past, no idea of time, and consequently no memory." But to quote this passage without explanation is gravely to misrepresent the illustrious French naturalist. Buffon was far from ignoring, indeed he distinctly enumerates the various obtrusive phenomena which often lead the vulgar to attribute, without qualification, both knowledge and memory to brutes. But, in fact, he distinguishes between* memory and memory. His words are: "Si l'on a donné quelque attention à ce que je viens de dire, on aura déjà senti que je distingue deux espèces de mémoire infiniment différentes l'une de l'autre par leur cause, et qui peuvent cependant se ressembler en quelque sorte par leurs effets; la première est la trace de nos idées, et la seconde, que j'appellerais volontiers réminiscence† plutôt que mémoire, n'est que le renouvellement de nos sensations," and he declares‡ true memory to consist in the recurrence of ideas as distinguished from revived sensuous imaginations.

This distinction is one which it is easy to perceive. That we have automatic memory, such as animals have, is obvious; but the presence of intellectual memory (or memory proper) may be made evident by the act of searching our minds (so to speak) for something which we know we have fully remembered before, and thus intellectually remember to have known, though we cannot now bring it before our imagination.

As with memory, so with other of our mental powers, we may, I think, distinguish between a higher and a lower faculty of each; between our higher, self-conscious, reflective mental acts—the acts of our intellectual faculty—and those of our merely sensitive power. This distinction (to which I have elsewhere§ called attention) I believe to be one of the most fundamental of all the distinctions of biology, and to be one the apprehension of which is a necessary preliminary to a successful investigation of animal psychology. It is, of course, impossible for us thoroughly to comprehend the minds of dogs or birds, because we cannot enter into the actual experience of such animals, but by understanding the distinction between our own higher and lower faculties|| we may, I think, more or less approximate to such a comprehension.

It may, I believe, be affirmed that no animal but man has yet been shown to exhibit true concerted action, or to express by external signs distinct intellectual conceptions —processes of which all men are normally capable. But just as some plants simulate the sense-perception, voluntary motions and instincts of animals, without there being a real identity between the activities thus superficially similar, so there may well be in animals actions simulating the intellectual apprehensions, ratiocinations, and volitions of man without there being any necessary identity between the activities so superficially alike. More than this, it is certain *à priori* that there must be such resemblance, since our organization is similar to that of animals, and since sensations are at least indispensable antecedents to the exercise of our intellectual activity.

I have no wish to ignore the marvellous powers of animals or the resemblance of their actions to those of man. No one can reasonably deny that many of them have feelings, emotions and sense-perception, similar to our own; that they exercise voluntary motion and perform actions grouped in complex ways for definite ends; that they to a certain extent learn by experience, and can combine perceptions and reminiscences so as to draw practical inferences, directly apprehending objects standing in different relations one to another, so that, in a sense, they may be said to apprehend relations. They will show hesitation, ending apparently, after a conflict of desires, with what looks like choice or volition, and such animals as the dog will not only exhibit the most marvellous fidelity and affection, but will also manifest evident signs of shame, which may seem the outcome and indication of incipient moral perceptions. It is no great wonder, then, that so many persons, little given to patient and careful introspection, should fail to perceive any radical distinctions between a nature thus gifted, and the intellectual nature of man.

But, unless I am greatly mistaken, the question can never be answered by our observations of animals, unless we bear in mind the distinctions between our own higher and lower faculties.

Now I cannot here even attempt to put before you what I believe to be the true view of our own intellectual processes. Still I may, perhaps, be permitted to make one or two passing observations.

Everybody knows his own vivid feelings (or sensations), and those faint revivals of feelings, simple or complex, distinct or confused, which are imaginations and emotions; but the same cannot be said as to thought. Careful introspection will, however, I think, convince anyone that a "thought" is a thing widely different from an "imagination"—or revival of a cluster of faint feelings. The simplest element of thought seems to me to be a "judgment," with an intuition of reality concerning some "fact," regarded as a fact real or ideal. Moreover, this judgment is not itself a modified imagination, because the imaginations which may give occasion to it persist unmodified in the mind side by side with the judgment they have called up. Let us take, as examples, the judgments "That thing is good to eat," and "Nothing can be and not be at the same time and in the same sense." As to the former, we vaguely imagine "things good to eat," but they exist *beside* the judgment, not *in* it. They can be recalled, compared, and seen to co-exist. So with the other judgment, the mind is occupied with certain abstract ideas though the imagination has certain vague "images" answering respectively to "a thing being" and "a thing not being," and to "at the same time" and "in the same sense;" but the images do not *constitute* the judgment itself any more than human "swimming" is made up of "limbs and fluid," though without such necessary elements no such swimming could take place.

This distinction is also shown by the fact that one and the same idea may be suggested to, and maintained in the mind by the help of the most incongruous images, and very different ideas by the very same image. This we may see to be the case with such ideas as "number," "purpose," "motion," "identity," etc.

But the distinctness of "thought" from "imagination" may perhaps be made clearer by the drawing out fully what we really do when we make some simple judgment, as, *e.g.* that "a negro is black." Here, in the first place, we directly and explicitly affirm that there is a conformity between the external thing, "a negro," and the

---

of note that Buffon long anticipated our contemporaries with respect to man's place in nature in so far as concerns his mere anatomy. For he did not hesitate to affirm that the Orang differs less from us structurally than it differs from some other apes.

* *Op. cit.*, tome iv., p. 60.

† Here he follows, without citing, the old distinction of Aristotle between memory and reminiscence.

‡ *Op. cit.*, tome iv., p. 56.

§ 'Lessons from Nature,' Murray, 1876, p. 196

|| Certain writers (as, for example, Professor Ewald Hering, of Prague) have used the word "memory" to denote what should properly be called "organic habit," *i.e.* the power and tendency which living beings have to perpetuate, in the future, effects wrought on them in the past. But to call such action as that by which a tree as it grows preserves the traces of scars inflicted on it years before, "memory," is a gross abuse of language—a use of the word as unreasonable as would be the employment of the word 'sculptor" to denote a quarryman, or "sculpture" to indicate the fractures made in rocks by the action of water and frost.

external quality, "blackness"—the negro possessing that quality. We affirm secondarily and implicitly a conformity between the two external entities and the two corresponding internal concepts. And thirdly, and lastly, we also implicitly affirm the existence of a conformity between the subjective judgment and the objective existence.

All that it seems to me evident that sentience can do, is to associate feelings and images of sensible phenomena, variously related, in complex aggregations; but not to apprehend sensations as "facts" at all, still less as internal facts, which are the signs of external facts. It may be conceived as marking successions, likenesses and unlikenesses of phenomena, but not as recognizing such phenomena as *true*. Animals, as I have fully admitted, apprehend things in different relations, but no one that I know of has brought any evidence that they apprehend them *as* related, or their relations *as* relations. A dog may feel shame, or possibly (though I do not think probably) a migrating bird may feel agony at the imagination of an abandoned brood; but these feelings have nothing in common with an ethical judgment, such as that of an Australian, who, having held out his leg for the punishment of spearing, judges that he is wounded more than his common law warrants.

Animals, it is notorious, act in ways in which they would not act had they reason; while, as far as I have observed or read, all they do is explicable by the association of sensations, imaginations, and emotions, such as take place in our own lower faculties. We cannot, of course, prove a negative, but we have no right to assume the existence of that for which there is no evidence, without which all the facts can be explained, and which if it did exist would make a multitude of observed facts impossible. Apes (like dogs and cats) warm themselves with pleasure at deserted fires, yet, though they see wood burning and other wood lying by, though they have arms and hands as we have, and the same sentient faculties, they never have, so far as I know, been recorded to have added fuel to maintain their comfort. Swallows will continue to build on a house which they see has begun to be pulled down, and no animal can be shown to have made use of antecedent experience to *intentionally* improve upon the past.

If, on the other hand, animals were capable of deliberately acting in concert, the effects would soon make themselves known to us so forcibly as to prevent the possibility of mistake.

Mr. Lewes has not hesitated to affirm* that "between animal and human intelligence there is a gap which can only be bridged over by an addition from without," and he also says:† "The animal world is a continuum of smells, sights, touches, tastes, pains and pleasures: it has no objects, no laws, no distinguishable abstractions, such as self and not self. . . . . . If we see a bud, after we have learned that it is a bud, there is always a glance forward at the flower and backward at the seed . . . . . but what animal sees a bud at all except as a visible sign of some other sensation?" As a friend of mine, Professor Clarke,‡ has put it: "In ourselves sensations presently set the intellect to work; but to suppose that they do so in the dog is to beg the question that the dog has an intellect. A cat, to bestir itself to obtain its scraps after dinner, need not entertain any *belief* that the clattering of the plates when they are washed is usually accompanied by the presence of food for it, and that to secure its share it must make certain movements; for quite independently of such belief, and by virtue of mere association, the simple objective conjunction of the previous sounds, movements, and consequent sensations of taste, would suffice to set up the same movements on the present occasion." Let certain sensations and movements become associated, and then the former need not be noted: they only need to exist for the association to produce its effects, and simulate apprehension, deliberation, inference and volition. "When the circumstances of any present case differ from those of any past experience, but imperfectly resemble those of many past experiences, parts of these, and consequent actions, are irregularly suggested by the laws of resemblance, until some action is hit on which relieves pain or give pleasure. For instance . . . . let a dog be lost by his mistress in a field in which he has never been before. The presence of the group of sensations which we know to indicate his mistress is associated with pleasure, and its absence with pain. By past experience an association has been formed between this feeling of pain and such movements of the head as tend to recover some part of that group, its recovery being again associated with movements which, *de facto*, diminish the distance between the dog and his mistress. The dog, therefore, pricks up his ears, raises his head, and looks round. His mistress is nowhere to be seen; but at the corner of the field there is visible a gate at the end of a lane which resembles a lane in which she has been used to walk. A phantasm (or image) of that other lane, and of his mistress walking there, presents itself to the imagination of the dog; he runs to the present lane, but on getting into it she is not there. From the lane, however, he can see a tree at the other side of which she was wont to sit; the same process is repeated, but she is not to be found. Having arrived at the tree he thence finds his way home." By the action of such feelings, imaginations, and associations—which we know to be *veræ causæ*—I believe all the apparently intelligent actions of animals may be explained without the need of calling in the help of a power, the existence of which is inconsistent with the mass, as a whole, of the phenomena they exhibit.

But if there *is* a radically distinct intellectual power or force in man, is such a distinction of kind so isolated a fact as many suppose? May there not exist between the forces which living beings exhibit other differences of kind?

Each living being consists of an aggregation of parts and functional activities which are evidently knit together into a unity. Each is somehow the seat or theatre of some unifying powers or condition which synthesises their varied activities, and is a PRINCIPLE OF INDIVIDUATION. This seems certainly to have been the opinion of Buffon, and it is to this opinion that I referred in speaking of the fourth cause to which he attributed the changes in organic forms. And to me it seems that we must admit the existence of such a living principle. We may analyse the activities of any animal or plant, and by consideration of them separately find resemblances between them and mere physical forces. But the *synthesis* of such forces as we find in a living creature is certainly nowhere to be met with in the inorganic world.

To deny this would be to deny the plainest evidence of our senses. To assert that each living body is made up of minute independent organisms, each with its own "principle of individuation," and without subordination or co-ordination, is but to multiply difficulties, while such a doctrine conflicts with the evidence of our own perceptions, which lead each of us to regard himself as one whole—a true unity in multiplicity.

The existence in each creature of a peculiar, co-ordinating, polar force, seems to be specially pointed to by the phenomena of serial and bilateral symmetry, by the symmetrical character of certain diseases, by the phenomena of monstrous growths, and by the symmetrical beauty of such organisms as the Radiolarian Rhizopods.

It also seems to me to be made evident, by the various activities of each animal, which are, as a fact, grouped in one in mutual interaction—an organism having been described by Kant as a creature, the various parts of which are reciprocally ends and means.

I think now I hear the exclamation—This is "Vitalism!"

* 'Problems of Life and Mind,' vol. i., p. 156.
† *L. c.*, p. 140.
‡ 'Questions on Psychology,' p. 9.

while some of my hearers may deem these matters too speculative for our Section.

But consciously or unconsciously, general conceptions of the kind exist in the minds of all biologists, and influence them in various ways, and their consideration, therefore, can hardly be out of place here; while as to "Vitalism," I am convinced I shall not be wasting your time in endeavouring to remove a wide-spread misconception.

The "Vitalism" which is so reasonably objected to, is that which supposes the existence in each living creature of some separate entity inhabiting the body—an extra-organic force within the living creature, and acting by and through it, but numerically distinct from it. But the view which I venture to put before you as that which is to my judgment a reasonable one, is that of a peculiar form of force which is *intra-organic*, so that it and the visible living body are one thing, as the impress on stamped wax and the wax itself are one, though we can ideally distinguish between the two. It is, in fact, a mode of regarding living creatures with prime reference to their activities rather than to their material composition, and every creature can of course be regarded either statically or dynamically. It is to regard any given animal or plant, not as a piece of complex matter played upon by physical forces, which are transformed by what they traverse, but rather as a peculiar immanent principle* or form of force (whensoever and howsoever arising), which for a time manifests itself by the activities of a certain mass of complex material, with which it is so entirely one that it may be said to constitute and *be* such animal or plant much rather than the lump of matter which we can see and handle can be said to constitute such animal or plant. On this view a so-called "dead bird" is no bird at all, save by abuse of language, nor is a "corpse" really a "dead man"—such terms being as self-contradictory as would be the expression "a dead living creature."

Thus the real essence, the substantial constituent, of every living thing is something which escapes our senses, though its existence and nature reveal themselves to the intellect.

For of course our senses can detect nothing in an animal or plant beyond the qualities of its material component parts. But neither is the function of an organ to be detected save in and by the actions of such organ, and yet we do not deny it its function or consider that function to be a mere blending and mixture of the properties of the tissues which ompose it. Similarly it would seem to be unreasonable to deny the existence of a living principle of individuation because we can neither see nor feel it, but only infer it. This power or polar force, which is immament in each living body, or rather which is that body living, is of course unimaginable by us, since we cannot by imagination transcend experience, and since we have no experience of this force, save as a body living and acting in definite ways.

It may be objected that its existence cannot be verified. But what *is* verification? We often hear of "verification by sensation," and yet even in such verification the ultimate appeal is not really to the senses, but to the intellect, which may doubt and which criticizes and judges the actions and suggestions of the senses and imagination. Though no knowledge is possible for us which is not genetically traceable to sensation, yet the ground of all our developed knowledge is not sensational, but intellectual, and its final justification depends, and *must* depend, not on "feelings," but on "thoughts." I must apologize to such an audience as that I have the honour of addressing for expressing truths which, to some of my hearers, may appear obvious. I would gladly suppress them as superfluous did not my own experience convince me that they are not superfluous. To proceed: "Certainty" does not exist at all in *feelings* any more than doubt. Both belong to thought only. "Feelings" are but the materials of certainty, and though we can be perfectly certain about our feelings, that certainty belongs to thought and to thought only. "Thought," therefore, is our absolute criterion. It is by self-conscious thought only that we know we have any feelings at all. Without thought, indeed, we might feel, but we could not know that we felt or know ourselves as feeling. If then we have *rational* grounds for the acceptance of such a purely intellectual conception as that of an immanent principle as the essence of each living creature, the poverty of our powers of imagination should be no bar to its acceptance. We are continually employing terms and conceptions—such, *e.g.*, as "being," "substance," "cause," etc.—which are intelligible to the intellect (since they can be discussed), though they transcend the powers of the imagination to picture.

(*To be continued.*)

* The word "principle" has been used to denote that activity which, together with material substance, constitutes a living creature, because that word calls up a less sensuous, and therefore less misleading, phantasm than any other. The old term ψυχή, or soul, has in modern times come to be associated with the idea of a substance numerically distinct from the living body, and capable of surviving the destruction of the latter. But as structure and function ever vary together (as do the convexities and concavities of a curved line), so "the principle of individuation" or soul of an animal or plant and its material organization must necessarily arise, vary, and be destroyed simultaneously, unless some special character, as in the case of man, may lead us to consider it exceptional in nature. Even in man, however, there seems no adequate reason for believing in the existence of any principle of individuation, save that which exerts its energy in all his functions, the humblest as well as the most exalted.

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act.

At the Birmingham Police Court, on Thursday, January 22, 1880, before A. Hill, Esq. (Chairman), Alderman Biggs and A. J. Elkington, Esq., Theodore Morris, trading as a chemist and druggist, at 199, Lodge Road, Birmingham, was summoned by the Secretary of the Chemists and Druggists' Trade Association of Great Britain, for an infringement of the 17th section of the Pharmacy Act, 1868. He was charged, "That he did, on the 2nd inst., unlawfully sell to W. F. Haydon certain poison, to wit, laudanum, being a preparation of opium, in a certain bottle, the label of which bottle did not set forth the name of the seller of the same, contrary to the statute in such case made and provided."

Mr. Henry Glaisyer, solicitor, Birmingham, appeared to prosecute. The defendant conducted his own defence.

Mr. Glaisyer, having explained the section of the Pharmacy Act on which the summons was based, said on the 2nd day of this month Mr. Haydon purchased at the shop of the defendant, No. 199, Lodge Road, two pennyworth of laudanum. The bottle was labelled "Poison, Laudanum. R. D. Hughes, Chemist, 199, Lodge Road." The contents of the bottle were subsequently analysed by Mr. Haydon and found to contain laudanum, a preparation of opium. Opium and its preparations are enumerated in Part II., Schedule A of the Act. The defendant is wholly unqualified to sell poisons scheduled under the Act, not being either a pharmaceutical chemist or a chemist and druggist; but he appears to do so under cover of Hughes's name. The defendant is the tenant of the premises at 199, Lodge Road, and has paid rates for those premises.

Mr. William Frederic Haydon, pharmaceutical chemist, and Secretary of the Chemists and Druggists' Trade Association of Great Britain, deposed that on January 2 last, he went to the defendant's shop at 199, Lodge Road, and purchased from the defendant himself two pennyworth of laudanum which he now produced, labelled "Poison. Laudanum. R. D. Hughes, Chemist, 199, Lodge Road." He subsequently analysed the contents of the bottle and found it to be laudanum, a preparation of opium. The defendant was not qualified to sell such poison, his name not appearing in the last published Register of Pharmaceutical Chemists and Chemists and Druggists. The name of Richard David Hughes appeared on that Register as a chemist and druggist, residing at 18, High Street, Denbigh.

Magistrates' Clerk: You do not deny selling this poison, I suppose?

The Defendant: No; but there is the name of the proprietor on the bottle.

Chairman of the Bench: How long have you been at the shop?

The Defendant: Eighteen months.

Chairman of the Bench: Was the shop taken in Mr. Hughes's name?

The Defendant: No; I opened it as a drysalter.

Magistrates' Clerk: Did Hughes ever live on those premises?

Defendant: No; but he has been backwards and forwards to Birmingham.

Mr Elkington: Are you Mr. Hughes's assistant, and paid by him as such?

Defendant: I am a salaried assistant, and over a certain sum all the money made out of the business belongs to me. I am the tenant of the premises and pay the rents, rates and taxes.

Chairman of the Bench: Do you ask for an adjournment to call Mr. Hughes as a witness? if not, we must decide the case on the evidence given.

Defendant: I would rather the case was settled now.

Chairman of the Bench: You must pay a penalty of 21*s*. and costs, or in default one month's imprisonment. I hope full publicity will be given to this case.

Poisoning by Chlorodyne.

Dr. Hardwicke held an inquest on Thursday, January 22, at the St. Pancras Coroner's Court, on the body of John Macham, aged 61, surgical instrument maker, of 37, Oak Village.

Mrs. Jane Macham, widow of deceased, said he had been ailing for the last twelve months, and had been to St. Bartholomew's and other hospitals for relief; he was also in the habit of taking Dr. Collis Browne's chlorodyne. On the night of Monday week, shortly after he went to bed, he laid on his back and made a peculiar noise. When she got up on the following morning she found him in the same position. She saw he had a bottle containing chlorodyne in the bed with him. Medical aid was procured, but he died about half-past twelve. The deceased began taking chlorodyne about three months ago, but she did not think he had had more than two bottles. He was very desponding in mind, fearing he would lose his trade. He said he could not bear it, and had said he would destroy himself.

Mr. Reuben Warne, surgeon, said that when called in, he found the deceased in a state of collapse, and death followed shortly afterwards. He had made a *post-mortem* examination. The heart was fatty, and the lungs and brain congested. There was no doubt the deceased had died from poisoning by chlorodyne.

The Coroner and Jury had considerable discussion as to the facilities for obtaining poisons, especially those contained in patent medicines.

The Jury then returned the following verdict:—"That the deceased committed suicide by poisoning himself with chlorodyne, being at the time in an unsound state of mind. The Jurors are further of opinion that the most stringent measures ought to be enforced to prevent the sale of poisons in the shape of patent medicines, and that at all events is should be made compulsory that a label should be affixed thereto bearing the word 'Poison,' as was compelled to be done in regard to the sale of laudanum and other poisons."—*Standard*.

Poisoning by a Liniment.

Mr. Collier, deputy coroner, held an inquest on Monday last at the Plough, Lewisham, on the body of William Charles Penny, aged 63, a builder, living at Lewisham Hill, who died from the effects of poison.

Fanny Richards, servant to the deceased, said on Thursday night the deceased, who was confined to his bed, asked for a sleeping draught he had been in the habit of taking, pointing to the mantelpiece, on which was a bottle. Her mistress poured it out and witness handed it to deceased, who drank it off. A moment after the bottle containing the sleeping draught was found at the foot of the bed, and it was then seen that the deceased had been given a liniment which he had been using for his leg. The wife exclaimed, "Oh, my darling husband, what have I done?" Witness ran for some salt and water, which was given the deceased and made him sick, and she then went for Mr. Shute. On her return the deceased had expired. There was one candle alight at the time, but it was at the opposite end of the mantelpiece. When Mrs. Penny poured the liniment out her eyes were suffused with tears, because of the pain her husband was in.

Mr. Shute, surgeon, said he supplied both the liniment and the sleeping draught; they were in similar bottles. The liniment was composed of two-thirds of aconite and one-third soap liniment, the former being a deadly poison and the latter harmless. The liniment and draught were of different shades in colour.

The jury returned a verdict of "Death from misadventure," but strongly recommended that some additional precautions should be used in sending out bottles containing poison, both as to colour and shape.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

---

[381]. Owing to the word grains appearing after 80 instead of after ij, the sentence looks rather vague, but no doubt the physician means 2 grains. It will therefore be 7 grains per dose the second week, 9 grains per dose the third week, and so on until 27 grains per dose, or 81 grains per day, is reached.

THE SALE OF PATENT MEDICINES CONTAINING POISONS.

Sir,—In a recent case of poisoning by chlorodyne brought before the coroner at St. Pancras,* the jury added a rider: "The jurors are of opinion that the most stringent measures ought to be enforced to prevent the sale of poisons in the shape of patent medicines."

Cannot the Pharmaceutical Society use their influence to restrict the sale of patent medicines to registered chemists only?

Are not all unqualified persons liable for the sale of chlorodyne and all medicines containing poisons?

In this neighbourhood the proprietor of a patent medicine has actually offered to supply licences to oilmen and grocers who will sell his preparations.

Islington, N. J. K.

Sir,—At the present time, when the question regarding the sale of poisons is before the public mind, I think the Pharmaceutical Society should collect all the facts which will be taken as evidence in considering the necessity of revising the Poisons Bill. That such a revision is necessary is quite evident whilst we daily see the wholesale distribution by grocers, drapers and others of such medicines as chlorodyne, Powell's balsam, Winslow's syrup, etc., etc., most of which contain in a greater or less degree some active poison, and many of which have proved their strength by their fatal effects.

Now, sir, should this revision of the Act take place, surely an opportunity is offered to the Pharmaceutical Society for stepping in and endeavouring to obtain for the pharmaceutical chemists the sole privilege of vending medicines of all kinds, whether containing poisons or whether ordinary Pharmacopœia preparations; the public would then have responsible people to look to, and their interests I am sure would be benefited.

Is it not reasonable, too, that the law should guarantee chemists some protection of this sort, in consideration of the expense it puts them to in order that they may pass their examinations? A lawyer's practice is protected from intruders, as is also the practice of a doctor; why, then, should chemists be left out?

By obtaining some real advantage of this sort the Society would be doing its legitimate duty as the representative body of an educated and responsible class of men, and would confer a benefit on both the chemists and the public of no small importance.

A PHARMACEUTICAL CHEMIST.

* See the previous page.

CREAM OF TARTAR.

Sir,—Two years ago we had doubts about the purity of a lot of cream of tartar we had purchased. We sent a sample to the public analysts here; the following is the result of their analysis:—

Bitartrate of Potash	88·04
(Hydrated) Tartrate of Lime	8·87
Iron and Alumina	·12
Sand and Silica	1·02
Water	1·92
	99·97

(Signed) McCOWAN and BIGGART.

This was accompanied with a certificate stating it to be a sample of genuine cream of tartar.

Possibly the above may be of some interest at the present time.

Greenock. MACNAUGHT BROS.

J. J. Point.—There is no law that would compel a chemist and druggist to supply medicine on a Sunday, but we do not think that anyone would refuse to do so in a case of serious illness.

T. O. Owen.—(1) See the paper on "Soluble Essence of Ginger," by Mr. J. C. Thresh, before, p. 193. (2) It has been pointed out by Dr. Symes (*Pharm. Journ.*, [2], vol. v., p. 161), that lemon juice may be preserved without the addition of alcohol by heating it to 150° F. and then excluding it from the air by carefully closing the full bottles at this temperature. The operation should be carried out during the winter.

W. M. Bishop.—See the note on the pharmacy of nitroglycerine in "The Month," before, p. 603.

A. P. S.—Ganot's 'Elementary Treatise on Physics,' or Deschanel's 'Natural Philosophy.'

T. W. Ogilvie.—*Cetraria glauca.* If our correspondent will compare the specimen sent with commercial *Cetraria islandica*, he will see that the latter has minute cylindrical prominences on the margin of the frond and has a paler under surface.

J. T. B. M.—The finely-divided peroxide of iron, known also as rouge, prepared by precipitating a hot filtered solution of sulphate of iron with concentrated solution of oxalic acid and decomposing the resulting oxalate of iron, after washing and partial drying, by heat.

T. Walton.—The principal alkaloids in the root of *Aconitum Napellus* are aconitine and pseudaconitine, both of them crystallizable, and the former present in relatively the larger quantity. These alkaloids, according to Wright and Luff, are decomposable into two others, aconine and pseudaconine, which may occur ready-formed in the root. They are accompanied by at least one other alkaloid, picraconitine, which is comparatively inert. In *A. ferox* root pseudaconitine is present in larger proportion than is aconitine, together with another apparently non-crystalline alkaloid. From Japanese aconite Wright and Luff have separated an alkaloid that they have named japaconitine, and which may or may not be identical with one observed by Paul and Kingzett.

Mr. C. Bennett is thanked for his communication.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. J. Wade, E. Wyborn, J. C. Thresh, Burroughs and Co., Ion, Dentist sine L.D.S., Tradesman, C.

TINCTURE OF SENEGA AS AN EMULSIFYING AGENT.*

BY HENRY COLLIER,

Teacher of Pharmacy, Guy's Hospital.

I had the honour of laying before the Pharmaceutical Conference at Sheffield emulsions of various fixed and volatile oils prepared by means of tincture of soap bark—the *Quillaia saponaria*. The employment of this tincture is by no means new, for it has been in use as an emulsifying agent for some years. I thought, however, that a useful purpose might be served by bringing forward, more prominently than hitherto had been done, this very useful agent in pharmacy. It has received official recognition in France, at least by the Paris Pharmaceutical Society, who have published a formula for the preparation of the tincture and described its use in their 'Rapport sur les médicaments nouveaux.' I also at the same meeting gave an account of the results of my experiments upon the saponaceous matter of quillaia bark. I there mentioned that this soapy principle was widely diffused throughout the vegetable kingdom, that it had been the object of numerous investigations and that most discordant results were given by different experimenters. The literature of senegin, or polygalic acid, the active matter of senega root, is not so extensive as that of saponin; different statements are made respecting it, and it is still a matter of doubt whether polygalic acid and saponin are identical. Senega root appears to have been first examined by Gehlen in 1804, who found, together with resin, a substance which he described as perfectly insoluble in water, but soluble in alcohol. To this principle was given the name of polygalin. This was associated by Pfaff, who called it "kratzender extractivstoff," and by Bucholz, who named it senegin, with saponin, which is soluble in water. Quevenne, in 1836 (*Journal de Pharm.*, 22—460), published a most exhaustive chemical examination of senega. He appears to have first obtained pure senegin, and according to him it is different from saponin. He gave it the name of polygalic acid, from the fact that it united with bases to form salts. It is not, however, an acid which will expel carbonic anhydride from alkaline carbonates, even with the aid of heat.

Bolly (*Annal. Pharm.*, 90—211), who did not, however, follow Quevenne's method of preparation, in his examination of senega regards saponin and senegin as identical.

I have not been able to find that since Bolly's work the saponaceous matter of senega root has been further chemically examined. W. Procter, junr., in 1861 (*Chem. News*, 1861—40), published his pharmaceutical researches upon polygalic acid, in which he recommends its use in 1 to 2 grain doses in powder or pill. The decomposition products of saponin and senegin or polygalic acid are the same, so that it is probable that these substances are identical, and that the differences in the statements of the various authors may be accounted for by the different degrees of purity of the substance they obtained. If it may be considered any testimony as to the identity of saponin and polygalic acid, I can state that tincture of senega and tincture of quillaia have a similar effect upon mercury. This metal, shaken with either of these tinctures, is quickly reduced to a very minute state of subdivision. They are alike also in their power of emulsifying fixed and volatile oils.

In recommending any particular agent for use in pharmacy it is essential to bear in mind the nature of the substance employed. Acacia, tragacanth or yolk of egg, which are generally used in making emulsions, possess no very active properties. Occasionally, however, active substances are employed in small doses, and they are then considered not to have any detrimental effect. For instance, fixed oils are very frequently made into emulsions by means of liq. potassæ. To use tincture of senega in medicinal doses as an emulsifying agent would certainly not meet with approbation, but in very small quantities there would not be the same objection. I have here examples of emulsions of various fixed and volatile oils prepared with tincture of senega of Pharmacopœia strength, but made by maceration only. These mixtures possess all the characters of good emulsions and they are very easily made. The following is the general formula for the fixed oils, cod liver, olive and castor:—

Oleum	℥ss.
Tinct. Senegæ	♏v.
Aq.	℥ss. Misce.

The same quantity of tincture has been used for ol. terebinthinæ ♏xx; copaiba ʒss; ext. filicis liquid. ʒj; chloroform. ♏x.

The Pharmacopœia dose of tincture of senega is from ʒss to ʒij. The use of a sixth part of the minimum dose could hardly be considered objectionable on account of the effect which it might produce. If so, solution of potash and lime water might also justly be removed from our list of emulsifying agents.

As regards the suspension of resins, I do not consider that tincture of senega is so useful as acacia or tragacanth; these substances require thick liquids or they will separate too rapidly. Tincture of quillaia was adopted by the Paris Pharmaceutical Society for the preparation of "émulsions des médicaments insoluble dans l'eau," and a formula is given for an emulsion of balsam of tolu, but a large quantity of spirit and of tincture is required and the mixture is not a very perfect one.

I have here a mixture containing—

Tinct. Tolu.	♏ 40.
Tinct. Senegæ	♏ 20.
Aq.	ad ℥j. Misce.

This is a very good emulsion, but the quantity of tincture is large, which of course is open to objection; a less quantity of tincture does not prevent the aggregation of the resin into lumps.

In conclusion, I trust you will consider that the fact of tincture of senega possessing emulsifying powers is a sufficient reason why I should have brought it before your notice this evening.

[*The discussion on this paper is printed at p.* 638.]

* Read at the Evening Meeting of the Pharmaceutical Society of Great Britain, February 4, 1879.

THE SUPPOSED ALKALOID OF PODOPHYLLUM.*

BY JOHN M. MAISCH.

In a paper "On the Proximate Principles of some Berberidaceæ and Ranunculaceæ," contributed by the late Professor Ferdinand F. Mayer to the *American Journal of Pharmacy*, 1863, pp. 97—100, the following sentences

* From the *American Journal of Pharmacy*, December, 1879.

are found :—"The rhizome of the mayapple contains both berberina and a colourless alkaloid, a resin, a free acid, a neutral odorous substance volatilizable in white scales and saponin. When the alcoholic extract of the rhizome is freed from alcohol and then mixed with water, the latter dissolves the acid, a considerable quantity of berberina and saponin, together with some resinous matter. The precipitate left after washing with water, the so-called resinoid podophyllin, is a mixture of a resin and the volatile principle, which are soluble in ether, and a portion soluble in alcohol, which is the other alkaloid in combination with saponin and brown resinous matter."

This being the first published assertion of the presence of an alkaloid in podophyllum, soon after I embraced the opportunity of ascertaining the correctness of the statement as far as the presence of berberina was concerned, by working up the mother-liquor from the preparation of the resin from several hundred pounds of podophyllum. It was evaporated to a small bulk, strongly acidulated by hydrochloric acid, and the resulting crystalline precipitate again dissolved in boiling water and treated with hydrochloric acid. On cooling and standing, deep yellow crystals were obtained, resembling those of commercial hydrochlorate of berberina, but evidently tinged with a notable quantity of brown colouring matter. The crystals, which weighed between one and two drachms, were laid aside for future examination and purification, but no opportunity presenting itself for several years, the substance was eventually lost. However, its appearance was so convincing that it seemed to furnish a valid reason for the addition of hydrochloric acid in preparing the officinal resin of podophyllum (*Amer. Jour. Pharm.*, 1863, p. 303).

When about the year 1868 or 1869 I undertook the separation of berberina from the officinal resin prepared by myself, I was surprised at not finding the alkoloid sought; but noticed in its stead the solubility in hot water of that portion of the resin which is soluble in ether (see *Amer. Journ. Pharm.*, 1874, p. 231). It is the same substance which was obtained by Wm. Hodgson in 1831 (see *Jour. Phil. Coll. Phar.*, iii., p. 273), by boiling the rhizome in water, and the laxative properties of which were ascertained by him. The various investigators who have since experimented with podophyllum could either not discover any alkaloid at all, or observed only slight indications of its presence through the reaction with one of the general reagents for alkaloids, notably with Mayer's test liquid. Since, however, the proximate composition of the resin as obtained from the rhizome collected in the spring and autumn varies to some extent, it seemed also possible that the alkaloid, if present, might be found in larger proportion at one period than at another. The valuable paper contributed by Mr. Biddle at the last meeting (see November number, p. 543)* does not completely remove the doubt. The mother-liquors from his experiments were presented and exhibited at the last meeting, and by Mr. Biddle kindly placed at my disposal for further investigation. One of the samples consisted of the concentrated washings of the resin prepared from the rhizome collected in March and April (No. 1); the other was a similar mixture obtained from the rhizome collected in May, July and October (No. 2); the latter had yielded the slightest reaction with Mayer's reagent.

The two samples were set aside for about a week, after which time both had separated a slight precipitate, and the clear liquids yielded no turbidity at all with Mayer's test. The liquid No. 1 was somewhat concentrated, allowed to cool, and filtered when it was rendered turbid on the addition of the test. It was now evaporated to a syrupy consistence, and, after standing for about two weeks, filtered from the resinous deposit, *a*, mixed with a little hydrochloric acid, and after twenty-four hours again filtered from the precipitate, *b*. The filtrate was rendered decidedly turbid on the addition of potassio-mercuriciodide. A portion of the acid liquid was agitated with ether the remaining portion was first rendered alkaline by the addition of sodium carbonate, and then likewise treated with ether. In both cases, on the complete evaporation of the ether, a yellowish amorphous mass, of a rather disagreeable odour, was left, which was agitated with dilute hydrochloric acid, the solutions being afterwards again tested with Mayer's reagent, without producing the slightest turbidity.

The resinous deposit, *a*, was dissolved in a little alcohol, the solution filtered, the filtrate precipitated by cold water acidulated with hydrochloric acid, and on the following day again filtered. The clear liquid gave no reaction with potassio-mercuric iodide, until after it had been concentrated, cooled and filtered. It was, however, noticed that the turbidity again disappeared, after a short time, while on other occasions it remained. The cause for this different behaviour was only determined after many repetitions, and was found to be a slight increase of temperature caused by the radiating heat from a heated iron plate, or by the accidental exposure of the test-tube to the direct rays of the sun; in fact the warmth of the hand was found to be sufficient for making the turbidity disappear entirely or partly. The cold liquid was now completely precipitated by Mayer's test; the precipitate, which was soluble in hot water, was well washed with cold water, dissolved in a little soda and the solution acidulated with hydrochloric acid; on passing sulphuretted hydrogen through the solution, not the faintest indication of the presence of mercury could be discovered.

The precipitate *b* was boiled with water, and filtered while hot. On cooling, the filtrate became turbid. It was again passed through paper, acidulated, and now yielded no turbidity with Mayer's test, until after it had been further concentrated; the precipitate had precisely the same behaviour as indicated above.

The mother-liquor, No. 2, was concentrated and treated with ether and potassio-mercuric iodide; the results were identical with those obtained with No. 1.

It will be observed that none of the experiments detailed above indicate the presence of even traces of an alkaloid, and the cause of the precipitation by Mayer's test must therefore most likely be sought for in the slight solubility in water of podophyllinic acid, one of the constituents of the so-called resin of podophyllum, since even Klunge's test for berberina has proven its entire absence. To test the correctness of this supposition, two samples of podophyllinic acid, prepared from the well-washed officinal resin with hot water and with ether, were dissolved in hot water, the filtered solutions cooled, again filtered, and these filtrates treated with Mayer's reagent, both with and without the addition of hydrochloric acid; but in no case was any turbidity observed. The slight quantity of this resinous compound which remains dissolved in cold water is equally soluble therein after the addition of some potassio-mercuric iodide; but it seems that some other constituent of the rhizome is capable of retaining for some time a somewhat larger portion of podophyllinic acid in complete solution, which is then precipitated by the test liquid mentioned, and perhaps by other salts, without, however, combining with the metal. Hence the clear mother-liquors, if tested shortly after the preparation of resin of podophyllum, may yield a precipitate with the test liquid, which would not be obtainable a few days later.

I believe that it may now be considered proven that the rhizome of podophyllum contains *no alkaloid* at any period of its growth. The yellow crystalline precipitate mentioned above must have doubtless been due to some accidental impurity in the drug (probably hydrastis?), which, from its minuteness, escaped detection before the article was ground.

* See *Pharmaceutical Journal*, before, p. 468.

The Pharmaceutical Journal.

THE REGISTRAR'S REPORT.

THE publication of the usual annual statistical Report as to the number of persons on the Registers and the numerical strength of the Pharmaceutical Society, which was presented by the Registrar to the Council at its last meeting, affords us the yearly opportunity of pointing out some of the bearings it has on the interests of the trade when considered in connection with former reports. The full meaning of the figures in certain directions cannot be fully estimated in the absence of other information,—such, for instance, as the relation they bear to the increase of the general population,—but so far as their indications can be followed they are of sufficient interest to justify us in directing attention to them specially on these periodical occasions.

It appears that the general Register of Chemists and Druggists now contains 13,551 names, or 242 more than at the beginning of the year 1879. This increase represents the difference between 403 additions, of which 360 were made in virtue of persons passing the qualifying examinations (Minor and Modified), and 161 erasures, of which 155 were made in consequence of deaths reported from various sources. But the number of 242 does not represent a real increase on the Register, as—taking the average of former years—it is probably reducible by about 100 names that have become subject to erasure through death and other causes, but which, they not having been reported, will remain on the Register till its next rectification by the Registrar under the special powers conferred on him by the tenth section of the Pharmacy Act.

With respect to the Register of Pharmaceutical Chemists it is satisfactory to find that the anticipation expressed a few weeks since in our yearly summary as to this most important class has been fulfilled. In the course of last year 77 persons passed the Major examination and thus became entitled to registration as pharmaceutical chemists, and as during the same time the erasures only amounted to 65 it follows that this class shows an increase of 12 on the new Register, the numbers now being 2299 against 2287, as given in the last previous report. It may be remarked that this increase, like that before referred to, is subject to reduction through unreported deaths, but probably not to the extent of doing away with it altogether. Satisfactory as this is as an improvement on the previous year, in which there was a decrease of 20, it is evident, in the face of the increase of 242 on the general Register of Chemists and Druggists, that the number of persons passing the Major examination is not yet equal to the task of maintaining the relative numerical proportions between the class of pharmaceutical chemists and the whole body of the chemists and druggists, impaired as it is by the death not only of those who like themselves had passed the highest examination, but also of a larger number of those who became pharmaceutical chemists without examination, by election as Members of the Pharmaceutical Society, in the earlier days of its history.

A very interesting point in connection with this Report is the information which it, taken together with the printed Registers, affords as to the progressive increase in the relative proportion of persons carrying on business as pharmaceutical chemists and chemists and druggists in virtue of having passed the legal examinations. By the courtesy of the Registrar, in supplying us with proof sheets of the forthcoming Registers, we are enabled to state these relations on the present occasion.

Taking first the Register of Pharmaceutical Chemists, the number of persons enrolled on it who have passed the Major examination is 1410, or 61·33 per cent., against 1346, or 58·84 per cent., on the previous Register, being an increase absolutely of 64, and relatively of 2·49 per cent. The relative proportion of Major men to the whole body of chemists and druggists is now 10·4 per cent.

The number of examined persons, irrespective of pharmaceutical chemists, who are on the Register of Chemists and Druggists in virtue of having passed the Minor examination is 2645, being an increase of 248, their percentage relation to the whole Register having at the same time been increased from 18·01 per cent. to 19·52 per cent. The total number of the two classes of examined men, therefore, now number 3055, or 29·92 per cent.

These details may be more conveniently represented in the tabular form, thus—

	January 1, 1879.		January 1, 1880.	
	Number.	Per cent.	Number.	Per cent.
Pharmaceutical Chemists:—				
Examined . .	1346 } 2237	10·01 } 17·18	1410 } 2299	10·40 } 16·96
Non-examined	941 }	7·17 }	889 }	6·56 }
Chemists and Druggists who have passed the Minor only	2397	18·01	2645	19·52
Remainder, including those who have passed the Modified . .	8625	64·81	8607	63·52
Total	13,309	100·00	13,551	100·00

The report on the numerical strength of the Pharmaceutical Society affords, on the whole, subject for congratulation, since it shows that there were at the commencement of the present year a larger number of registered chemists and druggists connected with it as Members and Associates than at any previous period of its history. The total number of the four classes was 4589, against 4536 in the previous year, or an increase of 53. Moreover this increase is sufficient, within one quarter per cent., to maintain the previous relative numerical proportions between the subscribers to the Society and the whole number of chemists and druggists on the Register. Although t may be hoped, and reasonably believed, that this proportion will be increased as years roll on, and the Register records more exclusively the names of examined persons, yet it ought not to be forgotten—as it would appear to be occasionally by some who might have been supposed to be better informed—hat upwards of one-third of all the persons legally entitled to carry on the business of a chemist and druggist in Great Britain are now voluntarily associated with the Pharmaceutical Society.

In examining the details of this report it will be found that there was last year (from the cause that has already been hinted at) a decrease of 19 Pharmaceutical Chemist Members. It is interesting to note, as throwing light on the nature of this decrease, that the number of pharmaceutical chemists elected and restored to membership last year (74) nearly equalled the number of persons who passed he Major examination (77), and thus became eligible for such membership. There was also a decrease of 13 Chemist and Druggist Members, a class that must eventually become extinct. On the other hand, there was an increase in the number of Associates in Business amounting to 66, and one of 19 in the Associates not in Business. The decrease in the first two classes was therefore 32, and the increase in the last two 85, leaving a nett increase, as stated before, of 53.

Besides the foregoing there has been in the class of Apprentices an increase of 31, there being at the close of the year 1071 Apprentices or Students of the Society on the Society's books, the number twelve months previously having been 1040.

The following table will enable a direct comparision to be made between some of the indications of the statistics of this Report and those of the one presented in February, 1879:—

	Jan. 1, 1879.		Jan. 1, 1880.

ADOLPHUS FREDERICK HASELDEN.

It falls to our lot this week to record the death, on Wednesday last, of Mr. Adolphus Frederick Haselden, a gentleman who in his time rendered valuable service to the pharmaceutical body, and especially to that portion of it constituting the Pharmaceutical Society of Great Britain. Mr. Haselden joined the Society as an Associate at its commencement, and became a Pharmaceutical Chemist Member in 1855. For many years continuously he served as a member of the Council, having been first chosen in 1859 to fill the vacancy caused by the death of Mr. Jacob Bell. In 1869 he was chosen Vice-President, and upon the resignation of Mr. Sandford, in 1871, he became President, which office he held until his retirement from the Council in 1873. Mr. Haselden also acted as an Examiner, with the exception of a short interval, from 1864 to 1877. Mr. Haselden contributed to this Journal a large number of papers which, besides being eminently practical, were frequently marked by a brightness and piquancy that gave evidence of considerable literary skill and rendered them very pleasant reading. As to the esteem in which Mr. Haselden was held nothing need be added to what has fallen from the lips of some of his former colleagues and is reported on another page.

SIR DOMINIC CORRIGAN.

We regret also to have to record the death of Sir Dominic Corrigan, Bart., the first President of the Pharmaceutical Society of Ireland. Sir Dominic took a great interest in the foundation of the Irish Pharmaceutical Society, and the vigorous evidence he gave before the Parliamentary Committee to which the subject had been referred no doubt contributed much towards securing the favourable report upon which the Act constituting the Society was based.

THE CALENDAR.

An advertisement in another page announces the fact that the Calendar of the Pharmaceutical Society for 1880 is now ready, and we call attention to it here, because we feel that were this valuable little annual better known among pharmacists, much trouble now spent in seeking information would be saved. Besides the lists of persons associated with the Society, the Pharmacy Acts and Charter, and the list of subscribers to the Benevolent Fund, the Calendar contains abstracts of a large number of Acts of Parliament and General Orders more or less affecting the carrying on of the business of a chemist and druggist. A list of these will be found in the advertisement. In the present issue also the Preliminary examination questions of the past year are included. In thus putting within the reach of the trade, for a nominal sum, a hand-book containing so much information the Council renders a service that might be taken more advantage of than at present is the case.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association will be held on Thursday next, 12th inst., when a paper will be read by Mr. I. R. James, on "Ostrich and other Pepsines." "A Report on Botany" will also be made by Mr. F. W. Branson.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, February 4, 1880.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT, IN THE CHAIR.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Richardson, Rimmington, Robbins, Savage, Shaw, Squire and Symes.

The VICE-PRESIDENT expressed his regret at the cause which led to his presiding over the meeting that day, namely, the illness of the President, Mr. Sandford, who was suffering from bronchitis, from, which, however, he was now recovering.

The minutes of the preceding meeting were read and confirmed.

EXAMINATIONS.

Mr. MACKAY asked whether he might remind the Council that some time ago it was arranged that there should be an interchange of visits between the Board of Examiners in London and the Board of Examiners in Edinburgh, and that the two Boards should visit each other in alternate years. There had now been a lapse of two years in this interchange. He did not wish to move a resolution on the subject, but simply to suggest that some arrangement might be made by the Council and the Board of Examiners by which a deputation might be appointed to visit Edinburgh at the April examination, or, if that was not convenient, at the July examination. In that case the examinations would be arranged so as to go on during the time that the deputation was present. An immense amount of good had accrued from the previous interchange of visits, inasmuch as the examinations were now conducted as much like each other as any two examinations could be.

Mr. HAMPSON asked whether there was a resolution on the subject, and whether the Council was bound to send a deputation to be present at the Scotch Board, or whether it was only done once with an understanding that it might be done again.

Mr. MACKAY said that it was done more than once.

The VICE-PRESIDENT said that he felt sure that the scope of the resolution was not simply that one visit should be paid.

Mr. SHAW said that the resolution was passed on account of a great diversity between the results of the examinations by the Scotch Board and the English Board. Was there now any difference between the results of the two examining boards? If so that might be a reason for the resolution being carried out.

The subject was then dropped until later in the meeting.

MEMBERS OF THE COUNCIL WHO RETIRE.

The lot being taken in the usual manner for the seven members of the Council who should retire in May next, the following names were drawn:—

Atkins.	Rimmington.	Squire.
Frazer.	Savage.	Symes.
Hampson.		

The following who remained in by lot last year now retire by rotation:—

Gostling.	Mackay.	Schacht.
Greenish.	Sandford.	Slipper.
Hills.		

The following remain in office for another year:—

Bottle.	Robbins.	Williams.
Churchill.	Shaw.	Woolley.
Richardson.		

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Evans, William Henry ....London.
Gascoigne, Charles ....Hurworth.
Kerr, Charles ....Dundee.
McCallum, Hugh ....Hong Kong.
McJannet, James...............East London, S. Africa.
Shillcock, George ....Bromley.

Chemists and Druggists.

The following registered Chemists and Druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected Members of the Society:—

Callaway, Lemuel.................Ipswich.
Henry, Edward Laurence ......Lewisham.
Mullock, Richard ....Birkenhead.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Brandsma, Dirk Gerhard ......Ware.
Dawson, William ....Greenwich.
Dixon, Herbert.....................London.
Freeland, Alonzo Joseph.........Angmering.
Hobbs, John Kingdon...........Harlesden.
Jones, James Lewis...............Llanerchymedd.
Jones, Owen William ....Flint.
Parker, Charles.....................Milnthorpe.
White, John Thomas ....Wordsley.
Willis, Blankley William ......Devizes.

Modified.

Frobisher, Frederick ....Selly Oak.
Hick, John ....London.
Littlejohn, Alexander ....London.
Negus, Samuel Thomas ....Northampton.

ASSOCIATES.

The following, having passed their respective examinations and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Bates, Frederic William ....Crowles.
Chadwick, John ....Accrington.
Cock, James ....South Molton.
Cormack, George ....Fochabers.
Dow, William ....Kinross.
George, John Irving...............Tunstall.
Irving, Thomas Stableforth ...Spalding.
James, Thomas Cragg............Dalton-in-Furness.
Jones, William Harris............Abergavenny.
Littlefield, James Clarence......Ventnor.
Moon, George William ....Malton.
Murison, John ....Fyvie.
Newman, Alfred Pointon ......Crewe.
Porteous, Arthur Alexander ...Kirkwall.
Richardson, Arthur ....Epworth.
Tatam, Sam. Blackmore Charles.Ottery St. Mary.
Thompson, Thomas Clay.........Bedworth.
Wilkins, Robert Elliott ....Surbiton.
Winfrey, Richard ....Long Sutton.
Wyborn, Edward ....Reading.

Modified.

Dwyer, John........................London.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adam, James Bell D. ....London.
Ansell, Alfred ....Birkdale.
Arnott, Daniel ....Pontypridd.

Banbury, Richard..................Camelford.
Batty, George Arthur ....Gt. Driffield.
Bell, Thomas........................London
Biggs, Frederick William ......Lichfield.
Briggs, George William ....Bulwell.
Buxton, Thomas ....Belper.
Carnaby, Francis William ......Blyth.
Chadwick, Arthur ....Leeds.
Chapman, Ingram William ...Crowle.
Clarke, Walter ....Bromley.
Coates, William Henry ....York.
Corder, Edmund Herbert ......London.
Cox, George Frecker ....Guernsey.
Dadley, Edwin B. ....Nottingham.
Davis, Norman ....Sunderland.
Doig, John ....Dundee.
Duckworth, Arthur ....Rochdale.
Featherstone, William B. ......Birmingham.
Fieldsend, John Francis ....Boston.
Flint, Francis Bramwell.........Leek.
George, Alexander Cosgrave ...Rusholme.
Horne, Albert D....................Manchester.
Humphries, Jacob ....Cleckheaton.
Hunt, John Osbaldeston.........London.
Jones, John Hughes ....Llangollen.
Laing, Arthur L....... ....Edinburgh.
Lloyd, James Clement............Lewes.
Mack, William Wilson ....Nottingham.
Martin, Alexander ....Leslie.
Nethercott, Walter John ......Stroud.
Nicholson, Thomas Tanner......London.
Orange, Frederick Charles ......Southsea.
Parker, Thomas Herbert ......Bedford.
Robb, Thomas ....Edinburgh.
Robinson, John Colburn ....London.
Short, Frederick William ......Chagford.
Smee, Walter Wallis ....Axminster.
Smith, Harry James ....Speenhamland.
Smith, William John ....Newcastle-on-Tyne.
Stephenson, Thomas ....Edinburgh.
Suttar, John ....Peterhead.
Tozer, Frederick Early ....Maidenhead.
Watson, Frederick Percy ......Lincoln.
Watts, Francis ....Wolverhampton.
Weddle, William ....Gateshead.
Weighill, William Lancelot ...West Hartlepool.
Wilde, Francis......................Andover.
Wilson, Alexander William ...Eastbourne.
Wood, Alfred Lyon...............Stonehaven.
Wylde, Samuel Roe...............Macclesfield.
Young, Herbert Edward ......Binfield.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

William Henry Evans, 1, Culvert Road, Battersea Park, London, S.W.

Anthony Tucker Roberts, 32, Buckingham Road, Brighton.

REGISTRATION.

The REGISTRAR said that three persons had severally made the statutory declaration that they were in business before the passing of the Pharmacy Act, 1868, and had applied for enrolment upon the Register. The applications were in due form, but as it appeared to him that the Council was sometimes under the impression that he did not exercise sufficient care in placing names on the Register, he had thought that he would bring the names before the Council before registering them. He would read the applications which had been made and the reports which he had received upon them.

The VICE-PRESIDENT said that the first question seemed to be whether the Registrar was perfectly justified in adopting such a course.

Mr. SYMES thought that what the Registrar proposed to do was perfectly unnecessary, unless there was some doubt cast upon the cases.

Mr. MACKAY thought that the Registrar ought to say whether he had the slightest doubt about the cases.

The REGISTRAR said that he had not.

The VICE-PRESIDENT said that the Council had better leave the responsibility of registration in the hands of the Registrar.

Mr. MACKAY asked whether it was to be understood that the Council was satisfied with the way in which names had been placed hitherto upon the Register? Was it an undoubted fact that the claims of all the persons whose names had been recently placed on the Register were perfectly satisfactory?

The REGISTRAR said that he should never think of placing any name on the Register unless he was thoroughly satisfied of the legitimacy of the claim. He might mention that the Council had recently placed a man upon the Register with whose claim he was not at all satisfied. He had kept him off as long as he could. He should like just to read one letter he had received, in reply to his inquiries as to the validity of a claim.

The VICE-PRESIDENT said that the Council had a great deal to do, not only then but generally, and he thought that it had better not undertake the duties of the Registrar as appointed under Act of Parliament. Of course, the members of Council would be very happy privately to assist the Registrar if he wished for assistance, but he thought that the action of the Council must only be in that form.

The REGISTRAR said that he should like to read one page of a letter which he had received in answer to inquiries which he had made about a person applying for registration. He had no objection to its being made public. He then read the following extract from the letter :—

"The inquiry your letter contains somewhat surprises me. . . . . (1) I presume that no one honoured with H.M. Commission of the Peace would sign a declaration without first ascertaining its 'exact meaning.' (2) By referring to the declaration I signed you would see that the words 'to my knowledge' were underlined and marked with a **X** in red ink ; so that my attention must have been drawn to the phrase unless I were 'colour-blind.' (3) Of course I 'adhere' to any declaration I have signed: this question is one of a character not often addressed to gentlemen."

That was the character of some of the letters which he got in answer to what were sometimes called his impertinent inquiries.

Mr. CHURCHILL said that his experience showed that the gentlemen who attested the legitimacy of applications for registration did not always know the person respecting whom they were attesting.

Mr. RIMMINGTON said that the Registrar's experience taught him that the papers which had to be signed were not always carefully read. In fact, he himself had recently met with a case in which a magistrate admitted that he had signed a paper *pro formâ*.

The REGISTRAR said that there were very few declarations by magistrates. He was more particular with magistrates than with medical practitioners.

Mr. RICHARDSON said that a magistrate had no knowledge whether a man was speaking the truth. He merely attested that he was told certain things.

Mr. BOTTLE said that it was within his knowledge that a magistrate had signed a declaration to the effect that A. B. and C. D. were carrying on business together, while he (Mr. Bottle) knew that C. D. was not a partner in the business, but merely served as a boy. He went and saw the magistrate with reference to the matter, when the magistrate told him that he had no knowledge of C. D., except from what his father had told him. He (Mr. Bottle) said to the magistrate, "Do you know that by giving this declaration you have rendered yourself liable to imprisonment without the option of paying a fine?" The magistrate replied in the negative, and before he would allow Mr. Bottle to leave the paper had to be torn up to satisfy him.

Mr. Robbins said that this went to show that the suggestion which he had made was the proper one, namely, that the Registrar should write and inquire whether anything was known of the people who were certified.

The Registrar's Report.

The Registrar presented his Report upon the Registers of Pharmaceutical Chemists and Chemists and Druggists; the Registers of Members, Associates and Apprentices of the Society; a Comparative Statement of the Numerical Strength of the Society; and an Analysis of Examinations for the year 1879.

Mr. Bottle said that he thought that the very succinct report which the Secretary had put into the hands of the Council was, on the whole, very satisfactory. It showed that although the number of pharmaceutical chemists subscribing to the Society was still decreasing, it had last year decreased in a smaller proportion. The decrease was 12 in 1876, 23 in 1877, 29 in 1878, and 17 in 1879. As a set-off against that, the apprentices connected with the Society had increased. In 1878 there was a decrease of 14, and in 1879 there was an increase of 31. This was, to his mind, exceedingly satisfactory, for it showed that they had, coming up amongst them, a class of young men from whom they might hope for the future. For some years the Society had seen persons passing the Major examination, and then not connecting themselves with the Society; but he would venture to suggest to young men that it was to their interest to connect themselves with the Pharmaceutical Society. Perhaps some of those who withheld themselves from the Society were not satisfied with what the Society had done and was doing; but the Society was capable of doing an immense amount of good, and, if it did not do all the good which those gentlemen thought that it ought to do, let them connect themselves with the Society and bring such influences to bear upon the Council as might incline the Society in the direction of good. He had felt a good deal of interest for nearly forty years in the Society, and it might be in the recollection of some of the older members of the Society that some years ago he went into an elaborate calculation as to when the Society would die out; but he had come to the conclusion, very satisfactory to himself, that it might be his fate to die out before the Society. For forty years it had been his privilege to labour in the interests of the Society with the view of helping to hand down a very useful institution to his successors.

It was then resolved—

"That the Registrar's Report be entered on the minutes and published in the Journal and Transactions."

The Report is printed on pp. 628 and 629.

Reports of Committees.

Finance.

The report of this Committee was received and adopted, and sundry payments were ordered to be made.

The report of the Committee included a recommendation to renew for five years the lease of the Society's rooms in Edinburgh at a rental of £85.

House.

The report of this Committee was also received and adopted.

Benevolent Fund.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a registered chemist and druggist, aged 50. Applicant had a grant of £10 in March, 1878.

£15 to the widow of a member, aged 70.

£15 to the widow of an annuitant. She has had three previous grants.

£15 to the widow of a registered chemist and druggist.

The report stated that the orphan child of the late Mr. Hall had been elected to the British Orphan Asylum without the necessity of any outlay on the part of the fund, and that the orphan child of the late Mr. Wiggin had been unsuccessful at the recent election at the London Orphan Asylum.

A discussion arose as to the propriety of continuing the payment from the fund to one of the annuitants.

The Registrar said that when the last payment was made to the individual in question, he had been informed, in accordance with instructions, that, unless he attended before the Committee and explained his conduct, the Committee would recommend that his pension be stopped. He attended at the next meeting and the Committee had an interview with him. The result was that the Committee decided that it would not recommend the Council immediately to withdraw his annuity. Then a letter from the annuitant was brought before the Council, stating that he would carry out the wishes of the Committee.

Mr. Hampson said that the Secretary ought not to pay this person anything without visiting him and paying him in his own house. There was reason to suppose that he was living in such a manner as to make him an unfit recipient of the fund. He thought that every annuitant should be visited in his own house if a doubt arose concerning him. Unless the person whose case was now under consideration would permit the Secretary to visit him in his own house, he (Mr. Hampson) should certainly recommend that no more money be paid to him.

Mr. Rimmington said that, to all appearance, the person in question was a most unworthy recipient of a pension.

Mr. Savage asked the Secretary whether annuitants appeared before him each time they were paid.

The Secretary said that, if they were living in or near London, he got them to call. If they were living at a distance from London, he sent a cheque either to the Local Secretary or to some other responsible person who would see them sign.

Mr. Symes said that, seeing that at the last meeting there were nine applicants for annuities, and the Council could grant only three, and that there was pretty clear evidence that all the nine were worthy persons, he thought that the Council ought most decidedly to hesitate before it continued to grant annuities to persons about whom there was any doubt. If there were more funds and there was not a superabundance of applicants, the Council might be more liberal; but under present circumstances, it ought to be most particular that the recipients of annuities should be worthy persons, and should live in a consistent manner.

The Vice-President said that in the present instance a certain opportunity had been given to the person in question to adapt his conduct somewhat more to what the Committee would like, and a date had been fixed, by which time it must be satisfactorily proved that he had changed. Perhaps it would be well not to reconsider the case until the expiration of that time.

Mr. Hampson said that the Secretary ought to have some guarantee that the money that was given to the man would be expended in the direction that the Committee desired—for the man's real benefit.

The Vice-President said that he had no doubt that the Secretary would do the best he could in that way.

Mr. Shaw said that during twelve years there had arisen only two cases in which the character of a recipient had been called into question.

The Secretary said that he always took the greatest possible care for the purpose of seeing that the money was properly disposed of. In the present instance, the

The Committee recommended the purchase of the following books for the Library:—

Hill (J.), Family Herbal, 1812.

König (J.), Chemie der menschlichen Nahrungs- und Genussmittel, 1880, Theil 2.

Piesse (G.W.S.), Art of Perfumery, 4th ed., 1879.

Royal College of Physicians of London, Translation of Pharmacopœia of 1836, by R. Phillips, 3rd ed., 1838.

The Curator had reported that the attendances in the Museum during December had been:—Morning: average, 12. Evening: average, 2.

He had also reported that he had received the following donations to the Museum, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Presented by Mons. C. Chantre:—

Bark and Gum of *Acacia pycnantha* and *Acacia decurrens*; a Japanese Root used in medicine, and Specimens for the Herbarium of *Eucalyptus occidentalis, leucoxylon*, and *Eucalyptus brachypoda.*

Presented by Professor Attfield:—

A Specimen of Lignite.

Presented by Mr. W. Southall:—

Seeds of *Ervum Ervilia.*

Presented by the India Office through Sir J. D. Hooker, K.C.B., from the India Museum collection:—

Several cases of Bombay Drugs, containing a number of valuable and interesting specimens.

Presented by Mr. R. Talling, of Lostwithiel:—

Specimens of Calamine (carbonate of zinc), Asbestos, Cobalt Ore, Iron Pyrites, and Fluor Spar.

Presented by Mr. C. B. Allen:—

Specimens of Cassiterite, Native Copper, Peacock Copper Ore, Blende with Tin, Redruthite, Copper Pyrites, Limonite, and Native Arsenic.

The Curator had reported that he had received an application for loan of Electrical Apparatus for Decomposition of Water, from Mr. A. H. Claypole, of Farnborough; and another for a loan of specimens intended to illustrate a paper to be read before the Chemists' Assistants' Association by Mr. G. W. Bullen.

The VICE-PRESIDENT said that it was a point of congratulation that the Museum continued to receive donations from important quarters; and the donations of books to the Library, which were rather numerous on this occasion, showed that the Society was appreciated by those who wrote and owned works of value.

The report and recommendations of the Committee were received and adopted.

Mr. GREENISH moved that the Journal and Transactions of the Society be sent to the University of Brussels regularly as published. The Museum had received donations from Professor Bommer, director of the Botanical Gardens, of Brussels. Professor Herlandt of that University had told him (Mr. Greenish) that he never saw the Journal of the Society.

The motion was seconded by Mr. HILLS and carried unanimously.

GENERAL PURPOSES.

The Council went into committee to receive the report of this Committee. It included the usual report of the Solicitor as to cases placed in his hands, and also correspondence with two persons against whom proceedings had been ordered.

Several other cases of alleged infringement of the Pharmacy Act were also reported, and in three cases a prosecution of the offenders was recommended.

The Council having resumed, the report and recommendations of the Committee were received and adopted.

PROCEEDINGS IN COMMITTEE.

In pursuance of notice, Mr. SAVAGE then moved the following motion—

"That motions made to go into committee of the Council be adopted or rejected without a discussion, beyond an explanation from the mover as to his reasons for doing so."

He said that the motion was so very simple and seemed so to commend itself, that it would scarcely require a word of explanation. He had thought that the Council might save a great deal of unnecessary talking if, when a member moved that the Council should go into committee, a vote were taken without discussion.

Mr. SHAW said that he had much pleasure in seconding the motion. At the last meeting he had made an observation to the same effect as the motion. It was very desirable that committees should report as fully as possible. The business of the committees was gone over the day previously to the meeting of the Council, and, when there was any matter which required to be discussed in private, any member of the Committee was competent to state at once succinctly the reasons for going into committee, in order that the time of the Council should not be taken up by unnecessary discussions.

Mr. SYMES said that while he sympathized with Mr. Savage's intention, which, he presumed, was to save a waste of time at the Council meetings, he was sorry that he could not at all follow him in the recommendation. When a member of Council stated that he had special reasons for wishing to discuss a subject in committee, as a rule the Council accepted his judgment and went into committee; but he should be sorry to see a resolution passed compelling it to do so. He would prefer that the matter should be left as one for the judgment of the Council. At the last meeting of the Council it went into committee, at the request of a member of Council, with reference to an application for membership, the discussion upon which might very well have taken place openly without the least offence to the person referred to. Going into committee was now a more troublesome thing than it used to be. He really saw no necessity for the Council hampering itself with a resolution of that kind, when the difficulties which it would incur were likely to be greater than those which it would save.

Mr. HAMPSON said that he must oppose the motion, because it was quite unnecessary. Hitherto the Council had not tied its hands in any way, and an occasion might arise when it would be extremely desirable in the interest of the Society that the propriety of going into committee should be discussed. At some future time the Council might be so constituted that the majority might desire to shirk discussion, and be disposed to hide themselves under the veil of a committee. He thought that it would be objectionable to pass a resolution which would allow of such a course. He believed that the common sense which prevailed in the Council was a sufficient guarantee that if it was desirable to go into committee it would be done. He objected to unnecessary restrictions, and believed that what the motion proposed was an unnecessary and an uncalled-for restriction.

Mr. SQUIRE said that he could not agree with the last two speakers. The motion would not bind the Council to go into committee; it simply required that it should vote at once upon the question. Those who did not want to go into committee could say so by their votes, but they need not waste three quarters of an hour in arguing the question. It seemed to him that the motion would save a great deal of time.

Mr. GOSTLING said that he should certainly vote for the motion brought forward by Mr. Savage, because it seemed to him that it would save a great deal of time. He believed that after a member had made a statement of his reasons for going into committee, the Council would be perfectly able to decide without discussion.

Mr. MACKAY said that he could not follow the objections which had been made against the motion. The proposal did not lay down a hard and fast line. He could not see how members would be bound to go into committee, seeing that they would be able to vote against it.

Mr. SYMES remarked that the motion said "without a discussion."

Mr. MACKAY: Precisely; but not without voting.

Mr. GREENISH said that he was sorry that he could not vote with Mr. Savage in this matter. He did not like to see the Council restricted, but would prefer that the same conditions should continue as had prevailed up to the present time. He had on many occasions seen a discussion on the question of whether the Council should or should not go into committee, and he thought that that discussion had been a benefit. It was objectionable to bind the Council with such a resolution as this.

Mr. BOTTLE said that he could not support his friend Mr. Savage in this matter. He should very much like to feel that the proposal formed part of the unwritten law of the Society rather than that it should be recorded in the statute book. There was this objection to it, that the mover of a proposition to go into committee might have a very weak reason for his proposal but somebody else might have a very strong reason, and the present motion would prohibit his stating that strong reason.

Mr. ATKINS said that it struck him that the motion itself was a very harmless one; but, at the same time, he could not support it. It would place too much power in the hands of the person who proposed to go into committee. There was a still stronger reason which had not been referred to. He hoped that the difficulty which no doubt was at the back of this motion would by-and-by be entirely removed, and that it was only a question of time for the reporting to be placed on more satisfactory grounds. They had better let matters rest as they were.

Mr. FRAZER thought that the motion was not wanted.

Upon a vote being taken, there appeared 6 in favour of the motion and 8 against it. The motion was therefore negatived.

DEATH OF MR. HASELDEN.

The SECRETARY announced that a message had just been received that Mr. Haselden, formerly President of the Society, had died that morning.

Mr. ATKINS proposed the following resolution on the subject:—

"That this Council having heard of the death of Mr. Haselden desire to express to Mrs. Sharp, the sister of the deceased gentleman, its most sincere sympathy at the loss which she has sustained, and at the same time to convey the assurance of the high esteem in which the late Mr. Haselden was held by the Council for the valuable services which he had rendered to pharmacy, and especially for the efficient manner in which he performed the duties of President of the Society."

Mr. SAVAGE said he had much pleasure in seconding the motion, having known Mr. Haselden very well, and having seen him frequently from the commencement of the attack of paralysis from which he had suffered, as he had been residing in Brighton.

Mr. ATKINS, in support of the motion which he had proposed, said that many gentlemen at that table had a more intimate and personal knowledge of Mr. Haselden than he had; but still, he knew him better than he knew some men of a former generation to his own. When he (Mr. Atkins) began to move more actively in pharmaceutical matters, he was brought into relations with Mr. Haselden and he learned to highly respect him for his integrity and straightforwardness of character, and for his urbanity as a man. The motion made no reference to Mr. Haselden's work as an examiner, but he believed that he had done an important work for that Society and for pharmacy generally in the examination room. He liked to think of Mr. Haselden as he liked to think of other men of the past who had more especially made their mark as pharmacists. Years ago he remembered reading with pleasure and profit Mr. Haselden's papers on pharmacy. They were pre-eminently practical papers, and they had sufficient accuracy and finish about them as scientific productions, and he believed that they would stand the most searching criticism; but they were pre-eminently papers that could be taken into their laboratories and shops and made useful for daily work. He felt that pharmacists owed a debt of gratitude to the memory of Mr. Haselden as an earnest, persevering, practical worker in pharmacy, and he was sure that they would all feel great pleasure in communicating an expression of their kindly feeling towards Mr. Haselden's sister as representing his family.

Mr. Frazer said that although not cognizant himself of Mr. Haselden's services as an examiner, he had heard of the value of them from other sources. He had a very high estimate indeed of Mr. Haselden, who was the first representative of that Council who officially visited Scotland. From the time of his visit, he (Mr. Frazer) had had much intercourse with him publicly and privately, and he had formed a very high estimate of his qualities, both personal and scientific.

Mr. Mackay said that he thought that there could not be a doubt as to what was the duty of the Council in this matter.

Mr. Greenish said that his knowledge of Mr. Haselden dated from the time when he (Mr. Greenish) became a member of the Council, and he had a very high opinion of the sterling character of that gentleman. As to his attainments as a pharmacist, he considered that they were of a very high order. The impression had been left on his mind that Mr. Haselden was a highly educated man.

Mr. Bottle said that he would like to add his expressions to those of the other members of the Council as to the services which Mr. Haselden had rendered. It was his privilege to be a member of the Council when Mr. Haselden was called upon to take the presidency under circumstances of some difficulty, and Mr. Haselden showed himself quite equal to the occasion. He had filled the office of President for two years, and acted for a short time during Mr. Sandford's absence. Those who had the privilege of being members of the Council at the time would bear in mind not only Mr. Haselden's value as a well educated and advanced pharmacist, but the urbanity with which he occupied the chair, and the kind consideration that he gave to every member of the Council.

Mr. Hills said that Mr. Haselden was an old friend and fellow student of his. He believed that he was on the Council for about fifteen years, and was ever active in the interests of the Society. It was with very great pleasure that he had been associated with him.

The motion was carried unanimously.

It was announced that Mr. Haselden's funeral would take place at Highgate Cemetery on the following Saturday. Some members of the Council expressed an intention to be present.

Weights and Measures Act.

The Secretary said that at the last meeting of the Council it was resolved to present a memorial to the Board of Trade, urging the necessity of a uniform practice under the new Act of marking measures in various parts of the kingdom. Since then the President had addressed the following letter to the Board of Trade, at Whitehall, on the subject:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square,
"London, W.C.,
"*January* 14, 1880

"Thomas H. Farrer, Esq.,
"Committee of Privy Council for Trade,
"Whitehall Gardens, S.W.

"Sir,—The time having arrived at which the standards of apothecaries' weights and measures described in the Order of Council issued on August 14 last should come into operation, and there appearing to be much difference of opinion and divergence of practice in the various district offices at which such weights and measures should be verified and marked, I am requested by the Council of this Society respectfully to draw the attention of the Board of Trade thereto.

"Chemists having become acquainted with the various communications which have taken place between your Board and this Council, naturally appeal to us for information as to the steps necessary to be taken in order to bring themselves into accordance with the law, and they report the difficulties which arise in different localities in their endeavour to do so.

"In one metropolitan district the inspector gave notice to certain chemists that all weights and measures must be examined and stamped, and proceeded to verify and mark them accordingly, at least six months ago.

"As far as I can understand, the standards had not then been delivered to any district office, nor have they generally been distributed even now. That this is undoubtedly correct seems to be proved by the fact that various district inspectors, on being applied to, reply that they are not yet in a position to perform this part of their duty.

"In one very important district the answer was that only measures holding a given quantity when filled to the brim could be recognized. In another case the district inspector replied in writing, 'Glass measures cannot be stamped unless they are made partly of metal.'

"By the reading of the Act, especially section 46, these seem to be entirely misconstructions, and the standards themselves, which, by the courtesy of Mr. Chaney, I have been permitted to see at the Standards Office, in Palace Yard, show by their graduations and subdivisions that it is so.

"It appears that although the law is clear and well understood at the chief office, very much may be left in the hands of the district inspectors as to the method of carrying it into effect. It is on this point that I venture now to trespass on you and to suggest that somewhat definite instructions of detail should be issued to all officials.

"It would be easy to demonstrate, should you be pleased to grant an interview to me and one or two members of the Council of this Society, that it would be impossible for chemists to carry on their business with measures always filled to the brim or with measures not having many subdivisions graduated.

"I have the honour to be, sir,
"Your obedient servant,
"G. W. Sandford,
"*President of the Pharmaceutical*
"*Society of Great Britain.*"

In reply thereto, a letter had been received, under date the 5th of January, to the effect that Mr. Farrer would receive a deputation from the Council. In accordance with this reply, a deputation, consisting of the President, Mr. Williams, Dr. Paul, and the Assistant-Secretary, had had an interview with Mr. Farrer, of the Board of Trade, at Whitehall, and he would read the following report of the deputation, which had been prepared. If Mr. Williams and Mr. Sandford had been in attendance at the present Council meeting they would possibly have amplified that report.

The VICE-PRESIDENT suggested, before the report was read, that in the absence of the President and Mr. Williams it would be advisable to invite Dr. Paul to attend the Council, and he, together with the Assistant-Secretary, would then be able to afford the Council any further information that might be desired.

This having been agreed to, Dr. Paul and the Assistant-Secretary were called and asked to take seats at the Council table, after which the Secretary read the report, as follows:—

"*Report of the Deputation to Mr. Farrer, Board of Trade, January* 23, 1880.

"Present—The President, Mr. Williams, Dr. Paul and the Assistant-Secretary.

"The deputation submitted to Mr. Farrer various reports of the different readings of the Weights and Measures Act so far as regards apothecaries' weights and measures in different districts, viz., that in one district the inspector had declared that only measures full to the brim could be stamped, thereby ignoring all the graduations at present in use and necessary on glass measures.

"That in another district the inspector had decided that glass measures cannot be stamped unless they are made partly of glass and partly of metal. A two ounce measure was submitted with the following graduations only:—½, 1, 2, 3, 4, 8 and 16 drachms, ½, 1 and 2 oz., and it was pointed out that such a measure was altogether insufficient for the use of chemists. This measure had been verified and marked by the inspector of the Marylebone district. That another inspector had refused to verify 6, 8, 12, or 16 oz. measures, or anything above 20 oz. A 20 oz. measure would simply be marked 1, 2, 3, 4, 5, 10, 20 oz., only seven lines on each.

"That there was a discrepancy in the rate of charge in different districts for verifying graduations.

"The deputation urged on Mr. Farrer the great importance of uniformity of practice in all districts, and the consequent necessity of all inspectors being in possession of similar apparatus for testing weights and measures, with certain instructions as to their use.

"Mr. Farrer replied that the Board of Trade had no power to issue detailed instructions as to the carrying out of the Act of Parliament; it could only advise the local authorities.

"He was decidedly anxious that there should be uniformity, and suggested that if the points in doubt could be embodied by the Pharmaceutical Society in a memorandum addressed to the Board of Trade, the Board would give the matter full consideration, and send such a detailed answer as might possibly have great weight with the district authorities, and tend to bring about a better state of things if the Society would print and distribute amongst them copies thereof."

The VICE-PRESIDENT said that what the Council now required was to ascertain from Dr. Paul and the Assistant-Secretary what occurred at the interview, before any discussion took place on the subject.

Dr. PAUL said that the report which had been read embodied everything. The chief remark of Mr. Farrer was that the Board of Trade was almost entirely passive in the matter, and that it had no power to direct. It could only advise those local authorities who came to it for assistance. The local authorities, except in a few instances, did not seem to have applied for assistance from the Board of Trade.

Mr. SAVAGE asked whether the Board of Trade was not waiting for some communication from the Pharmaceutical Society. If he understood rightly, it was anxious that the Pharmaceutical Society should convey its specific views in connection with the question.

Dr. PAUL said that the Board of Trade was scarcely anxious, but Mr. Farrer said that if the Council thought there was a difference of opinion among inspectors, or those who had to deal with the carrying out of the Act, and if the difference could be shown to exist and to affect individuals in the exercise of their business, a representation to that effect might fairly be made by the Council to the Board; and, if that were done, the Board might advise some mode of proceeding.

Mr. MACKAY said he thought that there could be no doubt that the Council of the Society could guide the Board of Trade very much in this matter. The Council might get the Board of Trade to print and issue a circular without waiting for applications from the inspectors. It would not be too much to expect the Board of Trade to have instructions printed in the form of a circular and sent to the local authorities, with a request that their inspectors should act upon those instructions.

Dr. PAUL said he thought that the object of Mr. Farrer's suggestion was that some plan should be arranged for the Council to address itself to local authorities, but not to the inspectors at all. The inspectors were the last people to be communicated with about the operation of the Act.

Mr. GREENISH said he supposed they received their instructions directly from the Board of Trade.

Dr. PAUL said, No, but from the local authorities. The Board of Trade had no power to instruct anybody at all. It was suggested by Mr. Farrer that any action taken by the Society should be in the shape of a communication to the local authorities, who alone had the power to put the Act into operation.

Mr. ATKINS asked whether the difficulty with regard to the Weights and Measures Act was restricted to chemists and druggists, or was there any deadlock at present with regard to the whole of the legislation on the matter?

Dr. PAUL said no doubt there were some difficulties in other quarters; but in speaking to Mr. Farrer the other day reference was made, exclusively, to apothecaries' weights and measures.

Mr. SAVAGE asked whether the Act of Parliament was simply left for the adoption or otherwise of the local authorities.

Dr. PAUL: Precisely.

The VICE-PRESIDENT said that he took it that the result of the deputation was very much to this effect, that Mr. Farrer, speaking with the authority of his Board, was prepared to receive from the deputation or from some other deputation representing the Pharmaceutical Society any statement of difficult points about which the Society required something like an authoritative declaration, and that, as far as possible, the Board of Trade would give a definite opinion upon those points for the guidance of any who appealed to the Society for advice.

Dr. PAUL said that Mr. Farrer reduced the question to three heads:—First to state the difficulties that had been met with; then to show the mode in which those difficulties affected people in the exercise of their ordinary business; and thirdly, to suggest the establishment of a scale of charges.

Mr. BOTTLE asked whether he understood Dr. Paul, that Mr. Farrer suggested that the Council should draw up and circulate to local authorities some expression of opinion.

Dr. PAUL said he understood him so.

Mr. BOTTLE asked if the Board of Trade would not do so.

Dr. PAUL said it would not. Mr. Farrer's suggestion was that the communication in the first instance should be from the Council to the Board of Trade and that then, as a matter of ultimate procedure, there should be a communication from the Council to the local authorities.

Mr. MACKAY said that he understood that the suggestion was that the Council of the Society should get information from chemists and druggists in certain districts and embody it in some report to the Board o

Trade, and that then, if the Board of Trade was persuaded by what the Council put before it, it would issue a manifesto to the local authorities, and then those authorities should instruct their inspectors to do what common sense would guide them to do.

Mr. Atkins said that evidently the Board of Trade felt a difficulty in dealing with the technical points of the Act with regard to pharmacy.

The Assistant-Secretary, in reply to an inquiry by the Vice-President, said that the paper which had been read as the report of the deputation was drawn up by Mr. Sandford and himself immediately after the deputation took place, and it contained what they remembered about it. It practically embodied what Dr. Paul had said. The general impression left on his mind, and apparently on Dr. Paul's mind, was that the Board of Trade seemed quite passive, and that it could do nothing. Mr. Farrer said to the deputation, "It is no good for us to try to drive the local authorities, as we do not want to get into trouble with them. We can lead them better than we can drive them. If they come to us and ask us questions, we can answer them, but we cannot volunteer advice or tell them what to do."

The Vice-President suggested that the whole business connected with this subject, having already been placed in the hands of a small committee, should be further considered by it.

Mr. Hampson proposed that the matter should be referred to the Law and Parliamentary Committee.

The Chairman thought that it would be well to have a small sub-committee to take the matter in hand.

Mr. Atkins seconded the motion for referring the matter to a committee.

After some discussion,

Mr. Hampson withdrew his proposal to refer the question to the Law and Parliamentary Committee, and agreed to a reference of it to a committee.

A motion referring the subject to a committee consisting of the President, the Vice-President, Mr. Greenish, Mr. Squire, Mr. Hills, Mr. Williams and Mr. Hampson, was accordingly put forward, and carried unanimously.

Interchange of Visits between the Boards of Examiners.

On this subject being again mentioned,

Mr. Mackay said that he had considered it his duty to bring it before the Council, because he had an impression that there was a distinct motion to the effect that a deputation from the London Board should attend the examinations in Edinburgh, and that one from the Edinburgh Board should attend the examinations in London, every year. He reminded the Council that no deputation had gone from one place to the other since June, 1878.

Mr. Hampson asked whether Mr. Mackay would give notice of a motion on the subject for the next meeting.

It was eventually agreed that the question should be introduced by the Secretary into the agenda for the next Council meeting, and that, in the meantime, the opinion of the Boards of Examiners on the subject should be sought.

Parliamentary Papers.

A request from the Editor to be supplied with the entire sessional Parliamentary papers, instead of simply with the "Daily Votes and Proceedings," was referred to the Library and Museum Committee for consideration.

The Use of the Word "Pharmacy."

The Secretary read the following communication, which had been addressed to the President and Council of the Society:—

"8, The Strand, Torquay,
"*Jan.* 31, 1880.

"To The President and the Council of
the Pharmaceutical Society.

Sirs,—Some time ago, as an Hon. Local Secretary, I inquired from Mr. Bremridge whether a 'Minor' had a legal right to style his shop a Pharmacy or Pharmaceutical Laboratory.

"Mr. Bremridge having submitted my inquiry to the General Purposes Committee, informed me that the 'various members of the Committee held different views on the subject, but the Committee collectively declined to express an official opinion.'

"Under these circumstances, as the point seems to me not an unimportant one, possibly involving and affecting the rights of 'Majors,' I venture to draw the attention of the Council thereto, and to request their official opinion thereon.

"Very faithfully yours,
"Edward Smith,
"*Hon. Local Secretary for Torquay.*"

Upon a vote being taken upon the question whether the communication should be entertained, the Council decided to entertain it.

Mr. Hampson moved that the letter should be referred to the General Purposes Committee for consideration.

Mr. Squire seconded the motion.

The Secretary read the following extract of a letter which he had written to Mr. Smith on this subject on the 9th January:—"My dear Sir, You will remember when you were on the Council, that Mr. Flux over and over again advised us that it was not the business of the Council to interpret the law, but to administer it."

Mr. Robbins moved—

"That Mr. Smith's letter be handed to the Solicitor for his opinion on the question submitted to this Council."

It would be impossible for the Law and Parliamentary Committee to say more on the subject than the members of the Council could say themselves.

The motion was seconded by Mr. Frazer.

The Vice-President said that the question had been before the Committee, which came to the conclusion that it declined to interpret the law.

Mr. Atkins said, then it was a case for a lawyer.

Mr. Frazer seconded Mr. Robbins's motion that the question should be referred *simpliciter* to the Solicitor.

Mr. Squire asked whether the Society would have to pay the fee for the Solicitor's opinion?

Mr. Robbins: Certainly.

Mr. Atkins understood that the question was not put merely in a theoretical way, but that the difficulty was one which had really practically presented itself.

Mr. Hills said that he knew a case in point.

Mr. Hampson said that it was extremely unadvisable that the Council should ask the Solicitor to give an opinion on such a matter until it had a *bonâ fide* case brought before it. If there was a case of offence against the law, the matter might be brought before the Council, but in the present instance it was asked to give an opinion on a question of law which might have been proposed simply from a desire for information or curiosity.

The Secretary said that Mr. Flux had some years since given his opinion that members and members only could assume connection with the Society, and that persons who had passed only the Minor examination were not legally entitled to claim that connection.

Mr. Rimmington said that that opinion did not cover the present case.

Mr. Mackay said that no doubt Mr. Smith had a particular case before him. It was a very common thing for a person, instead of calling his establishment a chemist's shop, to call it a pharmacy.

The Vice-President did not think that the Council would be advancing much by getting a definite case.

Mr. Mackay thought that a special instance ought to be obtained before an opinion was taken.

The Vice-President said that that would not materially alter the opinion.

Mr. Mackay said that he would rather have a tangible case.

The SECRETARY said that he knew very well the case to which Mr. Smith referred.

Mr. ATKINS said that there were other cases. Perhaps a legal opinion could be obtained quite as well or better apart from a definite instance.

Mr. MACKAY said, that as he gathered from the Secretary that he knew the case upon which Mr. Smith had founded his question, he would withdraw his objection.

The SECRETARY said that he knew of scores besides the case in question, and he should be very glad indeed to have this question settled.

The VICE-PRESIDENT said that the taking of the Solicitor's opinion would not commit the Council to anything.

The SECRETARY said this was a much larger matter than appeared on the surface. There were many persons who passed the Minor and never went to the Major, and if these persons were allowed to imply that they were pharmacists it would detract in a very great measure from the importance and dignity of those who qualified themselves for the higher examination.

Mr. HAMPSON withdrew his motion for referring the question to the General Purposes Committee and moved instead the following as an amendment upon Mr. Robbins's motion:—

"That before obtaining the opinion of the Solicitor on the question of law, the case of infringement be brought before us and investigated."

The amendment was seconded by Mr. SQUIRE.

Mr. GOSTLING said that the Council would be much better prepared to listen to a case after having had the Solicitor's opinion. Therefore he should support Mr. Robbins's proposition.

The amendment, on being submitted, was negatived by a majority of 4. The motion of Mr. Robbins was then carried *nem. con.*

THE SALE OF FOOD AND DRUGS ACT.

Mr. ATKINS mentioned the case of a highly respectable young chemist who had been twice prosecuted under the Sale of Food and Drugs Act, and in each instance without the slightest foundation. He (Mr. Atkins) felt that it was quite time for the Society to make a very decided and outspoken protest against the action of local inspectors in dragging chemists into court in such cases. However innocent a man might be, if plenty of mud were thrown at him some of it would be almost sure to stick.

SALE OF NARCOTICS.

The Council then went into committee on the subject of the sale and use of narcotics.

PHARMACEUTICAL MEETING.

Wednesday, February 4, 1880.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed,

The CHAIRMAN called on—

Mr. HOLMES, who, in describing the specimens on the table, said that the majority of them had been presented by Government through Sir Joseph Hooker, and formed a small portion of the materia medica collections which were originally in the India Museum. The specimens now exhibited represented only a portion of the donations that had been received by the Society. One or two of the specimens had been received from other sources. They were, specimens of tayuya and guaco, presented by Dr. Symes, which had been recently introduced into medicine in this country, the latter, he believed, being chiefly used by homœopaths for syphilis, paralysis and cancers. There was a singular resemblance between one of the Indian drugs on the table, viz., *Tinospora cordifolia*, and the tayuya in appearance, so that they might be easily mistaken for each other at first sight. There was also a specimen of some very astringent pods from South America, presented by Messrs. Curling and Co., which were imported into this country some time ago. When first received by the importers they were supposed to be the common locust bean. From the taste and appearance he should judge that they might be made available as a source of tannin. He could supply samples for investigation. Some of the Indian drugs on the table were very beautiful s pecimens, and were much better than those previously in the museum, while others were valuable acquisitions. Among these might be mentioned pods of *Mucuna pruriens*, showing the hairs (cowhage) *in situ*. Others were remarkable for their curiosity, especially one of trehala manna, as it was called. It consisted* of the cocoons of a small weevil, *Larinus maculatus*. These cocoons were the source of the peculiar sugar called trehalose. Two or three of the series of camphors were also of great interest; one was Ngai camphor, which was examined a short time ago by Mr. Plowman. Another was Borneo camphor, an excessively rare article in this country. Another, called ajwain-ka-phul, was a specimen of crystallized thymol, obtained during the distillation of ajowan seeds with water, the water being an official preparation of the Indian Pharmacopœia and used as a carminative. The crystals floated on the surface of the distilled water. Then there was a specimen of henbane from India which resembled that met with in commerce in this country, but the leaves were very much larger. They were not so deeply cut as those of the biennial kind. The odour was, if anything, more powerful in the Indian plant. It had occurred to him that as drugs from hot climates were generally more potent, and henbane was a very expensive and extensively used drug in this country, it might be profitable to obtain it from India. Then there was a specimen of wormseed from India, which to the naked eye closely resembled the Barbary wormseed in appearance. There was also a specimen of safflower-seed oil on the table. The seeds of the safflower were sometimes met with in drug sales in this country and were mistaken for sunflower seeds; under pressure they yielded a very pale limpid oil, which had a taste something like that of oil of almonds; whether it was a drying oil or not, he was not sure, but he should judge that it was not. There were also fine specimens of chiretta, one being false chiretta (*Ophelia angustifolia*) from Sylhet, in the north of India, and another being the genuine kind from the south of India. There were also two interesting specimens of assafœtida. One was the product of *Ferula alliacea*, and was never seen in English commerce. This was the kind mentioned by Dr. Dymock as being the only sort issued from the Government stores in Bombay, and as being a stronger and better assafœtida than the one which occurs in commerce in this country. The other kind of assafœtida, called candaharee hing, also was not met with in commerce in this country and, being rare and expensive, it was said to be used as a condiment only by the more wealthy classes in India. These specimens were, however, not so fine as those which had already been presented to the museum by Dr. Dymock. There were a few specimens of essential oils and aromatic herbs suitable for perfumery, to which it might be interesting to call attention. One of the oils, obtained from the flowers of *Lawsonia inermis*, better known as the henna plant, had an odour exactly like that of the tea rose. Another was the volatile oil of one of the screw pines, *Pandanus odoratissimus*, having a remarkable honey-like odour, resembling that of the flowers of Buddleia, and might, he thought, be used as an auxiliary to other perfumes to give them sweetness. The foliage of *Artemisia indica* was also very fragrant, and he should think that it might be used, in conjunction with another specimen which was on the table, in *pot pourri*. The latter, which appeared to be the leaves of some labiate plant, although erroneously labelled *Artemisia species*, had a

* See Hanbury, 'Science Papers,' p. 158.

remarkably pleasant odour. About two years ago this labiate drug came into commerce in London. He was rather interested in this drug, because the specimen he received two years ago came from Asia Minor, and the presence of it among Bombay drugs indicated that it might possibly, like other Arabian drugs, be originally produced in the latter country. The specimen he had originally received having been too comminuted to enable him to find an entire leaf, it had remained in his room for two years without his being able to identify it until the Indian specimen recently came into his possession. The exact species to which it belonged he had not yet determined. Then there were some specimens of what was supposed to be the aloes wood of Scripture (*Aquilaria Agallocha*), and also of the supposed spikenard of Scripture (*Nardostachys Jatamansi*), of which the museum previously contained some specimens. A small group of specimens which he had placed by themselves consisted chiefly of mucilaginous drugs. These were more largely used in India than in England, and some of them seemed to be worth a trial in this country. The spogel seeds (*Plantago Ispaghula*) were remarkably mucilaginous and were valuable in cases of diarrhœa in which a demulcent was required, and were said in the Indian Pharmacopœia to answer better in such cases than any other remedy. He believed that the seeds were taken mixed with water or other fluid and swallowed, and that in the intestines they gradually gave out mucilage, so that the action of the mucilage was continued for a long time. Another series of the specimens related to the manufacture of opium in India. There was a volume of the *Pharmaceutical Journal* (vol. xi.) in which the process had been described, and it might be referred to after the meeting. The jar on the table represented the jars in which the opium was carried into the factories. As a rule, these jars were surrounded by basket work, which was absent from this specimen. The wooden chest was a model of the chest in which the opium was packed. The opium was represented by balls of wood.

The CHAIRMAN said that he was glad to see the estimation in which Mr. Holmes held this collection of drugs, for which he believed the Society had to thank several persons, among whom was Dr. Cooke, whom he would presently ask to explain some few of the specimens, and who had done good service to the Society in helping to obtain for it a portion of the contents of the Indian Museum. Some members of the Society might very likely deplore the resolution which the Government had arrived at as to the distribution of that museum, but that resolution having been arrived at it was important that that portion of the specimens which touched upon pharmaceutical science should find its way within the Society's walls. He would now ask Professor Bentley to give some information upon the collection of specimens.

Professor BENTLEY said that he took a great deal of interest in the subject of Indian drugs and he was pleased to see on the table specimens of different kinds of assafœtida, different kinds of galbanum and other umbelliferous gum resins, as to which a great amount of our recent knowledge was due to the investigations of Dr. Dymock and the authors of 'Pharmacographia.' Those who were present that evening had an opportunity of seeing that the assafœtidas were very different in character from the kind that was known in this country. It was well known to those who were acquainted with the literature and science of the subject, that assafœtida varied in its character and was evidently derived from different plants. His colleague, Dr. Trimen, who was now on his way to Ceylon, and himself had figured in 'Medicinal Plants,' two plants which evidently yielded analogous products, *Ferula Narthex*, and *Ferula Scorodosma*. Besides these there was an assafœtida on the table from *Ferula alliacea* which presented a different character. The question of odour was one upon which persons differed. So far as he was concerned, he should prefer the odour of the assafœtida upon the table to the product which usually came to this country. The drug which we got in this country was considered in India to be an inferior assafœtida. Then there was a very interesting specimen of galbanum. Those who would take the trouble of comparing it with the galbanum known in this country would see that it was very different. There was no doubt that the two sorts were derived from different plants. There was the kind known as Levant galbanum, which was that which was ordinarily known in this country, and which was derived from *Ferula galbaniflua*. The present specimen appeared to be derived from a different species, probably *Ferula erubescens*, or that kind which was ordinarily known as Persian galbanum. It might be generally distinguished from it by the fact that in Persian galbanum there were generally found little portions of the stalks and fruits, whereas in the ordinary galbanum portions of roots were found. This matter was particularly interesting to him, for he and his friend, Dr. Trimen, had just brought to completion their work on 'Medicinal Plants.' It was only two days ago since that he had signed the index for the press. The work had occupied more than five years, and it might be conceived that he was glad to approach the completion of a work of that kind. Under these circumstances he was specially interested in seeing in the museum, under their energetic Curator, those specimens of drugs the plants yielding which had been figured in their book. As to the spogel seed, probably it might come into use in this country. He had no experience with regard to it, but he should judge that it was demulcent, as there was a great deal of mucilage in it. It was official in the 'Pharmacopœia of India.' It had the reputation of being useful in chronic diarrhœa. He must apologize for the remarks which he had made, which did not involve any new matter. He should not have ventured to make them had he not been called upon by the Chairman. He and Dr. Trimen had ventured to say in the preface of their forthcoming work that they believed that many of the plants which were now well known in India as yielding valuable drugs were worthy of much more attention than they had hitherto received in this country.

Dr. COOKE said that, having for eighteen years had charge of the botanical portion of the India Museum, he recognized a great many of these specimens as old friends. He had attempted to get into that museum as complete a series as possible of the drugs which were employed in all parts of India, whether those known to be of value or those which were used empirically. When it was resolved that the India Museum should be dissolved he took measures to put this Society into communication with the Secretary of State, in order that the whole of the materia medica collection might be transferred to the museum of this Society. He himself represented to the authorities the facilities which the Society afforded for exhibiting the drugs of the Indian Pharmacopœia, and those which were extra-officinal. Subsequently, official arrangements, of the nature of which he was even now totally unaware, were made, whereby the whole of the collections were transferred bodily to Kew. A guarantee to this effect was made in a speech in the House of Lords. They went to Kew accordingly, and there was an impression left behind at the India Office that no further assistance could be given towards the transfer of the collection to this Society. But he was under the impression that the whole of the special materia medica collection would ultimately be transferred to the Pharmaceutical Society. He must confess that he had been disappointed to find that what had been given to this Society was but a small proportion of that which he had hoped it would receive. He could only regret that the whole collection had not been disposed of in the best possible way. The samples of opium and of opium apparatus were parts of a collection, and he had no doubt that when this was understood at Kew the remainder would be sent. These were the metal mould in which the balls were made, and the earthenware mould in which the balls were dried. Then there was a large model of the stand on which the opium was dried of the ladles which were employed in baling it out, and of a press for making the opium into squares. There was also a peculiar "Hill opium" as it was called, containing rather more of the alkaloids than the generality of Indian opium. This was obtained from the northern district—Hyderabad and Scinde. There were two typical varieties of opium poppy cultivated in India—one with a short round capsule, and the other with an elongated capsule. So far as he had seen during a period of years, the scarification of the capsules in India was always longitudinal, and never transverse, whilst the Smyrna opium was divided in the contrary direction. The trehala which had been mentioned was the same as some specimens derived from that district some fifteen years ago. He took some specimens containing the beetle to Mr. Smith of the British Museum, and the insect was taken out and identified; and in one of the old series of the *Pharmaceutical Journal* would be found a note by him (Dr. Cooke) on the subject as the result of that examination. It was well to bear in mind that all the Indian drugs on the table, without exception, as far as he had observed, came from the Bombay side of India. It was important to observe, when drugs were received from India, whether they came from Bombay, Madras, or from Calcutta. He had noticed that a great many of the drugs coming from Bombay were those which were imported from Aden and from Africa, and they were drugs whose presence in India could not be accounted for under any other circumstances than their importation from Africa. One specimen was that of a drug which had been sent from India to the last Paris Exhibition. It consisted of the heads of *Gundelia Tournefortii*. Until then he had not seen it since he observed it in the Turkish collection in the first English Exhibition—that of 1851. The sample there exhibited was from Smyrna. The Kew authorities did not know it as an Indian plant, nor had heard of its being cultivated in India. Hence it was probable that the present specimen was one which had been imported from Aden into Bombay. As to the assafœtidas, he was pleased to see that the Society had one or two specimens; but there were five or six varieties of assafœtida in the Indian Museum and one was the peculiar kind to which he on one occasion drew Mr. Holmes's attention. It was a most peculiar ferruginous-looking, powdery assafœtida, such as he had never seen elsewhere. With reference also to sarcocolla, that was almost always sent to this country from Bombay or from Scinde. A short time since, he gave Professor Flückiger a portion of this substance for the purpose of investigating it as to its composition. His (Dr. Cooke's) own feeling was that it was rather more likely to be an umbelliferous plant than anything like penœa, to which it had hitherto been referred. He did not know whether Professor Bentley would agree with him in that opinion. The sample of *Coptis teeta* was a very fine one, and was larger than usual. It was better represented in the little cane bags, of which there was no sample on the table. In this form it was sent prepared by the hill tribes. He believed that it was only to be obtained from Assam. In all collections of drugs from India they got a large quantity of hyoscyamus seeds, which seemed to be employed in India as well as the hyoscyamus plant.

Mr. Holmes said with regard to the sarcocolla to which Dr. Cooke had alluded, he might say that a short time since he received some specimens containing fruits, from Dr. Dymock, of Bombay. They appeared to belong to the Leguminosæ, as had been stated by Dr. Dymock.

Mr. Gerrard remarked that a considerable number of the specimens of drugs of the late India Museum had been sent to University College, where there were a very large number of Indian students, and the collection would be properly displayed, and those students would be able, to some extent, to study the materia medica of their own country, and go home with at least some knowledge of the subject. Some of the drugs on the table seemed to be very fine specimens, and likely to prove of great value as curative agents. For instance, the conium fruits were exceedingly fine in form and size, and were uniformly bitter. The application of the rough test of a little potash solution developed the characteristic odour. Possibly these fruits might prove an abundant source of the alkaloid conia. There was also a specimen of the root of aconite. It was mentioned as *Aconitum palmatum*. He had found that this was bitter to the taste, but in no degree pungent, and it did not produce any of the irritating dryness of the throat which usually followed the swallowing or the chewing of a small quantity of European aconite. It was possible that this yielded atisine, an alkaloid found also in *A. heterophyllum*.

Mr. Holmes explained with regard to the specimen, that he put it on the table thinking it interesting in consequence of the occurrence of a recent case of poisoning by aconite, which was mistaken for horseradish. This was not one of the drugs recently received from Kew, and no specimen of it occurred in the collection presented from the India Museum. It had been presented some time since by Dr. Dymock, whose donations to this Society had been most valuable. With regard to this being a source of atisine, it might or might not contain it. Dr. Dymock had informed him that it contained a bitter alkaloid in quantity. At present some of the root was in the hands of Dr. Paul for examination. The aconite from which atisine had been obtained was *A. heterophyllum*, and was known as "atees," and not *A. palmatum*, the root of which was called "wakhma," and was quite different in character. The latter drug had a peculiar, cress-like odour, which was compared by Dr. Dymock to that of nasturtium. He thought that perhaps some of the aconite cultivated in gardens in this country might possibly have a similar odour, which might have led to its being mistaken for horseradish.

Mr. Greenish, said that he could confirm the remarks of Mr. Holmes with regard to the "wakhma." He had made sections of the two, and they were quite distinct. This aconite was one which in its character approached more to *Aconitum ferox*.

Dr. M. C. Cooke said that there was one feature in the root of *Aconitum heterophyllum* which was worth notice, namely, that, wherever it was broken transversely, the fracture exhibited a circle formed of vascular bundles. That was an unfailing test, whatever portion of the root was broken, these bundles were always visible.

The Chairman then asked Mr. Greenish to explain two instruments which had been placed upon the table, one being a polarimeter and the other a microscope.

Mr. Greenish stated that among the many pharmaceutical appliances of interest and value shown at the meeting of the German Pharmaceutical Society last year in Hanover, a microscope and a polarimeter, made by Schmidt and Haensch, of Berlin, especially claimed attention, and the makers were asked to send one of each for exhibition at one of the evening meetings of this Society, The microscope was mainly intended for the examination of the flesh of the pig, in search for trichina. The vertical spiral movement, by means of a slot in the outer body of the microscope, was, he thought, an improvement in the usual sliding body of such microscopes. The instrument was accompanied by two glass plates, one of them having five squares on it, each of one inch; in each of these squares was laid a piece of the flesh to be examined; this plate was then covered by the second, and both compressed by screws on the stage of the microscope. The stage was then moved by a lever, and the object, having traversed its full length of one inch, was, by a rack movement in front of the stage, advanced a little, but in the same plane, so that the return movement exhibited a new field for the object-glass. By this means, and with a few movements, every part of the suspected meat is brought into view. The examination of the five pieces on the one plate could thus be done with very great facility, and probably accomplish that which was said to have been done by some microscopists on the Continent—the examination of one pig per minute, or thirty pigs in half an hour. In one of the medical journals it was stated that in Germany flesh from the same pig was sent to one hundred microscopists for examination, and ten failed to detect the presence of trichina. With such an instrument as the one now before the meeting, with this mechanical arrangement, by which the entire surface must be brought under the object-glass, such a circumstance could scarcely have occurred. The polarimeter also seemed to be an instrument adapted to supply a want at the present time—that was, a well-made instrument at a moderate cost.

Dr. SYMES said that at the last Conference meeting at which he read the paper on the polarimeter, Professor Attfield pointed out that if the instrument could be produced at a cheaper rate, it would be more widely used amongst pharmacists. He (Dr. Symes) was of the same opinion. It would not only be useful in the examination of essential oils, as that was probably one of its least useful applications, the amount of rotatory power of those oils being a test, but one not to be taken alone, because rotation differed widely in different oils. He had examined samples of oil found in commerce and some which he had himself distilled, and found the rotation to vary very largely between the two samples. Following the idea of Professor Attfield he had had an instrument constructed by Messrs. Field, of Birmingham, who had undertaken to produce one for five guineas, to which price he had limited them, and he had insisted on its having a Jellett's prism, that being the best analyser. His instrument consisted of a double-refracting prism and analyser, and a lens for bringing the ray parallel, a tube to contain the fluid, and an analyser, consisting of a Jellett's prism. The ordinary prism consisted of a prism of calcspar, which had been cut into two, and then cemented together with Canada balsam; this was sufficient to throw one of the two rays out of the field. Jellett's prism was truncated, and then sliced lengthways in a line nearly parallel to its general axis, and the parts reversed. Professor Jellett pointed out that in this way he was able to get a sharper line of demarcation. The point which was read was the point of maximum density, and to determine that accurately it required an instrument which would give a large disc and show an even colour. The more sensitive it was the less the lateral movement that would be required to produce the change. Messrs. Field had accomplished their work very well, and made a very substantial and good instrument. He had had it in his hands less than a week; but he had examined it very fairly. He had tested tubes, and then sent them to a friend, who had examined them with two Laurent's instruments, one costing about £14 and the other £19. All the readings came out remarkably near, being less than half a degree out. The new instrument was produced at a very moderate price, and did its work very fairly indeed. The instrument ought to be supplied with a tube of 100 millimetres in length, as well as one of 200 millimetres. In highly rotating essential oils the rotation was far too great for a 200 millimetre tube, and the reading might possibly be got on the wrong side.

The CHAIRMAN expressed the thanks of the meeting to the gentlemen who had given the explanations of the exhibits.

A paper was then read on—

TINCTURE OF SENEGA AS AN EMULSIFYING AGENT.

BY HENRY COLLIER.

The paper is printed on p. 621, and gave rise to the following discussion:—

Mr. GREENISH said that Mr. Collier had stated in the early part of the paper that Bolly had considered saponin and senegin to be identical. But he (Mr. Greenish) thought that if Mr. Collier would read Bolly's account more closely, he would find that they were not identical, though there was very little difference between the reactions. Farther on Mr. Collier said, "I have not been able to find that since Bolly's work the saponaceous matter of senega root has been further chemically examined." He would call Mr. Collier's attention to a very elaborate paper on the subject in the *Archiv der Pharmacie*, 1875, by Christophson, who want very fully into the matter, and who found that the substances were not identical, though the quantity of senegin which he had at his disposal was not sufficient for ultimate analysis. Mr. Collier had said with regard to using liquor potassæ, "Occasionally, however, active substances are employed in small doses, and they are then considered not to have any detrimental effect." Liquor potassæ was not used as an emulsifying agent unless it was used on its own account, when its presence was required. He (Mr. Greenish) must make the same remark as he made at the Conference, that there were emulsions *and* emulsions, and, looking as a pharmacist at the specimens which had been shown by Mr. Collier, he would scarcely venture to call them good emulsions. Of course there might be a difference of opinion, but he simply expressed his own. The introduction of tincture of quillaia as an emulsifying agent might be admissible, and as far as he knew, tincture of quillaia did not possess any disagreeable properties in small quantities, but when they came to senega the case was altogether different. He regarded the introduction of senega as an emulsifying agent as utterly inadmissible, although the quantity of tincture of senega used as the emulsifying agent was only five minims. Of course, the fact that it would make an emulsion was interesting; but he was merely referring to its introduction into pharmacy. He had tried tincture of quillaia, and found that it answered better than tincture of senega; but it appeared to him that in neither case did they get what pharmacists considered a good emulsion. If solution of soap was used of the strength of the linimentum saponis of the Pharmacopœia, a better emulsion could be produced than with tincture of senega. He hoped that Mr. Collier would pardon him for these remarks; but it was better that these things should be criticized within the walls of the Society than that the criticism should reach the members from the outside.

Mr. GERRARD asked Mr. Collier whether he had any experience of the tincture of senega as an emulsifying agent upon tar. In that case he thought that the tincture of senega might be admissible. In his experience he had found that they might make most beautiful emulsions with powdered gum acacia. If a few grains were put to ½ an ounce of castor oil and 3 drachms of water poured upon it, and the mixture well stirred, in a minute and a half there would be obtained a beautiful white cream-like emulsion which would stand dilution with water to any extent, and it would stand for a week without separating one drop of oil. In the case of the tincture of senega emulsion described by Mr. Collier he had found that the oil separated after standing twenty-four or forty-eight hours, and formed a layer on the top. However, it was valuable to be made acquainted with the fact that senega and quillaia and preparations of those drugs would act as emulsifying agents.

Mr. COLLIER, in reply, said that as regards the examination made by Bolly, he certainly read the account very carefully; but perhaps he had made a mistake. As to liquor potassæ being used for making emulsions, it was a fact that it was so used when it was not required on account of any of its medical properties. In the Guy's Hospital Pharmacopœia it was used simply on account of its property of making an emulsion. As regards the property of emulsions, there seemed to be a doubt as to what an emulsion should be. Milk was regarded as a type of an emulsion, and this would, after a time, give a separation of cream. Mr. Gerrard had spoken of the separation of the emulsion after it had stood. Why should it not separate? It was part and parcel of the property of an emulsion to separate; but it separated, not into an oil, but into a cream. The principle of the action of quillaia and of saponin as emulsifying agents, was that they had the property of, as it were, getting between the particles of the oil and preventing their ever coming together again. As regarded tar, he had made an emulsion of it perfectly well by means of quillaia, and this was mentioned in the 'Rapport.' He had prepared an emulsion of tar, and in Guy's Hospital it was being used as an outward application. The advantage which senega possessed over quillaia was that quillaia had an unpleasant taste even in the small quantity of five grains, but in senega there was no taste that could be detected.

Professor ATTFIELD said he presumed that the action of the solution of potassa would be to make a soap with the oil.

Mr. COLLIER said that there was no doubt that it formed a sort of soap.

The CHAIRMAN said that he was sure that the meeting would wish to convey its thanks to Mr. Collier for his suggestive communication.

The next paper to be read was on—

THE DIFFUSIVE PROPERTIES OF SOME PREPARATIONS OF IRON IN RELATION TO DIALYSED IRON.

BY PROFESSOR REDWOOD.

The CHAIRMAN said that the time left was not sufficient to do justice to the paper, and therefore he would ask Professor Redwood to give an outline of it so that they might consider the subject before the next meeting.

PROFESSOR REDWOOD said the proposal that he should give an outline of the paper was one which entirely met his views. The paper was a long one; and it presented several points upon which an interesting discussion might take place. There had been recently brought to the attention of pharmacists a statment which was made by M. Personne to the French Academy of Medicine, upon the subject of dialysed iron.* This had led him (Professor Redwood) to think that it might be desirable to lay before the Society the result of a great number of experiments which he had made during several years, and the results of which had never been published. M. Personne stated that, having made an examination of that form of iron which had been recently prominently introduced to the medical profession under the name of dialysed iron, he had come to the conclusion that it was a very inert preparation. Such a statement as that going before the pharmaceutical world was calculated to induce them to make an inquiry as to whether the same character of worthlessness would apply to some other preparations which might be supposed to bear a close analogy to dialysed iron. Dialysed iron was really iron the oxide of which had been brought into a condition in which it remained apparently in a state of perfect solution; and that oxide of iron might be rendered almost entirely free from any salt radical such as chlorine. But in the preparations which were commonly sold it was not so entirely deprived. If it was entirely deprived it was very liable to lose its apparent solubility. It was, in fact, in what was designated the colloidal state of iron. Iron which was in that colloidal condition was characterized by its being free from the inky taste which salts of iron usually possessed, and free also from any strong styptic character. This was one of the characteristics which had caused dialysed iron to be very strongly recommended. There had, however, long been used in medicine certain other preparations of iron which possessed the same characters, namely, the scale preparations of iron—the citrates and the tartrates and other preparations of that class. Graham, who originally investigated this subject of dialysis, gave the names which were now applied in connection with the process, the preparations which were very low in their diffusing powers being styled colloidal, and those which diffused more freely being termed crystalloidal. Graham, moreover, observed that colloidal substances—those which were very deficient in diffusive power—were all uncrystallizable, aud generally speaking formed gelatinous hydrates, and were very free from taste; whilst, those substances which possessed in a high degree the power of diffusion usually belonged to the class of crystalline substances, and hence the names colloidal on the one hand, and crystalloidal on the other. As long ago as the year 1862 when he (Professor Redwood) had the honour of submitting a communication to the Society on the subject of dialysis, he stated, as the result of experiments which he had then made, that although it might be said that colloidal substances were always uncrystallizable, it could not be said that all uncrystallizable substances were colloidal. He had proved that fact at the time, and in the further carrying out of the subject he had from that time up to the present made a great number of experiments with different preparations, taking for instance, some of the preparations of iron which were entirely uncrystallizable, such as the scale preparations to which he had referred, and taking, on the other hand, the crystalline salts, and comparing their respective powers of diffusion. These experiments he had accumulated, and it was these that he proposed to bring forward in his paper. He might state broadly that the results of his experiments were to the effect that taking the scaled preparations of iron, such as the citrates of iron, and especially ammonio-citrate, it could not be said that those preparations were at all deficient in diffusive power. It might be said that they diffused even rapidly when they were submitted in the first instance to the process of dialysis; and, in point of fact, the best specimens of them appeared to diffuse as rapidly or nearly so as the crystalline salts, taking sulphate of iron, for instance, as a representative of the crystalline salts of iron. He found that at the commencement of the operation of dialysis, the uncrystallizable scale preparations in solution would pass through the septum freely and readily up to a certain point, but that a point was always reached when they ceased to diffuse further. One very important feature in the results of the experiments was that apparently some change of composition, the nature of which he was not at the present moment prepared to explain, took place in the salt during the process of diffusion. For instance, if he commenced with an ammonio-citrate of iron, which contained say 30 per cent. of oxide of iron, which was the usual proportion contained in a good scaling sample, it was always found that during the first two days it would diffuse freely, and that the salt which passed through the septum at first starting would contain rather a smaller proportion of oxide of iron than was contained in the salt before starting. That would occur to a slight extent; but after that first diffusion, the salt that passed through the septum would be richer and richer in the base, and would become more and more basic to the very end of the process. It was remarkable that while that increased basicity took place in the diffusate, the contents of the dialyser became very much more basic at the same time, so that, for instance, if they started with citrate of iron, which contained 30 per cent. of oxide, that which passed through the septum before the diffusion stopped would commonly contain, instead of 30 per cent., say something like 40 per cent. of oxide. And when the process at last stopped, and no further diffusion would take place, which would occur when about three-fourths of the salt had passed through, the contents of the dialyser would be found to be very rich in oxide of iron, and usually to contain about 60 per cent. —twice as much as was contained in the salt at starting. That seemed to be the condition which the salt acquired when, in point of fact, diffusion ceased, namely, that it became a highly basic salt; and when that great degree of basicity was arrived at, the iron was found to be in the colloidal state. But the remarkable part of the experiment was that, whilst the salt in the dialyser became more and more basic, the salt outside which had passed through underwent a similar change. Therefore, there seemed to be some change which yet remained to be in-

* See before, page 427.

vestigated. That was one point in the paper which he purposed to lay before the Society. He would give a series of results, which had been obtained day by day, showing the effect which he had mentioned. Of course he had not confined himself to ammonio-citrate of iron; but potassio-tartrate of iron had also been operated upon; and he might say generally that the result at which he had arrived was that potassio-tartrate of iron did not diffuse so readily as ammonio-citrate of iron, and this applied especially to the iron as a component part. A comparatively smaller proportion of the iron passed through than was the case with reference to the ammonio-citrate. Finally, he had been making some comparisons with regard to the iron in the state in which it existed in the dialysed iron. He was not going to express a decided opinion as to the value of dialysed iron in medicine, although M. Personne considered it very inefficacious. It was well known that if a few drops of dialysed iron were added to common water, the small quantity of saline matter contained in the water supply of London—about 20 grains to the gallon—decomposed the dialysed iron, and all the oxide of iron that was in it was precipitated. The dialysed iron could be diluted with pure distilled water, but it could not be diluted with common water. A few drops of dilute sulphuric acid, or of common sea salt, put into the dialysed iron would produce the same effect. M. Personne pointed out that in the stomach there was usually saline matter present in sufficient quantity to cause a decomposition of the dialysed iron, and he referred to experiments that had been made upon animals, showing that almost immediately dialysed iron was put into the stomach the iron was precipitated. Personne went further, and stated that iron so precipitated was insoluble in acids, and that was one of the characteristics of colloidal iron. Personne started by saying that the dialysed iron itself did not contain the iron in a real state of solution, but contained it in what he called a pseudo-solution, or a false solution, the solution not being absolute and perfect. He said that iron in that state would pass through the intestines and could not be absorbed, and therefore it could be of no real avail as a medicinal agent. What he (Professor Redwood) had ascertained with reference to this was, first, that when the oxide of iron had been precipitated in the way described, as it readily was, if it was collected and washed it would be apparently soluble in some acids. On the table was some which had been dissolved in a little acetic acid, and also some which had been dissolved in a little hydrochloric acid. The oxide so treated formed a perfectly clear solution which would pass through a filter. Then the question was, "Is that really in a condition in which it can be absorbed, in which it is capable of passing through a membrane or septum?" His experience certainly went to show that it was not. On the table was some of the precipitate which had been got from dialysed iron, and which had been again dissolved so as to make, apparently, a solution with hydrochloric acid, but what Personne, no doubt, would call a pseudo-solution. This had been for two days in a dialyser, and not a particle of the iron had diffused through the diaphragm. Hence it was seen that something more was to be considered than the question of whether oxide of iron would be separated in the stomach. It might be supposed that if the oxide of iron was separated in the stomach, it would be taken up again or re-dissolved by the hydrochloric acid which was present. There was certainly an appearance of such a result, but if the iron was again brought into a state of solution, the solution contained the iron in a state in which, as far as his experiments had gone, it could not be absorbed. He admitted that he had not made many experiments in that direction with dialysed iron. He hoped to have more to bring before the Society when the paper was read. This subject involved some points which appeared to him to present features of great interest and to call for investigation, more especially with regard to the change which the citrates and similar preparations appeared to undergo in the process of dialysis and the peculiar condition which the iron itself acquired. Observe how dialysed iron was obtained. They took the chloride of iron, which was, no doubt, in the crystalloidal state and which would diffuse and pass through the septum; but they began by making that chloride of iron as basic as possible by dissolving a large quantity of excess of oxide of iron in it. That would not render it completely colloidal, but they put it into the dialyser, and a great part of the hydrochloric acid with, in the first instance, a little of the iron, diffused away, and the salt became more and more basic. When, at last, it had acquired a very high degree of basicity, it was found to be in the colloidal state. It was a very remarkable fact if, as appeared to be the case, the very nature of the iron, as oxide of iron, should undergo a change during that operation, so that, whereas they started with oxide of iron which, combined with an acid, possessed the property of a crystalloidal substance and was capable of diffusion, it lost that property during the operation of dialysis, in which it became highly basic. That raised a question, which was one of the questions put forth in his paper, with reference to such preparations as ammonio-citrate of iron. Taking the best specimen of ammonio-citrate of iron, it was obvious from the experiment that, if they put a solution of it into a dialyser, a part of it, varying from a little more than half to three-quarters, would pass through and diffuse, and then what was left would be colloidal. The question was, did any of the iron exist in the colloidal state in the specimen originally; or might it not be conceived that the whole of the iron was originally in the crystalloidal state, in such a condition as they felt confident the whole of the iron would be in any sample of, for instance, chloride of iron, and that it was only during the process of dialysis that part of it became colloidal? Hence it was possible that, in the case of the scale preparations, the whole of the iron in the preparation itself might be in its normal condition crystalloidal, seeing that the diffusion commenced very freely and rapidly, and that the colloidal state which was at last found in part of the preparation was only the result of the operation to which it had been subjected.

Mr. Martindale said that he should like to make a remark lest it should go forth that dialysed iron was, in Professor Redwood's opinion, almost useless as a medical preparation. It had been suggested that the digestion of iron went on not as a chloride but as a chloro-albuminate, and it was possible that dialysed iron dissolved in the hydrochloric acid of the stomach would make a combination with the albumen. Experiments made by Dr. Gower in that direction had been published in the *Lancet*. Dr. Gower had put some patients for some weeks under chloroxide of iron, made by precipitating 4 parts of perchloride of iron with an alkali and dissolving the oxide in solution of perchloride of iron to form a basic oxychloride solution. He counted the number of red-blood corpuscles at different stages of the period during which the patient was under treatment with the iron. He tried the experiment with chloroxide of iron, with phosphorus, and with one or two other preparations. The blood corpuscles were counted by diluting the blood with a certain definite quantity of water and spreading it on a glass and using a microscope. The improvement in the patients was undoubted. He (Mr. Martindale) assumed that Professor Redwood agreed with Personne, that dialysed iron was almost useless as a medicinal agent; in this he differed from him.

The meeting was adjourned to March 3.

Communications, Letters, etc., have been received from Messrs. Henry G. Brown, B. Newham and Co., Hucklebridge, Savage, Turner, Gwalkin, Thresh, Griffiths, Wearing, Postans, Chichester, Inquirer, Cherry Laurel, Jacque, Ipecac, Blue Pill, Otto, L. W., J. T. C., J. J. B., S. B., J. S.

In consequence of the length of the official reports we are compelled to defer noticing several communications.

SIMPLE METHOD OF PREPARING A SOLUTION OF THE DOUBLE IODIDE OF BISMUTH AND POTASSIUM FOR USE AS AN ALKALOIDAL REAGENT.

J. C. THRESH.

Although it has been long known that a solution of the iodide of bismuth and potassium forms an exceedingly delicate reagent for detection of alkaloids, yet on account of the trouble involved in making such a solution it is not frequently employed; moreover in the majority of text-books it is not even mentioned.

Such a solution may almost instantly be prepared as follows:—

Take of—

Liq. Bismuthi, B.P.	℥j.
Pot. Iodid.	ʒiss.
Acid. Hydrochlor.	ʒiss.

Mix.

The resulting fluid is of a rich orange colour and when added to cold solutions containing an alkaloid produces immediately an orange red precipitate, which appears to be almost totally insoluble in cold water, though somewhat readily soluble therein when hot. In point of delicacy, it is at least equal to the solution of phosphomolybdic acid, which is both troublesome and difficult to properly prepare. One part of strychnia may be detected in 500,000 of water, and one of morphia in 20,000. All the other alkaloids examined fall between these extremes.

In presence of other organic matter I am inclined to think this reagent is more reliable as an indicator of the presence of an alkaloid than any of the solutions used for that purpose. It appears also to be applicable for volumetrically estimating the strengths of alkaloidal solutions, and the author is at present engaged in devising such a process.

THE DETECTION OF TRACES OF BISMUTH.

BY J. C. THRESH.

In testing for bismuth according to the methods usually given in the text-books of practical chemistry, the presence of large traces may very easily be overlooked, more especially when much lead is also present. A method devised by Professors Abel and Field (*Chemical News*, December 14, 1877; abs. Y. B. P., 1878, page 45), and which is exceedingly delicate, consists in adding part of the solution to be examined to a boiling saturated solution of lead iodide containing excess of potassium iodide. In the absence of bismuth the lead iodide is redeposited upon cooling in golden yellow scales, whereas when bismuth is present the deposited iodide is of a dark orange or crimson colour, according to the quantity of the metal in solution. By this reaction ·00025 gram of bismuth may be detected.

Recently, whilst engaged in making a solution of bismuth and potassium iodide for use as an alkaloidal reagent, I found much more minute traces of the metal could be detected without the addition of another special reagent to the already overstocked shelves of the chemist's laboratory.

This method consists in adding to the fluid containing free hydrochloric or organic acid only a little potassium iodide, when instantly a rich more or less deep orange coloured solution is formed. With 1 part of bismuth in 10,000 of water the colour is a distinct orange, with 1 in 40,000 the tint is still discernible in 1 c.c. of the solution, and with 1 in a million a decided yellow tint is evident when about 20 c.c. (·00002 gram) are placed in a nesslerizing cylinder.

To ascertain the effect of the presence of other metals a number of different solutions were made and examined, but in all cases the bismuth was detected with ease. Lead, antimony and mercury alone are likely to interfere, but the addition of an excess of potassium iodide dissolves the mercuric iodide first precipitated when mercury is present, and lead iodide is soluble in boiling water; in both cases the supernatant or resulting solution is colourless unless bismuth also is present, when the colour of the double iodide of potassium and bismuth is very evident.

With strong solutions of antimony containing much hydrochloric acid, iodide of potassium produces a reddish-yellow colour when added in excess. A small quantity of this reagent has no effect, whereas, when a trace of bismuth is also in the solution, a single drop of the reagent strikes the characteristic tint.

By aid of standardized solutions of bismuth and lead it was found that 1 part of the former in 10,000 of the latter could readily be detected, it only being necessary to add, first, excess of hydrochloric acid, and after filtration to pour a few drops of solution of potassium iodide into the heated fluid.

In neutral solutions (as in liq. bismuthi, B.P.) the iodide of potassium gives no precipitate or coloration; but if hydrochloric or any organic acid is now added a rich orange tint appears. When sulphuric or other strong mineral acid is present a dark brown precipitate falls, unless the acid is exceedingly dilute, in which case a red colour, but no precipitate, is produced. It is therefore advisable when a solution is strongly acid (the acid being mineral and other than hydrochloric) to add ammonia to slight alkaline reaction, and then excess of hydrochloric acid. After the orange colour has been developed the addition of the stronger acids is without effect; but ammonia at once decolorizes the fluid.

In analysing a complex mixture of inorganic salts, therefore, to detect bismuth, dissolve in hydrochloric acid the precipitate thrown down by addition of ammonia to the nitric acid solution of the sulphide insoluble in ammonium sulphide, and divide into two portions. To one add a little sulphuric acid (to detect lead) and to the other solution of potassium iodide. The merest trace of bismuth cannot by this method possibly be overlooked.

KOETTSTORFER'S PROCESS FOR THE ESTIMATION OF FOREIGN FATS IN BUTTER.*

BY A. F. DIMMOCK.

This process, which appeared in the *Zeitsch. für Anal. Chemie* (1879, p. 199), is a volumetric one, depending upon the fact that different fats require different quantities of potassium hydrate for their complete saponification. The process consists in treating the butter with a measured quantity of an alcoholic solution of potassium hydrate, saponifying,

* Read at a Meeting of the School of Pharmacy Students' Association.

then determining the amount of uncombined potassium hydrate present in the mixture by means of a standard solution of hydrochloric acid.

The solution of potassium hydrate contains 28 grams in 1 litre of alcohol, and the solution of hydrochloric acid 18·25 grams in 1 litre of water. The solutions should exactly coincide, *i.e.*, 10 c.c. of the hydrochloric acid solution should exactly neutralize 10 c.c. of the potassium hydrate solution, and should be verified from time to time. An alcoholic solution of phenol-phthalein (1 in 50), which in alkaline solution is of a rose-red colour, and colourless in neutral or acid solutions, is employed as an indicator. Two or three grams of the butter are weighed in a small beaker, and from 30 to 40 c.c. of the solution of potassium hydrate added, the beaker placed on a water-bath, and stirred until saponification is complete, when the beaker is covered with a watch-glass, and allowed to remain on the water-bath for fifteen minutes. About 5 c.c. of the solution of phenol-phthalein are added, and the liquid titrated with the standard solution of hydrochloric acid until the liquid is of a yellow colour. From the quantity of hydrochloric acid required the amount of uncombined potassium hydrate is calculated, and from that the amount of potassium hydrate combined with the fat. Koettstorfer found as the result of thirteen determinations of pure butter that for 1 gram from 0·2215 to 0·2324 gram of potassium hydrate was required for complete saponification. I have examined a sample of pure butter by this process, and found that 1 gram required 0·224 gram of potassium hydrate. The specific gravity of this sample of butter was 911·0. Koettstorfer also examined other fats by this process, thus:—

1 gram of stearin required 0·1888 gram of potassium hydrate.

1 gram of olein required 0·1900 gram of potassium hydrate.

1 gram of palmitin required 0·2080 gram of potassium hydrate.

1 gram of lard required 0·1970 gram of potassium hydrate.

Experimenting on these substances myself I obtained the following results:—

1 gram of olein required 0·1930 gram of potassium hydrate.

1 gram of palmitin required 0·2016 gram of potassium hydrate.

1 gram of lard required 0·1960 gram of potassium hydrate.

As lard, beef-fat, dripping, tallow, olein and margarin all require about the same amount of potassium hydrate, the average being represented by the number 0·1955, this number may be taken as the basis for calculating the amount of adulterant of a sample of butter. From the results obtained by Koettstorfer from pure butter, 0·2215 and 0·2324 gram, the two extremes, the mean 0·227 is taken as a standard of pure butter. If x = the percentage of admixed fat, and n the amount in grams of potassium hydrate required for complete saponification, then—

$$(\cdot 227 - \cdot 1955) : (\cdot 227 - n) = 100 : x.$$

If, for instance, the sample of butter required ·2016 gram of potassium hydrate, then—

$$(\cdot 227 - \cdot 1955) : (\cdot 227 - \cdot 2016) = 100 : 80\cdot 6.$$

The butter then contained 80·6 per cent. of admixed fat.

PREPARATION AND PROPERTIES OF PURE EMETINE.*

BY DR. PODWYSSOTZKI.

The author having examined specimens of commercial emetine obtained from several German manufacturers (*emetinum purum* and *emetinum album*) found them to consist of a dirty light grey coarsely pulverulent mass, which upon standing in the light gradually became darker and yellow coloured, and with solvents (dilute acids, alcohol, etc.), gave clear yellow solutions. If a particle of such a commercial emetine be moistened with ether or alcohol it runs together to a dirty brown-black extractive-like mass which assumes an intensely dark grey colour with a drop of perchloride of iron solution. These few simple reactions the author considers suffice to show that such commercial emetine is not the chemically pure alkaloid.

The quality of these impurities and the exact estimation of the constituents of ipecacuanha were used as indications of the direction in which the method of obtaining emetine requires to be modified. It was especially desirable that not the smallest quantity of tannic acid should remain in the emetine and that none of the colouring matters of the ipecacuanha or of the products of its composition should be mixed with it. The quantities of tannic acid occurring in various sorts of ipecacuanha were found to be very considerable, and the contamination of the emetine by it in the methods of preparation usually followed is, in consequence of its solubility in the most diverse solvents, unavoidable. But by treatment with perchloride of iron this tannic acid can be converted into a compound that is perfectly insoluble in ether and petroleum spirit, and the author utilizes this reaction in the preparation of pure emetine in the following way:—

The ipecacuanha powder is extracted with sulphuric ether in order to remove from it the liquid oil and a thick fatty or wax-like substance, as well as all colouring matters soluble in ether. The extraction with ether is a most important part of the process and must be continued until a drop of the extract evaporated on a watch-glass leaves neither a fatty nor a coloured spot behind. Towards the end of this operation petroleum spirit may be used and heat applied, by which it is more rapidly and perfectly completed.

Ipecacuanha treated in this way yields an ethereal extract containing a peculiar colouring matter, characterized by its forming a beautiful purple-red compound with alkalies, especially with barium hydrate. This colouring matter was isolated from the barium compound in the form of an acid, crystallizing from chloroform in intensely straw-yellow coloured needles, to which the name of erythrocephalein has been given. It was found to be present in the largest proportion in roots which yielded the greatest amount of emetine.

After the ipecacuanha powder has been freed from the remainder of the ether or petroleum spirit by evaporation, it is exhausted with moderately warm 85° alcohol, without acid being added. This treatment requires to be repeated two or three times, as the ipecacuanha does not readily yield to the alcohol and water the whole of the emetine contained in its cells, where it is combined with organic acids and surrounded by a large quantity of dextrin. The alcoholic extract is coloured by colouring matters insoluble in ether and contains also a considerable quantity of tannic acid coloured green by perchloride of iron. The alcohol is almost entirely removed by evaporating or distilling to a syrupy consistence, and then perchloride of iron dissolved in a small quantity of water is added in the proportion of 10 to 13 per cent. by weight of the ipecacuanha used. The point when a sufficiency has been added may be ascertained by placing a small portion of the extract on a porcelain dish and touching it with solid perchloride, when

* *Pharmaceutische Zeitschrift fur Russland*, xix., i.

no further green coloration should be produced. The whole then it thoroughly mixed in order that all the tannic acid may enter into combination. To the extract thus treated carbonate of soda in powder or concentrated solution is added—taking care to keep the mixture as thick as possible—until it has a strongly alkaline reaction, and acquires a chocolate colour. A large excess of soda is indispensable, and the compound of the ipecacuanha tannic acid with the iron is not decomposed by it.

To the alkaline mixture is now added a suitable quantity of petroleum spirit and the whole is placed in a retort in a water-bath, and frequently shaken while the spirit is boiling. The emetine dissolves in the hot spirit and from time to time some of the spirit is removed and tested. This is done by placing it in a watch glass and blowing through a glass tube a thin stream of atmospheric air into the solution. When the emetine falls as a white powder and remains as a deposit at the bottom, the hot petroleum spirit saturated with emetine is filtered and a fresh quantity of spirit added, and this is repeated until the petroleum extract only yields traces of emetine. When such a petroleum spirit extract is very rich in emetine the greater part of it is deposited spontaneously, after twelve hours standing in a cool place, as a white precipitate. From less concentrated solutions of emetine in petroleum spirit the alkaloid is not spontaneously deposited. It may then be obtained very pure and white by blowing air for some time through the solution, when it separates in the form of white flocks. The author has not obtained a perfectly white emetine by slow evaporation of the solution or by evaporation over a water-bath.

Since emetine as thus prepared is readily soluble in cold sulphuric ether this process may be modified in first treating the ipecacuanha powder made with a little hydrochloric acid into a thick paste with a sufficiency of perchloride of iron, then adding the carbonate of soda, and after standing some time again extracting the pasty mixture with renewed quantities of sulphuric ether. Upon shaking the united ethereal extracts with a small volume of water acidulated with acetic, sulphuric or hydrochloric acid, the alkaloid passes into solution, and the united acid solutions are treated with excess of soda and boiled with petroleum spirit, after which the alkaloid can be isolated as before described.

The emetine, either spontaneously precipitated or by the blowing of air, is rapidly collected upon a filter and then dried in a dark place over sulphuric acid.

In this manner the author obtained from the better sorts of ipecacuanha $\frac{3}{4}$ to 1 per cent of pure snow-white emetine, but from the inferior sorts only $\frac{1}{4}$ to $\frac{1}{2}$ per cent.

Emetine thus prepared has the following properties:—It dissolves readily in cold sulphuric ether, in chloroform, acetic ether, methylic, ethylic and amylic alcohols, carbon bisulphide, in spirit of all strengths, in oil of turpentine and essential oils, and in considerable quantity in fatty oils and fats, and in oleic acid. It is difficultly soluble in cold petroleum spirit and benzine, but easily soluble in them when heated, a portion of the emetine from such concentrated solutions being again precipitated on cooling. It is still more difficultly soluble in cold water (1 in 1000). From sulphuric ether, petroleum spirit, fatty oils and similar liquids insoluble or nearly so in water, it is precipitated by acids.

Its taste is very bitter and somewhat astringent, and the same is true of its salts. By the action of sunlight it becomes coloured yellow, which is specially intense if simultaneously long exposed to the air. When protected from direct rays of light it remains white, large fragments remaining white internally after becoming coloured on the outside. When an ethereal or alcoholic solution is allowed to evaporate very slowly it is deposited in extremely thin flakes, which being viscous agglutinate together into lamellæ; but when the solutions are more rapidly evaporated it is deposited in extremely small granules, which afterwards appear as a very fine powder. Its melting point is between 62° and 65° C. In water at this temperature it runs together into lumps having the colour of gum arabic; whilst warm these can be rolled into pellets, but after cooling they can be crushed to a sand-like powder.

If a very concentrated solution of emetine in petroleum spirit, ether or benzine be evaporated very slowly upon a paper filter there is formed on the edge of the filter an extremely delicate snow-white crust, which under the microscope is seen to consist of fine, very slender, fragile, acicular crystals, sometimes showing a stellar arrangement and sometimes irregularly disposed and interlaced with an apparently amorphous mass, consisting of transparent spherical bodies. This crystallized emetine is also quickly coloured superficially an intense yellow when exposed to the light.

Emetine has a strongly alkaline reaction, and is neutralized by acids, with which it forms salts. These salts do not crystallize in a regular form and can only be obtained in shining almost colourless lamellæ, by evaporating in a vacuum; when evaporated in the air they form a dark yellow lac.

The salts dissolve readily in water, spirit and fatty oils, but are insoluble in sulphuric ether, petroleum spirit and benzine. Only with tannic acid does emetine form a compound almost insoluble in water as an amorphous white powder; but the salts formed with gallic and other acids are readily soluble in water. All the salts of emetine, like the free base, gradually become yellow in the light, with the exception of the compound with tannic acid which does not undergo the least change. If a current of carbonic acid gas be passed through a colourless solution of emetine in ether to which water has been added the lower aqueous layer gradually acquires a yellow colour and in this way the emetine can be completely carried from the ether into the water as a carbonate. From aqueous solutions emetine is precipitated by all salts of the fixed alkalies or earths as a white or coloured powder, partialle soluble in an excess of the added salt. The chromate and nitrate of emetine are among the more difficultly soluble compounds, but they also dissolve when the liquid is warmed. Carbonates and caustic alkalies precipitate the alkaloid in the form of a more or less white powder, which can be washed on a filter, but always with some loss on account of its partial solubility in water.

When treated with concentrated sulphuric acid emetine gives, as has been observed by previous authors, oxalic acid. When heated with weak sulphuric acid in a sealed tube to 150° C. during three hours it is partially converted into a blackish-brown body, not having a bitter taste, whilst the remaining liquid contains a considerable quantity of undecomposed emetine.

With all the alkaloid reagents emetine gives, even after long standing, non-crystallizing precipitates. A drop of a freshly prepared saturated solution of phosphomolybdate of soda in concentrated sulphuric acid brought into contact with a particle of the alkaloid colours it brown, and if a drop of concentrated hydrochloric acid be then at once added, the brown rapidly passes to an intense indigo blue colour. This test has also been observed by the author to give characteristic reactions with other alkaloids.

THE PITURI PLANT.

The following is an extract from a letter written by Mr. Sylvester Brown and quoted in a paper read recently before the Queensland Philosophical Society by Dr. Bancroft:—

"I have during the last few months passed several times through the belt of country in which pituri has hitherto only been found. It is situated, so far as my means of observation serve, with the 138th meridian of east longitude passing through the belt about the middle, and I have met with the shrub anywhere in the vicinity of the longitude mentioned between the 23rd and 24th parallel south latitude, with a depth of fifty miles east and west. The pituri shrub, when full grown, is about 8 feet high, and the wood at the thickest part of the stem is up to 6 inches in diameter. When freshly cut the wood has a decided smell of vanille. It is very light and close-grained; colour, lemon. Dr. Bancroft's guess as to the seed is so far correct that the berry (which, when ripe, is black and like a small black currant) has inside very minute kidney-shaped seeds. I have secured some of the seed, picked by myself from the growing tree, and hope, when passing through Brisbane, to let Dr. Bancroft have an opportunity of continuing his investigation of this rare plant by endeavouring to grow some of it. I have also cut some samples of the wood, which I shall bring down unless absorbed, specimens and all, by early floods *en route.* I formerly heard many wonderful accounts of the rarity of pituri and the great difficulty of procuring it. These absurd reports were strengthened by the extreme value placed on it by inside blacks, who could only obtain it by barter. 'It grew on a rocky mountain in the Stony Desert, jealously guarded by the owners of the soil, who, in their periodical trips to obtain a supply, would have to carry three days' water in coolimans and paddymelon-skin water-bags.' I also heard that it 'grew only on a small extent of ground not exceeding twenty square miles;' whereas the fact is that it grows on the ridges of high spinifex sand-hills, and which sand-hills contain many cool springs and lakes, which will hold water much better than the fabulous stories told of pituri.

"There is one beautiful lagoon, with two smaller ones, just about the South Australian border, on or about the 23rd parallel of latitude, which—the blacks averring that it had never before been visited by white men, or 'pirri-birri,' as they call them here—I took the liberty of naming 'Pituria lagoons.' The water in these lagoons is beautifully clear and soft, and when full they will last nearly, if not quite, two years. Pituri grows on the sand-hills round them. Should the Government wish to make a pituri reserve, here is the place for it. The country in the vicinity is of no use for pastoral purposes, so a reserve of about 20 miles square, or 400 square miles, would be a cheap concession.

"The blacks break off the pituri boughs and tie them up in netting till dry; then, when thoroughly dry, they break the leaves up and enclose them in closely netted bags in the shape of a crescent. These are easily carried for the purpose of barter, which is carried on as far as Cooper's Creek and the Barcoo. Before chewing they burn the leaves of a shrub they call 'montera,' and moistening the ashes mix and chew. I have not noticed any abnormal result from the habit, though I have heard that a black unaccustomed to the weed becomes intoxicated thereby. I have some young plants in a box, which, if they grow, I shall endeavour to bring down, but as they have a journey of 1000 miles before them overland, the result is more than problematical, even should they elect to grow in the box. I am rearing one plant, which seems to be growing well, in my garden at the station. The seeds, however, may grow, and to facilitate selection of a proper soil I shall bring down a sample of mother sand for analysis. The suckers grow from long rough roots, which run about under the sand and throw up shoots as they go."

Dr. Bancroft remarks that the seeds did not germinate, though cared for diligently. He thinks that probably they were immature and that the berries of the pituri bush most likely fall off directly they ripen, as he finds this to be the case with *Duboisia myoporoides.*

THE HECTOGRAPH.

The following information, quoted from *New Remedies,* is supplementary to that previously published on the subject (see before, p. 486):—

A very good elastic copying mass will be obtained by using the following proportions: glue or gelatin, 1 part; water, 2 parts; glycerin, 4 parts; to this is to be added a few drops of carbolic acid, and enough whiting or white lead to make the whole milky. Other formulæ are said to be: glue or gelatin, 1; sugar or glucose, 1; glycerin, 6; barium sulphate ("terra alba"), 3½ parts.

The addition of barium sulphate and of dextrin facilitates (?) the removal of the writing with cold water. The so-called chromograph composition is made as follows:—100 grams of finest gelatin are melted with 400 to 500 cubic centimetres of moist barium sulphate, in a capsule, on the water-bath. 100 grams of dextrin are then added, under constant stirring, and finally, 1000 to 1200 grams of glycerin. The mass is then removed from the water-bath, stirred occasionally (to prevent the barium sulphate from precipitating), and cooled as much as possible, taking care, however, to have it still barely fluid. It is now poured into flat tin dishes, and rapidly cooled off. The above proportions need not be exactly followed with every kind of gelatin, since they all require somewhat different quantities of liquid to produce the same consistence. If the mass turns out too hard, more glycerin must be added; if the writing can be removed only with difficulty, even with lukewarm water, more filling (barium sulphate) or dextrin is necessary. The best and sharpest impressions are obtained by using the finest English gelatin, glycerin, and pure precipitated barium sulphate, washed by decantation, without dextrin.

A correspondent of the *English Mechanic* says:—"I have not been successful with the ink prescribed: 1 violet methylated aniline (Hoffman's purple?), 7 distilled water, and 1 alcohol; so I have bought it at the most extravagant price of 1*s.* per ½-ounce bottle; but acetate of rosaniline (roseine), boiled down in alcohol until it does not run in writing, forms a capital red ink. The purple ink is dosed with oil of almonds, I suppose, to mask its real composition.

"To use the process, write on any kind of paper with the ink, taking care that the writing is thick enough to show a green lustre on drying. When dry, place, it face downward, on the jelly, rub it gently to bring it well in contact, and leave for one or two minutes (five minutes are better); then peel it off. It will leave a large portion of the ink neatly transferred to the jelly; then place the paper to be printed on the writing, and pass the hand over it; bring it well into contact as before, peel it off, and it will bring away a perfect copy of the original. In this way, sixty to eighty copies may be made. By using a thick pen and plenty of ink, one hundred good prints may be taken."

THE RESINS CONTAINED IN JALAP.*

BY ALEX. F. STEVENSON, PH.G.

The U. S. P. officinal "Resin of Jalap" is obtained by evaporating an alcoholic tincture of jalap to a small bulk, pouring this into water to separate a small amount of accompanying aqueous extract, washing the precipitate several times with water, and finally straining and drying with a gentle heat. The title "Resina Jalapæ" does not seem to be quite appropriate; "alcoholic extract" would be a more proper name for it, as it certainly consists of two distinct resins, namely, "Convolvulin" and "Jalapin," which are not only physically, but chemically and therapeutically distinguishable the one from the other, as the following experiments and trials executed by myself, for the most part in the laboratory of this College, will, I hope, tend satisfactorily to show.

Having for this purpose procured some of the best "Resina Jalapæ" of the Pharmacopœia that the market afforded, I proceeded to free it of any mechanical

* Abstract of a thesis presented to the College of Pharmacy of the City of New York. Reprinted from *New Remedies,* December, 1879.

impurities that it may chance to contain (subsequently found to be silicious and ligneous matter, in small but unimportant quantities) by dissolving it in absolute alcohol, filtering, evaporating, and drying. Having thus got rid of the above impurities, I reduced it to a fine powder, and thoroughly incorporated with it an equal bulk of sand (which I had previously purified by boiling with acid and washing); to this mixture I again added its bulk of the same sand with similar precautions.

The reason for mixing sand with the commercial article was the better to facilitate the separation of the "jalapin" from the "convolvulin" by the method of percolation below described.

I may here state that the undermentioned process succeeded remarkably well, not only in the more important point, viz., of effecting a complete separation of the above resins, but also in offering a method so much quicker, cleaner, and more easily managed than that of precipitation, as usually followed in such manipulations.

Then, having divided the mixture into six portions, I carefully and tightly packed them into as many small numbered funnels, the necks of which were loosely stopped with cotton and fitted to small glass flasks by the aid of corks. They were also kept carefully covered with glass plates to prevent evaporation during the process. I then passed ether through No. 1, and the percolate through No. 2, and that of No. 2 through No. 3, and so on, continuing to pour fresh ether on No. 1, until, on evaporating a small quantity on a watch-glass, it left no residue; then adding the fresh ether to No. 2, and then to No. 3, and so on, as they successively became exhausted, and until a small portion of the menstruum passed through all the funnels showed no colour and left no residue on evaporation.

I then mixed the percolates and set the liquid aside, and having removed all the residues from the funnels, and thoroughly dried and repacked them as before, I continued the percolation with absolute alcohol in the same manner and order as above described, until completely exhausted.

Thus having completely separated the resins by means of these solvents, and removed the ether from that of the ethereal percolates with the aid of a water-bath, I obtained a dark-coloured "soft resin," of the consistence of thick molasses, having all the colour, odour, and taste of the resin of the Pharmacopœia, but differing from it and that of the alcoholic percolates mentioned below, in being totally soluble in ether, petroleum naphtha, carbon disulphide, and oil of turpentine, and also in possessing cathartic properties.

This is no doubt the jalapin of Mayer (formula, $C_{34}H_{56}O_{16}$) and the pararhodeoretin of Kayser.*

On evaporating the alcoholic percolates to dryness, I obtained a "hard resin," odourless and tasteless, but having the consistence and colour of that of the Pharmacopœia, and also retaining its therapeutic properties, but with the important difference of being entirely devoid of that disagreeable tendency to griping which almost always accompanies the catharthic action of jalap.

It also differs chemically from the officinal resin and that mentioned above as "jalapin" in being insoluble in ether, petroleum naphtha, carbon disulphide, benzol, and oil of turpentine, and also in giving off an odour much resembling whiskey when its solution in caustic potassa is slightly heated.

This is without doubt the convolvulin of Mayer (formula, $C_{31}H_{50}O_{16}$), and the rhodeoretin of Kayser.†

These experiments, which were at first made upon good commercial resin of jalap, were afterwards repeated so as to apply them to resin of jalap, prepared by myself from good commercial samples of whole as well as powdered jalap, and the results obtained were similar to those detailed above.

The following is a tabular statement of reactions distinguishing "jalapin" from "convolvulin" with the reagents mentioned:—

1. *Solvents.*

Solvent.	Jalapin.	Convolvulin.
Chloroform	Readily soluble.	Slightly soluble.
Ether	Very soluble.	Insoluble.
Petrol. naphtha	Slightly soluble.	Insoluble.
Oil turpentine	Slightly soluble.	Insoluble.
Benzol	Slightly soluble.	Insoluble.
Carbon disulp.	Easily soluble.	Insoluble.
Water	Slightly soluble.	Slightly soluble.
Muriatic acid	Slightly soluble.	Readily soluble.
Sulphuric acid	Very soluble, with production of maroon colour, changing to black.	Readily soluble, with production of bright-red coloration.
Caustic potassa	Easily soluble.	Easily soluble with production of odour of whiskey when heated.
Ammonia	Readily soluble, more so than convolvulin.	Slightly soluble.

2. *Reactions with oxidizing agents* on convolvulin and jalapin dissolved in sulphuric acid (conc.).

Agent.	Jalapin.	Convolvulin.
K_2CrO_4,CrO_3	Produces odour of rancid butter and reddish-brown colour.	Produces odour of rancid butter and olive-green colour.
$K_2Mn_2O_8$	Same reactions.	Same reactions.
KNO_3	Same reactions, but not so strong.	Same reactions.
$KClO_3$	Same reactions, but not so strong.	Same reactions.
MnO_2	Same odour and colour dark green.	Same odour and colour rose-pink.

In conjunction with this subject I also made several experiments in extracting the resin from the powdered drug, with alcohol of different sp. grs., especially those of 0·796 (absolute), and 0·835 (officinal), for the purpose of ascertaining if the yield would be thereby affected, and if so, which way, and also to determine the quantity of alcohol, sp. gr. 0·796, that would be required to completely exhaust the drug.

After six repetitions of the experiment on as many portions of the same sample of the drug, I found that the yield of resin was the same in every case, and that the measure of menstruum was also alike for each experiment, whether of sp. grs. ·835 or ·796, although the loss in weight of the drug after being exhausted, removed, and thoroughly dried was found to be greater in proportion as the alcohol was diluted.

* L. Gmelin's 'Chemistry,' vol. xv., page 345, and vol. xvi., page 405. Wöhler's 'Organic Chemistry,' "Remsen," p. 421. Watt's 'Dictionary of Chemistry,' vol. iii., p. 438, Husemann, 'Pflanzenstoffe,' p. 886.

† L. Gmelin's 'Chemistry,' vol. xv., p. 342, and vol. xvi., p. 154. Wöhler's 'Organic Chemistry,' "Remsen," p. 420. Watt's 'Dictionary of Chemistry,' vol. ii., p. 15. Husemann, 'Pflanzenstoffe,' p. 883.

The terms jalapin and convolvulin, particularly the former, have often led to misunderstanding. "Jalapin" is now applied only to the resin obtained from Orizaba root or Male Jalap, or from Scammony.

HOW URARI IS MADE.*

Dr. Richard Schomburgk, the director to the Adelaide Botanical Gardens, has just published a *brochure* in which he states what is known as to the method of preparing urari or curare, the famous deadly arrow-poison of some of the Indian tribes in British Guiana. His brother, in 1837, vainly endeavoured to witness the manufacture of this poison; but Dr. Schomburgk himself, in a visit to the Canuku Mountains, near Pirara, in 3° 33′ N. and 56° 16′ W., succeeded in getting an old Macusi Indian to show him the method of manufacture among that tribe. The Indian, after promising to comply with Dr. Schomburgk's request, tried every possible means of evasion, but the addition of more powder and knifes brought him to the scratch. The process was carried out in a small hut in the village, known as the urari-house. The Indian began first to take the bark from the strychnos, which they had brought from the Ilamikipang, and then produced the other ingredients and separated the required quantities. The native names of the other plants used are tarvieng, wakarimo, and tararemu, to all appearances species of strychnos. The Indian said they grew far away in the mountains at five days' distance. The preparation of the several ingredients would be according to weight as follows:—Bark of *Strychnos toxifera* 2lb; *Strychnos Schomburgkii*, ¼lb; arimaru (*Strychnos cogens*), ¼lb; wakarimo, ¼lb; root of tarvieng, ½oz.; root of tararemu, ½oz.; the fleshy root of muramu (*Cissus spec.*); four small pieces of wood of a tree of the species of Xanthoxyleæ, called manuca. The old Indian, having finished his preparations, went to his hut and returned with a new earthern pot, holding about seven quarts, and two smaller ones, also quite new, formed like flat pans. In the first vessel the poison was to be boiled, in the other it was to be exposed to the sun for condensation. The great strainer or funnel, made out of palm leaves, was cleaned, and fresh silk-grass was put into it to strain the fluid; a great block of wood sunk into the ground to serve as a mortar was cleaned, and in it the several ingredients were crushed. The urari preparer, after having arranged everything, built a hearth with three stones, laid the wood ready to light the fire, and went away to fetch (as Dr. Schomburgk was informed, for he had not exchanged a single word with the old Indian) the utensils to light the fire, though there was a large fire burning, which was of no use, having been lighted by profane hands. Neither dared the Indian use any water except that brought in the pot to be used for the operation; in fact, no other implement could be used but such as had been made by the cook, neither would he have assistance from any of the inhabitants. Any transgression of the sacred rules would nullify the operation of the poison. In addition to the fleshy root of the muramu, he crushed the several kinds of bark, but each one singly, on the mortar, lighted the carefully piled-up wood, and then threw first into the pot, which was filled with water, the bark of the *Strychnos toxifera*. As soon as the water began to boil the Indian added at certain intervals a handful of the other ingredients, except the muramu root. In doing so he bent his head over the pot, strongly blowing into the mixture, which he said afterwards added considerably to the strength of the poison. During the process he only kept as much fire as was necessary for slow boiling, carefully skimming the foam collecting on the extract. Within the next twenty-four hours the old man left the fire only for one moment, keeping the mixture at an equal heat. After the lapse of twenty-four hours the extract became thick, and was reduced by the boiling to about a quart, the colour being that of strong coffee. The old cook then took the extract from the fire and poured it into the strainer, the extract trickling slowly into another flat vessel, and left the remainder in the silk-grass. After exposing the strained extract to the sun for about three hours, he added the slimy juice pressed out of the root of the muramu, which had previously been soaked for a short time in the boiling poison, and then had been pressed out. The poison immediately exhibited a remarkable alteration, curdling to a jelly-like substance. After this peculiar process he poured the poison into earthern vessels, flatter than those before mentioned, for the purpose of bringing the poison to a consistence equal to that of thick treacle by exposing it to the sun. Afterwards it was poured into the peculiar small calabashes, or half-round earthern vessels, manufactured only for that purpose, where it ultimately changed to a hard substance. On the third day the poison was ready, when the cook, satisfied with the product, tried the strength of the poison on some lizards in Dr. Schomburgk's presence. He dipped the point of a pin into the poison, let it dry, wounded one of the lizards in one of the toes of the hind foot, and then let it run. In nine minutes the peculiar symptoms of the poison made their appearance, and one minute after the slightly-wounded animal was dead. A rat died in four minutes, and a fowl in three. The Indians declare the poison loses its effect after two years, but its power can be destroyed by pouring some manihot juice upon it. Dr. Schomburgk took some of the urari to Berlin with him, and made several experiments with it, when he found that it frequently took from fifteen to twenty minutes, according to the tenacity of life, before death ensued. A commission of scientific men was appointed by the German Government to report on the effects of the poison, and many experiments were made, from the frog to the horse. Professor Heintz made a careful analysis of the poison, and, though it was made from strychnos, he found it contained no strychnine. From experiments made by Professors Virchow and Münter they conclude:—1. That the urari kept dry will, after the lapse of five years, retain its intense and rapid efficiency. 2. That it has no effects like those of strychnine. 3. That it is not a tetanic poison, but operates by stupefying. 4. That urari causes palsy, produces a discontinuance of the voluntary movements of the muscles, with continued functions of the involuntary muscles of the heart, intestines, etc. 5. That the external application of urari is not fatal, but only when absorbed through a wound. 6. That death is not the direct result of poisoning, but of the discontinuance of the mechanical action of respiration. Urari, Dr. Schomburgk states, has been successfully used both in tetanus and hydrophobia.

* From *The Times*.

A HOMELY SUBSTITUTE FOR COD-LIVER OIL.*

Dr. Thomas Addis Emmet ('Principles and Practice of Gynæcology') recommends as a good substitute for cod-liver oil the fat of pork. For its proper preparation he gives directions as follows. A thick portion of a rib piece, free from lean, is selected and allowed to soak in water for thirty-six hours before being boiled, the water being frequently changed, to get rid of the salt. It should be boiled slowly and thoroughly cooked, and, while boiling, the water must be changed several times by pouring it off, and fresh water, nearly boiling, substituted. It is to be eaten cold, in the form of a sandwich, made from stale bread, and both should be cut as thin as possible. It is very nutritious, but it should only be given in small quantities until a taste of it has been acquired. It is the most concentrated form in which food can be taken in the same bulk, and Dr. Emmet has frequently seen it retained when the stomach was so irritable that other substances would be rejected. For this condition of the stomach, it may be rubbed up thoroughly in a porcelain mortar, and then given in minute quantities at a time. It is made more palatable by the addition of a little table-salt, and this will be well tolerated, while the salt used for preserving the meat, having become rancid, if not soaked out, will produce disturbance, even in a healthy stomach.

SATURDAY, FEBRUARY 14, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

APOTHECARIES' WEIGHTS AND MEASURES.

SOME weeks since we suggested that it would be useful if the Society's local secretaries or the secretaries of provincial associations were to communicate with the local authorities of their several districts respecting the steps to be taken under the new Weights and Measures Act, 1878, for the verification and inspection of apothecaries' weights and measures. At the same time we intimated that we should be glad to learn what progress was being made; but with one or two exceptions we have not heard anything further, except complaints of the inconvenience experienced in consequence of the uncertainty that prevails as to the carrying out of the Act in so far as it applies to apothecaries' weights and measures.

At the last two meetings of the Council this subject has been under consideration, and in pursuance of the resolution to present a memorial to the Board of Trade, urging the necessity of a definite and uniform practice under the new Act, a deputation waited upon Mr. FARRER at Whitehall last month. On this occasion it was represented that there was a very great discrepancy between the readings of the Act as regards apothecaries' weights and measures, and that some of the views adopted by inspectors in various places would, if enforced, place chemists and druggists under considerable inconvenience in the exercise of their business.

The reply received from Mr. FARRER was mainly directed to explaining the passive position of the Board of Trade in regard to the carrying out of the Act, and the absence of any power to give instructions, except to those local authorities that applied to the Board of Trade for assistance and direction. At the same time it was indicated that there was every disposition on the part of the Board of Trade to render any assistance required, and to support the Pharmaceutical Society in the endeavour to protect the trade from inconvenience by bringing about a definite and uniform mode of procedure for the verification and inspection of apothecaries' weights and measures.

Though this subject has been again referred to the further consideration of a Committee of the Council, it may not be out of place to point out the circumstances which render action by the Council desirable in the interests of the trade. In the first place it is to be remembered that, according to the provisions of the Act, any persons who have in their possession for purposes of trade weights and measures that have not been verified and are not stamped with proper marks of verification are liable to penalties of no inconsiderable amount. Consistently with these provisions chemists and druggists are liable to be summoned before a court of summary jurisdiction, and fined, and their weights and measures confiscated if they are not what they should be. After what has already been published in this Journal on the subject now referred to, it would be superfluous to waste much time in the endeavour to show that it is still practically an open question what apothecaries' weights and measures should be, and that herein lies one of the sources from which danger of inconvenience is to be apprehended. We do not believe there is anything in the Act itself to justify doubts or differences of opinion in regard to this question, but it is quite certain the inspectors of weights and measures in different localities do not agree in their reading of the Act.

This brings us to the most important circumstance to be considered in regard to the interest of chemists and druggists, viz., the course taken by the inspectors with apothecaries' weights and measures. Some simply say, "We have no instructions how to carry out "the verification and inspection of those weights and "measures; we have not been furnished with stan"dards for the purpose, and, therefore, we are not in a "position to do anything in carrying out the provi"sions of the Act." Others, again, take a different view and are ready to act, not upon any uniform system, but according to their individual interpretation of the Act. This is a state of things that ought not to be allowed to continue, and it cannot be expected that anything but trouble and vexation can be the consequence of such discordant opinions as have been expressed by the inspectors in different places.

According to our view of the matter, however, it seems more than probable that in most instances the inspectors of weights and measures are as yet without any adequate authority for dealing with apothecaries' weights and measures at all. If we refer to the Act itself, it will be seen that under the head of Administration, it lies with the local authorities to take the initiative in carrying out the provisions of the Act as to local verification and inspection of weight and measures. Section 50 states that for the purposes of this Act "the local authority" shall mean the authority mentioned in the fourth Schedule to the Act in respect to each of the different areas there mentioned, and on referring to the Schedule we find the local authority for a county consists of the justices in general or quarter sessions assembled, for a borough it consists of the mayor, aldermen and burgesses, acting by the council, and for the city of London it consists of the court of the Lord Mayor and aldermen of the city.

These several local authorities are empowered to provide local standards and places for their keeping, also proper means for verifying weights and measures by comparison, and for stamping weights and measures so verified. The local authorities are also empowered to appoint inspectors, and define their duties. To that end the local authorities are empowered to make, revoke, alter and add to bye-laws for regulating the work of verification and inspection. Until such action is taken by the respective local authorities of different districts and places in reference to apothecaries' weights and measures, it would appear that the inspectors have not really any authority to act or in any way to attempt to carry out the provisions of the Act respecting these weights and measures.

So far as we have been able to obtain any information, it does not appear that the local authorities throughout the country have generally, if at all, proceeded to take such action as would be necessary for authorizing their inspectors to deal with apothecaries' weights and measures. Why that should be the case we are at a loss to imagine, for though there are no provisions in the Act to enforce its being carried out, or for inflicting penalties for its not being put in force by the authorities empowered to carry it out, we cannot suppose that persistent disregard of the duties assigned to local authorities would be allowed to remain unprovided for by further legislation.

Under these circumstances there seems to be ample reason for the Council of the Pharmaceutical Society to communicate with some, if not all, of the local authorities corresponding to different districts and places throughout the kingdom, with the object of making known to them the inconvenience resulting from the uncertainty how the Act is to be carried out in its application to apothecaries' weights and measures, the need for some uniform procedure in the verification and inspection, and for the adoption of a suitable scale of fees. It is satisfactory to find that the Board of Trade, recognizing the importance of the interests involved and the desirability of protecting the trade from inconvenience, is willing to assist the Council in its application to the local authorities, and thus to give additional weight to its representations.

THE LIMITS OF A PUBLIC ANALYST'S DUTIES.

In the report of the annual dinner of the Sheffield Pharmaceutical and Chemical Society, at p. 651, it will be found that Mr. A. H. Allen, the public analyst for the borough of Sheffield and for the county, has furnished a striking illustration of the truth of the proverb *qui s'excuse s'accuse.* We have no intention of questioning Mr. Allen's desire that his pleasant intercourse with the pharmacists of Sheffield should suffer no diminution, and we heartily wish that it may be gratified, but we cannot agree with him in thinking that such a result is to be promoted by what he terms "his very outspoken remarks" as to his performance of the duties of public analyst. Those remarks appear to have been offered in reply to others indicating, as Mr. Allen thought, an impression that he was in the habit of initiating prosecutions under the Sale of Food and Drugs Act. Mr. Allen assured his audience nothing could be further from the truth, and that he held the public analyst had nothing to do with the initiation of proceedings. We are thoroughly in accord with the opinion expressed by Mr. Allen in the latter part of this sentence, but we cannot read his subsequent outspoken remarks without a misgiving as to the former part being borne out by them. At any rate his reference to cases in which he had been concerned appears to convey a different impression, especially the instance where he volunteered the opinion that a particular sample was not one to take proceedings about, and where the magistrates informed him that it was their business to decide that point, and his business was merely to state the results of his analysis. This view seems to us a very proper one, for although magistrates may not always be the best able to judge as to the propriety of instituting a prosecution, and though a public analyst may sometimes happen to have sounder opinions on this point, the expression of that opinion is in no way consistent with his official position. No doubt there is often a need of sound opinion to guide the authorities as to the propriety of prosecuting; but we think public analysts, out of regard for their office, and for the sake of maintaining a character for impartiality, should abstain from giving any such opinions, even when asked to do so.

In this sense we take exception to Mr. Allen's practice of "unhesitatingly condemning" spirit of nitrous ether even when it is extensively watered, inasmuch as by that proceeding he superadds to the functions of the public analyst those of the magistrate or of some other authority competent to decide whether prosecution is desirable. So long as public analysts commit such errors, they will continue to be subject to much adverse criticism, and we will even admit to unfair criticism, perhaps, but they are themselves to blame for that, and the disadvantage of such criticism is not to be done away with by self-laudatory assertions. We do not expect public analysts to be infallible, and would even be willing to pardon them for an occasional mistake, if they would only confine themselves to their own business and not muddle themselves with pharmacopœias present or past, with assumptions as to pharmacopœia standards for drugs being a rule for other purposes than they are intended for, and with the decision of such questions as that relating to milk of sulphur; if in short they would do their work as analysts thoroughly and well and leave other people to mind their own business.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, February 4, 1880.

Present—Charles R. O. Tichborne, LL.D., Ph.D., President; Mr. Bennett (Kingstown), Mr. Doran (Bray), Mr. Hayes.

Proposed by the President, and seconded by Mr. Bennett—

"That the meeting of this Council do stand adjourned to the ordinary day of meeting in March, in consideration of the death of Sir Dominic Corrigan, Bart., their late President, and that a letter of condolence be forwarded to Lady Corrigan expressing the great regret of the Council at her bereavement."

The President, in putting this motion, remarked that this was the second death within the last few months which was thinning off the original promoters of the Pharmaceutical Society of Ireland. If there was one person who had been associated with that Society more than another, or who had taken more than ordinary interest in its welfare, it was Sir Dominic Corrigan. His name had added lustre to their position, and even after ill-health had compelled him to resign his position on that Council, he had never forgotten them. He (the President) had, some few months before Sir Dominic's last illness, received a note from him asking news of the old Society, and he was sure that every member of that Council would feel with him (the speaker) that his loss meant something more than the loss of a public man—that it was the loss of a friend in council.

The motion was carried unanimously, and the meeting was adjourned to March 5.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eighth general meeting was held at the Royal Institution, on Thursday evening, January 29, the President, Dr. Charles Symes, in the chair.

The minutes of the previous meeting were read and confirmed.

The following donations were announced:—

The current numbers of the *Pharmaceutical Journal*, from the Society, and the *Canadian Journal of Pharmacy*, from the editor.

A paper was read, entitled

Coal Tar and its Distillation.

BY ALBERT KEHLSTADT, PH.D.

In distillation of coal, three principal products are obtained,—gas, tar and coke. Not much more than twenty years since the coal tar, which is now the basis of an extensive industry, was looked upon as a nearly worthless substance, to get rid of which the manufacturers were glad. The tar was a large source of inconvenience, as well for the gas works as for the habitations around them. Nobody thought of obtaining anything valuable out of it. The only use made of it was the use of its great antiseptic power, which is formed in the large amount of phenols it contains. It was used (and is yet) as a paint for iron and other metals, for wood, and in the manufacture of felt for roofing, etc. Efforts were made, and not very long ago, to obtain gas from it, by heating it again, but without satisfactory results.

In 1858 the tar became of great importance, as it was found to be a great source of all raw materials for the manufacture of artificial dyes. Already in 1842 Leigh, in Manchester, found benzene (discovered 1825 by Faraday) in the coal tar. In 1845 Hoffmann also detected the presence of benzene in the light coal tar oil and showed its identity with the substances discovered by Faraday (in the light oils arising from the manufacture of gas from oil) and Mitasherbich, who in 1835 got benzene by distilling benzoic acid with lime. In 1847 Charles Mansfield succeeded in obtaining benzene in larger quantities out of the tar, which he proved would be an inexhaustible source for this hydrocarbon. The use then made of benzene was principally the manufacture of nitrobenzene, employed as essence of mirbane in perfumery.

But it is to the valuable discovery, made by Perkins (London) in 1856, when he tried the action of oxidizing agents on certain salts of aniline and thus discovered the mauveine or aniline violet, that is due the enormous increase in the manufacture of coal tar products. Already in 1859 the aniline red or fuchsine was discovered by Verguin and Renaud Brothers, dyers, at Lyons. Since then every year has added new and useful applications, and science has gone on hand in hand with the astonishing development of the new industry, so that now all alizarine is produced in the artificial way out of coal tar products, which is certainly not one of the least triumphs of chemical investigations.

The tar as it is obtained by the distillation of coal is a heavy black or brownish-black thick and oily fluid, insoluble in, and more dense than water, and of offensive smell. It consists of a great number of very different bodies, differing in their physical and chemical characters. There are contained in it acids, alkalies and entirely neutral substances. The last mentioned compose the greatest part of the tar in relation to its weight and to its industrial importance. They are binary compounds consisting only of carbon and hydrogen and are therefore called hydrocarbons.

The following compounds have been found in the coal tar:—

C_5H_{10}, Amylene.
C_5H_{12}, Quintane.
C_6H_{12}, Hexylene.
C_6H_{14}, Sextane.
C_7H_{14}, Heptylene.
C_7H_{16}, Septane.
C_7H_{18}, Octane.
$C_{10}H_{22}$, Decane.
CnH_{2n+2}, Paraffin.
C_6H_6, Benzene.
C_7H_3, Toluene.
C_8H_{10}, Xylene.
C_9H_{12}, Cumene.
$C_{10}H_{14}$, Cymene, etc.
C_8H_8, Styrolene.
C_8H_{10}, Styrol.
$C_{10}H_8$, Naphthalene.
$C_{10}H_{10}$, Hydride of Naphthalene.
$C_{14}H_{10}$, Anthracene (Phenanthrene).
$C_{14}H_{12}$, Hydride of Anthracene.
$C_{12}H_{10}$, Azenaphthene.
$C_{16}H_{10}$, Pyrene.
$C_{18}H_{16}$, Chrysene.
Bitumene.
Benzerythrene.

Of acids and substances acting like acids have been found—

$C_2H_4O_2$, Acetic Acid.
C_2NS_2, Sulphocyanic Acid.
CS_2, Bisulphide of Carbon.
C_6H_6O, Phenol.
C_7H_8O, Cresol.
$C_8H_{10}O$, Phlorol.

Of alkaline compounds we find—

NH_3, Ammonia.
$C_6H_5NH_2$, Aniline.
C_5H_5N, Pyridine.
C_6H_7N, Picoline.
C_7H_7N, Lutidine.
$C_8H_{11}N$, Collidine.
$C_9H_{13}N$, Parvoline.

$C_{10}H_{15}N$, Corridine.
$C_{11}H_{17}N$, Rubidine.
$C_{12}H_{19}N$, Viridine.
C_4H_5N, Pyrrol.
C_9H_7N, Leucoline, isomer with Chinoline.
$C_{10}H_9N$, Lepidine.

This list cannot claim to be a complete one, for it is constantly growing.

It is at present extremely difficult to state the exact relations between the nature of the numerous bodies resulting by the distillation and the immediate composition of the coal. Though the physical qualities of the coal have a great analogy with those of carbon, coal is not carbon at all, not even impure carbon ; it is no simple substance; it is to be considered as the result of the association of several immediate principles, which are probably polymeric derivatives of the immediate principles composing plants. It has been tried at different times, and by different chemists, to treat coal with various solvents, acids, alkalies and neutral solvents, such as alcohol, ether, benzene, chloroform, etc., but without obtaining satisfactory results. The two first mentioned kinds of reagents are without action on coal, the latter extract only minimum quantities of the substances of the coal, which have not been made the subject of a thorough examination.

It is probable that more conclusive results would be arrived at if, instead of taking these easily volatile solvents, heavy coal tar oils of known composition were taken and the treatment of the coal effected under higher pressure than the atmosphere. Other reasons, quite independent of the above mentioned, are sufficient to account for the fact, that a question of such high interest as well for science as for manufacture has not yet found its solution. These are the great varieties of composition of the coals distilled and the widely-differing conditions under which the distillation takes place. For instance, the distillation of Boghead coal and of coal from St. Etienne (near Lyons) will give very different tars both in quantity and quality. Boghead gives about 20 per cent. of its weight in tar, very rich in paraffin, whilst St. Etienne coal yields scarcely 5 per cent. of tar, containing no paraffin at all. Tar from Newcastle coal scarcely contains anything else than naphthalene. Wigan cannel coal yields tar, containing chiefly benzene and phenol. Generally, coals rich in hydrogen yield the greatest amount of tar.

The different rapidities of raising the temperature to red heat can also cause notable changes in the succession and nature of the decompositions displayed in gas retorts, even in distilling coal of the same quality.

In what manner and in what degree these changes take place has yet to be determined, only experiments having yet been made with scientific skill and precision. The empirical observations have only arrived to the result, important by its general value, but very vague, that the same quantity of coal distilled at a high temperature yields more gas and less tar, and at a low temperature yields more tar and less gas.

The principal purpose in distilling coal is to get as much gas as possible, and the distillation therefore takes place under the influence of heat, increased quickly to redness, and this great heat is allowed to act on the products formed at lower temperatures. These conditions are not favourable to the large proportion of tar, but on the contrary favour the formation of gas on the one side, and of the least volatile product on the other side. The formation of the latter ones can go as far as to the carbon itself, which we find therefore always deposited in the retorts as retort coal. To diminish this decomposition and with it the loss of gas, all the products of the distillation are continually sucked out of the retorts by means of exhausters.

It has been proved by Berthelot that the higher and heavier hydrocarbons contained in coal tar, namely anthracene, naphthalene and chrysene, are produced by the action of red heat on the simpler ones, viz., toluene, etc.

The basic substances like aniline, etc., are very likely formed by the action of ammonia on the hydrocarbons *in statu nascenti*, and in the same way the acids might have been formed by the action of binoxide of carbon at these high temperatures.

We may expect, as soon as tar shall become the chief subject of the distillation, instead of being only a bye-product of another industry, that all scientific questions as to the way of the formation of each compound will soon be cleared up.

Should the electric light really be able to supersede the lighting by gas, then, of course, coal ought to be distilled for the purpose of getting tar. The manufacturers would then very soon, in their own interest, seek to fix the peculiar conditions under which such substances are produced, whilst others are not, or at least when the largest quantity of the desired substance is produced. They would take notice of the relations between coals of various sources and composition, and the quantity and quality of the produced tar. All this would in a short time furnish a valuable material, enabling science to complete her building.

The very great complexity of the tar, which contains simultaneously products of quite a contrary character, liquids and solids, acids, bases and neutrals, aqueous and oily, indicates clearly that, before being of any use, these components have to undergo a preliminary classification. After being freed from water the liquids have to be separated from the solids. The liquids again have to be subdivided into two classes, light oils or naphtha and heavy oils. The solids are classified into hard pitch, soft pitch, and asphalt (liquid pitch).

This classification is done by the distillation, and the separation is completed by supplementary processes chiefly consisting in alternative treatments with acid or caustic liquor.

Distillation.—The tar, being generally condensed together with the ammonia-water retains always mechanically enclosed, on account of its dough-like consistance, certain quantities of water. In cases where this quantity would be large, the tar has first to be freed from it, for it could become a cause of danger during the distillation. This is done by heating in stills for about twenty to thirty hours to 176° or 194° F., then the water is drawn off and the tar brought into the stills where it has to be distilled.

The tar worked up in the Liverpool Tar Works does not require this precaution; the small quantity of ammoniacal liquor goes over together with the naphtha.

Different kinds of stills are in use, horizontal cylinders, rectangular stills, or vertical cylinders with vaulted bottom, whose diameter is larger than the height. The volume of the tar diminishing considerably during the operation, so that the pitch at the end occupies only half the volume of the introduced tar, there would be a risk of burning the walls of the stills or superheating them, if the heat were allowed to act higher up on the walls of the still than to the level attained by the residue of the distillation. The pitch would then spontaneously catch fire and cause terrific explosions. The still must further not be heated by direct fire, for when the pitch is allowed to be too much heated, it deposits carbon, which would cause a loss of volatile products and a deterioration of the pitch.

The still, slightly inclined against the side opposite to the furnace, has on the bottom of this side a large stopcock and pipe to let the pitch run off. This stopcock has to be quite isolated from the still by a wall of bricks, in order to prevent the heavy vapours always accompanying the running off of the pitch from being drawn back by the strong draft of the chimney and thus being ignited. On the top the still has a man-hole and a still head, communicating with the condenser. The latter one, as used in the above-mentioned works, is an iron worm of about

8 inches inner diameter and cooled by fresh water running in the opposite direction to the vapours.

The stills are mounted in large furnaces and covered on the top with bricks, to avoid a loss of heat by radiation and the noxious influence of the atmosphere. They are charged twice a week with tar, 4000 to 8000 gallons, varying according to the size of the still.

By heating slowly, the very light oils pass over together with the ammoniacal liquor; these oils constitute the so-called naphtha, having a sp. gr. from 0·780 to 0·850; they pass over between 86° and 284° F., and are the material of which the benzol and toluol are made. They have a very strong smell, owing to the alkaline substances contained in them. After this naphtha, which is collected separately, comes over the light oil, at from 300° to 400° F.; its sp. gr. is 0·830–0·890 and it contains chiefly the phenols, which are also extracted from it. If the distillation is continued, heavy oils pass over, especially rich in naphthalene, and depositing crystals on cooling. When the operation comes towards the end very heavy oils pass over of a dark red-brownish colour, which, when allowed to cool, congeal to a yellow semi-fluid substance, the so-called "green-crease." The residue in the stills is the hard pitch; it is fluid enough to be run off, but on cooling it congeals to a black, shining, brittle solid mass, which softens only at high temperatures, about 140° F., and can, therefore, even in summer be transported in open packages.

It is this pitch which is used in paving the streets in Liverpool.

The tar, being distilled in this manner, yields on the average per ton:—455 to 490 fluid ounces ammoniacal liquor; 1015 to 1050 fluid ounces very light oil (naphtha); 3150 to 3500 fluid ounces light oils, still containing a little benzol and fit for use as lamp-naphtha; 10,500 to 10,920 fluid ounces heavy oils, creasote oils, etc.

A discussion followed, in which the President, Messrs. T. F. Abraham, Conroy and Davies took part.

Mr. Kehlstadt replied to the points raised in the discussion, and a unanimous vote of thanks having been passed to the author, the meeting closed.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

The annual dinner was held at the King's Head Hotel, Sheffield, on Thursday, the 5th inst. The chair was occupied of Mr. G. Ellinor, the President, and among the visitors were Messrs. A. H. Allen (borough and county analyst), W. T. Howie (Messrs. Barron, Harvey and Co) and J. Blair (Messrs. J. Brown and Co., armour-plate manufacturers), etc.

The usual loyal and patriotic toasts were proposed from the chair; also that of the Pharmaceutical Society, to which Mr. Howie replied. Mr. Allen proposed the Sheffield Society, which was acknowledged by Mr. E. R. Learoyd. In the course of his remarks Mr. Allen took the opportunity of saying that, judging from some observations that had been made, there was probably an impression that he was in the habit of initiating prosecutions under the Sale of Food and Drugs Act. Nothing could be further from the truth, the fact being that a public analyst really occupied more the position of a skilled witness consulted by the court, and had nothing to do with the initiation of proceedings. He made it a rule never to suggest the purchase of any particular kind of article unless he was requested to do so, or some kind of complaint reached him as to the quality of the things sold. The fact was that many of the inspectors entrusted with the enforcement of the Act had a notion that every case in which an article had not been found to be absolutely pure was a proper one for proceedings, and the analysts had continually to combat this idea. In one instance in which he (Mr. Allen) had been concerned he actually prompted the defence to ask him, in the witness box, whether, in his opinion, the case was a proper one for proceedings, and on his replying in the negative, the case was dismissed. In another instance, he added a remark to his certificate that the sample was not one to take proceedings about, and received, in consequence, a letter from head quarters informing him that the propriety of proceedings was for the bench to consider, and that the analyst's business was simply to state the results of his analysis. It had been stated that he was in the habit of condemning spirit of nitrous ether if it did not strictly respond to the B. P. tests. This was quite a mistake. Provided the sample was fairly rich in nitrous ether he took no exception to it; but it was well known that spirit of nitrous ether was extensively watered and that the dilution greatly hastened its decomposition. If he met with a sample which was destitute of nitrous ether, whether it had been watered or not, he unhesitatingly condemned it. This was often spoken of as a hardship, seeing that decomposition occurred spontaneously. The same plea might be held to justify the sale of stinking fish or rotten hams. It was the duty of those who dealt in perishable articles to see that they were in good condition. Public analysts were subject to much adverse and occasionally very unfair criticism, but the fact was that as a body they did their work remarkably well. A great deal was made of any case in which an analyst erred through indiscretion or other causes, while the many thousands of samples which passed through their hands annually were forgotten. People did not expect their lawyers, their judges, their government, their doctors or their generals to be infallible; but if an unfortunate analyst erred in any way, or even showed himself unacquainted with the forgotten pharmacopœias of the last century, the whole force of the trade influence was brought against him and he was considered a fair subject for public abuse. As an instance of this, might be mentioned the memorable milk of sulphur decision, where by means of legal quibbles a judgment was given which many leading pharmacists admitted was unjustifiable, and the better part of the trade generally regarded as a step in the wrong direction. The association which conducted that defence successfully did much to injure pharmacists in the eyes of thinking men, as did those who played fast and loose with the Pharmacopœia, and quoted it one day as the standard authority on drugs, while, if it suited their purpose, on the next day pooh-poohed it as of no value at all and as in no way to be regarded as authoritative. Such juggling did not escape notice, and was a discredit to these who practised it, while it tended to bring the whole trade into disrepute. In concluding, Mr. Allen said that from the reception his very outspoken remarks had met with, he felt sure that his meaning had not been misinterpreted, and that his pleasant intercourse with the pharmacists of Sheffield would suffer no diminution on that account.

Mr. Councillor Dobb in eulogistic terms then proposed "The President," and, in responding, Mr. Ellinor thanked the company for the very hearty manner in which they had drunk his health. He hoped it would be his care and study to conduct the business of the Society in a manner acceptable to its officers and members. Unity was strength, and it was desirable that all chemists and druggists in the district should be members, and he gave several reasons for supporting local institutions. The question was not what had the association done or what was it doing? but what had it averted? When the trade was threatened with legis lation which would affect the interests of the trade, meetings were called, petitions signed and forwarded to members of Parliament, organized united efforts put forth, and by the personal and combined action of this and other local societies, the evil was averted. To the meeting of the Pharmaceutical Society in London on January 9, 1879, representatives were sent by this Society and doubtless the tone and action of that meeting was the means of averting much evil. The "patent" question was one presenting many difficulties not easy of solution, and he thought the better plan would be not to introduce any new ones, no matter how good, and by every lawful means to supplant those in general use by their own preparations. He regarded the so-called homœopathic medicines sold by grocers as containing no medicine, the pilules being sugar of milk and the so-called tinctures, simply proof spirit, and said he thought that the grocers must have instructions from those who supplied them that they must not sell the No. 1 pilules or tinctures, as they would then be liable under the Pharmacy Act. He described an amusing incident of a customer interrogating a grocer's assistant as to the action of a medicine. He expressed a hope that the friendly intercourse of the officers and members which had so marked the past would also show itself during his year of office, and that he would when the time came relinquish his post unsullied to a worthy successor.

Mr. J. S. Burnell proposed "The Vice-President and Council," to which Mr. J. Preston replied.

Mr. Otley proposed "The Joint Honorary Secretaries," to which Mr. Newsholme responded.

The remaining toasts were "The Visitors," proposed by Mr. Hall, acknowledged by Mr. Blair, and "The Ladies," proposed by Mr. A. Wood.

The attendance was not quite equal to that of former years, but as every care had been taken to conduce to the comfort of those present, altogether a very pleasant and enjoyable evening was spent.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fourth meeting of the session was held in Anderson's College, 204, George Street, on February 4, Mr. A. Kinninmont, F.C.S., President, in the chair.

The minutes of the previous meeting having been read and adopted, the President called upon Mr. Jos. A. Clarke to give a critique on an address of Dr. A. Buchanan on "Alcohol," delivered in Anderson's College to the Medical Students.

After Mr. Clarke's remarks there ensued a lively discussion, in which Messrs. Kinninmont, Paterson, Walker, Taylor and Hunter (Secretary) took part, after which a hearty vote of thanks was given to Mr. Clarke, for his critique.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The annual supper of the Association was held at the Flying Horse Hotel on Wednesday evening, January 28, when thirty members and friends sat down, under the presidency of Mr. R. Fitzhugh F.C.S., the vice-chair being occupied by Mr. J. Lewis.

After the usual loyal toasts had been given by the chairman and duly honoured, Mr. C. W. Warriner proposed "The Pharmaceutical Society," which was responded to by the local secretary, Mr. Fitzhugh. Mr. C. A. Bolton next gave "The Teacher of the Science Classes," which was acknowledged by Mr. R. Widdowson. Mr. F. H. Spencer then proposed the toast of the evening, "Success to the Nottingham and Notts Chemists' Association," and coupled with it the name of the President, who suitably replied. "The Officers of the Association" was next proposed by Mr. Humphreys and acknowledged by the Hon. Secretary, Mr. R. Jackson. Mr. Ault next gave "The Vice-President and Council," to which Mr. F. White replied. The remaining toasts were "The Visitors," proposed by Mr. Wilford and responded to by Mr. George; "The Chairman;" "The Vice-Chairman," and "The Ladies."

Some capital songs were well sung by Mr. Gascoyne, Mr. M. Ments and Mr. C. Fletcher, Mr. King presided at the pianoforte and a most enjoyable evening was spent.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The fifth meeting of the session was held on the evening of Wednesday, February 4, in the rooms of the Pharmaceutical Society, 119A, George Street; Mr. Robertson, Vice-President, in the chair.

The Secretary having read the minutes of the previous meeting, a paper on "Cinchona Barks" was read by Mr. Fraser.

Mr. Fraser traced the early history of the cinchona plant from the time when, as a medical agent, its efficacy was first ascertained by its having cured the wife of the Peruvian Viceroy, the Countess Chinchon, of a fever, until its introduction into Europe somewhat later, whither it was imported by Jesuits from Rome. Although it met with much opposition at first, he showed how on its admirable properties becoming known, it speedily attained to high repute. In France, during the reign of Louis XIV, its use was entirely prohibited, but having been employed with great success as a "secret remedy" by an English physician resident there, the Government finally persuaded its possessor to disclose his secret in exchange for a large sum of money and various other rewards. Since then it has been held in high estimation in all parts of Europe. During the year 1872, no less than 28,450 cwt. were imported into the United Kingdom alone. The original habitat of the plant was the valleys and eastern slopes of the Andes in South America; but attempts to acclimatize it in other countries had met with considerable success. The Dutch were the first to make the attempt, and though experiencing repeated failure, were at length successful in establishing a colony of healthy plants of the *Calisaya* species, in the forests of Java. The British Government had also established a plantation on the Neilgherry Hills in India, and on a similar plantation, established by the Indian Government in British Sikkim, the report for 1878–9 states that no fewer than four million trees are planted. Mr. Fraser then entered rather minutely into details concerning the official species, and showed the points of resemblance and of difference between them. Of all the various species employed in medicine, the *C. Calisaya* was undoubtedly the most valuable; but other species, the *C. Succirubra* notably, were fast rising into importance. On the Sikkim plantation, for instance, of the four million trees growing there, no fewer than three and a-half million belonged to this species. The alkaloids of the red bark, he remarked, had for some time been used in medicine under the name of "Cinchona Febrifuge;" but the popularity of this preparation was considerably impaired, by its containing a nauseating principle. The essayist next passed under review the various alkaloids obtained from the bark, and stated the principal tests for distinguishing one from the other. The best means of detecting adulterations were also pointed out.

Numerous specimens of the various kinds of barks were exhibited in illustration of the subject, as also living specimens of *Cinchona succirubra*, and *Cephaelis Ipecacuanha*, illustrative of the cinchona order.

Remarks were made upon the paper by several members, and afterwards a hearty vote of thanks was awarded to Mr. Fraser for his most interesting and highly instructive paper. A vote of thanks was also awarded to Mr. Sadler, Curator of the Royal Botanic Gardens, for his kindness in supplying the plants.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The annual meeting of the above Association, held at the Church Institute, terminated on Thursday evening the 29th ult., it having been adjourned from the previous Tuesday. The President, Mr. John Wood, occupied the chair.

After the usual preliminary business the Hon. Secretary, Mr. Joshua Naylor, read his annual report, in which he stated that whilst he could not congratulate the members on the rapid progress of the Association during that time, yet on the other hand he did not see anything to cause despair; in fact, financially the Association was stronger now than twelve months ago, notwithstanding that its number still remained small. It must not be forgotten that changes with assistants and apprentices were of frequent occurrence, and this fact made it difficult to keep an association composed so entirely of these classes in a satisfactory condition, for in many cases no sooner had an assistant begun to take an interest in the Association and avail himself of the facilities it offered than he had to leave the town. Considering the above, and seeing that there was no chemists' association in Oldham, it was to be regretted that the chemists of the town did not take a greater interest and more active part in the working of the Association, which must inevitably be to the advantage of the masters, inasmuch as it would be a means of uniting them more closely together in their business pursuits. At the same time it should be distinctly understood that most of the principal chemists of the town had hitherto given very valuable pecuniary aid to the Association. Another matter of great importance was the desirability of the masters using their influence in securing the aid of leading gentlemen in the business, by inducing them to come and give lectures occasionally. Lectures, essays and papers had been given on various subjects. In addition to these, examinations, classes and conversaziones had been conducted on botany, chemistry, materia medica and pharmacy. The Association was also again indebted to various persons for donations of books, journals, etc.

The Treasurer, Mr. Robert Taylor, then made his financial statement, showing that the expenditure for the past year was £7 18*s.* 1*d.*, and the income £10 10*s.* 10*d.*, leaving a balance in favour of the Association of £2 12*s.* 9*d.*

The officers for the ensuing year were then elected, with the following result:—President, Mr. John Wood, re-elected; Vice-President, Mr. John Boyd; Treasurer, Mr. Robert Taylor, re-elected; Hon. Secretary, Mr. Joshua Naylor, re-elected.

A hearty vote of thanks was given to the officers for their services during the past year.

The chairman then gave his annual address, dwelling chiefly on the business of the past year and expressing himself dissatisfied with the work done, hoping that the members would individually and collectively display more energy and thereby raise the Association to a higher standard during the coming year.

A cordial vote of thanks to the chairman terminated the meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, Feb. 5, Mr. Warren De La Rue, President, in the chair. The following certificates were read for the first time:—M. Bechler, W. J. Dibdin, A. C. Fryer, C. C. Graham, C. P. Sheibner, J. R. Skelton. The following communications were read:—

Note on the Assumed Formation of Ozone by the Atmospheric Oxidation of Phosphorus. By C. T. Kingzett.—The author criticized a short paper recently read before the Society by Professor McLeod on the above subject. The quantitative experiments in Professor McLeod's paper consisted in aspirating air over phosphorus partly submerged in water and then heating the gas to a temperature at which peroxide of hydrogen is assumed to be decomposed into water and oxygen. Any water formed was absorbed in a weighed sulphuric acid tube. In one experiment 2760 c.c. of air thus treated increased the weight of the sulphuric acid tube 0·0006 grm., while the gas which passed through, liberated iodine in a potassic iodide mixture, equal to 1·8 c.c. of decinormal sodium thiosulphate. Professor McLeod then proceeds: "Now as 1 c.c. of the thiosulphate corresponds to 0·017 grm. of hydroxyl, which on decomposition by heat would form 0·009 grm. water, and as we may reasonably assume that at 200° at least the half of any hydroxyl that might be present would be decomposed, we should in the last experiment expect an increase of about ·016 grm. in the sulphuric acid tube instead of only 0·0006 grm." Professor McLeod therefore concludes that the active agent cannot be hydroxyl and is consequently ozone. The author of the present paper contends that the above argument falls to the ground because 1 c.c. of decinormal thiosulphate is not equivalent to 0·017 grm. of hydroxyl, but only to 0·0017 grm., so the gain in the sulphuric acid should be 0·0016 and not 0·016 grm. Passing exposure to 200° would probably not decompose a very small quantity of peroxide of hydrogen diffused through nearly three litres of air. The author therefore does not accept Professor McLeod's experiments as in an any sense conclusive, and hopes to present shortly a further communication on the subject.

The Secretary then read a paper entitled—

Contributions from the Laboratory of the University of Tôkiô, Japan. II. On Persulphocyanate of Silver. By R. W. Atkinson.—In a previous paper (*Chem. Soc. Journ.*, ii., 1877, 254) the author proved the above salt to have the formula $Ag_2C_2N_2S_3$; also, that when boiled with water, this yellow salt was converted into a black precipitate in which the ratio of silver to sulphur varied, the variation being at that time attributed to the presence of some silver sulphocyanate in the silver sulphide, which formed the main bulk of the substance. From further experiments the author concludes in the present paper that the body mixed with the sulphide is some undecomposed persulphocyanate. The reaction being—

$$2H_2C_2N_2S_3 + 4AgNO_3 = (Ag_2C_2N_2S_3 + Ag_2S) + C_2N_2S_2 + 4HNO_3$$

The actual proportion of the two insoluble silver salts formed depends on the influence of time, temperature, and the quantity of free acid present. The author has not been able to isolate the cyanogen disulphide, but is at present examining the orange-red sublimate formed when dry silver persulphocyanate is heated, in the hope that it may contain the missing body. The paper contains several tables giving the results of many experiments as to the influence of variations of time, temperature, and the quantity of the free acid present on the above decomposition.

On Methylated Dioxethylenamines. By H. F. Morley.—Wurtz showed that ethylene oxide unites directly with ammonia, forming mono- di- and tri-oxethylenamine; and that by treating glycollic chlorhydrin or ethylenic oxide with a solution of trimethylamine, neurine chloride is obtained, Baeyer having proved neurine to be trimethyoxethylenammonium hydrate—

$$C_2H_4\left\langle\begin{matrix}N(CH_3)_2CH_3HO\\OH\end{matrix}\right. .$$

Various similar compounds were subsequently prepared, but no one had investigated the action of mono-and dimethylamine on glycollic chlorhydrin. These reactions the author has studied in the present paper; he has prepared and analysed the platinum salts of mono-and dimethyldioxethylenamine. The first crystallizes in orange-red prisms, the second separates in small yellow crystals.

Note on Igasurine. By W. A. Shenstone.—The author has prepared some so-called igasurine of Desnoix. Four gallons of an aqueous decoction of nux vomica beans, from which the alkaloids had been precipitated by boiling with lime, were evaporated; on examination the residue contained notable quantities of strychnine and brucine. The quantity of strychnine present being sufficient to explain the superior activity of the so-called igasurine over that of brucine. The other property which was supposed to distinguish it from brucine, viz., its superior solubility, being of little importance, as the solubility of brucine varies with its purity. Igasurine is, therefore, a mixture of brucine and strychnine.

Mr. Howard and Dr. Wright commented on the utter uselessness of the solubility of an alkaloid as a test of its nature unless the alkaloid was perfectly pure.

Professor Tidy remarked that there was a marked difference between the physiological action of igasurine and strychnine.

On some Reactions of Tertiary Isobutylic Iodide. By L. Dobbin.—Primary isobutylic iodide, prepared in the usual way from the corresponding alcohol, was allowed to flow from a dropping funnel into a boiling alcoholic solution of potassic hydrate. Isobutylene was formed and collected in a gas holder. The isobutylene was then shaken vigorously with fuming solution of hydriodic acid, the mixture being iced. The product thus obtained was separated from the aqueous hydriodic acid solution, treated with dilute potassic hydrate, dried with calcic chloride and filtered. On prolonged shaking with a 12 per cent. solution of hydrocyanic acid, tertiary isobutylic iodide dissolves. After treatment with zincic oxide and distillation, some quantity of trimethylcarbinol was obtained in crystalline masses melting at 25·5, boiling at 82° C. A combustion was made, and numbers obtained closely agreeing with those calculated. It was afterwards found that the hydrocyanic acid takes no part in the reaction, which occurs equally well when water alone is used. This furnishes the first example of an alcohol radical being decomposed by water at ordinary temperatures. On mixing tertiary isobutylic iodide with the quantity of zinc oxide necessary to combine with the iodine present, the temperature being kept at about 15° C., isotributylene was formed and identified by its vapour density, analysis, etc.—

$$6\,\begin{matrix}CH_3\\CH_3\end{matrix}\!\!>\!\underset{\displaystyle CH_3}{\overset{}{C}}\!\!-\!I + 3\,ZnO = 2\,C_{12}H_{24} + 3\,H_2O + 3\,ZnI_2$$

Lermontoff also prepared this substance (*Liebig's Ann.*, 196, 116) by the action of calcic oxide at 100° C. in sealed tubes, on tertiary isobutylic iodide, saturated with isobutylene; that chemist found it, however, to be mixed with isodibutylene, and gives no quantitative results. The author of the present paper obtained no sensible quantity of isodibutylene and the reaction was effected at the ordinary temperature. Wislicenus observed that when tertiary isobutylic iodide was acted on by sodium, a considerable quantity of gas was formed. The author has studied this reaction and analysed the gas which was obtained mixed with atmospheric air; 630·6 c.c. were obtained by the action of 1 grm. of sodium. The gas contained C_4H_8 16·5 per cent., C_4H_{10} 11·4 per cent., H_2 18·07 per cent. The formation of hydrogen is explained by the polymerization of some of the isobutylene. Thus by decomposing tertiary isobutylic iodide by sodium, the bodies formed are isobutylene, isotributylene and hydrogen, with small quantities of a hydrocarbon not absorbed by fuming sulphuric acid. No isodibutylene was found.

The Society then adjourned to February 19, when a ballot for the election of Fellows will be held.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, January 22, Mr. R. H. Parker, Vice-President, in the chair.

A note "On a Supposed Reaction of Aconitine," was read by Mr. A. J. Evans, in which the author drew attention to the fact that it is still stated in text-books on chemistry that aconitine gives with phosphoric acid a violet tint, although T. B. Groves in a paper* read before the British Pharmaceutical Conference, in 1873, stated thus:—"As for the phosphoric acid reaction producing a blue colour, I have never succeeded in obtaining it. It is probably due to some accidental impurity, and I believe Professor Flückiger has arrived at the same conclusion." Mr. Evans had examined a sample of aconitine which also did not give the reaction.

A vote of thanks was accorded to Mr. Evans.

Mr. A. F. Dimmock then delivered his report on "Analytical Chemistry."

* "Further Experiments on Nepaul Aconite and on the Characteristics of the Aconitines."

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Buffon.*

BY PROFESSOR ST. GEORGE MIVART, F.R.S., SEC.L.S., V.P.Z.S.

(*Concluded from page 618.*)

It seems to me that the spirit which would deny such realities is the same spirit which would deny our real knowledge of an external world at all, and represent any material object as "a state of consciousness," and at the very same time represent "a state of consciousness" as the accompaniment of a peculiar state of a material object—the body.† This mode of representation may be shortly, but not unjustly, described as a process of intellectual "thimble-rigging," by which the unwary spectator is apt to be cheated out of his most valuable mental possession—his rational certainty.

The same spirit asserts that our psychical powers never themselves enter into the circuit of physical causation, and yet few things would seem more certain to a plain man than that (supposing him to have received a message saying his house is on fire) it is his *knowledge* of what has been communicated which sets him in motion. To deny this is to deny the evident teaching of our consciousness. It is to deny what is necessarily the more certain in favour of what is less so. If I do not know this I know *nothing*, and discussion is useless. As a distinguished writer has said: "That we are conscious, and that our actions are determined by sensations, emotions and ideas, are facts which may or may not be explained by reference to material conditions, but which no material explanation can render more certain." The advocate of "Natural Selection" may also be asked, How did knowledge ever come to be, if it is in no way useful, if it is utterly without action, and is but a superfluous accompaniment of physical changes which would go on as well without it?

As we may be confident that thought not only is but also acts, as well as that there are things which are not psychical, but which are physical; so I would urge that the conception of living things, which I venture to put before you, is one which may be rationally entertained.

Assuming for the moment and for argument's sake that it may be accepted, what light does our knowledge of ourselves throw upon the intimate life-processes of lower organisms? We know that with us a multitude of actions, which are at first performed with conciousness, come to be performed unconsciously; we know that we experience sensations‡ without perceiving them; we

* Presidential Address to the Biological Section of the British Association, Sheffield, August, 1879.

† Those who deny that we have a real power of perceiving objects, refute themselves when they speak of "purely physical changes," or of anything "physical" of which feelings are but the "accompaniment" or "subjects." For according to them "matter" is but a term for certain "states of consciousness," while they represent each state of consciousness as a function of matter. According to this, let a represent a "state of consciousness, and b a physical state." Then a sensation and its physical accompaniment may be represented by the symbol $a+b$. But a physical state is itself but a state of consciousness with its objective correlate, and is, therefore, $a+b$. We thus get an equation infinitely more erroneous than $b=a+b$, because the b of the $a+b$ is itself ever again and again $a+b$.

‡ As when having gazed vacantly through a window we

know also that countless organic activities take place in us under the influence and control of the nervous system, which either never rise into consciousness at all, or only do so under abnormal conditions. Yet we cannot but think that those activities are of the same generic nature, whether we feel, perceive, or attend to them or not. The principle of individuation in ourselves, then, evidently acts with intelligence in some actions, with sentience in many actions, but constantly in an unperceived and unfelt manner. Yet we have seen it undeniably intervene in the chain of physical causation.

An animal is an organism all the actions of which are necessarily determined by the adjustments of its various organs and by its environment. But even its sensations cannot be regarded as mere accompaniments of its activities, but as guides and directing agencies intervening in the circle of its actions, and as facts, in the chain of physical causation. The sight of a stick may change the course of actions which a dog would otherwise have pursued—that is, the feeling of the moment, together with the faint recurrence of various past feelings and emotions therewith associated which the sight of the stick calls up, may cause such change. Besides its feelings, the general and the organic movements of the dog are, like our own, governed by a multitude of organic influences which are not felt, but which operate through the nervous system, and so must be taken as parallel with those which are felt, *i.e.*, as unfelt, nervous psychoses. The animal, then, like each of us, is a creature of activities partly physical, partly psychical, the latter —both the felt and the unfelt—being directive and controlling.

As we descend to the lowest animals, the evidence as to sentience fades. Yet from the resemblances of the lowest animals and plants, and from the similarity of the vegetative functions in all living creatures, we may, I think, analogically conclude that activities also take place in plants which are parallel with and analogous to the unfelt psychoses of animals. As Asa Gray has said with respect to their movements: "Although these are incited by physical agents (just as analogous kinds of movements are in animals), and cannot be the result of anything like volition, yet nearly all of them are inexplicable on mechanical principles. Some of them at least are spontaneous motions of the plant or organism itself, due to some inherent power which is merely put in action by light, attraction, or other external influences."

I have already adverted to insectivorous plants, such as *Dionæa*. In such plants we have susceptibilities strangely like those of animals. An impression is made, and appropriate resulting actions ensue. Moreover, these actions do not take place without the occurrence of electrical changes similar to those which occur in muscular contraction. Hardly less noteworthy are the curious methods by which the roots of some plants seek moisture as if by instinct, or those by which the tendrils of certain climbers seek and find appropriate support, and having found it, cling to it by a pseudo-voluntary clasping, or, finally, those by which the little "Mother-of-a-thousand" explores surfaces for appropriate hollows in which to deposit her progeny.

Nevertheless, nothing in the shape of vegetable nervous or muscular tissue has been detected, and as structure and function necessarily vary together, it is impossible to attribute sensations, sense-perceptions, instincts, or voluntary motions to plants, though the principle of individuation in each acts as in the unfelt psychoses of animals and harmonizes its various life processes.

The conception, then, which commended itself to the clear and certainly unbiassed Greek intellect of more than 2000 years ago, that there are three orders of internal organic forces, or principles of individuation, namely, the rational, the animal, and the vegetal,* appears to me to be justified by the light of the science of our own day.

I come now to the bearing of these remarks on the science of biology generally.

Animals and plants may, as I have before said, be regarded either *statically*, by anatomy, or *dynamically*, by physiology.

Physiology, as usually understood, regards the properties of the ultimate morphological components of organisms, the powers of the various aggregations of such components, *i.e.*, of the various "tissues" and the functions of the different special aggregations and arrangements of tissues which constitute "organs."

But as each living creature is a highly complex unity —both a unity of body and also a unity of force, or a synthesis of activities—it seems to me that we require a distinct kind of physiology to be devoted to the investigation of such syntheses of activities as exist in each kind of living creature. I mean to say that just as we have a physiology devoted to the several activities of the several organs, which activities are the functions of those organs, so we need a physiology specially directed to the physiology of the living body considered as one whole, that is, to the power which is the function, so to speak, of that whole, and of which the whole body in its totality is the organ.

In a word, we need a *physiology of the individual.* This science, however, needs a distinct appellation. I think an adequate one is not far to seek.

Such a line of inquiry may be followed up, whatever view be accepted as to the nature of those forces or activities which living creatures exhibit. But if we recognize, as I myself think our reason calls on us to recognize, the existence in each living being of such a "principle of individuation" as I have advocated the recognition of, then an inquiry into the total activity of any living being, considered as one whole, is tantamount to an inquiry into the nature of its principle of individuation. Such an inquiry becomes "*Psychology*" in the widest and in the original signification of that term —it is the Psychology of Aristotle.

Mr. Herbert Spencer has already made a great step

---

revert to the pages of a manuscript we may be writing and see there the spectra of the window bars we had before unconsciously seen. Here the effect on the organism must have been similar to what it would have been had we attended to it—*i.e.* it was an unfelt sensation.

* Difficult as it confessedly is to draw the dividing line between animals and plants, such difficulty is not inconsistent with the existence of a really profound difference between the two groups. That there should be a radical distinction of nature between two organisms, which distinction our senses, nevertheless, more or less fail to distinguish, is a fact which on any view must be admitted, since animals of very different natures may be indistinguishable by us in the germ, and in the earlier stages of their development. The truth of this is practically supported by the late Mr. Lewes, who says (as to the difference between the protoplasms from which animals and plants respectively arise): "That critical differences must exist is proved by the divergence of the products. The vegetable cell is not the animal cell, and although both plants and animals have albumen, fibrine and caseine, the *derivatives* of these are unlike. Horny substance, connective tissue, nerve tissue, chitine, biliverdine . . . . and a variety of other products of evolution or of waste, never appear in plants; while the hydrocarbons abundant in plants are, with two or three exceptions, absent from animals. Such facts imply differences in elementary composition; and this result is further enforced by the fact that when the two seem to resemble, they are still different. The plant protoplasms form various cells, but never form a cartilage cell, or a nerve cell; fibres, but never a fibre of elastic tissue; tubes, but never a nerve tube; vessels, but never a vessel with muscular coatings; solid "skeletons," but always from an organic substance (*cellulose*), not from phosphates and carbonates. In no one character can we say that the plant and the animal are identical; we can only point throughout the two kingdoms to a great similarity accompanying a radical diversity." — ('The Physical Basis of Mind,' p. 129.)

towards reverting to this original use of the term, for he has made his "psychology" conterminous with the animal kingdom, having made it a history of the psychoses of animals. But the activities of plants must not be ignored. A science which should include the impressionability and reactions of a Rhizopod, and exclude the far more striking impressionability and reactions of Venus's Fly-trap, and of other insectivorous plants, the recognized number of which is greatly on the increase, must be a very partial and incomplete science. If pyschology is to be extended (as I think Mr. Spencer is most rational in extending it) to the whole animal kingdom, it must be made to include the vegetable kingdom also. Pyschology, thus understood, will be conterminous with the whole of biology, and will embrace one aspect of organic dynamics, while physiology will embrace the other.

Physiology will be devoted (as it is now) to the study of the activities of tissues, of organs and of functions, *per se*, such, *e.g.*, as the function of nutrition, as exhibited in all organisms from the lowest plants to man, the functions of respiration, reproduction, irritability, sensation, locomotion, etc., similarly considered, as manifested in the whole series of organic forms in which such powers may show themselves.

Psychology will be devoted (according to its original conception) to the study of the activities of each living creature considered as one whole—to the form, modes and conditions of nutrition and reproduction as they may coexist in any one plant; to these as they may coexist with sensibility and motility in any kind of animal, and finally to the coexistence of all these with rationality, as in man, and to the interactions and conditions of action, of all these as existing in him, and here the science which corresponds to the most narrow and restricted sense of the word, psychology, *i.e.*, the subjective psychology of introspection, will find its place.

Psychology in the widest sense of the term, in its oldest and in what I believe will be its ultimate meaning, must necessarily be, as to its details, a science of the future. For just as physiology requires as a necessary antecedent condition a knowlege of anatomy—since we must know that organs *exist* before we investigate what they *do*—so psychology requires as a necessary antecedent condition an already advanced physiology. It requires it because we must be acquainted with the various functions, before we can study their synthesis and interactions.

When, however, this study has advanced, one most important result of that advance will be a knowledge, more or less complete, of the innate powers of organisms, and therefore of their laws of variation. By the acquisition of such knowledge we shall be placed in a position whence we may advance, with some prospects of success, to investigate the problem of the "Origin of Species"—the biological problem of our century.

This reflection leads me back once more to my starting point, the merits of the great French naturalist of the last century, whose views as to variation, and as to animal psychosis, have enabled me to bring before you the questions on which I have presumed to enter. Buffon's claims on our esteem have, I think, been too much forgotten, and I rejoice in this opportunity of paying my debt of gratitude to him by recalling them to recollection. As to the questions which his words have suggested to me and upon which I have thus most imperfectly touched, the considerations I have ventured to offer may or may not commend themselves to your approval; but, at least, they are the result of not a few years of study and reflection, and I am persuaded they have consequences directly or indirectly affecting the whole field of biological inquiry, which belief has alone induced me to make so large a call upon your patience and your indulgent kindness.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held on February 11, Mr. F. W. Branson in the chair.

A paper was read by Mr. J. Woodland, entitled "Flowers and their Fertilization," in which the parts of a flower, with their uses and modifications, were described; the process of fertilization, together with agents which render their aid to this process, such as insects and wind, occupied the latter part of the paper, reference also being made to the views on fertilization of plants held by Darwin and Henslow.

After a discussion by a full meeting a vote of thanks to the author concluded the business of the evening.

Parliamentary and Law Proceedings.

Poisoning by Arsenic.

An inquest has been held at Nineveh Farm, Benenden, by Mr. G. Hinds, coroner, on the bodies of a farmer named Mark Boorman and his child.

Mrs. Jane Boorman, wife of deceased, stated that on the Wednesday morning, the deceased came home to breakfast and complained of feeling poorly, and told her that he thought he would take a dose of sulphur, and asked her to go and fetch the jar from the pantry, and as she brought what she thought contained sulphur, he mixed a dose in a jam pot, and took some. The child, Mark, seeing the jam pot, asked for some jam. Deceased said it would not hurt him, and gave him the spoon to lick. Shortly afterwards deceased complained of feeling very sick, and went out into the open air. He came in again after some little time, and said he had been sick, and then complained of being cold. He then went to bed, and his feet were very cold. He continued vomiting, and complained of being in pain towards Thursday morning. During Thursday she wanted to send for Dr. Joyce, but deceased thought the vomiting was caused through biliousness. About two o'clock, she sent for Dr. Joyce, and he came about half-past five. Deceased died about 8 p.m. on Thursday, and the child on Saturday night.

Dr. Joyce stated that he was called to see deceased on Thursday. He arrived home a little before five o'clock, and went at once to see deceased, whom he found vomiting and suffering a great deal of pain in the belly. On inquiring what he had been taking, Mrs. Boorman told him that he had taken a dose of sulphur on Wednesday morning. He looked at some that was left, and felt sure that deceased had taken poison. He remained with deceased until he died at 8 p.m. Took some of the mixture that was left in the jar, and after analysing it found that it contained a great quantity of arsenic. On Saturday, in company with Dr. Piggott, of Sandhurst, he made a *post-mortem* examination, and found that deceased had died from blood poisoning, caused by taking arsenic, which was in the mixture he had taken for sulphur.

The jury returned a verdict that both died through inadvertently taking poison.

The arsenical compound taken by the deceased is stated in a local newspaper to have been "Cooper's Sheep Dipping Composition."

Prosecution for the Sale of Vinegar alleged to be unfit for Food.

At the Droxford (Hants) Petty Sessions, on Thursday, January 22, Mr. Benjamin Boghurst was summoned for selling adulterated vinegar. A constable went to the defendant's shop and asked for a pint of vinegar. Mrs. Boghurst said she did not think she could draw so much, but managed to do so by tilting the cask.

Mr. Arthur Angell, the county analyst at Southampton, certified that the vinegar contained 3·9 per cent. of acetic acid, dead insects, organic matter and vinegar eels. It was turbid and filthy, and swarmed with microscopic organisms. In his opinion it was not fit for food.

In reply to Mr. Bullen, barrister, who defended, Mr. Angell said the liquid was of the substance of vinegar, but he could not swear that it was malt vinegar. There was no difference between the acetic acid of either malt vinegar or wood vinegar. He could not say that the vinegar eels were injurious to health.

In defence, Mr. Bullen said his client had purchased the vinegar from a well-known firm at Winchester, who had received it from Messrs. Grimble and Co., of London.

Both the defendant and Mr. Aylward, of Winchester, were called to give evidence, and both denied that the vinegar had been adulterated, and the head of the firm of Grimble and Co. said they occasionally obtained the assistance of Dr. Graham to analyse the vinegar.

Professor Voelcker gave evidence that the vinegar contained 4·22 per cent. of acetic acid. He did not find in it any microscopic organisms, only vinegar eels, and these could not be said to be present in swarms. It was of pleasant taste and odour and was not decomposed. The vinegar eels were not injurious, as they were generated and nourished in brown vinegar. Although the sample was not so bright as he should like to use, it was free from adulteration.

Professor Graham also gave evidence that the vinegar was fit for food, and the bench dismissed the case.

Prosecution under the 17th Section of the Pharmacy Act.

On Thursday, February 5, Thomas Hutchinson, carrying on business as a chemist in Sumner Lane, Birmingham, was summoned before the Birmingham magistrates, at the instance of the Chemists and Druggists' Association, for selling a certain poison—viz., oxalic acid—in a packet the cover of which did not set forth the name of the seller, as required by the Pharmacy Act. The name on the packet was Thomas Powers, and the defence was that he was the real owner and occupier of the business, and that the defendant merely acted as his agent. Mr. Thomas Powers was called in support of this plea, and stated he was a qualified chemist and druggist living at Stratford-on-Avon, and that the business in Birmingham was carried on by the defendant solely as his agent. In cross-examination he declared his inability to tell when the premises were taken, what they were rented and rated at, or who was the landlord. He had lent Hutchinson £200 for the purpose of the business, and received interest on that sum. The agreement between them was only a verbal one.

The magistrates convicted the defendant and fined him 20*s*. and costs.—*Times*.

Suffocated by a Piece of Liquorice.

On Friday, February 6, at Penzance, Mr. John Roscorla, borough coroner, held an inquest upon the body of Mr. Absalom Bennett. It appeared that Mr. Bennett was taken suddenly ill about one o'clock on Thursday morning when he complained of a choking sensation and took a piece of liquorice to give him relief. He almost immediately died without a struggle.

Mr. John Symons, surgeon, Penzance, said that when he arrived deceased was quite dead, and in making an after examination, he found a large piece of liquorice sticking in Mr. Bennett's windpipe, which in all probability was the cause of his death.

A verdict of "Suffocated by a large piece of liquorice accidentally sticking in the windpipe" was unanimously returned.—*Western Morning News*.

Obituary.

Notice has been received of the death of the following:—

On the 10th of January, 1880, at Shenstone, near Kidderminster, Mr. James Pocklington, Pharmaceutical Chemist, late of Sydenham. Aged 61 years. Mr. Pocklington had been a Member of the Pharmaceutical Society since 1842.

On the 19th of January, 1880, Mr. Seraphin Hooker, Chemist and Druggist, High Street, Cheltenham. Aged 42 years.

On the 21st of January, 1880, at Cheyne Walk, Hackney, Mr. John Buchan Wheeler, Chemist and Druggist. Aged 76 years.

On the 24th of January, 1880, at Nottingham, Mr. James Oscroft, Chemist and Druggist, Ilkester. Aged 31 years.

On the 26th of January, 1880, Mr. Richard Appleyard, Chemist and Druggist, Little Horton. Aged 48 years.

On the 5th of February, 1880, Mr. Joseph Mead, Chemist and Druggist, High Street, Ramsey, Hunts. Aged 76 years.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Answers.

[385]. I had a prescription sent me a few days ago for a liniment containing "ol. sinapis sem.," and upon making inquiries was informed by the prescriber that "ol. sinapis, B.P.," was intended.

J. T. C.

[385]. A reference to any work on botany would have saved Mr. Talbot a very mortifying rebuff from the doctor and would have shown him that sem. sinapis, like the almond, contains both a volatile and a fixed oil, and that the latter was the only one that could be used in the proportion ordered. So it strikes

"An Unregistered Apprentice."

Queries.

[386]. What are the proper consistence and colour of zinci oleas? I find it can be obtained very brown and brittle, like a hard plaster, or of a much lighter colour and softer consistence, by simply altering the length of time that heat is applied or the degree.

Dubius.

[387]. In preparing infus. buchu should the remainder of the leaves, after decantation, be pressed to obtain the mucilage, or should the liquid be merely allowed to run from the leaves without pressure? One preparation differs very materially from the other.

Dubius.

℞ Acid. Nit.-Mur. Dil. . . . . . . ℥ij.
Tinct. Nucis. Vom. . . . . ʒj.
M. 25 minims in water twice daily.

On mixing, after various colour changes, it assumes a straw colour; but after a few hours action is set up, which keeps the contents of the phial in a continual ferment, and on attempting to pour out the dose brisk effervescence ensues. Why?

T. T. J.

[389].

℞ Quin. Disulph.,
Ferri Sulph. Exsic.,
Ext. Hyoscyam. . . . . . āā gr. xvj.
Aloes Soc. . . . . gr. iij.
M. divid. in pil. xvi.

I had the above handed to me the other day. Would any reader inform me what excipient to use?

XENOPHON.

---

[390]. "Jacque" would feel much obliged if some gentleman could tell him how the following should be dispensed:—

℞ Liq. Quinæ Ammon. (gr. iv. ad ℥j) ℥v. (*sic.*)
Bromidi Ammonii . . . . . ℥iss.
Syr. Aurantii . . . . ℥ss.
Liq. Strychniæ . . . . ♏xxij.
Aquæ . . . . ad ℥iv.
M. ft. mist.

---

[391].

Magnes. Sulph. . . . . ℥j.
Magnes. Carb. Pond. . . . . . . ℥ss.
Potass. Iodid. . . . . ℈ij.
Tr. Cardam. Co. . . . . ℥j.
Vin. Colchici . . . . ℥ij.
Aquæ Menth. Pip. . . . . . . ad ℥viij.

This mixture, in the course of some weeks, deposits a considerable firm crystalline mass, growing up from the bottom of the bottle. Can any of your readers explain the reaction and why considerable time is required for its development?

W. SYMONS.

---

[392]. Will any reader kindly tell me through the Journal how he whould dispense the following prescription?—

℞ Glyceroli Plumbi Diacet. . . . . . ℥ij.
To be applied to the parts as directed every night and morning.
Sodæ Biboracis . . . . ℥ij.

W. R. N.

I dispensed it separately, and in the course of a few days I received a letter stating as follows:—"The powder and liquid you sent me the other day were in London made up as an ointment for application."

INQUIRER.

Notes and Queries.

[649]. TINCTURE OF CHERRY LAUREL LEAVES.—Can you favour me with any information concerning a tincture of the leaves of the common or cherry laurel (*Prunus laurocerasus*), said to have been used successfully in Vienna as a remedy for neuralgia?

It would be desirable to know, not only the proportion of leaves to spirit and the dose, but also whether young leaves should be used, or those of mature growth, on account of the percentage of hydrocyanic acid. If you can give me any information on the subject, I shall feel much obliged.

CHERRY LAUREL.

THE USE OF THE WORD "PHARMACY."

Sir,—The 12th section of the Pharmacy Act, 1852, says, after prohibiting the use of the title "pharmaceutical chemist," "or to assume, use, or exhibit any name, title, or sign implying that he is registered under this Act," etc., etc. Now, if I were to exhibit on a door or window the name "surgery," would that imply I was a surgeon? Then if I were to exhibit the word "pharmacy," or "pharmaceutical laboratory," would that imply that I was a pharmaceutical chemist or pharmacist?

And yet this is the question our Council has referred to the solicitor. What is the good of an Act of Parliament, if it does not mean what it says? To my mind our Acts are very clear; but I am quite certain of this, solicitors are the very last persons to interpret them. Solicitors and barristers always take different sides, and common sense sits on the bench; at least, this is my humble experience and opinion. Chemists and druggists have nothing whatever to do with *pharmakon*, root or branch; the Act of 1852 absolutely protects it, in the same way as the Act of 1868 does the word "chemist."

Several of our members are clamouring for a new Act. If they will read their present ones and not treat them like Greek oracles and invoke the assistance of a soothsayer, they will find if they go further they will fare much worse. Let us keep what we have.

GEORGE MEE.

Sir,—With reference to the discussion at the last meeting of the Council relative to the use of the word "pharmacy," as applicable to the shop of a chemist and druggist, I beg to call attention to the fact that it is so used in the Society's own Calendar.

In the particulars of the Jacob Bell Memorial Scholarships, under the heading "Eligibility" we read—

"Candidates . . . . have passed not less, or been engaged not less, than three years in the *pharmacy* of a registered pharmaceutical chemist or *chemist and druggist.*" The italics are mine.

ALFRED PEEL.

Sir,—I was very pleased to see from your last week's issue that the attention of Council had been drawn to an encroachment upon the rights of "Majors" by a great many of the Minor men who are in business at the present time, and which is chiefly committed by younger men or by those who have lately opened new businesses; consequently, the sooner this evil is checked the better will it be both for the Society and those connected with it.

I think, sir, it must be very apparent to the Council of the Pharmaceutical Society that if they continue to allow those who have not taken the higher qualification to delude the public by advertising themselves as "qualified by pharmaceutical examinations," etc., they cannot be surprised if there should be a great decrease in the number of those who present themselves for the Major, because this will in a short time materially detract from the superior ability and dignity which have been heretofore attached to that qualification.

This grievance and injustice is more especially felt in the large provincial towns, where we may fairly say that nine-tenths of the public either do not or cannot distinguish a pharmaceutical chemist from a chemist by pharmaceutical examination, and the consequence is that the latter will soon take the place of the former if the Society do not bestir themselves and check the practice while yet in the bud; otherwise I fear that the "Majors" of the future will be unknown in the provinces, and the "few" who do aspire to it will remain near Bloomsbury Square and the immediate neighbourhood.

A VOICE FROM THE MIDLANDS.

Sir,—In looking over the proceedings of the Council as reported in last Saturday's Journal, I regret to find the death of our esteemed friend Mr. A. F. Haselden, who was one of my examiners for the Major and my certificate bears his signature.

Another matter which I think ought not to pass Majors unobserved is the "Pharmacy" question. At the passing of the 1868 Act, we had membership given to any who registered, examined or non-examined, that liked to pay for it. Membership prior to 1868 was always understood to be for passing the Major, and those who had passed the Major not wishing to become members (not being in business on their own account), became Major Associates. Somehow or other a new construction or interpretation was given and the Major Associateship was struck out of existence. The least that ought to have been done was to have created a Fellowship, and those who had passed the Major before the 1868 Act came into operation should have been made Fellows.

"Pharmaceutical chemist," and every form of it, is protected by the several Acts. The question is, "How can you have a pharmacy without a pharmacist?" On commonsense grounds, I think no one is legally entitled to call his place of business a pharmacy unless he is a pharmacist.

With all due respect to our Solicitor, though he may have given his opinion over and over again, as the Secretary says, yet I believe the list of Major Associates was published over and over and over again.

It appears quite plain that we shall have to interpret the law and the Council administer it. And we have had a good illustration that lawyers cannot or do not always properly interpret the law. That an impenetrable substance does sometimes intercept somewhere is the inference one might draw in the case of the Doncaster coroner (I believe a lawyer) and the difficulty our Solicitor had to make him understand the "true interpretation of the Pharmacy Act." I hope the Council will obtain the further true interpretation of that Act that "pharmacy" can only legally be used by a real pharmacist, and forthwith administer the same.

MAJOR.

PATENT MEDICINE LEGISLATION.

Sir,—In the last Council meeting attention was drawn to the continual decrease of the members of the Pharmaceutical Society. The report winds up by saying that the Council went into committee on the sale and use of narcotics. The connection between the two topics is not perhaps so obvious to some members of the Council as it is, especially just now, to most country chemists. There has been a good deal of writing and talking on the latter subject in connection with patent medicines. What is now wanted is prompt and decisive action on the part of the Council. This would most decidedly help to remove the prejudice and apathy which now tend to prevent chemists from joining the Society. There can be no doubt of the existence of this ill feeling, not only among outsiders but also among some who are now subscribers to the Society. Those who move among country chemists, and in fact many London ones, are obliged to hear strong language used as to the inaction of the Council with regard to the practical and trade interests of the great body of the trade, to whom the every-day experience of life brings home the lesson, that the dream of being raised to the status of a profession will only be realized in the millenium.

No doubt much of this prejudice is founded on misapprehension, but still it exists, and the object of my writing is to urge that the "set time" for action is now come. The abuse of narcotics has been discussed in all our leading newspapers, thus showing that public opinion is ripe for legislative action. It is surely fortunate that in the published correspondence the Pharmaceutical Society has come in for much unjust censure, that being a powerful argument for their claiming from the Legislature powers which they do not now possess, but which they have been publicly blamed for not using. For one I have done my best to defend the Pharmaceutical Society in a letter which appeared in the *Daily News*, in reply to one from a medical man.

If it be asked in what way action should be taken, I reply, just on the lines mentioned by me at the 1878 Annual Meeting, and suggested before that in a letter of mine which appeared in this Journal, viz., by making it compulsory that all patent medicines and proprietary articles which contain any article mentioned in the Poison Schedule should (subject to a heavy penalty on the maker for omission) have the nature and proportion of such articles plainly stated both on the outside of the package and also fixed on each bottle or box, and then extend the restrictions of the Sale of Poisons Bill to all such articles.

This would meet the public demand contained in much of the newspaper correspondence and would at the same time prevent the sale of such medicines by grocers and hawkers. It would also probably tend to make some popular cough medicines safer, by causing a reduction of the opiates now put in to produce decided effects.

If there were also an intimation given to the Chancellor of the Exchequer that the patent medicine licence may be judiciously increased from 5*s.* to 10*s.*, no respectable chemist would object. It would also be well if a list of all taking out such licences were hung up in the Inland Revenue offices.

These proposals are surely definite, practical and called for by outside public opinion, and most chemists, I think, would be satisfied if the Council would join with the Birmingham committee in introducing a Bill on such a basis. To aim at more with regard to patent medicines, would probably end in failure.

Barnstaple. W. SYMONS, F.C.S.

THE BOARDS OF EXAMINERS.

Sir,—All who take an interest in the examinations ought to rejoice at the action of the Council in endeavouring as far as possible to assimilate the standards at the London and Edinburgh Boards of Examiners. I think all will agree that the interchange of visits was a most important step in that direction; but another subject that appears to me of equal moment is the commonly prevailing opinion amongst students that there is a greater diversity in point of severity in the questions given by individual members on the London Board than there is between the two Boards collectively; and I believe that and the short time at the disposal of the examiners principally account for the success of some who have themselves but a faint hope of passing, when better men go to the wall.

I will mention as an example the chemistry portion of the examination, which in my time was generally conducted by the same four gentlemen. If a candidate who was in any way weak in that subject had been allowed to select the examiner he wished to go before, I believe that one would have had all or most of the work to himself.

Having only been up once for the same examination, I cannot speak authoritatively from personal experience, but young men who are on the eve of presenting themselves, let them be ever so ably trained by a teacher, naturally seek the experience of their friends who have already undergone the ordeal, and get the tale of the successful and the plucked ones.

As for myself, I can only speak in the highest terms of the examiners, as I found them most kind, encouraging and courteous; and a pure desire to remedy a grievance, if it really exists, prompts me to write on the subject.

St. Clears. R. WILLIAMS.

THE WEIGHTS AND MEASURES ACT.

Sir,—I was very pleased to see the letter in a recent issue, from F. H. McIntyre and Sons, concerning the weights and measures, and to find that others like myself are in a state of perplexity.

May I ask if the measures are any improvement on the old style? Besides the trouble of using two measures for one quantity, it necessarily entails the dispensing counter being encumbered with a larger amount, which is a very unwelcome change to dispensers.

I think the best measure is the one which combines simplicity with accuracy, and as such can see no fault in the old ones. They have answered their purpose for a long time without any evil results. Why, then, need the change? Are chemists a set of babies not capable of using them? Or is it a new-fangled idea adopted to please those who are never content with the same thing long?

I think we have enough bogies already, in the shape of co-operative stores, public analysts, the Poisons Act, and the sale of patents, without introducing another in the shape of fresh measures. In fact, our profession is fast getting a case of maximum trouble and minimum profits.

Great cry has been made of late about the sale of narcotics, all blame falling, as usual, on the poor chemist, of course. If a man means to kill himself, he will, and all the chemists in the world will not stop him. If, then, a man deliberately obtains poison in conformity with the Act and commits suicide, or through carelessness causes his own death, the chemist again has all the blame and censure. We are quite enough fettered as regards poisons, and the Act is sufficient to prevent mistakes taking place with sane people. When some weak-minded people take their own lives let not the slur be cast on us, or we had better become grocers, selling all drugs, etc., except poisons. ION.

Might not the Pharmaceutical Society of Great Britain have a Representative in the House of Commons?

Sir,—I do not know if the question of the Pharmaceutical Society having a representative in the House of Commons has even been thought of by any of the members of the Council, but it might not be out of place for the Council to consider the matter—seeing that at present there are six disfranchised seats in the House, which will shortly be allocated, and also having in mind that a scheme for the re-distribution of seats may be brought forward sooner or later.

Without entering into the arguments *pro* and *con.*, I would merely throw out the hint that the matter may not be altogether unworthy of consideration, and, if considered, the time may not be far distant when the pharmaceutists of Great Britain may be represented in Parliament in the same way as the graduates of our Universities are at present.

PHARMACEUTIST.

Oleum Aloes.

Sir,—I observe in your issue of January 31st ult., p. 613, Dr. M. Craig mentions that a specimen of "oleum aloes" was "presented to the Pharmaceutical Society, London, and unfortunately the bottle containing it was broken, and the oil was lost." This statement is incorrect.

The specimen in question was stated in a letter sent to me by Messrs. T. and H. Smith, to have been sent with other valuable specimens for exhibition at the Conference Meeting, which was held in London in 1874, at the rooms of this Society.

The hamper containing the specimens was directed to my care, and the most careful investigation of its contents failed to reveal the presence of the bottle of "oleum aloes." None of the specimens, so far as I remember, then exhibited by Messrs. T. and H. Smith were presented to this Society.

I should not have troubled you with this communication had not Dr. Craig's remarks implied carelessness on my part.

E. M. HOLMES, *Curator.*

Museum, 17, Bloomsbury Square.

Mitcham Oil of Lavender.

Sir,—What is to be done about Mitcham oil of lavender? In these days when the Council of our Society are called upon to do almost everything, it may not be out of place to inquire whether the present price (125*s.* per. lb.) of this essential oil, producing as it does such an exquisitely beautiful perfume, is to be allowed to continue, in which case there can be little doubt that it must ultimately not only bring into use very inferior oils, but destroy the popularity of the perfume altogether from this enormous cost.

Surely it is a time for some enterprising men to turn their attention in a direction which shall produce the original thing at a much less price, and yet allow a sufficient margin for paying all expenses of growth and labour.

YOUNG AND POSTANS.

S. J. Fisk.—We know nothing of any such society; but the initials quoted are already used to indicate fellowship of another society.

G. H. Lodge is recommended to apply to the Registrar under the Dental Act.

G. Farie.—Possibly the loan of the *clichés* might be obtained from the advertisers, whose property they would usually be.

H. E.—Probably a reference to the advertising columns would disclose what you require, but we cannot undertake to recommend books upon the subject of "diseases which chemists have very often to treat."

"*Theta.*"—We do not think the manufacture of iodine from sea-weed is carried on on the British coast except in Scotland, but among the conditions necessary to make such a manufacture successful would be a plentiful supply of the algæ rich in iodine and cheap labour. See vol. ix., pp. 302 and 486.

"*Bos.*"—Blaine's 'Outlines of the Veterinary Art.'

G. Spencer.—Your question is too general. The answer to it would depend upon what the colour was due to; it might be a physical property of the substance itself.

E. Lloyd.—We know of no other way than writing to the Solicitor of the Inland Revenue Department.

"*En Avant.*"—Proctor's 'Lectures on Pharmacy' is the nearest approach to what you require with which we are acquainted.

Minor.—We think not, but apply to the Secretary of the College of Surgeons.

R. J. L.—See before, pp. 486 and 644.

Fruit.—In the absence of any information as to the actual composition of the mixture we are unable to express an opinion.

"*Inquirer.*"—See a paper on the "Cultivation and Manufacture of Patna Opium," *Pharm. Journ.* [1], vol. xi., p. 205, and another by Mr. Maltass, on the "Production of Opium in Asia Minor," *Pharm. Journ.* [1], vol. xiv., p. 395.

"Οπο."— Probably "aniline green."

"*Ipecac.*"—The information will be found in the "Students' Number" of either of the medical journals, published usually in September.

J. Wearing.—We cannot give you the address required, but possibly the information might be obtained by applying to the editor of the *Grocer*.

J. J. J.—(1) Blaines' 'Outlines of the Veterinary Art.' (2) See the next answer.

Proprietary Preparations.—In reply to numerous inquiries referring to the compositions of proprietary preparations we are quite unable to give any information, but would suggest that wherever it is desirable to institute such inquiries they would be best answered by a chemical examination of the article in question.

A. P. S.—Information as to the sale of scheduled poisons by unregistered persons should be sent to the Registrar under the Pharmacy Act, 17, Bloomsbury Square.

L. W.—We do not know that sugar occurs at all as a natural constituent in the flours of cereals.

Inquirer.—Recipes for Composition Powder will be found in vol. viii., p. 498, and other places in the present series.

Tradesman.—*Pomade Hongroise.*—The following recipe is given by Piesse ('Art of Perfumery'):—

"White Wax	1 lb.
Oil Soap	½ ,,
Gum Arabic	½ ,,
Rose-water	1 pint
Otto of Bergamot	1 oz.
,, Thyme	½ drachm

"Melt the gum and the soap in the water by a gentle heat, then add the wax, constantly stirring the ingredients together; when of a uniform consistency, put in the perfume."

"*Dubius.*"—(a) The Weights and Measures Act applies to Ireland with certain modifications that are specified in sections 76 to 85 inclusive. (β and γ) See Dispensing Memoranda.

Communications, Letters, etc., have been received from Messrs. Barnard, Howard, Mackay, Mushens, Smout, Newham and Co., Andrews, Churchill, Welborn, R. J. L.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 582.)

CHAVAK. PIPERACEÆ.

Under this name the stem of the pepper plant is sold in the Bombay shops. It is jointed, about as thick as the little finger, and has the taste and odour of black pepper.

PIPER LONGUM, *Linn.:* PIPERACEÆ. *The fruit and root. Vernacular.*—PIPLI (Hind., Bomb., Beng.); TIPPILI-MULAM (Tam.).

History, Uses, etc.—Long pepper, in Sanskrit Pippali, is an old-established article of the Hindu materia medica; the root Pippali-mula is also extensively used, and is found in every druggist's shop throughout the country. Both drugs are considered stimulant, carminative, alterative and laxative, and are prescribed in chest affections, dyspepsia and palsy. Besides being administered by the mouth these drugs enter into the composition of medicinal snuffs and liniments. Dutt gives us the following peculiar method of administering long pepper as an alterative tonic:—An infusion of three long peppers is to be taken with honey on the first day, then for ten successive days the dose is to be increased by three peppers every day, so that on the tenth day the patient will take thirty at one dose. Then the dose is to be gradually reduced by three daily, and finally the medicine is to be omitted. Thus administered it is said to act as a valuable alterative tonic in paraplegia, chronic cough, enlargements of the spleen and other abdominal viscera (Chakradatta in Dutt's 'Hindu Mat. Med.,' p. 243). Mahometan writers, under the name of Dar-filfil, describe long pepper as a solvent of cold humours; they say it removes obstructions of the liver and spleen, and promotes digestion by its tonic properties; moreover it is aphrodisiacal, diuretic and emmenagogue. Both it and the root (Filfil-muiyeh) are much prescribed in palsy, gout, lumbago and other diseases of a similar nature. A collyrium of long pepper is recommended for night blindness; made into a liniment, it is applied to the bites of venomous reptiles. We learn from Roxburgh ('Flora Indica,' i., p. 155) that it is in Bengal only that *Piper longum* is cultivated for its pepper. When the ament is full grown it is gathered and daily exposed to the sun till perfectly dry, after which it is packed in bags for sale. The roots and thickest part of the creeping stems, when cut into small pieces and dried, form a considerable article of commerce all over India, under the name of Pippula-moola; for which purpose it is particularly cultivated in many of the valleys amongst the Circar mountains. This sort is more esteemed and bears a higher price than that of Bengal, where by far the largest portion is cultivated. It, as well as the pepper, is chiefly employed medicinally, and the consumption of both of these drugs is very great. *Piper longum* was formerly cultivated at Poway, near Bombay. It appears to grow well in gardens in Bombay, but requires plenty of manure.

Description.—The ament of *P. longum* is composed of a number of small berries crowded together round a common axis. The spikes vary in length, and taper slightly towards the apex. Each berry is about one-tenth of an inch from base to apex, and of an obovoid form; the structure is essentially the same as that of the fruit of *P. nigrum*. Long pepper when freshly picked has hardly any aroma; in the process of drying; it gradually develops an aromatic taste and odour.

Pipla-mul, or pepper root, when fresh is a fleshy, crooked and knotted root, about the size of a goose-quill, with many smaller rootlets branching from it. The cortical portion is very thick, and covered by a thin smooth brown epidermis. The central woody column is soft, and divided into from 4—6 wedge-shaped portions by from 4—6 very conspicuous medullary rays.

Microscopic Structure.—The epidermis of the root consists of several rows of tangentially extended brown cells. The parenchyme of the cortex is chiefly composed of large thin-walled cells loaded with starch, and containing drops of essential oil. Amongst them are scattered cells containing a refractive yellow substance (resin). The central woody column is also loaded with starch, and contains as many resin cells as the cortex. The medullary rays are abundantly provided with large scalariform vessels.

The anatomy of the fruit hardly differs from that of *Piper nigrum*; but the albumen does not contain any volatile oil.

Chemical Composition.—Generally considered to be similar to that of black pepper.

Commerce.—Three kinds of long pepper are met with in the Bombay market. 1st. Singapore, which is identical with the long pepper of European commerce and is produced by *P. officinarum*, D.C. 2nd. Bengali or léndi-pipli, the produce of *P. longum*, Linn., cultivated in Bengal. 3rd. Swaheli, imported from Zanzibar, a very inferior kind of pepper, the greater part of the catkins being immature and no thicker than a knitting needle.

Value, Singapore, Rs. 7-12 per maund of 41 pounds, Bengal, Rs. 9, Zanzibar, Rs. 5. Pipla-mul is also of three kinds.

Mirzapore, Rs. 10–40; Bengal, Rs. 7–7½; Malwa, Rs. 50 per maund of 41 pounds.

SALIX CAPREA, *Linn.:* AMENTACEÆ. *The flowers. Vernacular.*—BÉD-MUSHK (Pers. and Hind.). The distilled water, MA-UL-KHILAF.

History, Uses, etc.—This species of willow is frequently mentioned in Persian books as a well-known popular remedy. In Arabic it is called Khiláf-ul-Balkhi.

The Persian settlers in India have introduced the flowers and distilled water, but they are only used by the better classes of Mahometans and Parsees. Meer Muhammad Husain describes Khiláf-i-Balkhi as cephalic and cardiacal, deobstruent and tonic; it is one of the popular domestic remedies which are used in almost every kind of slight ailment. The Arabic word Khiláf is equivalent to the genus *Salix*. Two kinds are usually described in Persian books on materia medica, Bed-mushk and Bed-i-sádah or Bed-i-bari; the latter is called Safsáf in Arabic.

A description of *S. caprea* will be found in English botanical works; it is one of those willows which yield salicin.

The bark of *Salix tetrasperma*, Roxburgh, indigenous in this part of India, appears to be quite inert.

BETULA BHOJPATTRA, *Wall.:* AMENTACEÆ. BHURJA PATRA (Sans.), BHUJPATR (Hind., Beng., Bomb.).

This requires a brief notice as the bark is much used all over the country for writing medicinal charms on, and is to be found in every druggist's shop. This bark is well known as the material upon which the ancient Sanskrit manuscripts of northern India are writtten. Dr. Buhler in his account of a tour in Cashmere in search of Sanskrit manuscripts, says:—"The Bhûrja MSS. are written on specially prepared thin sheets of the inner bark of the Himalayan birch, and in variably in Sarada characters. The lines run always parallel to the narrow side of the leaf, and the MSS. present therefore the appearance of European books, not of Indian MSS. which owe their form to an imitation of the Tâlapattras. The Himalaya seems to contain an inexhaustible supply of birch-bark, which in Kásmir and other hill countries is used both instead of paper by the shopkeepers in the Bazaars, and for lining the roofs of houses in order to make them water-tight. It is also exported to India, where in many places it is likewise used for wrapping up parcels, and plays an important part in the manufacture of the flexible pipe-stems used by hukâ smokers. To give an idea of the quantities which are brought into Srînagar, I may mention that on one single day I counted fourteen large barges with birch-bark on the river, and that I have never moved about without seeing some boats laden with it. None of the boats carried I should say less than three or four tons weight.

"The use of birch-bark for literary purposes is attested by the earliest classical Sanskrit writers. Kalidâsa mentions it in his dramas and epics; Sásruta, Varahâmihira (*circa* 500—550 A.D.), know it likewise. Akbar introduced the manufacture of paper, and thus created an industry for which Kâsmîr is now famous in India. From that time the use of birch-bark for the purpose of writing was discontinued, and the method of preparing it has been lost. The preparation of the ink which was used for Bhûrja MSS. is known. It was made by converting almonds into charcoal and boiling the coal thus obtained with gomûtra (urina bovis); this ink is not affected by damp or water." (*Journal Bomb. Branch Royal Asiatic Society*, vol. xii., No. xxxiv., A.)

———

KISHMISH-I-KÁWALIYAN or MUIZAK-I-ÂSLI: LORANTHACEÆ?

This is the name of a small, shrivelled, soft fruit imported from Persia; it is called Dibk and Kasús in Arabic and appears to be the berry of some species of *Viscum*. The author of the 'Makhzan-uladwiya' has the following account of it:—"A berry smaller than the seed of *Cicer arietinum*, green when fresh, but when dry shrivelled and of a brown colour; the contents are moist and viscid, the seeds about the size of poppy seeds.

"The plant is parasitic upon the pear and other trees and consists of several branches; the leaves are like those of the pomegranate and of a pale green.

"Properties resolvent and laxative, a solvent of corrupt humours, which it withdraws from the system. When steeped in hot water, strained, and beaten up with the kernels of the walnut or castor oil (which is the usual form of administration) it clears the system of bile and phlegm, removes obstructions, and is a remedy for lumbago, piles, etc. Applied externally it promotes the suppuration, or causes the dispersion of tumours and enlargements. Sportsmen use it as birdlime, and dyers as a mordant for crimson."

PINUS LONGIFOLIA, *Roxb.*: CONIFERÆ. *The wood and turpentine. Vernacular.*—SARAL, CHIR, (Hind.). *The turpentine.*—GANDAH-BIROZAH (Hind. and Bomb.).

History, Uses, etc.—The wood, in Sanskrit Sarala, and the turpentine, Sarala-drava, are mentioned as medicinal in Sanskrit works; plasters, ointments and pastiles for fumigations are directed to be made from the turpentine. The latter under the name of gandah-birozah is found in all the Indian bazars and appears to have all the properties of ordinary turpentine though differing from it in appearance. Oil of turpentine, does not appear to have been known to the ancient Hindus.

Description.—Gandah-birazah is a dirty-white opaque substance of a soft and sticky consistence having a strong turpentine odour. It is said to yield a good oil when distilled.

Commerce.—The turpentine can be purchased in Bombay at Rs. 8 per maund of 41 pounds.

———

ZINGIBER CASSUMUNAR, *Roxb.*: AMOMACEÆ. *The rhizome. Vernacular.*—BAN-ADA (Hind. and Beng.), NEESAN. (Bomb), KARPUSHPOO (Teling.).

History, Uses, etc.—The rhizome of this species of *Zingiber*, though used medicinally by the country people, appears never to have been an article of commerce in India. In the Concans it has a reputation as a remedy in diarrhœa and colic. The fresh rhizome is rubbed down with water for administration. The Sanskrit name is Vanárdraka.

Description.—An excellent figure of the plant will be found in Roscoe's 'Monandrian Plants.' The fresh rhizomes are 1—2 inches in diameter, jointed, compressed, with numerous white fleshy radicles to some of which white tubers are attached. Each joint of the rhizome is furnished with a leaf-bud. The epidermis is scaly, light brown, the interior of a rich golden yellow. The odour is powerful and not very pleasant, like a mixture of ginger, camphor and turmeric; the taste hot and camphoraceous.

Microscopic Structure.—The epidermis is formed of many layers of compressed and obliterated cells. The parenchyma consists of large polyhedral cells; those in the cortical portion of the rhizome are nearly free from starch, but those in the central portion are filled with large ovoid starch granules. In all parts of the rhizome large cells full of a golden yellow essential oil abound. The vascular system resembles that of turmeric.

(*To be continued.*)

OSTRICH AND OTHER PEPSINES.*

BY I. R. JAMES.

During the last two or three years the French and English medical press have been discussing a new pepsine, called "ostrich pepsine," which has excited some amount of attention, and accounts of its probable benefits have found their way into the *Pharmaceutical Journal*, as well as a specimen into the museum of the Society. It is thus described in the *Medical Times and Gazette* by M. Ebelot:—"The stomach of the ostrich is celebrated for its incredible power of digestion. The abundance of pepsine to which it owes this faculty has created among the Indians a curious commercial fraud. They dry it, and sell it literally for its weight in

* Read at a meeting of the School of Pharmacy Students' Association.

gold. It is used for the purpose of restoring worn-out stomachs." A correspondent to the *Pharmaceutical Journal* says:—" In the Argentine Republic ostrich pepsine is prescribed by medical men, and known by the public as 'pepsina nostra.' A good wine is made by digesting the stomachs in wine. I consider this a useful article; but being a rough preparation our pepsine is preferable."

Beyond these and similar statements no definite statistics of experiments have been published, so far as I know. It is of the utmost moment that it should be given a fair and impartial trial by those who have the means at their disposal of testing it, as injustice might be done to a medicine which when properly prepared is proved by medical men to possess great therapeutic value; while, on the other hand, a worthless preparation would receive credit for performing a service which it is totally incapable of rendering. Before giving the results of my experience with ostrich pepsine, I think that the following brief history relating to this bird will not be altogether without interest.

The American ostriches contain two species—*Rhea Americana* and *Rhea Darwinii*, which, although closely allied to the African species, *Struthco camelus*, rarely attain to more than half the size. These birds inhabit various parts of South America to the southward of the Equator, but are principally found on the great plains in Buenos Ayres and the adjoining states. They are of a uniform grey colour, except in the back, which has a brown tint; they also differ from the true ostrich in having the head and neck covered with feathers and the feet furnished with three toes. The feathers of the wing and tail, though elongated, possess none of the beauty of the African ostrich, and are but little esteemed as articles of dress or ornament, being only employed in the manufacture of light brushes for driving away flies, or cleansing articles from dust. Their food consists mainly of grasses, roots, and other vegetable substances; but they will occasionally eat animal food, being known to come down to the mud-banks of the rivers for the purpose of eating the little fish that have been stranded on the shallows. Darwin, who had frequent opportunities of observing these birds, has given an excellent account of their habits. He says: "They take the water readily, and swim across broad and rapid rivers, and even from island to island in the bays. They swim slowly, with the greater part of the body immersed and the neck extended a little forward. On two occasions I saw some ostriches swimming across the Santa Cruz river, where it was 400 yards wide, and the stream rapid." It is polygamous; the male bird prepares the nest, collects the eggs (which are frequently laid by the females at random on the ground) and performs all the duties of incubation. Darwin says four or five females have been known to lay in the same nest, and the male when sitting lies so close that he himself nearly rode over one. All this time they are very fierce, and have been known to attack a man on horseback, trying to kick and leap upon him.

Whilst conducting my experiments upon ostrich pepsine my attention was drawn to another preparation, called "Ingluvin," thus described in the *Medical Times and Gazette* for May 10, 1879: "This is a new remedy, prepared by Warner and Co. from the *ventriculus callosus gallinaceus*. It is said to be superior to pepsine as a remedy for feeble, painful and imperfect digestion, and may be prescribed in the same manner, doses and combinations. . . . Ingluvin prepared from the gizzard of the chicken is the nearest approach to ostrich pepsine that can be obtained in Europe, we suppose." Naturally, I felt a little curious to test this preparation, and applied for some to the agents, who most readily supplied me. Below I have tabulated the results obtained.

Fresh eggs were kept in boiling water for one hour and then allowed to get quite cold; after depriving them of their shells the whites were cut into the thinnest possible slices—not minced, as it is easier to observe the progress of the digestion of albumen if it be sliced than if it be minced—and care was taken to reject any portion of yolk. Fifty grains of coagulated albumen thus prepared was placed in each wide-mouthed bottle and covered with 5 drachms of distilled water containing 1 per cent. of hydrochloric acid, sp. gr. 1·16. The quantity of pepsine was then weighed out and added to the mixture of albumen and dilute hydrochloric acid. The bottles and their contents were then placed in a water-bath and kept at a temperature of 98° to 102° F. for four hours, when digestion was regarded as complete.

Kind of pepsine employed.	Weight of pepsine employed.	Results.
Pig Pepsine . .	½ grain . .	Digested.
Ostrich Pepsine .	2½ grains . .	Not digested.
" " .	5 " . .	" "
" " .	10* " . .	" "
Ingluvin . . .	2½ " . .	" "
" . . .	5 " . .	" "
" . . .	10* " . .	" "

From the results detailed in the foregoing table, and contained in the bottles shown, it will be seen that the albumen is scarcely acted upon at all, and that both ostrich pepsine and ingluvin are practically destitute of the power of digestion.

We know how dominant ideas exercise a powerful effect on the bodily functions. Dr. Carpenter says, "A strong direction of the inward consciousness to any part, especially if attended with an expectation of something being about to happen, is quite sufficient to change the physical action of a part." If the South American Indians' imagination were similarly appealed to, it might be they would derive the extraordinary benefit attributed to ostrich pepsine after partaking of 7 or 8 pounds of beef, which, on the authority of Dr. Symes, they are in the habit of indulging in.

We have heard of late a great deal about elevating the position of pharmacists and chemists and druggists generally. As a step in this direction, and believing as I do that the examination of new remedies is a duty which we owe to medical men, I would suggest that we pay more attention to the testing of substances purporting to be remedial agents which from time to time find their way into our pharmacies and are prominently brought before the notice of practitioners; for it is a matter of considerable importance that the accuracy of facts be well sustained before they are given to the profession, many of whom have no facilities for verifying them. If any of you wish to work in this direction, lest you should think, after excluding the above-named winged animals, that pepsine can only be obtained from the stomachs of pigs, calves and sheep, I have much pleasure in placing before you other kinds. I am indebted to Mr. Lloyd

* Finding that twenty times as much ostrich pepsine and ingluvin had so little effect, I did not think it necessary to pursue the experiments further.

Bullock for the samples of pepsines shown, which I have found to possess considerable digestive activity, although inferior in this respect to the pepsine of the pig. One of the specimens is unique of its kind, viz., pepsine from a human stomach, which I need hardly say is not intended for medicinal use.

In the stomach of the river crayfish is found a plentiful supply of a yellowish-brown, feebly acid juice, which possesses an energetic fermenting power and rapidly dissolves fibrin, but the *addition* of a few drops of a dilute hydrochloric acid solution stops the action. Also, a somewhat similar ferment to pepsine, discovered by Fick and Murisier in the stomachs of frogs, pikes and trout, differs from it (pepsine) in being more active at a low temperature, as at 20° F., while it loses its digestive power at the temperature of the blood (96° to 98° F.)

NOTES ON ECONOMIC BOTANY OF THE WESTERN UNITED STATES.*

BY J. T. ROTHROCK, LATE A. A. SURGEON, U.S.A.

Berberis aquifolium, Pursh. "Oregon Grape."—According to Dr. Engelmann this is al o called in Colorado "mountain grape," and the juice when fermented makes, on the addition of sugar, a palatable and wholesome wine.

Caulanthus crassicaulis, Watson. "Wild Cabbage."—Sometimes used as food when a better substitute cannot be found.

Fremontia Californica, Torr. "California Slippery Elm."—Though totally unlike eastern slippery elm in its botanical characteristics, the inner bark develops large quantities of mucilage when wet; in this respect sharing the peculiar properties of some other members of the order. Used in California to make poultices, etc.

Larrea Mexicana, Moricand. "Creasote-bush."—Common from Western Texas to Kern County, California, and southward into Mexico. Dr. Loew's examination proves that "the reddish-brown exudate on the branches" will yield a red colouring matter, showing all the reactions of cochineal.

The alcoholic extract of the leaves on evaporation yields a greenish-brown residue of a specific and somewhat disagreeable odour, more strongly perceptible on boiling the extract with water. This residue is only to a small extent soluble in water, and the solution has an acid reaction. It yields a light-yellow precipitate with acetate of lead. The part of the alcoholic extract that is soluble in water is easily soluble in alkalies. It also dissolves in nitric acid at a moderate heat, whereby oxidation takes place. On addition of water a yellow brittle mass is precipitated. The Mexicans are said to use an infusion of the leaves for bathing in, in rheumatic affections.†

Rhus diversiloba, T. and G. "Poison Oak; Yeara."—Much like the poison oak of the Eastern States. Common on the Pacific coast. For remedy see *Grindelia robusta*.

Prosopis juliflora, DC. "Mesquit," "Algaroba" of the Mexicans.—Grows from South-eastern California east to Texas, where it attains the tree size, and forms dense thickets; extends south into South America. The gum exuding from this tree closely resembles gum-arabic in appearance and in its properties, and may some day become an important article in trade. The pods while yet in pulpy condition are a valuable forage, eagerly eaten by animals, and on which they actually thrive while making hard marches. The beans contain 30 per cent. of grape sugar. Dr. Loew asserts that the Comanche Indians prepare an alcoholic beverage from them. As a fuel it ranks with the hickory of the Eastern States, and the charcoal made from it is said by Dr. Loew to be of the best quality for metallurgical and smelting purposes. Besides this species there is another, hardly less useful, *i.e.*, *P. pubescens*, Benth., the screw-bean, the pods of which are ground into flour by the Indians. The wood of both species is of great value in some of the arts.

Oxytropis Lamberti,* Pursh, in Colorado; and *Astragalus Hornii*, Gray, and *Astragalus lentiginosus*, Dougl., var. *Fremontii*, Watson, in California, are known as loco-plants. The term *loco*, simply meaning "foolish," is applied because of the peculiar dementia induced in the animals that are in the habit of eating the plant. In Arizona I was told that *Hosackia Purshiana*, Benth., produces effects similar to the above plants, but I have no certain knowledge concerning it.

Whether the animals (horses chiefly) begin to eat the plant from necessity (which is not likely) or from choice I am unable to say. Certain it is, however, that once commenced they continue it, passing through temporary intoxication to a complete nervous and muscular wreck in the later stages, when it has developed into a fully marked disease, which terminates in death from starvation, or inability to digest a more nourishing food. The animal towards the last becomes stupid or wild, or even vicious, or again acting as though attacked with "blind staggers."

Dr. Horatio C. Wood has recently brought to light (*Phila. Med. Times*, vol. vii., p. 510) a new alkaloid in *Sophora speciosa*, Benth. This he names "sophoria." In its action it resembles calabar bean. This alkaloid is a spinal sedative, producing death through the respiration. One-twentieth of a grain of an impure specimen of this alkaloid produced a profound sleep, lasting many hours, in a half-grown cat. Mr. Bellinger, of Texas, states that the Indians near San Antonio use the bean as an intoxicant, half a bean producing "delirious exhilaration, followed by a sleep which lasts two or three days," and it is asserted that a whole bean would kill a man.

Mr. Lemmon has noted *Astragalus Mortoni*, Nutt., "as a deadly sheep poison" in California.†

This order (*Leguminosæ*) was, until lately, regarded as on the whole rather innocuous, but recent discoveries have brought to light quite a number of plants of bad repute.

Eucalyptus globulus, Labill. "Australian Blue Gum."—Now planted by thousands in Southern California. This tree is of a very rapid growth, and makes withal a solid, close-grained, enduring timber. Mr. Cooper, of Santa Barbara, estimates the gain in growing this to be greater than that derived from the cereals. As to its value from a medicinal standpoint, I am free to say it has in every instance disappointed me in its antiperiodic effects. I do not regard it (though I have used it heroically) as in any sense the peer of the preparations derived from cinchona. It is, however, not improbable that the enormous evaporation from the surfaces of the leaves and young shoots may be a means of improving the sanitary condition of a moist, boggy, ague-cursed area, when the trees are planted in masses, but the idea that any mere cordon of trees around a home would protect it appears improbable, not to say preposterous. However, I am bound to say we are yet without sufficient data on which to base an absolute conclusion. In such regions as the Sanoita Valley, Cienega or San Pedro, in Southern

* From the Report on the Botanical Collections made in Nevada, Utah, California, Colorado, New Mexico and Arizona, from 1871 to 1875, in connection with the U.S. Geographical Surveys, west of the one hundredth meridian, in charge of Lieut. Geo. M. Wheeler, Corps of Engineers, U.S. Army. From *Report upon U.S. Geographical Surveys*; vol. vi., Botany. 4to with 31 plates. Washington, 1878.

† See Wheeler's 'Reports,' vol. iii., pp. 608–9.

* The alcoholic extract of this plant failed, when hypodermically injected by Dr. H. C. Wood, to produce symptoms of poisoning in the lower animals. He hence concludes it is a mistake to regard it as one of the "loco" plants.

† See Brewer and Watson, 'Bot. of California,' vol. i., p. 165.

Arizona, it would doubtlessly flourish, and a few years hence be of immense value as a timber tree. The Southern Rio Grande Valley offers another suitable spot for its introduction. While these species will not endure cold weather, it is to be remembered that there are others of the genus that are hardier and almost as valuable as timber. These would probably be well worth a trial in Arizona and New Mexico.

Mentzelia albicaulis, Dougl.—The Indians in South-eastern California pound up the seeds of this, making thus one of their forms of pinoli (see later on, under *Salvia Columbariæ*). Sometimes also used by them in a kind of cake.

Cucurbita perennis, Gray. "Chili Cojote," and "Calabazilla," in Southern California.—Brewer and Watson assert, in 'Fl. Cal.,' p. 239, "that the pulp of the green fruit is used with soap to remove stains from clothing, and that the macerated root is used as a remedy for piles, and the seeds are eaten by the Indians."

Cymopterus Fendleri, Gray. "Chimaja," of New Mexico.—This plant emits, when in decoction, a peculiarly strong and pleasant odour, not unlike *C. anisatus*, which it closely resembles. The residents in and about Santa Fé are in the habit of using this as the chief ingredient, after whiskey, to form a warming stomachic "bitters," which is immensely popular, as anything is likely to be which improves in any way the whiskey of the region. A less objectionable use is made of it by using it as a stuffing in a leg of roast mutton, the whole mass of which it permeates with its pleasant flavour. It is not unlikely that ere long this plant will be made the basis of another quack constitutional invigorator. There is probably no doubt of its being a good carminative, and it may also prove to a certain extent tonic.

Osha.—This root, so well known in and around Santa Fé, is derived from an unknown plant, probably a *Peucedanum*. Better specimens are desirable, as it is altogether probable the plant is an old, well-known species. It may have remedial powers that will stand investigation.

Eupatorium Berlandieri, DC.—A specimen of this was handed me at the Chiricahua Agency in Southern Arizona, and the statement made that the Apache Indians there were in the habit of using it as a substitute for tobacco. At first I was disposed to accept the statement *cum grano salis*, but have since discovered that other species are elsewhere used in a like manner. On trial I find the smoke devoid of any marked flavour, but rather acrid when passed through the nostrils. It also appears to have some more marked property in a very slight degree, as indicated by a gentle nervous tremor induced in smoking. The dry leaves, when rubbed in the hand, emit a faint, rather resinous odour. There is no doubt but that it would be quite as pleasant and satisfactory as much of the drugged cheap tobacco now on the market.

Grindelia robusta, Nutt, or "Gum Plant" of California.—This plant has recently come into notice as a remedy in poisoning from *Rhus diversiloba* (Poison Oak of California). So far as I know it has not been tested on our Eastern oak,* which is another species, and for which the *Fluid Extract of Serpentaria*, as advised by Dr. Henry Hartshorne, acts almost as a specific when applied locally. The resinous exudation on the leaves of the *Grindelia* is applied in California, or it has been used in the form of a tincture. Concerning the wide range of usefulness anticipated in medicine for *Grindelia*, I am in the highest degree sceptical.

Bigelovia veneta, Gray. "Damiana" in Northern Mexico.—The plant is found just outside our borders, and may reach within our domains. I introduce it here because it is so closely related to *B. Menziesii*, which extends abundantly from San Diego to Arizona, and as far north as Utah, so as to be by some regarded as identical. Concerning Damiana, or, as it is oftener called, *Yerba anti-rheumatica*, we have of late heard much in

* It has been tried in the Eastern States with varying success.

medical journals as an aphrodisiac. There are a number of other claimants for the name Damiana. Of this one I am free to confess I consider it utterly worthless as a remedial agent. The resinous exudation on it somewhat resembles that found on *Grindelia robusta*, and was probably the means of attracting attention to it.

Pectis angustifolia, Torr., and *P. papposa*, Gray, appear to have been generally noticed because of their *peculiar odour of lemons*. Indeed, Dr. Loew suggests that in the former this might be turned to commercial account.

Artemisia.—Several Western species have been reputed as of use in ague and mountain fever by the prospectors of the West. They are used in decoction. I am not prepared to vouch for their efficacy, however. Some species are said to "owe decidedly stimulating properties to their aroma and bitterness."* The current ideas concerning some of our Eastern species would go for something in confirming the estimate placed on the Western ones.

Asclepias leucophylla, Engelm. var. *obtusa*, Gray. "Milkweed."—Has about Fort Tejon, California, the reputation of "locoing" the sheep. How well merited this is I am unable to say.

Eriodictyon.—In California, I believe, the name "Yerba Santa" is used for both *E. tomentosum* and *glutinosum* of Bentham. An infusion of the leaves in whiskey or other alcoholic liquor is reckoned almost a panacea by the native population. Precise clinical trial is yet needed to determine its true value.

Eritrichium fulvum, A. DC.—I have received from my friend, Mr. William L. Kennedy, of Fort Tejon, California, abundant specimens of this plant, collected in white paper, which it had stained completely with a *bright orange-red* colour. Mr. Kennedy accompanied the specimens with the remark that "the fresh root and leaves are used by the squaws to paint their faces, and that the colour is not inferior to the finest rouge." From the abundance of the juice, as manifested by the stained paper in which I received the plants, I infer that the plant might be turned to some commercial account. The colouring matter is not confined to this species.

Salvia Columbariæ, Benth., is the "Chia" of Southern and Central California. I abstract the following brief account I have given of it from the *Botanical Bulletin*:—

"During the summer of 1875 my attention was called, while in Southern California, to a mealy preparation in popular use among the Indians, Mexicans and prospectors. On inquiry I found it was called 'chia.' Further examination proved that it was furnished by the seeds of *Salvia Columbariæ*, Benth. The seeds are collected, roasted and ground, in the native way, between two stones. This puts it in the condition in which I first saw it. It is used as a food by mixing it with water and enough sugar to suit the taste. It soon develops into a copious mucilaginous mass, several times the original bulk. The taste is somewhat suggestive of linseed-meal. One soon acquires a fondness for it and eats it rather in the way of a luxury than with any reference to the fact that it is exceedingly nutritious besides. It is in great demand among the knowing ones who have a desert to cross, or who expect to encounter a scarcity of water, and what there is of bad quality. By preparing it so thin that it can be used as a drink, it seems to assuage thirst, to improve the taste of the water, and, in addition, to lessen the quantity of water taken, which in hot countries is often so excessive as to produce serious illness.

"As a remedy it is invaluable, from its demulcent properties, in cases of gastro-intestinal disorders. It also holds a place among domestic remedies for the same purpose that flaxseed occasionally does with us, *i.e.*, a grain of the seed is placed in the eye (where it gives no pain) to form a mucilage by means of which a foreign body may be removed from the organ. I have found it of great service as a poultice. As a matter of archæo-

* See 'Le Maout and Decaisne,' English edition, p. 505.

ogical interest, it may be noted that quantities of this seed were found buried in graves several hundred years old. This proves that the use of the seed reaches back into the remote past. Indeed, I find several allusions to the name 'chia' in the second volume of Bancroft's great work on the 'Native Races of the Pacific States,' pp. 232, 280, 347, 360. 'Chianpinoli' appears to have been made by the so-called Aztec races from corn which was roasted and ground as the chia was. Chia was among the Nahua races of Ancient Mexico as regularly cultivated as corn, and often used in connection with it. Indeed, it was one of the many kinds of meal in constant use, and which appear to have gone then, as now, under the generic name of pinoli."

Abronia fragrans, Nutt.—The delicious perfume of the flowers of this plant suggests the inquiry as to whether it could not be utilized as a toilet adjunct. Specimen number 127 of the New Mexican collection, when taken at Agua Azule, was fairly loading the air with its matchless fragrance.

Anemopsis Californica, Hook. "Yerba de Mansa."—This plant, if we may at all credit popular report, is well worthy of further investigation as a remedial agent. Unfortunately I have mislaid my notes, and can say nothing more definite now than that it is regarded as a diuretic, and is largely used in baths for rheumatic affections. It is rather unsafe to venture an opinion on its mere appearance; but if I were to do so, I should say it would probably drop into that somewhat vague class of remedies known to physicians as alteratives.

Yucca Baccata, Torr., along with other species of the same genus, is, like Agave, also known to the Mexicans as *Amole*, and the root is used by them in washing. Dr. Loew has recently furnished an analysis of the root (vol. iii., p. 609, Wheeler's 'Reports') and finds the froth produced on agitating the pounded root in water is due to saponin. Of course its marked detergent properties depend on this. The leaves of this also furnish a coarse fibre.

Euphorbia.—The various prostrate species of this genus have, in the south west, a popular reputation as a remedy in bite of rattlesnakes, tarantulas, etc.; and, to meet the demand for it, a tincture is kept on hand in the shops. In absence of this (on the authority of Dr. George Thurber), the fresh leaves bruised, or the dry ones steeped in wine, are applied to the wound. These plants are there known as *Yerba de la Golondrina*. While not wishing to cast discredit upon the remedy used in this way (and that, too, after the venom has usually been taken into the general circulation), I can only say it is hard to understand how it could be of service.

Populus tremuloides, Michx. "American Aspen."—Dr. Loew reports the bark of this tree to be used by the Indians in intermittent fever. It has long been more or less of a domestic remedy, and, indeed, of a certain class of practitioners, for this disease. It is not a little remarkable, however, that it should also be used by the Indians, and we can only account for the fact that it does possess some remedial power in this direction, which a "hit or miss" empiricism has led them to discover. Dr. Loew's analysis of the bark yields salicin and populin. The former was long ago in common use in intermittents. It is, therefore, probably slightly antiperiodic as well as tonic in its action.

Ephedra antisyphilitica, C. A. Meyer. "Canutillo; Tepopote; Whorehouse Tea."—The names, scientific and popular, might be regarded as sufficiently indicative of the alleged properties of the plant. The stems of the plant are largely used in decoction as a remedy in gonorrhœa. Precise clinical results are wanting to determine its real value. However, by common consent among the populace, and so far as I can learn from medical men of the region, it is of real service. Its close botanical relationship to the balsam-producing *Coniferæ* would appear to suggest that this, too, must contain a ike product. This, however, is not confirmed by the careful analysis of Dr. Loew (vol. iii., Wheeler's 'Reports,' pp. 611 and 612).

The above-ground portion is there shown to yield an aqueous extract of "acid reaction and an astringent taste, resembling that of tannin." No body resembling an organic base or alkaloid was found.

The filtrate of the aqueous solution proved the presence of tannic and tartaric acid. Pectin was also shown to be in filtrate by the "jelly-like precipitate produced by the addition of alcohol." The tannin belongs to the glucoside group, furnishing sugar on treatment with acid and various other compounds, and, upon dry distillation, pyrogallic and carbonic acids. This tannin splits up into sugar "*and a red amorphous powder*." The powder Dr. Loew considers quite a distinct body, which he names *ephedrin*, and to this he attributes (and probably correctly) its remedial properties. So concurrent is the testimony in favour of this plant that it is well worthy of a fair trial in hospital practice.

Agave Palmeri and *A. Parryi*, Engelm. "Mescal."—The subterranean trunk of most (or all) the Agaves contains, like that of the Yuccas and many other plants of these families, a great deal of mucilage, which, when mixed with water, has detergent properties to a considerable degree. These "roots" and the whole plants thus used are known to the Mexicans by the name of "Amole" (Englemann).* Mescal whiskey is prepared by distillation from the juice which has been collected in the cavity caused by removal of the just starting flower-stem and the inner leaves. The quantity yielded is almost fabulous. This whiskey contains a large percentage of alcohol, and it is said that it is impossible to adulterate it so that the adulteration cannot at once be detected in the taste. Hence it is hardly surprising that those who are "advised to take stimulants" take so kindly to "Mescal." Fresh from the still it is even hotter than corn whiskey equally new.

ANEMOPSIS CALIFORNICA (HOOKER).—YERBA MANSA.†

BY J. U. LLOYD.

This is a small perennial plant growing in damp situations in the southern part of California and Northern Mexico. The leaves are mostly radical, smooth, of a firm texture, and borne on sheathing petioles. The stem is about 6 inches high, bearing a clasping leaf near the middle, and terminating in a spike of flowers. The flowers are small, apetalous, cohering into a thick spadix, which is surrounded at the base by about six petaloid bracts, giving the entire inflorescence the appearance of a single terminal flower. A prominent character of the plant is its tendency to produce stolons.

In 1876 the writer received a specimen of the plant through the kindness of Dr. George, of California. It was known as "Yerba Mansa" in his neighbourhood, and used as a domestic remedy. This specimen was fresh, and upon cultivation grew vigorously, passing the hard winter of 1878–79 with impunity. The characteristics of the native grown plants were preserved, but while there was a rapid increase in the number of plants by means of runners, none have blossomed.

The plant, which belongs to the order *Saururaceæ*, was noticed in this journal, December, 1878, p. 589, by Dr. Edward Palmer in his interesting article upon "Plants used by the Indians of the United States,"‡ as follows:—

"The root of this plant is a great remedy among the Indians of Arizona and Sonora, in Mexico and Southern California. It has a strong peppery taste and odour. A tea made from the roots and a powder prepared from the

* In his paper on Agave in *Transact. of Acad. of St. Louis*, 3308, etc. See also *Botany* of Clarence King's 'Reports,' p. 497.

† From the *American Journal of Pharmacy*, January.

‡ See *Pharmaceutical Journal* [3], vol. ix., p. 774.

same and applied to venereal sores are a great remedy. The powder is advantageously used on cuts and sores, as it is very astringent. The leaves, after being wilted by heat, and applied to swellings, are a sure cure." In connection with this the following examination may be of interest.

All parts of the plant exhale, when broken, a pungent, disagreeable, penetrating odour. The taste is aromatic and peppery. Alcohol readily extracts all the sensible characteristics. Water simply becomes flavoured when boiled with the root, the filtrate being astringent and highly charged with glucose. It does not afford precipitates with the usual reagents for alkaloids. The odour and taste of the plant is derived from a volatile oil; this is obtained, according to our experiments, in the proportion of 6 fluid drachms to the avoirdupois pound by distilling the dried root with water.

Essential Oil, A.—This is heavier than water, yellowish, very refractive, and to the taste sharp, pungent and possessing in a high degree the characteristic odour and flavour of the plant. It dissolves in all proportions in alcohol, ether, chloroform and carbon disulphide. When mixed with an equal bulk of sulphuric acid heat is evolved, and a thick, dark red liquid results. This dissolves in alcohol and chloroform, with production of a beautiful red colour; is insoluble in ether, but becomes thinner when mixed with it and permitted to separate. This substance does not retain the odour of the oil.

When the essential oil is poured upon the surface of freshly prepared nitromuriatic acid in a test tube and gently agitated, it turns blue; then with evolution of nitric oxide and a sudden increase of temperature decomposes, the result being a brownish resinous substance; the natural odour of the oil disappears, and the underlying acid changes to a red colour.

When the essential oil is in like manner poured upon the surface of hydrochloric acid and gently agitated, a gradual change in colour to deep blue results; in the course of twenty hours passes into violet, then changes to purple, and lastly to brown. The natural odour of the oil remains.

After distillation with water the root has a slight odour of the oil, an astringent taste and a benumbing action upon the tongue.

Alcohol seems to extract all the sensible properties of the recently dried root. When percolated with this menstruum a dark reddish tincture results. Upon evaporating from it the alcohol at 150° F., the residuum separates into a reddish oil, B, and a stiff gummy substance, C.

Characteristics of the Oil, B.—It is heavier than water. The odour and taste are exactly like those imparted when the root is chewed. It dissolves in alcohol, ether, chloroform and disulphide of carbon, but from the latter solution a small amount of flocculent reddish matter separates. When the solution in disulphide of carbon is filtered, a light-coloured oil results, seemingly similar to the essential oil A, obtained by distillation, the colour being somewhat darker. The flocculent red precipitate is astringent and deliquescent, absorbing moisture and forming a red liquid. It is the material that gives the red colour to the oil B, and constitutes a considerable proportion of the bulk of the—

Gummy Substance, C.—This is purified from adhering oil by trituration with carbon disulphide, the residuum being granular, astringent and peppery, and of a brownish colour, soluble in dilute alcohol, and mostly soluble in glycerin. It dries by exposure to cool atmosphere, but melts to a varnish-like substance at the temperature of 125° F. to 150° F. When the dry powder is triturated with water a flocculent substance remains, astringent to the taste, soluble in glycerin, alcohol and dilute alcohol; insoluble in chloroform, ether and carbon disulphide; precipitates black from solution in glycerin and dilute alcohol, with ferrous sulphate, and is negative to action of the usual precipitants for alkaloids. The filtrate from the precipitate C, after rubbing with water, is almost colourless, astringent, precipitates black with ferrous sulphate, and when boiled with Fehling's solution yields a heavy red precipitate. It fails to respond to reagents for alkaloids. When the precipitate C is triturated with ether and chloroform, a portion dissolves, and an astringent substance remains, which deliquesces upon exposure, forming a red gummy substance, eventually liquefying. This seems to be the same as the substance that separated from the oil B by the action of carbon disulphide.

The residuum within the percolator, after extraction with alcohol, seemed thoroughly exhausted. Water and acidulated water are somewhat astringent after maceration with it, odourless, react with Fehling's solution, but not with tests for alkaloids. Ether and disulphide of carbon fail to extract a vegetable wax, resin or other constituent worthy of attention, and inert extractive matter and mineral salts of no importance, together with woody matter, thus far have been found.

TAYUYA.*

(*Trianosperma ficifolia*, Mart.)

BY DOMINGO PARODI.

The botanical collections of Lorentz and Hyeronimus, classified by Grisebach in his last work, 'Symbolæ Argentinæ,' comprehend eleven species belonging to the family of the Cucurbitaceæ, but no mention of the *Trianosperma ficifolia* and two undetermined species of *Cyclanthera* and *Prasopepon* that I have met with in the neighbourhood of Buenos Ayres. Of these the *Trianosperma ficifolia*, Mart. (*Bryonia ficifolia*, Lam., Dict. i., 498), is the celebrated tayuya, employed by the natives of these localities from remote times for the cure of a large number of infirmities, and still generally used in domestic medicine in the various provinces, in Paraguay and in Brazil. In Brazil it is called "Leroy vegetal," in reference, no doubt, to the supposed universality of its sanative virtues and its very decided emetico-cathartic effects upon the organism.

Dr. Ubicini has attempted to introduce the use of this medicine into Europe, and if the clinical experiments to which he refers can be accepted as positive results, the tayuya is not a simply purgative agent, but should be considered a powerful excitant of the lymphatic system and a very active depurative.

In my alphabetic catalogue and notes upon the ordinary plants of Paraguay, published in 1860 and 1877, I stated with respect to tayuya as follows:—"The part used is the root, which is white internally and covered with a reddish epidermis. Its taste is at first amylaceous, afterwards acrid, bitter and disagreeable. It contains much fecula. The active principle, tayuyina, is soluble in water and in alcohol, and is capable of producing violent emetico-cathartic effects when administered either in the form of an aqueous decoction (of the root) or an alcoholic tincture. It possesses energetic properties, operating upon the gastro-intestinal organs with great promptitude and violence. It is used in serious cases of dropsy, paralysis, obstinate cutaneous disorders, syphilis, etc. It is a medicine in which the common people place great faith, and from which, in fact, they obtain occasionally favourable results. Its therapeutic use is, notwithstanding, subject to the same inconveniences as the official *Bryonia alba* and other drastic analogues of the same family. It is employed in doses of 2 to 4 grams, in infusion or decoction, and lately the hydroalcoholic tincture in the proportion of one part of the root to four of the vehicle has been recommended in doses of 6 to 15 drops, progressively augmented, in the treatment of tertiary syphilis and as a deobstruent and depurative."

---

* Abstract from a paper in the *Revista Farmacéutica* (Buenos Ayres), vol. xvii., p. 6.

I have intentionally reproduced this note, because, notwithstanding that Velloso, in his 'Flora,' cites and describes the *Bryonia Tayuya* in 1810, and Martius, in his treatise on the Brazilian materia médica, describes it and modifies the genus as *Trianosperma Tayuya* (1838), and in my catalogue I quote it under the name of "tayuya" (1860), in October, 1875, Mr. Stanislas Martin bestowed this name as a novelty, saying, singularly, that no author mentioned it and referring to Martius and Velloso. The old 'Formulario' of Chernovitz likewise mentions various species of tayuya, and it appears incredible that a chemist or botanist should make definite references to the products of those regions without consulting the works treating of them.

The tayuya belongs to the second series of the excellent taxonomic arrangement of cucurbitaceous plants by Bentham and Hooker. It is really a *Trianosperma* and not a *Bryonia*, as I have confirmed by an examination of the female flower, which has the ovules erect and not horizontal; the style with three stigmas expanded, the fruit with three seeds and the tendrils (*zarcillos*) frequently, but not constantly, trifid.

An analysis of tayuya made by M. Yvon gave the following results:—

Water	11·57	Water	11·57
Organic Matter	76·96	Glucose	0·84
		Crystallizable matter soluble in alcohol (Tayuyina).	0·24
		Resin	1·17
		Essential Oil	—
		Starch	17·32
		Organic acids, woody matter and loss	57·39
Inorganic Matter	11·47	Silica	1·02
		Lime	4·71
		Magnesia	3·12
		Iron and Alumina	1·23
		Potash and Soda	1·39
	100·00		100·00

Acids, Sulphuric and Hydrochloric.

With regard to the active components of tayuya the most extensive and complete work is that of Peckolt. Martius refers to an investigation of Herberger, with which I am not acquainted.

In the preparation of the trianospermina of Peckolt (the tayuyinum of Martius) the alcoholic extract of the root is treated with cold water, which leaves the resins undissolved. The solution is freed from precipitable matter by treatment with the neutral and basic acetates of lead successively; after filtration excess of lead is removed by sulphuretted hydrogen, the solution is again filtered, then evaporated to a syrupy consistence, and the salts of potash allowed to crystallize, and separated. Alcohol is added to the mother liquor to separate gum, and ether to the filtrate to separate sugar, and the liquid evaporated to dryness. The amorphous residue is redissolved in water and the solution precipitated with tannic acid. The precipitate is dried, triturated with calcined magnesia, dried, and exhausted with alcohol; the resulting tincture is evaporated to a syrupy consistence and shaken with ether. The ether takes up the trianospermitina, which crystallizes upon evaporation. The liquor separated from the ether contains trianospermina (tayuyinum) and a bitter substance; the one crystallizes upon the addition of alcohol and is separated, the other remains in the mother liquor.

Trianospermina occurs in colourless and odourless needles; it has a rather pungent taste and an alkaline reaction. When heated it volatilizes completely. It is soluble in water, such a solution being precipitated by basic acetate of lead and perchloride of platinum. It is also soluble in alcohol and in ether.

Buenos Ayres.

SATUREJA JULIANA.*

BY P. SPICA.

This plant, called "*erva de ibbisi*" in the Sicilian dialect, is used by the peasantry to prepare a decoction which is taken in cases of intermittent fever; it is a herbaceous plant of the labiate order, having an aromatic odour, and somewhat pungent taste. In order to ascertain to what the active properties of the plant were due, the residue left on evaporating the alcoholic extract of the plant was washed with cold alcohol to free it as much as possible from chlorophyll, then dissolved in boiling alcohol, precipitated with an alcoholic solution of lead acetate, and filtered boiling. After separating the excess of lead by adding ammonia carbonate to the clear liquid, it was concentrated and precipitated with water. The substance was further purified by treating its alcoholic solution with animal charcoal and again precipitated with water. The white gelatinous product was separated by means of ether into two compounds, one of which, moderately soluble in ether (m. p. 204—205°), gave numbers agreeing with the formula $C_{34}H_{58}O_4$, or, with less probability, $C_9H_{16}O$. The other substance, which is much less soluble in ether, especially in the cold, does not melt even at 250°, and above that temperature it is decomposed; the results of the analysis agree with the formula $C_{35}H_{56}O_4$. The more soluble substance acquires a greenish-yellow tinge when boiled with dilute sulphuric acid, but otherwise remains unchanged; a minute quantity dissolves, but the solution does not reduce Fehling's test, although when evaporated at 100° it blackens and emits an odour between that of wax and caramel. This is only a preliminary notice, the author intending to examine the plant more carefully as soon as he can obtain a sufficient quantity.

NEW PRESERVING FLUID.†

The Prussian Secretary of State for Education has caused the publication of the following compound, and method of its application, discovered by Wickersheimer, the preparator of the anatomical museum of the University at Berlin, who had at first patented the compound, but was induced to renounce his patent claims.

1. *Liquid.*—In 3000 parts of boiling water dissolve 100 of alum, 25 of sodium chloride, 12 of potassium nitrate, 60 of potassa, and 10 of arsenious acid. Let cool and filter. To every 10 litres of the filtrate, add 4 litres of glycerin, and 1 litre of methylic alcohol.

2. *Use.*—Its application differs with the special objects to be preserved. In general, the objects must be impregnated with it. If the objects are to be preserved dry, they are soaked in the liquid from six to twelve days, and afterwards dried in the air. Ligaments, muscles, and other animal objects remain perfectly soft and moveable. Hollow organs, as lungs, intestines, should be filled with the liquid, previous to immersion in it. After being taken out, and before drying, it is advisable to inflate them with air. Injecting the liquid into a corpse, will preserve the latter completely, and the muscular tissue will always retain the natural colour of fresh corpses. To preserve the external appearance of the latter, they should be well impregnated externally, and enclosed in air-tight cases. This is only necessary to preserve the exact original appearance; if it is not done, the body will keep equally well, if thoroughly injected, but the exterior will gradually become somewhat dry and dark coloured. Plants may likewise be preserved by this liquid.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 21, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF POISONS AND CHEMISTS' CHARGES.

THE outcry against the abuse of narcotics, which, like a nine days' wonder, ran the round of the daily papers some weeks since, was certainly deserving of consideration in so far as it related to the baneful practice which we are assured has in various ways become habitual with a large number of persons. And if the consideration of this subject were prosecuted with a temperate regard to fact, it is possible that some good might be effected by striking at the root of the inducements to use such drugs without proper medical direction, and of the facilities by which persons disposed to such indulgences succeed in obtaining their supplies of narcotics.

Accepting the medical testimony given as to the vast extent of the evil and its mischievous consequences, there seems to be ample reason for recognizing the necessity for interference. We do not in the least degree question the propriety of accepting that testimony, and there are, moreover, other circumstances which justify inferences in support of it. Those who are best informed as to the facts of the case must therefore regret to see that many of the writers dealing with the subject have abandoned the rational course of seeking to expose the ways in which harm is done, and to suggest practicable means of counteracting it, and have devoted themselves to launching vague as well as unfounded charges againsts chemists and druggists.

The example first set in this direction by the coroner for Doncaster, who condemned the Council of the Pharmaceutical Society for not doing what it was not the business of that body to do, has more recently been followed by others who endeavour to throw upon chemists and druggists the entire responsibility for the misuse of narcotics and other dangerous drugs. In regard to the sale of these and other poisonous articles in the form of patent medicines, for instance, the actual state of the law is entirely disregarded, and notwithstanding the fact that the sixteenth section of the Pharmacy Act exempts patent medicines from the operation of the antecedent provisions as to the sale of poisons, chemists and druggists are blamed for selling patent medicines containing poison as though their doing so indicated a disregard for the public good and an actual breach of the law.

It should, however, be remembered that whatever mischief may be done by the sale of some patent medicines without precautionary labels, and the various other observances that are by law necessary in selling the poisons in their undisguised state, it is not the chemist and druggist that is in fault, but the present state of the law. In the first place the composition of patent medicines being secret, it is merely a matter of conjecture that any one of them contains poisons. Beyond this the sale of patent medicines is a branch of business that is not confined to chemists and druggists, but may be carried on by any one who pays five shillings a year to the Government for a licence.

But even under these circumstances it is probable that a remedy might be found for any mischief resulting from the sale of patent medicines containing poison, for although the sixteenth section of the Pharmacy Act exempts patent medicines from being subject to the preceding portion of the Act, the seventeenth section declares that it shall be unlawful to sell any poison either by wholesale or retail unless the box, bottle, vessel, wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and the word "poison," and with the name and address of the seller of the poison.

Legal authorities are of opinion that this section of the Pharmacy Act is in itself amply sufficient both for preventing the sale of patent medicines containing poison without the observance of such precautions as are proper for warning purchasers against the danger of misusing them, and also for punishing any persons who sell them incautiously. It is considered that all that would be requisite for this purpose would be the proof that the article in question did, as a matter of fact, contain poison, and that the provisions of the seventeenth section had not been observed by the seller. So far this section applies to the sale of "any poison," and these words appear to have a wider scope than the poisons within the meaning of the Act, which are enumerated in schedule A. This is further indicated by the fact that after declaring it shall be unlawful to sell "any poison," except in accordance with the provisions above mentioned, the same section goes on to specify how the poisons within the meaning of the Act are to be sold, and it declares that it shall be unlawful to sell any one of those poisons which are in the first part of schedule A to any person unknown to the seller unless introduced by some person known to the seller and without making an entry in a book kept for the purpose, stating the date of the sale, the name and address of the purchaser, the name and quantity of the article sold, and the purpose for which it is required. This entry is to be signed by the purchaser, and any person selling poison otherwise than as provided in the section is liable upon summary conviction to a penalty of five pounds for the first offence and of ten pounds for the second or any subsequent offence.

If the opinion we have referred to be correct, that the provisions of the seventeenth section of the Pharmacy Act are applicable to the sale of patent medicines containing poison, a ready and effectual remedy for the indiscriminate sale of these articles is already in existence, and it is in the power of anyone to have recourse to it. If such be the case, there is no ground for the complaint lately made in the newspapers, that nothing is easier than to evade the whole letter and spirit of the Pharmacy Act. The patent medicine stamp would no longer act as a protection by which poisons could be distributed broadcast, "under artfully-designed names," with the result of producing serious mischief. The *Manchester Courier* had lately the following sensible remarks on this subject:—

"But is it quite true that the law as it stands is not strong enough to reach the cases? If deadly poisons are being sold as patent medicines surely the magistrates have power under the Sale of Poisons Act to deal with them, whatever be the names adopted to conceal the true nature of the transaction. An analytical chemist would have no difficulty in discovering the real character of these dangerous preparations, and if a representation were made to the magistrates, and it was found to be impossible to deal with them in consequence of the stamp, the Legislature would then have good reason to provide fresh precautions for the public safety."

Amongst members of the drug trade, an opinion has for some time past been gaining ground that in accordance with the general spirit of the Pharmacy Act, none but specially qualified persons should be permitted to engage in the sale of poisons or dangerous drugs under any conditions, either in their normal state or in the form of patent medicines, and there is now a decided disposition to apply to Parliament for a repeal of the exempting provision of the Pharmacy Act. At the present time the opportunity is favourable for such a step, in so far as there has been a strong expression of opinion on the subject of the mischief done by the secret and dangerous narcotic preparations in common use. But the view of the case suggested by our Manchester contemporary seems to promise a more speedy and certain result, and one that would be to a large extent effectual in securing the object desired.

Another of the modes of attacking chemists and druggists has been well illustrated by an anonymous writer in the *Times* of last Monday, who describes himself as "A Physician," and from that point of view expounds his views on "the outrageous character of chemists' charges." The signature adopted by this writer is one calculated to carry some weight with the public, and probably more than the publication of his real name would have entitled him to. His opinions are very strong and decided, but they are so little in accord with those entertained by physicians who from extended practice are brought into frequent communication with dispensing chemists, that we are disposed to infer he is "A Physician" of the order which delight in the display of a big brass plate announcing the multifarious nature of their practice in virtue of second-rate qualifications. If this inference is correct, we need not wonder that "A Physician" should express astonishment that a dispensing chemist, or shopkeeper as he terms him, did not profess to charge for medicine according to the cost of drugs. This quotation alone is sufficient to gauge the fitness of "A Physician" to constitute himself the censor of chemists' charges, and it is only the publication of his letter in the *Times* that lends some kind of adventitious importance to his opinions.

It may be assumed that it was on this account mainly that the President of the Pharmaceutical Society has replied to "A Physician" and exposed the fallacious nature of the statements in which he charges chemists with making extortionate charges for dispensing medicines. Mr. SANDFORD accounts for the opinions of "A Physician" by suggesting that he imagines compounding a mixture according to a prescription is just as simple an operation as retailing tea and sugar, and he disposes of the argument drawn from the alleged intrinsic value of the ingredients in a particular mixture referred to by showing that since the three-halfpence worth of material may have been arsenic, strychnine, prussic acid, or some other deadly poison, it was not the value of it that was to be considered in regard to the remuneration of the dispenser, but the skill, care, and responsibility involved in the performance of his duties so as not to endanger the patient's life. A person who was by mistake served with two pounds of butter for the price of one pound would certainly be less damaged than the butterman; but if some patient of "A Physician" furnished with medicine under similar conditions had a drachm of strychnine put into his mixture instead of a grain the disadvantage to him would be disproportionately greater than that to the dispensing chemist. But it is scarcely necessary to argue this matter, for as Mr. SANDFORD says, with good reason, chemists may rejoice in the confident assurance that the better class of physicians and surgeons heartily acknowledge the right of chemists to be fairly remunerated for skill and responsibility in the exercise of their calling.

PROSECUTION FOR THE SALE OF ALLEGED DEFECTIVE MERCURIAL OINTMENT.

JUST at the time of going to press we learn that in a prosecution of a chemist and druggist at Droxford, for the sale of a preparation that was labelled "mild mercurial ointment," on the ground that it was not of the British Pharmacopœia strength, the magistrates have dismissed the case and allowed costs.

CHEMISTS' ASSISTANTS' ASSOCIATION.

THE next meeting of the above Association will be held on February 25, at 32A, George Street, Hanover Square, when a paper on "New Remedies," will be read by Mr. I. R. JAMES.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING will be held on Thursday the 26th inst., at 8·30 p.m., when a paper will be read by Mr. E. A. REILLY on "Butter Analysis," and a report will be made on Organic Chemistry.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, January 7, 1880.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President; Dr. A. Smith, Vice-President; Mr. Brunker, Dr. Collins, Mr. Doran (Bray), Mr. Goodwin, Mr. Hayes, Mr. Hodgson, Mr. Holmes, Mr. Simpson.

The minutes of the meeting held on December 3, 1879, were read and signed.

The President informed the meeting of the death, on January 6, of Mr William Allen, of Henry Street, Dublin, a member of the Council.

Proposed by Mr. Hodgson, seconded by Dr. Collins, and resolved:—

"That we have heard with much regret of the death of our respected colleague, William Allen, Esq., of Henry Street; and we desire to convey the expression of our sincere sympathy to Mrs. Allen, and the members of her family, under their sad bereavement."

Read a letter, dated November, 29, 1879, from Dr. A. H. Jacob, respecting a death from poison at Coagh, Co. Tyrone.

The Registrar was directed to acknowledge the receipt of the letter, and ask for particulars of the case, with a view to action by the Council.

Read a letter, dated December 2, 1879, from Dr. Grimshaw, the Registrar-General of Births and Deaths for Ireland, informing the Council that he had issued a circular to all the registrars of deaths in Ireland, requiring them to send information to the Registrar of this Society of the death of every pharmaceutical chemist which takes place in Ireland.

The receipt of Dr. Grimshaw's letter to be acknowledged, with thanks.

Read a letter, dated December 22, 1879, from Dr. Mason, Secretary to the Ledwich School of Medicine, Dublin, asking the Council to recognize the lectures of that school.

The Registrar was instructed to acknowledge the letter from the Ledwich School of Medicine, and to state in reply that we do not require lectures, and consequently cannot grant the request.

Proposed by Mr. Brunker, seconded by Mr. Hayes, and resolved:—

"That in respect to the memory of the late Mr. Allen, the meeting do now adjourn to Wednesday, 14th inst., at the usual hour."

ADJOURNED MEETING OF THE COUNCIL.

Wednesday, January 14, 1880.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President; Dr. A. Smith, Vice-President; Sir George Owens, M.D., Messrs. Brunker, Doran (Bray), Goodwin, Hayes, Holmes, Oldham, Simpson.

Proposed by Mr. Holmes, seconded by Dr. Aquilla Smith, and resolved:—

"That William Whitla, M.D., L.A.H., of Monaghan, be elected a member of Council in the place of Mr. Allen, deceased."

Proposed by Dr. A. Smith, seconded by Mr. Holmes, and resolved:—

"That Mr. Stanley Oldham be appointed auditor, in the place of the late Mr. Allen."

The reports of the Preliminary examination held on Monday, January 5, and of the examination for the licence as pharmaceutical chemist held on Wednesday, January 7, were laid on the table.

Seven candidates presented themselves at the Preliminary examination, of whom six passed, and one was rejected.

At the Pharmaceutical examination, five candidates presented themselves, of whom one failed, and the following four passed, and were registered as pharmaceutical chemists:—

John Patrick Harold, Ormond Quay, Dublin.
John Murphy, Queenstown, Co. Cork.
Robert O'Halloran, George Street, Limerick.
Michael Joseph O'Reilly, Bolton Street, Dublin.

Proposed by Mr. Hayes, seconded by Mr. Brunker, and resolved:—

"That the clauses as to fees in pages 64 and 66 of the Calendar be amended to read thus:—

Page 64 (*Preliminary Examination*).

"In case of rejection, the fee of £2 2*s*. shall be retained; but the candidate may present himself, after the lapse of six months, for a second examination without additional payment."

"In any further examination the candidate will be required to pay the amount of the examiner's fee."

Page 66 (*Pharmaceutical Examination*).

"In case of rejection, the fee of £5 5*s*. shall be retained, but the candidate may present himself, after the lapse of six months for a second examination, without additional payment."

"A rejected candidate may present himself again for re-examination after a lapse of six months; but he will be required to pay the amount of the examiners' fees."

Proposed by Dr. A. Smith, seconded by Mr. Holmes, and resolved:—

"That one thousand copies of the 'Sale of Poisons (Ireland) Act, 1870,' and also of the 'Pharmacy (Ireland) Act, 1875,' be printed, and be kept in stock."

Messrs. Browne and Nolan's bill for stationery for the past year was ordered for payment, and the Council then rose.

The next meeting of Council will be held on Wednesday, March 3, and not on March 5 as stated by mistake in last week's Journal.

OBITUARY.

The Registrar has received official information of the deaths of the following Pharmaceutical Chemists:—

On the 4th of April, 1878, at Cartron Lodge, Sligo, Mr. John Denning, of Sligo. Aged 29 years.

On the 12th of August, 1879, at No. 3, Emerald Terrace, Dublin, Mr. John Marischal Diack, late of Fairview, Co. Dublin. Aged 41 years. Mr. Diack had been a Member of the Pharmaceutical Society of Ireland since November, 1876.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The ninth general meeting was held at the Royal Institution on Thursday evening, February 12, the President, Dr. Charles Symes, in the chair.

The minutes of the previous meeting having been read and confirmed, the following donations were announced:—The current number of the *Pharmaceutical Journal* and the Calendar of the Pharmaceutical Society of Great Britain for 1880, from the Society; the Twenty-seventh Annual Report of the Liverpool Free Public Library; and the Report of the Liverpool Engineering Society for 1879.

Mr. William J. Rogers was elected an associate.

Mr. Edward Davies, F.C.S., called attention to a new method of preparing hydriodic and hydrobromic acids. The process for hydriodic acid consists in heating a mixture composed of 20 grams of iodine and 60 grams of copaiba oil in a retort connected with an upright condenser and purifying the gas by passing it through a drying tube. As the evolution of gas slackens fresh iodine is added and the process continued until 150 grams of iodine have been used.

In preparing hydrobromic acid by this method, the bromine must be slowly dropped into the retort containing the oil and the gas purified by passing through three drying towers.

After a few other communications of a miscellaneous character, the President read the paper for the evening, entitled—

The Relation of the Pharmacist to the Pharmacopœia.

BY C. SYMES, PH.D.

The existing and growing importance of the Pharmacopœia is, I feel assured, a sufficient apology (if, indeed, apology be needed) for bringing the subject before the members of this Association this evening. Indeed, this very importance makes me hesitate to deal with the relationship, seeing that I have neither time nor opportunity for dealing with it as thoroughly as I could wish, or it deserves.

We are, or ought to be, on the eve of preparation for a new edition of the British Pharmacopœia. Some copies of this work are probably still on hand, but I trust no sordid considerations have been the cause of delaying what is admitted on all hands to be a necessity demanding early attention.

Let us first consider the nature of the work itself and then the duties, qualifications and responsibilities of those who have to do with it.

The word pharmacopœia has been applied to various books more or less related to pharmacy and therapeutics, but *the* Pharmacopœia at once suggests a work possessing authority, the dictates of which are enforced by law.

I need not trouble you with the early continental pharmacopœias, dating from Nuremberg, 1542; in fact, a full description of them, were I in a position to give it, would in no way help our subject. The first work of the kind in this country was published in 1618 by the Royal College of Physicians, and was known as the London Pharmacopœia. Successive editions appeared in 1627, 1635, 1650, 1697, 1721, 1746, 1787, 1809, 1824, 1836 and 1851. The pharmacopœia by the Edinburgh College of Physicians was first published in 1699, for use in Scotland, and that of Dublin, for Ireland, not until 1807. These works were intended to indicate the particular kind of drugs and chemicals which were regarded as the most important of medicinal agents, to provide formulæ whereby they should be prepared and rendered suitable for administration, and to form the official medium of communication on those subjects between the physicians and the apothecaries; for apothecaries were then, and, indeed, have been until quite recent times, the legally recognized dispensers of medicines in the three countries. As might be supposed, the earlier London editions did not long satisfy the requirements of those who had to use them, hence they appeared in somewhat rapid succession. The materia medica was largely composed of animal substances of a nature somewhat disgusting to our modern cultivated tastes. The elixirs, confections, unguents, etc., were composed of ingredients whose name was legion, which were compounded according to formulæ based on empiricism, a single remedy often appearing in varied forms, such as crabs' eyes, oyster shells, stag's horn, etc. No scientific exposition could be given of the action of the remedies and no logical explanation of the simple, yet tedious, processes which they were put through to render them fit for the mysterious ignorance which encircled the healing art. The works were written in the Latin language, and the processes, imperfectly described, were gone through with the most religious observance of detail, often without in any way affecting the substance operated on, so that clearly no pharmaceutical skill was required. By the date of the first Dublin work, 1807, pharmacy had made some real progress, and pharmacopœias had discarded many useless remedies and introduced others of a more rational kind; the various processes had been revised and slowly brought more or less in accord with the dictates of science. But it was only slowly—very slowly—that physicians gave up prescribing barbarous remedies; indeed, within the present week we have prepared what may be regarded as a relic of the past, in the form of tinctura fuliginis, for which we, in common with other houses, have an occasional demand.

Three different pharmacopœias, published by three different colleges, in the United Kingdom, could not fail to possess differences which might, and doubtless did, occasionally lead to serious consequences, and in the early part of the present century suggestions were made for the production of a British Pharmacopœia. But so great were the prejudices to be overcome, and so slowly were concessions made, that it was not until 1864 that the work was accomplished. There were reasons for the delay, one of which corresponds with the suggestion that I have given at the commencement of this paper as possibly acting prejudicially against the immediate issue of a new edition of the existing work.

In the *Pharmaceutical Journal*, January 1, 1846, it is stated that the first official attempt to obtain a united pharmacopœia had been made and had failed, it further adds, "The distance between the three capitals was the assigned cause of the failure of the attempt; but there is reason to believe that other obstacles existed. We have been told that the Dublin College having, at the time the proposition was first made, recently printed a large edition of their pharmacopœia was unwilling either to indemnify the publisher, or to inflict on him the injury which he would have sustained by the sacrifice of his stock on hand, in the event of the work being superseded."

The Medical Act of 1858 conferred on the General Medical Council the right of "publishing under their direction a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed; and containing such of the matter relating thereto as the General Council shall think fit, to be called the British Pharmacopœia, which, shall, for all purposes, be deemed to be substituted throughout Great Britain and Ireland for the several above mentioned pharmacopœias." The first result, which appeared in 1864, was, as you all know, an acknowledged failure, and it was soon found desirable to supersede it by a new edition, which appeared in 1867, to which has since been added an appendix. This is by far the best work of the kind that has been produced in this country. That pharmacopœias have not always been regarded as models of perfection is evident from the following remarks by Professor Redwood in his second edition of Gray's 'Supplement.' "But the value of these formulæ is not, in all cases, confined to the aid afforded to the pharmaceutist in dispensing prescriptions; many of them are for processes the products of which are identical with those ordered in our own pharmacopœias, yet the instructions being different and sometimes better, they may be advantageously referred to by the manufacturer, the scientific inquirer, and those engaged in framing new pharmacopœias." Here then, imperfection in working details at that date (1848) are clearly recognized, and however perfect the present book might have been when published in 1867 there must now be much that requires revision and much that ought to be added; if in the seventeenth century a pharmacopœia became obsolete in a few years, what must a work of the kind be after thirteen years' existence amid the rapid strides of chemistry and pharmacy in the latter part of the nineteenth century?

Let us now turn to consider the pharmacist and see what his position has been and his relation is to the Pharmacopœia.

One of the earliest and by no means the least distinguished of pharmacists in this country was Ambrose

Godfrey Hankwitz, who flourished early in the eighteenth century and whose interesting history has been epitomized by Mr. Ince (*Pharm. Journ.*, vol. xviii., pp. 126, 157 and 215, 1st series). We cannot, however, follow the progress from his time to the present from the information at my disposal, but passing over nearly a century we find ignorance largely prevailing, the practice of pharmacy largely in the hands of apothecaries, who, prescribing for and treating diseases, failed to give attention to chemistry and the science of pharmacy (probably found it more profitable), and so the remedies they used and dispensed were carelessly prepared. Gradually, however, men who were essentially chemists and druggists developed, and leaving the practice of medicine to the physician and apothecary, devoted themselves specially to the preparation and dispensing of medicines, and the superior knowledge of those subjects which they thus gained soon attracted the notice and jealousy of the latter; but truth and right must sooner or later prevail, and notwithstanding various attempts on the part of the apothecaries to put down their opponents, they grew and prospered. Indeed, this very persecution, together with measures of medical reform, which included vexatious clauses bearing on chemists and druggists, had the effect of bringing them together for defensive purposes and the maintenance of their rights, and ultimately founding the Pharmaceutical Society. This Society laid down for itself a grand programme, not merely for the defence of trade interests, but for the better education of pharmacists and for elevating the practice of pharmacy, the necessity for which will be evident from some remarks in an editorial by one of its most worthy founders, Jacob Bell, in 1844 (*Pharm. Journ.*, vol. iv., p. 1, 1st series), "In almost every civilized country, the education of pharmaceutists and the practice of pharmacy are regulated by stringent laws, and, as well as other matters relating to public health, under the control of the Government. In Great Britain this has never been the case, and while the Legislature has not overlooked the safety of the public in reference to medical practitioners, the compounders and vendors of medicine have been passed over and allowed to take their own course. As a natural consequence of this oversight a great number of uneducated persons have encroached upon the province of the chemist and druggist, who have therefore been stigmatized as a body of men possessing no legal qualification and comprising many individuals unworthy of confidence."

Although there were men of undoubted ability within the ranks in those days, yet it is quite certain that the charge of ignorance did not apply solely to the interlopers here referred to. Mr. Phillips's 'Illustrations of the Present State of Pharmacy in England,' given about that date, is really an unfavourable criticism on the pharmacist. Time and effort wrought considerable advancement, and fifteen years later Mr. Bell writes, "When it was proposed to constitute pharmacy, on the ground of qualification, as a branch of the profession, the general opinion might be condensed into these words, 'It may be desirable, but you will never succeed.' While the existing defects in this department of medicine were continually felt, and occasionally brought under public notice by some serious or fatal event resulting from the incautious use of dangerous materials by ignorant persons, the notion of converting the trade of a chemist and druggist into a profession was not popular, and would probably never have been attempted if circumstances had not combined, at a favourable moment, to excite some *esprit de corps* among the previously disunited members of the pharmaceutical body. . . . The Pharmaceutical Society is no longer a theory, all that was projected at the outset has been carried into practice, and only requires to be perservered in and allowed to proceed, in order to realize all that the most sanguine hopes could have imagined."

This prophecy has been amply fulfilled, and at the present moment there are distributed throughout the country men of ability, both in the science and practice of pharmacy, sufficiently numerous to demonstrate both to the medical profession and the public that the labours of the Pharmaceutical Society have not been in vain. We have already seen that pharmacy was originally in the hands of the apothecary, and that as his knowledge increased in the practice of medicine, so it diminished in the science and art of preparing the remedies, and as the medical practitioner of to-day is considerably in advance of the apothecary of fifty years ago in the practice of medicine, so is the pharmacist of to-day equally in advance of him in the practice of pharmacy. As these two distinct, yet closely allied, professions have developed and have approached their natural position, so has each left to the other the study of its particular subjects, and as a necessary result the physician and the surgeon of the present day know very little of practical pharmacy. It is true the curriculum of medical education requires attendance at a course of lectures in chemistry, botany, and materia medica and three months' practical chemistry, but the majority of students go through these as a matter of form, as a burden they would willingly be rid of. They regard anatomy, physiology, pathology and the practice of medicine as their sheet anchor, and as constituting the essentials of their profession; and this view is not only one pertaining to the students, but is endorsed by men of position.

The book we were just now considering, viz., the Pharmacopœia, is one in the compilation or revision of which thorough knowledge of botany, materia medica, chemistry and practical pharmacy are essential, and were I to tell you that in China or Japan the production of such a work was entrusted to a highly respectable class of men, but who had not made these subjects their special study, while there existed amongst them a body of men who had made these branches of science their almost exclusive study, and yet these latter had no real share or recognized position in the editorship, you would regard it as one of the many absurdities with which we accredit benighted people. But when we find that it is in enlightened England where such an anomaly exists there is good reason for expressing astonishment. A certain relationship does exist between the pharmacist and the Pharmacopœia, but certainly not that of authorship; it is a law to him; a law in the framing of which he has no share, and which often deals harshly and unjustly with them. It prescribes the official drugs and chemicals which he shall employ, tests for determining their purity, processes for preparation and descriptions more or less of what such preparations should be, and as from what I have said it is not probable that all this is correctly rendered, it is obviously unfair that the responsibility of any imperfections should rest on the pharmacist, which in practice it does.

In the hands of certain ignorant and overbearing public analysts this work has been an instrument by which a considerable amount of injustice has been perpetrated, instances of which have became quite familiar to us; happily not in our own town, from the fact that we have a gentleman in that capacity not only possessing considerable ability, but also good common sense.

New processes and new remedies are constantly arising, but these are of no avail to the physician until they have passed through the hands of the pharmacist. Is it not reasonable, then, to assume that in the revision of so important a work as the British Pharmacopœia he should have a legal position on an editorial committee?

Taking the United States Pharmacopœia as the one which best compares with our own, the national convention for its revision is composed of physicians and pharmacists; the latter not being brought in by some side wind to furnish gratuitous and unacknowledged advice, but with an acknowledged position in which they confer on terms of equality with those who represent the higher professional position. It would certainly be well were the number of the latter somewhat increased; but even as the body is now constituted, a very excellent work is produced, in which the substantial results of progressive knowledge are utilized, and such as is unreal or unproved is discarded. A quotation from the preface of the last edition will show the tendency and scope of the work. "In accordance with the resolution of the convocation, the scope of the work has been extended rather than abridged; and it has been the desire of the committee to adapt it to the wants of our extended country without losing sight of the conservative character necessarily pertaining to a national pharmacopœia. Such a work must necessarily follow in the wake of advancing knowledge, it is no part of its mission to lead to the paths of discovery. It should gather up and hoard what has been determined to be positive improvement, without pandering to fashion, or to doubtful novelties in pharmaceutical science. By such apprehension of the duties imposed upon it has the committee been guided." There is certainly nothing too advanced in this; indeed, the present number of *New Remedies*, which has come to hand just as I am closing this paper, contains an editorial article so thoroughly *apropos* that I will trespass on your time to make a quotation from it. It is a criticism on a recent paper by Dr. Edes, of Boston, Professor of Materia Medica and Therapeutics in the Harvard University, entitled "The Relation of Drug Manufacturers to the Progress of Therapeutics." The doctor appears to object to the large number of medicines in use, and says, "If one has in his pocket a vial of morphia and another of sulphate of atropia he has all that is essential in thirty-two preparations." The critic says—"The object of the Pharmacopœia is to offer definite and carefully considered standards and processes for all drugs and galenical preparations which are likely to be employed in the practice of physicians; and just so far as it fails to meet this demand, does it encourage manufacturing pharmacists to make and sell preparations peculiar to themselves. The fact of the matter is, that most physicians, like Dr. Edes, ignore the fact that pharmacopœial revision can only be effective when they co-operate with pharmacists in agreeing upon such standards, and, therefore, pharmacopœial revision has been left to a few who have become more noted for an obstinate adherence to bygone customs than for an appreciation of present needs."

Now if these remarks apply at all in America, how much more do they in this country, where the right of pharmacists to dictate in any way in pharmacopœial revision is utterly ignored. Indeed so hopeless does the position appear at present that a motion in the Pharmaceutical Council by Mr. Hampson, supported by Mr. Schacht, Mr. Greenish and myself, proposing to make an attempt to obtain such legal position, although it received some sympathy from other members, was thought either unwise or premature at present and was lost by a large majority, and doubtless the gentlemen who opposed had good reasons for entertaining the opinion they did (*Pharm. Journ.*, Dec. 6, p. 452). Until, however, the Pharmacopœia Committee is properly constituted we shall have little real progress; little real sympathy between men who should be working hand in hand for the benefit of the two professions.

In conclusion let me offer a few remarks on one or two preparations as illustrative of the benefit that would arise from the proposed interchange of views between prescribers and dispensers of medicines. It has been ascertained that continued boiling injures the medicinal efficacy of senega, consequently the decoction which was officinal in the P.L. is absent in the B.P., its place being filled by the infusion, and yet most medical men prescribe the decoction; omitting it from the Pharmacopœia clearly does not prevent its being prescribed or impart information to the prescriber. Fluid extract of bark is usually assumed to be four times the strength of the bark itself, and is prescribed in doses accordingly; whereas, it is known to pharmacists that such is not the case and if this becomes known to the practitioner he falls back on the preparation of some special maker, just as he does with regard to phosphorus pills when he finds those of the B.P. useless unless combined in some form. Liq. atropiæ, B.P. is sometimes prescribed as "drops for the eye," but is not the preparation intended, as the spirit present causes considerable pain when applied. This preparation might with advantage be omitted from the Pharmacopœia, inasmuch as the neutral solution of the sulphate answers equally all purposes. These and many other things might be known, but the average practitioner does not hold the average pharmacist in sufficiently high esteem to learn from him.

If, however, a Pharmacopœia Committee, such as I have indicated, were constituted, and its members met from time to time to consider and discuss the matter in hand, and were to issue reports of progress, such reports would be read with interest by all concerned and would shed light where now much obscurity prevails. The work when finished would approach perfection much more closely than it now does; our position as pharmacists would be advanced and brought into accord with that of our continental and transatlantic brethren; indeed the benefit would be mutual and all would soon feel the advantage of a properly existing relationship between the physician, the pharmacist and the Pharmacopœia.

The paper gave rise to the following discussion:—

Mr. A. H. Mason, in proposing a vote of thanks, said that the right of pharmacists to have a voice in pharmacopœial revision was indisputable, and agreed with Dr. Symes that a committee consisting of medical men and pharmacists would be a more competent body than a committee consisting of medical men only. The fact, however, must not be overlooked that the Medical Council availed themselves of the service of able pharmacists in the work of revision, and that they had also the privilege of taking note of the opinions and experiences of pharmacists from the various journals in which such were published, and he considered that by this latter means the practical knowledge of pharmacists could, in a very satisfactory manner, be brought to bear upon the work of revision.

Mr. R. Sumner had great pleasure in seconding the vote of thanks. He thoroughly concurred in what had been said by Dr. Symes respecting the importance of having men upon the Pharmacopœia Committee who were thoroughly conversant with pharmaceutical operations, and he considered that the Pharmaceutical Council would be acting in conformity with the wishes of pharmacists by using their influence to obtain this privilege.

Mr. Conroy, though agreeing with Dr. Symes as to the desirability of having competent pharmacists on the Pharmacopœia Revision Committee, thought that it would be undignified for a body like the Pharmaceutical Society to in any way attempt to thrust their services on the Medical Council, and more especially so when the manner in which their former advances in this matter had been met by that body was considered.

Mr. B. Dickens concurred in the desire that pharmacists should be permitted to bring their practical knowledge to the aid of the theoretical members of the Pharmacopœia Committee. He said that it would greatly assist dispensers if prescribers would adhere more than they sometimes do to the language of the Pharmacopœia, where its terms would express their intentions. A carefully drawn table of doses was also a desideratum, and he would like to see adopted the practice which had been so much advocated that prescribers ordering a dose exceeding the maximum in such a table should so emphasize their writing as to make the intention manifest; the chemist would then feel no hesitation in supplying it.

Dr. Symes, in reply, said that it was quite true the Pharmacopœia Committee could take note of any new preparations and new processes which appeared in the various journals; indeed a sum of money had been granted for the purpose of keeping a record of such things for use in future editions; but this only partially met the requirements; it was in the unpublished, minor, practical details that a pharmacopœia usually erred. Such details could, of course, be furnished privately by practical pharmacists; but such would not be representative. The preface of the Pharmacopœia acknowledged that Professor Redwood and Mr. Warington had really done the work of revision on the last occasion under a committee of physicians; but that was not pharmaceutical representation either. They had no legal standing, no voice, no vote, as to what should be inserted or omitted, or how this or that should be prepared, and the Committee could alter their work as they pleased. He was pleased to have the support of an old member of the Association like Mr. Sumner in the views he had put forward. He (Dr. Symes) had not considered the question of doses in this paper. As regards the Pharmacopœia, it was a medical one; but Mr. Dickens's remarks were very *apropos* on the present occasion. It would be remembered that about two years ago a chemist refused to dispense half an ounce of tincture of digitalis for a dose; the patient, suffering from delirium tremens, died, and there was considerable discussion of the subject both in medical and pharmaceutical journals. It was suggested on all hands that some special indication of the intent should be given when large doses such as these were prescribed. This matter was quite as serious, perhaps more so, to the pharmaceutical than to the medical profession, and yet nothing satisfactory had been arrived at. This particular case had been forgotten, and the question of large doses now remained exactly where it did before. If such a committee as he had suggested were in existence they would doubtless deal with such a question, and arrive at satisfactory results and recommendations, which, possessing authority, would be regarded.

A unanimous and hearty vote of thanks having been passed to Dr. Symes, the meeting closed.

MEETING OF THE CHEMISTS AND DRUGGISTS OF BRISTOL AND CLIFTON.

A meeting of the chemists and druggists of Bristol and Clifton was held this day at the Athenæum.

A large majority of those practising pharmacy in the neighbourhood were present, and several letters explaining unavoidable absence were forwarded.

Mr. G. F. Schacht was requested to preside.

The Chairman briefly stated the cause of their assembling together—namely, the recent public announcement on the part of an important "wholesale and retail" firm of pharmacists trading in Bristol of their adoption of "co-operative" prices in the retail portion of their trade, accompanied by the issue of a cheap price-list, a copy of which they had forwarded to every family in the neighbourhood, and he invited a free discussion of the position thus thrust upon them.

After ample consideration of the whole subject, the following statement of opinion was unanimously adopted:

"It is the opinion of the meeting that the application of so-called "co-operative" prices to retail pharmacy would, if generally adopted, render its practice as a separate and distinct industry absolutely impossible, and that therefore the trade of chemists and druggist would soon cease to exist.

"It is also the opinion of this meeting, that chemists and druggists as a body fulfil a distinct public want, and that their destruction would be not only a hardship to those now in business, but would be attended with great inconvenience to the public generally."

BUXTON.

A meeting was held at the Coffee Tavern, Spring Gardens, Buxton, on Friday, the 13th inst., the intent being to form a Chemists' Assistants and Apprentices' Association during the ensuing winter; Mr. G. Jackson in the chair. After a few preliminary remarks, the Chairman put to the vote the advisability of forming an association or not. The question was carried unanimously in the affirmative. The following were then elected officers:—Mr. H. Wilson, President; Mr. Chell, Treasurer; Mr. J. R. Lynn, Secretary.

It was then proposed to call a second meeting to discuss the plans and projects for the coming session.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Law and Parliamentary Committee of this Association was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on February 13, 1880, at 1 p.m.; Mr. Thomas Barclay (Birmingham), President, in the chair.

Present—Messrs. Andrews (London), Churchill (Birmingham), Cross (Shrewsbury), Hampson (London), Holdsworth (Birmingham), Symes (Liverpool), and the Solicitor of the Association.

The Secretary said Mr. Jones was too ill to be present.

Mr. Barclay said Mr. Southall was unwell and absent from home.

The minutes of the previous meeting of the committee were read and confirmed.

The Secretary reported that on October 10, 1879, Mr. E. Davis, of Newport, was defended by the Solicitor of the Association, acting under the instructions of the Committee, in an action brought against him under the Sale of Food and Drugs Act for the sale of soda water alleged to contain no soda, but a trace of lead,—Professor Attfield and Mr. Stoddart gave evidence in support of the defence; and that on January 9, 1880, Mr. William Blissett, of Romsey, was defended by the Association in an action under the same Act of Parliament for having sold cream of tartar containing 6 per cent. of tartrate of lime. Both these summonses were dismissed by the magistrates, but without costs. That was the second occasion upon which the Association had defended Mr. Blissett for prosecutions brought against him under that Act. The adjourned hearing of a third case, in which the Association was defending one of its members, would be heard on the 19th.

The Secretary said that in compliance with the instructions of the Committee he had, by means of printed and written communications addressed to various influential members of the trade residing in different parts of the country, obtained a number of suggestions as to the best means of restricting the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists. That he had also held private conferences in Hull, Bristol and Sheffield, all of which were well attended and at which a very strong opinion was expressed that the Pharmacy Act, 1868, should be amended in so far as it dealt with patent medicines. Some practical suggestions relating to this subject were also obtained from the gentlemen attending these conferences. The papers bearing on these matters were laid upon the table and carefully perused by the Committee. After a considerable amount of discussion, the Secretary was instructed to prepare a report for presentation to the next meeting of the Executive on the action that had been taken by the Committee, embodying the information and suggestions that he had obtained, and recommending that the Executive should approach the Council of the Pharmaceutical Society with a view to induce that body to take steps to so amend the Pharmacy Act, 1868, as to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists.

The Secretary reported that on February 6 last, he had given evidence for Messrs. Flux, Slade and Co., in the Birmingham County Court, in support of an action instituted by the Council of the Pharmaceutical Society against J. G. Earp, Cheapside, Birmingham, for an infringement of the 15th section of the Pharmacy Act, and that this was the first case in which that Society had used his evidence in a court of law.

The Secretary further reported that since the Committee had last met he had taken proceedings under the 17th section of the Pharmacy Act, in the police courts, against seven illegal traders, and that the particulars of these cases were as follows:—

William and Thomas Cussons and others, trading as the Hull and East Riding Supply Association, at Lansdowne Terrace, Beverley Road, Hull. Poison purchased, chloral hydrate and morphia pills. Fined 40*s.* and costs.

John Hayhurst, Bamber Bridge, Preston. Poison purchased, vermin killer. Fined 10*s.* and costs.

Daniel Tudor Williams, 4, Merchant Street, Aberdare. Poison purchased, sheep dipping composition. Fined 2*s.* 6*d.* and costs.

W. W. Brewis, 1, New Street, Newcastle. Poison purchased, vermin killer. Fined 40*s.* and costs.

Hubert Murray, 110, Kirkgate, Leeds. Poison purchased, oxalic acid. Fined 50*s.* and costs.

Theodore Morris, 119, Lodge Road, Birmingham. Poison purchased, laudanum. Fined 21*s.* and costs.

Thomas Theophilus Hutchinson, Summer Lane, Birmingham. Poison purchased, oxalic acid. Fined 20*s.* and costs.

Communications were read from a member of the Association stating that he had been threatened with proceedings for the recovery of damages, his assistant having sold quicksilver and nitric acid alleged to have been improperly mixed. After some considerable discussion, it was moved by Mr. Holdsworth, and seconded by Mr. Andrews:—"That the Solicitor be instructed to defend a member of the Association threatened with an action for damages, consequent upon the sale of nitric acid and mercury alleged to have been improperly mixed, should the Secretary find on personal inquiry that the statements submitted to the committee are substantiated."

On being put to the meeting, Messrs. Andrews, Barclay, Churchill and Holdsworth voted for, and Messrs. Cross and Hampson against the motion, Mr. Symes not voting. The motion was consequently carried.

The Secretary was instructed to obtain prints of the medical bills, to carefully peruse them, and if they appeared to contain any clauses affecting the interests of the trade, to then place them in the hands of the Solicitor for his opinion.

A number of communications were read from members of the Association and instructions given to the Secretary as to the manner in which he should deal with the same.

Proceedings of Scientific Societies.

ROYAL INSTITUTION OF GREAT BRITAIN.

Spectroscopic Investigation.*

BY JAMES DEWAR, M.A., F.R.S.,

Fullerian Professor of Chemistry, Royal Institution, etc.

In Kirchhoff's celebrated paper "On the Relation between the Radiating and Absorbing Powers of Different Bodies for Light and Heat," the remarkable experiments of reversing the bright lines of lithium and sodium by causing sunlight to pass through the vapours of those metals, volatilized in the flame of a Bunsen burner, are described. Bunsen and Kirchhoff reversed the stronger lines of potassium, calcium, strontium, and barium by deflagrating their chlorates with milk-sugar, before the slit of the solar spectroscope. Recent researches on the artificial formation of Fraunhofer lines have been made by Cornu, Lockyer and Roberts.

Cornu improved upon a method previously used by Foucault. It depends upon so arranging the electric arc that the continuous spectrum of the intensely heated poles is examined through an atmosphere of the metallic vapours volatilized around them. By this means Cornu succeeded in reversing several lines in the spectra of the following metals, in addition to those above mentioned, viz., thallium, lead, silver, aluminium, magnesium, cadmium, zinc and copper. He observed that, in general, the reversal began with the least refrangible of a group of lines, and gradually extended to the more refrangible lines of the group, and drew the conclusion that a very thin layer of vapour was sufficient for the reversal. In almost every case the lines reversed are the more highly refrangible of the lines characteristic of each metal.

Lockyer's plan was to view the electric arc through the vapours of the metals volatilized in a horizontal iron tube. The iron tube had its ends covered with glass plates, and was heated in a furnace, a current of hydrogen passing during the experiment. He did not succeed in observing any new reversal of bright lines, with the exception of an unknown absorption line which sometimes appeared when zinc was experimented upon. He confirmed, however, the channelled-space absorption spectra observed by Roscoe and Schuster in the cases of potassium and sodium, and recorded channelled-space spectra in the case of antimony, phosphorus (?), sulphur and arsenic (probably). "As the temperature employed for the volatilization of the metals did not exceed bright redness, or that at which cast iron readily melts, the range of metals examined was necessarily limited, and in order to extend these observations to the less fusible metals, as well as to ascertain whether the spectra of those volatilized at the lower temperature would be modified by the application of a greater degree of heat," a new series of experiments were undertaken by Lockyer and Roberts, in which the combined action of a charcoal furnace and the oxyhydrogen blowpipe was employed. A lime crucible after the form of Stas was used to replace the iron tube. By this means they obtained still no new reversal of a metallic line, but they observed channelled-space spectra in the cases of silver, manganese, chromium and bismuth. They observed, however, that the metal thallium gave the characteristic *bright* green line, the light of the arc not being reversed.

In the above-mentioned experiments, the coolness of the ends of the tube, which acted as condensers of the metallic vapours, and the continual change of density and temperature necessarily produced by the maintenance of a current of hydrogen through the tube, appear to account for the failure in observing reversals.

The following facts have been acquired during the course of a long series of conjoint experiments with my distinguished colleague, Professor Liveing, of Cambridge*:—

In order to examine the reversal of the spectra of metallic vapours, it is more satisfactory to observe the absorptive effect produced on the continuous spectrum emitted by the sides and end of the tube in which the volatilization takes place. For this purpose it is convenient to use iron tubes about half an inch in internal diameter, and about 27 inches long, closed at one end, thoroughly cleansed inside, and coated on the outside with borax, or with a mixture of plumbago and fireclay. These tubes are inserted in a nearly vertical position in a furnace fed with Welsh coal, which will heat about 10 inches of the tube to about a welding heat, and observations are made through the upper open end of the tube, either with or without a cover of glass or mica. To exclude oxygen, and avoid as much as possible variations of temperature, hydrogen is introduced in a gentle

* Lecture delivered at the Weekly Evening Meeting of the Royal Institution of Great Britain, Friday, June 6, 1879.

* "On the Reversal of the Lines of Metallic Vapours," Nos. I., II., III., IV., V., VI., 'Proc. Roy. Soc.,' 1878-1879.

stream by a narrow tube into the upper part only of the iron tube, so that the hydrogen floats on the surface of the metallic vapour without producing convection currents in it. By varying the length of the small tube conveying the hydrogen, the height in the tube to which the metallic vapour reaches may be regulated. Thus different depths of metallic vapour may be maintained at a comparatively constant temperature for considerable periods of time.

By this means the characteristic lines of the volatile metals thallium and indium may be easily reversed.

Metallic lithium, alone or mixed with sodium, gave no results. Similarly, chloride of lithium and metallic sodium, introduced together, gave no better results. To a tube containing mixed potassium and sodium vapour, lithium chloride was added. Now the bright red lithium line was sharply reversed, and remained well defined for a long time. The lithium line was only reversed in a mixture of the vapours of potassium and sodium, and it seems highly probable that a very slightly volatile vapour may be diffused in an atmosphere of a more volatile metal, so as to secure a sufficient depth of vapour to produce a sensible absorption. This would be analogous to well-known actions which take place in the attempt to separate organic bodies of very different boiling points by distillation, where a substance of high boiling point is always carried over, in considerable quantity, with the vapour of a body boiling at a much lower temperature.

Sodium and potassium, when observed in such tubes, give none of the appearances noted by Lockyer, "On a New Class of Absorption Phenomena," in the 'Proceedings of the Royal Society,' vol. xxii., but the channelled-space spectrum of sodium described by Roscoe and Schuster in the same volume of the 'Proceedings' was often seen. Potassium gives no channelled-space absorption, but continuous absorption in the red, and one narrow absorption band, with a wave length of about 5730, not corresponding with any bright line of that metal.

The absorption spectrum of sodium vapour is by no means so simple as has been generally represented. The fact that the vapour of sodium in a flame shows only the reversal of the D lines, while the vapour, volatilized in tubes, shows a channelled-space absorption corresponding to no known emission spectrum, appears to be a part of a gradational variation of the absorption spectrum, which may be induced with perfect regularity. Experiments with sodium exhibit the following succession of appearances, as the amount of vapour is gradually diminished, commencing from the appearance when the tube is full of the vapour of sodium, part of it condensing in the cooler portion of the tube, and some being carried out by the slow current of hydrogen. During this stage, although the lower part of the tube is at a white heat, as long as the cool current of hydrogen displaced metallic vapour, on looking down the tube it appeared perfectly dark. The first appearance of luminosity is of a purple tint, and, with the spectroscope, appears as a faint blue band, commencing with a wave length of about 4500, and fading away into the violet. Next appears a narrow band in the green, with a maximum of light, with a wave length of about 5420, diminishing in brightness so rapidly on either side as to appear like a bright line. This green band gradually widens, and is then seen to be divided by a dark band with a wave length of about 5510. Red light next appears, and between the red and green light is an enormous extension of the D absorption line, while a still broader dark space intervenes between the green and the blue light. The dark line in the green (wave length about 5510) now becomes more sharply defined. This line appears to have been observed by Roscoe and Schuster, and regarded by them as coinciding with the double sodium line next in strength to the D lines, but it is considerably more refrangible than that double line. In the next stage, the channelled-space spectrum comes out in the dark space between the green and blue, and finally in the red. Gradually the light extends, the channels disappear, the D line absorption narrows, but still the dark line in the green is plainly discernible. Lastly, there is only D line absorption.

The method of observation described may be used to observe emission as well as absorption spectra; for if the closed end of the tube be placed against the bars of the furnace so as to be relatively cooler than the middle of the tube, the light emitted by the vapours in the hottest part is more intense than that emitted by the bottom of the tube. This succeeds admirably with sodium.

The volatility of rubidium and cæsium rendered it advisable to try the effects first in glass tubes. For this purpose a piece of combustion tubing had one end drawn out and the end turned up sharply, and sealed off (like an ill-made combustion tube of the usual form), so as to produce an approximately plane face at the end of the tube; a small bulb was then blown at about an inch from the end, and the tube drawn out at about an inch from the bulb on the other side, so as to form a long narrower tube. Some dry rubidium or cæsium chloride was introduced into the bulb, and a fragment of fresh cut sodium, and the narrow part of the tube turned up, so as to allow the tube and bulb to be seen through in the direction of the axis of the tube. The open end was then attached to a Sprengel pump, and the air exhausted; the sodium was then melted, and afterwards either dry hydrogen or dry nitrogen admitted, and the end of the tube sealed off at nearly the atmospheric pressure. It is necessary to have this pressure of gas inside the tube, otherwise the metal distilled so fast on heating that the ends were speedily obscured by condensed drops of metal. Through these tubes placed lengthways in front of a spectroscope, a lime light was viewed. On warming the bulb of a tube in which rubidium chloride had been sealed up with sodium, the D lines were of course very soon seen; and very soon there appeared two dark lines near the extremity of the violet light, which, on measurement, were found to be identical in position with the well-known violet lines of rubidium. Next appeared faintly the channelled spectrum of sodium in the green, and then a dark line in the blue, very sharp and decided, in the place of the more refrangible of the characteristic lines of cæsium in the flame spectrum. As the temperature rose, these dark lines, especially those in the violet, became sensibly broader; and then another fine dark line appeared in the blue, in the place of the less refrangible of the cæsium blue lines. During this time no dark line could be observed in the red; but as the temperature rose, a broad absorption band appeared in the red, with its centre about midway between B and C, ill defined at the edges, and though plainly visible not very dark. The lines in the violet had now became so broad as to touch each other and form one dark band. On cooling, the absorption band in the red became gradually lighter without becoming defined, and was finally overpowered by the channelled spectrum of sodium in that region. The double dark line in the violet became sharply defined again as the temperature fell. There are two blue lines in the spectrum of rubidium taken with an induction-coil very near the two blue lines of cæsium; but they are comparatively feeble, and the two dark lines in the blue observed in the places of the characteristic blue lines of cæsium must have been due to a small quantity of cæsium chloride in the sample of rubidium chloride. These blue lines were not, however, visible when some of the rubidium chloride was held in the flame of a Bunsen's burner, nor when a spark was taken from a solution of the chloride; but the more refrangible of them (Cs*a*) was visible in the spark of an induction-coil, without a Leyden jar, taken between beads of the rubidium chloride fused on platinum wires.

(To be continued.)

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday the 12th inst. Mr. H. Allen, Vice-President, in the chair. A paper was read by Mr. J. R. James, on "Ostrich and other Pepsines," which is printed on p. 662. Specimens of the pepsines from the stomachs of the ostrich and also from other animals were exhibited and the digestive power possessed by each shown. After a discussion, the thanks of the meeting were awarded to Mr. James for his interesting paper. Mr. F. W. Branson then delivered his report on botany, the subject being "The Origin and Development of the Embryo Sac in Phanerogamia." The researches of Strasburger and Marshall Ward on this subject were described and illustrated by diagrams, showing the development of the embryo sac. The meeting then adjourned.

Parliamentary and Law Proceedings.

The Pharmaceutical Society of Great Britain *v.* Earp.

At the Birmingham County Court, on Friday, the 6th inst., before J. Motteram, Esq., Q.C., the Judge, the Pharmaceutical Society of Great Britain sued Joseph G. Earp, of 22, Cheapside, Birmingham, in respect of a penalty of £5, incurred under the 15th section of the Pharmacy Act, by a sale of "oxalic acid" and "white precipitate," the defendant not being a chemist and druggist within the meaning of the Act.

Counsel appeared on both sides, and the defence relied upon technical objections raised by the defendant's counsel, which were successively considered and disposed of by the learned judge, and judgment was given for the penalty of £5 with costs.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Answers.

[385]. Considering the quantity ordered, I should be disposed to think that the fixed oil of mustard was intended, unless it was desired to produce an action quite or nearly approaching vesication, which is just possible. I cannot understand why Mr. Talbot failed to obtain the information from the doctor; I have always found them courteous and willing to explain. Anyhow the failure is unfortunate.

South Norwood, S.E. J. H. Baldock.

[386]. Oleate of lime should be soft and white; if hard, brittle, or dark in colour, it is an indication that the heat has either been too great or too long applied (*vide* Gmelin's 'Chemistry,' vol. xvii., p. 72).

South Norwood, S.E. J. H. Baldock.

[389]. The ferri sulph. exsic. has a tendency to reacquire its water of crystallization; but if the excipient used, either syrup, or perhaps better, soft honey (mel depuratum), be added so as to make the mass somewhat soft, and it be quickly rolled, the pills will soon harden, and retain their shape.

South Norwood, S.E. J. H. Baldock.

[392]. It is not clear why "Inquirer" sent the two ingredients separately, or what he imagined was to be done with the borax. The glycerole of subacetate of lead (described by Dr. B. Squire, in the *Pharmaceutical Journal* [3], vol. vi., p. 881, May 6, 1876), mixed with the borax in the proportions indicated, makes a nice ointment, and in that way I should have dispensed it.

South Norwood, S.E. J. H. Baldock.

Query.

[393]. In the following prescription what should be used for the dec. senegæ,—the P.L. preparation of that name or the inf. senegæ, B.P.?

℞ Æther. Chlor. . . . . ʒj.
Muc. Acac.
Syr. Ros. āā . . . . ℥j.
Tinct. Lupul.
Syr. Rhœad. āā. . . . . ʒiiss.

The Death Rate of Chemists and Druggists.

Sir,—As a supplement to your statistical record of week before last, will you permit me to add some particulars which I think will prove interesting.

The first table shows the number of deaths recorded from March, 1875, to July, 1879, and the average age at death:—

Date.	Total Deaths. Age Recorded.	Deaths. Age not Stated.	Total Deaths	Average Age at Death.
1. March to June 30, 1875 . .	30	2	32	53·2
2. July 1, 1875, to July 1, 1876 .	121	14	135	51·02
3. ,, 1876, ,, 1877 .	119	16	135	51·21
4. ,, 1877, ,, 1878 .	119	3	122	50·68
5. ,, 1878, ,, 1879 .	131	4	135	52 16
Total	520	39	559	51·4

The second table shows the number of deaths at various ages, and the percentage:—

Age at Death.	1*.	2*.	3*.	4*.	5*.	Total.	Per cent.
20 to 30	5	10	10	8	13	46	8·84
30 to 40	5	27	28	29	25	114	21·92
40 to 50	3	21	21	25	19	89	17·11
50 to 60	3	25	23	23	29	103	19·8
60 to 70	7	25	24	21	27	104	20·
70 to 80	7	11	6	11	16	51	9·8
80 and upwards . .	0	2	7	2	2	13	2·5

The records from which the above tables are calculated are not sufficiently extensive, either in point of time or of detail, to justify any conclusions being drawn from them at present; but they are interesting as far as they go, and may serve as a basis for future calculations; in the meantime to reassure those who lately in your correspondence columns took such a gloomy view of the healthiness of our occupation, I subjoin another table (extracted and condensed from one of the returns following the census), which has been kindly furnished me by a gentleman who takes great interest in the subject of vital statistics.

* These numbers refer to the dates in previous table.

The first column shows the occupation, the second the proportion of deaths to each thousand then living. The nearest round numbers are used to avoid fractions:—

Clergymen	14–
Barristers	11–
Solicitors	20+
Physicians	30–
Surgeons	20–
Law Clerks	20–
Chemists and Druggists	15+

34, *Leinster Terrace.* FREDERICK ANDREWS.

CHEMISTS' PRICES.

Saturday, Feb. 7, 1880.

"SHOPS *v.* STORES.

"*To the Editor of the Times.*

"Sir,—On Friday or Saturday in last week a prescription, containing 16 grains of chloral in 4 ounces of water flavoured with a little ginger, was made up for me by a chemist in Bond Street. His charge for this was 3*s*. Yesterday the same prescription was made up at the "Stores" where I usually deal. The charge was 8*d*.

"How thoroughly the public should sympathize with the indignation felt by tradesmen against co-operative stores!

"I am, sir,
"Yours faithfully,
"FRANCIS R. HULLAH.

"*Grosvenor Mansions, Victoria St., S.W., Feb.* 6."

Monday, Feb. 9, 1880.

"SHOPS *v.* STORES.

"*To the Editor of the Times.*

"Sir,—For the lower price of the stores your correspondent who complains of the chemist's price can only obtain medicine, however pressing the emergency, during forty-four hours of the week, while at the chemist's he can be served any hour, day and night. Surely the difference of cost is but proportional to the difference of security arising from medicines being obtainable at the chemist's at any time —a consideration most material when health, perhaps life, are at stake.

"ÆQUITAS."

Sir,—With respect to the above correspondence, I was not at all satisfied with the reply given by "Æquitas," who does not attempt to show that the medicine was obtained at an unseasonable hour of the night, and so we may infer that it was had in business hours. But "Æquitas" informs us that medicine can be obtained at the chemist's at such times as the stores are closed by those who are willing to pay nearly five times the price charged at the stores during forty-four hours of the week.

Now, of course, a person would not go to Bond Street to get a thing cheap, and I readily admit that a chemist has a right to charge what he pleases for his work, whether he charges it at high or at low prices; just as one artist will be content to receive as many shillings for a painting as another artist would charge guineas; but with respect to high charges, the chemist should remember that they sometimes become prohibitory, and I have known a mother refuse to call in a medical man in a serious case, because his high charge would prevent her purchasing food for her large family.

JOSEPH LEAY.

Downside Villa, Chilcompton, Bath.

THE USE OF THE WORDS "PHARMACY" AND "QUALIFIED BY PHARMACEUTICAL EXAMINATIONS" AS APPLIED TO CHEMISTS AND DRUGGISTS.

Sir,—I have read some of the letters on this subject, and should like to express an idea or two of my own. I have every sympathy with pharmaceutical chemists in defending their position, and feel sure they will not object to just claims of chemists and druggists.

The Major examination does not include pharmacy as a subject, so that we may fairly suppose that when a person has passed the "Minor" he has a perfect right to call his shop a "pharmacy," or else what is the use of him being passed in that particular subject?

Persons cannot become chemists and druggists without passing the Preliminary and Minor examinations, which are the Society's own. Therefore, "A Voice from the Midlands," whoever he may be, may consider them so far "qualified by pharmaceutical examinations." The same gentleman should remember that Minor associates in business support the Pharmaceutical Society equally the same as Major members.

Bradford. H. WRIGHT.

THE USE OF THE WORD "PHARMACY."

Sir,—Now that the use of the word "pharmacy" is being discussed, I should like to write a few words in reference to its meaning. Mr. George Mee states that chemists and druggists have nothing whatever to do with pharmakon root or branch. If my memory serves me, φάρμακον, pharmacon; a medicament, or as Pereira has it, a drug, is the word from which pharmacy is derived, and that pharmacy is the art of compounding and preparing medicines. If this be correct, a man who is legally qualified to perform that office is literally and virtually a pharmacist.

"A Voice from the Midlands" seems very much distressed on account of the Minor men being allowed to delude the public by advertising themselves as qualified by "pharmaceutical examinations," etc., from which I infer that both the Minor examination and those who have passed it have nothing whatever in common with pharmacy. This seems to me rather contradictory, since the above examination is conducted in the house of the Pharmaceutical Society, by pharmaceutical chemists, one of the subjects (which by no means receives the least attention) is called pharmacy, and to the best of my knowledge is not even repeated in the Major examination.

In France chemists enjoy a higher prestige than we do here; there are two grades as in England, first and second class, the former are *bacheliers-ès-sciences*, but both are pharmacists, and their establishments are called pharmacies.

A member of the Council remarked at the last meeting that many Minor men were in the habit of calling their establishments pharmacies instead of chemists' shop. I would therefore suggest the following model for the facias of future chemists and druggists, "Jones, chemist's shop." Much has been said about raising the status of the drug trade, but if those engaged in pharmacy are to be lowered in their own estimation, I consider the proposed step a retrograde movement in that direction.

OLIVER ROGERS.

Paris.

Sir,—I read with very great pleasure the letters on "Pharmacy" in your issue of February 14, and I think with the writers of those letters that it is high time a stop was put to the practice of chemists and druggists using the words "pharmacy" and "pharmaceutical laboratory" to designate their places of business.

I maintain, sir, that they are the exclusive property of pharmaceutical chemists; if men who only hold the Minor qualification are allowed to do this thing, where is the use of a man passing the Major examination? As the matter stands now, the public are at a loss to knew what difference there is between the two. I think the time has arrived for the Council to take the matter up in earnest.

There is another matter I would like to draw attention to, that is, the title "chemist." From the Pharmacy Act, 1868, I read, "It shall be unlawful for any person to assume or to use the title chemist and druggist or chemist or druggist, etc., etc., unless such person shall be a pharmaceutical chemist or chemist and druggist within the meaning of the Act, and be registered under this Act." From this I gather that the title "chemist" belongs only to a pharmaceutical chemist or chemist and druggist. Then how is it that analysts and others throughout the kingdom are allowed to use it with impunity?

PH. C.

Sir,—I think it will be wise for the Council to consider well its course before entering upon the persecution, for persecution it will be, of any registered chemist and druggist who has ventured to call his shop a "pharmacy." I have called mine the "—— Road Pharmacy" now for ten years, and can conscientiously state in so doing I had not the remotest idea of trenching upon the rights of the Major men. I found when I commenced business that the grocer named his stores the "East-end grocery establishment," and so on, and the draper, "the well-known drapery," etc. The pharmaceutical chemist himself does not disdain the use of such terms as "apothecaries' hall," "medical hall," and I being on the Register, with a legal right to make up and retail any of the preparations of the Pharmacopœia, adopted the word "pharmacy" as a proper and reasonable title.

For nine years I have paid annually my guinea to the funds of the Society. Is this now to be used against me as one of the supposed infringers? I consider the letters in last week's Journal most ungenerous.

Not ten doors from my pharmacy, patent medicines are being sold at a branch post-office. Scarcely one hundred yards distant the public can procure at a grocer's all drugs and chemicals not actually poisons within the meaning of the 1868 Act.

I submit then, is this the time to quibble within the borders? Surely there is enough outside to complain of and demanding serious and prompt attention, without raising in our very midst rival persecution associations.

ANOTHER VOICE FROM THE MIDLANDS.

Sir,—Having read letters in your last week's issue of the *Pharmaceutical Journal*, on the above subject, allow me in a few lines to express my surprise at the step a few Major members wish the Council to adopt. In the first place, what is a pharmacy? In my idea it is an establishment set apart for the sale and manipulation of "pharmaceutical preparations;" therefore, if a chemist is not qualified sufficiently to call his establishment a "pharmacy" he is not fit to be a chemist and the Minor examination is no good to him and a complete farce. I quite hold with the higher examination; but as all men cannot spare the money and time involved in obtaining that qualification, I do not see why the bulk of us are to be deprived of our rights by a clique, and I feel very sorry that at the last Council meeting one of the members did not speak on behalf of the bulk of qualified chemists, namely, "Minor men." I, no doubt in common with others, subscribe towards the "Society," but I certainly shall not any more if those funds instead of protecting our privileges are used detrimentally to our interests. I have had relatives in the business for fifty years past, and when I compare their access into business with its privileges and our access into the business now with its reduced profits, etc., the comparison is not very encouraging.

I am in business in a midland manufacturing town, and all round me the business is being trespassed upon by unqualified persons. I think if the money spent in squabbling over the use of the word "pharmacy" was devoted for the purpose of altering this state of affairs, it would be of much more benefit to all the Major members, and, indeed, the trade at large.

A YOUNG BEGINNER.

APOTHECARIES' WEIGHTS AND MEASURES.

Sir,—In your leading article in the last issue of the *Pharmaceutical Journal*, you wished to know from the local secretaries or others, "Whether any, and what action had taken place with the local authorities respecting the new Weights and Measures Act, 1878, for the verification and inspection of apothecaries' weights and measures?"

Now, sir, I think chemists are already beset with troubles and difficulties enough in carrying on their business, and Acts of Parliament have hitherto done them little or no good, and this last Act, if heedlessly and injudiciously enforced, would place the trade under considerable inconvenience and annoyance. As, therefere, there appears to be much doubt and uncertainty in the meaning of this Act, and inspectors who may be appointed by the local authorities might be interpreting it in different ways, I considered it the wisest course under all the circumstances and in the interests of the chemists in Bath, to move the following resolution at the committee of the town council which takes cognizance of these matters:—

"That in the opinion of this committee it is not necessary at present to provide local standards of apothecaries' weights and measures." (*Carried.*)

WILLIAM BRIGHT, *Alderman.*

Bath.

N.B.—I have acted on the assumption that this Act is permissive in its character.

OIL OF LAVENDER.

Sir,—In your last week's number I noticed an article by Messrs. Young and Postans, on the present high price of oil of lavender and the effect it would most likely have on the sale of lavender water; also a suggestion to induce some enterprising men to turn their attention to the cultivation of the plant.

As an old grower of lavender, the cultivation of which has been carried on by members of my family for about sixty years, I may be able to show that, however enterprising growers may be, they cannot produce oil of lavender, even at a moderate price, if the seasons, etc., are against them.

In the first place, there is a large amount of disease in the plant to contend with, destroying some thousands each year, and many just coming into bearing, one or two years old; secondly, the late frosts in May destroying the young spikes; and lastly, the most important of all, the want of bright sunny weather during the months of May, June and July, the yield of essential oil entirely depending on this. It will therefore be seen, however highly the land be manured, the plants well trimmed and kept clean, expenses kept low, it will after all depend in great measure upon the season, as it does with most crops. For instance, I have noticed for some years past that a good lavender season is a good wheat season, but in these cases the weather has been warm and bright, and *vice versâ* when an absenee of sun and the weather wet. I have only to refer to last year as regards both crops, each yield being unusually low. I quite agree with Messrs. Young and Postans that the present price of oil of lavender is likely to bring into use inferior oils and in many cases destroy the popularity of this beautiful perfume; but I would recommend all who have a name for lavender water to use only English oil, if they get but a smaller profit.

If any member of the Pharmaceutical Society could find out the cause of the disease now existing in the lavender plant, and a remedy, it would confer a great boon upon the growers and enable them in some measure to reduce their prices.

Hitchin. SAMUEL PERKS.

J. R. P.—In the latter part of the 17th section of the Pharmacy Act it is provided that those provisions in the former part of the section which relate solely to poisons in the first part of the schedule shall not apply to sales by "wholesale to retail dealers in the ordinary course of wholesale dealing."

T. F. E. and S. M. R.—A communication asking for an explanation, forwarded to the writer at the address given by him, has been returned through the dead letter office.

"*Hibernicus.*"—Only those persons who are registered under the provisions of the Pharmacy Act, 1868, can legally carry on business as a pharmaceutical chemist or chemist and druggist in Great Britain.

E. F. F.—We are not acquainted with any experiments that have been made in the direction to which you refer.

G. Spencer.—If, as you say, the colour is due to two of the ingredients, we do not know how it can be removed without affecting the perfume.

E.—The subject has been so recently discussed that the time has hardly arrived for reopening the subject.

Simplex will find what he wants if he refers to the advertising pages.

W. H. S. will oblige by repeating his question.

C. L. S.—The second ingredient is no doubt "mucilago acaciæ." With respect to the last see the Dispensing Memoranda.

"*Ceratum.*"—For Unguentum Galeni, see vol. viii., pp. 506 and 518.

T. W. Ogilvie.—(1) *Parmelia saxatilis.* (2) *Parmelia physodes.*

W. P. D.—Your communication has been forwarded to the Advertisement Agents, Messrs. J. and A. Churchill, 11, New Burlington Street, to whom all letters relating to advertisements for this Journal should be sent.

Tayuya.—See a paper on the botanical origin of this drug, before, p. 667.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Chandler (Chicago), Bagnall, Renninger (Minnesota), Cotton, Baldock, Agathos, Major, Nil Desperandum, E. S.

The Pharmaceutical Journal.

SATURDAY, FEBRUARY 28, 1880.

THE INTENTION AND SCOPE OF THE PHARMACY ACT.

After many delays, the appeal of the London and Provincial Supply Association against the decision of Lord Chief Justice Cockburn and Mr. Justice Mellor has at length come before the higher Court of Appeal, the presiding judge on this occasion being Lord Justice Bramwell, who it will be remembered was, several years ago, counsel for the Pharmaceutical Society when an attempt was made to dispute the powers of the Council under the Pharmacy Act, 1852.

Our readers will remember that one of the grounds upon which the Lord Chief Justice and Mr. Justice Mellor decided the previous appeal against the London and Provincial Supply Association was the view that the Pharmacy Act being really a means of protection to the public, it was essential that no association of persons should be free from liability to penalty for doing that which in their individual capacity would unquestionably be an offence. For this reason they held that all persons, "natural or artificial," should come within the scope of the prohibitory sections of the Act.

The point raised by Mr. Wills at the hearing of the further appeal was briefly whether the prohibition against selling poisons without being a registered chemist and druggist extends to limited companies. That, at least, may be taken to be the drift of his argument, although, as will be seen from our report of the case, Mr. Wills seemed to confound a member of the Pharmaceutical Society with a chemist and druggist registered under the Pharmacy Act, 1868.

Mr. Wills contended that inasmuch as part of the qualification for being registered consists of an examination, a limited company was incapable of qualifying itself, but he did not adopt the decision of the county court judge, that so far as the interests of the public are concerned it was sufficient if the persons employed by the company to deal out poisons, to compound prescriptions, and actually to effect the sale of poisons, were qualified within the meaning of the Act.

In support of the contention that companies were not included within the scope of the Act, Mr. Wills argued that though the term "person" is capable in law of including corporation, still in the language of modern Acts of Parliament that was not so, but that where "person" was intended to include corporation there was an interpretation clause saying so. Various Acts of Parliament were cited as illustrating this view of the matter.

Rather by implication than otherwise, Mr. Wills, in his argument, treated the Pharmacy Act as one of a nature to ensure protection of the class of persons exercising the business of chemists and druggists, as by reference to the Act of Parliament passed in the reign of Queen Elizabeth, providing that it should not be lawful to exercise any craft or business without having been regularly apprenticed. In doing this he omitted any reference to the fact that the Pharmacy Acts were both passed, for the reason that it was deemed expedient for the safety of the public that persons keeping open shop for the retailing, dispensing and compounding of poisons should possess competent and practical knowledge of their business, and have been examined with that object and registered before commencing business.

In reciting the history of the Act of 1868, he suggested that it took its origin from the Pharmaceutical Society seeing the opportunity presented by what he termed the "great scare" then prevailing, as to the alarming facility with which persons were able to get possession of poison, and applying to Parliament under that influence to obtain an Act of Parliament, which he represented as having done a good deal for the Society, though he did not say anything of the benefit it conferred upon the public by preventing incompetent persons from carrying on a business which frequently involves possibilities of life or death.

But this reticence was not the only point in which Mr. Wills's representation of the case admits of being questioned. He went still further and did not hesitate to declare that what the Pharmaceutical Society really wanted to do, and what he had no doubt was the real object of the movement, was to shut up the co-operative stores, because co-operative trading was really the thing which hit the trade so hard.

In the present state of popular feeling in regard to co-operative trading this connection of the action of the Pharmaceutical Society with designs against the existence of co-operative stores is calculated to prejudice the question at issue unduly. As that question now stands it may be regarded that its decision involves a contest between common sense views and legal logic and that in this contest the former would be severely handicapped if the popular prejudice in favour of co-operative trading in any way came to exercise an influence.

The situation is a critical one for the drug trade, no less than for the safety of the public, and we commend to our readers a careful perusal of the report of the arguments put forward by the counsel for the appellants, as well as the remarks made by the judges themselves, as showing the disfavour with which the idea of protection of class interests is regarded. Even when the Attorney-General at the commencement of his address referred to the point that after all the question must be what did the Legislature intend when the Pharmacy Act was passed, and when he pointed out the importance of considering in whose interest it was passed, not that of chemists and druggists, but for the protection of the public, insisting that from that point of view if a man devotes himself to a particular profession or business, spending time and money in securing the requisite knowledge in carrying it on, it was reasonable that the Legislature should think it well he should be protected in its exercise, the comment of Lord Justice BRAMWELL was that "the presumption is against protection now-a-days."

The view insisted upon by the Attorney-General was that the meaning of the provision that it should be unlawful to sell or keep open shop for selling had reference to the proprietors and not to those who actually sold on their behalf, that the object of the Legislature was to prevent shops being kept for the sale of poisons except by qualified and responsible persons. Lord Justice BAGGALLAY and Lord Justice THESIGER entertained some doubt on this point, and suggested that in this case the public might have less protection than if the seller were understood to mean the person actually effecting the sale, since a qualified proprietor might leave his shop entirely in the hands of a person like the famous boy referred to in "Pickwick." The liability of the proprietor for the consequences of such a proceeding might, however, be taken, as the Attorney-General showed, as a guarantee against such neglect.

The extent of the report prevents our doing more than sketch in this general way some of the prominent features of the addresses on both sides.

THE EVENING MEETING.

AT the next evening meeting of the Society, to be held on Wednesday, the 3rd of March, a paper will be read by Professor REDWOOD, "On the Diffusive Properties of some Preparations of Iron;" another by Mr. H. G. GREENISH, "On Cantharides," giving an account of results obtained in the examination of three samples for the estimation of cantharidin; and a third by Mr. THRESH, "On the Volumetric Determination of Alkaloids."

SCHOOL OF PHARMACY.

THE courses of lectures on "Chemistry and Pharmacy" and "Botany and Materia Medica," in connection with the Pharmaceutical Society's School of Pharmacy, 17, Bloomsbury Square, will commence on Monday, March 1, at 9 o'clock in the morning, when Professor REDWOOD will give his first lecture on "Chemistry." Professor BENTLEY will commence his course on "Botany," on Friday morning, March 5. Students who have but a limited time at their disposal will find the ensuing five months to be a favourable period for studying at the School of Pharmacy, for between the 1st of March and the end of July, they will not only have the opportunity of attending in the laboratory and the usual courses on chemistry and pharmacy, and materia medica and botany, but also the lectures and demonstrations on "Systematic and Practical Botany," which are delivered at the Royal Botanic Society's Gardens, in the Regent's Park, where every opportunity will be afforded them of obtaining a practical acquaintance with medicinal plants.

WE learn from the *Birmingham Daily Mail* of last Wednesday that Mr. W. F. HAYDON has been appointed Secretary of the Birmingham Exchange and Chamber of Commerce. We understand that there were two hundred and seventy-five candidates for the office, and that the election of Mr. HAYDON by the Joint Committee was unanimous.

Parliamentary and Law Proceedings.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* THE LONDON AND PROVINCIAL SUPPLY ASSOCIATION, LIMITED.

This appeal, which has been a long time in the paper, came on for hearing on Monday last, February 23, in the Appeal Court, Westminster, before Lord Justice Bramwell, Lord Justice Baggallay and Lord Justice Thesiger.

Mr. Wills: My lord, this is an appeal from a judgment in the Queen's Bench Division reversing the judgment of the County Court in an action in which the Pharmaceutical Council sued a limited company for penalties under the Pharmacy Amendment Act, 1868. The point submitted to your lordships is whether the penalties and prohibitions contained in that Act, against any person carrying on the business of a pharmaceutical chemist in selling certain specified articles, apply to a limited company.

Lord Justice Bramwell: Is it pharmaceutical or pharmakeutical?

Mr. Wills: I do not know, my lord.

Lord Justice Bramwell: I remember asking the late Lord Chief Baron, who was an authority on everything, and he said the rule was that the sound of "c" was not affected by a silent vowel that followed it, and therefore it would be pharmakeutical.

Mr. Wills: If we adopt the Greek pronunciation it is no doubt a "k," but it has become so English that one is tempted to Anglicize it.

Lord Justice Bramwell: Do not suppose I am attempting to teach you; I am only telling you what the late Lord Chief Baron said.

Mr. Wills: I am always glad to hear anything coming from his lips; it is always well worth listening to; and I shall endeavour to benefit by the information your lordship has been kind enough to convey.

Lord Justice Bramwell: It is a curious case, because we say "pharmacy," no doubt.

Mr. Wills: Now, my lord, the short point is whether the prohibition in that Act against selling poisons without being a registered member of the Pharmaceutical Society extends to limited companies, and the way it arises is this. I need not read the case, because the point is very short and the case is perfectly clear. A person of the name of Mackness carried on business as a wholesale and retail grocer, and so on, in Tottenham Court Road. It struck him that he would like to become a limited company, and he associated with himself the necessary number of people and turned himself into a limited company, under the name of the London and Provincial Supply Association, Limited, and then they added to the other business the business of a dispensing chemist. Mr. Mackness was not a qualified chemist himself, but he employed—and the case finds that he employed—a person named Longmore, who was a qualified person under the Act, and two assistants under him, and that Longmore attended to the department and nothing else, and that he and the two persons who served under him, and who dealt out these articles, were properly qualified persons. The persons, therefore, who actually compounded the prescriptions and who actually physically effected the sale were qualified within the Act. But, of course, inasmuch as part of the qualification consists of an examination, and so on, a limited body was incapable of qualifying itself, and the question for your lordships will be, whether the Act was intended to apply to limited companies and corporations as well as to individuals. Very shortly, my lords, my argument will be divided into two parts, and I may shortly put the two points which I propose to make to your lordships thus: in the first place, I shall show to your lordships that although, of course, undoubtedly "person" or "*persona*" is capable in law of including corporation, that in the language of modern Acts of Parliament, especially those that impose penalties, it is not so, and that in the language of modern Acts of Parliament it is universal that where "person" is intended to include corporation there is an interpretation clause saying so. That is portion No. 1. The second portion of my argument will be to show from the Act itself that, as it seems to me, it cannot possibly have been intended, looking to all the provisions of the Act, that "person," which is used over and over again in the Act of Parliament, can have been intended to include a corporation, because in some places it makes nonsense of it. Those are shortly the two points of my argument. In the first place I propose to show to your lordships that "person" does not necessarily mean, in an Act of Parliament, and does not in fact mean in modern legislation, corporation. My learned friend the Attorney-General, who argued this case with conspicuous ability, of course, in the court below, quoted a passage from Lord Coke to show that in the Act of Elizabeth, which relates to holding lands in mortmain, "*persona*" or "person" meant and included corporations. Of course I do not quarrel with that general doctrine that "*persona*" in law is capable of including corporate bodies, artificial, non-natural persons as well as natural persons; but I think I shall show your lordships that in modern legislation that certainly is not the case. Now, my lords, this Act was passed in 1868. For a considerable time before 1868 to the present time it has been, I believe, the universal practice of draftsmen to put in an interpretation clause with respect to the word "person" when it is intended to extend it. There was, as your lordships know, a general Act of Parliament passed, the 13 and 14 Vic., cap. 21, which is commonly known as Lord Brougham's Act, for shortening the language of Acts of Parliaments, which provided that words used in the singular should comprehend the plural and words of masculine gender should comprehend the feminine, unless there was something repugnant to it in the context. But it did not go on to say that "person" should include a corporation, although it was already at that time the commonest thing in interpretation clauses to find the three things following one upon the other, that singular should include the plural, that masculine should include the feminine, that person should include a corporation or corporate body. Therefore, at that time the Legislature, when proposing to shorten the language of Acts of Parliament, drew the distinction, I think for very obvious reasons, because in the great majority of Acts of Parliament there is no question arises and "person" is only intended to comprehend natural "persons," and the inconvenience of having a general clause of that sort with a specific exception would, I think, very much outweigh the inconvenience of reading "person" in its ordinary sense, and extending it when necessary. Now, my lords, to show that that was so, I refer to one general Act of Parliament which bears on this subject, which was a few years earlier. In the 7th and 8th Geo. IV., cap. 28, sec. 14, there is that which is marked in the margin as a rule for the interpretation of all criminal statutes, but it does not go quite so far as that, because it is enacted that wherever this or any other statute referring to any offence, whether punishable by indictment or summary conviction, in describing or referring to the offence, has used or shall use words importing the singular number or masculine gender, the statute shall be understood to include several matters as well as one matter, several persons as well as one person, feminine as well as masculine, and bodies corporate as well as individuals. Well, my lord, I use that, and I think legitimately, to show that it was felt that there might be a difficulty in so extending the expression "person" to non-natural "persons" if it had not been for specific enactment. That specific enactment does not cover this case, because this is not a case of conviction before a magistrate; this is a case of an action for a penalty brought in the county court, and therefore that Act does not cover this specific case, and so the court below held. It only throws light upon it. Of course, the use which the Attorney-General made of it was to suggest that that was really the expression of the common law, and that it illustrated the rule of interpretation.

Lord Justice Bramwell: A sort of declaratory Act.

Mr. Wills: Yes, my lord, as far as it went. I submit, on the contrary, that is hardly so, and I think the constant presence of an interpretation clause would have been necessary if that had been so, and that really the fairer inference from that is that without some such enactment you would not read "person" as including corporate bodies. There have been several decisions, I need not go through them, in criminal cases in which "person" has been held, under the specific language of Acts of Parliament, not to include corporate bodies. I will just refer your lordships to the last case that I know of on that subject, which is one in the Common Pleas Division, quite a late one, the Guardians of St. Leonard's, Shoreditch, *v.* Franklin, in the Third Common Pleas Division, page 377. There, by a local Act, a penalty was imposed on coal dealers knowingly selling one sort of coal for another, and the penalty is recoverable by the person who shall inform and sue for the same. "Held, that a Board of Guardians, being a corporation, did not come within the term 'person' and could not sue for the penalty." Lord Coleridge said, "So far as I know this is a case *primæ impressionis*, but not without clear authority bearing on the question, although not directly deciding it. The plaintiff corporation having had coals supplied by the defendant, not only sue him for damages for breach of contract in failing to supply good coals, but proceed further to sue him for a large sum for the breach of duty of which he has been guilty in violating 1 and 2 Will. IV., cap. 76. The corporation say that the breach of contract was so bad that they are entitled not only to damages but to the penalties imposed by sec. 45, which exceed the sum of £25 and are recoverable under sec. 85, 'by the person or persons who shall inform and sue for the same.' It is suggested that the corporation are within the terms of sec. 85 and can sue. Undoubtedly the corporation may be in one sense included within the terms 'person' or 'persons.' But the Act must be construed *secundum subjectam materiem*, and I must ascertain whether it would be reasonable that a corporation should be within the words. If the case had arisen under one of the old penal statutes it would have been too clear for argument, as some of the conditions precedent to maintaining the action would have been such as a corporation could not from its very nature perform; and therefore to have held a corporation included in the words 'person' or 'persons' would have made nonsense of the Act." His lordship is there following out very much the same line of argument I propose to address to your lordships by-and-by on the second head of my argument. "I agree that such a construction would not make nonsense of this Act; but the general current of authorities seems to show that a corporation cannot be common informers. The argument that in numerous statutes, corporations are empowered to sue has an important bearing against the plaintiffs, for the fact that it has been thought not only well but prudent to include corporations in special terms rather tends to show that they otherwise would not have been included. No doubt the provisions in many statutes enabling the recovery of penalties have been extended to corporations, not, however, by making corporations do things beyond their nature, but by saying that things done by others on behalf of corporations should give them the same advantage as if done by them. The statutes as to inspection and exhibiting interrogatories in legal procedure, etc., which prescribe that certain acts shall be done for corporations by certain officers, all tend to show that corporations are by the very necessity of their nature excluded from doing such acts. I think it undesirable that corporations should be common informers. The general dictum of the text books is against it. Under all the earlier statutes corporations could not have been informers, and I think they cannot be so in this case." Of course I cannot quote that as deciding this case, but only to illustrate that "person" need not necessarily include a corporation and that you must look at the *subjectam matériem*. Now, my lords, I have looked, of course, to see what was the common practice in Acts of Parliament about the time, and in the older days before them, by taking up the very volume in which this Act of Parliament is contained, and, looking through the statutes for 1868, I find no less than four statutes in that volume, which when it is necessary that penalties should be inflicted upon corporations as well as upon private individuals, or rights given to them, contain an interpretation clause. The first of them is cap. 45, sec. 5, which is an Act relating to Sea Fisheries, where numerous penalties of course are imposed for the preservation of fisheries, and it is enacted there that the word "person" wherever used shall include corporate bodies. The next, my lord, is cap. 60, and that is the Act relating to the Curragh of Kildare, which was proposed to be used for the purpose of an encampment. The Act recited that there were numerous persons entitled to various rights over the common which would be interfered with, and it was desirous to make provision for their protection. I do not think, as far as I remember—I looked at it cursorily—that there are penalties imposed there; but there is an interpretation clause, and "person" is said to include in that Act corporate as well as non-corporate bodies. Then, my lords, comes cap. 119, which is as to the regulation of railways, and there by sec. 2, also, the interpretation clause is made to cover corporate existences as well as natural persons by the word "person." The last is cap. 131, which is the Artizans and Labourers' Dwellings Act. There also, there being rights of compensation given and also penalties imposed, "person" is made to include corporations. Now, my lords, I believe that I might go through every volume of the statutes in or near about that time and find exactly the same state of things. In the first Public Health Act, which is 10 and 11 Vic., cap. 63, the interpretation clause contains three things: masculine shall include feminine (of course, the 13 and 14 Vic. had not been passed), singular shall include plural, and person shall include corporation; and in that volume—the 10 and 11 Vic.—having chanced to open that, because I happened to recollect it, and thought I recollected that interpretation clause, there are no less than six more Acts of Parliament all containing exactly the same thing. Those are the Acts relating to the consolidation of the clauses usually applicable to markets and fairs, to gas works, to commissioners, to cemeteries, waterworks and towns' improvement. That is going back a few years. Now, I will just go forward. I cannot pretend to have gone through the whole of the Acts of Parliament since to see, but I have looked into the last two or three volumes of the statutes, and I find precisely the same state of things provided. In 1876 there are two Acts of Parliament, cap. 69, which relate to the Sheriff's Court of Scotland, and in sec. 63 "person" is extended to corporate bodies. In the Pollution of Rivers Act, cap. 75, sec. 21, it comes in the middle of the Act, but there also there is a similar clause. So in 1877 there is one Act of Parliament, the Fisheries Act, cap. 42, in which sec. 13 contains the interpretation clause, and there is the same interpretation given. In the year 1878—I have not looked further down than that—there are several. There is the Irish Public Health Act, which is cap. 52, sec. 2 is the interpretation clause. There is the Roads and Bridges for Scotland Act, which is cap. 51, and sec. 3 is the interpretation clause. There is the General Act of Parliament, that very important Act of 1878, as to weights and measures, which of course is to have a general application, and of course imposes a number of penalties, that is cap. 49; sec. 7 contains the interpretation clause and there the same language is used. Also, there is the other Act, of very wide application, which beyond all doubt would be applicable to a number of corporate existences, limited companies, as well as private individuals, the Factory and Workshops Act, cap. 16, and in sec. 96, which is the interpretation clause, there is the same thing. I think I have shown your lordships sufficient to show that both before and since that time this was the current language of Acts of Parliament. I will give your lordships one further illustration, which is in the rules of the Judicature Act, which by the Act of Parliament are to have the force of Acts of Parliaments, and which of course were drawn by persons very familiar with the ordinary language of Acts of Parliament. There the word "person" is applied to a corporate body. I cannot help thinking that the truth is, whatever may have been the state of things in the time of Elizabeth, to which Lord Coke's dictum—I should hardly call it a dictum, but Lord Coke's statement—applies, whatever may have been the practice at that time, that the modern practice I cannot help thinking is all one way. I have looked cursorily through the Acts and found those I have stated to your lordships. Of course, I do not ask your lordships to take any negative statement of mine for more than it is worth. All I say is, the impression left on my mind is that there are no Acts of Parliament where I should expect them to have the application beyond the ordinary use of language, in which that is not provided for. I will not say it is not so, but none caught my eye, or else I should have looked at them with more care in order to see. But it seems to me I am well founded in saying that that has become the habit, and had become the habit long before this Act of Parliament was passed.

Lord Justice Thesiger: Will you give me the reference to that in Lord Coke?

Mr. Wills: 2 Coke's Institutes, page 722. It is a comment, my lord, on the 39th Elizabeth, cap. 5, which, as I said before, is the Mortmain Act. It is about the erection of hospitals and houses of correction. The language of the Act is that "all and every person or persons seised of an estate in fee simple, their heirs, executors, and assigns shall have full power, strength and lawful authority for the next twenty years, by deed enrolled in a court of chancery, to erect hospitals," and so on. Then his comment on that is that "all and every person or persons"—"these words reasonably do extend to every body politic and corporate, but not to such as are restrained by any Act of Parliament, etc., but doth extend to such bodies politic and corporate as mayors, commonalties, burgesses and the like, and to all other "persons" whatsoever."

Lord Justice Bramwell: There is no case decided; it is only that passage.

Mr. Wills: No, my lord, only that passage.

Lord Justice Bramwell: Really I cannot help thinking that that might have been very different if that were a decision of his lordship on a case that had come before him, and that was arranged on both sides. I should have ventured, if I had been on the other side, to have asked why the word "successors" was not put in.

Mr. Wills: It struck me, my lord, when I was reading the Act of Parliament, but of course I am not concerned to say very much about it, because it expresses the general rule of law, which is that "person" in law does mean corporate bodies, if there is nothing whatever to qualify it.

Lord Justice Bramwell: And the reason of the thing is so, that is the way the Lord Chief Justice suggests, and there is no difficulty in applying it.

Mr. Wills: I challenged my friends in the court below in the course of the argument, which was very ably conducted, and you see who represents my learned friend the Attorney-General now, and my friend made a very vigorous reply upon me, and a successful one, and, therefore, I am disposed to think it was a good one, but I challenged my learned friend to cite any case in which there had been an indictment or proceeding against a corporation for a breach of a statute which contained the word "person," without the interpretation clause, and none such exists. I believe none such exists, at any rate none such was quoted. Of course that does not decide the matter either way; it might either be that the case had never arisen, or if it had arisen, people thought it too clear the other way, and that in that way there is no decision, but at all events no case was produced, and I do not cite any further cases to your lordships on this point. Now I think I have said all that is necessary to say on that first point at the present moment. I have condensed it as much I can, and one cannot make it clearer by going over the ground twice. There it lies. I believe that is the habitual course in modern Acts of Parliament, and if my friend can shake what I have said there, what he points out will be better worthy of attention than my belief at present. But I believe that will prove to be so, whatever may the case formerly. Verbiage was certainly rather the predominant rule in Acts of Parliament, and I believe that the tendency has been, and that it has become perfectly settled in the use of modern draftsmen that they do not use the word "person" as including "corporation" without saying so. Now having said thus much, I pass to the more specific consideration of the Act of Parliament with which we have more particularly to deal. My lords, there was one other point which was taken in the court below, and was taken before the learned county court judge, which I have forgotten to mention. I think it is only due to him I should mention it, because it is the point, if I remember rightly, on which he decided it, and he was a very learned gentleman, the late Mr. George Lake Russell, whom probably your lordships knew. I knew him very well, and respected him very much, and was certainly attached to him. The view he took was that the statute to which I am about to call your lordships' attention, which prohibits the selling or keeping open shop by a person unqualified, had not been broken where the actual sale was effected by a person who was qualified, although the owner of the shop was a limited company who could not be qualified. Now, my lords, I confess I felt myself, and still feel, much difficulty in seeing my way to that conclusion. I only hope that your lordships will think Mr. Russell's view was better founded than it occurs to my mind it was, but the language of the Act of Parliament being "person who shall sell or keep open shop for the sale," I confess I felt a great deal of difficulty, and do feel a great deal of difficulty, in saying that the person who kept open shop for the sale is anybody but the owner of the shop.

Lord Justice Bramwell: I am not going to indicate any opinion, but it did occur to me immediately you mentioned the case, that if it should be said against you, why this mischief is not provided for in the case of a corporation, you possibly might say, then if it is not, the individual doing it would be liable.

Mr. Wills: The individual would certainly be hit. I will show your lordships presently the individual who did it certainly would come within the terms of the Act, because he sells, and there is no doubt about that.

Lord Justice Bramwell: What I mean is this: suppose a man kept a shop who is not qualified, and suppose he kept an unqualified shopman.

Mr. Wills: He being qualified?

Lord Justice Bramwell: No, neither master nor servant being qualified. I am not going even to indicate an opinion, for I have not got one, but possibly it might be said it was a wrongful act on the part of the man who sold, which he could not justify because he was the servant of the master. Do you see what I mean?

Mr. Wills: I think that is so, my lord. I will come to it presently. I think there is very good ground for saying that in this Act of Parliament "sell" means the person who physically effects the sale — the hand that does it—because there is another section which is intended to mean the master of the shop, and does say so, and therefore here when it does not it would seem to refer to the actual seller. The words I felt pressed with on this point, and do feel great difficulty in supporting Mr. Russell's view, are "keep open shop for the sale."

Lord Justice Bramwell: What is the conviction, what is the charge here? That he had sold?

Mr. Wills: Both, my lord; both sold and kept open shop. But I feel bound to say that at the time I argued the case down below I was not aware of a case which I stumbled upon perfectly accidentally—since I take no credit for having found it, but I happened to come across it at Leeds the other day—which certainly is an authority, as far as it goes, and one which goes a considerable way in favour of the view taken by Mr. Russell. It is a good sporting case, Reynard *v* Chase, and it is found where Reynard very often is found, at the opening of a burrow. It is the first case in the first volume of Burrow's Reports. There, my lords, it was an action for a penalty under the 5th Elizabeth, chap. 4, for exercising the trade of brewer without having served an apprenticeship. The facts were, that there were two partners, one of whom was under the Act, for he had served his apprenticeship, but the other was not, for he never had. It was found that the one who was not qualified never had interfered in the business and simply was a partner taking his share in the profits and bearing his share of the losses, and Lord Mansfield held that he did not come within the Act. Lord Mansfield says, "When we have no doubt, we ought not to put the parties to the delay and expense of a further argument, nor leave other persons who may be interested in the determination of a point so general unnecessarily to anxiety and suspense." They were very clear therefore in the particular case before them. "The defendant has a share of the profits with Cox in moieties, and is liable to the debts of the partnership, but it is positively found that during all the time charged he never acted in or exercised the trade. He was not by the terms of his agreement to act in the trade, the other partner was to do the whole and had a particular salary on that account. It is not found that either Cox or any servant under him was set to work by Chase, or that Chase did any act whatever in exercising the trade. He was only concerned in the profit. Now, although this may be for some purposes exercising a trade in respect of third persons who deal with a partnership as creditors and within the meaning of the statute concerning bankrupts, yet the present question is, would it be exercising the trade contrary to this Act? I think Mr. Fisher has laid his foundation right against extending the penal prohibitions beyond the express letter of the statute. First, it is penal law; secondly, it is in restraint of natural right; thirdly, it is contrary to the general right given by the common law of this kingdom, and I will add, fourthly, the policy on which the Act was made has, from further experience, become doubtful. Bad and unskilful workmen are rarely prosecuted." Then, my lords, he says, "Let us consider whether the present case be within the letter. The letter of the Act is 'after the 1st of May it shall not be lawful for any person, other than such as do now lawfully use any right, to set up, occupy, use or exercise any craft, mystery or occupation, now used or occupied within the realm of England, excepting he has been brought up therein seven years at least as an apprentice, nor to set any person on work on any mystery not being a workman at this day, except he be an apprentice or has served an apprenticeship, upon the pain that every person wilfully offending shall forfeit and lose for every fault 40*s*. for every month.'" Now, my Lord Mansfield says, "The Act was made early in the reign of Queen Elizabeth, and afterwards, when a great number of manufacturers took refuge in England from the Duke of Alva's persecution, they brought trade and commerce with them, and enlarged our notions. The restraint of trade by this Act was thought so unfavourable that in 33 Elizabeth in the Exchequer it was construed away, or it was held by judges in that case, which construction, however I take not to be law now that if one who had been an apprentice of seven years, but in one trade, he may exercise any trade named in it, although he has not been an apprentice to it. All these observations only show that this Act, as to what enforces the penalty, ought to be taken strictly and according to the construction as made by former judges being favourable to the qualification of the persons attacked for exercising a trade, even where they had not actually served an apprenticeship, they have by a liberal interpretation extended the qualification for exercising a trade much beyond the letter of the Act, and have confined the penalty and prohibition to a case precisely within the express letter. Let us consider whether in the present case it comes within the letter or meaning of this Act. The whole policy of the Act was to have trades carried on by persons who had skill in them. Here the personal skill of the defendant makes no real difference in the case." That is very much what I should say here, "for the person who is skilful acts everything, and receives no directions from this man." In this case the assistant who did the work and served out the poisons; "he acts everything and receives no directions from this man, and neither did nor was to interfere." Mr. Justice Benson was of the same opinion. I do not think there is anything else in the decision. It goes some distance further on, but there is nothing else that makes anything for or against me. If there is anything else my learned friend will have an opportunity of seeing it. Now, my lord, I will show your lordship what the exact words and the exact nature of the Act of Parliament with which we have to deal are. I take leave to observe first, my lord, that this was an amending Act, and that it was an amendment of a former Act which constituted the Pharmaceutical Society an incorporated society, and something, I think, will turn on that. I reserve my remarks on the former Act until I have brought the provisions of this conspicuously before your lordship. It is an amending Act. Until about the 15 and 16 Vic., I think chemists and druggists, or persons exercising skill in the compounding of medicines, selling of drugs, and so on, were under no discipline, or subject to no necessity for qualifying at all. The Act of 15 and 16 Vic. gave a corporate existence to the Pharmaceutical Society, and gave them power for admitting persons as members of their Society by examination, and so on. It provided, if I remember rightly, I am not quite sure about that, that you were not to call yourself a pharmaceutical chemist unless you belonged to the Society; but it imposed no restriction on carrying on the trade.

Lord Justice Bramwell: I can tell you that is so, for I had the honour to be their counsel when they were attacked. I remember contending for them that their claims were very small. They proceeded most politically and most wisely. They began with a very small request to Parliament, and they got it. They said all their rights were that nobody shall assume the name which indicates he is a member of their Society. I think the case is reported. I remember the Chief Baron was on the other side.

Mr. Wills: I do not know the case, my lord.

Lord Justice Bramwell: He declared that society would be shaken to its foundation if we succeeded. However, we did.

Mr. Wills: There was no prohibition against anybody dealing in these drugs. Then there came, as the Attorney-General pointed out, somewhere about 1866, 1867 or 1868, some cases of poisoning which were reported, in which it was shown that people were able to get possession of poisons with alarming facility and there was a great scare about it, and this led to legislation. The Pharmaceutical Society saw their opportunity, and they went to the Government and obtained an Act of Parliament which did a good deal for them. And now, my lords, what they want to do is really what I have no doubt is the real object of this movement, to shut up the co-operative stores, because that is really the thing which hits them so hard. They would not care about a little affair of this kind, but if they succeed in this they will shut up the dealing in drugs by the Army and Navy and the Civil Service associations, and all those associations who make them up a great deal cheaper than you can get them at Apothecaries' Hall, or elsewhere. They procured their Act of Parliament, and my view of it, which I am going to submit to your lordships, my view certainly on anxiously looking at the Act, is that the person who drew the Act at this time did not think about limited companies. They were already in existence—the earliest of them really, I am told, came into existence two or three years before this Act passed—but they had not attained the importance they have now, and had not interfered with tradesmen as much as they have, and I do not think that the draftsman of this Act thought about dealing in poisons or dealings in any way affected by this Act by any but natural persons. But the Act of Parliament undoubtedly does a great deal for those persons who are recognized, who have passed the examination of the Pharmaceutical Society. It does not in terms prevent other people making up medicines; but inasmuch as in the list of poisons which are prohibited to be sold by any except properly qualified persons is comprehended something which is found in pretty nearly every prescription of any importance, nobody can carry on business unless he comes within the Act; I mean if the Act prohibited him. Therefore incidentally it does affect most importantly the power of carrying on a dispensing chemist's business. Now, my lords, I will say at once I think this is an imperfect Act. I think the provisions for the protection of the public are imperfect in many respects. It does not seem to me to be quite happily conceived; because it would certainly follow from one reading which was argued for strenuously by the Attorney-General, that a properly qualified person might carry on business with any number of unqualified assistants and never interfere in it himself. That should not be. It also follows from my reading of it, and I cannot escape from that—I know the inconvenience and I am not going to blink that for a moment—it would follow that a limited company might carry on the business without any protection to the public at all. I will not say without any protection, but with much scantier protection, because if I am right the protection would be insufficient in such a case. Inasmuch as if a limited company chose to have an unqualified assistant the only way in which the Act would apply would be by hitting the unqualified assistant who actually effected the sale; and I quite agree with the learned Attorney-General who says that is an unsatisfactory protection, because he would be a person who might be here to-day and gone to-morrow, and to be able to sue him for a £5 note in the county court is not very satisfactory. I think, my lords, in saying that I really have pointed out the extent of the inconvenience which my construction involves; at all events, no other inconvenience was pointed out in the argument in the court below.

Lord Justice Bramwell: That puts me in mind of an argument which I have always thought a most stupid one—that you ought to be at liberty to maintain an action against a corporation for malicious prosecution when they could not be guilty of malice, because if you are to go against the subordinate officials who were malicious, and who did prosecute, they might not be worth powder and shot. A most mischievous and stupid argument in my opinion. I do not say it is in this particular case.

Mr. Wills: That is very much the line of argument as far as the argument arises, the argument *ad inconvenientem*. What was said was this. I think I can put before your lordships what was put before the court below, and give an outline of the argument on both sides, almost in a couple of sentences. What they said was: this is an Act which imposes a general prohibition against any except persons qualified under the Act dealing in these things. Now, if by reason of your being a limited company it is physically impossible for you to qualify yourselves under the Act, *tant pis pour vous*, and it does not in the least affect the general prohibition, if you are within it, because you cannot submit yourselves to examination. So much the worse for you. That is their argument. My argument on the other side is this : the chief feature of the provisions which the Act of Parliament made shows that this case was not contemplated, because if an Act of Parliament had been asked at that time of day, in 1868, to impose a prohibition on all limited companies from carrying on a business, of this kind by qualified assistants, Parliament would not have given it, and therefore they did not intend to do by a side wind that which they would not have done directly. And, therefore, I say that, although I grant it may perfectly well be that large words and prohibition may be universal, and that the way of getting out of that prohibition may be such that a limited company cannot, from its very nature, get out of the difficulty, and it may therefore follow as you say that the limited company are indirectly prohibited and prevented from carrying on the business, yet I say it is fair to look at the the other side of the case and see whether there is any reason why in the nature of things a limited company should have been intended to be prohibited. Is it not much more probable that if Parliament had been thinking of including corporate bodies under this prohibition they would have put in a clause, and said that if a company carries it on the head manager or some responsible person shall be a duly qualified person, which would have effected all the protection which the public desire? It would not have suited the Pharmaceutical Society quite so well, and they would rather stand on their Act as they have got it now, with the interpretation which they have succeeded in getting in the court below, but I cannot believe myself that Parliament either then or now, would for a moment think of shutting up all these bodies. I do not believe there would be a chance of getting such an Act of Parliament, and I do not believe there was in 1868, and if that be so, it is a very fair argument for showing that it is not likely Parliament intended to do that indirectly which it would not have done directly. That is a short outline of the argument on both sides. Now, my lords, I will just go through the Act as shortly as I can, but it is absolutely necessary that I should go through the sections to some extent one by one,—it will not take very long,—in order to show your lordships that there is passage after passage where, as it seems to me, corporate bodies cannot be intended to be meant by the word "person," and if not in one place, then I say "person" must receive the same meaning throughout the Act. I pointed out in the argument in the court below, and I will point it out again, and I just make the observation now because your lordships will see the force of it, or the want of force of it as the case may be, as we go through the sections. I pointed out that if this restriction prevails at the present moment the Apothecaries' Hall itself is within it.

Lord Justice Bramwell: I was just going to ask that question.

Mr. Wills : They are liable to prohibition.

Lord Justice Bramwell: I was waiting to see if there was an exception in favour of Apothecaries' Hall.

Mr. Wills : No, my lord ; there is not.

Lord Justice Bramwell : That is a company.

Mr. Wills : The Apothecaries' Hall could bring itself within the Act in this way, that all persons who had carried on the business of chemists and druggists at that time, who at that time were already started and established in business as chemists and druggists, were entitled, on proving that to be the case, to send in a claim in writing signed by them, and with some householder to certify that they were persons who had been in business a certain time, and register themselves ; and Apothecaries' Hall might in that way have brought itself under it ; but it has never registered itself, and never dreamt of it, and it is at this present moment just as liable to the Act as any one else.

Lord Justice Bramwell : How can a corporation send in a thing in writing ?

Mr. Wills : There is this, also, my lord, and it does seem to me to be a very strong argument. A corporation never dies. It may dissolve itself, but it cannot undergo a natural death, and as long as it is worth carrying on it may be carried on. Now, the result may be that if any unhappy little company had been in existence before 1868, and had then registered itself under this Act of Parliament, it might go on for all time enjoying the privilege of compounding medicines and selling them over the counter, and keeping open shop, and yet there would be no clause in the Act of Parliament anywhere which could make it in the smallest degree an offence if it carried on its business by a parcel of boys or children, or persons who did not know the difference between Epsom salts and oxalic acid. That very nice boy, the assistant of the chemist in "Pickwick," whose presence in the shop was not considered by the court as a reason why his master should be excused from serving as a juryman, might be employed by this company until he had acquired his experience. Now, my lords, I pressed that illustration of the Apothecaries' Hall rather prominently in the court below, and I seemed at one time to make some impression on the court, but the Lord Chief Justice gave an answer to it which I will point your lordships' attention to when I come to deal with the judgment, but which I venture to think is wholly—I speak with great respect—untenable. His lordship suggested that every individual member of the corporation was a properly qualified person ; but that cannot make any difference. You cannot confuse the individual corporators with the corporate body.

Lord Justice Baggallay: Would every future member of the Apothecaries' Society be necessarily qualified?

Mr. Wills : In point of fact, instead of all the members of Apothecaries' Hall being duly qualified, I believe none of them are, because, by the provisions of this Act of Parliament, as soon as a man carries on the business of a medical man and compounds his own drugs, he is to cease to be a pharmaceutical chemist, and I believe that is the status of the individual corporators of Apothecaries' Hall. But I confess I was a little surprised at the difficulty which I experienced in the court below in maintaining my proposition, that you cannot for a moment think of importing the qualification of individual corporators into the question of the qualification of the corporate body. The corporate body has an existence of its own; it is an essence in law and it does not matter one straw what the individual corporators are with respect to that. The Act in question is the 31st and 32nd Vic., cap. 121. It is called an Act for Regulating the Sale of Poisons and to Alter and Amend the Pharmacy Act of 1852. It begins with a general recital which formed the groundwork of the argument below, and formed the groundwork of the judgment of the court against my view that it is perfectly general:—"Whereas it is expedient, for the safety of the public that persons keeping open shop for the retailing, dispensing or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge, of their business, and to that end, that from and after the day herein named all persons not already engaged in such business should, before commencing such business, be duly examined as to their practical knowledge, and that a register should be kept as herein provided, and also that the Act passed in the fifteenth and sixteenth years of the reign of her present Majesty, intituled an Act for Regulating the Qualification of Pharmaceutical Chemists, hereinafter described as the Pharmacy Act, should be amended." Of course that is perfectly general. At the same time it is open to the observation which I made upon it below, and which I venture to repeat, that in that very section the mention of examination shows that the examination being just as general, the area of the examination being as general as the area of the whole recital, it shows that the person who drew that was not thinking of the particular case of corporate bodies. Now, my lords, the first section is, from and after a given day, "it shall be unlawful for any person to sell or keep open shop for retailing, dispensing or compounding poisons, or to assume or use the title chemist and druggist, or chemist or druggist, or pharmacist, or dispensing chemist or druggist, in any part of Great Britain, unless such person shall be a pharmaceutical chemist or chemist and druggist within the meaning of this Act, and be registered under this Act, and conform to such regulations as to the keeping, dispensing and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council." Then by section 2, certain scheduled articles are declared to be poisons within the meaning of this Act, and they are a very large and wide category. Arsenic and its preparations, prussic acid, cyanide of potassium and all metallic cyanides, strychnine and all poisonous vegetable alkaloids and their salts, aconite and its preparations, emetic tartar, corrosive sublimate, cantharides, savin and its oil, ergot of rye and its preparations, oxalic acid, chloroform, belladonna and its preparations, essential oil of almonds, unless deprived of its prussic acid, opium and all preparations of opium and of poppies. It is a schedule which is also capable of indefinite increase at the will of the Council of the Pharmaceutical Society with the approval of the Privy Council, and therefore the effect of the legislation may be, I think, and am perfectly justified in saying, to prevent the exercise of the trade of a dispensing chemist by anybody except those who may lawfully do so, either under or notwithstanding this Act. Then the 3rd section, which is important in my point of view, is this——

Lord Justice Thesiger: The number of poisons may be added to by the Pharmaceutical Council?

Mr. Wills: Yes, my lord, with the consent of the Privy Council. It is a list capable of indefinite extension. However, it is a pretty ample list as it is, and you could not carry on the business of a dispensing chemist if you were prevented from dealing in chloroform, for instance, or prevented from dealing in one of the most ordinary drugs in these days in domestic medicines, aconite. The 3rd section is one on which I place some reliance. "Chemists and druggists within the meaning of this Act shall consist of all persons who at any time before the passing of this Act have carried on in Great Britain the business of a chemist and druggist in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners, also of all assistants and associates, who before the passing of this Act shall have been duly registered under or according to the provisions of the Pharmacy Act, and also of all such persons as may be duly registered under this Act." The subsequent section preserves the right of carrying on their business to those who had been chemists and druggists before the passing of the Act, subject only to the necessity for registration. I am trying in all these sections to see how it would bear on the case of a limited company, and if a limited company were in existence and could register itself at the time of the passing of this Act it would follow that it might remain for all time, if for all time it were profitable to carry on that business. Of course, with regard to ordinary and natural persons, in time the existing race of unqualified people would die out, but the unqualified corporation or association which was in existence at that time might go on for ever. The 4th section is: "Any person who at the time of the passing of this Act shall be of full age and shall produce to the Registrar on or before the 31st day of December, 1868, certificates according to schedule E to this Act that he had been for a period of not less than three years actually engaged and employed in the dispensing and compounding of prescriptions as an assistant to a pharmaceutical chemist or to a chemist and druggist as defined by clause 3 of this Act, shall, on passing such a modified examination as the Council of the Pharmaceutical Society, with the consent of the Privy Council, may declare to be sufficient evidence of his skill and competency to conduct the business of a chemist and druggist, be registered as a chemist and druggist under this Act." Then the 5th section is: "The persons who at the time of the passing of this Act shall have been duly admitted pharmaceutical chemists or shall be chemists and druggists within the meaning of the Act shall be entitled to be registered under the Act without paying any fee for such registration; provided, however, as regards any such chemist and druggist, that his claim to be registered must be by notice in writing signed by him and given to the Registrar with certificates according to the schedules C and D to this Act; and provided, also, that for any such registration" the person shall pay a fee.

Lord Justice Bramwell: I do not want to interrupt and I do not object to a critical examination of this Act. I should think it is necessary, although it may be called splitting hairs. I should think it is absolutely necessary; but is the general effect of the Act of Parliament that in future a qualification from the Pharmaceutical Society shall be obtained?

Mr. Wills: Yes, my lord.

Lord Justice Bramwell: And that for the past it shall apply to persons who have got a qualification from the Society or who have been *de facto* carrying on business.

Mr. Wills: That is so, my lord.

Lord Justice Thesiger: It is like that Apothecaries Act of 1815, I think it was, where a future qualification was to be got from the company, but persons actually in practice were entitled to remain.

Mr. Wills: Yes, my lord. Of course it would have been ruin to many people, and it was felt it would not do.

Lord Justice Bramwell: That is the general purport of it.

Mr. Wills: Yes, my lord. Schedules C and D seem to me very strong for showing that "person" in this Act of Parliament, or in this part of it at any rate, could not be intended to mean companies. Schedule C is the declaration of a person who was in business as a chemist and druggist before the Pharmacy Act. It is "I, ——— residing at ——— in the county of ———, hereby declare that I was in business as a chemist and druggist in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners at ———, in the county of ———, on or before the ——— day of ———." Then it is to be signed and dated. Then schedule D, which is a declaration to be signed by a duly qualified medical practitioner or magistrate respecting the person who was carrying on business as a chemist and druggist, is in this form: "I, ——— residing at ———, declare that I am a duly qualified medical practitioner [or magistrate], and that to my knowledge ———, residing at ———, in the county of ——, was in business as a chemist and druggist in the keeping of open shop for the compounding of prescriptions of duly qualified medical practitioners before the —— day of ——." Now, my lord, I do not know whether setting a corporation seal would answer to signing, but it is scarcely reasonable to suppose that the person who drew that was thinking of companies. Of course what he thought of is nothing to the purpose; but it is hardly possible that the Legislature should have used language of that sort if they intended to meet the case of limited companies.

Lord Justice Thesiger: I suppose it will be conceded to you, Mr. Wills, that in a great many of these sections the word "person" cannot possibly include corporations. If you take section 4, "Any person who, at the time of the passing of the Act, shall be of full age——"

Mr. Wills: So, again, where people present themselves for examination. A limited company cannot apply for examination.

Lord Justice Thesiger: Then it will be said that a certain qualification being required, a corporation cannot acquire, they may come within the general prohibition.

Mr. Wills: That is the argument; in fact, that was as I put it just now. If you cannot comply with the Act of Parliament, if you cannot present yourself for examination, by reason of your being incorporated, and be examined, so much the worse for you.

Lord Justice Baggallay: If it had been intended to exclude a corporation nothing would have been easier than to say "no corporation shall keep shop or sell poisons."

Mr. Wills: That is what it would come to. Now here in the 11th section there is a section which must have had its analogue if corporations had been intended to be touched by these Acts. In case of the death of any pharmaceutical chemist the registrar of deaths is to transmit to the Registrar under the Act a certificate and the Registrar is on receipt of notice to make the proper entry in his register. There ought to be an analogous provision that in case of the winding up of a company which had been registered under this Act, under sections 3 and 5 combined, a return should be made.

Lord Justice Baggallay: In the case of death, the executors have certain privileges, have they not?

Mr. Wills: They may carry on, by means of duly qualified assistants, so long as it is necessary to the winding up of the business. There is no provision of any sort or kind touching the case of a company. Then there is evidence of qualification to be given. An annual register is to be published and there again the language seems to show that nobody was thinking of a case like this. He is to make a correct register of all persons registered as chemists and druggists, and the names shall be in the alphabetical order according to the surname. Now, no one can tell what the surname of a registered company is. Where is the Apothecaries' Hall to go—under the "A's" or under the "H's?"

Lord Justice Bramwell: "Apothecaries' Company" they are probably called.

Mr. Wills: Yes, my lord. Is "Apothecaries" the Christian name and "Company" the surname, or *vice versâ*? Now, my lords, then comes section 15, which is, that after the 31st of December, any person who shall sell—that is the section upon which the present action is founded—"any person who shall sell or keep an open shop for the retailing, dispensing or compounding poisons, or who shall take, use, or exhibit the name or title of chemist and druggist or chemist or druggist, not being a duly registered pharmaceutical chemist or chemist and druggist, or who shall take, use or exhibit the name or title pharmaceutical chemist, pharmaceutist or pharmacist, not being a pharmaceutical chemist, or shall fail to conform with any regulation as to the keeping or selling of poisons made in pursuance of this Act, or who shall compound any medicines of the British Pharmacopœia, except according to the formularies of the said Pharmacopœia, shall for every such offence be liable to pay a penalty or sum of five pounds, and the same may be sued for, recovered and dealt with in the manner provided by the Pharmacy Act, for the recovery of penalties under that Act." Then section 16 is the section to which Lord Justice Baggallay called attention just now, which enables an executor or the representatives of a deceased pharmaceutical chemist to carry on business by means of properly qualified assistants so long as may be necessary for winding up, but no longer. Then there are regulations to be observed in the sale of poisons by section 17, which is the section which seems to me to indicate that the sale means, except under the section which has specific provisions, the actual physical act of handing over the counter, and does not point so much to being interested in the proceeds of the sale, because under this section it is provided that nobody shall sell unless the buyer is known to him, or he has a certificate of who he is and so on, and there is a penalty imposed upon the seller, and then it is said that the person on whose behalf any sale is made by any apprentice or servant shall be deemed for the purpose of this section to be the seller. That is not to apply to any legally qualified apothecary supplying medicine to his patient. Then, my lord, section 18 is—"Every person who at the time of the passing of this Act is or has been in business on his own account as a chemist and druggist as aforesaid, and who shall be registered as a chemist and druggist, shall be eligible to be elected and continue a member of the Pharmaceutical Society, according to the bye-laws thereof." Now, my lord, the bye-laws of the Pharmaceutical Society contain, of course, no provision for including companies or corporate bodies in any way on their list, or giving them any privileges through their recognized officers. Therefore, that is a section which again shows that we are thinking of natural persons. Then there are other sections. The following sections relate to the qualification for persons being elected on the Council of the said Society, which comprehends every person who has been in business on his own account as a chemist and druggist and so forth at the time of the passing of this Act. Of course, they do not mean these to include corporations under the word "person." In the 22nd section, again, there are provisions made that a certain fund which belongs to the said Society shall be applied to the use of distressed members and their widows and orphans and also for all persons who may have been and have ceased to be members or associates of the said Society or who may be or have been duly registered as "pharmaceutical chemists or chemists and druggists, and the widows and orphans of such persons." Of course, nobody supposes that a limited company or corporation would be intended to be included under that. Now, my lords, I really think I have drawn your attention to all the passages which are material in this Act of Parliament. I wish to admit the full strength of the argument *ad inconvenientem*. My construction shows that an amending Act is necessary to make this Act perfect, because there ought, of course, to be some provision for insuring that limited companies, if they carry on this business, should be properly qualified societies. There is this protection, that the person who effects the sale would be liable in one construction of the Act, if "sale" means as I have been submitting it does, the act of the person who receives the money and hands the thing over the counter; then there would be that protection, and he must be a regularly qualified assistant, or he would be liable to the penalties, and I grant that the protection is not complete.

Lord Justice Thesiger: I suppose you would say that any person who shall sell in the 15th section does mean the person actually selling.

Mr. Wills: I think so. My reason for thinking so is that section 17 contains a specific declaration of what the word seller means.

Lord Justice Thesiger: In that particular case for the purposes of that section the person on whose behalf the sale is made is to be deemed to be the seller, which you say seems to show that in the 15th section it does mean the actual seller.

Mr. Wills: I think so, my lord. That is how it strikes me.

Lord Justice Thesiger: And "for the purpose of this section," that is the 17th, "the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller." That seems rather to point out that in the 15th section it means the actual seller.

Lord Justice Baggallay: The 17th is much more sweeping. It covers wholesale dealers as well as retail.

Lord Justice Bramwell: I suppose in this 15th section, the words must be read in the same way in the plural, that is "from and after December 31, 1868, any person or persons ——"

Mr. Wills: Yes, my lord.

Lord Justice Bramwell:——"who shall sell or keep an open shop, or who shall take, use or exhibit the name or title of chemist and druggist, or chemist or druggist, not being a duly registered pharmaceutical chemist or chemist and druggist." You are to read it in the plural.

Mr. Wills: Yes, my lord.

Lord Justice Bramwell: How would that be? A. and B. are in partnership. A. is within the Act and is qualified. Are they both liable for penalties, or is B. liable?

Mr. Wills: Unless you read the Act in the same way that Lord Mansfield did, in that case it would be so. Lord Mansfield's case rather seems to be an authority in point if that question were to arise.

Lord Justice Bramwell: If it is held that if A. and B. are in partnership, A. is not liable if B. is qualified, and B. actually sells; then why not hold that neither A. nor B. is liable if neither A. nor B. sells, but C. their qualified shopman does?

Mr. Wills: I do not feel pressed by the word "sell," my lord, but I feel pressed by the words "keep open shop," because I cannot get out of that in the same way. It seems very difficult to say that my shopman or assistant is the person keeping open the shop.

Lord Justice Bramwell: Yes.

Lord Justice Thesiger: Then there is rather a strange construction if the person "who shall sell" means "actually" sell, and the person who keeps open shop means the master. There is nothing to hit the master apparently if he keeps a person who is not qualified.

Mr. Wills: There is nothing.

Lord Justice Thesiger: The person himself may be hit, but as the boy you spoke of just now and not the master.

Mr. Wills: It is the fact, my lord.

Lord Justice Bramwell: It is a curious expression, "Keep open shop." One would think that if they did it on the sly and did not keep open shop they would not be liable.

Mr. Wills: I think what they meant was to distinguish it from the case of the physician or medical man or apothecary making up his own medicines for his own patients. If that is what is meant I do not know. That is one of the sections that made me think that this Act of Parliament really was passed rather in the interests of the pharmaceutical chemists than in the interests of the public as to a considerable part of it, because there is no provision in this Act of Parliament except about the sale, if it has the limited meaning I suggest. There is no provision that would hit the case of a man keeping open shop by means of unqualified assistants, and I do not think the draftsman was thinking about that. I think he was thinking of keeping poachers off the business.

Lord Justice Baggallay: I suppose at the time this Act was passed, the idea had not struck anybody of persons being formed into a company to carry on the business of druggists?

Mr. Wills: It had been done for some time.

Lord Justice Baggallay: But no company had been formed for the purpose of this business.

Mr. Wills: Probably not for this purpose; but I am told the stores were already in existence and were beginning to carry on this business.

Lord Justice Baggallay: As early as 1868?

Mr. Wills: I am told so, my lord. It is a thing I do not know myself, but I inquired, and I was told that the Civil Service Supply Association, which was the earliest, began business in 1866. But substantially, your lordship is right.

Lord Justice Bramwell: Might not some of those societies at Oldham have been in existence at that time—the Pioneers?

Mr. Wills: They were in existence a long time ago. They are mentioned in Mr. Matthew Hill's life, which is much earlier.

Lord Justice Bramwell: There may have been—I do not know—not what is called a co-operative company (that is to say stores for the benefit of the customer rather than of the store); but there may have been a company that carried on business for profit, might there not, and sold drugs?

Mr. Wills: I should think so. I do not know. I believe, my lord, that Apothecaries' Hall is in that point. There is no doubt about that.

Lord Justice Baggallay: They are under a charter.

Mr. Wills: Yes, my lord; but if the construction contended for by the respondents is right here, their charter does not save them from this Act in any way. They are liable. It is almost a *reductio ad absurdum.* I do not think, my lord, I have much more to say, and I will reserve anything else I have to say for my reply. I submit it is really a *casus omissus.* I do not shrink from the suggestion that there are inconveniences.

Lord Justice Bramwell: You are bound to admit that if they had thought of it they would have put in companies; but they would have put in something you say which would have exempted them.

Mr. Wills: That would not, to use a vulgar expression, have "squelched" them altogether. This is an Act which prevented limited companies carrying on business as chemists and druggists altogether.

Lord Justice Bramwell: One word before you sit down or before you finish. Somebody ought to tell us what the court below said.

Mr. Wills: I beg your lordships' pardon. I was forgetting that. The case is reported.

Lord Justice Bramwell: They are subjected to a penalty. Is there any provision here or does it point to some general Act as to what is to be done with the penalties?

Mr. Wills: Yes, my lord. The penalties are provided for.

Lord Justice Bramwell: The penalty is to be levied on the goods and chattels, I suppose.

Mr. Wills: Yes, my lord. That is in the Pharmacy Act which is amended by this Act.

Lord Justice Bramwell: What is to happen if they have no assets on which the fine could be levied?

Mr. Wills: I do not think that is provided for. It is a county court execution. You may summon them. You might commit them to prison. County courts have that power.

Lord Justice Bramwell: How was the penalty recoverable? Is it recoverable in the county court under the Pharmacy Act?

Mr. Wills: Yes, my lord. It is section 15 in this Act which I have been calling your lordship's attention to, which gives the penalty. It says—"the same may be sued for and recovered and dealt with in the manner provided for in the Pharmacy Act" (that is the 15th and 16th Vic. cap. 61). Section 12 of that Act is this—"From and after the passing of this Act, it shall not be lawful for any person not being duly registered as a pharmaceutical chemist according to the provisions of this Act to assume or use the title of pharmaceutical chemist or pharmaceutist in any part of Great Britain, or to assume, use, or exhibit any name, title, or sign implying that he is registered under this Act, or that he is a member of the said Society, and if any person not being duly registered under this Act shall assume or use the title of pharmaceutical chemist or pharmaceutist, or shall use, assume, or exhibit any name, title, or sign implying that he is a person registered under this Act, or that he is a member of the said society, every such person shall be liable to a penalty of £5, and such penalty may be recovered by the Registrar to be appointed under this Act in the name and by the authority of the said Society in manner following, that is to say: In England or Wales, by plaint under the provisions of any Act in force for the more easy recovery of small debts and demands." Then by section 14, "All and every sum and sums of money which shall arise from any conviction and recovery of penalties for offences incurred under this Act shall be paid as the Commissioners of Her Majesty's Treasury shall direct." Now, my lord, of course the only way of enforcing that would be by the county court process—that is primarily by *fi. fa.*

Lord Justice Bramwell: That does not tell either one way or the other. Undoubtedly, corporations are subject to county court process.

Mr. Wills: Yes, my lord.

Lord Justice Bramwell: Now what did the court say?

Mr. Wills: I have the Pharmacy Act here, but I think I have said enough about what the original Act was. I did call your attention to the fact that this is an Act amending that Act—that that Act began by small beginnings, and the only prohibition there was against using the title. Your lordships will find I am sure, on looking through that statute—the original Act—I will not repeat the process, but by going through it section by section, I think it is impossible not to say that the notion of a corporate body or a limited company was not in the mind of the framer of the Act or of the Legislature when it passed that Act, and therefore presumably, this Act was intended to cover the same ground as that.

Lord Justice Bramwell: I do not know that there is anything in it; indeed, I think there is not, to say the truth, but by section 16 of the first Act a false declaration is made a misdemeanour on the part of the person making it. A corporation could not in its corporate capacity be guilty of a misdemeanour, could it?

Mr. Wills: Of some misdemeanours they can.

Lord Justice Bramwell: But they could not be guilty of the misdemeanour of making a false declaration.

Mr. Wills: No, they could not, because that implies a false mind. My lord, the case in the court below is reported in 4 Q.B.D., 313, but it is also much more fully reported in the *Pharmaceutical Journal*, which has done great justice to every one of the arguments on each side, I am sure. The Lord Chief Justice says this was an appeal from the decision of the judge of the Bloomsbury County Court.

Lord Justice Bramwell: I think you may omit the statements of facts.

Mr. Wills: Yes, my lord.

Lord Justice Bramwell: "Upon this state of facts the question presents itself," that is the middle of page 89.

Mr. Wills: Yes, my lord. "Upon this state of facts the question presents itself whether the defendant company as such is amenable to the penal enactment of the statute."

Mr. Lumley Smith: The constitution of the company, my lord, is, I think, worth a little attention, at the end of the first column.

Mr. Wills: I think that is mere matter of prejudice. It is what I have already stated. I said a person named Mackness, who carried on business as a chemist and druggist, thought it would suit his purposes to become a limited company.

Mr. Lumley Smith: He was a grocer.

Mr. Wills: I told the Court so. He got certain persons to take the requisite number of shares to make a limited company of it. They added to the business of grocers the business of dispensing chemists. I could not state it, I think, with less prejudice. I do think, both with regard to my learned friend the Attorney-General and Mr. Lumley Smith, it was a little unworthy of them in the court below to say so much about that, because really it cannot influence the judgment of the Court in any way in one way or the other. This is a limited company. It is within the provisions of the Limited Act.

Lord Justice Bramwell: Of the law of the land.

Mr. Wills: Yes, my lord. Whether Mr. Mackness was a very wicked person in bringing himself within the law or not, it did seem to me a little bit unworthy of my friends, the Attorney-General and Mr. Lumley Smith, to say so much as they did in the court below about it. It is either right or wrong.

Lord Justice Bramwell: Do not say unworthy—not dignified.

Mr. Wills: The learned judge says: "It was fully admitted on the argument, nor could it be contested, that if this had been an ordinary partnership the individual partners—at all events such of them as were not qualified under the statute—would have incurred the penalties which it imposes."

Lord Justice Bramwell: Was that admitted?

Mr. Wills: The only observation I have to make with regard to that, in excuse of myself for not contesting it more strongly, is that I was not aware of the case in Burrows, and it did seem to me that under the language of the Act of Parliament that that did follow, and that any unqualified person being associated as partner with a qualified person would still be keeping open shop without being qualified. But the court below had not their attention called, as they ought to have had, to the case in Burrows, which I referred to.

Lord Justice Bramwell: I am not sure that would have helped you, because there the court held that the man was not within the Act of Parliament because he did not carry on the mystery of brewing.

Mr. Wells: Yes, my lord.

Lord Justice Bramwell: But how could it be said of you as a corporation of the different members of the partnership—would not one as much as the other have kept open shop?

Mr. Wills: I should have thought that the man who exercised the trade of brewing did keep open shop if he were interested in it.

Lord Justice Bramwell: The art and mystery he exercised was not that of the trade of a brewer, but of making beer, was it not?

Mr. Wills; No, my lord, the trade of a brewer. "Set up, occupy or exercise any craft, mystery or occupation without being apprenticed." It was alleged in the declaration that he set up——

Lord Justice Bramwell: That must be something that relates to any dealings with other people.

Mr. Wills: Yes.

Lord Justice Bramwell: They held that he was not within the Act of Parliament, because although he sold beer as much as the other man, he did not make it.

Mr. Wills: Yes, my lord. The court, therefore, were justified in saying that I did not contest, as I probably should have done, if I had known of that case at the time, the proposition that the individual partners, at all events those not qualified under the statute, would all have incurred the penalties. "The intention of the Legislature appears clearly to have been to prevent any shop or establishment to exist for the sale of poisons, except under the immediate superintendence and control of a duly qualified proprietor. It is not enough that the proprietor employs a qualified person to manage the business. The master must himself be duly qualified."

Lord Justice Bramwell: Here again, is that so?—"Except under the immediate superintendence or control of a duly qualified proprietor." Is it to be said that if a duly qualified proprietor were ill and confined to his bed for six months, that he would be subject to penalties under this statute?

Mr. Wills: I do not think he would be subject to penalties if he never went near the place, if he owned the place.

Lord Justice Bramwell: So long as he was qualified.

Mr. Wills: He might have a number of unqualified assistants. It is a most incomplete Act.

Lord Justice Thesiger: That is assuming "the seller" means that, and even if it does not, even if it means the actual seller, still the master might leave his business entirely, so long as he is qualified; he might take no part in it for years.

Mr. Wills: It is a mistake to treat an Act of Parliament like that, drawn so carelessly in the interests of the public, as one as to which there is any difficulty in saying that there is a *casus omissus*, which has not been provided for. Then his lordship says, "The master must himself be duly qualified. Two parties could not combine to carry on the joint business of grocer and chemist, though the one attending to the latter department of the business might be a qualified chemist. There would be nothing to ensure in such a case that in the absence of the qualified partner the other might not take upon himself to act in his stead, and thus the security against fatal mistakes in the dispensation of medicines which the statute was intended to insure might be seriously compromised. The defendants are therefore within the scope of this legislation."

Lord Justice Bramwell: That is another difficulty. I do not say it is not right; but you do not accede to that, because, according to that, if there were two partners in a private co-partnership, one entirely qualified, and the other not, both of them would be liable.

Mr. Wills: Yes; both of them would be liable.

Lord Justice Bramwell: Because they would be persons keeping an open shop for the sale of drugs without such persons being qualified.

Mr. Wills: Yes.

Lord Justice Bramwell: It constantly happens, as everybody must know, that in country towns the business of a chemist is very rarely carried on separate from some other business.

Mr. Wills: It generally is in a grocer's shop in very small towns. What would you say to the case of a person who lent money on such terms as would constitute him a partner without a qualification. He would be within this legislation. "The defendants are therefore within the scope of this legislation; the case comes within the evil against which the statute was intended to provide a remedy. But they are said not to be within the statute as being an incorporated company, the main ground on which this contention rests being that the Act in question, in its prohibitory as well as penal clauses, uses the term 'person,' a term which it is contended cannot be properly applied to a corporate body. The objection thus founded on the use of the word 'person' in the penal clauses of the Act would seem at first sight to present some difficulty; but when the scope and purpose of this legislation are taken into account the difficulty does not appear to be insuperable." So that at all events I have the satisfaction of having made some impression on their lordships in that direction and showing that there was a difficulty. "Reliance was placed by the Attorney-General, in his argument in support of the appeal, on the enactment of the 14th section of the 7 and 8 Geo. IV., cap. 28,"—that is the one I read to your lordships, which provides that in respect of offences punishable by indictment or summary conviction "persons" shall include a body corporate. "But that Act," says the learned Chief Justice "is expressly confined to proceedings on indictment or summary conviction, and therefore cannot apply here where the proceeding is by civil action. It shows, no doubt, the disposition of the Legislature to include corporations under the general designation of person or individual in penal statutes, but the terms of the Act will not admit of its application to the present case." I think I might very fairly say it shows something else; it shows that the Lord Chief Justice felt that there was a necessity for such a definition where they intended so to deal with the matter. "To solve the question, we must therefore confine our attention to the statute itself on which this action is brought. That an incorporated company is within the mischief against which this legislation was directed is, I cannot help thinking, quite obvious." There, of course, I agree. "If a company, by reason of its being incorporated, is not within the provisions of the Act and amenable to its penalties, and effect is to be given to the argument of Mr. Wills, it necessarily follows that such a company might openly carry on the business of chemists and druggists and sell poisons without a single member of the company or even the person employed to conduct this portion of the business being qualified." There, my lord, the only criticism I venture to make on that sentence is that there, again, the Lord Chief Justice is dwelling upon that person, a member of the company, which seems to me to have really nothing to do with it. "The person actually selling the poisons might be amenable, and it was probably with a view to avoid this that, in the present instance, a qualified person was employed to manage this department of the defendants' business; but the company employing him would enjoy complete immunity. A person desiring to combine the business of a chemist and druggist with that of a grocer would have only to get one or two persons to join him, providing them with a share or two, as appears to have been done in the formation of this company, and so forming an incorporated company, to set the statute at defiance. It cannot be supposed that the Legislature can have contemplated a result so entirely at variance with the policy and purpose of the Act, or intended to place incorporated companies on a different footing in this respect from that of ordinary partnerships or individuals. It is, no doubt, possible that, although joint stock companies existed at the time this statute was passed, the formation of such companies for the purpose of combining trades hitherto carried on singly, and among other things for that of superadding the business of the chemist to that of the grocer or provision merchant, may not have been present to the minds of those who framed and passed this statute. Still, if the case, though unforeseen, is within the mischief which the Legislature had in view, and the enactment is large enough to embrace it without any forced or strained construction being put on the language of the Act, it is our duty to advance the remedy intended to be afforded. It is true that the term used in the first section of the Act is 'persons,' and that, ordinarily speaking, this word would not be applicable to a corporation." Therefore the court below seems to have thought at all events that, to take Lord Coke's remark in its integrity, "a person" ordinarily included corporation in Acts of Parliament. I ought to say, in justice to the court below, I take blame to myself. I do not think I understood the case quite so well then as I do now, and I did not point out to their lordships nearly so fully as I have done to-day the extent to which that habit of interpreting "person" to mean corporation had prevailed in modern legislation. I did point out to the court the Judicature Acts and the case of the Public Health Act of 1848 and the Public Health Act of 1875, but all these other cases I was not aware of. I did not expect to meet with quite so much difficulty on this subject. I had formed too sanguine a view of this case and did not point out to the court the ingrained habit of modern legislation. Besides the Acts I have mentioned, the same thing went on down to the Bankruptcy Act of 1869, which I forgot to mention just now. "But when the meaning and effect of the enactment is looked at without too close an adherence to its precise phraseology, it amounts to no less than a general prohibition to everyone not qualified according to the Act from dealing in poisons or carrying on the business of a chemist and druggist. The fallacy of the argument urged on behalf of the defendants is, that it assumes that the prohibition is addressed to individual persons; but the provision, being universal, must extend to all persons, whether acting in an individual or corporate capacity." Now, my lord, that is not quite a just representation, I think, of my argument, because if I had been properly understood below, I certainly did not mean to say that. What I meant to say was, looking at the Act altogether, see if you cannot detect that the notion of a corporation never was present to anybody's mind when it was passed. I certainly did not say that the Act assumed that the prohibition was intended for individual persons. I have no doubt the prohibition was supposed by the person who drew the Act to cover all cases that needed prohibition. "The defendants, it is true, in thus infringing the law, are not acting in their individual capacity."

Lord Justice Bramwell: If I understand that question I should have thought it meant this: the provision, being universal, must extend to all persons, whether acting in an individual or corporate capacity in this sense. Very well then, if you are members of a corporate company, yet if you are the people who keep open shop, and are not qualified, you are personally liable.

Mr. Wills: Yes, my lord, perhaps that is it.

Lord Justice Bramwell: Of course, you would not mind. You might be open to another proceeding; but that seems to me to be the proper consequence of what his lordship says there.

Mr. Wills: What appears to me must be meant is this: that persons who join together for the purpose of doing that which the Legislature have prohibited, would be hit in their individual capacity; but a person who was a member of a corporate body, which might or might not do wrong, unless he joined in the result, and did the wrong thing, I think could not be liable.

Lord Justice Bramwell: You cannot maintain an indictment against a corporate company for libel, can you, or can you not? I forget how it has been decided.

Mr. Wills: I think not, my lord. There was a good deal of discussion on that in the court below; but I think we could not find any case in which it had been held.

Lord Justice Bramwell: Suppose an Act of Parliament says any person publishing a libel should be subject to three years' imprisonment—suppose a publication by a company—there are corporations for the purpose of publishing a newspaper. The persons actually concerned in the publication of the libel, although they were corporators, would be within the statute.

Mr. Wills: I think so, if they were actually concerned in it so as to be principals, my lord.

Lord Justice Bramwell: There could not be a doubt about it.

Mr. Wills: In that case there could not be a doubt about it; it would not matter whether they were corporators or not. But if all they did was that they held shares in a company which published the *Times* or some other paper, I should not think that would make them individually liable.

Lord Justice Bramwell: I should think not. I think the consequence of what his lordship says here would be that all persons were addressed by the prohibition, and that they might say very well it is addressed to them, whether corporators or not.

Mr. Wills: I think that is so. Then his lordship goes on: "The defendants, it is true, in thus infringing the law are not acting in their individual capacity, and may not—but on this it is unnecessary to pronounce any opinion—be liable individually. But in their aggregate or corporate capacity they are breaking the law;"—that is the question;—"and being in the latter capacity, as well as individually within the prohibition, they must, if capable of being sued for it, be also amenable to the penalty, and must for this purpose be taken to be sufficiently persons within the meaning of the statute." There, my lord, I do not quarrel with that. If the penalty has been incurred they can be sued for it, but it does not advance the consideration of the question of whether this Act of Parliament really did touch the case of a corporate body. "The fact so strenuously insisted on by Mr. Wills, that in other sections of the Act the word 'person' is applicable to individual persons only, and not to a corporate body, only tends to show that the adoption of the business of chemists and druggists by incorporated companies like the present was not contemplated when the Act was passed." That is a good deal of what I have been saying, my lord.

Lord Justice Bramwell: That will not show that somehow or another, therefore, the Legislature has made provisions for a thing which was not contemplated. It may be so.

Mr. Wills: "It by no means shows that the prohibition being general and the mischief clearly within the statute the company, though as such they may be incapable of complying with some of its requirements, as for instance, to undergo examination under section 6, ought not to be held to be within the penal clauses of the Act, or should be allowed openly to break the law under the belief that they are beyond its reach. In the present case it so happens that a member of the company and who manages the chemical department of its business, Mr. Henry Edward Longmore, is a qualified chemist. But it is not as a member of the company that he so acts, but as the paid servant of the company." I venture to think that there there is the same fallacy, if I may respectfully say so, running through his lordship's judgment; that the fact of the individual members being qualified or not qualified had anything whatever to do with the matter in hand. "It is clear, therefore, that his being qualified will not exonerate the other members of the company who are not so. Nor would it be otherwise even if it were as a member of the company that he so acted. So long as any of the company are disqualified, the body is disqualified, and the one who, though himself qualified, acts for the body becomes a party to their offence, and becomes liable conjointly with them. The qualified chemist who, in partnership with a grocer, carried on the business of grocer and chemist would be as liable to the statutory penalty as his unqualified partner." That is the proposition your lordship was putting just now. Now, my lord, the rest of the judgment I do not think I need trouble your lordship with, for this reason. It turned on a point which I was very unfortunately misunderstood by the learned Chief Justice as taking, and upon which he stopped me in a very early part of my argument, and delivered judgment in my favour. Then the Attorney-General was heard upon it; it was a point I had not meant to take, and I had not meant to take it because I did not think it was tenable. It led to a very long discussion, and a very long argument indeed, by the Attorney-General, who disposed of it, having asked for leave to appeal. He then began again, and slew the warrior that I had never put in the fore-front. The point which was taken—it must have been my fault for so expressing myself—was this. His lordship said in terms: You have just struck the right chord; but I did not think I had. He understood me to contend that a corporate body could not be indicted or proceeded against summarily. I will not read it, but his lordship delivered judgment in my favour on that point on an earlier day. I could not get up and say I had not intended to take that point. I was never so embarrassed in my life. The Attorney-General then asked for leave to appeal, and after having asked for leave to appeal, the Lord Chief Justice invited him to a consideration of the point he had just dealt with, and the Attorney-General spent two or three hours in arguing that point. It never struck me to take that, because one has had so many cases in which one has had either to prosecute or to defend companies for misdemeanours, and I have had so many cases in the Court of Queen's Bench in which I have had to deal with summary convictions of companies.

Lord Justice Bramwell: This is an action to recover a penalty in the county court. Did the court at first say that a corporation could not be summoned?

Mr. Wills: Could not commit an offence so as to be subject to any penalty. They treated this as an offence. They said it was a breach of the statute, and therefore an offence, and I think for the moment the fact that it was a proceeding in the county court was a little lost sight off, and the learned Lord Chief Justice did really deliver judgment in my favour on that point, which I had not taken, that a corporate company could not be guilty of an offence, and could not be proceeded against, either by indictment or by summary conviction. The remainder of the judgment goes to that point, and therefore I do not trouble your lordship with any observations upon it.

Mr. Lumley Smith: My lord, I have an application to make on behalf of my learned friend the Attorney-General. He is anxious to be allowed to support this judgment, but he is still occupied at the Old Bailey by that case which is going on, and he wishes to ask the indulgence of your lordships if you will, after my learned friends have been heard to-day, allow him to be heard on Wednesday. I am told there are very few interlocutory matters.

Lord Justice Bramwell: Would you like it before you address us youself?

Mr. Lumley Smith: I do not think it will be necessary for me to say much to your lordships.

Lord Justice Bramwell: I think we are bound to accede to that application.

[Adjourned for a short time].

Mr. Wills: If your lordships will allow me, I will just hand in a portion of the argument and discussion to which I was referring just now, from which you will see that I was well founded in the definition I gave of that portion of the judgment to which I referred. Now, my lords, I propose to call your lordships' attention to Mr. Justice Mellor's judgment:—"I have come, with considerable hesitation, to the conclusion, that our judgment should be for the plaintiffs, and that both questions submitted to us must be answered in their favour. I was for some time inclined to think that the circumstances of the defendants' case were not within the contemplation of Parliament when the Pharmacy Act, 1868, was passed, and that although clearly within the mischief intended to be provided against, words sufficiently comprehensive had not been used in framing the Act to include the acts of the defendants, and that, consequently, it became a *casus omissus*. A fuller consideration of the provisions of the Act 31 and 32 Vic., cap. 121, has, however, brought me to the same conclusion as that expressed by my Lord Chief Justice in his judgment in this case. I think that the great object of the Legislature was to prevent the sale of poisonous or dangerous drugs by persons not qualified by skill or experience to deal in such commodities. It, therefore, proposed to form into one association all persons who for the future should alone be deemed to deal in the same, and who should be registered under the provisions of the Act which we are now considering. It accordingly provided for the interests of all chemists and druggists who had been in business as such previously to the passing of the Act, but with regard to the future it made careful provision for the examination and registration of all persons who should in future form the only qualified body of persons who should be permitted to keep open shop for the retailing or compounding of poisons, and I now think that the sections which mainly embarrassed me as to the extent of the prohibitive sections are really, when carefully considered, only the provisions regulating the steps which in future are to be taken by all persons who desire to obtain the privilege of keeping open shop and retailing, dispensing or compounding the poisonous drugs in question, and who, upon being registered as pharmaceutical chemists, or chemists and druggists, within the provisions of the Act, will become qualified so to do. To incorporate such a society, to whose members in future the sole privilege of keeping open shop as chemists, or chemists and druggists, for the sale, or dispensing or compounding poisons should be intrusted, rendered it necessary to prohibit all other persons, not so registered or qualified, from keeping open shop or retailing, dispensing or compounding such drugs for sale, and from assuming the title of pharmaceutical chemist, or chemist and druggist, and, therefore, whilst one set of sections are qualifying and intended to regulate for the future the mode in which persons should become qualified as members of the association, and to provide for the government of the body incorporated, the sections 1 and 15 of the Act which contain the prohibitory words, upon the meaning of which we have to decide, have an entirely distinct effect The object of those sections is absolutely to prevent the danger assumed to be likely to arise to the public by the keeping open shop for the retailing, dispensing or compounding poisons, by any persons not being qualified pharmaceutical chemists, or chemists and druggists, and the intention and scope of those sections and the general object of the Act is absolutely to exclude, from the time of the passing of the Act, all persons other than the registered members of the Pharmaceutical Society from keeping open shop or retailing, dispensing or compounding of poisons. Now, before the passing of the Act, 1868, all persons, whether 'natural persons' or 'artificial persons' constituted by incorporation for trading purposes, might either as individuals or as corporations have kept open shops and retailed, dispensed or compounded poisons. It was essential, therefore, to the effectuating the objects of the Act, that all persons, whether natural or artificial, should for the future be prevented from dealing as before in the prohibited matters; and the cases cited by the Attorney-General in his argument show that an incorporated company may commit an offence either of nonfeasance or misfeasance, and may be punished by indictment for the same as if the act had been done by a natural person. We may well, therefore, interpret the word 'person' in the 1st and 15th sections so as to include not only any natural person, but any artificial person created by the law, which would be capable of committing the offence referred to in the 15th section, as having committed it by the course of proceeding actually adopted by the defendants; and we are authorized upon the principle of decided cases to say not only that the 'offence' has been committed by the defendants, but that they are liable to be punished for it under the provisions of the 15th section."

Lord Justice Bramwell: I think the effect of my brother Mellor's judgment is this, every person, including corporation, is every body; it may be there are no clauses enabling a corporation, but the prohibition including corporations is every body. Under this it may be there are no provisions which will enable a corporation to qualify.

Mr. Wills: Yes, my lord.

Lord Justice Bramwell: Then you are liable to a penalty. That is the effect of my brother Mellor's judgment.

Mr. Wills: It is what I put before under the head of "so much the worse for you." The prohibition is general; the means of getting out of that prohibition are such as are inaccessible to a corporation—so much the worse for the corporation.

Lord Justice Bramwell: So much the worse for you if you cannot carry on that business.

Mr. Wills: Of course that may be so. The only thing I have to observe on that judgment—which of course is perfectly logical, if that is the intention of the prohibition; there it is and one cannot quarrel with it,—the only thing I have to remark is that it really takes no notice of the argument which I addressed to the court below, and which I have repeated to-day, which at all events, deserves to be disposed of in some way or other. It does not take the slightest heed of the fact that there are very numerous Acts of Parliament about this time which do treat the word "person" as requiring that kind of definition if it is intended to include it, and it gives the go-by altogether to everything that was said on the particular Act itself. Of course I do not complain of that; all I mean is, it does not dispose of the argument.

Lord Justice Bramwell: It takes no notice of this argument, as it seems to me, which would be of very little use to you, except in so far as this particular case is concerned, that if the statute hits you it hits you personally, the particular vendor, the man who does it. A., B., C. and D., keep open shop in the name of the corporation of something Supply Company, and therefore they are guilty of an offence.

Mr. Wills: There again that rather begs the question.

Lord Justice Bramwell: That may give you success in this case, that argument.

Mr. Wills: I venture to dispute the correctness of that proposition, that A., B., C. and D, keep open shop. I do not think they do. It is the incorporated company.

Lord Justice Bramwell: If the incorporated company publish a libel on A. B.?

Mr. Wills: That will not render the individual members liable.

Lord Justice Bramwell: Would it not in a criminal case? I should be sorry to think that.

Mr. Wills: If the purpose for which the corporation exists is that of publishing libels, granted; but, if I take shares in a railway company, for instance, and the railway company publish a libel in its report on one of its servants, it would be very hard to hold me criminally liable. I always thought that was the safeguard persons got in becoming members of a corporation, that they sink their individual essence. Of course, if they have personally interfered; for instance, the director who votes for a resolution that a libel shall be published, he is liable.

Lord Justice Bramwell: That is what it means.

Mr. Wills: But, as it seems to me, the individual corporator is not.

Lord Justice Bramwell: Certainly not the individual corporator.

Mr. Wills: I should hardly think so. I did not quite appreciate a good deal of this discussion. I have been all along in a great difficulty with regard to a great deal of the discussion which took place in the court below which was raised by the court as to the individual corporators. I have always felt a difficulty in dealing with it because the thing seems so clear.

Lord Justice Bramwell: I do not think it is an unimportant consideration, for this reason. Suppose that the penalty, if any, is incurred by the individual, and that A., B., C. and D. are the persons who are actively keeping the shop open, then A. may be a perfectly qualified person. Well, if it were a private partnership, and A.'s qualification would exonerate, you say it ought; but here, if A.'s qualification would not exonerate, then you come to what I cannot help considering a preposterous condition of things—that is to say, that A., B., C. and D. may carry on the business, A. being perfectly qualified, A. being always there, B., C. and D. being dormant parties, and not being there, and yet they are all liable te a penalty; whereas if A. were perfectly qualified and carried on the business alone and never came near the shop, and his assistants were not qualified, they would not be liable.

Mr. Wills: It is so. It seems almost a *reductio ad absurdum*.

Lord Justice Bramwell: It justifies one in saying that possibly some such consideration as this arises, whatever may be the mischief of the Act of Parliament the Legislature either has not hit it in every case or has hit it much too hard

Mr. Wills: Yes, my lord. In fact, my lord, it seems to me one is justified in saying that with so imperfect a piece of legislation that a view which is rather based on the assumption that it is a perfect piece of legislation intended to meet all cases and to meet them adequately is hardly just. It is a piece of—one does not like to say blundering legislation, because it is not one's business to rail at what the Legislature has done—but a piece of imperfect legislation, and in which, it is no injustice to say, there is an important class of cases which has escaped the attention of the Legislature, and as to which the Lord Chief Justice seemed to think my remark was very well founded, when I said it was very much better to allow the Legislature to remedy mistakes they have made than to strain Acts of Parliament in order to meet cases which might very probably have been meant to be met, but which are not met, as you find in this particular case. This is the result, that by straining the Act of Parliament to comprehend this case you do indirectly a great deal more than what you can credit the Legislature with, and you do that which I venture to say in 1868 could not have been done, and I am sure the Attorney-General, in his capacity as a member of the Legislature, would never propose to-day to the Legislature to do, namely, to shut up all these societies. With these observations, I leave the case in your lordships' hands.

Mr. Finlay: I am with my learned friend, Mr. Wills, and I do not propose to add very much to what has been said. Our proposition in the first place is this, that if there is an enactment that no person shall do a thing unless he complies with a certain condition, and that be one which in the nature of things a corporation cannot comply with, that the word "person" in the enactment is not to be read as including a corporation. A great deal was said in the court below about the passage in the 2nd Institute, and that was relied upon as laying down a general rule, that "person" is to include corporation. Apart from the authority of the passage,—and it is not a decision, it is a mere dictum by Lord Coke in his capacity as text writer,—but apart from that it is not a a general dictum such as is supposed, as appears from an examination of the language of the passage. It is a mere dictum as to the construction of the particular statute. The statute is one that relates to the erection of hospitals by any person seised in fee.

Lord Justice Bramwell: I do not think you need trouble yourself about that. I am not going to say anything disrespectful of Lord Coke at this time of day, but it is such a long way beside the present question. I see the court did not rely on it, and it is not necessary to go into it.

Mr. Finlay: Not in the judgment, my lord, but a great deal was said about it in the course of the argument. When one looks carefully at the passage, it will be seen that it does not even affect to lay down any general proposition.

Lord Justice Bramwell: All Lord Coke says is that "person" may mean corporation.

Mr. Finlay: In this statute. The word in the passage is that it includes corporations as a rule. I think when one looks at the passage critically that that is the result. I am not going to trouble your lordships by discussing it further after what has been said.

Lord Justice Thesiger: Would your argument go as far as to contend that in modern times "person" without any interpretation clause, cannot mean a legal as well as a natural person?

Mr. Finlay: I do not think it is necessary for me to say that. All that I say is that in deciding whether "person" includes corporation, one must look at the matter of the statute and at the context, and if it appears from the context that the provisions and conditions imposed are conditions that corporations cannot possibly comply with, then "person" is not to be read as including corporations. That was strongly illustrated in a case in the first Leach Crown Cases, page 180—arising on a statute of George II.—Harrison's case. The judges were dealing with the statute of George II. against forgery, and that provided against forgery with intent to defraud any person. The judges decided the word "person" there would not include a corporation, so that the intent being to defraud the Bank of England, a pardon was granted, on the opinion of the judges. The head note is this, after referring to another point in the case, as to the entry of the receipt of money under the statute of George II., cap. 22, it goes on thus:—"But that statute did not extend to cases where the offence was committed with intent to defraud a corporation until the 18 George III., cap. 18." That is certainly a very strong case indeed to show that the word "person" does not necessarily include a corporation. If one were to remark on the case as decisive, instead of it being the rule that "person" includes corporation, one would say the rule is the other way, because certainly the case was positively within the mischief the statute intended to deal with. Then, my lords, the Factories Act. It may perhaps be worth while just to mention that, in 6 George IV., cap. 94, the words of the 2nd section are "for advances made on the security of goods by any person or persons, body or bodies, politic or corporate," so that very clearly the Legislature thought it necessary to mention bodies corporate or politic in addition to persons. Then in the 5th and 6th Vic. they use simply the word person without an interpretation clause, providing that person shall include corporations as well as individual persons. So that it is really very difficult to say after such decision that there is any rule of law that the word person is to include corporations. A case was decided upon the Mortmain Act, the case of Walker *v.* Richardson, which I only refer to for the purpose of illustrating that principle, that in deciding this principle the context of the Act must be looked at. That is in 2 Meeson and Welsby, 882.

Lord Justice Baggallay : The context there would include the preamble.

Mr. Finlay : Yes, my lord. Baron Alderson says :—"The statute would seem not to extend to the present case since it speaks in the preamble of improvident alienation or disposition made by languishing or dying persons to the disinherison of lawful heirs," which words are not applicable to bodies corporate. And Baron Parke says :—"The 3rd section must be considered with reference to the enacting part of the section which refers to grant, by any person or persons whatever." That extends only to grants by natural persons. Now, my lord, we come to the question whether this particular statute was meant to include corporations, and I am going to say very little upon it because I think every point has been made already.

Lord Justice Baggallay ;—The reference to the context including the preamble would rather tend to the view that the evil is to be guarded against as much in the case of a corporation as in the case of an individual.

Mr. Finlay : Yes, my lord; but at the same time the preamble would seem to contemplate the case of an individual actually keeping shop in the sense of being there and attending to the business. That is the recital that it is necessary that those who are engaged in keeping shop should have a practical knowledge of the business. And if that is to be referred to, one might say that in aid of the contention that the words "sell" or "keep open shop" in the 15th section are not satisfied unless the master takes some active part in the business. What I was about to say with reference to the statute is this, that the 1st section provides: "It shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title of chemist and druggist, or chemist, or druggist, or pharmacist, or dispensing chemist or druggist, in any part of Great Britain, unless such person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act, and be registered under this Act." Now, it is impossible for a corporation to be registered under this Act, having regard to the provisions of the Act as to registration. Can it on any principle be contended that if a section of an Act of Parliament says no person shall do a particular thing unless he comply with a particular condition, and that condition is one which in the nature of things a corporation cannot comply with; can it on any principle be said that that enactment is to extend to a corporation ?

Lord Justice Bramwell: Mr. Finlay, your argument is like this. It shall be unlawful for any person to sell or keep open shop unless such person shall do what he cannot do.

Mr. Finley: Yes, my lord; it comes to that. If the word "person" is to be used as including corporation it comes to that.

Lord Justice Bramwell: "Any" person and "such" person are the same. "Such" person is evidently not a corporation, because he cannot be. He cannot be within the scope. But, if "any" person and "such" person is the same, then "person" is not corporation. Q. E. D.

Mr. Finlay: Eliminating what is immaterial it comes to this. No corporation shall keep open shop for the sale of drugs unless the corporation is registered, which no corporation shall be. It is an enactment of that sort. Surely the question whether "person" includes corporation is, to say the very least of it, an open one, and when you find that the provision of the Act is one that a corporation cannot comply with, it leads to the inference that the word "person" does not include corporation. The question is, what is the extent of the prohibition by the Act? With great submission to the judgment of the court below, the question is, what is prohibited—what persons are prohibited—and to start with the assumption that the Act prohibits all persons, including corporations, from doing a particular act, is, of course, to decide the very question under discussion.

Lord Justice Bramwell: Suppose the words had been, "It shall be unlawful for any person to sell," and so forth, "unless such person shall have been bound apprentice and have served his time?"

Mr. Finlay: Then it would have been contended that inasmuch as a corporation cannot be apprenticed they are not entitled to carry on the business. Take another illustration. Suppose it were, "No person shall carry on business unless," as might have happened some years ago, "he first took the oath of allegiance." A corporation could not do that, and therefore the corporation could not carry on the business. That is really the whole case, and I will not say any more about it.

The further argument was adjourned until Wednesday.

The hearing of this case was resumed on Wednesday morning, when the argument for the respondents was commenced by the Attorney-General, as follows :—

The Attorney-General : May it please your lordships, I appear with my learned friend, Mr. Lumley Smith, for the respondents in this case, and I hope to be able to satisfy your lordships that the decision of the Court of Queen's Bench was correct. The question which was raised by my learned friend, Mr. Wills, for the appellants, was very fully argued, and no doubt it is present to your lordships' minds. It seems to me the question entirely depends on the construction of the Pharmacy Amendment Act of 1868. My learned friend referred to matters outside of that Act, but I do not think you will come to the conclusion that those matters to which my learned friend did refer have much, if anything, to do with this case. My learned friend, Mr. Wills, did, I believe, draw your attention to a number of statutes in which there were interpretation clauses, to show that the word "person" in this particular statute is to include corporations, and so on. I have no doubt there are a number of statutes in which, for abundant caution, interpretation clauses of that kind are inserted, and I dare say I should be able to find your lordships statutes in which there is no such interpretation clause, and statutes in which the word "person" must include corporations if it be necessary to do so, but I take it that the general rule is laid down very well by Lord Coke in the 2nd Institute, page 122, and it is this, "That the word 'person' in the abstract includes corporations, the exception is where 'person' occurs alone in one part of the statute, and 'person' or body corporate in another, in which the word 'person' alone does not include the word corporate." That is the doctrine laid down by Lord Coke, and it seems to be a doctrine founded in good sense, and one which ought to prevail. I do not mean to say that that would entitle me to your lordships' decision, because after all, the question must be, what did the Legislature intend when the particular Act to which your lordships' attention is referred, was passed. I think it is very important to consider in whose interest this statute was passed. It is not, as I gather from my learned friend's argument was rather shadowed out by him, at least so I understand, that this is an Act passed in the interest of pharmaceutical chemists. That is not so. This is a statute which is passed in the interest of the public, and for the protection of the public, and the preamble of the Act shows very clearly that this is so, because the preamble is this, "Whereas it is expedient for the safety of the public."

Lord Justice Bramwell: I should think that there could not be a doubt about that, Mr. Attorney, any more than that all the statutes which require examination of medical men, or of solicitors previous to their being admitted, or what not, are not made for the benefit of the body whom they will join, but for the benefit of the public.

The Attorney-General: Those statutes are made perhaps for the benefit of both, because if a man devotes himself to a particular profession, and spends time and money in securing the requisite knowledge in carrying on that business, perhaps the Legislature thinks it well that he should be protected from any invasion.

Lord Justice Baggallay: This is an extension or amendment of the Act of 1852, which expressly states that it is for the public safety.

The Attorney-General: The amending Act, to which I refer your lordship's attention, expressly states so. I do not know that it is necessary to argue this point. I only wish to draw your lordship's attention to the preamble, because it is very explicit and throws great light upon the other parts of the Act.

Lord Justice Bramwell: The presumption is against protection now-a-days.

The Attorney-General: That is a political question into which I would rather not enter. There are people in this world who think protection is a good thing.

Lord Justice Bramwell: Not many.

The Attorney-General: I think a good many, my lord.

Lord Justice Baggallay: Not enough to raise the presumption that the Legislature would pass an Act for protection.

The Attorney-General: It is not necessary for me to argue that point to your lordship, but if it is assumed that this is for the protection of the public, that is all I want to make out. I should like to read the preamble, because it is very important. The preamble is this:—"Whereas it is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business, and to that end, that from and after the day herein named, all persons not already engaged in such business should, before commencing such business, be duly examined," and so on. No doubt at the time this Act was passed it was known that great danger was incurred in consequence of persons being able to get without any difficulty poisons. The Act only applies to poisons; it does not apply to drugs ordinarily, but to poisons, and those poisons are inserted in a schedule. Before this Act was passed, any person might go into any druggist's, or any shop in fact, and purchase any poison he thought proper, which no doubt was a very dangerous thing. Then we come to the first section: "From and after the 31st day of December, 1868, it shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title chemist and druggist, or chemist or druggist, or pharmacist, or dispensing chemist or druggist, in any part of Great Britain, unlesss such person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act, and be registered," and so on; and conform to such regulations. Now, therefore, the mischief that the statute was intended to remedy was this, that persons could very easily obtain poisons, and perhaps much injury ensued, and the remedy intended to be applied was to prevent any shop being kept open for the sale of poisons, or to prevent the sale of poisons in any shop which was not kept by a qualified person. I use that expression for the sake of brevity. My learned friend, Mr. Wills, says that this case of the corporation was a *casus omissus*, and the Legislature had not in their minds a corporation. I do not care whether it is a *casus omissus* or not. The Legislature had in their mind this, to prevent any shop being kept open for the sale of poisons, except by particular persons, that is to say, qualified persons, and surely it appears from this 1st section of this statute that that was the object of the Legislature. If it was the object of the Legislature to prevent any shop being kept open for the sale of poisons except by qualified persons it was their object to prevent their being kept open by corporations as well as by anybody else. Just conceive what would be the consequence, assuming for a moment that I am not right, if your lordships will be kind enough to do so, in saying this was the object which the Legislature had in view. Then if a corporation is not within the terms of this Act, although the Legislature has intended to provide that no shop shall be kept open for the sale of poisons, except by qualified persons, nevertheless every corporation in the country might keep open a shop for the sale of poisons, and without it being at all necessary for the corporation to employ any qualified person, if corporations are not within this Act. Take this particular corporation, which was formed in the curious way which has been described to your lordships for the purpose, apparently, of evading the law—this London Supply Association. The London Supply Association might sell arsenic, strychnine, prussic acid, or oxalic acid to any extent without having a single qualified person there who would see that the poisons were properly labelled, or that the public were in any way protected. That must be of consequence, and surely that would be an entire frustration of the object which the Legislature intended to accomplish.

Lord Justice Baggallay: If it is not inconvenient to you I should like to ask you one question before we go any further. Do you limit the meaning of the words "to keep open shop?" Do you consider the only person who keeps open the shop is the person who receives the profit derived from the shop, or the person who presides and manages the shop?

Lord Justice Bramwell: The master.

The Attorney-General: The master.

Lord Justice Baggallay: The person who would derive profits from keeping the shop.

The Attorney-General: Who would have the profits or a share of the profits. I put it as high as this. If you have a partnership of five persons, I take it that the five persons would keep that shop, and that all five of them must be qualified.

Lord Justice Baggallay: Is it not a possible construction that a person may be said to keep an open shop who has the management and control of the shop?

The Attorney-General: No, my lord; I think not.

Lord Justice Baggallay: I only suggest it. I do not say that it is my view.

The Attorney-General: If so, a man who, having nothing at stake,—who cannot be proceeded against practically, I mean, because he has nothing to lose,—anybody might put a man of that kind, if he happened to be qualified, into a shop, and all would be right, although he might carelessly sell poisons and persons might be very much injured, and no proceedings could be taken against the master. The master is the interested person. He is the person who has entire control over the business, and the master making a profit out of the business, or hoping to make a profit out of the business, is the person who generally sees that that business is properly carried on. A mere servant, at a weekly wage, who has just enough to enable him to subsist on, has no particular interest in the matter besides. Take the words, "It shall be unlawful for any person to sell or keep open shop;" what would be the meaning of those words ordinarily? If one is asked whether a man is keeping open shop, surely the answer would be, "Yes, he is," if he is the master of the shop—if he is the owner of the business. Put aside for a moment this question of qualification; supposing the question were who was keeping open the shop which belonged to Swan and Edgar, Regent Street, could it be said that the principal clerk there, or the principal assistant was keeping open the shop?

Lord Justice Baggallay: I only asked the question because it had been passing through my mind. Does the proprietor sell, or the person actually standing behind the counter?

The Attorney-General: I think the proprietor sells. Undoubtedly, if the proprietor sells by an agent, he sells. It may be that the servant would sell as well.

Lord Justice Thesiger: There is a little doubt, possibly, about that, Mr. Attorney, taking the 15th section compared with the 17th. In the 17th, where they intend the master by the word "seller," they say so expressly, and that looks rather as if they had considered that when "sell" or "seller" is used before it refers to the man who actually sells. I do not say that that affects your argument.

The Attorney-General: Under the 17th section there is this difference that the acts there described subject the person committing them, if I recollect the section rightly, to a criminal prosecution. The acts mentioned in the 15th section do not subject the seller or the person who keeps open the shop to a criminal prosecution, but subject him to a civil action.

Lord Justice Thesiger: The words I refer to are in the middle of section 17.

The Attorney-General: The words are these. After describing what is to be done, it says, "And for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller, but the provisions of this section, which are solely applicable to poisons," and so on. Those are the words. If those words had not been inserted here, it would have been quite possible that any servant of the keeper of the shop, who sold a poison without the proper label, and without the box, bottle, vessel, wrapper or cover in which the poison is contained being correctly labelled by the name of the article and the word "poison," and with the name and address of the seller of the poison, might be proceeded against criminally, as it is a summary proceeding before the magistrates, which may result in a conviction.

Lord Justice Baggallay: There appeared to me to be this difficulty. If selling has reference to the person who actually sells, who may be a qualified assistant, and the prohibition upon keeping open shop is to be applied to the master, you may have a possible case of the sale by an assistant being perfectly lawful, whereas, keeping the shop by the master is unlawful, and liable to a penalty.

The Attorney-General: That would be so. I think that is a very excellent reason, my lord, for not adopting the construction of my learned friend. Because, take a shop where poisons are sold, a shop, we will suppose, into which the public are invited by an advertisement, "Poisons procurable here;" that shop is kept open by unqualified persons. It is their shop; they get all the profit and they keep a wretched, broken down druggist—a man who has been a dissipated character, who has brought himself to the verge of ruin—and for 15*s.* a week they put him in that place to sell in this business, and he sells the poisons, and very likely kills a whole street. Then he could be proceeded against, according to the construction suggested for the moment by your lordship, by civil action, which would result in nothing, because he would never be able to pay the £5 penalty, and the keepers of the shop who got the profits could not be proceeded against at all. That would certainly be an extraordinary result.

Lord Justice Baggallay: Only the case you have put presumes that the person who sells is a person who is supposed to be competent to sell by having passed his examination.

The Attorney-General: Yes; he is qualified.

Lord Justice Baggallay: Qualified to deal with the article he sells.

The Attorney-General: He has no interest in the business, he does not care what happens. Surely the intention of the Legislature was to fix on some responsible person, to make it the duty of some responsible person to keep open the shop and to effect the sale, not necessarily by his own act, but by his servants if required. Of course, if a man is keeping open a shop for the sale of poisons, he knows that he may, in the event of a mistake being made, be rendered liable in damages, or be rendered liable to pay penalties, and of course he becomes very careful, and the business is properly and carefully conducted; otherwise not. Then again, if I may say so, in answer to Lord Justice Thesiger's remark, it does not seem to me that there was any particular necessity for describing in the 1st section who the seller is, or who the person keeping open the shop is. It was not necessary that there should be any such paragraph inserted in that section as is inserted in the 17th section. But when you come to the 17th it is necessary in order that the matter may be made clear. Let us take for instance the first provision in this 17th section, it shall be unlawful to sell poisons without the proper label, and the label is to contain the name of the article, and the word "poison," and the name and address of the seller of the poison. Now, if there had been no explanatory paragraph anybody might have assumed that if an assistant in the shop had sold this poison the label which was to be put upon it ought to contain his name, and not the name of the keeper of the shop. Then again it goes on, "and it shall be unlawful to sell any poisons of those which are in the first part of schedule A under this Act, or which may hereafter be added thereto, to any person unknown to the seller, unless introduced by some person known to the seller." I take it that means that the poison must not be sold to the person unknown to the pharmaceutical chemist, the keeper of the shop, not that it may be sold to a man who happens to be known to the assistant who effects the sale and hands it over to the customer. Therefore to make that clear, there it is necessary that you should have a paragraph explaining who that seller is. I dare say I might pick out other provisions in this section which would also demonstrate the necessity for this paragraph. "And on every sale of any such article the seller shall, before delivery, make or cause to be made an entry in a book to be kept for that purpose," and so on. Those two illustrations I think will suffice to make my argument clear. What I wish to lay before your lordships on this part of the case is this. "Seller" in this statute means the same thing as the keeper of the open shop. The keeper of the open shop means the proprietor, the owner, the person who carries on the business, or the persons who carry on the business.

Lord Justice Thesiger: If that be so, Mr. Attorney, then the public has less protection than it would have had if the seller meant the person actually selling, because in that case the proprietor must be qualified, and the person actually effecting the sale is not. If your view be right, so long as the proprietor is qualified he may leave the shop entirely in the hands of that famous boy Mr. Wills referred to, and poison the whole street.

The Attorney-General: So he may; but then if this Act requires the proprietor to be qualified, and as the proprietor would be liable for all the injury which would or might be occasioned in consequence of any mistake, he is not likely to allow—I do not say unqualified persons—but to allow any careless person to make sales of poisons. If I am at liberty to refer to what one knows about it, I might say, is it conceivable that poisons are not sold in the shops of pharmaceutical chemists always by pharmaceutical chemists? I presume that there are many persons in those shops who sell drugs and poisons who have not the requisite qualification, that is, have not been subjected to examination.

Mr. Justice Bramwell: Can you tell me this. Supposing a wholesale house which sells poisons, say, dealers in arsenic by the ton, for ought I know; must they be registered under this Act?

The Attorney-General: No, my lord, there is an express provision with regard to wholesale dealers. It is in section 16, I think. Perhaps I had better read section 16, because something was said by my friend about this section and about the consequences which might happen.

Lord Justice Bramwell: It says: "It shall not interfere with the business of wholesale dealers supplying poisons in the ordinary course of wholesale dealing."

The Attorney-General: Allow me just to read this, as a good deal was said by my friend about it. "Nothing hereinbefore contained shall extend to or interfere with the business of any legally qualified apothecary, or of any member of the Royal College of Veterinary Surgeons of Great Britain, nor with the making or dealing in patent medicines" (though I do not know why patent medicines were exempted, "nor with the business of wholesale dealers." My learned friend said if the contention which was presented by the respondents was right, the Apothecaries' Society would be prevented from selling. But that is not so, because the Apothecaries' Society was incorporated by charter, and that charter was confirmed by an Act of Parliament, the 55 George III., and all the members of the corporation are apothecaries, and therefore the corporation itself is an apothecary.

Lord Justice Bramwell: I do no not know about that.

Lord Justice Baggallay: Query a duly qualified apothecary. It does not necessarily follow that every individual member is a duly qualified apothecary within the meaning of this Act.

Lord Justice Bramwell: Let me ask you this question. There is a firm of chemists, every one of whom is a member of the Pharmaceutical Society—six of them. They take in the son of one of the partners, who is also a member of the Pharmaceutical Society. I rather think, there being seven, they must then register as a company, must they not?

The Attorney-General: I think there cannot be a partnership of seven persons unless they are registered.

Lord Justice Bramwell: Then what would happen? would the firm be at liberty to carry on this sale of poisons?

The Attorney-General: Not according to my construction.

Lord Justice Bramwell: Because *quâ* corporation they would not be a pharmaceutical chemist.

The Attorney-General: Is your lordship assuming there may be corporations? I was under a mistake about that. I understand that the provision as to there not being a partnership of more than seven persons applies to banking only.

Lord Justice Bramwell: I think not, I think you are wrong there.

The Attorney-General: The words are:—"No company, association, or partnership consisting of more than ten persons shall be formed after the commencement of this Act for the purpose of carrying on the business of banking unless registered as a company."

Lord Justice Bramwell: I think there is some other one.

Lord Justice Baggallay: The 6th section of the Companies Act provides that any seven or more persons associated for any lawful purposes may become registered.

The Attorney-General: The Lord Justice Bramwell puts the case to me of the proper number. Then it goes on, "no company, association, or partnership consisting of more than twenty persons shall be formed after the passing of this Act for the purpose of carrying on any other business that has for its object the acquisition of gain," and so on.

Lord Justice Bramwell: You are not likely to get twenty chemists into partnership, to be sure. It is no use testing the meaning of this Act of Parliament by supposing impossible cases, therefore I withdraw my question.

The Attorney-General: I daresay your lordship might say that my construction by the construction under which or by reason of which I wish to except the Apothecaries' Company might be somewhat strained; there is nothing in the case to show it, but I was told that all who belong to this company are qualified apothecaries.

Lord Justice Bramwell: But are they pharmaceutical chemists?

Lord Justice Baggallay: They are licentiates.

The Attorney-General: They are within the exemption of section 16. Section 16 is that "nothing in this Act shall apply to any legally qualified apothecaries or any member of the Royal College of Veterinary Surgeons." It may be that although it was intended to qualify all apothecaries there may be a slip, but I do not know that that will invalidate my argument or affect it at all. It is clearly the intention to protect the Royal College of Veterinary Surgeons, and if the Royal College of Veterinary Surgeons is to be protected or excepted, one cannot very easily see why the Society of Apothecaries should not be protected—duly qualified apothecaries.

Lord Justice Baggallay: It is perhaps rather difficult to say so, but it is not a protection to the Royal College of Veterinary Surgeons, but to all individual members of the College, and in the same way the protection is to individual apothecaries; possibly if every member must be an apothecary it may make the corporation apothecary too.

The Attorney-General: If the members of the Apothecaries' Company are not apothecaries they ought not to be protected, but it so happens that they are. Then it goes on, "And upon the decease of any pharmaceutical chemist or chemist and druggist, actually in business at the time of his death, it shall be lawful for any executor, administrator, or trustee of the estate of such pharmaceutical chemist or chemist and druggist, to continue such business, if, and so long only as such business shall be *bonâ fide* conducted by a duly qualified assistant." That shows what the intention of this Act is, and that throws great light, I think, on the 1st section, because if it had been the intention of the Legislature that persons should be safe, that people who kept this open shop should be safe, if sales were effected by a legally qualified assistant, it would not have been necessary to insert this provision; but when the Legislature had to deal with the case where the pharmaceutical chemist or druggist died, and it was necessary that his business should be carried on until the estate was wound up and realized for the benefit of his family, then it inserts this express provision.

Lord Justice Thesiger: I think that does fortify your view as to the meaning of the word "sell" very much.

The Attorney-General: And also keep open; because take the case of a chemist who died, leaving a widow, and leaving the whole of his business by his will to his widow. Of course she is not a qualified chemist, but she would keep open this shop; she would be the person who would keep open the shop, and unless there had been some such provision as this, the unhappy widow in the case supposed would have been liable to be sued for the penalty. Then the Legislature says no; we will have an express provision to meet that case, and if the widow conducts the business until it is wound up, by means of a duly qualified assistant, she shall be protected.

Lord Justice Baggallay: She would be in a better position than her husband. Her husband could not have carried on the business unless he were qualified, but she may carry it on by a qualified assistant.

The Attorney-General: That is to meet that which is a very hard case, because the business might have been destroyed otherwise. Then it goes on, "A duly qualified assistant within the meaning of this clause shall be a pharmaceutical chemist." Then there is another analogous provision which I think was relied on by my learned friend, which perhaps I had better refer to here. This is section 11. "Every registrar of deaths in Great Britain, on receiving notice of the death of any pharmaceutical chemist or chemist and druggst, shall forthwith transmit by post to the Registrar," and so on. Now I understand my friend to argue that this is applicable to a person, and it cannot be applicable to a corporation because a corporation cannot die, it goes on for ever unless it is wound up. Well, but then my reply to that is, I do not say that it is applicable to a corporation, I say that a corporation cannot carry on the business of a vendor of poisons. It may be a misfortune that it should not be able to carry on the business of a seller of poisons, but the Legislature has said that it shall not, and therefore it is not necessary that the death of a corporation should be certified, and the name of the corporation struck off. I do not know that it is necessary that I should go to this extent, but it seems to me that even if a corporation consisted of twenty-five members, every member being a qualified pharmaceutical chemist, I would submit that they could not carry on that business of keeping open a shop for the sale of poisons, because the individuality of the members is, so to speak, done away with, and the corporation is an obstruction. I do not say that it is necessary, perhaps it may be imprudent of me to present that proposition to your lordships; but it seems to me that that would follow from the language of this Act. Then, if I am right in saying that the 1st section was intended by the Legislature to prohibit the selling of poisons, or the keeping open of a shop for the sale of poisons by anybody except by a properly qualified person or persons, and, if I am right in my contention that the seller spoken of in this section is the master, and that the keeper of the open shop is the master, then it would be clear, I think, that the Legislature did intend that no one—corporation or person—should keep open shop for the sale of poisons, and should sell poisons as the master by his own hands, or by the hands of his agents, unless he was duly qualified. Therefore, it must come to this, that no shop should be kept open for this purpose unless by a duly qualified person. Then that would exclude a corporation by the intention of the Legislature. And supposing it had stopped there, whether there would have been any remedy or not against a corporation keeping open shop for the sale of poisons, could it be said that it was intended by the Legislature that a corporation might open a shop for the sale of poisons? I should think that if there had been no subsequent clause imposing a penalty, or giving a remedy, if a corporation did open a shop for the sale of poisons, the corporation would have infringed and disobeyed this Act, and might be liable to prosecution for so doing. Then there follow several sections which describe the various kinds of qualification, and the registration of pharmaceutical chemists, and chemists and druggists, and so on, and sections providing for the examinations; and then at section 10—"It shall be the duty of the Registrar to make and keep a correct register in accordance with the provisions of this Act, of all persons who shall be entitled to be registered under this Act, and to erase the names of all registered persons who should have died, and from time to time to make the necessary alterations in the addresses of the persons registered under this Act." The argument I have used on the 11th section is, I think, applicable to that too. It might be said you cannot erase the name of a corporation because a corporation does not die; but the answer to that is, "Oh! but then a corporation cannot carry on this business." Then comes section 15, and that is the important section which gives the remedy. "From and after December 31, 1868, any person who shall sell or keep open shop for the retailing, dispensing or compounding of poisons, not being a pharmaceutical chemist, or shall fail to conform to any regulations as to the keeping or selling of poisons within the regulations of this Act, or who shall compound," and so on, "shall, for every offence, be liable to pay the sum of £5, and the same may be sued for, and recovered and dealt with in the manner provided by the Pharmacy Act for the recovery of penalties;" that is to say, the action must be brought in the county court. That is the provision of the Pharmacy Act of 1852. If the mischief is what I say, and the corporation keeping open shop are within the mischief, or when they do that they constitute the mischief which was intended to be remedied, surely there is no reason simply because the word "person" is used that therefore "person" could not include corporation. Lord Coke says, "That it does include corporations unless there is some thing in the suit to show that it was intended it should not." And though the Court of Queen's Bench at first when this case was being argued were inclined to come to the conclusion that corporations were not within this section, because corporations could not be rendered liable for torts; upon cases being cited to the court bearing on this subject, to which I can refer if necessary,—but I should think that it was not necessary to show that corporations can be rendered liable for torts—their lordships in the Court of Queen's Bench came to the conclusion that that point, at all events, was not fatal to the plaintiffs. Then take such a case as this. Supposing a corporation is got up for the purpose of evading this law, as apparently this was,—at all events, just the number which was required to make a corporation took shares,—supposing they had no knowledge of chemistry or of poisons, no qualification of any sort, but they simply want to make a profit. They know very well that if they can sell poisons they will have a large sale, and can make an enormous profit by the sale of poisons; indeed, chemists and druggists appear to me to make an enormous profit out of everything they sell; they want to do a fine business; they turn themselves into a corporation or into a limited company. The real owner of the business has perhaps nearly all the shares, and the others have just a sufficient number of shares to qualify them. Then they open this shop and they sell poisons to any extent, and there is not a single individual who has anything to do with the business who knows one poison from another. Surely the consequences would be alarming; but supposing, in addition to doing that, although the corporation is not qualified and the members of the corporation are not qualified, they stick up over their door, "London Supply Association, Pharmaceutical Chemists."

Lord Justice Bramwell: No.

The Attorney-General: They would not be liable for doing it. They would not be liable to any penalty. They might add they were chemists and druggists, and they would be liable to no penalty. Why? Because, according to my learned friend, a corporation is not included in this Act, it is a *casus omissus.* That must be the consequence, I do not see how anybody can avoid coming to the conclusion that that must be the consequence. And so in that way the whole of the provisions of this Act, which were intended for the benefit of the public, and to protect the public from danger, and to preserve the health and lives of the public would be evaded, as they were evaded in this instance. And there would be no necessity, as far as I can see, in such a case to have any qualified person about the premises at all. There is no provision for it. In this particular case they did appear to have had a qualified person there to sell the poisons and dispense the drugs. On the other hand it is found in the case that on some occasions at all event poisons were sold by unqualified persons.

Lord Justice Bramwell: I want you at some time or other to meet a difficulty which has occurred to me. I quite agree with you that a corporation may be guilty of a tort, there is no doubt about that. For instance, a publishing company may publish a libel and be liable. I do not say they could be indicted for it.

The Attorney-General: I think they could.

Lord Justice Bramwell: But generally speaking, the law directs itself against the illegal acts of individuals, not corporations, now may not this be a solution? I am not going to give judgment against you, or for you, or anything of that sort, but merely telling you what has occurred to me. The Act of Parliament says, "it shall be unlawful for any person to sell, keep open," and so on. There is a corporation which does sell and does keep open. Is not the true construction of the Act of Parliament that the persons who do it, who do it actually, who do it *de facto*, are the persons who are prohibited by section 1, and who by section 15 are liable to these penalties? If that is right it would go to show that this present action in the county court was not maintainable, but it would go equally to show that you might maintain an action against the individuals who carry on this business, if they are not within the Act of Parliament. Do you follow me? Is not that the more rational meaning of the Act of Parliament, if I may venture to say so? Then you may say—Now I will sue you, A. B., because I say you are keeping open a shop for the sale of poisons? He says, No, I am not. Why are you not? He says, Because I am one of a corporation, it is a corporation that does it. Then you reply, Well; but I say you do it; it is you who are doing it in fact. Just suppose that in your code you were to say, It shall not be lawful for any person to publish a libel on anybody else, and whoever does shall be subject to an indictment to be punished by fine and imprisonment. Then the corporation publishes a libel. You could not indict the corporation, you would indict the individual. If he said, But I am one of the corporation; I am the assistant, or the shopman, or the servant, the answer would be, It is you who have done it. Have I made myself understood?

The Attorney-General: I think so. The answer, I think, by a member of a corporation would be thus: You might take a corporation formed to carry on the business of a large chemist. We may assume a corporation formed to carry on the joint businesses of Bell and Company, in Oxford Street, and Savory and Moore, about the largest chemists in the country. You might have a corporation consisting of two hundred or three hundred, some of them, we will say, ladies, living at the very extremity of Englant, north or south, who never go near the premises, and who do not know anything what is done there at all. How could it be reasonably said that they are within the provisions of this Act of Parliament?

Lord Justice Bramwell: I agree unless it should be shown that they specially order the unlawful act. Then you go to the man who is actually doing it.

The Attorney-General: Nobody can be actually doing it; no member of a corporation will be actually doing it.

Lord Justice Bramwell: Still you go to the man who does it.

The Attorney-General: Then the man who does it would escape.

Lord Justice Bramwell: Why?

The Attorney-General: He does not keep open the shop.

Lord Justice Bramwell: That is what I doubt; under this Act of Parliament I doubt if he does it. It is he who does it *de facto*; he is the man who actually does it. You say to him, What is your excuse? He would say, I do not do it.

The Attorney-General: Take a corporation such as I have described. It must necessarily carry on its business by means of a manager or assistant. The members, the corporators, may know, and probably would know, nothing in the world about it. Still, the shop is there; it is kept open for their profit; the sales are all made on their behalf. Could it be said that it was the intention of this Act of Parliament to make the assistants and managers liable and not the master?

Lord Justice Bramwell: Why not?

The Attorney-General: Because it says so.

Lord Justice Bramwell: Though you have a master, he would be liable, too,—the individual and the master,—because one man would do it and the other would order it.

The Attorney-General: Why not the corporation?

Lord Justice Bramwell: Because I am not sure you could make out the corporation did order it.

The Attorney-General: How could you make the manager liable if he were duly qualified?

Lord Justice Bramwell: If you could not hit the manager because he is a duly qualified chemist, then you ought not to hit these people, provided they are. It seems to me the whole thing becomes more rational in that way. Take the case of a dormant partner, a non-interfering partner in a chemist's shop; two men, or a man and a woman, if you like, partners in a chemist's shop. The woman never appears and never has anything to do with it, but the man is a duly qualified chemist; would it not be a very unreasonable thing to say it could not subsist without both the man and woman being liable to a penalty?

The Attorney-General: I do not see anything unreasonable in it.

Lord Justice Bramwell: Do you think a woman ought not be a chemist?

The Attorney-General: They may be chemists or anything they like if they become qualified.

Lord Justice Bramwell: Women become qualified under this Act?

The Attorney-General: Yes, may lord, there are several. I would let women with all my heart do anything they like that is decent and proper, but let them be qualified. If your lordship's view was correct it would come to this—that a class of people who had no qualification and no knowledge might keep open a shop, and they might take a partner who happened to be qualified; who was a dormant partner and never came near the place at all, and they would be protected.

Lord Justice Bramwell: There are no end of difficulties in this Act; that difficulty would be retorted upon him in this way. A. B. is owner of a chemist's shop, he has got an assistant in whom he has unlimited confidence and who may be perfectly competent. A. B. is a pharmaceutical chemist and the assistant is not.

The Attorney-General: Then A. B. is responsible.

Lord Justice Bramwell: For what?

The Attorney-General: For keeping open shop.

Lord Justice Bramwell: But he is a pharmaceutical chemist.

The Attorney-General: He is responsible for any damage that may arise.

Lord Justice Bramwell: Not for a penalty?

The Attorney-General: No; but for the proper conduct of that shop. It is to his own interest that it should be properly conducted.

Lord Justice Baggallay: In order to see that I am quite right as to what I understand to be your construction of the statute, I should like to put one case of everyday occurrence. Take the case of a duly qualified pharmaceutical chemist in a country town. The trade of a chemist is not a very good one in a country town, and he joins with it the trade of a grocer. He is a duly qualified chemist, and he has in his employment a man who is very well qualified for weighing out a pound of tea and making up a pat of butter in the grocery department, and he sends that man round to make up a box of pills which may contain some preparation of aconite, which is one of the poisons in the schedule. Would there be any penalty on any person in that case according to your construction?

The Attorney-General: Is your lordship assuming that the chemist enters into partnership with anyone?

Lord Justice Baggallay: No, he is entirely alone. He is a pharmaceutical chemist by examination and registration, but the business is not sufficient to maintain him and he joins the business of grocery to that of chemist and druggist. In the grocery department he has a very good assistant for a grocer, who weighs out pounds of tea, makes up pats of butter and things of that kind; but he sends him round to sell some of the poisons contained in the schedule A, or to make up pills which have got aconite in them. Would either he or the assistant be liable to a penalty according to your construction of the Act?

The Attorney-General: Not under the 15th section.

Lord Justice Baggallay: I mean under that section. That is the case we are dealing with at present. I thought that would be your answer.

The Attorney-General: Both the owner and seller in that case would be properly qualified men.

Lord Justice Baggallay: He might be liable to a penalty if he put a non-qualified man to do the work, but that would not be under this statute; at least I do not think it would.

Mr. Wills: Nor under any other.

The Attorney-General: I do not think he would be liable. If that were so, and that were the intention of the Legislature, the Legislature would have said so.

Lord Justice Baggallay: I thought that would be your reply. I merely wished to see if I rightly followed your construction of the Act.

The Attorney-General: Yes, my lord; at first I thought you were referring to the case of a partnership. What Lord Justice Bramwell put was about individual members of a corporation.

Lord Justice Bramwell: It would be the directors who would be hit, if anybody.

The Attorney-General: The directors, as a rule, know nothing about it.

Lord Justice Bramwell: I was going to that. I do not want to suggest it, but suppose no penalty had been provided, and there had been a prohibition that it should be unlawful. It would have been an indictable misdemeanour.

The Attorney-General: Yes, my lord.

Lord Justice Bramwell: Who would have been indicted then?

The Attorney-General: I do not know. Corporations have been indicted for misfeasance in certain cases. Cases are cited in the Court of Queen's Bench.

Lord Justice Bramwell: They are indictable for non-repair of a road. That there is no doubt about.

The Attorney-General: I am sorry I have not brought the authorities with me. In the Court of Queen's Bench the Lord Chief Justice says: "Being thus of opinion that a company, though incorporated, is none the less within the prohibition of the statute, I come to the remaining question whether such a company is capable of being sued for the penalty provided by the 15th section. Upon this point the authorities referred to by the Attorney-General in his argument appear to me to afford a satisfactory answer. Although it is true that a corporation cannot be indicted for treason or felony, it was established by the case of Reg. *v.* The Great Northern of England Railway Company that an incorporated company could be indicted for misfeasance—as in cutting through and obstructing a highway—though they could not be indicted for treason or felony or offences against the person."

Lord Justice Bramwell: Have they ever been convicted? It is very easy to indict anybody or anything; but have they not been convicted of a nuisance?

The Attorney-General: Yes, my lord.

Lord Justice Bramwell: A corporation may be guilty of nuisance, may it not?

The Attorney-General: Yes, my lord. I believe I am quite right in saying they have been convicted. The difficulty, of course, is what would happen when they have been convicted.

Mr. Wills: I think, in one case, my lord, either the Great Northern, or the Manchester, Sheffield and Lincoln, I forget which, they shunted backwards and forwards over the road that leads to the station at Lincoln. They were indicted. I think there were two or three trials; but they were convicted, I know.

Lord Justice Bramwell: I think that may be done; but that really would be a corporate act. Then you would say this keeping open a shop is?

The Attorney-General: I should suppose what would happen would be this: the corporation would be indicted for a nuisance, and supposing the case is proved against them, and the jury returned a verdict of guilty, then the judge would sentence the corporation to the payment of a fine. I suppose that could be done as a common law misdemeanour, and the punishment for a common law misdemeanour is fine or imprisonment, or both. The judge would sentence the corporation to pay say £1000, and I suppose there would be some means in law to enforce the payment of the fine. I cited three cases in the Queen's Bench on this subject; one of them, I think, is not mentioned. The first case is Yagra *v.* The Bank of England, in the 16th East, page 6. In this case several instances are given of actions against corporations for false returns to writs of *mandamus*. Then there is, again, the case of The Queen *v.* The Birmingham and Gloucester Railway Company. That was an indictment for a misfeasance. And then there is further the case against the Great North of England Railway Company, which is a case of misfeasance—cutting through and obstructing a highway. The Lord Chief Justice goes on to say: "In the present instance we are dealing not with an indictment or information, but with an action in a civil court. Though the sum to be recovered is no doubt a penalty for the infraction of the statute, the means to be resorted to for its recovery are of a purely civil character. If a corporation can be indicted for misfeasance, I am wholly at a loss to see why it may not be proceeded against in a civil suit for the recovery of a penalty which it has incurred by disobedience to a statutory prohibition." I should think that there could be no doubt about that, that they may be proceeded against, always provided that they were within the Act; and there would be no difficulty in suing a corporation for a penalty in respect of a corporate act, always provided it was the intention of the Legislature that the corporation should be liable.

Lord Justice Bramwell: I think you contend that if there were six partners chemists, and one of them was not qualified, the whole six would be liable to the penalty for keeping open a shop.

The Attorney-General: I think so, my lord.

Lord Justice Bramwell: You contend that?

The Attorney-General: At all events, the one who was not qualified would be liable.

Lord Justice Bramwell: But would the others?

The Attorney-General: I do not know. If your lordship asks me what my opinion is, I should say, "yes," because they have not complied with the statute. But it is not necessary.

Lord Justice Bramwell: I asked you what you contend.

The Attorney-General: I should say, my lord, it is not necessary for me to contend that.

Lord Justice Bramwell: If there were seven of them, and they were incorporated, the corporation would be only liable to one penalty.

The Attorney-General: Yes.

Lord Justice Bramwell: Then a corporation can infringe the Act on cheaper terms than individuals.

The Attorney-General: The Act says it shall be unlawful for any person to say or do so-and-so—to keep open a shop. I do not think anyone can contend that this word "person" in the first section may not be read "persons." I think it is Lord Brougham's Act which would apply to that, which says that the singular includes the plural; and, therefore, if you read it in this way, "From and after this date it shall be unlawful for any persons to keep open a shop unless they are qualified," what would that mean, except that they must be all qualified?

Lord Justice Bramwell: But only one penalty.

The Attorney-General: Perhaps only one penalty. If my construction is right it would be only one penalty.

Lord Justice Bramwell: Then afterwards it goes on, "And if any person——"

The Attorney-General: Again you must read the plural for the singular, "And if any persons."

Lord Justice Bramwell: "Any person or persons shall, and such person or persons shall," and so on.

The Attorney-General: Yes, my lord.

Lord Justice Bramwell: I have often said I think there is a great deal of very—what shall I say—lively criticism on Acts of Parliament by people who, if they were to draw them, would draw them, perhaps, as well as those who have drawn them. But this certainly is a very curious Act of Parliament, because it says it shall be unlawful for any person to sell poisons, not one poison, so that an individual to be liable for selling must sell "poisons."

The Attorney-General: In one place it says, "it shall be unlawful to sell any poison." Which section is your lordship referring to?

Lord Justice Bramwell: To the 1st section.

The Attorney-General: I do not think that this Act is drawn as clearly as it might be. But there again Lord Brougham's Act comes in, that the plural must be the singular and the singular the plural.

Lord Justice Bramwell: You say that "poisons" may be "poison."

Mr. Wills: No; under Lord Brougham's Act singular may mean plural; but not plural singular, I think.

The Attorney-General: I have a pretty clear recollection of it, and it says the plural shall mean singular, and singular plural, if I recollect rightly; and masculine shall mean feminine, and feminine masculine. My friend has looked at it more recently than I have; but I believe that is right. It would have been better if the gentleman who drafted this had stuck to the singular or the plural all throughout. But in order to get rid of the little trouble of saying "poison or poisons," he has used sometimes one and sometimes the other.

Lord Justice Bramwell: That comes in after about keeping open shop; but I suppose under the first words of the Act of Parliament if a man met his friend in the street, and this friend were to say to him, I want some poison to kill a dog, or what not, and his friend says, I happen to have a little bottle of prussic acid in my pocket, and sold it to him, he would be subject to a penalty under this Act of Parliament.

The Attorney-General: I think he would. I dare say that this word "sell" was levelled against such an act as that. I understand and believe—of course your lordship will only take it as part of my argument that it may be so—that there was before this Act passed a practice of hawking about opium in various country districts, and people began to like opium, and preferred it to alcohol—a most dangerous and pernicious thing. Hawkers used to take about little supplies of opium and sell in country districts.

Lord Justice Bramwell: Then that same person, if he were ever so much a pharmaceutical chemist, would be within section 17 and subject to a penalty there.

The Attorney-General: If he did not comply with the provisions.

Lord Justice Bramwell: I have supposed it is a sale in the street.

The Attorney-General: He might put a label on it—put poison on it, sold by John Jones. In that case I presume the vendee would have been introduced to the seller.

Lord Justice Bramwell: Now, I should like to put this case. Suppose a man who sold a bottle of poison to his friend had been sent out by a pharmaceutical chemist to deliver it to somebody—not dishonestly selling, but saying I will let you have this, and going back and getting another; who would be liable to the penalty then? I should think the individual, would he not?

The Attorney-General: I should think so.

Lord Justice Bramwell: You would say because he would not be authorized to sell by his master—true.

Mr. Wills: I beg your pardon, Mr. Attorney, the plural does include the singular, and the singular the plural in Lord Brougham's Act.

The Attorney-General: I thought so. Before I sit down I should like to call your lordships' attention to the 17th section. I do not want to repeat it all over again, but there are certain things which must be done provided for by the 17th section, and which are to be done on the sale of any poison. Any person selling poison otherwise than as herein provided shall, upon a summary conviction before any justice, be liable to a penalty not exceeding £5 for the first offence, and £10 for the second, and so on. Very well; supposing a servant of the corporation sold a poison and did not label it properly, it is clear that the corporation would be liable to this penalty, because the penalty is to be recoverable by a summary proceeding, and the provisions of 7 and 8 Geo. IV., cap. 28, would apply. I do not say it was necessary that the provisions I am about to read should be inserted in this statute, or any statute, but they are in this statute, and they are these: the 7th and 8th Geo. IV., cap. 28, section 14, provides, "That whenever a statute relating to any offence, whether punishable by indictment or conviction, in describing the offence or offenders uses words importing the singular number, or masculine gender only, it shall be understood to include several matters as well as one matter, several persons as well as one person, males as well as females, and bodies corporate as well as individuals." So, in that case, the body corporate would be clearly liable. Therefore, this very serious consequence would ensue. The corporation is an abstraction—it cannot itself sell in the ordinary sense. It must employ somebody else to sell, and if the person who was employed by the corporation sold the poison and did not label it poison or did not put the address upon it, or did not do any of the other things which are mentioned in this 17th section, the corporation would be liable to the penalty of £5, and yet if a corporation keeps open a shop and advertises it as a shop for the sale of poisons, and infringes in any way it thinks proper the provisions of the 1st section the corporation cannot be made liable, apparently, because the remedy is by civil action instead of by summary proceeding or criminal procedure. That is a very extraordinary thing.

Lord Justice Bramwell: Supposing the assistant was in the shop, and the customer was known to him and he sold the goods.

The Attorney-General: I do not think that would be enough.

Lord Justice Bramwell: Who would be liable?

The Attorney-General: The master.

Lord Justice Bramwell: Would anybody else?

The Attorney-General: I think so. Surely it is not enough that the person to whom the sale is effected shall be known to the assistant. Let me read that part of the section again; "and it shall be unlawful to sell any poison of those which are in the first part of Schedule A to this Act, or may hereafter be added thereto under section 2 of this Act, to any person unknown to the seller, unless introduced by some person known to the seller."

Lord Justice Bramwell: Who was the seller?

The Attorney-General: I will show your lordship in a moment. "And for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller."

Lord Justice Thesiger: Then you cannot construe the words literally and strictly. I mean if "seller" is to mean "sellers," then if there were three or four chemists and druggists, properly qualified, in partnership, unless the buyer were known to all of them there would be strictly and technically an offence. That cannot be intended.

The Attorney-General: Surely if a man is known to a member of a partnership, he is known to the partnership.

Lord Justice Thesiger: I doubt that.

The Attorney-General: If there are five partners it does not follow that because all five of them are sellers that one of them is not a seller if he is known to A. and B., and is not known to C. and D. A. is the seller although he sells generally with B., C. and D.

Lord Justice Bramwell: The perplexities about this Act are never ending. If it was necessary to make that statement in section 17, and otherwise, the seller would have been the *de facto* seller; does not that show that in other sections of the Act of Parliament seller means the *de facto* seller?

The Attorney-General: No, my lord. I tried to point out why it was necessary in this section to define seller. Take the very beginning of it. It shall be unlawful to sell any poison, either wholesale, and so on, which is not labelled with the name of the article and with the name and address of the seller of the poison. Therefore it is obvious it is desirable to clear that up, it might be construed to be the name of the actual seller, the immediate seller. Then, again, it shall be unlawful to sell any poison, and so on, to any person unknown to the seller. Again that is ambiguous. Again it is necessary to have that cleared up. There are obvious reasons why the seller should be explained in this section, which do not apply to sections 1 and 15, and, moreover, there is this further reason, that in section 17 we are dealing with a criminal act, and the remedy is a criminal proceeding; in sections 1 and 15 it is a civil proceeding.

Lord Justice Baggallay: If I follow your contention aright as to the construction, you would say that not only for the purpose of section 17, but for the purpose of all the rest of the Act, the person on whose behalf the sale is made is to be deemed the seller.

The Attorney-General: That is my contention, only I say that it was not necessary to express that in section 1, whereas there were some reasons for stating it in section 17, because it might possibly be thought by anybody reading section 17 that the particular man who made the sale would be liable to the criminal proceeding.

Lord Justice Baggallay: If it was intended to be so throughout the Act, it would have been very convenient to have stated so and not to have stated it in the individual terms in which it is.

The Attorney-General: I do not mean to say the Act might not have been drawn to make the intention a great deal clearer. But that is an observation which might be made with regard to a great many Acts.

Lord Justice Bramwell: I should think under section 3, if there were a corporation that might apply to the Apothecaries' Company, "Chemists and druggists within the meaning of this Act shall consist of all persons who, at any time before the passing of this Act, have carried on in Great Britain the business of a chemist and druggist in the keeping of open shop for the compounding of prescriptions." And the Apothecaries' Company have done such a thing, have they not?

The Attorney-General: I understand so. They have for many years.

Lord Justice Bramwell: Admirable medicines they sell, according to my humble judgment. Then that would exempt them, which was considered one argument against you.

The Attorney-General: I think it would.

Lord Justice Bramwell: It strikes me that the 3rd section authorizes the Apothecaries' Company going on and continuing.

The Attorney-General: Yes, my lord.

Lord Justice Bramwell: It is not to be lawful for them to do it, unless he shall be a pharmaceutical chemist or a chemist and druggist within the meaning of this Act. Then a chemist and druggist within the meaning of this Act, shall consist of all persons who at the time carried on business. You say "person" there means a corporation, and that would exempt the Apothecaries' Company.

The Attorney-General: Either under that section of the Act the Apothecaries' Company would be exempted or under section 16.

Lord Justice Bramwell: I do not see why under section 16.

Mr. Wills: They must be registered also.

Lord Justice Bramwell: Must they?

Mr. Wills: Yes, my lord, under section 1 they must be registered under the Act.

Lord Justice Bramwell: They could go and get themselves registered.

The Attorney-General: That is the general provision.

Mr Wills: If they can sign that form. I do not know whether they can.

Lord Justice Bramwell: However, what I was going to say was this: If the 3rd section hurts you with that difficulty, I think perhaps you are entitled to retort that is a *casus omissus* of the Apothecaries' Company; and if the 3rd section hurts you with that difficulty, if it is one, does not it do this? Does not it show that corporations might be chemists within the meaning of the Act, and also that the provisions of the Act are such that no future corporation could be formed?

The Attorney-General: It might be.

Lord Justice Bramwell: If so, why?

The Attorney-General: Because they cannot be qualified.

Lord Justice Bramwell: I know, that is why; they cannot fly, because they have no wings; but why should not they have them? That is what I meant by why If the Legislature contemplated that existing corporations might continue their business, why has it made no provision for new corporations?

The Attorney-General: Because the only corporation which was contemplated was the Apothecaries' Company, and the Apothecaries' Company, as I understand, consists altogether of qualified apothecaries.

Lord Justice Bramwell: I should think this must be read, *mutatis mutandis*, "I, residing at ———, in the county of ———, hereby declare that we, a corporation, carry on business," and so on.

The Attorney-General: I do not myself see why, because immediately before the passing of this Act there happened to be one corporation which it was necessary to protect or except, that therefore it would follow that it was the intention of the Legislature to enable all other corporations to sell poisons. Your lordships will bear in mind that this Act only applies to the sale of poisons, it is not to be supposed that people cannot sell drugs. I have no doubt all the co-operative stores sell drugs and I suppose they also sell poisons, but it is very undesirable that they should be allowed to do so. Now, my lords, having placed my argument before your lordships, I hope intelligibly, I should like now to read the judgment. I do not know whether my friend read it.

Lord Justice Bramwell: Yes.

Lord Justice Baggallay: Does the Act of 1869 throw any light upon it? I think it only had reference to veterinary surgeons.

The Attorney-General: The Act of 1869 is an Act to amend the Pharmacy Act, and the 1st section is this— "Anything contained in the first fifteen sections of the recited Act shall not affect any person who has been registered as a legally qualified medical practitioner before the passing of this Act; and the said clauses shall not apply to any person who may hereafter be registered as a legally qualified practitioner, and who, in order to obtain his diploma for such registration shall have passed an examination in pharmacy; nor shall the said clauses prevent any person who is a member of the Royal College of Veterinary Surgeons of Great Britain, or holds a certificate in veterinary surgery from the Highland and Agricultural Society of Scotland, from dispensing medicines for animals under his care." Under the Medical

Act of 21 and 22 Vic., cap. 90, apothecaries are medical practitioners. The schedule of medical practitioners begins thus—members and licentiates or extra-licentiates of the Royal College of Physicians of London; and it goes through a number of others; and No. 8 is licentiates of the Society of Apothecaries of London, so that they are medical practitioners. Then, my lords, I will just refer to the Acts about solicitors. Could a corporation carry on business as a solicitor? Could there be a Universal Legal Advice Company, Limited, sending their clerks before judges in chambers, conducting business in the course of drawing deeds, and so on?

Lord Justice Bramwell: Clearly not as personal and individual acts, because if a man instructs a solicitor to appear for him his appearance is accepted. You must test it in this way: not the business of a solicitor proper, but that which is auxiliary business, that of preparing conveyances.

The Attorney-General: I do not know whether a conveyancer has to undergo the qualification or not.

Lord Justice Bramwell: Surely the Solicitors' Act prohibits anybody who is not a licensed conveyancer from drawing and charging for conveyances, or as a solicitor. Surely that must be so.

The Attorney-General: I think so. There is a penalty on persons acting in the business of solicitors, unless they come within particular classes—conveyancers and so on, I believe.

Lord Justice Bramwell: So that you may put that illustration what would happen if a corporation did it?

The Attorney-General: If it was only necessary to take out a licence, I do not know whether a corporation might not take out a licence, but if it is necessary that there should be a qualification that the person who does the business should pass an examination, I should say the corporation cannot.

Lord Justice Thesiger: The judgment of the court below has been read.

The Attorney-General: Then I will not trouble your lordships by reading the judgment, but I should just like to refer to this passage in the Lord Chief Justice's judgment, where he says—"Upon this state of facts the question presents itself whether the defendant company, as such, is amenable to the penal enactments of the statute. It was fully admitted on the argument, nor could it be contested, that if this had been an ordinary partnership the individual partners, at all events such of them as were not qualified under the statute, would have incurred the penalties it imposes. The intention of the Legislature appears clearly to have been to prevent any shop or establishments to exist for the sale of poisons except under the immediate superintendence and control of a duly qualified proprietor." Then a little further on he says—"It is no doubt possible that although joint-stock companies existed at the time this statute was passed, the formation of such companies for the purpose of combining trades hitherto carried on singly, and among other things for that of superadding the business of the chemist to that of the grocer or provision merchant, may not have been present to the minds of those who framed and passed this statute. Still, if the case, though unforeseen, is within the mischief which the Legislature had in view, and the enactment is large enough to embrace it without any forced or strained construction being put on the language in the Act, it is our duty to advance the remedy intended to be afforded." It does not seem to me that I can say more upon the matter, which is fully before the court.

Mr. Lumley Smith: My lord, I have nothing to add except that as the Attorneys' Act has been mentioned, I think it was under the old Attorneys' Act that where an attorney carried on business as an attorney, but had an unqualified partner, that there the partner was liable to penalties. That was decided, and I put that forward to meet this case which my friend quoted of Reynard *v.* Chase. This is an old case reported in Burrows, in which it was held that a man who was not qualified was not liable to a penalty. I should pair off against that the decisions under the Attorneys' Act, where it certainly was held that the unqualified person who had acted as a partner was liable to penalties.

Mr. Wills: I do not know if my friend thinks there is any analogy in the Attorneys' Acts, because I am quite certain of this from all I know of them that they require to be very carefully examined. There are many misconceptions prevalent as to what is and what is not prohibited by them. I know I have had occasion during the last two or three years, for the Incorporated Law Society, to look into the Acts of Parliament, and we have found things which are commonly supposed to be prohibited cannot be hit by anything in the Act. I do not know enough of them to say whether or not there is any analogy in these cases, but in dealing with them I am sure it would not be safe to adopt this without looking to see what the terms of the Acts are. I am not sure that they do not contain conditions such as you describe—the condition of the person who takes an unqualified partner. I will not say one way or the other. I only say that I am sure you cannot draw any satisfactory analogy without looking to see if the language of the Acts would justify your lordships in questioning the construction put upon the words of this Act. Now, with regard to the principal subject in dispute between us, I propose to say very little, because I cannot add materially to what I said before. I knew very well what the great portion of my friend the Attorney-General's argument would be, because I had the advantage of hearing it before, and I have not heard from him to-day anything more than I heard in the court below, and therefore there is not very much more for me to say, but I do wish to point out this. I think I may sum up a large part of what one has to say on each side of the question in almost one or two sentences. In the first place I say that when you look at section 1 and you find a prohibition to a person to keep open shop and to sell poison unless he shall comply with certain regulations and do certain things and, you find that these things are things which in the very nature of them a corporation cannot do, it is at least as good an argument to say that the corporation was not thought of by the framer of the Act, as to say because several things are to be done which a corporation cannot do, it incidentally follows that—what I am sure cannot be the real intention of the Legislature—no corporation can, under any circumstance, carry on this trade. Then as following that out, the second observation I would make, and it is a broad one and lies on the surface, is this, and it goes to the very root of the thing. There is nothing objectionable in itself in this business being carried on by corporations. There is nothing objectionable in the money being found and the establishment being kept by corporations, provided the actual thing done is done by qualified persons; and if the Act were really as complete as it is incomplete, or if it were an Act which was really *bonâ fide* prepared for the purpose which it professes to have, the protection of the public, and that these sections were not really the trade protection of a set of persons, provision would have been made to meet the case of companies. I cannot suppose that in the year 1868 my learned friend the Attorney-General, or any member of the Government in the House of Commons, would have had a chance of passing an Act which said in terms that any business of this kind should be prohibited to corporate existences. Therefore, if you find that language has been specially used which can only in a strained way be construed to apply to them, and if you find one set of terms used throughout the Act (and in many places it is impossible to read the word "person" as comprehending corporation), surely the case is a broad one, that it is a *casus omissus*, and that the framer of the Act, in drawing the Act, and the Legislature, in passing the Act, were thinking of the ordinary common case of a physical natural person carrying on business, and meant to hit that case, and that nobody thought of the case of corporate existences. Surely if they had done so it is reasonable to suppose that what would have been done would have been a prohibition to such associations enacted. There is no difficulty in the Attorney-General working hard now, and he can do very much what he likes at present, and I dare say will be able to do so for a good while to come. There is no difficulty in his going to Parliament and getting an Act of Parliament of this kind if the protection of the public requires it. I do not think it does, because the Act is incomplete as it is. I contended before that, as far as the word "sell" is concerned, it hits the person actually and physically making the sale. I do concede to the Attorney-General what he said that is not so adequate a protection as putting a penalty on the owner of the shop.

Lord Justice Bramwell: Do you say that in the 1st section the word "seller" applies to the actual shopman in the shop who sells the drug, or to his master?

Mr. Wills: In the 1st section, does your lordship mean, or the first of the two sections we have been discussing?

Lord Justice Bramwell: The 1st section.

Mr. Wills: Where it is "sell or keep open shop for retailing or dispensing."

Lord Justice Bramwell: Do you mean to say the seller there means the master or the shopman?

Mr. Wills: I have been contending that it means the shopman, for this reason. If that section stood alone, and if the 15th stood alone, I do not think I should so contend, because it seems to me that what was in the mind of the man who wrote those words when preparing section 1 was that he wrote down "sell," and then it occurred to him, but the master very often will not sell. He first thought of the master who effected the sale with his own hand, and then it occurred to him, "Oh! but very often it is sold by an assistant, and therefore I will say 'keep open shop.'"

Lord Justice Bramwell: It occurred to me that the explanation of that section is this. He began by saying: "If any person shall sell;" but says somebody, "You will not be able to prove the sale, but you will be able to prove the keeping of the shop to sell, and people do not keep shops to sell without selling," and therefore he put in "selling or keeping open shop to sell."

Mr. Wills: That probably is so *ex majore cautelâ*.

Lord Justice Bramwell: That would indicate that the master was meant.

Mr. Wills: I think so. I do not think, looking at it and applying common sense to these matters, that if it were not for the 17th section, I should be disposed to think as at present advised that the reasonable construction was that seller meant the same person as kept open shop, and that both of them meant to hit the master and not the man; but then comes section 17, which is very carefully prepared, and that says in this particular section the seller shall mean the person to whom the shop belongs.

Lord Justice Baggallay: A special penalty is fixed to a branch of that section.

Mr. Wills: A special penalty recoverable in a particular way. It is a carefully drawn section. It would follow, and it does follow, from any construction however elaborate, that may be put on the words of that section, that an offence would be committed if the master of the shop is not the person who actually makes the entry in the book, because the entry which is to be made in the book is to be made by the seller. Then come these subsequent words which say, "For the purposes of this section seller shall mean the owner of the shop." Of course in practice, and in reasonable practice, the person who makes the entry is not the owner of the shop, who knows nothing but what his man goes and tells him, but it is the person who actually effects the sale. He is responsible and there seems to be no reason why the hand of the master should be concerned in making that entry. Therefore, this is an incomplete piece of legislation, and I cannot help thinking that an injustice is done to those sought to be affected by it, by treating it as a complete and effective piece of legislation, which was intended to hit all round and which contains perfect provisions in itself.

Lord Justice Bramwell: Who is liable under section 15? that part which says, "or who shall compound any medicines of the British Pharmacopœia, except according to the formularies of the said Pharmacopœia." That would be the assistant who compounded them, would it not?

Mr. Wills: I should think so, my lord. If so, there is a change of person. If the original idea of the draftsman was kept up, the keeping open shop ought to relate to the master here with regard to compounding. It is very difficult to say that that means anybody except the person who actually does it.

Lord Justice Bramwell: Are you willing to adopt the argument in the alternative which I have suggested to the Attorney-General, that the statute is applicable to persons, that it is not applicable to corporations, but that the directors of this company might be charged with the penalty? Say you have kept open this shop, you were the managers—you were the principals—you have kept it open for the benefit of your corporation who are personally liable; therefore unless you are within the Act of Parliament, and so on. That is an argument which, if well founded might relieve you of all trouble in this particular case.

Mr. Wills: And might be just as disastrous in another.

Lord Justice Bramwell: When they brought the action against you for £5 penalties, and charged the managers with being the people who did it.

Mr. Wills: I confess I have not considered that question at present sufficiently to deal with it.

Lord Justice Bramwell: I wish you had thought of it. Speaking for myself, I may say that I think possibly this action may have been brought wrongly—that it ought to have been brought against the man who did it. On this sort of general principle the Act of Parliament which created illegalities made them in individuals and not in corporations, unless you find something in them expressly making it so.

Mr. Lumley Smith: You can sue a firm now by their corporate name.

Lord Justice Bramwell: You sue them in their partnership name now, certainly; that is true.

Mr. Wills: I see there are directors. I was looking to see whether there were directors of this company or not. After the hard names which had been used again by my friend, the Attorney-General, about evading Acts of Parliament, about the broken-down chemists and druggists being employed, it seemed possible it might turn out that there were no directors at all in the company, but I find there are.

Lord Justice Bramwell: How many?

Mr. Wills: There are three. I should think they are neither of them qualified.

Lord Justice Bramwell: I want to know why, in all good sense, if these three men are pharmaceutical chemists, as they well might be——

Mr. Lumley Smith: It is found by the case that Longmore is the only person who was qualified. He was a shareholder, but he only had one share.

Mr. Wills: That we must meet when our day comes, and we must consider it. I confess I have not considered it at present. Of course I must grant this. I am not going to stand up here and say that any man may indirectly break the law, if the law is broken, where he cannot do it directly. If he is really breaking the law in his individual capacity he must answer for it. Of course, there always comes the question whether he is. My argument, I think, to a great extent would be the same, namely, if this is a *casus omissus*, if the carrying on of this business by corporate bodies is not forbidden by this Act, and is not hit by it, then the persons who avail themselves of that state of the law are not breaking the law. As far as I can at present see the question would be to some extent the same as in this. I submit to your lordships, generally and shortly, that it is safer to allow a thing, which, as your lordships might think the Legislature might very well have made provision against, to let it go by—let the Legislature take care of itself, and the public—than to strain penal Acts of Parliament for the purpose against whom it was not meant. As an illustration of the incompleteness of this Act, because it is on that I am dwelling now, I cannot but think myself that if the Legislature had thought of the case of corporate bodies and limited companies, which were very largely in existence at that time, carrying on this kind of business as well as others, that they would have made reasonable provisions; because there can be no objection in itself to any business of this kind being carried on by capital found in that way any more than any other, and the real objection is to having these drugs dealt in by persons who do not know how to use them.

Lord Justice Bramwell: You may say to the Attorney-General, the case of a corporation is not within the mischief, because a corporation may have a properly qualified dispenser to serve out its drugs, and then it would not be within the mischief; but here general words, if they comprehend the case, comprehend one not within the mischief. Do you follow me?

Mr. Wills: I do, my lord. There is this also, showing really the incompleteness of this Act. It is the effect of this Act that a properly qualified person may live in Rio de Janeiro, Timbuctoo, or anywhere else, and carry on a business of this kind in London by means of a set of people, not one of whom possesses a qualification, and yet no offence would be committed, if the Attorney-General's view is right. If my view is right, that it is the seller who sells, and as was suggested by the court, I do not know what view the court may take of it, that keeping open the shop is answered by the person who does actually keep open the shop, then he is hit; that is, the unqualified person who deals in this sense for another person is hit by it. But if the Attorney-General's reading is right, and these words mean to affect the master,—and he must say so for the purpose of the present case,—if so, then if I happen to possess a qualification, I may live on my means, I may have the whole business of this kind, which it is supposed the public want this ample protection against, carried on by people who are totally unqualified. "Oh," says the Attorney-General, "it is his interest to have properly qualified people, and therefore it is not necessary." Of course that applies equally to the case of a limited company. It is their interest, because they would be civilly responsible in exactly the same sense, and in exactly the same way as a natural person would be.

Lord Justice Bramwell: I should like to put this. A company constituted for the retailing of goods, one of these co-operative associations, but no particular goods specified—none enumerated—if such a thing as this is unlawful, it would be *ultra vires* the directors to sell it, and the corporators would have a right to say you have no more authority to do this than you have to do any other illegal or prohibited thing. Who would be liable then, the corporators or the directors who did it?

Mr. Wills: Civilly, do you mean, or under the penalty clause?

Lord Justice Bramwell: Under the penalty clause, if you please.

Mr. Wills: I cannot help thinking it must be the persons who actually did it.

Mr. Lumley Smith: Corporations have been held liable for the fraud of their managers. That was so in Barwick's case.

Lord Justice Thesiger: That would be carrying on the authorized business of the company in an unauthorized way. The question here would be whether there was any authority from an individual shareholder, or all the shareholders who carry on the business, at all.

Mr. Wills: I cannot help thinking, my lord, that the mere fact of my being a shareholder in a company which does an unlawful act, that unlawful act not being specifically the object of the corporation, which the directors, as persons who carry on the business of the company, might do or might not, cannot make me liable to penal clauses for an offence. It would be a most alarming notion. We are most of us, more or less—some of us much less, but all of us more or less—shareholders in railway companies, canal companies, or one species of investment of that kind or another, and it would certainly startle us very much to be told that if those companies go and do an act which subjects them to a penalty, that we should be personally liable. I can understand it, of course, if the directors say to their servant, now, you go and do the illegal act; and he does it, on all ordinary principles it seems to me they are liable just as they would be if they did it themselves. It does not matter that they are entitled directors of a corporation.

Lord Justice Thesiger: That might be a question as to how the fund should be supplied. Supposing the corporation does an improper act, which the corporation may have been prosecuted for, the shareholders might raise the question whether the directors who had actually authorized that unlawful act had any right to take the funds of the company to pay the fines; but it could not prevent the corporation being liable to be indicted.

Mr. Wills: Not at all. I am dealing with the case of an individual corporator—of an individual shareholder. It would not prevent the corporation being liable clearly, if it were incident to the business. If it is completely outside the business then I imagine it is not the act of the corporation; it is *ultra vires*, using that difficult and ambiguous term in, I think, its proper sense, because it is an act which then is expressly or impliedly prohibited by the constitution of the company, and therefore in that sense is *ultra vires*. Then when it is *ultra vires* in that sense, I suppose even the corporation is not liable.

Lord Justice Thesiger: I do not know that. You may be right, but I should think the corporation there would be liable for doing it *de facto*. They have done it.

Mr. Wills: There always comes the question, I know it is a very difficult question under the particular circumstances, whether it is really the corporation who has done it. If it is a thing beside the business of the corporation, and is expressly or impliedly prohibited by their constitution and their deed, then I suppose it is really not the Act of the corporation, but the act of the individual or individuals who have carried it out, executed it, or authorized it, and which would be, I should think—I put the proposition with great submission, because I know the difficulties which have arisen, but I should think that under those circumstances it would not be the act of the corporation, but would be the act of the individual who authorized it. Now, my lords, I venture for all these reasons to submit to your lordships that it is better to confine the Act to what we can clearly see that it did mean, than to attempt to give it a completeness which we cannot give altogether, because we cannot make it satisfactory from beginning to end by extending it to a case which could hardly have been within the intention of the Legislature. I will only venture to remark, in conclusion, that my friend, the Attorney-General, has not thought fit, as far as I can see, to refer in any way to the numerous instances which I cited from the statute book, as showing that the habit of the Legislature has been to introduce an extending clause into the definition or interpretation of Acts of Parliament, where in cases of Acts of Parliament containing provisions of this kind, imposing penalties or granting rights to persons, it has been thought necessary to extend it, or justice required, that it should be extended to corporations. I cannot help thinking that the Attorney-General, who has no doubt heard what has been said, must have felt that I made good that point—and I cannot help thinking that I have—that the habitual practice of the Legislature has been to insert such clauses where they meant them to be so extended. In these very statutes, in three or four in stances, it is very clear that it is done. In the Bankruptcy Act I know it is the same; I happened to look the other day. I jumped over a long period, but I showed that up to the present time that has been the constant practice of Parliament; and I do venture to submit to your lordships that is a consideration which cannot be thrown out of your minds when your lordships are deciding the question that is raised in this case.

Lord Justice Baggallay: Is this statement in the judgment of the Lord Chief Justice admitted by you,—"Longmore, as has been been stated, is, and at the time of the sale of the poisons in question was, a duly registered chemist and druggist within the Pharmacy Act, 1868, and the business of the drug department was conducted by him with the aid of two qualified assistants. He, with the two assistants, attended regularly to the drug department, and to nothing else."

Mr. Wills: That is found in the case.

Lord Justice Thesiger: I suppose he purchased the drugs as well as sold them?

Mr. Wills: That I cannot tell.

Lord Justice Thesiger: That is rather an important part of the business as regards the protection of the public.

Mr. Wills: I cannot go beyond the four corners of the case. I think Mr. Russell's statement of fact does find that Longmore and these two other persons were persons who attended to this department, and to nothing else.

Mr. Lumley Smith: You will find as a fact, also, in the case, that on one occasion when poison was sold, it was sold by a person not qualified.

Lord Justice Baggallay: Is it stated there?

Mr. Lumley Smith: Yes, my lord; the evidence is set out as part of the case.

Mr. Wills: I will read the case.—"The said William Mackness is the managing director of the said company. He is not a duly registered pharmaceutical chemical or chemist and druggist within the meaning of the said Pharmacy Act, 1868. Henry Edward Longmore is the only shareholder who is a 'pharmaceutical chemist' or 'chemist and druggist' within the meaning of the Pharmacy Act, 1868. The business of the said company is carried on at 113, Tottenham Court Road aforesaid, and includes amongst other departments for the sale of various goods a chemist and druggist's shop or drug department, which is an open shop for the retailing, dispensing and compounding poisons within the meaning of the Pharmacy Act, 1868. The said poisons are sold to the public, and not merely to members of the defendant company. The said Henry Edward Longmore is, and at the time of the sale of poisons hereinafter mentioned was, a duly registered chemist and druggist within the Pharmacy Act, 1868, and the business of the said drug department was at the several times aforesaid and is conducted by the said Henry Edward Longmore, with the aid of two qualified assistants. The said Henry Edward Longmore (with the aid aforesaid) at the times aforesaid attended and still attends regularly to the said drug department and to nothing else, and he and his assistants were and are the servants of the defendants, the company, and paid by salary or wages. On the 4th of February, 1878, the said H. E. Longmore, acting on behalf of the defendants, sold at the said premises two pennyworth of red precipitate. On the 20th of February, 1878, the said H. E. Longmore, acting on behalf of the defendants, sold at the said premises two pennyworth of oxalic acid. On the 19th of March, 1878, the said H. E. Longmore, acting on behalf of the defendants, sold at the said premises solution of perchloride of mercury as an ingredient in a prescription made up by him. On the 20th of March, 1878, the said H. E. Longmore, acting on behalf of the said defendants, sold at the said premises a pennyworth of white precipitate."

Lord Justice Baggallay: That is the whole of the case, is it?

Mr. Lumley Smith: You will find on the next page that this packet was sold without any label.

Lord Justice Baggallay: Is it found on the special case?

Mr. Lumley Smith: Yes, my lord. It shows it was unskilfully sold.

Mr. Justice Baggallay: That might have made him liable to the other penalty. Can you refer me to the decisions under the Attorneys and Solicitors' Act? Can you mention any particular case?

Lord Justice Thesiger: Have you a copy of the county court judge's judgment?

Mr. Lumley Smith: If you would like to have it in print, my lord, we can furnish you with it. It is printed in the *Pharmaceutical Journal.* Tench *v.* Roberts was one case I referred to, in Maddock and Guilder, 145; and Hopkinson *v.* Smith, in 1 Bingham, page 13. The county court judge gives his reasons at the end of the case; but if your lordship would like to have the judgment, it is printed.

Mr. Wills: My lords, on looking at the words of the Act of Parliament, they are so broad, I do not think they can leave any doubt. They provide that any solicitor, and so on, acting for any person, not being qualified, or permitting or suffering his name in any way to be used, and so on, in any action, suit, or matter, or signing any process, or doing any act which will enable an unqualified person to appear or practise in any respect, and so on.

Lord Justice Bramwell: Is there anything about drawing conveyances?

Mr. Wills: I do not think there is, my lord. I know I looked at the matter some time ago. There is the Stamp Act, that is all.

Lord Justice Bramwell: We must take time to consider our judgment in this case.

Correspondence.

THE DIFFUSIVE PROPERTIES OF SOME PREPARATIONS OF IRON.*

BY PROFESSOR REDWOOD.

Attention has recently been directed to the properties possessed by oxide of iron as it exists in dialysed iron, and founded on the observation of these properties it has been inferred that dialysed iron is a very inert preparation. The iron exists here in what Graham has designated the colloidal state, in which it has a very low diffusive power. It was observed by Graham that substances which in solution possessed very low diffusive power were characterized by the absence of the crystallizing property and that they generally formed gelatinous hydrates, while substances of high diffusive power generally belonged to the class of crystalline bodies. Hence the names *colloid* and *crystalloid* applied to these two classes of substances.

But although substances of very low diffusive power are always found to be uncrystallizable, it cannot be inferred that the absence of crystalline property will be necessarily attended with low diffusive power. I proved this experimentally many years ago, and briefly stated the fact in a communication made to this Society on Dialysis in 1862. Yet the opinion appears to be often entertained that the diffusive property of substances in solution bears some relation to the power they possess of assuming a crystalline condition; and as we have now several preparations of iron, largely used and considered to be efficacious medicines, which are entirely devoid of the power of crystallizing, it may be of use to show the position which these and some other preparations occupy with regard to their diffusive properties.

If, as stated by M. Personne in his recent communication to the French Academy of Medicine, a notice of which appeared in the *Pharmaceutical Journal* of last November, dialysed iron is incapable of being absorbed during its passage through the intestinal canal, and is therefore inactive, and if this is due to the colloidal state of the iron, it might be expected that other preparations of iron would, at any rate to some extent, owe their activity as medicinal agents to their diffusive properties.

Now among the preparations of iron which have become most largely used in medicine are the scaled preparations, which, in common with dialysed iron, are often preferred to the crystalline salts of iron on account of the absence of the inky taste which characterizes the latter. This absence of inky taste and strong styptic property may tend to induce a belief that the scaled preparations of iron are either colloidal, like dialysed iron, or at least that they are deficient in diffusive power, for colloids are usually marked by absence or deficiency of taste.

The experiments, the results of which I am about to lay before the Society, were made for the purpose of showing what the relative diffusive power of some of the salts of iron is, and to what extent this is connected, in such salts, with their crystalline or amorphous condition.

The dialyser used in the experiments consisted of a glass jar, the membrane-covered mouth of which was 5½ inches in diameter; and this rested in the mouth of a white earthen dish. Two thousand grain-measures of either a 5 per cent. or a 10 per cent. solution of the salt used was put into the glass jar, and 25 ounces of water into the dish. The diffusate was usually removed at the expiration of two, but sometimes of three, days, at the commencement of an experiment, although a longer time was allowed for each separate diffusion when the action became sluggish towards the end of an experiment.

1. *Citrate of Iron, Ferric Citrate.*—Some simple citrate of iron was made in the usual way, by dissolving to saturation, moist, recently precipitated hydrated peroxide of iron, in solution of citric acid. After being scaled and dried at 212°, it was found to contain 32·29 per cent. of ferric oxide, Fe_2O_3. Aided by heat it was perfectly soluble in water, the solution being acid to test paper. 200 grains of this salt dissolved in water to make 2000 grains (10 per cent. solution) was put into the dialyser. At the expiration of two days the diffusate was removed, evaporated to dryness, and the residue dried at 212° F. It amounted to 51·26 grains, or 25·63 per cent. of the salt, and on being incinerated it gave 22·45 grains or 43·75 per cent. of oxide of iron. It thus appeared that the iron was diffusing more rapidly than the acid with which it had been combined. Fresh water being introduced into the dish the diffusion subsequently went on more slowly, but the results still showed that the iron was diffusing more rapidly than the acid. At the end of fifteen days, 125·59 grains of the salt had passed through the membrane.

The results of the experiment are given in the following tabulated statement:—

200 grains of citrate, containing 64·58 grains of Fe_2O_3 in dialyser.

Days.	Amount of salt diffused.	Amount of Fe_2O_3 in diffusate.	Per cent. of salt diffused.	Per cent. of Fe_2O_3 in diffusate.
2	51·26	22·45	25·63	43·75
4	44·81	19·45	22·41	45·63
4	20·50	8·67	10·25	42·26
5	9·02	4·10	4·51	45·45
14	6·37	3·68	3·18	57·77
29	131·96	58·35	65·98	
	Residue in dialyser.			Per cent. Fe_2O_3 in residue.
	4·86	2·75	—	56·65
Total . .	136·82	61·10		
Loss . .	63·18	3·48		
	200·00	64·58		

It will be seen that of the 200 grains of the salt, containing 64·58 grains of Fe_2O_3, put into the dialyser, 131·96 grains of salt, containing 58·35 grains of Fe_2O_3, had diffused in twenty-nine days, and that there was then a residue in the dialyser amounting to 4·86 grains of salt, containing 2·75 grains of Fe_2O_3. There was thus an apparent loss in the process of 63·18 grains of salt, but of only 3·48 grains of Fe_2O_3, the latter no doubt partly arising from adhesion to the septum. No entire cessation of diffusion was observed.

The citrate of iron used in the experiment was, as it always is, acid to test paper, and the first two diffusates were so also, but the third and subsequent diffusates were neutral, indicating the disappearance of some of the acid radical.

2. *Ammonio-citrate of Iron.*—This salt, as met with in commerce, usually contains about 30 per cent. of peroxide of iron, Fe_2O_3, but the proportion

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, March 3, 1880.

varies in different samples. Several samples were submitted to dialysis.

(2, *a.*)—A 10 per cent. solution of ammonio-citrate, containing 30·21 per cent. of Fe_2O_3, was dialysed and the results examined as in the previous experiment. At the expiration of two days, 124·59 grains or 62·29 per cent. of the salt had diffused, and this contained 27·22 per cent. of Fe_2O_3. At the end of another four days, 25·79 grains more of the salt with 32·90 per cent. of Fe_2O_3 had diffused, making the total diffusate in six days 150·38 grains, or 75·19 per cent. of the salt put into the dialyser, and 70 per cent. of the iron contained in the salt. The diffusion afterwards went on very slowly, yielding only 3·79 grains in ten days, and at the end of twenty-two days from the commencement, when the diffusion had nearly stopped, the dialyser contained 20·26 grains of a salt in solution, in which the Fe_2O_3 amounted to 61·61 per cent.

(2, *b.*)—A 10 per cent. solution of a salt containing 30·9 per cent. of Fe_2O_3 was dialysed for two days. The diffusate gave 108·94 grains, or 54·47 per cent. of dried salt, containing 27·9 per cent. of Fe_2O_3. In four days more another diffusate was obtained, giving 37·36 grains, or 18·68 per cent. of the salt, and containing 34·44 per cent. of Fe_2O_3. In this case 73·15 per cent. of the salt and 70 per cent. of the iron contained in the salt had diffused in six days. The diffusion then, as in the previous experiment, went on very slowly, and at the end of sixteen days it had nearly stopped, although the dialyser still contained 19·55 grains of a salt with 52·48 per cent. of Fe_2O_3 in it.

(2, *c.*)—A 10 per cent. solution of a salt containing 30·65 per cent. of Fe_2O_3 was put into the dialyser. In two days the diffusate gave 96·11 grains, or 48·05 per cent. of the salt, and this contained 31·42 per cent. of Fe_2O_3. In four days more another diffusate was obtained, which yielded 27·60 grains, or 13·8 per cent. of the salt, and contained 37·46 per cent. of Fe_2O_3. In this case 61·85 per cent. of the salt, and 66·15 per cent. of the iron contained in the salt, had diffused in six days. The diffusion had now entirely stopped, although there still remained 32·45 grains of a salt containing 22·55 grains of ferric oxide in the dialyser.

In the three preceding experiments, the solutions used, and the diffusates obtained, were neutral to test paper. The citrates employed were apparently good commercial samples, well scaled and perfectly soluble, but they evidently differed in constitution, as indicated by difference in the results of their diffusion, for they were all treated similarly and subjected to the same conditions. It will especially be observed that diffusion in the case of (2, *c.*) ceased entirely at the end of six days, although the dialyser still contained 32·45 grains of a salt in which there were 22·55 grains of ferric oxide, but this being in the form of a highly basic salt was no longer diffusible.

With the view of trying the effect of altered conditions on the salt used in the last experiment, a solution made alkaline with ammonia was used as follows:—

(2, *d.*)—A 10 per cent. solution of the citrate used in experiment (2, *c.*) was made strongly alkaline with ammonia. In two days the diffusate gave 92·65 grains, or 46·32 per cent. of a salt containing 32·59 per cent. of Fe_2O_3. Another diffusate was obtained in four days more which yielded 17·55 grains, or 8·77 per cent. of salt containing 51·22 per cent. of Fe_2O_3. In this case 55·09 per cent. of the salt, and 63·93 per cent. of the iron had diffused in six days. And now, at the end of six days, diffusion had stopped, as in the previous experiment, while the dialyser still contained an undiffusible salt containing 68·38 per cent. of Fe_2O_3.

The following table will show the principal results of dialysis in the preceding four experiments:—

Ten per cent. solutions (200 grains of ammonio-citrate of iron in 2000 grains of solution) dialysed for six days.

	Amount of salt diffused.	Per cent. of salt diffused.	Per cent. of Fe_2O_3 in diffusate.	Diffusion on sixth day.	Per cent. of F_2O_3 in salt not diffused.
(2, *a*)	150·38	75·19	28·2	not ended	61·61
(2, *b*)	146·30	73·15	29·5	not ended	52·48
(2, *c*)	123·71	61·85	32·7	ended	69·49
(2, *d*)	110·20	55·10	35·5	ended	68·38

Having observed that diffusion stopped when the salt in the dialyser became highly basic, and that the diffusate as well as the contents of the dialyser became more and more basic as the process proceeded, results which I shall have to refer to hereafter, I thought that probably by starting with a salt containing less than the usual proportion of oxide of iron the diffusion might be carried further than it had been found possible to carry it in the preceding experiments.

I obtained a good, well-scaled, neutral, and perfectly soluble sample of ammonio-citrate of iron, containing only 25·92 per cent. of Fe_2O_3. 10 per cent. and 5 per cent. solutions of this salt were submitted to dialysis, in the way already described, and the results obtained are given in the following tabulated statements:—

(2, *e.*)—10 *per cent. Solution.*

Days.	Amount of salt diffused.	Per cent. of salt diffused.	Per cent of Fe_2O_3 in dried diffusate.
2 . .	92·23 grs.	46·10	21·56
2 . .	30·62 „	15·31	32·23
3 . .	23·37 „	11·68	33·13
3 . .	8·16 „	4·08	35·50
3 . .	2·27 „	1·13	37·40
4 . .	·55 „	·27	39·43

At the end of twenty-eight days, diffusion having stopped, the salt still left in the dialyser was found to contain 61·26 per cent. of Fe_2O_3.

(2, *e.*)—5 *per cent. Solution.*

Days.	Amount of salt diffused.	Per cent. of salt diffused.	Per cent. of Fe_2O_3 in dried diffusate.
2 . .	66·65	33·32	25·07
2 . .	25·73	12·86	30·12
3 . .	17·91	8·95	32·44
3 . .	6·4	3·2	35·88
3 . .	2·47	1·23	36·01
4 . .	1·64	·82	38·94
6 . .	1·14	·57	40·01

At the end of twenty-eight days, diffusion having stopped, the salt in the dialyser was found to contain 68·54 per cent. of Fe_2O_3.

3. *Potassio-Tartrate of Iron, Tartarated Iron.*—This salt, which, until the adoption of the process now given in our Pharmacopœia, was commonly supplied in the form of an imperfectly soluble powder, is now produced in soluble transparent scales. But as it is more susceptible of change from slight variation of the conditions to which it is subjected, it is less uniform in composition and properties than the salt previously referred to,—the

ammonio-citrate. Several samples of potassio-tartrate of iron were submitted to dialysis.

(3, *a*.)—A 10 per cent. solution of potassio-tartrate containing 31·09 per cent. of Fe_2O_3 was put into the dialyser. In two days 94·02 grains or 47·01 per cent of the salt had diffused, containing 22·67 per cent of Fe_2O_3. In four days more a further quantity of 25·99 grains, or 12·99 per cent. of the whole was obtained, containing 32·97 per cent. of Fe_2O_3, Only slight diffusion took place beyond this. The residue left in the dialyser at the end of ten days contained 65·36 per cent. of Fe_2O_3.

(3, *b*.)—A 10 per cent. solution of potassio-tartrate, containing 36·25 per cent. of Fe_2O_3, submitted to dialysis gave in two days a diffusate from which 53·01 grains, or 26·5 per cent. of a salt containing 8·82 per cent. of Fe_2O_3 was obtained. In four days more another product of 22·32 grains, or 11·16 per cent. of the whole, and containing 7·03 per cent. of Fe_2O_3 was obtained. The residue left in the dialyser contained 62·70 per cent. of Fe_2O_3.

(3, *c*.)—A 10 per cent. solution, the same as the last, but rendered alkaline with potash, after being dialysed for two days gave a diffusate containing 79·83 grains, or 39·91 per cent. of dry salt, with 12·31 per cent. of Fe_2O_3. In another four days, 33·7 grains or 16·85 per cent. of the salt had diffused, containing 10·71 per cent of Fe_2O_3. The residue in the dialyser contained 60·30 per cent. of Fe_2O_3.

The following table gives the principal results of the preceding three experiments :—

Ten per cent. solutions (200 grains of potassio-tartrate of iron in 2000 grains of solution) dialysed for six days.

	Amount of salt diffused.	Per cent. of salt diffused.†	Per cent. of Fe_2O_3 in diffusate.	Diffusion on the sixth day.	Per cent. of Fe_2O_3 in salt not diffused.
(3, *a*)	120·0	60·0	24·9	not ended	65·36
(3, *b*)	75·33	37·66	8·2	not ended	62·70
(3, *c*)	113·53	56·76	11·8	not ended	60·30

It thus appears that the potassio-tartrate of iron is a less diffusible salt than the ammonio-citrate, and this especially applies to the iron as a constituent of the salts. It also appears on comparing the results of experiments (3, *a*) and (3, *b*), that the salt containing the larger proportion of oxide of iron diffuses more slowly than the other, and that the diffusate contains a smaller proportion of iron.

4. *Citrate of Iron and Quinine.*—This preparation, for which, in its most approved form, an available process was first published in the present edition of the British Pharmacopœia, although a somewhat indefinite, or at least an undefined, compound, is an important and valuable medicine, and it seemed desirable in connection with the present object of this inquiry to determine the extent to which it is capable of undergoing diffusion through a membrane.

A 10 per cent. solution, containing 200 grains of a good sample of citrate of iron and quinine, gave a diffusate in two days yielding 76·8 grains of dry residue, containing 21·65 per cent. of ferric oxide. In two days more it gave a further diffusate yielding 21·18 grains of dry residue containing 28·8 per cent. of ferric oxide ; and again, in two days more it gave 16·6 grains of a residue with 27·7 per cent. of oxide, making the salt diffused in six days equal to 57·29 per cent. of that put into the dialyser. The proportion of quinine in relation to the iron was not determined in this case, and in this and other respects further experiments have yet to be made ; but it is evident from the results obtained that citrate of iron and quinine is a freely diffusible preparation.

5. *Sulphate of Iron, Ferrous Sulphate*, $FeSO_4.7H_2O$. —A 10 per cent. solution (200 grains in 2000 grains of solution) slightly acidulated with sulphuric acid and dialysed for two days gave a diffusate yielding 36·4 grains of ferric oxide, and dialysed for four days more it gave a further diffusate yielding 14·7 grains of ferric oxide, thus making the amount of iron, reckoned as ferric oxide, diffused in six days, 51·1 grains, corresponding to 35·7 grains of iron, and as the salt put into the dialyser contained 40·2 grains of iron, it follows that 89·2 per cent. of the iron had diffused in six days.

The experiment was carried on for two days longer, in which time a further diffusate yielding 3·76 grains of ferric oxide was obtained, making the total amount of iron diffused in eight days equal to 96 per cent. of the whole.

6. *Persulphate of Iron, Ferric Sulphate.*—A solution was made by dissolving 200 grains of ferrous sulphate, converting it into the ferric salt, and making it up to 2000 grains. The solution therefore contained the same amount of iron as that used in the preceding experiment, namely, 40·2 grains Fe. Dialysed for two days it gave a diffusate yielding 34·9 grains of ferric oxide, and in four days more it gave a further diffusate, yielding 14·2 grains of ferric oxide, thus making the amount of iron as ferric oxide 49·1 grains, corresponding to 34·12 grains of iron, diffused in six days, or 85·3 per cent. of the iron put into the dialyser.

The experiment was carried on for two days longer, when a further diffusate was obtained, yielding 4·1 grains of ferric oxide, making the total amount of iron diffused in eight days equal to 93 per cent. of the whole.

7. *Chloride of Iron, Ferrous Chloride*, $FeCl_2.4H_2O$.—A 10 per cent. solution, 100 grains in 1000 grains of solution, dialysed for two days gave a diffusate, yielding 33·96 grains of ferric oxide, and dialysed for four days more it gave a further diffusate, yielding 4·3 grains of oxide, making 38·26 grains of ferric oxide, corresponding to 26·8 grains of iron, or 95·7 per cent. of the iron contained in the dialyser, diffused in six days.

8. *Perchloride of Iron, Ferric Chloride.*—100 grains of ferrous chloride converted into a ferric salt, and diluted to 1000 grains, gave results nearly coinciding with those of the ferrous chloride.

On comparing the results of the foregoing experiments, it will be seen that while the sulphates and chlorides, and especially the latter, stand pre-eminent in regard to the extent and rapidity with which they undergo liquid diffusion through a membrane, it cannot be said, in a medical sense, that the scaled preparations, and especially those made with citric acid, are deficient in diffusibility, for the latter being given in much larger doses than the former would be absorbed into the system to fully an equal extent.

9. *Dialysed Iron.*—Although most of the experiments hitherto described in this paper were made simply for the purpose of showing the relative diffusibility of preparations of iron which are used in medicine, without reference to dialysed iron, and of ascertaining how far the diffusive property of such preparations is affected by their crystalline or amorphous condition, yet as the immediate object of pub-

lishing the results at this time was to show that the scaled preparations of iron of the Pharmacopœia are not subject to the objections which have been recently urged against dialysed iron, I have been led to make some experiments with the view of ascertaining how far the properties ascribed to dialysed iron are really possessed by it, and are likely to affect its medicinal efficacy.

Dialysed iron has been largely introduced to the notice of the medical profession, and strongly recommended as an efficacious chalybeate, which is free from objections that attach to other chalybeate medicines. It would appear to have some strong recommendations if it could be clearly shown that it is capable of being absorbed during its passage through the intestinal canal. But while it is freely admitted that it has the advantage of being nearly tasteless, free from astringency, and not liable to cause constipation or gastric disturbance, it has at the same time been broadly asserted that it is perfectly inert on account of its colloidal nature,—that the oxide of iron is precipitated in the stomach in a state in which it is insoluble in the acids of the stomach and incapable of undergoing liquid diffusion.

The following experiments were made with a sample of dialysed iron containing 5·28 per cent. of ferric oxide and ·23 per cent. of chlorine. The iron was completely precipitated by adding to the dialysed iron twenty times its volume of water of the London water supply.

(9, *a*)—The oxide of iron obtained from 100 grains of the dialysed iron by addition of 2000 grains of New River water, was collected on a filter, washed with distilled water and digested with water to which hydrochloric acid of known strength was gradually added until the oxide of iron became apparently dissolved, a clear and permanent, although not brilliant, reddish-brown liquid resulting. It was found that 1·44 grains of hydrochloric acid (HCl) was thus required for the 5·28 grains of oxide of iron. This solution was put into a dialyser, but at the end of two days not a trace of iron had passed through the septum.

(9, *b.*)—Another similar quantity of precipitated oxide was digested with double the quantity of hydrochloric acid, namely 2·88 grains of HCl, but the result at the end of two days was the same. None of the iron had diffused.

(9, *c.*)—Another similar quantity of oxide, namely, 5·28 grains, was digested with 7·5 grains of hydrochloric acid (HCl), this being the quantity required for converting the ferric oxide into ferric chloride, in the event of such conversion occurring. In this case it was found that after the liquid had been in the dialyser for two days a very small quantity, ·1 grain, of the iron had diffused.

In the last three experiments the oxide had been digested at a temperature of 100° F., for about an hour, before putting the liquid into the dialyser.

(9, *d.*)—In this experiment the oxide of iron and hydrochloric acid, in the proportion for forming ferric chloride, were boiled together for several minutes, and the liquid after cooling was put into the dialyser. At the end of two days a trace of iron had passed through the septum, but not more than in the preceding experiment.

The hydrochloric acid in these experiments was greatly in excess of that usually present in the free state in the stomach, which according to Lehmann is about ·125 per cent.

A suggestion having been made that the colloidal iron of dialysed iron, although not diffusible when brought into a state of apparent solution with hydrochloric acid, even when this is much in excess of what is required for such solution, might be taken up by the albuminoids in the stomach and thus rendered assimilable, experiments were made in that direction.

(9, *e.*) A dilute solution of albumin with hydrochloric acid was digested for two hours with dialysed iron at 100° F., and then left in a dialyser for two days, but no iron was found in the diffusate.

(9, *f.*)—A peptone was prepared by dissolving 50 grains of coagulated albumin with 2 grains of pepsin in 500 grains of 1 per cent. dilute hydrochloric acid, adding 50 grains of dialysed iron, and digesting them together for two hours at 100° F. This was put into a dialyser for two days, but here again not a trace of iron was found in the diffusate.

In view of these results it can hardly be conceived that dialysed iron should be an active or efficacious medicine. At any rate it remains for those who advocate its use to suggest a theory by which medicinal activity may be reasonably ascribed to a substance having the properties which this preparation has been proved to possess.

[*The discussion on this paper is printed at p.* 723].

HOW TO USE GLUE.*

Every one, almost, can use glue in a fashion, but few know how to apply it so as to obtain all its advantages. Pieces of wood carelessly glued together will come apart under the slightest strain, while the same cementing material, applied as it should be, will hold the pieces together so tenaciously that if a fracture occur, it will be at a new place and not at the joint. The 'Workshop Companion' gives the following practical and useful directions for the selection of glue and its proper application. It says:

Good glue is hard, clear (not necessarily light-coloured, however), and free from bad taste and smell. Glue which is easily dissolved in *cold* water is not strong. Good glue merely swells in cold water, and must be heated to the boiling point before it will dissolve thoroughly.

Good glue requires more water than poor, consequently you cannot dissolve six pounds of good glue in the same quantity of water you can six pounds of poor. The best glue, which is clear and red, will require from one-half to more than double the water that is required with poor glue, and the quality of which can be discovered by breaking a piece. If good, it will break hard and tough, and when broken will be irregular on the broken edge. If poor, it will break comparatively easy, leaving a smooth, straight edge.

In dissolving glue, it is best to weigh the glue, and weigh or measure the water. If not done there is a liability of getting more glue than the water can properly dissolve. It is a good plan, when once the quantity of water that any sample of glue will take up has been ascertained, to put the glue and water together at least six hours before heat is applied, and if it is not soft enough then, let it remain longer in soak, for there is no danger in good glue remaining in pure water, even for forty-eight hours.

From careful experiments with dry glue immersed for twenty-four hours in water at 60° Fahr., and thereby transformed into a jelly, it has been found that the finest ordinary glue, or that made from white bones, absorbs

* From the *Druggists' Circular and Chemical Gazette*, February, 1880.

twelve times its weight of water in twenty-four hours; from dark bones, the glue absorbs nine times its weight of water; while the ordinary glue made from animal refuse absorbs but three to five times its weight of water.

Glue, being an animal substance, it must be kept sweet; to do this it is necessary to keep it cool after it is once dissolved, and not in use. In all cases keep the glue-kettle clean and sweet, by cleansing it often.

Great care must be taken not to burn glue, and, therefore, it should always be prepared in a water-bath.

Carpenters should remember that fresh glue dries more readily than that which has been once or twice melted.

The advantage of frozen glue is that it can be made up at once, on account of its being so porous. Frozen glue of same grade is as strong as if dried.

If glue is of first-rate quality, it can be used on most kinds of wood work very thin, and make the joint as strong as the original. White glue is only made white by bleaching.

Liquid Glue.—1. A very strong glue may be made by dissolving 4 ounces of glue in 16 ounces of strong acetic acid by the aid of heat. It is semi-solid at ordinary temperatures, but needs only to be warmed, by placing the vessel containing it into hot water, to be ready for use.

2. Dilute officinal phosphoric acid with two parts, by weight, of water, and saturate with carbonate of ammonia; dilute the resulting liquid, which must be still somewhat acid, with another part of distilled water, warm it on a water-bath, and dissolve it in enough good glue to form a thick syrupy liquid. It must be kept in well-closed bottles.

3. A most excellent form is also *Dumoulin's Liquid and Unalterable Glue.* This is made as follows: Dissolve 8 ounces of best glue in $\frac{1}{2}$ pint of water in a wide-mouthed bottle, by heating the bottle in a water-bath. Then add slowly $2\frac{1}{2}$ ounces of nitric acid, sp. gr. 1330, stirring constantly. Effervescence takes place under escape of nitrous acid gas. When all the acid has been added, the liquid is allowed to cool. Keep it well corked, and it will be ready for use at any moment. It does not gelatinize, or putrefy, or ferment. It is applicable to many domestic uses, such as mending china, wood, etc.

Mouth Glue.—Good glue, 1 pound; isinglass, 4 ounces. Soften in water, boil and add $\frac{1}{2}$ pound fine brown sugar; boil till pretty thick, and pour into moulds.

Portable Glue.—Put a piece of shredded gelatine into a wide mouthed bottle; put on it a very little water, and about one-fourth part of glacial acetic acid; put in a well-fitting cork. If the right quantity of water and acid be used, the gelatine will swell up into worm-like pieces, quite elastic, but at the same time firm enough to be handled comfortably. The acid will make the preparation keep indefinitely. When required for use, take a small fragment of the swell gelatine, and warm the end of it in the flame of a match or candle; it will immediately "run" into a fine clear glue, which can be applied at once direct to the article to be mended. The thing is done in half a minute, and is, moreover, done well, for the gelatine so treated makes the very best and finest glue that can be had. This plan might be modified by dissolving a trace of chrome alum in the water used for moistening the gelatine, in which case, no doubt, the glue would become insoluble when set. But for general purposes, there is no need for subsequent insolubility in glue.

ASPIDOSPERMINE.*

BY G. FRAUDE.

Some account of this alkaloid has already been given by the author. The bark containing it is that of *Aspidosperma quebracho blanco* (Schlectendahl). Further analyses show aspidospermine to have the composition $C_{22}N_{30}N_2O_2$. Concerning its preparation, the author finds that the liquors obtained after a precipitation of the alkaloid by means of sodium carbonate yield a further quantity by treatment with phosphotungstic acid. This precipitate is treated with baryta-water, and the solution thus obtained with carbonic acid to precipitate the barium; the alkaloid is then extracted by means of alcohol from the residue left on evaporation. One part of aspidospermine is soluble in 6000 parts of water at 14°; this solution has a bitter taste. It is also soluble in 48 parts of alcohol (99 per cent.) at 14°, and in 106 parts of pure ether at the same temperature.

A small quantity of aspidospermine treated with a few drops of concentrated sulphuric acid, and then with a little lead peroxide, gives a cherry-red coloration, which has a violet shade if the alkaloid is not quite pure.

Iodic anhydride and sulphuric acid produce the same reaction, whilst potassium dichromate and sulphuric acid give a brown zone slowly changing to an olive-green. Chlorine reacts on aspidospermine suspended in water, producing a white flocculent mass, which is not dissolved by hydrochloric acid; this compound begins to decompose at 145°. Bromine acts similarly.

Aspidospermine sulphate, $(C_{22}H_{30}NO_2)_2H_4SO_4$, is obtained by evaporation and drying at 120° as a hard, transparent, resinous mass. The *hydrochloride* $3(C_{22}H_{30}N_2O_2)+4HCl$, has similar properties to the sulphate. By treating solutions of the base with potassium chromate the *chromate* is obtained as a yellow precipitate, which on exposure to the air becomes green. The *perchlorate* is obtained by adding aqueous perchloric acid to a not too dilute solution of the base.

Hydrochloric acid solutions of the base are precipitated by potassium mercuric iodide in yellow flocks; by potassium sulphocyanide, as a white flocculent precipitate; by iodine dissolved in potassium iodide, as brown flocks; by picric acid, as a yellow precipitate; and by tannin, as a white precipitate. Further, these solutions reduce Fehling's solution when boiled with it.

According to Penzoldt (*Berl. klin. Wochenschrift*, 1879, 14), the bark of *Aspidosperma quebracho blanco* has important medicinal properties.

* From *Ber.*, [12], 1560—1562. Reprinted from *Journal of the Chemical Society*, January, 1880.

THE MEMORIAL TO THE BOARD OF TRADE RESPECTING THE WEIGHTS AND MEASURES ACT.

Since the meeting of the Council on Wednesday last a reply has been received from the Board of Trade to the Memorial then mentioned* as having been forwarded by the President of the Pharmaceutical Society respecting the carrying out of the Weights and Measures Act as affecting chemists and druggists. The following is the text of the Memorial and Reply:—

"Pharmaceutical Society of Great Britain,
"17, Bloomsbury Square,
"London, W.C.
"February 25, 1880.

"To the Committee of Privy Council for Trade.

"The Council of the Pharmaceutical Society desire to bring under the notice of the Board of Trade certain difficulties, misconceptions and varied readings of the Weights and Measures Act, 1878, so far as regards 'apothecaries' measures,' which have arisen in the minds of those with whom rests the administration of the law.

"Inasmuch as these measures have always been, and must continue to be, of an entirely different character from the ordinary commercial measures hitherto subject to supervision, it is hoped that the Pharmaceutical Society will not be deemed intrusive in thus appealing to the highest authority.

"At present, apparently, the 'standards' have been only partially distributed; the time, therefore, seems fitting for some authoritative reading of the Act to be

* See p. 718.

placed in the hands of the various district inspectors with the new standards.

"The following different opinions have been brought to the notice of the Pharmaceutical Society, and seem to require correction:—

"1st. One inspector, on being applied to for the purpose of verifying and marking the graduated measures used by chemists, informed the applicant that those only could be verified which contained the given quantity when 'full to the brim,' and that no subdivisions would be marked. Such measures would be perfectly useless.

"2nd. Another inspector gave it as his decision that glass measures must be made 'partly of glass and partly of metal.'

"3rd. A third inspector intimated to chemists in his district, as long ago as July or August last, that their measures should be sent to him for verification. Many measures graduated in the usual manner were so sent, and returned to their owners with his mark of authority. More recently, the same inspector, on measures being sent to him, has verified them only as to a small number of graduations, excluding others absolutely necessary for the sale of drugs as well as for compounding them. Thus from a 2-ounce measure which requires fourteen subdivisions he has virtually abolished seven.

"Much difference of opinion seems to exist as to whether the subdivisions of graduated measures are to be verified at all, or merely the top line, indicating what may be called the denomination of the measure.

"The doubts of inspectors have probably arisen from their being in possession only of the bronze standards, and it may be hoped, therefore, that on receiving graduated glasses from the 'Standards Office' they will get a clearer insight into their future work. For verifying 'standards' the graduated pipettes would no doubt be extremely accurate in the hands of skilled operators, but for the use of the ordinary officers throughout the country the graduated beakers would be more suitable and sufficiently correct.

"It is hoped that on the delivery of the graduated standards to local authorities attention will be particularly directed to the Order in Council, dated August 14, 1879, in which apothecaries' measures are very fully described, and a careful study of which would apparently render the working of the Act easy.

"It is of importance also that there should be uniformity of charge for verifying and marking measures, and in consideration of the number of graduations necessary on glass measures that charge should be very moderate, if it be compulsory to verify all of them. At present it appears to be uncertain how far the scale of 'Fees to Inspectors,' set forth in the 5th schedule of the Act of 1878, is to be applied to graduated apothecaries' glass measures.

"It has been asserted that all weights and measures used in any distict must bear the authoritative stamp of that district. According to the reading of the Council of the Pharmaceutical Society it appears that if a person require to have weights or measures verified it must be done by the inspector of his own district; but that once verified they may be used in every district within the scope of the Act.

"The Council would be glad to have this authoritatively stated.

"GEORGE W. SANDFORD,
"*President.*"

"Board of Trade,
"(Standards Department),
"7, Old Palace Yard, S.W.,
"March 3, 1880.

"*Weights and Measures Act*, 1878.

"Sir,—I am directed by the Board of Trade to acknowledge the receipt of your communication of the 25th ultimo, enclosing a Memorial to this Board on the difficulties which seem to exist among some inspectors as to the verification of apothecaries' weights and measures, and to make the following reply:—

"In the first place, I have to point out that the justices and town councils are charged under the above Act with the duty of verifying all weights and measures used in trade, and that it is for these local authorities to give to their inspectors such instructions with regard to apothecaries' weights and measures as they may deem requisite.

"I am further to point out that the Board of Trade can give no authoritative opinion as to the legal construction of the Act, and consequently any opinion which they might offer on the legal questions adverted to in the memorial would be of no authority, and might only mislead.

"They are, however, always anxious to secure uniformity of practice in the various districts of inspection, and are therefore ready to give any information in their power as to providing standards, and verifying weights or measures. If, having regard to the opinions of the inspectors referred to in the memorial, your Society should think it right to call the attention of their respective local authorities to the inconveniences arising from the different practices adopted in their respective districts, the Board of Trade, on their part, are only too glad to help the Society by any means in their power.

"Although the verification of measures and weights for the use of chemists and druggists is a work requiring more than ordinary care, the Board are unable to see, either in the use or cost of the standards necessary for verification, any reason why local authorities can not efficiently carry the Act into effect with regard to such weights and measures. In commercial centres the present inspectors might perhaps at first find an unusual amount of verification work to do, but the local authorities have, under the Act, power to appoint additional inspectors if they are really wanted.

"The Board of Trade are advised that an apothecaries' ordinary graduated glass measure containing ten or fifteen subdivisions may be accurately verified in four or five minutes, by anyone having the least technical knowledge, and that the cost of a complete set of standard glass measures for the use of an inspector, as shown in the attached diagram, is not more than £1.*

"The Standards Office is prepared, moreover, as notified in the regulations (A. 5), issued last year, to verify standards for the use of inspectors, either of 'pipette,' 'beaker,' or 'flask' shapes.

"Each subdivision or line on a graduated glass measure should be verified by separate comparison with a standard in the manner shown in the diagram.

"At the Standards Office measures are verified under the Act whether they are made partly of glass or partly of metal, or whether they are made wholly of glass or wholly of metal. It is evidently necessary, as indicated in the memorial, that a glass measure should be verified by a standard made also of glass.

"The amount of fees to be taken by local authorities for verifying apothecaries' (with other) weights and measures has been under the consideration of this Board, and a circular on the subject will be shortly issued to all local authorities.

"Finally, as it would appear that a measure or weight once stamped by a local inspector need not bear the authoritative stamp of the particular district in which it may be used, it is probable that in some districts the local authorities may hardly deem it necessary at present, for verification purposes alone, to provide standards of apothecaries' weights and measures.

"I am, sir,
"Your obedient servant,
"T. H. FARRER.

"The President of the
"Pharmaceutical Society
'of Great Britain,
"17, Bloomsbury Square, W.C."

* It is intended to print the diagram in an early number.

The Pharmaceutical Journal.

SATURDAY, MARCH 6, 1880.

DISPENSING CHEMISTS' CHARGES.

After the unreasonable complaints that have appeared in some of the newspapers on this subject, it is especially satisfactory to find one of the leading medical journals dealing with it in a temperate and sensible manner. We should have been glad to see some medical practitioner of acknowledged authority, who was also cognizant of the services rendered by dispensing chemists, come forward individually and point out that it would be impossible to render those services on the basis of a remuneration such as the grocer or draper is content with; but, failing this, the expression of opinion in the *Lancet* of last week may fairly be taken as representing the views of the better class of medical practitioners, and as calculated to remove erroneous impressions on the part of the public.

The position taken up by Mr. Sandford in his letter to the *Times* is thoroughly accepted by the *Lancet*, and it is admitted that the dispensing chemist can never be remunerated for the special knowledge and special responsibility of his calling by a mere reference to the cost of the drugs he dispenses. It is on the contrary admitted that he must be paid, not only for his own special knowledge, but for that of his assistants for whose services he often has to pay highly.

At the same time it is held to be desirable, for the sake of patients requiring medicine, that the charges of dispensing chemists should not be so far beyond the actual cost of drugs as to constitute any impediment to medicines being obtained by all classes. While admitting it may have been too readily assumed that dispensing chemists alone are to be blamed for the existence of any such disadvantageous influence, it is held that in consequence of being, in regard to the public somewhat more neutral and less personally interested than the medical man is in the importance attaching to the supply of drugs to satisfy the need of sick persons, dispensing chemists have acquired the habit of regarding drugs and the preparations of them according to physicians' prescriptions rather as luxuries to be well paid for than as necessaries to be supplied abundantly on the basis of moderate profits.

In reference to this point the *Lancet* remarks that the hard necessities of life compel medical men to adapt their charges to the means of their patients, and it is held that a similar adaptation has not been sufficiently applied by dispensing chemists. As a consequence of this it is considered that many cases are but "slightly healed," or driven to medical charities, when a more thorough curative result and a maintenance of independence might have been secured if it were easier to obtain the required supplies of medicine. Though we do not altogether give our assent to this opinion to the extent that the *Lancet* seems to suggest, we thoroughly concur with our contemporary in thinking that the chemists of this country only want to see that the very importance of their calling necessitates its adaptation to the means of the bulk of the people, and that in this adaptation lies the secret of the further development and future prosperity of pharmacy.

But while sharing this opinion we must also point to the necessity of its being made apparent how the dispensing chemist is to get a chance of adapting the charge for his services to the requirements and necessities of the general public. Dispensing as now carried out by pharmacists is to so great an extent limited to supplying the wants of the wealthier class, that this circumstance has tended to make the dispensing chemist look upon it as a matter of luxury rather than otherwise, and it is this consideration of the subject which leads us to recognize a plan by which all requirements may be satisfied. We are glad to learn from the *Lancet* that there is a general feeling in the medical profession that the time has come when the work of dispensing should be discontinued by medical practitioners and relegated to chemists. Such a course would not only leave medical men more time for their special work, but by increasing the business of dispensing chemists materially facilitate the adoption of a lower scale of charges for medicine dispensed by them.

It is indeed discreditable that, in this age of division of labour, no means have been devised of entirely separating the work of the dispenser from that of the medical man, and that, notwithstanding the application of tests to ensure educational qualification and the possession of skill by every dispensing chemist before he can commence business, that portion of his business should so often be conspicuous only by its absence, as it is in many provincial places.

But in referring to this point and in rescinding the assumption that chemists only were to blame the *Lancet* says it is certain that many medical men in general practice find chemists reasonable enough in their charges and ready enough to take dispensing duties off their hands by an arrangement which leaves the medical man responsible to the patient for medicines, while the chemist acting as dispenser is paid by the medical man. We join with the *Lancet* in asking why such an arrangement should not be more extensively and generally adopted? Its advantages on both sides are manifest, and it would soon, we think, be apparent that the advantage to patients would also be considerable.

As regards the facilities for obtaining medicine according to the prescription of consultants, the *Lancet* fairly points out that it must be a matter of great importance to the public to be able to command careful and neat dispensing of first rate drugs at any hour of the night or day at their own door, and on the other hand it must be a matter of interest to the dispensing chemist to do this work on terms that will not alienate his neighbours and customers. It seems, however, probable that it is less in regard to this kind of business than in regard to the dispensing of medicines in provincial places and the poorer parts of large towns that there is room for a considerable reform and for the adoption of a system by which the medical men will gain freedom from irksome duties and the dispensing chemists a more suitable occupation than they are sometimes constrained to take up. This is an object towards which the trade has long been looking forward hopefully, and we trust that there may soon be evidence that medical men are generally willing to do their part in promoting its realization.

THE CHEMISTS' BALL AND THE BENEVOLENT FUND.

We are glad to be able to announce that the anticipation expressed by the Chairman at the recent Chemists' Ball, as to its possible relation to some who were not present, has been fully realized, for at a meeting of the Committee held last week, to wind up the business, it was decided to give to the Benevolent Fund a donation of thirty guineas out of the proceeds of this most successful gathering.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association will be held on Thursday next, the 11th inst., when a paper will be read by Mr. H. Allen, on "Wind and Weather." A report will be made on "Materia Medica" by Mr. R. H. Parker.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next meeting of the above will take place on March 10, at 32a, George Street, Hanover Square, when a paper on "Vegetable Foods: their Manufacture and Nutritive Value," will be read by Mr. F. W. Collinson. The chair will be taken by the President, Mr. F. W. Branson.

DIGESTIVE FERMENTS AND ARTIFICIAL DIGESTION.

Among the series of lectures announced to be delivered at the Royal College of Physicians during the present month, the Lumleian Lectures, by Dr. W. Roberts, upon "Researches on the Digestive Ferments and the Preparation and Use of Artificially Digested Food," will probably be of special interest to some of our readers. These lectures will be delivered on the 12th, 17th and 19th inst., at five o'clock each day.

We have received a report of the Executive Committee of the Chemists and Druggists' Trade Association, but are compelled from want of space to defer its publication till next week. We observe that in consequence of the appointment of Mr. Haydon as Secretary of the Birmingham Chamber of Commerce his resignation has been accepted, and that candidates for the office lately held by him are invited to send in applications as stated in an advertisement to be found on another page.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, March 3, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Richardson, Robbins, Savage, Shaw, Squire, Symes, Williams and Woolley.

The minutes of the previous meeting were read and confirmed.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Bucher, William Henry.
Cherrington, George Widdowson.
Corlett, Edwin.
Drew, Henry William.
Fryer, Charles Harry.
Park, Charles James.
Tanner, Herbert.
Taylor, James Bennett.
Wise, Joseph Norman.

Elections.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Drew, Henry William ....London.
Fryer, Charles Harry ....Brighouse.
Griffith, Samuel ....Weston-super-Mare.
Park, Charles James ....Devonport.
Porter, Thomas.....................Rochdale.
Tanner, Herbert ....Wendlebury.
Taylor, James Bennett ....Bedford.

The following, an Associate of the Society before 1842, having tendered his subscription for the current year, was elected a Member of the Society:—

Prevett, John ....Sheffield.

Chemists and Druggists.

The following registered Chemists and Druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected Members of the Society:—

Hulme, Thomas ....Pendleton.
Low, Joseph ... .London.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Culverwell, John Sayer ....Southampton.
Hooper, William ....Nagasaki (Japan).
Kenny, Thomas ....Hull.
Pattrick, George ....Crayford.
Taylor, George ....Bournemouth.
Walker, William ....Greenock.
Watson, Robert ....London.

Modified.

Frizell, Richard W....... . ...London.

ASSOCIATES.

The following, having passed the Minor examination and tendered (or paid as apprentices or students) their subscriptions for the current year, were elected "Associates" of the Society:—

Abington, Leonard Yates ......Newcastle-un.-Lyne.
Austin, Alfred ....Birmingham.

Bancroft, James ....Halifax.
Carveth, William Uglow.........Plymouth.
Christopherson, Fred ....Ipswich.
Cooper, Henry Samuel ....Droitwich.
Fry, Samuel ....Bishops Waltham.
Gossling, William Richard ......Wimborne.
Hobson, George William.........Buxton.
Jenkins, Evan ....Lampeter.
Jones, John Albert ....Liverpool.
Kennett, Edward...................Sandgate.
Killick, Charles Rowe............London.
Naysmith, Andrew ....Arbroath.
Newton, George Harry ....Ashby-de-la-Zouch.
Peake, William Alexander ......Charlton-in-Dover.
Robinson, George Duncan R....York.
Taylor, Fred ....Exeter.
Thomas, John ....Crosswell.
Wale, George ....New Malden.
Welstenholme, Abel Joseph ...Southport.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adcock, Herbert Dickson ......Alcester.
Bays, James Thomas ....Peterborough.
Braithwaite, John Oldham ......London.
Davis, Ifor............................Dowlais.
Darroll, William Burwell ......Warminster.
Fairbanks, William John ......London.
Foster, Henry Simpson ....Rotherham.
Fraser, Alexander ....Lochmaben.
Fuller, Arthur Edward ....Cambridge.
Greaves, Harry.....................Wakefield.
Green, Charles Alfred Parker...London.
Gribble, Edmund Arthur ......Stockwell.
Griffin, John Willifer ....Banbury.
Hubbard, Henry Joseph.........Norwich.
Ivatt, Albert........................Cottenham.
Jackson, Walter ....Catterick.
Keene, Walter F. W. ....Margate.
Pegg, James Alfred...............Mansfield.
Sheffield, Arthur John...........Beverley.
Siddall, George Ward ....Plymouth.
Swift, Augustus Dickerson......Spalding.
Thomas, Richard ....London.
Tucker, Percy ....Exeter.
Whyte, Peter ....Fraserburgh.

One person was restored to his former status in the Society upon payment of the current year's subscription and a fine.

Restorations to the Register.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:

David Powell Evans, 8, Battersea Park Road, Surrey.
Charles Read, West Street, Banwell, Somerset.

Additions to the Register.

The Registrar reported that—

Angus Sinclair Brown, Doncaster,
John Watson, 6, Parsonage Grove, Laisterdyke, Bradford,
George Edward Ransom, Kirmington, near Ulceby, Lincolnshire,
William Augustine Tolley, 69, Wharfdale Road, King's Cross, London, N.,

having severally made the statutory declaration that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been duly supported by duly qualified medical practitioners, their names had been placed on the Register.

Auditors' Report.

The Secretary presented the auditors' report and the balance sheet, which had been already submitted to and approved by the Finance Committee.

Mr. Williams suggested that any discussion on the accounts should be adjourned to the next meeting.

The Vice-President suggested that the report of the auditors had better be adopted, leaving any discussion of the balance sheet to the next meeting. The financial statement and the balance sheet covered two distinct periods.

The President said the auditors' report simply referred to the correctness of the amounts, and any discussion on details could not affect it.

Mr. Woolley said he had only received the financial statement on Saturday last, and that he had not been able to go into it.

Mr. Bottle thought it premature to discuss the auditors' report, as the bye-law stated it was to be presented at the Council meeting in May.

Mr. Churchill asked what was meant by saying that the two statements referred to two distinct periods.

The Secretary explained that the one was the actual statement of money received and money paid during the year; the other represented the general financial position of the Society.

It was then resolved that the report of the auditors and the balance sheet now presented be received, but that the consideration of both should be deferred until the next meeting of the Council.

The Secretary said that he hoped any member who wished to put questions with respect to the accounts would give him notice beforehand, so that he might be prepared to reply to them.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts ordered to be paid.

HOUSE.

The report of this Committee included a recommendation that a room at the top of the house should be converted into a bedroom for the house porter.

The report was received and adopted.

The President said he was glad to say that the alteration had been already carried out, and a very comfortable room had been made, in which the porter slept for the first time on the previous night. The arrangement would be very much for his benefit, and add to the security of the premises.

Mr. Bottle suggested that as the room was very large, a slip might be partitioned off, and used for storage.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£15 to a registered chemist and druggist formerly a member, and now suffering from severe illness.

£15 to the widow of a registered chemist and druggist.

£10 to a registered chemist and druggist, aged 70, and suffering from chronic disease. Applicant has had three previous grants.

Two other cases were before the Committee, but no grant was recommended, applicants having received relief very recently.

The report and recommendations were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The Librarian's report had been received and included the following particulars:—

	Attendance.	Total.	Highest.	Lowest.	Average.
January	Day	396	21	4	15 nearly.
	Evening	184	16	5	9 ,,

Circulation of books.	Town.	Country.	Total.
No. of entries	149	74	223
Carriage Paid		£1 4s. 6d.	

The following donations to the Library had been reported, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Commentar zur österreichischen Pharmacopoe, von F. C. Schneider und A. Vogl, 3e Aufl., 1880, Lief. 4. From Dr. Vogl.

Cooley, A. J., Cyclopædia of Practical Receipts, 6th ed., 1880, pt. 16 (conclusion). From Messrs. Churchill.

Institute of Actuaries, Journal, 1879. List of Members, 1879. From the Institute.

Owens College, Manchester, Calendar, 1879-80. From the College.

Prior, R. C. A., On the Popular Names of British Plants, 3rd ed., 1879. From the Author.

Royal Institution, Proceedings, 1879. From the Institution.

Squire, P., Companion to the British Pharmacopœia, 12th ed., 1880. From the Author.

Squire, P., Pharmacopœias of London Hospitals, 4th ed., 1879. From Alex. Bottle, Esq.

The Committee recommended the purchase of the following books for the Library:—

Beale (L. S.), How to Work with the Microscope, 5th ed., 1880.

Bloxam (C. L.), Chemistry, 4th ed., 1880.

Dioscorides, De Materia Medica, comment. illustr. C. Sprengel, 1829-30.

Educational Year-Book for 1880.

Skertchly (S. B. J.), Physical System of the Universe, 1878.

Theophrastus, Opera omnia, ed. ill., F. Wimmer, 1866.

The Professors had attended the Committee, and reported satisfactorily as to their respective classes.

The Curator had reported the average attendance in the Museum to have been:—Morning, 10; Evening, 2. He had also reported that he had received from Kew another case of Indian drugs from the late India Museum, and the Committee resolved that a special letter of thanks be sent to the India Office.

The following donations to the Museum had been received:—

Specimens of Indian Dill Seed and Oil distilled from it in England. From Mr. Umney.

Fruit of *Strychnos Ignatii*. From Professor Henslow.

Applications for duplicates of Indian drugs had been received from Professor Fluckiger, of Strassburg, Professor Herlant, of Brussels, Professor Henslow, of St. Bartholomew's Hospital, Herr Dittrich, of Prague, and Herr Oberdorffer, of Hamburg. Duplicate specimens had been exchanged with University College Hospital.

The Curator had been instructed to report what duplicate specimens he had at his disposal, and also any applications he might receive for them.

The Committee recommended that a complete set of parliamentary papers be procured regularly as published, at a cost of £16 7*s*. for the session.

The report and recommendations of the Committee were received and adopted.

WEIGHTS AND MEASURES.

This Committee had held two meetings, at the first of which a series of questions was agreed to, to be sent to the Local Secretaries and Members of the Council. At the second meeting, held February 25, it appeared from the replies received that no steps had yet been taken to carry out the provisions of the Act as regards apothecaries' weights and measures. A memorial to the Board of Trade had been agreed upon, which had been forwarded.

The PRESIDENT said he had received an acknowledgment from the Board of Trade of the receipt of the memorial.

Mr. RICHARDSON said the authorities at Leicester had decided not to take any steps at all at present.

Mr. HAMPSON said he had not been able to attend the Committee, but he should like to know if the desirability of endeavours to obtain a repeal of this portion of the Act had been considered.

The PRESIDENT replied in the negative.

Mr. HAMPSON thought the subject was well worthy of consideration. It seemed to him a mistake had been made in acquiescing in this legislation as it affected chemists and druggists. The State required from them certain qualifications, and yet, after that, it claimed the right to go in and inspect their professional utensils. He had no objection to the public being protected to the extent that it should be sure of obtaining the due weight or measure of articles sold over the counter in the ordinary retailing of drugs and chemicals, but a distinct line should be drawn between that kind of business and the work of the dispensing department. He thought the Council should seriously consider whether it would not be desirable to ask the Legislature to relieve chemists and druggists from this legislation. This was only a beginning, and the next step would probably be to authorize the testing of dispensing scales. The inspectors who usually tested the accuracy of weights and measures of the ordinary rough kind were totally unfit to carry out the Act of Parliament fairly. He saw no end to the difficulties which would arise unless it were repealed.

Mr. GREENISH said the views just expressed were entertained by more than one member of the Committee. It was stated at the first meeting of the Committee that the Act could not possibly be carried out as regards chemists' measures, and also that chemists being taxed about 50 per cent. on the value of their measures, which would be the result, would be very unjust. He thought the only way out of the difficulty would be to get that portion of the Act repealed.

The PRESIDENT said the question of repealing the Act did not come properly before the Committee, which was appointed under certain circumstances. A communication had been addressed to Mr. Farrer, a deputation had waited on him, and he suggested that a memorial should be presented to the Board of Trade, which he said would no doubt be considered and receive a reply which would be useful. The work left to the Committee was simply to prepare the memorial, not to consider the repeal of the Act. Apothecaries' weights and measures were introduced into the Act at the suggestion of the Council, because otherwise their use would have been illegal. It must be remembered that weights and measures used in dispensing might also be used in the way of trade; the same 2 ounce measure used in dispensing might be used to sell tincture of rhubarb or castor oil, and the inspector had a perfect right to examine it. The State had a right to see that the law was carried out properly. It was nonsense to say that because a man was highly qualified he was necessarily an honest man. Of course he ought to be so, but there were some men who were not what they ought to be; but whether they were or not, the honest man who had his measures right would have no objection to the inspector coming and seeing them. As far as chemists were concerned he thought the Act was a boon to them, because they could now get glass measures much more carefully graduated than they could before. If the inspectors were unfit to do the work, that was the business of the Government; The trade stood now in a very good position with the Government, and he did not think the smallest difficulty was likely to arise, especially if the Government would give such an answer to the memorial as would authorize the Council to send out a circular to the local authorities, which would tend to bring about the easy and uniform working of the Act.

Mr. HAMPSON said he understood on a previous occasion it was stated that Mr. Farrer said he had no authority over these gentlemen, and that any circular sent out would be merely a matter of suggestion.

The PRESIDENT said Mr. Farrer said his board had not the duty of interpreting the Act; that rested with the county boards, borough councils, etc.; at the same time a report had been issued, inviting local inspectors to communicate with the central board in case of doubt or difficulty.

Mr. ROBBINS said he had lately called on the inspector of his district, who was very attentive, and showed him his standards and the method of using them. The measures were open at the top and required no skill in using, as they had merely to be brim-full. He had a 1 oz. and 2 oz. measure, but could only use the 1 oz. The drachm measure was done by a pipette. He said he had not marked any measures for chemists, not having had any application except from one wholesale house. He also said that chemists need not fear anything like prosecution at present. His opinion was that if nothing were said about it the Act would become a dead letter as far as 2 oz. measures were concerned.

Mr. SYMES remarked that the replies received to the circular implied that no steps had yet been taken, and yet the memorial said that certain complaints and misconceptions had arisen, which would suggest there was a considerable amount of agitation amongst inspectors and the trade. Whilst approving of any memorial which the Council might send to the Board of Trade, he must say he disapproved of sending a circular to the inspectors direct.

The PRESIDENT thought it would be time enough to consider sending such a circular when the Council was in a position to do so.

Mr. SYMES said he would obey the President's ruling, though he thought others had gone considerably more wide of the subject than he had. By the very action the Council was now taking it was inviting interference on the part of the inspectors, and if continued long enough, it would lead to persecution. If the matter were only left alone the trade would be much better off. The President had said that the misconception or qualification of the inspectors was not the business of the Council, and if that were correct, it seemed to him the Council would be interfering in a matter which was clearly not its business.

Mr. RICHARDSON thought one good result from the Act would be the introduction of more accurate glass measures, for in his experience nothing varied more than those now sold. The same difficulty might not be experienced in London as was in the provinces, but he could only say the whole of the Leicester chemists were very much dissatisfied with the Act, and they hoped it would not be carried out at all. They felt very much, as Mr. Hampson had pointed out, that it was an insult to them as educated men that the Act should have been passed. He should like to ask if surgeons who kept dispensaries would be obliged to comply with it.

The PRESIDENT said the deputation which waited on the Board of Trade was informed that it would have nothing to do with compounding medicines, but the same measures which were used in dispensing were also used in selling by retail, and the possession of measures not properly authorized was an offence under the Act. The Council was not inviting interference at all. He had also seen the Westminster inspector, who showed him certain standards he had received; some were bronze measures, and some inspectors were using these, but they would not answer every purpose, because there were no graduations between 1 oz. and 2 oz., or between 5 oz. and 10 oz.

Mr. ATKINS could not join in any of the encomiums on this Act of Parliament so far as it affected chemists, but he feared it was rather too late to contemplate a reaction. It was passed and must be accepted. As far as he could see in his own neighbourhood the Act was a dead letter and was likely to remain so. With regard to one remark of the President, as to the appointment of the officials being a Government act, that was hardly correct, because the inspectors were to be appointed by the local authorities, though their appointments must be confirmed. Most of these gentlemen were simply waiting on providence, waiting for instructions and asking what was to be done. They were really doing nothing and he hoped they would not do anything. From time immemorial, in the country, chemists had been exempt as a privileged body from the action of inspectors—at least in his district—being considered specially qualified and educated, and they had never been interfered with. To show the ignorance which existed with regard to this matter, he might mention that a few days ago some measures were sent to a public institution by order of the secretary; they were obtained from a well-known house in London, but they were all returned with the inquiry if the official stamp had been affixed to them. Of course the answer was that no official stamp had yet been furnished or could be obtained.

Mr. FRAZER said the President had stated that the Act took no cognizance of measures used in dispensing; but as he understood, any conviction under the Act would not be for the use of measures, but for the possession of them, and as they might be used for any purpose the Act would of course apply to a dispenser as well as anyone else, if he kept a shop.

Mr. ROBBINS said the first question put to him by the inspector was, Are you a professional chemist, because if so, I have nothing to do with you; and the next question was whether the measures used for dispensing were considered to be used in selling, if not, it would be a question whether they would come under the Act.

Mr. FRAZER said he had applied to the officials in Glasgow and found that the corporation, through its proper officer, had applied to the proper quarter in London for a set of proper measures, and as soon as they arrived chemists would be informed of it.

Mr. WOOLLEY said his sympathies were to a considerable extent with Mr. Hampson, although he did not see that the Society could have opposed the passing of the Act in the first instance. He thought before any attempt was made to repeal it, it had better be allowed to get into full work. It was passed in 1878, and was to come into operation on January 1, 1879, but here was March, 1880, and the Act was not yet in operation.

The PRESIDENT reminded Mr. Woolley that a certain portion of the Act, namely, with regard to apothecaries' measures, only came into operation, by an Order in Council, on January 1 in this year.

Mr. WOOLLEY said at any rate there had been a considerable delay, and he thought the Government was finding out that it had got hold of a very difficult subject to manage. The inspector at Manchester did not know how he was going to carry the Act out; his present office was something like a superior smithy; of course he wanted a room like a laboratory with proper appliances for testing these delicate weights and measures. His appliances at present were not at all suitable, and he had not even yet got the standards for apothecaries' weights. He fancied the difficulties in a place like Manchester would be a pretty fair sample of what they would be all over the country, and the trade might very well wait until the Act got into operation before troubling themselves further about it.

Mr. CHURCHILL said it did not seem to be known to the Council that a trader could only be fined for having an unjust weight which was used for the purposes of trade. A case had just been decided in Norfolk, in which some weights and a rusty old platform scale were seized by the inspector, but on the case being tried before the magistrates, they were ordered to be restored to him, as they were not used for the purpose of selling.

Mr. WILLIAMS thought some members seemed to have forgotten the history of the passing of this Weights and Measures Bill. The Council never liked the Bill, and opposed it, but limited the opposition to that portion which it thought affected the interests of chemists and druggists. He considered the rest of the Bill very crude, as it merely re-enacted old legislation without any scientific attempt at rearrangement. By the representations of the Council, however, the Government was induced to agree that apothecaries' weights should be included in the legal weights, whereas in the Bill, as originally passed, it would have been illegal to have, and any chemist would have been subject to penalties for having apothecaries' weights and measures in his possession. The Council obtained that concession from the Government, and apothecaries' weights were now legalized, which they never had been before. The question of the subdivision of measures did not occur to the Committee who waited on the Board of Trade originally, or it might perhaps have obtained all that was required then; but it was an omission which was now to be regretted. The Council did not want its constituents in the trade to be annoyed by inspectors coming to them and summoning them before the magistrates for being in possession of measures which were not stamped. It did not in any way wish to urge on the application of the Act, but rather to check it, and also to make it so plain that the inspectors could have no difficulty in understanding it. Individually, he should be very glad if the way could be seen to getting a repeal of at least a portion of the Bill, and he had heard there was a movement for bringing in an amended Bill during the present session; if so, it would be most proper for the Council to take steps to get clauses inserted which would relieve the trade from all difficulty, but until there was more definite information about this it would be better to wait.

Mr. Shaw said the report stated that the Act had not been adopted in any case, but it certainly had been adopted in Liverpool, Manchester, and other places.

Mr. Symes said it certainly was not adopted in Liverpool.

Mr. Shaw said the authorities in Liverpool had adopted a portion of it, and were supplying themselves with standards as fast as they could. The authorities could not, of course, carry it out until they were in possession of the standards, and those were being supplied as fast as possible.

The President said it was a general Act which applied to the whole kingdom, though the activity with which it was carried out in different districts might vary.

Mr. Shaw said he understood Dr. Paul to state that it was optional with the various authorities.

Mr. Squire said a good deal had been said against this memorial to the Board of Trade and against the Council taking any action in the matter, but it occurred to him it was much better, since the Act was passed and would sooner or later come into force, for the Council to regulate, as far as possible, these standards, and the action taken under the Act, than to leave it to the first poor chemist who happened to be brought up before the magistrates to defend himself single handed.

Mr. Symes said he had said nothing against the memorial as it stood. He understood the Act was permissive, and that magistrates were not compelled to carry it out.

The President said it was not permissive, but compulsory.

Mr. Bottle said the 43rd section showed it was compulsory, but he thought if the Council did not make too much stir in this matter, very likely as far as dispensing weights and measures were concerned the local authorities would not feel the Act compelled them to interfere. The schedule referred to the measures used in the sale of drugs, and he thought probably inspectors and local authorities would not interfere with weights and measures used in dispensing, but would be glad to get rid of their responsibility on that head, which really would involve very serious difficulties in country places. Many inspectors were perfectly competent to inspect ordinary market scales and measures, but utterly incompetent to go into the question of grains and drachms. If the Act were to be carried out fully, the authorities must have a scientific man whose decision would be respected.

The report and recommendations of the Committee were then adopted.

The Annual Meeting.

It was resolved that the annual meeting should take place on Wednesday, the 19th of May, at 12 noon, and that the preparation of the annual report be referred to the Library, Museum and Laboratory Committee.

The Conversazione.

On the subject of the conversazione a long discussion ensued, more especially with regard to the question of providing refreshments. It was ultimately resolved that in the event of the conversazione being held this year at South Kensington or any other public place refreshments should not be provided by the Society. It was also resolved—

> "That a conversazione be held on Wednesday, May 19, and that the President, Vice-President, with Messrs. Hills, Williams, Greenish, Squire and Robbins, be appointed a committee for making the necessary arrangements for holding the same at South Kensington or some other public place."

Local Secretary.

Mr. John Thomas Windle was appointed local secretary at Chesterfield, in place of Mr. Greaves, who had resigned.

General Purposes Committee.

The Council, as usual, went into committee to consider the report of this Committee, which included the usual report of the Solicitor with regard to cases placed in his hands.

On resuming, the report and recommendations were received and adopted, including a recommendation that the Solicitor be instructed to commence proceedings against a person charged with a breach of the Pharmacy Act.

Medical Acts Amendment.

Mr. Shaw said he saw the Parliamentary Committee on the Medical Acts Amendment Bills was reappointed, and suggested that some of the London members be appointed a committee to watch the Bills.

Mr. Greenish said there were several Committees which had to sit during the ensuing month, and he thought they would have more work than the London members could spare time to attend to.

The Secretary said the proceedings in the House of Commons were daily watched, and if anything required attention he should at once communicate with the President.

Mr. Williams suggested that it would be well to have a small Committee nominated, which the President could summon if he thought necessary.

Mr. Robbins said this had practically always been done formerly.

Mr. Williams thought it would be better to have a formal appointment, and accordingly, on the motion of Mr. Shaw, seconded by Mr. Atkins, it was resolved—

> "That the members of Council residing in London be appointed a Committee to watch the progress of the Medical Bills now before Parliament as well as any other question affecting chemists which may arise during the session."

Sale of Patent Medicines.

The President read several communications which had been received on this subject: one from the Chemists and Druggists' Trade Association, enclosing a resolution urging upon the Council to take steps to amend the Pharmacy Act with regard to this matter, another from a meeting at Manchester, another from Rochdale, another from Sunderland, and another from Bolton, all recommending that steps should be taken to restrict the sale of patent medicines containing poisons to properly qualified chemists and druggists. The communication from the Trade Association also included a resolution that the Association was of opinion that the Council of the Pharmaceutical Society ought to take part in the preparation of any future Pharmacopœia.

The PRESIDENT said it was not necessary to pass any resolution with regard to these communications, but the Secretary would no doubt inform the writers that the subject had already been before the Council, and was receiving due consideration.

EXHIBITION OF PHARMACEUTICAL APPARATUS, ETC.

Mr. SYMES then moved the following resolution, of which he had given notice:—

> "That in order to render more interesting the annual meeting, arrangements be made for an exhibition of chemical and pharmaceutical apparatus, and other objects of special interest to pharmacists, in the Society's rooms on the occasion, and that the Library and Museum Committee be requested to consider and report on the best means of carrying out this resolution."

In doing so he said he had the satisfaction of feeling that it would commend itself very largely, if not entirely, to the members present, inasmuch, as it had for its object the promotion of the interest of members and associates in the Society. Most of the members present had no doubt happy recollections of the old conversaziones, which were held in that building, which were of a character somewhat different from what the conversaziones now were, and their success might be gathered from the fact that they became so popular that the building was no longer capable of accommodating those who attended. The conversaziones had now been held at South Kensington for some years, and were no doubt calculated in a certain way to keep up the status of the Society, but it must have occurred to some that with all their glories, it was much like having to play "Hamlet," with more brilliant scenery and more distinguished actors, but with Hamlet himself left out. It was with a view of restoring this vital portion of the conversazione, as it originally existed, that he moved the present resolution. At the annual meeting members came from all parts of London and the country; they often arrived some time before the chair was taken and spent their time in the museum, but though that was no doubt very valuable and useful to students, it was scarcely of the character fitted to attract practical men of business. He had heard such men asking the Curator if there was anything new he could show them, when he would point out some new specimens of bark or something of the kind, which was really of no interest to them. They would probably have liked to see on the table the latest improved pill machine or pill coating machine, different forms of tincture presses, mixing machines, laboratory apparatus and so on; and some of the specimens shown at the evening meetings, when there was very little time to examine them, might also be placed on the table, and the Curator might be there to explain them, since many members were present then who did not attend on any other occasion in the year. He knew no better means of introducing members to each other and keeping up their interest in the Society. He proposed to supplement, not to supersede, the present conversazione. It was now six years since anything of the kind was attempted, and then it was in connection with the Conference, and ten years since it was done in connection with the annual meeting. He believed on the present occasion it would be a success and hoped the motion would be supported.

Mr. RICHARDSON seconded the motion. He had a very vivid recollection of the great success which attended a similar exhibition some years ago. Country chemists did require a certain amount of education with regard to new scientific apparatus used in pharmacy and chemistry, which could only be obtained in the metropolis, and it would probably have the effect of bringing more country members up to the meetings, because although they might not be fond of listening to the long speeches which were often given in the theatre, they might have some interest in coming up to examine new apparatus. He hoped the exhibition might be made annual, and believed it would increase in usefulness every year. The British Medical Association had a similar exhibition at its meetings, and though that began on a somewhat small scale, it was now becoming an important element. He hoped there would be no opposition to this motion, for though it might entail some trouble on the officials, he thought that need not amount to much. The only doubt he felt was whether Mr. Symes was not rather late in bringing the subject forward, and whether there was sufficient time to get many manfacturers to exhibit.

Mr. WILLIAMS asked when it was proposed to open the exhibition.

Mr. SYMES said he proposed it should be open during the day of the annual meeting, from nine to twelve in the morning, and after the meeting closed there would be an opportunity for members to inspect it.

Mr. WILLIAMS thought the whole of the time of the day of the annual meeting was pretty well occupied.

Mr. RICHARDSON saw no objection to allowing the articles to remain for another day or two.

Mr. SHAW said everyone could visit the exhibition at his own convenience.

Mr. ATKINS asked if the Society had any room to hold it in.

The PRESIDENT asked if the last exhibition at the time of the Conference was a success.

The SECRETARY said his impression was that it was a failure.

The PRESIDENT said he had received a letter from Mr. Rimmington saying that he could not attend the Council, but his vote would be decidedly against Mr. Symes's motion for an exhibition, as being useless, troublesome and expensive.

Mr. HAMPSON said on first consideration of this subject he was disposed to give it the cold shoulder, as he felt there was scarcely time to carry it out in a satisfactory manner; but on further consideration he thought the experiment might be made for one year. It would be an advantage to country members, and was certainly worth a trial; but the Committee in carrying it out ought to be careful in its selection, and only receive those things which were of real interest to pharmacists.

Mr. ROBBINS observed that the exhibition at the meeting of the Medical Society was displayed on the night of the conversazione.

Mr. RICHARDSON said that was true, but it remained open the whole week.

Mr. ROBBINS thought if the exhibition were in connection with the conversazione there would be no difficulty in making it a success, but the great drawback would be that there would be nothing to induce exhibitors to send in anything interesting. He did not think there would ever be six people in the room at the same time if it were kept open for two days, and that being so it could hardly be expected that manufacturers would send apparatus with persons to take charge of and explain them, so that if the experiment were tried once he did not think it would be repeated. There was certainly no time on the day of the annual meeting.

Mr. GREENISH said it seemed theoretically very desirable that members should see all new medicines and new apparatus, and no doubt those present at the annual meeting would be very glad of the opportunity afforded them; but it seemed to him a very difficult matter to carry out. Nine-tenths of these things were simply sent in as a means of advertising, and it would be very desirable and necessary for the Committee to keep out that element, and only show those things which would be useful to pharmacists and were known to possess some merit. This would be placing a very great respon sibility on the Committee, and he was very sorry not to be able to vote for the motion.

Mr. ATKINS agreed that such an exhibition was desirable, if practicable, but there appeared to be great difficulties in the way. If the Society had not suitable accommodation there was a fatal objection at the outset; if it had, the next question was, could the exhibition be extended beyond the day of the annual meeting? for if not it would certainly not be worth while to undertake it.

Mr. WILLIAMS said he should like to vote for the motion if he could, but he could not see his way how to do it.

Mr. BOTTLE thought the only way of squeezing in such an exhibition would be to abandon the annual dinner and take it on the day before the annual meeting. It was no use asking exhibitors to send valuable instruments and implements for an indefinite time; they would only send them for a short period when they could send some one to take charge of them, nor could the Council undertake the custody of the articles under any other conditions. If it were held concurrently with the dinner or the conversazione it would certainly detract from the success of one of those meetings, but if the Council thought it well for one year to let such an exhibition have the preference he had no objection.

Mr. WOOLLEY thought Mr. Bottle had placed undue obstacles in the way of manufacturers exhibiting. At Manchester, it was found that manufacturers were willing to send heavy machinery long distances, and he had no doubt that in London a still greater readiness would be shown. As to the exhibition competing with the dinner and the conversazione, he rather thought it would tend to bring a great number of pharmacists up to London.

Mr. CHURCHILL was sorry to see the quantity of cold water thrown on this proposal. If a small exhibition of objects used in pharmacy were held in the museum or some other room at the time of the annual meeting, people could easily look at them before or after the proceedings.

Mr. FRAZER thought the chief difficulty would be to get a small committee told off to take charge of it and get it up. If it could be got up it would be a very good thing and would be more profitable and more appreciated than the debates which took place in the theatre. At all events, it might be tried for one year.

The VICE-PRESIDENT said the only difficulty which occurred to him was the question of space. Some time ago, he urged the idea of a permanent museum of apparatus used in pharmacy, and he received some support, but the unanswerable argument against it was want of space. That would not apply so much to a temporary exhibition of this kind, though of course the advantages would not be so great. He saw great difficulty in having it anywhere except in the laboratory, and although it was true that the arrangements with the head of the laboratory department were now different from those in force a few years ago, he thought Professor Attfield would be very willing to lend every assistance. It might be worth while to request a committee to undertake the matter, for he certainly considered it rather a scandal that pharmacists should have no opportunity in connection with the Society of seeing new apparatus and comparing it with the old. If a man wanted to produce anything new, he could get no assistance whatever in that house. He was not so sanguine as some as to the great advantages which would result, but some benefit would certainly arise, and it ought not to be attended with a large amount of trouble or inconvenience.

Mr. SYMES, in reply, said one of the objections was that the day of the annual meeting was an exceedingly busy day, and no doubt it was to the members of the Council; but he did not propose that they should undertake the duty of bringing apparatus there and exhibiting it, which duty might well be deputed to the Curator. It had also been argued that the Council would not be able to attend; but with all due deference to the Council it was rather a scheme for the benefit of the members at large than for the Council. With regard to space, the table in the museum would hold a considerable amount of apparatus and would perfectly satisfy him as an exhibition, at any rate, for the first occasion. It might be made to hold a great deal of useful and interesting apparatus. He had that morning spoken about it to the Curator, who had said that he believed it would be a great success and told him that people from the country often came and asked him about articles which had been exhibited at the evening meetings as long as twelve months before. The Secretary had doubted the success of the last exhibition, but probably, as had happened to himself, when he had been actively engaged in getting up such an exhibition, he was not quite in a position to form an impartial opinion, and the other people who had been present seemed to think it very successful. It had been also stated that the only object of manufacturers was to advertise their productions, but he thought if they took the trouble to send apparatus they deserved to be advertised.

The motion was then put and carrried.

REPORT OF EXAMINATIONS.

January and February, 1880.

ENGLAND AND WALES.

Feb.	Candidates. Examined.	Passed.	Failed.

INTERCHANGE OF VISITS BETWEEN THE BOARDS OF EXAMINERS.

Mr. WILLIAMS moved—

"That a deputation, consisting of the President, Vice-President and Messrs. Benger, Brady and Gale, attend the April meeting of the Board of Examiners in Scotland."

He said that on the general principle he thought some doubt was sometimes expressed as to the benefit to be derived from such a proceeding, but he must give it as his opinion, having watched the examinations both at

London and Edinburgh, that a deputation of this kind was of the greatest benefit, not only tending to making the two Boards uniform in practice, but in bringing about good feeling between them. He was sure the gentlemen named would be very efficient representatives of the London Board, would render assistance to their brethren in the north, and no doubt bring back many valuable hints.

Mr. Frazer seconded the motion, saying he knew these deputations were always welcomed in Scotland.

The motion was carried unanimously.

The Chemists' Ball.

The Secretary read a letter from Mr. Carteighe, thanking the Council for giving the use of its rooms for the Committee meetings of the Chemists' Ball, and stated that he had also received a cheque for thirty guineas to the Benevolent Fund.

The North British Branch.

A draft lease of the Society's premises in Edinburgh for a further term of five years, at a rent of £85 per annum, was submitted and approved.

Honorary Corresponding Members.

The President reminded members that at the next meeting the list of honorary members proposed for election must be submitted.

PHARMACEUTICAL MEETING.

Wednesday, March 3, 1880.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed,

The Chairman called attention to a large number of specimens on the table, and said that, as there was some very interesting matter to be brought before the meeting in the shape of papers, he thought it would be desirable to postpone any remarks with respect to them. The majority constituted a further grant from the collection formerly in the India Museum.

A paper was then read on—

The Diffusive Properties of Some Preparations of Iron.

BY PROFESSOR REDWOOD.

The paper is printed on p. 709, and gave rise to the following discussion:—

The Chairman said he was sure that the meeting would agree with him in considering the paper to be a very valuable one. He regretted that he could not see present any representatives of the medical profession. The meeting would have been very glad to hear the opinions of medical gentlemen expressed in the discussion which was likely to take place. In the meantime, they could appreciate the elaborate care with which Professor Redwood had pursued his investigations, which had extended over many years.

Mr. Williams said that he must certainly congratulate Professor Redwood upon his very excellent paper. It related to a subject which he (Mr. Williams) had thought a great deal upon, and worked upon in the way of business, and he thought that it cleared up a great deal with respect to which there had been a difficulty hitherto. He gathered from the paper that there was probably a compound of iron containing about 62 per cent. of oxide of iron, which compound was not diffusible. Professor Redwood seemed to have obtained a residue which would no longer diffuse, and in which that was the proportion of ferric oxide. He should like to ask whether Professor Redwood intended to carry on the investigation with a view of ascertaining the exact nature and constitution of this body, and whether, in fact, he had isolated that most peculiar and interesting basic chloride of iron which appeared to be a definite substance. It would be very interesting to know more about it in its isolated state, if it could be so obtained. From the vegetable salts, at any rate, the citrate and the tartrate, Professor Redwood always seemed to get a compound in which the 62 per cent. of iron was the standard and permanent quantity. The curious fact that when the oxide of iron precipitated by water from the dialysed solution was dissolved again in hydrochloric acid, the hydrochloric solution was still not diffusible, was a most important point in the paper, and one which was most unexpected; for he (Mr. Williams) should have supposed that when the oxide was dissolved in the proper quantity of hydrochloric acid it would at once be brought back to the state of the ordinary perchloride. In practice, in dealing with a solution of chloride of iron which by chance had been made basic, it had been usual to attempt to bring it back to its proper condition again by adding hydrochloric acid to the solution. Professor Redwood's experiments, however, would seem to show that that process was a mistake, and that the iron was not really so brought back to its proper condition. After the statement of Professor Redwood it would be necessary perhaps to ascertain by other experiments whether it was right or wrong thus to bolster up a preparation which perhaps had gone wrong. He spoke as a manufacturer, and perhaps he spoke feelingly. The paper altogether involved some most important points, not only practical, but also theoretical and medicinal.

Professor Redwood said it would perhaps be convenient to reply at once to the question which had been raised by Mr. Williams. He had referred to that residue of the diffusion in which somewhere about 62 per cent. of oxide of iron was obtained when the diffusion had appeared to stop. He would first observe that it was rather too much to say that diffusion had absolutely stopped. In all the experiments that were made by Graham, even with such very undiffusible substances as tannin or tannic acid, it was impossible to say that no diffusion would take place. As far as he (Professor Redwood) knew, a slight amount of diffusion would take place even with the most undiffusible substances. When a small quantity of iron went through in the experiment in which a large quantity of hydrochloric acid was added to the oxide, he did not look upon that as a regular case of diffusion. It was just an instance of the minute quantity that would pass through even in the case of the most undiffusible of substances. With regard to the residue, he had made an experiment or two, but he had not carried them to an extent which would have justified him in incorporating them in the paper. He had been very anxious to know what was the condition of the iron in the residue after it had been in the dialyser for twenty-eight days without any practical quantity going through. He had taken some of the residue, and, instead of evaporating it and drying it to estimate the iron, he had added to it a slight amount of alkali—carbonate of potash. When ammonio-citrate of iron in its ordinary condition was taken, the oxide of iron could not be precipitated with ammonia. It could, however, be precipitated with carbonate of potash after long boiling. But this was never easily done, and sometimes there was great difficulty in doing it at all. But in the present case, upon taking the residues and just dropping in a very small quantity of solution of carbonate of potash, the precipitate went down at once. He took the precipitate and redissolved it with the smallest practicable quantity of hydrochloric acid, just as he had done with the iron from the dialysed iron. He then put it into a dialyser, and it diffused perfectly well, and therefore it was clear that the oxide was not in the same state as that in which it existed in dialysed iron, but that there was some difference which remained to be accounted for.

Professor Attfield said that in his young days he was told that if medicine was not nasty, it would do him no good; and although he did not agree with that statement at the time, he was now disposed to think that the advice was wise, for it really would seem that the tongue was a dialyser, and that if medicine did not give a strongish taste, either nasty or nice, as the case might be, it might be concluded that it would not dialyse, and that therefore it would pass through the alimentary canal without getting into the blood. He, however, wanted to ask a question on that point of some one who had a sufficient amount of physiological knowledge to state whether such was or was not the case. In common with most chemists, he had studied the action of dialysis; but he wanted to know whether the action of medicinal and other substances, in passing through the alimentary canal, was, so far as regarded the act of nutrition, dialysis only or whether it was dialysis and something else. Were there not in the alimentary canal pores occurring here and there, through which there would pass particles larger than those which would pass through a septum? If so, it might be that, after all, dialysed iron, so-called, was a useful medicine; for the experiments which they had heard described that night, and those of Personne, really pointed to the proposition that non-diffusible substances were useless as medicine. He thought that a deal more had to be done in the way of experiment before that conclusion could quite be arrived at, though he must say that the experiments which had been described to them went far to support the proposition. The other chief proposition, which seemed to be led up to by Professor Redwood's experiments—both those which he had now referred to, and those that he made some years ago—was that non-crystallizable substances were not always non-diffusing, and he had spoken in support of the scaled compounds, which he described as being totally devoid of crystalline character. So far as chemists knew, perhaps that was so; but he did not think that it followed that because chemists did not know that they could be crystallized, therefore they could not be. In fact, he rather preferred to be led by Graham's great generalization and to consider, at all events for the time being, that if a substance did diffuse it therefore probably was crystalline. Professor Redwood's experiment, in which he got a diffusion of the scaled compound containing a very large proportion of iron, only led him (Professor Attfield) to the conlusion that the basic scaled compounds were, or probably would be found to be the crystalline ones. He should like to hear of some experiments being made in that direction, experiments in which hydrate of iron and citric acid were brought together in such molecular proportions as to give one, two, three or more distinct oxy-compounds; and then experiments could be made with a view of ascertaining whether those compounds would crystallize or not. He should not be surprised if they did. Holding rather tightly to Graham's theory, he must plead guilty to hoping that they would. Besides that, the very fact that such compounds, placed on a dialyser, decomposed, and that there went through a compound different from that which was left behind, seemed to show that the scaled compounds were not distinct, single chemical substances, but were mixtures. It might be that if they could be separated from such a mixture, or, by synthesis, compounds could be produced which together would form such a mixture, one or more of those compounds would be found to be crystalline. The third point in the paper which struck him as being extremely interesting was that in which it was proved that hydrate of iron dissolved in hydrochloric acid had different properties from chloride of iron. Of course, here there was room for speculation as to the cause of that; for after what Professor Redwood had stated such must be accepted to be the fact. He would himself rather not view the action at present as being one in which there was a different condition of iron. He would rather consider that in the case of the non-diffusible preparation there was an oxide of iron, it might be hydrate of iron, and might be oxyhydrate of iron, united with hydrochloric acid; and that in the diffusible preparation there was a true chloride of iron, or, to put it more shortly, that there were two distinct chemical compounds, one a hydrochlorate of oxide of iron and the other a true chloride of iron.

Mr. Martindale said that he did not come forward for the purpose of defending dialysed iron, although at the last meeting, lest it should have gone forth that dialysed iron was useless, he took up a slight defence of that preparation with a little reserve upon the decision to which Professor Redwood seemed inclined to come. Since the last meeting he had asked some of his medical friends what they thought of it, and they were somewhat inclined to agree with Professor Redwood that it was not so active as many other preparations of iron, such as the strong acid preparations, the chlorides and sulphates. At the last meeting he, on Dr. Gowers' authority, defended a corresponding preparation, the basic oxychloride of iron, prepared not by dialysis, but by taking a pasty ferric oxide and dissolving it in perchloride solution, and getting about four molecules of the hydrate to be taken up by one of the ferric chloride. Dr. Gowers, whom he had seen since the last meeting, was, he believed, willing if opportunity occurred, to take up investigations with regard to dialysed iron itself. But with regard to his experiments on chloroxide he (Dr. Gowers) stated in the *Practitioner*, of July, 1878, and also in the *Lancet*, of May 11, 1878, that in one of the two cases there referred to, the increase of the number of the red blood corpuscles went up in one case from 47 per cent. to 102 per cent. from February 20 to May 22. The counting was performed by a special apparatus by the aid of a microscope. Then in the other case, that of an extremely anæmic girl, there was only 26 per cent. of the corpuscles counted at one date, but they increased up to 92 per cent. in a very short period. Further Dr. Gowers stated that when the iron was omitted for a time, the number of corpuscles fell, but it rose again when the iron was resumed. This occurred with the basic oxychloride of iron. He (Mr. Martindale) would not defend dialysed iron at all, for Professor Redwood's experiments tended to show very much against it; but still he was inclined to give the Scotch verdict, that it was "not proven," and that careful clinical observation was required to supply what was wanted further on the subject. If dialysed iron was as useless as Professor Redwood supposed, then an attempt should be made to produce something like that which Dr. Gowers wanted to get for use in a case where the patient was suffering from extreme anæmia and no strong acid preparation of iron could be borne. In that case Dr. Gowers wanted to get a preparation that would not irritate the stomach. The patient was suffering from gastric irritation; and therefore he tried the oxychloride with these good results. If it gave such good results it was a preparation which ought to be used in preference to dialysed iron and the stronger acid preparations, such as the chloride, sulphate, or the ferric chloride, in these cases. It was not for pharmacists "to suggest a theory by which medicinal activity might be reasonably ascribed to a substance having properties which this preparation had been proved to possess." Facts were wanted, not theories, and the search must not be limited to chemical facts, but extend also to therapeutical ones. It was quite true, as Dr. Gowers had particularly pointed out in one part of his researches, that it was only in a case where the patient was anæmic that the preparation was of any help at all. If the patient was not needing iron, no increase of the red blood corpuscles took place. It was only when the patient was needing iron that any improvement took place, and that improvement, as he showed, took place in two ways, an increase of the amount of hæmoglobin, and also, as he clearly showed in the article in the *Practitioner*, by an increase of the number of corpuscles as well as the amount of the hæmoglobin contained in the blood.

Dr. Symes said that as Professor Redwood had mentioned his name in connection with the suggestion of the last experiment which he had made, he might remark that it was made at the suggestion of some medical men connected with the Liverpool School of Medicine, who for a long time had prescribed dialysed iron, assuming that it was the iron that had passed through the dialyser, and not that which remained. However ridiculous that might seem, this mistake was only brought to their notice by a letter which appeared in the *British Medical Journal*, where a London medical man had also discovered the same thing, and he believed that the discovery tended to bring dialysed iron into disrepute. The Liverpool gentlemen came to him, and rather called him to account for not telling them before that it was the other way about. They then suggested that he should determine whether dialysed iron was digested at all. He made the same crude experiment which he had explained to Professor Redwood; but there was just one little difference between Professor Redwood's experiments and his (Dr. Symes's). That difference might account for a little difference in the result. Professor Redwood prepared his peptone much as he (Dr. Symes) prepared his, and digested it for two hours with dialysed iron at 100°, and then Professor Redwood dialysed the preparation for two days. Instead of this he (Dr. Symes) mixed his dialysed iron with the peptone, and dialysed them at once, and maintained them at the temperature of 100° for two hours. He presumed that Professor Redwood's digestion for two days was not done in a dialyser.

Professor REDWOOD: No.

Dr. SYMES said that in his experiment the digestion being done in the dialyser, certainly assumed more of the character of what was likely to occur in the stomach and intestinal canal. He found that iron diffused through, and so decided was the result on testing for iron that he at once came to the conclusion that a certain amount of the iron had digested, and he never even repeated the experiment, but assured the medical gentlemen that at least some of the iron digested. He had that day received a pamphlet, in which it was stated that Dr. Longwood, of Massachussets, had made some experiments of the same physiological kind which Mr. Martindale had mentioned. Dr. Longwood had given the iron to anæmic patients and, by means of a suitable apparatus, a glass slide divided into squares, examined the blood of the patients after giving the iron at different times and under all circumstances. He had photographed the appearances presented in a number of experiments, and he had certainly determined that the number of corpuscles had really increased in the patient after giving dialysed iron when the patient was in a suitable state for receiving it. Dr. Longwood had mentioned an experiment which was interesting to pharmacists. He took 40 parts of dried dialysed iron and digested it for five hours at 100° Fahr., with about 200 grams of an artificial gastric juice. After digesting it for that length of time, he filtered it carefully, and he found that an amount of dialysed iron equal to 40 parts had lost 15 parts of iron, really digested and become soluble in the gastric juice, and passing perfectly clear through the filter. He (Dr. Symes) must say that it struck him that it would have been better if he had tried to dialyse it again. But he gave details which showed that he did succeed in digesting 15 parts of dialysed iron out of 40 parts in the course of five hours.

Mr. POSTANS said that Professor Redwood, in his very valuable paper, had brought out one or two things which appeared as very important offshoots. Professor Redwood had strongly advocated the use of ammonio-citrate of iron. He (Mr. Postans) might be permitted to allude to one thing in connection with the experiments which had been so ably conducted. He noticed that the Pharmacopœia said that ammonio-citrate of iron when incinerated on exposure to air left not less than 27 per cent. of oxide of iron. In the first experiment Professor Redwood had taken a 10 per cent. solution, and he found that the ammonio-citrate of iron contained 32·21 per cent. of peroxide; in the second experiment it contained 30·9 per cent. of the peroxide; in the third it contained 30·65 of peroxide; and in the fourth it contained 25·92 per cent. of peroxide. In these days of standard weights and standard solutions, and standard everything, it appeared important that manufacturers should supply dispensing chemists with preparations of ammonio-citrate of iron in every respect in accordance with the British Pharmacopœia.

Mr. UMNEY, alluding to ammonio-citrate of iron, said that he thought everyone knew that the statement in the Pharmacopœia was incorrect. He was quite assured that Professor Redwood knew that the percentage, at any rate, of ferric oxide as stated in the Pharmacopœia did not represent the ammonio-citrate of pharmacy.

Professor REDWOOD: I do not say so.

Mr. UMNEY said that if an ammonio-citrate was properly prepared, it would contain 30 per cent. of ferric oxide. The Pharmacopœia preparation containing 27 per cent. was not to be met with at the present time in commerce.

Mr. LUFF said that he should like to reply very briefly to a query that emanated from Professor Attfield. He took it that the passage of iron from the alimentary canal into the circulatory system was purely a process of diffusion. There were openings from the walls of the stomach and of the intestines into the interior, such as the peptic glands, the glands of Lieberkühn, and the glands of Brunner; but their function was simply to discharge fluids into the interior, and not to remove fluids from the interior of the stomach or from the intestinal canal. Moreover, supposing that there were actual pores, there were no actual pores into the capillaries of the blood-vessels into which the iron must pass. He took it, therefore, that the passage of the iron must be purely an act of diffusion.

Professor REDWOOD, in reply, referred first to what had been stated by Mr. Umney. He (Professor Redwood) was not prepared to say that the representation given in the Pharmacopœia was by any means an incorrect one. On the contrary, he considered it to be strictly correct. It was stated in the Pharmacopœia that ammonio-citrate of iron should not contain less than 27 per cent. of oxide of iron, and that was a perfectly correct statement. He was quite aware that the article as met with in commerce usually contained more than that proportion, and having had considerable experience in the manufacture of this article he knew that it was impossible to define exactly what the proportion would be. Referring to the commercial samples he had used in his experiments, the proportion of oxide of iron had ranged from 25·9 up to 31 or 32 per cent., and his experiments went to show that the sample with the smallest proportion underwent a better and more sustained diffusion than some of those with a larger proportion. The more generally occurring proportion was certainly 30 per cent. or more, and this arose from the fact that the preparation was more easily scaled when it contained the larger proportion. There might be another reason, but he would not ascribe to manufacturers the motive that by increasing the proportion of oxide they diminished the cost of manufacture, oxide of iron being cheaper than citric acid. With reference to the observation Professor Attfield started with, that a medicine must be nasty if it was to be of any use, he would observe that ammonio-citrate of iron was not a nasty preparation, and it was essentially a preparation in which there was as little of the styptic and inky character about it as there was even in the dialysed iron. This was one of the great recommendations of that and the corresponding preparations of iron. He admitted there was force in Professor Attfield's suggestion that possibly in the process of dialysis or diffusion the salt broke up into two or three compounds, and that a salt which was uncrystallizable in the state in which it would be used, might nevertheless consist of a mixture of salts some of which were crystallizable. And, moreover, although it was not at the present time known that these scaled preparations were capable of crystallization, it might yet turn out that some of them were so. One of the experiments he made some years ago was upon glycerine, which at that time was looked upon as perfectly uncrystallizable. He found that glycerine would diffuse freely, quite as well as cane sugar, and very soon afterwards it was shown that glycerine might be obtained in a crystalline form, although it crystallized with great difficulty. The fact that certain substances had not hitherto been obtained in a crystalline condition would have induced many to look on them as amorphous, and therefore as colloidal, and, if colloidal, as not capable of being absorbed to any very appreciable extent during their passage through the intestinal canal. With reference to what Mr. Martindale had said, he (Professor Redwood) was quite prepared to admit that the oxychloride which he had referred to might have medicinal efficacy, although dialysed iron might not. He did not, however, say that dialysed iron had no medicinal efficacy. He only wanted to see some theory in accordance with which they could reconcile its properties with medicinal activity. Although Mr. Martindale had suggested that he (Professor Redwood) should make the experiment with oxychloride, he did not consider that that would be at all conclusive. It did not bear upon his subject. Oxychloride might be anything. It might be iron in so highly basic a condition that it would not pass through, or there might be in it a large proportion of iron which would pass through. With reference to Dr. Symes's observations, he was much obliged to him for having pointed out what he seemed to consider a defect in his experiment with peptone. He freely admitted that the experiment would have been more satisfactory as made by Dr. Symes.

A cordial vote of thanks was accorded to Professor Redwood for his paper.

In consequence of the lateness of the hour, a paper by Mr. Henry Greenish, entitled a "Note on Cantharides," which will be printed next week, was taken as read, and the meeting was then adjourned until Wednesday, the 7th of April.

EXAMINATIONS IN LONDON.

February 18, 1880.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Three* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bucher, William Henry ....Crediton.
Cherrington, Geo. Widdowson...Newark.
Corlett, Edwin ....Ramsey.
Drew, Henry William............Southwark.

MINOR EXAMINATION.

Twenty-two candidates were examined. *Twelve* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bainbridge, Arthur ....Birkenhead.
Bartlett, Arthur Henry ....Newport, I. W.
Beech, Joseph ....Birmingham.
Booth, Frank.........................Mansfield.
Carveth, William Uglow.........Plymouth.
Christopherson, Fred ....Ipswich.
Coleman, Edward..................Kidsgrove.
Cooper, Henry Samuel ....Droitwich.
Davidson, Peter ....Insch.
Fry, Samuel ....Bishop's Waltham.

February 19, 1880.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Fryer, Charles Harry ....Leeds.
Park, Charles James ....Devonport.
Tanner, Herbert ....Wendlebury.

MINOR EXAMINATION.

Twenty candidates were examined. *Eleven* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Abington, Leonard Yates ......Newcastle-un.-Lyne.
Elborne, William ....Grantham.
Fazan, Charles Herbert ....Colchester.
Fryer, John ....Stockton-on-Tees.
Gledhill, Robert ....Dewsbury.
Gossling, William Richard ......Wimborne.
Griffiths, William..................Neath.
Harries, David ....St. Clears.
Jenkins, Evan ....Lampeter.

February 25, 1880.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Four* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Taylor, James Bennett ....Bedford.
Wise, Joseph Norman ....Carlisle.

MINOR EXAMINATION.

Twenty candidates were examined. *Twelve* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Johns, Henry Benj. Jeffery ...Southampton.
Jones, John Albert ....Liverpool.
Kennett, Edward ....Sandgate.
Killick, Charles R. ....London.
Knights, George Ekins ....Ashby-de-la-Zouch.
Knott, Henry Archer ....Walthamstow.
Newton, George Harry ....Ashby-de-la-Zouch.
Oliver, Henry Charles Hewitt Maidstone.

MODIFIED EXAMINATION.

Three candidates were examined. *Two* failed. The undermentioned passed, and was declared qualified to be registered as a Chemist and Druggist:—

Wright, Walter....... ....London.

February 26, 1880.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

MINOR EXAMINATION.

Twenty-seven candidates were examined. *Eight* failed. The following *nineteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jones, John James ....Kidderminster.
Mills, Richard Powell ....Weston-super-Mare.
Moore, Henry ....Brighton.
Nelson, Harry ....York.
Palmer, James Spencer ....Penzance.
Parker, William Marris ....Walcot.
Peake, William Alexander......Charlton-in-Dover.
Price, Frederick ....Liverpool.
Robinson, George Duncan R....York.

Slicer, Walter .... Bingley.
Smith, John .... Liverpool.
Sutcliffe, Isaac .... Mossley.
Taylor, Fred..................... Exeter.
Thomas, John .... Crosswell.
Thornley, Frederick..................... Devizes.
Tookey, Edwin James .... Birmingham.
Webb, William Henry .... Hereford.
Webster, George S. Gothard ... Alfreton.
Wolstenholme, Abel Joseph...... Southport.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the University of Cambridge.

Coleman, Thomas..................... Bicester.
Sharpe, William Salisbury ...... Bourne.
Smith, Ernest .... Dudley.
Wilson, Francis Charles .... Rugby.

Certificate of the College of Preceptors.

Chaston, Alfred E. .... Winchester.

Certificate of the Royal College of Surgeons of England.

Fooks, Henry .... London.

EXAMINATION IN EDINBURGH.

February 18, 1880.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Fifteen candidates were examined. *Five* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Drummond, John Alexander ... Elgin.
Glanville, George Grantley...... London.
Hutcheon, William .... Montrose.
Jackson, Thomas .... Scorton.
Marsden, William .... Manchester.
Miller, John Hean .... Newburgh.
Noble, Alexander .... Glasgow.
Simpson, Alexander..................... Huntley.
Stewart, William .... Helensburgh.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, Feb. 19. Mr. Warren De La Rue, President, in the chair. The list of officers and council proposed by the Council for the ensuing year was read from the chair:—President, H. E. Roscoe; Vice-Presidents, F. A. Abel, C.B., B. C. Brodie, Warren De La Rue, E. Frankland, J. H. Gladstone, A. W. Hofmann, W. Odling, Lyon Playfair, A. W. Williamson, J. Dewar, J. H. Gilbert, N. S. Maskelyne, V. Harcourt, R. Angus Smith, J. Young; Secretaries, W. H. Perkin and H. E. Armstrong; Foreign Secretary, Hugo Müller; Treasurer, W. J. Russell; other members of Council, M. Carteighe, C. Graham, C. W. Heaton, H. McLeod, E. J. Mills, J. M. Thomson, W. C. Roberts, W. A. Tilden, W. Thorp, T. E. Thorpe, J. L. Thudichum and R. Warington. The following gentlemen were elected auditors:—Messrs. A. J. Greenaway, G. H. Makins and F. J. M. Page, being proposed by Mr. Warington and seconded by Mr. C. G. Neison. The following certificates were read for the first time:—E. C. Copas and H. H. Slater. During the evening the following gentlemen were balloted for and declared duly elected Fellows of the Society:—Messrs. J. C. Evans, W. H. Glazier, J. Hogarth, K. W. Hedges, R. Howell, A. Lloyd, W. Macnab, A. R. Miller, J. McCarthy, G. H. Morris, P. Mathews, W. O. Prosser, H. J. Pasley, W. B. Roberts, G. Salet, A. G. Salamon, T. Terrell, G. Wilcock and W. H. Wood.

During the evening the President mentioned that he has recently seen a crystal prepared by Mr. J. B. Hannay, of Glasgow, which had been examined by Mr. Nevil Story Maskelyne and found to have the angles, lustre, hardness, etc., of the diamond. A similar crystal had been burnt and found to contain 97 per cent. of pure carbon. It was, therefore, to all intents and purposes, a diamond.

The following papers were read:—

On the Production of Ozone during the Combustion of Coal Gas. By R. H. Ridout.—Some years ago the author possessed a Bunsen burner, which always emitted the smell of ozone; by means of an aspirator and a suction-tube it was determined that the greatest production took place at the apex of the flame. The burner, however, was injured, and the author has not been able to get the same action again either with it or with other burners. He noticed subsequently, while working with singing flames, the same smell; in consequence, he made several experiments: a glass tube, $\frac{1}{8}$ inch bore, conveying coal gas, was placed inside another tube $\frac{5}{8}$ inch bore, 15 in. long. A strip of iodized paper was pasted inside the tube throughout its length. The gas burned with a blue flame. After a short interval the paper was discoloured, and on being moistened gave the oxidizing reaction, commencing at a point about half an inch above the flame and decreasing towards the top. The author endeavoured to apply this method of providing ozone to technical purposes, but without success. From several experiments the author concludes that the sulphur in the coal gas is eliminated as sulphuric acid under the above circumstances. Various experiments were now made to determine the nature of the body which gave the blue reaction with starch. It was not absorbed by passing it through caustic potash or water, which would remove all oxides of nitrogen, whilst no oxidizing action was observed in a bichromate of potash solution, indicating the absence of peroxide of hydrogen. The author concludes, therefore, that the substance formed was ozone. Ether and alcohol burned from wicks of capillary glass tubes gave similar results. Ozone was also produced by the flame of a minute glass Herapath blow-pipe, as long as the cone was perfect and of a violet colour; but as soon as the inner bright green cone was exposed the production of ozone ceased. The same violet colour attends the formation, whilst a green tint indicates the destruction, of ozone in the electric discharge.

Mr. Warington rather doubted whether all the oxides of nitrogen would be retained by the absorbing apparatus described.

Dr. Armstrong mentioned that this production of ozone by gas flames under certain conditions had been patented some time since.

Mr. Riley had noticed the smell of ozone round the tuyeres of blast-furnaces which were not working properly.

Mr. Kingzett insisted on the great difficulty in removeing traces of ozone from a comparatively large quantity of air. A very long tube and a current of low velocity were essential. He did not think that the experiment just related proved the formation of ozone.

Dr. Wright confirmed the statements made by Messrs. Warington and Kingzett. Carbonic acid would pass through caustic potash, and hydrochloric acid through silver nitrate solution unless special precautions were taken.

The President said he had used a washing vessel with spiral divisions with great success, a large amount, 20–30 ft., of washing surface being thus obtained in a moderate compass.

The author having briefly replied, Dr. Russell took the chair and called on Professor McLeod to make some remarks upon the production of ozone by the passage of moist air over phosphorus. At the last meeting Mr. Kingzett pointed out an error in some calculations which the author had recently brought before the Society; the correctness of this criticism the author frankly admitted, but did not think that the necessary alteration in the results invalidated his arguments (*Chem. Soc. J.*, Feb., 1880) as to the formation of ozone during the slow oxidation of phosphorus. In his opinion the evidence was quite conclusive without the quantitative experiments. He had investigated the reaction simply to satisfy himself as to its nature, and at the commencement thought that hydroxyl was probably formed, but the results of about a hundred experiments had convinced him that the substance formed was ozone. He had not observed any evidence of the formation of hydroxyl. Thus phosphorus was placed in a cylinder with sulphuric acid and bichromate of potash. After some time the liquid and the phosphorus were removed and the gas shaken up with water; the liquid did not affect potassium iodide and starch whilst the gas instantly turned the mixture blue. He was glad to hear that Mr. Kingzett was continuing his researches on the subject, and would be pleased to learn that the substance was peroxide of hydrogen and still more gratified if it turned out to be ozone.

Mr. Kingzett in reply said that he believed Andrews had shown that the active substance in air, in which phosphorus had been allowed to oxidize slowly, was removed by prolonged agitation with water, and that a French chemist had recently observed that the water gave the reactions of ozone, but went on to show that this reaction was due to phosphorous acid. He did not think that the presence of ozone had been thoroughly established.

Mr. R. H. Ridout then gave an account of some new and improved laboratory appliances which were exhibited. A test-tube brush, a piece of red or black indiarubber tubing about 3 inches long and ¼ inch bore has seven longitudinal and parallel slits made to within ¼ inch of each end. One end is then inverted and turned back until it is over the other end, the tube is finally secured to a wooden handle with twine.—A blow-pipe for spirit lamp or gas.—A hydrogen sulphide apparatus: Two Winchester quarts are fitted up like wash bottles, the long tubes being connected together by a short piece of indiarubber tubing. The short tube of one bottle is open, the other has a piece of indiarubber tubing and a pinch cock. This tube is connected with a sulphuretted hydrogen apparatus and the pinch-cock opened; the gas drives the oil, with which the Winchester quart is filled, over into the other bottle which is empty, when the first bottle is filled with SH_2 the apparatus is ready for use. The liquid to be treated is placed in a flask having an indiarubber cork and tube; when the liquid is boiling the latter is connected with the above apparatus and the steam allowed to condense; the SH_2 is rapidly absorbed by the liquid. The liquid is again boiled to drive back the superfluous gas into the bottle. No smell is perceptible during the operation.—Filter funnel: The author has had funnels made with stem 0·5 mm. inside, and sides ground to an angle of 60°; no platinum cone is necessary. He has also contrived an apparatus for delivering the liquid and precipitate into the centre of the filter paper.—Continuous aspirator: This consisted of a piece of ⅝ inch lead tubing bent into a circle with a hole $\frac{1}{10}$ inch in the centre of the concave part of the bend. A suction tube is soldered into this hole. As the velocity of a current of water passing round the bend is greatest on the outside a relative vacuum is caused on the inside.—Filter pump: A vacuum is obtained by filling a flask with steam and condensing it.—Apparatus for taking the gravity of liquids in terms of water at the same or other temperature: Two graduated U tubes are connected by a T tube provided with a pinch-cock, the liquids are placed one in each U tube; air is then blown in by the T tube and the pinch-cock closed. The liquids are displaced inversely as their gravities. One U tube, B, is kept filled with pure distilled water, consequently

$$\frac{\text{displacement in B}}{\text{displacement in A}} = \text{Sp. gr. of A.}$$

Messrs. Wooley of Manchester make the filter funnel. Messrs. Townson and Mercer supply the other apparatus.

Dr. Armstrong then made some remarks on—

Some Recent Researches on the so-called Unsaturated Compounds.—Results recently obtained by several perfectly independent investigators have thrown doubt on the theory usually held as to the constitution of the above substances, and reopen the question of the presence of dyad carbon in these compounds. Menschutkin has pointed out (*Berl. Ber.*, xiii., 163), from his experiments on the etherification of hydrosorbic and sorbic acids that the former is a primary and the latter a tertiary acid, *i.e.*, that the former contains the group CH_2COOH and the latter the group C,COOH. Fittig has shown that hydrosorbic acid is either $C_3H_7CH=CHCOOH$ or $CH_3CH=CHCH_2CH_2COOH$, the latter appearing to be the more probable. Menschutkin's observations would seem to point in the same direction. But, from an acid having this formula, it is not possible to derive an acid containing the group C,COOH unless it be assumed that two atoms of hydrogen are withdrawn from the carbon atom with which the COOH group is associated, and consequently, that sorbic acid contains a dyad carbon atom. Reference was then made to Fittig's suggestion of the formula CH_3CH (COOH), C,COOH for either citra or mesaconic acid. The determination of the rate of etherification of the three pyrocitric acids by Menschutkin's method would seem to promise interesting results, although as it is to be expected that the phenomena will be complicated by the occurrence of isomeric change, the method is not so likely to furnish any very conclusive evidence in this case. Lastly, Dr. Armstrong drew attention to the recent important paper by Brühl (*Liebig's Annalen*, 200), and especially to the remarkable conclusions arrived at by him with reference to bodies of the acetylene type.

After a few remarks by Mr. Williams and Dr. Wright, the Society adjourned to March 4, when a lecture will be delivered by Prof. T. E. Thorpe, "On the Relation between the Molecular Weight of a Body and its Specific Gravity when in the Liquid State."

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held on Wednesday evening, February 25, Mr. Branson in the chair, when a paper was read by Mr. I. R. James, on "New Remedies."

The author proceeded to describe some of the most used new remedies of the present time, such as caffeine, ethylic, ether, menthol, chaulmoogra oil, duboisine, picrotoxin, hammamelis, *Fucus vesicatoria*, iodoform, etc.

The paper was illustrated by some excellent specimens, and at its close an interesting discussion followed, in which several members took part.

A vote of thanks to Mr. James, proposed by Mr. Robinson, and seconded by Mr. Tharle, brought the proceedings to a close.

Correspondence.

Royal Naval Reserve.—A correspondent asks for information whether in all ports where the Royal Naval Reserve musters for drill, the medicines with which the men are supplied are as a rule dispensed by the medical men who prescribe them.

W. J. R.—The Acts of Parliament and Orders of the Board of Inland Revenue that relate to the keeping and sale of methylated spirit will be found in the Calendar of the Pharmaceutical Society for the present year.

Communications, Letters, etc., have been received from Messrs. Flückiger, Greenish, Abraham, Haydon, Mackay, Gehe and Co., Learoyd, Woodland, Jackson, Druce, Secretary of Chemists' Assistants' Association, A. A. P., G. C. R. O., J. R Y., J. W., E. T. G., X. Y. Z., W. J. R., Embryo, Ball, Junior, Mathetes.

NOTE ON CANTHARIDES.*

BY HENRY G. GREENISH.

In the autumn of last year, a sample of cantharides was handed to Professor Dragendorff, of the Pharmaceutical Institute, by a chemist of this town, with the remark that he had not succeeded in preparing an active Drouott's plaster from the flies, and doubted, therefore, their good quality.

I willingly acceded to Professor Dragendorff's request to determine quantitatively the amount of cantharides in the sample, and, in doing so, followed the method indicated by him in 'Die chemische Werthbestimmung einiger starkwirkender Droguen,'† which is briefly as follows:—

25 to 30 grains of the powdered flies are freed from oil by treatment with petroleum ether. Cantharidin being not insoluble in petroleum ether, a correction must be made in the amount of cantharidin found to compensate for the loss incurred by treatment with this solvent. This loss has been determined by Dragendorff to be for 100 c.c. petroleum ether 0·0108 gram cantharidin.

The flies freed from oil are now thoroughly moistened with solution of soda, and the mass thus produced dried in a porcelain dish on the water-bath. By this treatment, during which quantities of ammonia gas are evolved, a soluble cantharidate of soda is formed, which is subsequently decomposed by hydrochloric acid. It must be borne in mind that not all the cantharidin in the flies is present in the free state. Dragendorff has already shown‡ that cantharides containing about 0·3 per cent. cantharidin yielded only half that quantity to boiling water, the remainder being extracted by solution of potash. Among the combinations of cantharidin insoluble in water occur probably salts of lime and magnesia; among the soluble, cantharidic acid, possibly cantharidate of ammonia, etc. (the ammonia being derived from the albuminous substances by their decomposition during the drying of the flies).

The dried mass (containing now cantharidate of soda) is removed from the dish and finely powdered. It is then transferred to a flask, 25—30 grams of chloroform added, and the whole rendered strongly acid by the addition of dilute hydrochloric acid. This is then well shaken with from 25—30 grams of pure ether, the ether-chloroform solution separated and shaken with distilled water. The shaking with ether is repeated until cantharidin ceases to pass into solution. The major part of the ether can be recovered by distillation, the residue being allowed to evaporate to dryness in a flat bottomed glass dish. This residue is then transferred with the aid of a small quantity of absolute alcohol to a tared filter, and washed first with alcohol and then with two or three cubic centimetres of water. Should traces of oil still adhere to the cantharidin they may be removed by washing with petroleum ether. The quantities of these liquids used must be noted, since a slight correction has to be made, viz., for 10 c.c. alcohol 0·0077 gram, for 1 c.c. water 0·0005 gram. The washed cantharidin is dried at 100° C., weighed, and the corrections for petroleum ether, alcohol and water added to the figure so found.

Proceeding in this way 31·1405 grams of the flies in question yielded me 0·2022 gram of nearly white cantharidin. The corrections for petroleum ether, alcohol, and water amounted to 0·0303 gram, total cantharidin 0·2325 gram, equivalent to 0·746 per cent. This is largely in excess of the amount of cantharidin found by Dragendorff in good samples of Spanish flies, viz., 0·351 to 0·5 per cent., and serves to illustrate in a striking manner the remarks on cantharides by that chemist published in the *Pharmacist.**

"Apothecaries frequently complain that some cantharides do not furnish an active blistering plaster; that the same furnish, even when treated with acetic ether, an extract so poor in cantharidin, that with its aid no good Drouott's blistering tissue can be produced. In most cases the opinion is expressed that the flies contain too small a percentage of cantharidin. My experience teaches me to discredit the latter opinion. It is possible to obtain good preparations even from such apparently poor cantharides, it being only necessary to thoroughly extract the cantharidin they contain. . . . . I would say that by the aid of soda or potassa the entire amount of cantharidin contained in the flies may be rendered active. The finely powdered flies are mixed to a paste with diluted alkaline lye of about 1·1 sp. gr., heated in the water-bath for twenty-five to thirty minutes, when sufficient muriatic acid is added to have a trifling surplus of the same, and the whole mass is dried rapidly in the water-bath. The residue, which we may call prepared cantharides, is powdered anew, and employed for the preparation of the plaster, or for the extract with acetic ether for use upon tissue."

Had the Spanish flies examined been subjected to this treatment with solution of soda and hydrochloric acid, they would have yielded a blistering plaster of the activity of which there would have been no doubt.

I am able to give a further proof of the very imperfect nature of the exhaustion of the flies by ether in the estimation of cantharidin in the residue after treatment with that menstruum. Forty pounds of such residues were sent to Professor Dragendorff by a house in St. Petersburg engaged in the manufacture of large quantities of Drouott's plaster. The treatment of a kilogram had yielded such an unexpectedly large quantity of cantharidin as to offer an inducement to estimate the same more exactly.

29·297 grams of the exhausted flies, finely powdered, yielded me 0·2218 gram of nearly pure cantharidin; correction for alcohol and water 0·0192 (the flies having been previously exhausted with ether no correction for petroleum ether was necessary); total amount 0·2410 gram, equivalent to 0·822 per cent. of cantharidin.

The average quantity of oil removed by ether being about 12 per cent., we may reckon the amount of cantharidin in the original flies not extracted by ether to be 0·723 per cent., and assuming the cantharides to have been equally rich in cantharidin with the first sample the amount of that principle extracted by ether would amount to only 0·023 per cent.

Manufacturing druggists would do well, therefore, to turn their attention to their cantharides residues, especially such as have been extracted with simple solvents (ether, alcohol, etc.), in which salts of cantharidin are insoluble. The marc, for instance, from tinct. cantharidis still contains a considerable pro-

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, March 3, 1880.

† St. Petersburg, 1874.

‡ *Pharmacist*, v. 78; *Pharm. Journ.* [3], ii. 1029.

* *Loc. cit.*, p. 79.

portion of cantharidin. The only English price list at my disposal, that of Messrs. Southall Brothers, quotes cantharidin at 1*s.* per grain, and leaves no doubt of the profitability of working up residues containing $\frac{3}{4}$ per cent. of that principle.

That other species of *Cantharis* may excel *Cantharis vesicatoria* with regard to the amount of cantharidin contained in them, is shown by the estimation of a sample of *Cantharis adspersa* presented to the Museum of the Pharmaceutical Institute, by Professor Arata, of Buenos Ayres. Although the flies arrived mouldy and in bad condition I succeeded in obtaining from 12·3195 grams of dry insects 0·2917 of very nearly pure white cantharidin; correction 0·0256; together 0·3173 gram; equivalent to the very large amount of 2·573 per cent. Noticeable in this sample and in the first sample of *Cantharis vesicatoria* is the comparatively small quantity of fixed oil. While Dragendorff finds as an average in good cantharides 12 per cent., I have obtained from *Cantharis vesicatoria* (approximately) 7·7 per cent., and *Cantharis adspersa* only 2·6 per cent. Possibly the weather prevalent during the life of the insect, the age of the same, etc., may have an influence on the amount of oil and cantharidin.

Dorpat, Russia.

ORIGIN OF THE CALISAYA LEDGERIANA OF COMMERCE.

BY JOHN ELIOT HOWARD, F.R.S.

I have been induced to review the question of the origin of the now celebrated bark above named; and am able to publish for the first time details which, at the request of Mr. Ledger, I withheld in 1876, when I gave extracts from his letters in my 'Quinology of the East Indian Plantations.'

We are indebted not to systematic botanists, but to the experience and practical sagacity of an Indian, for our knowledge of the best kinds of calisaya bark; whilst to Mr. C. Ledger belongs the whole credit of the enterprise of obtaining the precious seed to which the hope of future success attaches in Java and perhaps in other parts of the East Indies.

I have pleasure in *now* recording the name of the above-mentioned Indian servant of Mr. Ledger—Manuel Incra Mamani—to whom was entrusted in 1861 the commission of obtaining the seed of the best calisaya. At page 48 of my (unfortunately) little accessible 'Quinology of the East Indian Plantations' will be found many details, but I now quote more fully from Mr. Ledger's original letters. Under date December 22, 1874, I find the following:—

"Manuel Incra Mamani delivered the seed he had collected in June, 1865. He then told me that the best bark trees had not produced ripe seed for four years previously. When the trees were full of flower and most promising a frost (*helada)* in April destroyed it all. The inferior sorts had not suffered. He had been cutting bark with his sons and patiently waited for opportunity for complying with my orders, obtaining only the best sort.

"He assured me, too, he had seen several parties collecting seed for gentlemen in La Paz; that they did not obtain a single good seed till 1865; and this assertion seems now to be corroborated by result of Schuhkraft's remittances in those years. (See further.)

"After paying him well, he returned to his home in Bolivia, having engaged with me before leaving to obtain more seeds of the Rojo, the Morada, the Naranjada, the calisaya of Moco-moco."

The sequel is a sad one. After relating the particulars of the murder of another servant (Cabrera), Mr. Ledger says—

"Poor Manuel is dead also; he was put in prison by the Corregidor of Coroico, beaten so as to make him confess who the seed found on him was for; after being confined in prison for some twenty days, beaten and half starved, he was set at liberty, robbed of his donkeys, blankets and everything he had, dying very soon after."

The first portion of the above seed passed into the hands of the Dutch Government. In my work the reader will find particulars about its reception in Java. Owing to Mr. Ledger's good drying and care, the seed arrived in such condition that it had not lost its germinative power. I inspected the remainder at the request of the British purchasers, and found it apparently of the best quality and condition. The capsules reminded me of those of "*Cinchona Calisaya*, var. *microcarpa*, Wedd.," published by Dr. Weddell in the 'Annales des Sciences Naturelles,' 1870. This I recognize as the source of the Zamba sort, of which I have magnificent specimens. Dr. Weddell says: "Les cascarilleros du pays me l'ont signalée comme donnant une écorce supérieure en qualité a celles des autres variétés croissant dans les mêmes lieux, et j'avoue que j'ai été heureux de voîr cette appréciation de l'homme des bois confirmée par M. Howard."

In fact it is only in this description that Dr. Weddell approached the best sorts, the *Calisaya vera* being by no means equal in produce.

In his second journey Dr. Weddell obtained specimens of the Zambita, Verde and Morada varieties of calisaya, of which he obligingly gave me specimens, which are now before me. The bark of these sorts, especially the Zambita and the Morada, resembles considerably that of the Ledgeriana.

I do not assert entire identity. The seed producing the Ledgeriana was gathered, according to Manuel, from about fifty trees, chiefly of the Rojo sort. These different forms of the best calisaya are distinguished by the cascarilleros by the colour of the leaves; and Ledger thinks my plate of the *Calisaya Anglica* resembles in the colour of the leaf that of the Rojo. Elsewhere he gives me, as descriptive of the same, that of *sangre de toro*, or bull's blood. The variation in the colour and form of the leaves does not seem to have any connection with the value of the bark.

I have said that Dr. Weddell published the Zamba or Zambita sort as the var. *microcarpa*; but not having seen the flowers, his description leaves much to be desired. The *Calisaya Ledgeriana* of Java is, as I have shown, the legitimate produce of the seed of the fifty trees above mentioned. I should think that no botanist has been within some hundred miles of the almost inaccessible banks of the Mamore, where these were met with, or of the Beni, where Pedro Rada collected from trees (as he told me), from 120 to 150 feet in height, some of the finest calisaya bark ever brought into the English market; conveying his precious cargo by the long and perilous navigation of the Rio Madeira, as I described in Seemann's *Journal of Botany* in 1869. This sort was called Morada; and if the coloured drawing given there is compared with my plate V. in 'Quinology of the East Indian Plantations,' it will be found closely to resemble.

We have then no means of further botanical description, except from Java; and from thence I have been supplied with forty-four excellent specimens, comprising all the barks cultivated. These I fully described in the work above named, and from these published the first description of the sort as "*Cinchona calisaya*, var. *Ledgeriana*, How." The Ledgeriana has a peculiar character, to be recognized in the seedlings at a very early stage, but variable as to form and colour in the after-growth. It must be admitted that the most striking characteristic of the Ledgeriana is the bark, which is at once recognizable by a person familiar with these observations; but scarcely capable of being made the basis of botanical definition. The flowers are also described as small, white and "nutantes;" but I am not certain that this is capable of being asserted without some slight modification. I hope to succeed in flowering my own specimens, which I would then describe more perfectly. On the whole I have found it best to present to the reader of my book three forms of the plants, relatively (according to the analysis of the flower) the *male*, *female* and *neuter* forms—that is those in which the above elements preponderate, or are in even balance. The male (*macho*) plants in the cinchonæ are always the most highly coloured.

The male, or *macho* form (plate IV.), is the most coloured (and should be more of the *bull's blood* colour). The contents of this bark, as given from the tree itself by Moens are (per cent.):—

Quinine	9·06
Cinchonine	0·10
Amorphous Alkaloid	1·40
Total	10·56

The female form (*hembra*), plate V., has leaves of a green colour, and gave to the same chemist:—

Quinine	9·90
Amorphous Alkaloid	2·09
Total	11·99

(Of this I have given a fine plant to one of our Ceylon cultivators, who is about sending it out to India).

The third form, plate VI., gave:—

Quinine	9·97
Amorphous Alkaloid	1·70
Total	11·67

Compare these with the "*Calisaya Javanica*," of Hasskarl, which gave (in average of eighteen samples, 1879, Moens):—

Quinine	0·70
Cinchonidine	0·50
Quinidine	0·30
Cinchonine	1·20
Amorphous Alkaloid	0·30
Total	3·00

and the "*Calisaya Javanica*," of Schuhkraft (average of sixteen samples, 1879, Moens):—

Quinine	0·50
Cinchonidine	0·30
Quinidine	0·20
Cinchonine	1·20
Amorphous Alkaloid	0·20
Total	2·40

It must be well understood that none of these sorts originated in Java, but were and are well distinguished as "best" and "inferior" in their native country.

The idea of any of them originating by *crossing* in the Java plantations is therefore perfectly illusory.

If asked how they originated in their native forests, the answer must be, that of this we are entirely ignorant. We approach the question so well investigated by Alexis Jordan as to the varied forms of European flowers. Although I have described the *Ledgeriana* as a *variety* of the *Calisaya vera*, it is only as conforming to the present state of botanical science that I use the word. It is as consistent with common sense to believe that by fusing together a half-crown and a penny, one could produce a sovereign, as to believe that by blending inferior varieties one could educe the *Calisaya Ledgeriana*, the best, by far, of all. I do not at all deny that hybridization takes place in the plantations in India, nor that in some cases good results may follow. The only practical inquiry into this question was carried on by McIvor; who thought he had attained a great success in a *pubescent* hybrid, from which he sent me some good bark; but when afterwards, with much pains and care, he was good enough to send me a section of the tree, it was quite different, and a correspondent of mine in the Wynaad informs me that as sent to him it is altogether a failure. Specimens both of the good bark and of the tree may be found in the Museum.

If my readers will take a map of South America they will find the distance from Coroico (Calisaya district) to Huanuco (grey bark) is 680 miles; from Huanuco to Loxa (crown bark) is 500 miles; from Loxa to Riobamba (red bark) is 180 miles; from Coroico (Calisaya) to Pasto (Pitayo bark) is 1400 miles; and from Coroico to the Lancifolia and Cordifolia district is 1500 miles. We need not then suspect any interference of the pollen at these distances. In fact, all that we can recognize is the existence of permanent allied forms; and the difficulties are insuperable, even in imagination, in conceiving how they could have diverged from one centre. It is like the attempt to find a common centre for several intersecting circles.

It is no doubt very inconvenient to the systematic botanist to admit this; but to distort facts and suppress all that we have already gained in knowledge of *nature* for the sake of *system* is simply absurd.

The *Calisaya Ledgeriana* is then the legitimate descendant of the finest sort (or sorts) of the Bolivian forests; subsisting even there under different forms, especially distinguished by the colour of the leaves; but agreeing in the production of a large amount of very pure quinine. The flowers appear in South America to be very sensitive to frost; but they are abundantly fertile under favourable circumstances; 20,000 plants were raised by Van Gorkom and 60,000 by McIvor from the one bag above described. The climate at Ootacamund did not suit. Nevertheless, some of the trees, though stunted and mostly perishing, have produced excellent bark. The reason why it is not more largely sent into Europe is, I understand, that in Java they are wisely thinning out the inferior trees and allowing the best to develop themselves. In British India on the contrary, I am afraid many of the best "succirubra" and "officinalis" trees are being cut down. I thus send for the information of your readers a few facts which may be of interest, and in conclusion must express my regret that those who have toiled and suffered in introducing these valuable trees into India should have been so ill rewarded. Ledger lost his time and his servants, and yet both the British and Dutch governments refuse him the slightest compensation for his losses.

EXTRACTION OF PERFUMES WITH CHLORIDE OF METHYL.

BY PROFESSOR CAMILLE VINCENT, ECOLE DES ARTS ET METIERS.*

Some months ago a manufacturing perfumer, M. Massignon, came to consult me respecting the employment of chloride of methyl (which has the property of dissolving fats, resins and essential oils) in the extraction of the odorous principles of scent-producing plants. I expressed my belief that it might be so employed, but told him that I had no *data* in point at my command.

An experiment subsequently made with scent-woods succeeded, but the product possessed a very unpleasant odour, the commercial chloride of methyl used for industrial purposes retaining a pyrogenous product with a very persistent odour. I therefore turned my attention to the purification of the methyl, which in itself has a sweet ether-like smell; and in this I succeeded perfectly by treating ordinary methyl chloride with concentrated sulphuric acid, which completely absorbed the unpleasant odour. Chloride of methyl liquefied after the above treatment was found to leave no odorous residue on evaporation; it is perfectly suited for the extraction of perfumes, and when subsequently evaporated, leaves them with their limpidity and delicacy wholly unimpaired. My first experiment was made with orange flowers in a glass vessel; and the product thus obtained was pronounced by several experts to be superior to neroli obtained in the ordinary way by distillation with water. Encouraged by the success which had thus far attended my efforts, I had an apparatus constructed of sufficient size to test the practical value of the discovery by operating upon several kilogs. at once of different kinds of flowers. It consisted of the following parts:— 1. A digester, in which the flowers to be extracted were placed; 2. A receiver for the liquefied methyl chloride previously purified with sulphuric acid; 3. An air-tight vessel to receive the methyl chloride after passing through the flowers, in which a vacuum could be produced with the aid of an air-pump; 4. An air-pump to exhaust the last named vessel, and to drive the methylic vapour into a cold coil, whence it returns, in a liquefied state, into receiver 2. The air-pump and coil formed part of an ice-making machine.

The extraction of the perfume, as for example, of roses, is thus performed. The digester 1 is filled with flowers. Upon these is turned, with the aid of a conical stop-cock attached to receiver 2, a portion of the liquid chloride of methyl contained in the latter vessel. A couple of minutes are allowed for digestion, and then the liquid is run off into receiver 3. Another charge of methyl is given, which is filtered through the flowers into vessel 3, like the preceding, and so on until the flowers are supposed to be exhausted. The air-tight receiver 3 is now partly filled with the liquid methyl charged with the odorous principles of the flowers washed by it. Any portions of chloride remaining in the digester can be removed with the air-pump and by passing steam through the residue of the flowers, receiving the watery vapour in a gasometer, the chloride in each case being returned to receiver 2 through the cold coil. The chloride of methyl charged with odorous principles in vessel 3 must now be evaporated *in vacuo*. For this purpose a current of water at 86° F. is passed round the vessel, whilst the air-pump is at work. When the manometer attached indicates an internal pressure of half an atmosphere, the operation may be considered as completed. The air-tight receiver is opened, and the odorous principles are found in the residuum of fatty matter and wax left by the evaporated methyl. Treated with alcohol cold, this residuum yields up the perfume of the flowers in its full potency and delicacy.

In this way may be obtained, not only the perfumes of flowers generally extracted by distillation, but also of others, as the jasmine and violet, which on account of their easy destructibility are prepared chiefly by *enfleurage* or maceration in fat. Specimens of the perfumes extracted with deodorized methyl chloride have been sent to the Société d'Encouragement. The results with all kinds of scent-producing plants, flowers, seeds, barks and roots alike, show that the yield by the methylic process averages 25 per cent more than by ordinary distillation with water.

M. Massignon is erecting an apparatus on the above principle at Cannes, which will be capable of extracting 1000 kilogs. (20 cwt.) of flowers daily, and which he hopes will be in work in the course of the present month. The refrigerator attached to the apparatus manufactures 60 kilogs. of ice per hour.

* *La Nature*, January, 1880.

ESTIMATION OF IODINE IN VAREC.*

BY O. SCHOTT.

The author describes the method finally adopted by him for estimating the iodine value of samples of varec. Exactness is necessary, since the percentage of iodine is usually only from 0·1 to 1·5. Bunsen's method of titration with standard sodium thiosulphate solution was found to yield precise results if the starch solution was carefully prepared and filtered, a deep blue coloration, disappearing at last on the addition of a single drop of decinormal thiosulphate solution and reappearing on addition of a drop of iodine solution; it was therefore considered unnecessary to add excess of thiosulphate and titrate back with iodine solution. From 25 to 50 grams of dried and powdered varec were extracted with warm water several times, and the solution made up to a litre; 100 c.c. of this liquid was mixed with a few drops of sulphuric acid and allowed to stand in a warm place for twenty-four hours to remove the hydrogen sulphide; the liquid, after having been evaporated to about a third its volume, was run through a small filter to remove the sulphur, and the filter was washed with as small a quantity of water as possible. This liquid was then mixed with ferric sulphate or ferric ammonium sulphate and the iodine distilled over into a small quantity of potassium iodide solution contained in a U-tube, kept cool by immersion in cold water, the end of the delivery tube dipping several millimetres below the surface of the iodide solution. Boiling for fifteen minutes will usually distil over all the iodine, but after the residual liquid has cooled it should always be tested by carbon bisulphide or chloroform, since sometimes only long continued boiling completely removes the iodine. The iodine contained in the potassium iodide solution is then titrated with thiosulphate. The author also tried extracting the iodides from the varec by alcohol; this method had the advantage of leaving undissolved most other salts, and especially the sulphides; the cost of the alcohol made it undesirable. A sample of varec, which yielded 0·376 per cent. of iodine by the palladium method, gave by the above process an average percentage of 0·33, and duplicate analyses of two other samples made with great care yielded 1·701 and 1·676 for the one and 1·426 in both analyses of the other sample.

The Pharmaceutical Journal.

SATURDAY, MARCH 13, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE MEDICAL BILLS.

THOUGH the impending dissolution of Parliament will postpone for some time longer any action to be taken in reference to the subject of medical reform, it will not be out of place to give some account of the proposed legislation as affecting unregistered persons. Three Medical Act Amendment Bills are now before the House of Commons—one brought in by Dr. LUSH, Sir TREVOR LAWRENCE and Sir JOSEPH MCKENNA; a second brought in by Mr. ARTHUR MILLS, Mr. CHILDERS and Mr. GOLDNEY, and a third, brought in as the Government Bill, by Lord GEORGE HAMILTON and Sir HENRY SELWYN-IBBETSON. All of these agree in proposing the repeal of so much of the twentieth section of the Apothecaries Act, 1815, as relates to any person acting or practising as an apothecary, and it may hence be inferred there is a tolerably general opinion that it is desirable to do away with any further possible application of that section of the Apothecaries Act with the object of interfering with counter practice by chemists and druggists.

The penal sections of the several Bills present little or no features of difference in the main, being directed entirely against the use of titles by unregistered persons, and only in so far seeking to restrict the practice of medicine or surgery. The penalty for such improper use of titles as would imply that the person using them was registered or entitled to be registered, is fixed at a maximum of twenty pounds. The provisions of the several Bills also extend to the use of the designations physician, surgeon, apothecary or doctor, or that of any medical diploma, or the use of any designation or description used to distinguish registered practitioners of medicine or surgery, and implying qualification to practise medicine or surgery. Any person who does this when practising for gain, or professing to practise, or publishing his name as practising medicine or surgery, or being engaged for gain in or professing to be engaged in, or publishing his name as being engaged in the cure or treatment of diseases or injuries, is also to be liable on summary conviction to a fine not exceeding twenty pounds.

This, we take it, is the extent to which the provisions of this section of the three Bills are intended to apply, but the grammatical construction of the section does not make the intention quite so clear as might be desired.

In the Government Bill and in that distinguished as Bill No. 2, it is provided that persons registered under the Dentists Act, 1878, are to be at liberty to use the designation of dentist or of licentiate in dentistry, or dental surgery, or of certified dentist, notwithstanding the proposed provisions against the use of medical titles. These two Bills also agree in providing that prosecutions for offences under the section relating to unregistered persons shall not be instituted by private persons except with the consent of the General Medical Council, but they may be instituted either by the General Medical Council, by a Branch Medical Council, or by a medical authority if it be thought fit by such Council or authority.

PHARMACY IN VICTORIA.

THE Pharmacy Board of Victoria appointed by the Governor in Council, in pursuance of the Pharmacy Act, 1876, having arrived at the termination of its term of office, has presented a report of its proceedings during that period for the information of the Colonial Government and of the registered pharmaceutical chemists of Victoria. We are often asked for information as to the state of pharmaceutical affairs in the colony, and for this reason a brief *résumé* of the work done by the sister body may be acceptable to our readers.

Since the time when the Board was appointed it has continued to hold a meeting once a fortnight or once a month for the transaction of business. After the appointment of officers and the adoption of a common seal, certificate of registration, etc., examiners in chemistry, materia medica, practical pharmacy and Latin were appointed for the Preliminary and Modified examinations, one of these being Mr. WILLIAM JOHNSON, who was a student at the School of Pharmacy in Bloomsbury Square in 1845, when the laboratory was first opened.

While holding office the Board has held seven Preliminary examinations, at which thirty-six apprentices attended. Of these, thirty passed, and several of the number were above the educational standard demanded. Eleven Modified examinations have been held since the appointment of the Board. These two examinations embraced both written and oral questions in chemistry, materia medica and practical pharmacy, together with the reading of Latin prescriptions, sufficient to test thoroughly the candidates' knowledge of the art of dispensing and of the quality of drugs and chemicals. It is stated that since the commencement of the examinations a marked improvement in the candidates has been observed, and that in some instances considerable ability has been displayed.

Schools of Pharmacy have been established in Victoria, at Ballarat and Sandhurst, in connection with the schools of mines at those places, and it is reported that satisfactory progress is being made by the pupils attending. Up to the present time, however, nothing has been done towards carrying out the suggestion of the Pharmacy Board that lectures and examinations for pharmaceutical students should be established in connection with the University of Melbourne. The number of students already registered for the course of study required for the Major examination is, however, increasing so far that measures will have to be taken for establishing a School of Pharmacy in Melbourne if the Council of the University continues to neglect the subject.

The Pharmaceutical Register has been published annually as directed in the Act, and during the three years there were registered in all six hundred and twenty-seven pharmaceutical chemists and forty-seven apprentices. There have been eight convictions for carrying on business without being registered. The gross receipts during the three years have amounted to £1623 3*s.* 6*d.*, and the expenditure to £1032 17*s.* 6*d.*

The Board refers with pleasure to the satisfactory working of the Act, and expresses the opinion that if it continues to be administered with care and diligence the pharmaceutical chemists of Victoria will be found equal to any in those countries where pharmacy has been fostered for many years under legislative enactments.

ALKALI ACTS AMENDMENT.

A Bill to amend the Alkali Acts, 1863 and 1874, and to provide for the more effectual condensation of noxious and offensive gases in alkali and other works, has been prepared and brought into the House of Commons by the President of the Local Government Board and the Home Secretary. The Alkali Act, 1874, provided that the "best practicable means" should be used in every alkali work to prevent the discharge into the atmosphere of noxious gases under the Act. The present Bill proposes to fix a maximum, and provides that the acid gases evolved in the process of manufacturing sulphuric acid or sulphates in such works shall be so condensed that the total amount of acid gas in each cubic foot of air, smoke or gas escaping into the chimney shall not exceed what is equivalent to four grains of sulphuric anhydride. Sulphuric acid, nitric acid, chemical manure, sulphate and muriate of ammonia, gas liquor and coke works are proposed to be placed under similar restrictions as to sulphur gases, whilst the provision as to using the best practicable means for their condensation is extended to other noxious gases evolved in such works. The Bill also extends the scope of the Alkali Acts to cement, copper, nickel, spelter, lead ore and galvanizing and tinplate works, glass works where sulphate of soda or common salt is used, salt glazing potteries, tar dye and distillery works, and generally to any other works where processes are conducted giving off sulphur, nitrogen or chlorine acids, provision being made that the Local Government Board may from time to time limit by order the amount or proportion of any specified noxious or offensive gas which is to be permitted to escape from any such works. There is also a provision against the deposit of alkali waste where any liquid containing acid may come into contact with it or the drainage from it.

PRICE LIST FOR MANCHESTER AND DISTRICT.

We have received a copy of a new edition of the List of Retail Prices recommended for adoption by the Council of the Manchester Chemists and Druggists' Association. The nearest practicable approach to uniformity in the charges made by chemists and druggists is very desirable, and it is satisfactory to find that the effort of the Manchester Association to secure this uniformity in its district has met with the acceptance indicated by the issue of a third edition. The new "List" contains several additions; but it is compiled on the same lines as the previous editions. It is published by Mr. Silverlock, from whom copies may be obtained, or from Mr. H. Woolley or Mr. F. B. Benger, the Secretaries to the Association.

THE ANNUAL DINNER.

On Wednesday next, at 12 o'clock, a meeting will be held at 17, Bloomsbury Square, to appoint a committee to make the necessary arrangements for the usual Dinner of the Members of the Pharmaceutical Society and their friends, in connection with the Annual Meeting of the Society in May.

THE TRADE IN CHEMICALS.

The trade in chemicals having been referred to by a high authority as an index to the general prosperity of the country it is interesting to find that the latest returns issued by the Board of Trade show that it has been marked by increased activity this year as compared with last. From these returns we learn that the value of the exports of "alkali" from Great Britain and Ireland during the first two months of the present year amounted to £839,355, and that of the "chemical products and preparations" to £331,094. This is an excess of £45,120 on the former and £75,204 on the latter item for the corresponding months of last year. During January and February also the value of "Peruvian" bark imported amounted to £125,136, against £115,788 in 1879, and the value of the exported bark was £134,145.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next meeting of the above will be held at 32a, George Street, on Wednesday evening next, March 17, when a paper will be read by Mr. S. Hardwick, on "Assimilation in Plants."

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The fourth meeting of the session was held in the rooms of the Society, 119A, George Street, Edinburgh, on the evening of Thursday, February 26. Mr. J. B. Stephenson in the chair. The minutes of the previous meeting were read and confirmed.

The Honorary Secretary announced the following contributions to the library:—The *Canadian Pharmaceutical Journal* for February, from the Ontario College of Pharmacy: the *Pharmacist and Chemist* for February, from the Chicago College of Pharmacy; the *Journal of the Chemical Society*, for January, from Mr. Mackay.

A number of the North American drugs mentioned at the last meeting were exhibited.

A lecture on "What is Matter?" illustrated by experiments, was delivered by Cargill G. Knott, Sc.D. Edin., assistant to the Professor of Natural Philosophy, Edinburgh University. It is intended to publish Dr. Knott's paper in a future number.

Dr. Knott was most successful in his experiments, and on concluding, on the motion of Mr. H. C. Baildon, seconded by Mr. J. R. Young, a hearty vote of thanks was accorded to him for his interesting communication.

Examinations in London.

Provincial Transactions.

ABERDEEN CHEMISTS AND DRUGGISTS' ANNUAL CONVERSAZIONE.

The fourth annual conversazione of the Aberdeen Society of Chemists and Druggists took place on Wednesday, February, 18, in the Music Hall. There were about two hundred present. Mr. William Giles was in the chair, and was well supported. The proceedings commenced with a concert in the Square Room, which was taken part in by a number of ladies and gentlemen, and the various readings, recitations, songs, etc., were well rendered and appreciatively received.

In a short introductory address which he delivered, the Chairman said—"Before proceeding to the amusement of the evening, I have pleasure in congratulating you upon the success with which our social meetings have been attended hitherto and upon the brilliancy of this assemblage. Our annual conversazione has now attained a high reputation. Such meetings as the present, which lead us away from the cares and anxieties of business are, when properly directed, most enjoyable, and are well calculated to promote social intercourse and the interchange of those friendly relations which happily exist throughout the trade, and which are very essential amongst a class whose interests are so closely bound together. When I see the variety as well as the excellence of our programme, I think it would be out of place for me to occupy your time with anything I could say in the shape of a speech. On occasions such as these, speeches have to give place to the more cheerful occupations of music and song, while they, in their turn, have to give place to dance. At the same time, I ask your indulgence whilst I make a few remarks with regard to the present position of the society. The question how best to provide sufficient means of education for the assistants and apprentices to enable them to pass the examinations of the Pharmaceutical Society has from time to time been under the earnest consideration of this society. As you are aware, those presenting themselves for examination require a knowledge of various subjects in addition to that which is usually acquired at the dispensing counter. In order to supply this knowledge, and at the request of the assistants and apprentices themselves, the classes for instruction in chemistry, materia medica, and pharmacy have been resumed, and are again being gratuitously conducted by Messrs. Gordon and Strachan. The lectures on these subjects are attended with a greater measure of success this session than last, in so far as number of pupils and regularity of attendance are concerned. This is particularly encouraging from the fact that it shows that those for whose benefit the classes are intended are becoming aware of the importance and the advantage of the excellent quality of instruction obtainable, together with a better appreciation of the valuable services of the teachers. Specimens are being collected to form a museum for guiding and assisting the pupils in their studies, and for such of them as may be preparing for the Minor examination this part is of the greatest importance. The great difficulty, however, in connection with the successful conduct and arrangement of these is the want of adequate accommodation, and to remedy this the society are looking out for rooms to lease for themselves where the library could be kept, the classes meet, a museum be formed, and the whole business of the society transacted. The accomplishment of the whole projected scheme at once would, I believe, incur a larger expenditure than the society's exchequer is in the meantime able to meet. But as the benefits to be derived from it are common to all of us in town, I trust the whole of the masters will interest themselves in this matter, and should they do so, I venture to predict that there is a sufficient amount of energy amongst us to overcome any obstacle of that kind, so that we would soon be in a position to proceed with the whole scheme, and to establish a properly equipped laboratory and museum in such a way as will reflect credit upon the society and prove a lasting benefit to the assistants and apprentices."

At the close of the entertainment, a cordial vote of thanks was accorded to the chairman, on the motion of Mr. Ritchie; and, on the motion of Mr. Sinclair, a like compliment was awarded to the ladies and gentlemen who had contributed to their amusement.

Dancing was commenced shortly after ten o'clock in the ball-room, which was splendidly decorated, excellent music being supplied; and supper was served shortly before midnight. During the evening a very enjoyable dramatic performance was given in the West Front Room.

GLASGOW LITERARY AND PHARMACEUTICAL ASSOCIATION.

The first annual festival of the Glasgow Pharmaceutical and Literary Association took place in the Blythswood Academy, on the evening of Thursday, February 19, when there was a large attendance of members and friends. The President, Mr. James Shaw, occupied the chair, and was supported on the platform by Mr. John Arnot, Mr. A. C. Boothman, Mr. A. B. Chalmers, and others. The chairman in the course of a short address quoted statistics showing the marked progress of the Association since its formation towards the close of 1879. The evening's enjoyment was greatly enhanced by the admirable rendering of glees, songs and readings, by ladies and gentlemen who had kindly volunteered their services. An assembly followed.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fifth meeting of the session was held in Anderson's College, 204, George Street, on Wednesday, March 3, Mr. A. Kinninmont, F.C.S., President, in the chair.

After the minutes of the previous meeting had been read and adopted, the President asked Mr. J. C. Hunter to deliver his short discourse on "Infusorial Animalcules."

Mr. Hunter began his remarks by giving a short description of the invention of the microscope and its importance in the study of those minute organisms, also referring to the first of the now numerous band of searchers in the till then unseen world, viz., Lewenhoeck, and his labours and discoveries with his own microscope of small power. Passing on from that time through the investigations of Ehrenberg, Buffon and others, he touched also upon the two theories of the early part of this century, viz., Biogenesis and Abiogenesis. Mr. Hunter then referred to the invaluable researches of Pasteur and Pouchet in France, and lastly, the experiments of Bastian, Tyndall and Dallinger were briefly described, and the conclusions of the last two experimenters were stated.

After remarks from various members, the President called for a cordial vote of thanks to Mr. Hunter for his well delivered remarks on the "Infusoria." This having been given the meeting closed.

LEEDS CHEMISTS' ASSOCIATION.

The sixth meeting of the session was held in the library of the Chemists' Association, on Wednesday evening, February 18, the President, Mr. Councillor Stead, in the chair, when Mr. E. O. Brown gave a lecture on "Aerated Waters," after which an interesting discussion followed.

A cordial vote of thanks was accorded the lecturer at the close.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The half-yearly meeting of the above Association was held at the rooms, 4, Halford Street, on Tuesday, Feb. 3, 1880. The President, Mr. J. J. Edwards, in the chair. The President having opened the meeting with some appropriate remarks, called upon the Secretary to read the report for the twenty-second session.

The report stated that during the past session an improvement had taken place in the affairs of the Association, and a hope was expressed that, with a determination on the part of the executive to adopt the best mode of carrying on the work of the Association to meet the requirements of pharmaceutical students, together with the active co-operation of the members, the coming session may be one of continued progress and in every respect a thorough success. The laboratory has been rearranged, and by the purchase of apparatus and chemicals, put into working order, so that ordinary chemical experiments may readily be performed. The chemistry prize, given by Mr. Thirlby, has been gained by Mr. F. W. Lewitt.

The adoption of the report having been proposed and seconded, it was carried unanimously.

After the Treasurer's report, showing a balance in hand of £4 10*s*. 10*d*., had been received and adopted, the President called upon anyone who might have any suggestion to make, relative to the affairs of the Association, to address the meeting.

Mr. Brampton then rose, and stated that it has been thought by some of the members, that the time had now arrived when it was desirable to make some change in the mode of carrying on the work of the Association, the principal arguments in favour of a change being—(1st) the altered state of affairs in pharmaceutical education since the Association was originated, and the necessity for meeting these changes in a satisfactory manner; (2nd) the difficulty experienced in conducting the classes so as to benefit to the full extent all the members of the Association; (3rd) the inability of the committee to get suitable teachers; and (4th) the unwillingness of the members to attend regularly two classes a week, besides engaging in the necessary private study. Under these circumstances it was thought advisable that some effort should be made to adapt the machinery of the Association to meet the wants of the members as far as possible. The most feasible plan that presented itself was to discontinue the classes, and in their stead to have papers on subjects of pharmaceutical interest read by members or other gentlemen, on one evening in each week; the rooms also to be open on two other nights in each week, and curators appointed from time to time, who would take charge of the rooms on those occasions and assist in every possible way those members who come to perform chemical experiments, or for private study.

After debating this proposition, it was ultimately resolved that the plan proposed by Mr. Brampton should be tried as an experiment during the forthcoming session, and that Wednesday nights should be reserved for lectures, papers, etc., it being left to the committee to arrange for two other nights on which the rooms should be open for private study.

The meeting then proceeded to elect a committee for the ensuing session, Messrs. Bott and Watchorn being scrutineers. As the result of a ballot, Messrs. Brampton, Burford, W. B. Clark, Edwards, Lewitt, Masters and Thirlby were appointed to serve as a committee. This proceeding brought the half-yearly meeting to a close.

LIVERPOOL CHEMISTS' ASSOCIATION.

The tenth general meeting of the thirty-first session was held at the Royal Institution, on Thursday evening February 26, the President, Dr. Charles Symes, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations announced:—The current numbers of the *Pharmaceutical Journal*, from the Society; and the *Canadian Pharmaceutical Journal*, from the Editor.

Mr. A. Carson was elected an associate.

Mr. Shaw called attention to the alleged want of uniformity in carrying out the Weights and Measures Act in different parts of the country, some inspectors not recognizing any weights except those bearing their own local stamp. He stated that the Council of the Pharmaceutical Society were in correspondence with Mr. Farrer, of the Board of Trade, as to the stamping of weights, and the verifying and marking of glass measures, and he (Mr. Shaw) trusted that the result would be satisfactory. The inspector of weights and measures in Liverpool had not yet completed his arrangements, but expected to be able shortly to do so.

Mr. T. F. Abraham said that in compliance with a suggestion in the *Pharmaceutical Journal*, and a circular from the Pharmaceutical Society, he, as local secretary, had had some interviews with the chief inspector of weights and measures. That gentleman said that he was only in possession of a small portion of the apparatus required to carry out the provisions of the new Act, and had not received instructions from the corporation to take action under the Act; but that, assuming that in due course such orders would be issued, he had made application for the necessary standards, etc. He had had only one application for the testing of apothecaries' measures, and that was from a wholesale firm. He (Mr. Abraham) would make known through the *Pharmaceutical Journal* when anything further transpired.

The President said he was not aware of any action having been taken in Liverpool, and he believed very little had been taken anywhere else. He thought it unfortunate that standards had been provided, as it was optional with local authorities to adopt them. There had been, in his opinion, far too much agitation on this bit of legislation, and he trusted it would not be continued, otherwise the inspectors would feel that they must do something, and this would lead to undue action on their part, and persecution of the trade in consequence. The President then called attention to a "Simple Perfected Test for Diabetic Sugar," published by Dr. L. S. Oppenheim, in the *Louisville Medical News*. It is a modified form of the ordinary copper test. After pointing out the gradual change which is always going on in Fehling's and other solutions of this kind, Dr. Oppenheim suggests the following:—

Pure sulphate of copper . . .	50 grains.
Pure glycerine	1 fluid ounce.

1 drachm (= $6\frac{1}{4}$ grains of the sulphate) will reduce 1 grain of grape sugar, in the presence of caustic alkali. Double its volume of liq. potassæ is added to the measured quantity of the solution at the time of using. The use of glycerine, the President said, is by no means new, as it is mentioned in Sutton's 'Volumetric Analysis,' published in 1871, page 187, and is ascribed to Löwe, but here it is used instead of the alkaline tartrate. Some such simple means of preserving the copper solution, to avoid the necessity of standardizing each time it is used, he (the President) considered a desideratum.

After some further observations by Messrs. Davies and Watt, the President called upon Mr. Astrup Cariss to read the paper for the evening, entitled "Chemistry in Relation to Sanitation."

The paper gave rise to a lengthened and interesting discussion, in which the President, Messrs. T. F. Abraham, Conroy, Davies, Kehlstadt, Shaw and Watt took part.

On the motion of Mr. Shaw, seconded by Mr. Davies, a hearty vote of thanks was accorded Mr. Cariss for his paper, and the meeting closed.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of this Association was held at Britannia Chambers, Pelham Street, on Tuesday evening, February 24. There was a good attendance of members and associates, and the chair was occupied by the President Mr. R. Fitzhugh, F.C.S.

The Honorary Secretary. Mr. R. Jackson read the minutes of the last meeting, which were confirmed, and then announced that he had received the following donations to the library:—'The Year-Book of Pharmacy,' 'The Calendar of the Pharmaceutical Society,' and 'The *Pharmaceutical Journal*' regularly since last meeting, and a vote of thanks was awarded to the donors.

Two gentlemen were elected associates.

The President then read a letter from the Sub-Committee appointed by the Council to examine the essays in the competition for prizes offered by Mr. J. H. Atherton, F.C.S., and Mr. W. Widdowson; the first prize being awarded to Mr. E. H. Judge and the second to Mr. W. Gill.

Mr. F. H. Spenser then delivered a most interesting and instructive lecture on "Sound," of which the following is a syllabus:—

Sound a physical phenomenon.—Cause of sound.—How the air is affected.—Sound waves.—Law of inverse squares.—Sound not transmitted through a vacuum.—Intensity.—Velocity.—How determined.—Reflection.—Echoes.—Whispering galleries.—Influence of tubes.—Destruction of waves.—Speaking trumpet.—Ear trumpet.—Stethoscope.—Refraction.—Difference between a musical sound and a noise.—Resonance.—Pitch.—Intensity and quality of musical sounds.—Interference.—Beats.—Musical instruments.

The lecture was illustrated by several experiments and was listened to very attentively.

At the close Mr. W. H. Parker proposed a hearty vote of thanks to the lecturer, which was seconded by the chairman and carried unanimously.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Executive Committee was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on Friday, February 27, 1880, at 1 p.m., Mr. Thomas Barclay (Birmingham), President, in the chair; Mr. Robert Hampson (London), Vice-President.

Present — Messrs. Andrews (London), Bell (Hull), Churchill (Birmingham), Cross (Shrewsbury), Holdsworth (Birmingham), Jervis (Sheffield), Kerr (Dundee), Mackenzie (Edinburgh), Shaw (Liverpool), Walker (Coventry), and the Solicitor of the Association.

The minutes of the previous meeting were read and approved.

Reports of Sub-Committees.

The report of the Law and Parliamentary Committee was then read. It stated that the question of endeavouring to obtain the exemption of all registered chemists and druggists from jury service had been fully discussed by the Committee, and although it was admitted that it was a very sore point with the trade, and one which should be dealt with at the earliest opportunity, yet the Solicitor, having advised that no effective steps could be taken until an amended Pharmacy Act or Jury Bill was before the Legislature, the Committee considered it would be mere waste of labour and money to move in the matter at that time. That three cases in which members of the Association had been sued under the Sale of Food and Drugs Act, had been successfully defended by the Association, the summons in each case being dismissed by the magistrates; costs to the amount of three guineas being allowed in one of these cases. That a member had been defended in a prosecution brought against him by the Excise authorities, and another member in two summonses taken out against him under the Weights and Measures Act, and that a mitigated penalty only was inflicted in these cases, and that full reports of all these cases had been forwarded to the trade Journals for publication. That ten cases under the 17th section of the Pharmacy Act had been undertaken by the Secretary for the sale of poison improperly labelled by unregistered persons, a fine having been inflicted in each case.

It was moved by Mr. Bell, seconded by Mr. Jarvis, and unanimously resolved:—"That the report of the Law and Parliamentary Committee be received and entered on the minutes."

After some little discussion as to the advisability of defending members against whom action was taken under the Weights and Measures Act or the Inland Revenue Acts, it was moved by Mr. Bell, seconded by Mr. Mackenzie, and unanimously resolved:—"That it be a suggestion from the Executive Committee to the Law and Parliamentary Committee, that they consider the desirability of appointing a Sub-Committee to deal with urgent cases."

It was moved by the Vice-President, seconded by Mr. Andrews, and unanimously resolved:—"That the report of the Law and Parliamentary Committee be adopted."

A special report from the Law and Parliamentary Committee on the information they had obtained as to the best means of bringing about modifications in the Pharmacy Act, 1868, to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists, was then read. It detailed the means employed by the Committee to collect desired information; it stated that numbers of circulars and written communications had been forwarded from the office to influential members of the trade, residing in various parts of the country, asking for information and suggestions on the sale of patent medicines containing scheduled poisons, with a view to aid the Executive in bringing about an amendment in that portion of the 16th section of the Pharmacy Act bearing on patent medicines. The replies to these communications in a condensed form were included in the report. That private conferences of the trade had been held by the Secretary at Hull, Bristol and Sheffield, all of which were well attended, and, at each of which, a resolution was carried to the effect that it was desirable that the Pharmacy Act, 1868, should be so amended as to restrict the sale of scheduled poisons under cover of the patent medicine stamp to chemists and druggists, and that the Association be requested to approach the Pharmaceutical Society with a view to bring about that object.

It was moved by Mr. Holdsworth, seconded by Mr. Andrews, and unanimously resolved:—"That the special report of the Law and Parliamentary Committee on the information they have obtained, as to the best means of bringing about modifications in the Pharmacy Act, 1868, to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists, be received, adopted, and entered on the minutes."

Mr. Hampson moved the following resolution:—"That this Executive respectfully urges the Council of the Pharmaceutical Society of Great Britain to take steps to amend the provisions of the Pharmacy Act, 1868, in order to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists." He thought that such a resolution, if passed, would show the Pharmaceutical Council that the trade was active in the matter, and would strengthen the hands of that Council, and he was quite sure that it would meet with their proper support and consideration. He was extremely anxious that the two societies should work in harmony, as before long there was little doubt that it would be necessary to approach Parliament, for the purpose of obtaining an amended Pharmacy Act.

Mr. Jervis said he had great pleasure in seconding the resolution.

Mr. Mackenzie said he thought no drugs should be sold except by registered chemists and druggists, and he would move as an amendment, that the words "and such other articles as the Pharmaceutical Council may think desirable," should be inserted in the body of Mr. Hampson's resolution following the word "poison."

This amendment not being seconded, the original resolution was put to the meeting, and carried *nem. con.*

The report of the Finance Committee was then read. It stated that the income of the Association derived from subscriptions and donations, from the last audit up to that date, amounted to £890 14*s.* 6*d.*, and the expenditure during the same period had been £887 12*s.* 3*d.*; 137 chemists had joined the Association since the last audit, and there had been 95 erasures from the register during the same period.

It was moved by Mr. Churchill, seconded by Mr. Cross, and unanimously resolved:—"That the report of the Finance Committee be received, adopted, and entered on the minutes."

Resignation of the Secretary.

The President said the next business on the agenda was to receive the resignation of the Secretary, Mr. Haydon having been appointed to the Secretaryship of the Birmingham Exchange and Chamber of Commerce. While congratulating Mr. Haydon upon the position he had just obtained, the Association would deeply feel the loss of his services. Mr. Haydon had been selected for this appointment out of 275 applicants from all parts of the country, and had been appointed by the unanimous vote of the joint committee, a circumstance which showed that the trust and confidence which the Executive had placed in him was well warranted. He (the President) had no doubt that in his new sphere, their Secretary would serve his new committee as successfully and faithfully as he had served the Executive of the Chemists and Druggists' Trade Association. The Committee were fortunate in that Mr. Haydon would not be leaving Birmingham, and would therefore be at hand to aid them with his advice. The Executive would, of course, accept Mr. Haydon's resignation and do their best to obtain a suitable successor.

After some very complimentary remarks from the members of the Committee as to the manner in which Mr. Haydon had performed his duties,

It was moved by Mr. Hampson, seconded by Mr. Andrews, and unanimously resolved:—"That this Committee expresses its great regret at losing the valuable services of Mr. Haydon, and empowers the Law and Parliamentary Committee to take all steps which they may deem necessary to obtain and to provisionally appoint a Secretary in the place of Mr. Haydon, and to make arrangements with Mr. Haydon for temporarily continuing his charge of the office."

The British Pharmacopœia.

Mr. Hampson said he wished to move the following resolution:—"That this Executive is of opinion that the Pharmaceutical Council, as representing pharmacy, should be legally empowered, in conjunction with the Medical Council, in framing and amending the future edition of the British Pharmacopœia." He had hesitated a considerable time before deciding to bring the resolution before the Executive, for the simple reason that he had endeavoured to pass a similar resolution before the Pharmaceutical Council and failed. It had occurred to him, however, that the Chemists and Druggists' Trade Association was a representative body, and ought to have some weight on such a subject, and he did not therefore feel in any way deterred by the course taken by the Pharmaceutical Council, or that he should be acting improperly or committing any "breach of privilege,"—that was the phrase now in use—in bringing forward the resolution, he regretted to say he was unable to get passed by the Pharmaceutical Council. He felt that a great mistake had been made by that Council in not accepting the resolution, inasmuch as the same expressed the views which generally prevailed on the subject. The Pharmaceutical Council ought to take the lead in pharmaceutical matters, and it ought to be above the average opinion of the country, but he regretted to see that it was much behind the general opinion of pharmacists. Several years since he had endeavoured to pass a similar resolution, and was equally unsuccessful. Now he thought it was for the Chemists and Druggists' Association, an Association consisting essentially of chemists and druggists and of pharmacists, to express an opinion on the subject. He considered it to be the interest and duty of the Executive to pass the resolution unanimously. It would strengthen the hands of the Pharmaceutical Council. Honestly speaking, he felt ashamed to bring the resolution forward before the Executive, believing it to be the duty of the Pharmaceutical Council to ask the Legislature for power to have an equal share in the preparation of the Pharmacopœia. In every other country such was done. In France they were about making a new codex, and, as a matter of course, the pharmacists took an equal position with medical men in framing that codex. By asking for a legal position with their medical friends, he did not feel that they were stepping out of their proper limits. He should say they lacked dignity were they not now to move in the matter. At the present time there were three or four Medical Bills before the House of Commons and he thought it would be a fitting time to ask some member of Parliament, whose name was on the Bills, to introduce a proviso giving them the power required. The question was one that had cost him a great deal of thought, and one that ought to receive the sanction of every pharmacist who respected his calling.

Mr. Mackenzie said he had great pleasure in seconding the resolution. He considered the compounders of medi cine had an equal interest with the prescribers in the preparation of the Pharmacopœia.

The resolution was then put to the meeting, and carried unanimously.

Medical Bills.

The Solicitor said there were three Bills before the House of Commons, the object of which was the amendment of the Medical Act of 1858; one was promoted by the Government, another was in the charge of Dr. Lush and other members, whilst the third was backed by Mr. Arthur Mills and other members. The Government Bill, if similar to that presented last session, would provide for the repeal, amongst others, of the penal section of the Apothecaries Act, 1815, and each of the other Bills contained a similar provision.

After some little discussion, it was moved by Mr. Shaw, seconded by Mr. Bell, and unanimously resolved:—"That the Law and Parliamentary Committee be directed to watch the proceedings of the Select Committee appointed by the House of Commons to consider the Medical Bills, and to take such action as they may deem necessary."

Annual General Meeting,

It was moved by Mr. Walker, seconded by Mr. Bell, and unanimously resolved:—"That the Fourth Annual General Meeting of the members of the Association be held in London, on the day preceding the Annual General Meeting of the Pharmaceutical Society."

Election of General Committee.

It was moved by Mr. Bell, seconded by Mr. Shaw, and unanimously resolved:—"That the second election of the General Committee be conducted on the same lines as before, and that the official auditors of the Association be engaged to superintend the same."

Several communications from the secretaries of local chemists' associations, and from members of the Association, were read, and instructions given to the Secretary as to the manner in which he should deal with the same.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on March 4. Mr. Warren De La Rue, President, in the chair. The list of officers as announced at the last meeting was read from the chair. The following certificates were read for the first time:—A. E. Black, C. H. Gimingham, W. Regester, W. Robinson, H. C. Stephens.

The President then called upon Professor Thorpe to deliver his lecture—

On the Relation between the Molecular Weights of Substances and their Specific Gravities when in the Liquid State.—The lecturer said that he proposed to give the substance of the results of some work with which he had been engaged for the last four or five years, it consisted of a critical and experimental examination of Kopp's laws relating to specific volume. Many attempts had been made to trace a relation between the specific gravity and molecular weight of a liquid, but no definite conclusions were arrived at until Kopp published his well known memoirs, the principal reason of failure being that the previous observers did not compare the liquids under comparable conditions. Kopp was the first observer who, by dividing the specific gravities of liquids, taken at the temperatures at which their vapour tensions are equal to the standard atmospheric pressure, *i.e.*, at their ordinary boiling points, into their molecular weights, obtained certain comparable values which are known as specific volumes. If the specific gravities are referred to water at 4° C., these values represent the number of c.c. occupied by the relative molecular weights of the liquids expressed in grams at their respective boiling points under normal pressure. Thus the specific volume of water is 18·8, *i.e.*, 18 grams water at 100° occupy 18·8 c.c. The numbers so obtained were first shown by Kopp to exhibit certain definite relations which may be briefly indicated as follows:—1. In many instances differences in specific volume are proportional to differences in corresponding chemical formulæ. Thus a difference of CH_2 in a homologous series corresponds to a difference of about 22 in the specific volume. 2. Isomeric and metameric liquids have, as a rule, the same specific volume, exceptions occuring in certain sulphur and oxygen compounds. 3. The substitution of an atom of carbon for two of hydrogen makes no alteration in the specific volume of members of certain groups of organic liquids. It would seem to follow from Kopp's observations that the specific volume of a liquid formed by the union of two other liquids is equal to the sum of the specific volumes of its components. Another conclusion which Kopp states with caution is that members of the same family of elements possess identical specific volumes. Thus the common value for Si, Ti and Sn seems to be about 35, for P, As and Sb about 27. On the basis of these conclusions Kopp was able to calculate certain fundamental values which are, as a rule, constant for each element. Thus carbon has always the value 11, hydrogen 5·5. Certain exceptions, however, occur with oxygen and sulphur. Thus the specific volume of water being 18·8 and of hydrogen 11, we get as specific volumes of O 7·8. In aldehyde, C_2H_4O, we have (C)22 + (H)22 = 44; its specific volume is 56·2; thus the value for oxygen is 56·2 − 44 = 12·2, and so on for other substances. It appears that when oxygen is united to an element by both its affinities its specific volume is 12·2, when attached by only one it is 7·8. Sulphur has similarly two values, 28·6 and 22·6. Thus the constitutions of such bodies as phosphoryl trichloride may be elucidated. If P is trivalent the constitution of this substance would be

$$\begin{array}{c} Cl \\ | \\ P-O-Cl \\ | \\ Cl \end{array}$$

If pentavalent—

$$\begin{array}{c} Cl \\ | \\ Cl-P=O \\ | \\ Cl \end{array}$$

From determinations of the specific volume of $POCl_3$ it seems that the phosphorus is trivalent. The specific volume of nitrogen also seems to be variable from Kopp's researches; it has a value in the amines of 2·3, in cyanogen and certain nitro-compounds of 17, and from recent researches of Ramsay its value seems to vary in different amines, and, moreover, has a distinct value in the pyridine series. Buff suggested, as the atomic value of an element is variable its specific volume might be a function of that value; the evidence adduced is not, however, conclusive. There is no known reason why O, S and N should alone possess variable specific volumes. Recently much interest has accrued to the question from the relations which have been shown to exist between the atomic weight and the chemical and physical characters of an element; probably the specific volume is a periodic function of the atomic weight. On reviewing the question the following problems seemed to the author well worthy of solution. 1. Has an element in combination an invariable specific volume? or may not the volume be modified by the number of the atoms of that element in the molecule? Is it quite independent of the general complexity of the molecule, or may not the specific volume of the molecule be a function of its weight? 2. Do the various members of a given family of elements possess identical specific volumes, or may not the volume be a function of the atomic weight? 3. Would a re-examination of the cases of the variable atomic values show that the specific volume of an element is a function of that value, as Buff supposes? 4. The hypotheses of Mendelejeff and Meyer indicate the need for additional and more exact determinations of the values for the specific volumes of the element. 5. To multiply examples of the aid afforded by a knowledge of the specific volume of a compound in elucidating its constitution. The author then drew up a scheme of work involving the determination of the specific volumes of fifty-two liquids, inorganic and organic, those liquids being preferred which boiled below 200°, and which could without great difficulty be obtained pure and in large quantity. The results of the observations determine the specific volumes of the following seventeen elements:—

H; F,Cl,Br,I; O, S,Cr,N,P,V,As,Sb; C,Si,Ti,Sn.

The author then gave a short account of the methods used to prepare some of the liquids, and the care taken to ensure and ascertain their purity. Great reliance was placed on vapour density determinations; a modified form of Hofmann's apparatus was employed. The vapour required to heat the liquids was introduced from below and the vapour density tube has no etched scale, to prevent risk of cracking, only one mark being made on the tube, readings being taken by a separate moveable brass scale divided into millimetres. The whole mass of mercury within the tube is uniformly heated to a known temperature. 300 c.c. of mercury and 150 c.c. of liquid (for the boiler) are required to work the apparatus. To determine the specific volumes the author has adopted the principle used by Kopp:—1. To determine the specific gravity of the liquid at some convenient temperature. 2. To ascertain its boiling point with the utmost exactitude. 3. To determine with great care its rate of expansion, say, between 0° and the boiling point. In this way, at all events, a number of accurate and important physical data would be put on record, even if the main object of the investigation was not attained. The author then described the apparatus and methods used in these three determinations. Two sets of thermometers were used: one of three by Casella, from −9 to 160°, graduated into tenths, each tenth being about 1 mm.; the second set was by Geissler, and also consisted of three, with a range from −14 to 170°, graduated into tenths, each degree being about 6 mm. These were carefully compared with Kew standards and calibrated. Careful determinations of the fixed points of the thermometers were made, and their variations plotted in curves. The dilatometers were constructed of flint glass; the stem of each instrument was about 50 centimetres long, graduated into millimetres; the bulbs contained 2 to 4 c.c. Each bulb was heated and cooled several hundred times before being used; no important change of capacity was observed during the determinations. The dilatometers were calibrated by the introduction or removal of known weights of mercury. Air was removed by exhaustion with a Sprengel pump, and subsequent introduction of pure warm mercury by a capillary tube which reached to the bulb. Nine dilatometers were used. As the thermometers used were long, great care was taken in obtaining a correct expression for the correction due to the portion of the stem not surrounded by vapour. In the formula $\delta\ (t-t')n$, the author has taken for δ (apparent expansion of glass for 1°), a mean value of 0·000163, and gives a table of corrections calculated on this value. The specific gravity bottles used held 4 to 20 c.c., and were fitted with ground glass stoppers. All weighings were made by the method of vibrations, and all reduced to a vacuum. The author then described the arrangement adopted for filling the dilatometers with the liquids, originally devised specially for liquids altered by exposure to air, but found so convenient that it was adopted in all cases. The method used in determining the expansion was then given. Two forms of apparatus were employed, one for temperatures below 65°, filled with water, heated by steam, the other filled with oil, heated by a lamp; the capacity of each bath was over 20 litres. Up to 25° the temperature could be obtained absolutely constant; but above, two series of readings were taken, one with the temperature rising very slowly, the other with the temperature falling. In reducing the observations, the author largely availed himself of the arithmometer of Thomas (de Colmar), without which the labour of the calculations would have been insuperable. Some experiments proved that Matthiessen's objection to the dilatometrical method, viz., that it gave uniformly low rates of expansion, was unfounded. The author arrived at the following conclusions:—1. That a difference of CH_2 in a homologous series does correspond to a difference of about 22 in the specific volume. That carbon has a constant specific volume of 11 and hydrogen of 5·5; there is no valid reason for accepting Buff's hypothesis that the specific volume is a function of the atomic value of an element. As far as sulphur and oxygen are concerned, the author has obtained results identical with those of Kopp. The inference of Kopp that members of the same family have the same specific volume does not appear to be well founded. Lastly, it seems that the specific volume is a periodic function of the atomic weight.

The President then proposed a vote of thanks to Professor Thorpe for his lecture, and the able way in which he had explained the results of his elaborate investigations.

Dr. Wright asked if any experiments had been made with chloric or perchloric acid, in order to determine the quantivalence of chlorine in these bodies.

Dr. Armstrong commented on the difficulties in accepting the view of the triad nature of P in $POCl_3$, when the reactions of the body were taken into consideration, especially as Professor Thorpe had himself prepared a pentafluoride.

Dr. Japp pointed out the danger of using the specific volume as an evidence of the atomicity of an element too freely; thus, for instance, according to the evidence derived from a determination of specific volume, the two atoms of S in CS_2 had different values, one 28·6, the other 22·6.

Dr. Gladstone asked if Professor Thorpe had compared the specific volume in any way with the refractive energy.

Professor Thorpe, in reply, said that he had no intention of experimenting with chloric or perchloric acid until he had finished all the observations he wished to make with his apparatus. He admitted that there were difficulties in assuming that phosphorus was a triad in $POCl_3$, but thought that there was evidence to support that view; also, that there was some physical evidence that the two atoms of sulphur were not identical in carbon disulphide. He had not compared the specific volume with the refractive index.

The thanks of the meeting were given to Professor Thorpe for his lecture.

The apparatus for determining the vapour density and the arithmometer were exhibited.

The Society then adjourned to March 18, when Professor Tidy will read a paper on "River Water."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, February 26, Mr. R. H. Parker, Vice-President, in the chair. A paper was read by Mr. E. A. Reilly on "Butter Analysis."

After a historical sketch, the author described the old methods of butter analysis and then described the process of Angell and Hehner for the estimation of foreign fats in butter. The following is a brief abstract of the paper:—

All natural fats are mixtures of different triglycerides, and, with the exception of butter, the group of animal fats consists of tri-stearin, tri-palmitin and tri-olein. The equivalent of these glycerides and of the acids they furnish on decomposition being very high and but little differing from each other, theory predicted that they would yield, on saponification and decomposition of the soap with dilute mineral acid, nearly equal amounts of fatty acid.

This, then, was the foundation stone, so to speak, of Messrs. Angell and Hehner's investigations.

The author finds that the following is the best way to work the process accurately :—

The butter fat has first of all to be obtained in a state fit for analysis by removing the curd, salt and water respectively. About 3 grams of the fat are to be saponified in a small porcelain basin with caustic potash and about 30 c.c. alcohol (free from resin). After complete saponification dilute and decompose the butter soap with dilute hydrochloric acid. Collect the fatty acids (after fusing them in the liquid) on a weighed filter and thoroughly wash with boiling distilled water. Drain and dry them in a small weighed beaker. The fatty acids of all animal fats (except butter) being on an average 95·5, and butter fat being 87·5, it will at once be apparent how a calculation has to be made in order to arrive at the proportion of foreign fat in a sample of butter.

This paper was discussed at length by Dr. Senier, Messrs. Hutchinson, Parker, Branson, Jewson and the Secretary.

A report on Organic Chemistry was made by the Secretary, which included the following note on—

The Conversion of the Acids of the Fatty Series into the Acids of the Lactic Series.

BY WYNDHAM R. DUNSTAN, F.C.S.,

Assistant Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

The acids of the fatty or acetic series and the acids of the lactic series are both obtainable from alcohols by the substitution of one atom of oxygen for two atoms of hydrogen. The acids of the fatty series are formed by the oxidation of the alcohols of the C_nH_{2n+1} series. Methyl alcohol is the first member of this series, and by substituting one atom of oxygen for two of hydrogen we obtain the first member of the fatty series of acids—formic acid.

$$\underset{\text{Methyl alcohol.}}{\left\{\begin{matrix} H \\ CH_2OH \end{matrix}\right.} \qquad \underset{\text{Formic acid.}}{\left\{\begin{matrix} H \\ COOH \end{matrix}\right.}$$

Ths other members of this series are formed from the alcohols in a similar manner.

$$\text{Ethyl alcohol} \left\{\begin{matrix} CH_3 \\ CH_2OH \end{matrix}\right. \text{yielding acetic acid} \left\{\begin{matrix} CH_3 \\ COOH \end{matrix}\right.$$

$$\text{Propyl alcohol} \left\{\begin{matrix} C_2H_5 \\ CH_2OH \end{matrix}\right. \text{,, propionic acid} \left\{\begin{matrix} C_2H_5 \\ COOH \end{matrix}\right.$$

$$\text{Butyl alcohol} \left\{\begin{matrix} C_3H_7 \\ CH_2OH \end{matrix}\right. \text{,, butyric acid} \left\{\begin{matrix} C_3H_7 \\ COOH \end{matrix}\right.$$

and so on. In considering the relations of these acids to each other, the first member, formic acid, may be taken as a type, the other acids being formed by the substitution of the monad radicals of the C_nH_{2n+1} series for the hydrogen in the non-carboxylic portion of this acid.

The acids of the lactic series are formed by the oxidation of the alcohols of the C_nH_{2n} series, or glycols, one atom of oxygen being substituted for two atoms of hydrogen. The first member of this series of alcohols is not known, and therefore the first member of the lactic series of acids cannot be obtained by the usual method. If it existed its formula would be $CH_2(OH)_2$ and the acid obtainable from it would have the same empirical formula as carbonic acid.

$$\underset{\text{Methylene glycol.}}{\left\{\begin{matrix} OH \\ CH_2OH \end{matrix}\right.} \qquad \underset{\text{Carbonic acid.}}{\left\{\begin{matrix} OH \\ COOH. \end{matrix}\right.}$$

The other acids are formed by oxidation from the following known glycols:—

$$\begin{matrix}\text{Ethylene} \\ \text{Glycol.}\end{matrix} \left\{\begin{matrix} CH_2OH \\ CH_2OH \end{matrix}\right. \text{yielding glycollic acid} \left\{\begin{matrix} CH_2OH \\ COOH \end{matrix}\right.$$

$$\begin{matrix}\text{Propylene} \\ \text{Glycol.}\end{matrix} \left\{\begin{matrix} CH_3CHOH \\ CH_2OH \end{matrix}\right. \text{yielding lactic acid} \left\{\begin{matrix} CH_3CHOH \\ COOH \end{matrix}\right.$$

$$\begin{matrix}\text{Butylene} \\ \text{Glycol.}\end{matrix} \left\{\begin{matrix} C_2H_5CHOH \\ CH_2OH \end{matrix}\right. \text{yielded oxybutyric acid} \left\{\begin{matrix} C_2H_5CHOH \\ COOH \end{matrix}\right.$$

We have now to consider the relations of the acids of the fatty series to the acids of the lactic series. The latter acids can be obtained from the former by the replacement of one atom of hydrogen in the non-carboxylic portion of the acid by hydroxyl; thus formic acid, the first member of the fatty series, would yield an acid having the same formula as carbonic acid.

$$\underset{\text{Formic acid.}}{\left\{\begin{matrix} H \\ COOH \end{matrix}\right.} \qquad \underset{\text{Carbonic acid.}}{\left\{\begin{matrix} OH \\ COOH \end{matrix}\right.}$$

$$\underset{\text{Acetic acid.}}{\left\{\begin{matrix} CH_3 \\ COOH \end{matrix}\right.} \qquad \underset{\text{Glycollic acid.}}{\left\{\begin{matrix} CH_2OH \\ COOH \end{matrix}\right.}$$

$$\underset{\text{Propionic acid.}}{\left\{\begin{matrix} C_2H_5 \\ COOH \end{matrix}\right.} \qquad \underset{\text{Lactic acid.}}{\left\{\begin{matrix} C_2H_4OH \\ COOH \end{matrix}\right.}$$

$$\underset{\text{Butyric acid.}}{\left\{\begin{matrix} C_3H_7 \\ COOH \end{matrix}\right.} \qquad \underset{\text{Oxybutyric acid.}}{\left\{\begin{matrix} C_3H_6OH \\ COOH \end{matrix}\right.}$$

The usual method of effecting this conversion is first to treat the fatty acid with chlorine, forming a chloro-fatty acid and then to decompose this with potassium hydrate. On treating formic acid, however, with chlorine we get the molecular structure broken down and thus by this method obtain no experimental clue as to its representative in the lactic series. This is not the case with the higher homologue, acetic acid; by treating this with chlorine we obtain monochloracetic acid, thus—

$$\left\{\begin{matrix} CH_3 \\ COOH \end{matrix}\right. + Cl_2 = \left\{\begin{matrix} CH_2Cl \\ COOH \end{matrix}\right. + HCl$$

Treating this with potassium hydrate we obtain glycollic acid—

$$\left\{\begin{matrix} CH_2Cl \\ COOH \end{matrix}\right. + KOH = \left\{\begin{matrix} CH_2OH \\ COOH \end{matrix}\right. + KCl$$

When the other acids of the fatty series are treated in this manner we obtain the corresponding acids of the lactic series, proponic acid yielding lactic acid, butyric acid yielding oxybutyric acid, etc. It has long been known that many organic bodies are capable of reducing cupric salts, cuprous oxide being formed and the organic substance oxidized. It has been shown more recently that cupric formate when heated in sealed tubes with water is decomposed, carbonic acid being formed and metallic copper deposited—

$$\left\{\begin{matrix} H \\ COO\diagdown \\ COO\diagup \\ H \end{matrix}\right. Cu'' + H_2O = \left\{\begin{matrix} OH \\ COOH \end{matrix}\right. + Cu + \left\{\begin{matrix} H \\ COOH \end{matrix}\right.$$

Lately P. Cazeneuve* has shown that if cupric acetate be treated in the same manner it is converted into glycollic acid, some acetic acid remains and cuprous oxide is deposited in crystals visible to the naked eye.

The method of procedure is as follows:—10 grams of cupric acetate in powder are mixed with 25 grams of water and the mixture heated in a sealed tube to 200° C., being kept at this temperature for one hour. The tube contain crystals of cuprous oxide and the liquid is of a greenish blue colour. When the tube is opened a little carbonic acid is disengaged. This is probably due to a further decomposition of the cupric acetate and is accompanied by the production of propionic acid; but this reaction is variable and of secondary importance; it is probably represented by the following equation:—

$$2\left\{\begin{matrix} CH_3 \\ COO\diagdown \\ COO\diagup \\ CH_3 \end{matrix}\right. Cu'' + H_2O = CO_2 + \left\{\begin{matrix} C_2H_5 \\ COOH \end{matrix}\right. + Cu_2O + 2\left\{\begin{matrix} CH_3 \\ COOH \end{matrix}\right.$$

* *Compt. Rend.*, No. 11, 525; *Bull. Chem. Soc. Par.*, No. 2, 1879.

The solution after filtration and evaporation at a temperature which does not exceed 50° C., or *in vacuo*, yields minute crystals, which are insoluble in cold water, and consist of glycollate of copper. After evaporation to dryness and treatment with cold water, glycollic acid and free acetic acid are dissolved out.

It is not yet known whether by heating cupric propionate we should obtain lactic acid, or by heating cupric butyrate oxybutyric acid. I have found, however, that on heating cupric butyrate with water to a temperature of 200° C., decomposition takes place, crystalline cuprous oxide being deposited; but have not as yet determined the composition of the liquid. If it be found that all the other acids of the fatty series are by this method transformed into their representatives in the lactic series, we have experimental evidence for regarding carbonic acid as the first member of the lactic series of acids as theory indicates. I have not here discussed the other evidence for so regarding carbonic acid as an organic acid, but only so far as it is concerned in the present reaction.

Parliamentary and Law Proceedings.

Offence against the Pharmacy Act.

On December the 16th a person was summoned at the Liverpool County Court, charged with carrying on business as a chemist and druggist without being registered as required by law.

The defendant had been trading in partnership with a registered person.

The local secretary, at the request of the Pharmaceutical Society of Great Britain, had obtained the necessary evidence, and Messrs. Stone and Fletcher, for Messrs. Flux, Slade and Co., represented the Society.

Defendant paid into court £5, the penalty sued for, but as the payment was on the day before that appointed for the trial application for costs was made, and the Court ordered payment accordingly.

The penalty of £5 and costs, £4 14*s.* 6*d.*—together £9 14*s.* 6*d.*—has since been paid.

Prosecution under the Pharmacy Act.

On Thursday, February 26, an important case under the Pharmacy Acts of 1852 and 1868 was disposed of in the Ayr Court before Sheriff Orr Paterson. The complaint was at the instance of the Pharmaceutical Society of Great Britain against George Bardo, shipmaster, Troon, and libelled two contraventions of the Acts named against respondent—the first being that not being a duly registered pharmaceutical chemist, or a chemist and druggist, or a legally-qualified medical practitioner within the meaning of the said Acts, he did, within "the medical hall," West Portland Street, Troon, keep an open shop for retailing, dispensing, or compounding poisons, and on 20th February sold a certain quantity of laudanum, being poison under the said Acts; and second, that he sold the poison without the bottle in which it was contained being labelled with his name and address as seller thereof. Bardo pleaded not guilty. A lengthened proof was entered into, the lines of defence taken up by the respondent being that the business was carried on in the said "medical hall" by the late Dr. Reid, of Troon, and subsequently by a Mr. Bell, to whom Bardo alleged that he had sold the business on the 16th inst. It appeared, however, from the evidence that Bardo had leased the shop some years ago, and still continued lessee; that the rent was paid by him, and his name appeared on the valuation roll as tenant; that the drawings of the shop were regularly paid over during Dr. Reid's and Bell's occupancy to Bardo's sister-in-law, apparently for behoof of the family; and that, after the 16th instant, when the sale of the business was alleged to have taken place, Bell continued paying over the drawings as formerly. It was pleaded that Bell, being a registered chemist and druggist under the Act, was the seller of the drugs, and that the respondent neither sold the drugs nor kept the open shop for the sale of them; and also that Bardo did not carry on the business.

The Sheriff held that Bardo was proved to be lessee of the shop and proprietor of the business, and under the Act was keeping open shop, and also that he had sold the poison in question without having a label with his name attached. His lordship therefore held both contraventions proved, and imposed a penalty of 10*s.* for each contravention, with £6 18*s.* 6*d.* of expenses. Mr. D. Dougall, solicitor, appeared on behalf of the Pharmaceutical Society, and Mr. C. B. Rowan, solicitor, for Bardo.

Mercurial Ointment.—Prosecution under the Sale of Food and Drugs Act.

At the Droxford Petty Sessions, on February 19, 1880, before George Atherley, Esq. (Chairman), Walter J. Long, Esq., Admiral Rice and Admiral Phillamore, Mr. John Howard Richardson, chemist and druggist, of Bishop's Waltham, was charged on two summonses for having sold (1) mercury ointment which was not of the nature, substance and quality of the article demanded by the purchaser, that is to say, was not genuine mercury ointment, but was a mixture of mercury, fat and moisture; (2) mercury ointment which, to his knowledge, was mixed with certain ingredients, to wit, fat and moisture, so as to affect injuriously the quality and potency of such drug.

Mr. Godwin, solicitor, of Winchester, conducted the prosecution for the local authorities, and Mr. Henry Glaisyer, solicitor, of Birmingham, instructed by the Chemists and Druggists' Trade Association of Great Britain, appeared for the defence. It was agreed that the summonses should be taken together.

Mr. Godwin said that on December 18, in last year, Sergeant Groves went to the defendant's shop at Bishop's Waltham, and asked for three ounces of mercury ointment or mercurial ointment. He paid the person who supplied him with the article purchased, and in accordance with the provisions of the statute he divided the sample into three parts, one of which he gave to the seller, one he forwarded to the county analyst, and a third portion he retained. On January 22, last, the case was first called on, and on the application of Mr. Ford, who, on that occasion, represented the defendant, the bench requested the magistrates' clerk to forward the third sample remaining in the hands of Sergeant Groves to Somerset House, for analysis. The portion that had been sent to Mr. Angell, the county analyst, was analysed by him, and he had fowarded his certificate to the effect that said sample contained

19 per cent. of mercury
81 ,, of fat and moisture, and added the observation that genuine mercury ointment should contain 48 per cent. of mercury. The ointment sold therefore came under the provisions of the 4th and 6th sections of the statute. The 4th being as follows:—"No person shall, except for the purpose of compounding as hereinafter described, mix, colour, stain, or powder, or order or permit any other person to mix, colour, stain, or powder, any drug, with any ingredient or material, so as to affect injuriously the quality or potency of such drug, with intent that the same may be sold in that state, and no person shall sell any drug so mixed, coloured, stained, or powdered, under the same penalty in each case respectively as in the preceding section for a first and subsequent offence." And then the 6th section says:—"No person shall sell to the prejudice of the purchaser any article of food, or any drug, which is not of the nature, substance and quality of the article demanded by such purchaser, under a penalty not exceeding £20; provided, that an offence shall not be deemed to be committed under this section in the following cases,"

and then follow the exemptions. It was quite clear that if a drug ought to contain 48 per cent. of mercury and only contained 19 per cent., it could not have the potency it ought to have, and could not have the same effect.

Sergeant Groves, called to prove the sale, said he asked for three ounces of mercury ointment, for which he paid 9*d.*, 3*d.* per ounce. The box containing the ointment was labelled after it was supplied to him, the label having the words "Mild Mercurial Ointment. Poison." He asked for mercurial ointment and how it was sold. The assistant did not say 3*d.* per ounce the mild; there was no such word used.

Mr. Angell called, sworn and examined by Mr. Godwin, said he was the analyst appointed by the authorities of the county. He received from Sergeant Groves a sample of mercurial ointment to analyse, which he analysed, and gave the certificate that had been handed in. Mercurial ointment should contain 48 per cent. of mercury, the sample sent did not contain more than 19 per cent., and it would require about two and a half times as much of such an ointment to effect the purpose of the purchaser as would be required if the genuine ointment containing 48 per cent. of mercury had been sold, mercury being the only active ingredient.

Cross examined by Mr. Glaisyer.

You have given us a long list of your qualifications, but nothing whatever as to your knowledge of drugs or pharmacy?—I have no knowledge of pharmacy, I have never attended a pharmaceutical school.

You have never had any training in pharmacy?—No.

You know nothing of drugs as drugs?—Yes, I do.

Where did you gather that knowledge?—As a pupil of Dr. Hassall.

How long have you been studying chemical analysis?—Many years.

As applied to drugs?—For more than eight years.

You say you received this mercurial ointment and analysed it, and that your certificate is generally correct. I want you to be a little more precise than that. You say you found 19 per cent. of mercury. How did you arrive at that result?—A weighed quantity was taken, the fat was separated with ether, until the residue in the main ran together in metallic globules. I noticed that slight oxidization had taken place and I knew that this might cause a slight over-estimation of the quantity of mercury present.

Then it was the residue extracted from the fatty matter that you weighed and found to be in the proportion of 19 per cent. of the whole?—That is so.

You say that might be an over estimation. What was there besides mercury?—Oxide of mercury.

Anything else?—Perhaps a slight trace of sulphide.

You are required, I take it, to find out what was actually present in the sample of ointment you analysed, and you only state in your certificate that it contained 19 per cent. of mercury; but what did it contain besides mercury?—I can tell you how much mercury there was in it, because I have since made another analysis by another process and I find, by what is called the sulphide method, that the ointment contained 15·8 per cent. of mercury.

You say you found 81 per cent. of fat and moisture. You do not allege, I suppose, that the moisture present is an adulteration?—Certainly not.

Then you remark at the bottom of your certificate, "genuine mercury ointment should contain 48 per cent. of mercury." Do you adhere to that statement?—I obtained that information by reading the British Pharmacopœia.

Then the word "genuine" is put in by you advisedly?—It is.

What is the date of the Pharmacopœia to which you refer?—1867, with additions to 1874.

Is that the first Pharmacopœia in which mercurial ointment appears?—Oh, no.

Have you referred to others?—To several.

Can you give me the formula for mercurial ointment appearing in each?—In the 1836 Pharmacopœia there is a mild form of ointment ordered.

What do you find ordered in the 1836 Pharmacopœia?—I cannot remember the proportions.

Will you give us the formula appearing there (book handed to witness) under the head of mild mercurial ointment?—No, I cannot give it from this. Mine was an English translation; this is pharmaceutical Latin.

That is the original Pharmacopœia of 1836?—There are symbols there I do not understand.

You have not brought your English translation with you?—No.

You know the contents of the certificate received from Somerset House; do you agree with it?—I perfectly agree with that certificate.

Does this same Pharmacopœia of 1836 order another preparation of mercurial ointment?—I do not know.

If I tell you it does will you contradict me?—I will not.

And if I tell you that that strong mercurial ointment contains 50 per cent. of mercury, are you prepared to admit the fact?—I shall not contradict you.

You recollect the mild is about 16 per cent.?—Yes.

Admiral Phillamore: What Pharmacopœia have you referred to?—To one or two, but I cannot recollect the dates.

Mr. Glaisyer: You know perfectly well, as a fact, that both mild and strong mercurial ointments are still articles of commerce?—I do.

Then you say there are these two articles still in use, the mild containing about 16 per cent. of mercury and the strong about 49 or 50 per cent.?—Yes.

Is the preparation which contains 16 per cent. mentioned in any other Pharmacopœia?—I do not know.

What about the different hospitals in London?—They use both kinds.

Do they use any other than the mild, containing 16 per cent.?—I will not say; I do not know.

Do you know anything about the pharmacopœias of the London hospitals?—I have seen them, but I have not referred to them in this case.

Re-examined by Mr. Godwin.

You have been asked about the Pharmacopœia of 1836. I suppose that was superseded by the Pharmacopœia of 1867?—It was.

And that we go with the Pharmacopœia as we do with all books of authority, by the last published edition?—Quite so.

And that the Pharmacopœia printed in 1867 is the only standard authority?—Yes; the only one I should refer to.

Then the one of 1836 is obsolete?—It is a curiosity.

You have been asked as to mild mercurial ointment?—If this had been sent to me as mild mercurial ointment I should not have given this certificate.

But as an analyst and a chemist you know no acknowledged mild mercurial ointment?—I know there is such an article sold.

As a chemist and an analyst, is there such an article known as mild mercurial ointment?—It is a curious question you have put to me. You ask me to answer it from a scientific point of view, and mild mercurial ointment is not a scientific product.

You say chemists sell an article that they call mild mercurial ointment?—Yes.

That is not genuine mercurial ointment, you say?—In my opinion it is not.

The genuine mercurial ointment ought to be of Pharmacopœia standard?—Quite so.

Admiral Phillamore: As a matter of fact, which is most in use, the strong or the mild?—I should think the mild.

Admiral Phillamore: About the value of these two articles, which is the proper price at which they should be sold?—I have no knowledge whatever.

Mr. Glaisyer: I shall prove that, sir.

Mr. Godwin: Then I put in the certificate from Somerset House.

Magistrates' Clerk: Read the following certificate:—

"The sample of mercurial ointment referred to in the annexed letter, and marked "bottle No. 5," was received here on the 27th ultimo. The sample was securely sealed. We hereby certify that we have analysed the ointment, and declare the results of our analysis as follows:—

Mercury	15·28 per cent.
Fat and moisture . . .	84·72 „
	100 „

"The above results agree with what is known in the retail drug trade as "mild mercurial ointment," and for the preparation of which a formula was given in the London Pharmacopœia, 1836.

"As witness our hands this 16th day of February, 1880.

"(Signed) J. BELL. R. BANNISTER. G. LEWIN."

Mr. Godwin: That is my case.

Mr. Glaisyer, having sketched the nature of the defence he proposed to offer, called

Samuel Fry, an assistant to Mr. Richardson, the defendant, and manager of his business at Bishop's Waltham, who said: I recollect the sergeant coming into the shop. He asked for mercurial ointment, he likewise asked how it was sold. I said 3*d.* per oz. the mild; he said he would have three ounces, with which I supplied him. We had some conversation. He said it was rather an unpleasant duty he had to perform. He said the ointment was for analysis. He divided the sample into three parts, giving one to me.

What label did you put on the article sold?—It was labelled "mild mercurial ointment, poison," and Mr. Richardson's name and address.

What did you charge him for it?—Ninepence for the three ounces.

Was it labelled before he divided the sample?—Yes.

Was it labelled before he paid for it?—It was.

Did you sell this to him distinctly as mild mercurial ointment?—I did; that is the preparation we usually sell.

You charged him 3*d.* per oz.?—Yes.

Do you keep the strong mercurial ointment in stock?—Yes.

What's your price for that?—Sixpence per ounce.

Do you sell much of the strong ointment?—I never sold any in my life.

What sale have you for the other?—We mix about two pounds at a time, which might last three months.

What experience have you had of the trade?—I have been in the trade seven years.

And the result of that experience with regard to the strong ointment?—I have never sold it or seen it sold.

Cross-examined by Mr. Godwin.

Have you any qualification, Mr. Fry?—I am a properly qualified chemist and druggist.

You have never seen the strong ointment sold?—No; the strong ointment would contain about 50 per cent. of mercury.

That's about the Pharmacopœia strength?—It is.

Have you seen the British Pharmacopœia now in use?—Certainly.

The ordinary mercurial ointment in the British Pharmacopœia contains about 48 per cent. of mercury?—Yes.

And the British Pharmacopœia is the recognized authority for drugs?—Not in every case.

Do you mean to say that every country chemist can set up his own authority?—No.

You recognize this Pharmacopœia as an authority?—Yes, as one authority.

When did you obtain your qualification as a chemist and druggist?—Yesterday.

You say that Sergeant Groves came into your shop, and asked for mercurial ointment, and how it was sold, and you said 3*d.* per ounce the mild, and that he then said he would have three ounces?—Yes; that is so.

You have heard what Sergeant Groves has sworn with regard to the use of the word "mild" on that occasion?—I have heard what he said. The word was used by me, but not by him.

You adhere to that statement in spite of what Sergeant Groves says?—In spite of what anyone may say.

Suppose a person came into your shop and asked for mercurial ointment, would you ask whether they required the mild or the strong?—If they came without a prescription or authority I should supply the mild.

Do not you know that by doing that you would supply them with a drug not of its proper potency?—By doing that I may perhaps save their lives.

That has nothing to do with it.—If I labelled the ointment sold mild mercurial ointment I sell it as such.

Re-examined by Mr. Glaisyer.

You say that you should not supply the strong unless it was ordered by a medical man?—Certainly not.

You regard this British Pharmacopœia, I take it, as a guide for medical men?—Exactly.

Supposing you have a drug asked for that does not appear in that book?—Then we must go to the last authority that does contain it.

Chairman of the Bench: Do you often get prescriptions ordering the strong ointment?—I have never seen a prescription containing mercurial ointment.

If a prescription came to you containing mercurial ointment, what would you use?—It would depend upon the date of the prescription. If the prescription was dated subsequent to the issue of the British Pharmacopœia I should use the British Pharmacopœia preparation containing 48 per cent. of mercury.

As a matter of fact you never have supplied either kind of ointment in a prescription?—I have not, sir.

Mr. J. H. Richardson called, sworn and examined by Mr. Glaisyer.

Your name is John Howard Richardson, and you are a registered chemist and druggist, carrying on business at Alresford and Bishop's Waltham?—Yes.

The last witness is your assistant at your Bishop's Waltham establishment?—He is.

Supposing you had a prescription sent to you ordering mercurial ointment, what would you supply?—I should supply the ointment of the British Pharmacopœia if the prescription was dated after 1867.

How many years' experience have you had in the drug trade?—Between seventeen and eighteen. I have been at Havant, Portsea, Southsea, Bishop's Waltham and Alresford.

And what has been your experience with regard to the sale of this ointment?—I have never supplied the strong ointment, except on the written authority of a physician or surgeon.

Professor Attfield called, sworn and examined.

You are Professor of Practical Chemistry to the Pharmaceutical Society of Great Britain, a Fellow and Member of the Council of the Institute of Chemistry, and a Fellow and until lately a Member of the Council of the Chemical Society, author of a Manual on Chemistry?—Yes.

You are also an analyst?—Yes, of from twenty-five to twenty-six years' standing.

Are you well acquainted with the nature and quality of drugs?—Yes.

What is mercurial ointment?—Mercurial ointment is a mixture of mercury and fat. The proportions vary considerably. The lowest proportion that I know is $12\frac{1}{2}$ per cent. of mercury. Ointment of that strength is now used at the Hospital for Diseases of the Skin and at King's College Hospital. In the present Pharmacopœia of the London Hospital the strength is $16\frac{1}{2}$ per cent.; Middlesex Hospital $16\frac{1}{2}$ per cent. The British Pharmacopœia strength is about 49 per cent. as has already been stated.

When was the preparation known as mercurial ointment first ordered?—It was first ordered in the London Pharmacopœia of 1721, a copy of which I now hold in my hand. It is written in Latin. There is only one form for the ointment in this Pharmacopœia. This is the first or "blue" mercurial ointment, and it contained between 19 and 20 per cent. of mercury. The next authority was the London Pharmacopœia of 1746. Two varieties of the ointment are therein mentioned. Mercurial ointment, mild,—the word is *mitius*,—containing about 20 per cent., and strong, *fortius*, containing about 33 per cent. of mercury. The next authorized preparation is that of the London Pharmacopœia, 1836, the mild 16 to 17 per cent. of mercury, the strong 50 per cent. of mercury. The British Pharmacopœia, which is stated in the preface to have for its object, "not so much the selection as the definition of substances which the physician prescribes, and which are required to be kept at one safe and uniform standard of strength and composition," orders a preparation containing about 48 or 49 per cent. of mercury.

Do you know the custom of chemists and druggists throughout the country?—The custom is to keep two kinds of ointment, the mild and the strong.

Can you give us the proportions of mercury they contain?—The strong contains nearly half its weight, and the mild about 16 per cent. I can say of my own knowledge that the mild is the article as a rule sold to the public. The strong is the article put into medicines prescribed by physicians after the date of the British Pharmacopœia.

Admiral Phillamore: But a person asking for mercurial ointment; an ordinary customer?—The common practice is to sell the mild.

Mr. Glaisyer: Have you received an official sample in this case?—Yes, on January 22, and I analysed it and found it to contain about 16 per cent. of mercury.

Admiral Rice: That you say is the ordinary article of trade?—Yes.

Admiral Phillamore: And the price paid 3*d.* per ounce, that is a fair value for the mild preparation?—Yes.

Mr. Glaisyer: What is your opinion of the ointment you have analysed in this case?—I consider it to be a genuine mercurial ointment. The proportion of mercury I found there is in accordance with the proper practice and custom of the trade. It is the only "Trooper's" ointment. Further than that the strength of the preparation is founded on official directions. The use of the mild preparation also harmonizes with hospital pharmacy, as indicated in certain hospital pharmacopœias, which I consider to be good authorities.

Cross-examined by Mr. Godwin.

You talk about the British Pharmacopœia, and you have gone back to 1721 and 1746, but is not this British Pharmacopœia, printed in 1877, the Pharmacopœia in general use at the present time?—For certain purposes.

For all the drugs of the country?—No, certainly not.

Then what is the authority for drugs at the present time?—There are many authorities and I have quoted several.

Do you mean to say that the recent edition of the Pharmacopœia does not supersede the former editions?—So far as its object is stated, and that object I have referred to in the paragraph I have read from the preface.

You have, no doubt, read the Act of Parliament under which these proceedings are taken, the word "drugs" is mentioned there; to what drugs do you suppose it is intended to apply?—I consider the word applies to all drugs.

Does not the word apply to drugs as authorized by the British Pharmacopœia at present in use?—Most certainly not to these alone.

Take the Pharmacopœia of the present time; it is a revised edition—I think the preface says it is revised?—The prefatory pages state that the Pharmacopœia of 1867 has had some additions made to it.

Is not the object of publishing one edition after another of such a book as this, to add new things that are useful?—Yes.

To be the authority on all drugs in use in the country?—Most certainly not.

Why the second paragraph of the preface of the British Pharmacopœia states, "And by a subsequent Act, the 25 and 26 Vic., cap. 91, which recites, amongst other things, that different Pharmacopœias have hitherto been in use in England, Scotland and Ireland, and that the Pharmacopœia to be published by the General Council is intended to supersede the above-mentioned Pharmacopœias, it is enacted that the British Pharmacopœia, when published, shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-mentioned Pharmacopœias; and any Act of Parliament, Order in Council or custom relating to any such last-mentioned Pharmacopœias shall be deemed, after the publication of the British Pharmacopœia, to refer to such Pharmacopœia."—All that refers to the drugs of physicians' prescriptions and not to drugs generally.

Then you mean to say that this book is not the authority?—I say that book is an authority for physicians' prescriptions and for the drugs therein named, as noticed in the paragraph from the preface which I have read.

Re-examined by Mr. Glaisyer.

You have been asked a number of questions about the drugs which could properly be considered as drugs within the meaning of the Sale of Food and Drugs Act?—Yes.

And my friend has endeavoured to get out of you that no drugs are so included except those mentioned in the British Pharmacopœia, but there are many drugs that have come into use since that Pharmacopœia has been published?—Oh yes.

And those drugs if adulterated would properly come within the four corners of this Act?—Certainly.

Now are there old drugs which are commonly asked for by the public, which do not appear in the present Pharmacopœia?—Yes, many.

Therefore the deduction, if the Sale of Food and Drugs Act applies only to drugs mentioned in the British Pharmacopœia, many adulterated drugs might be sold for which offences no prosecution could be brought?—Clearly so.

Admiral Phillamore: This substance has long been sold?—This article containing 16 per cent. of mercury has been sold for nearly half a century without let or hindrance, and the public would be put to much inconvenience were the sale stopped now.

Mr. Glaisyer: Might not great danger attend the use of strong mercurial ointment in certain cases if supplied promiscuously?—It is within my knowledge that strong mercurial ointment has seriously injured health.

The magistrates then retired and after an absence of about a quarter of an hour the Chairman of the Bench said, The magistrates have had this case under their careful consideration for some little time, and under all the circumstances of the case they dismiss it.

Mr. Glaisyer: With costs, sir? We have been brought here to defend this case at very considerable cost.

Mr. Godwin: I cannot agree with my friend's suggestion. It seems to me that it has been a very proper inquiry. It was carried out by the authorities of this district; it was not a malicious prosecution or an improper one, and I submit to the bench that it is not a case in which this court ought to accord costs of any description, much less heavy costs.

The bench again retired and ultimately decided to allow three guineas as costs.

Prosecutions under the Weights and Measures Act.

At the East Dereham Petty Sessions, on February 20, 1880, before R. C. Brown, Esq. (Chairman), and H. E. Hyde, Esq., John Cock, pharmaceutical chemist, of

Shipdham, was charged on two summonses—(1st) that on the 22nd day of January last, at the parish of Shipdham, he unlawfully had in his possession for use for trade, four weights not stamped as required by law; (2nd) that on the 22nd day of January last, at Shipdham, he had in his possession one weighing machine, which was there found by the inspector to be unjust.

Mr. Glaisyer appeared for the defendant, instructed by the Secretary of the Chemists and Druggists' Trade Association of Great Britain.

On the first summons being taken, Edward Symonds was sworn, and said he was a Superintendent of the Police and Inspector under the Weights and Measures Act for the Mitford and Launditch divisions of the county of Norfolk. On the 22nd of January last he visited the defendant's shop at Shipdham and tested the weights there and he found a 4 lb. weight unstamped. He afterwards went into the gig shed, which was used as a warehouse as well, and there found three weights, two 4 lb. weights and a 2 lb. weight, none of which were stamped. On testing them he found one of the 4 lb. weights found in the warehouse one drachm light, and the other 4lb. weight half a drachm light.

Mr. Glaisyer for the defence, said he was not prepared to contend that the weight found in the shop was stamped in accordance with the provisions of the Act, but his answer, as far as that weight was concerned, was that at the time appointed by the officer for the rectification and marking of weights in October last, the defendant sent the bulk of his weights for the purpose of having them verified and stamped. He could not dispense with the whole of his weights at one time, so he sent a portion. This one weight in question was kept with one or two others for the purpose of conducting his business, whilst the remainder of his weights were being inspected by Mr. Symonds, and he had not subsequently had an opportunity of sending them for verification. The question of stamping was a trivial matter, because it was not alleged on the part of the prosecution that this particular weight was short weight or that it was in any way inaccurate as to its weight. The simple charge was that it was not stamped as required by law. With regard to the other weights that were found in the gig shed, the inspector had admitted that he was told by the defendant that these pieces of iron were used for making a sheep dip, that is to say for roughly weighing out different proportions of different ingredients for manufacturing a sheep dipping composition. They were used by the defendant not as standard weights by which to sell his goods, but as rough guides in mixing heavy materials in the manufacture of sheep dip.

Chairman of the Bench: All the weights found on the premises not stamped may be forfeited, I believe.

Magistrates' Clerk: They are liable to be forfeited, but the Act does not say they shall be forfeited.

Chairman of the Bench: We inflict a low penalty of 5*s*., and the one weight found in the shop will be forfeited.

Mr. Glaisyer: Then, sir, you convict only on the one unstamped weight found in the shop, which has not been proved to be of short weight.

Chairman of the Bench: Yes, and the other weights found in the warehouse must be returned to Mr. Cock.

With respect to the second summons, Inspector Symonds said on the 22nd of January last, he visited the defendant's premises and went into his gig house, and with three of the weights mentioned in the last summons and others, he found a weighing machine with weights standing by it. He tested the machine and found it very nearly 3½oz. deficient against the purchaser. It was a platform machine and not a hanging beam scale.

Mr. Glaisyer said the defence to this summons was simply a repetition of his previous remarks as applied to the pieces of iron that were found with this machine. This machine and the pieces of iron were used purely and simply for roughly weighing out different proportions of ingredients for mixing into a sheep dipping composition, and he could prove that all articles kept in that warehouse were taken into the shop to be weighed previous to being sold.

Evidence to this effect having been given by two witnesses, the case was dismissed and the machine ordered to be returned to Mr. Cock.

Poisoning by Godfrey's Cordial.

An inquest on Percy Edwin and Margaret Ethel Makin, twin children, who had been poisoned by an overdose of Godfrey's cordial, was held on Thursday, February 12, at Hindsford, Atherton, before J. B. Edge, Esq., coroner.

Lydia Makin, the mother of the children, said that in consequence of having been kept awake by them at night, she sent a young woman, named Sarah Jane Newton, for a pennyworth of Godfrey's cordial, from a woman named Betsy Molyneux, who manufactured it. Newton took a two ounce bottle. (The bottle was produced by Sergeant Kelly, who said Dr. Trail had taken a portion of the contents.) She told Newton to ask what quantity she was to give a child six weeks old, and word was returned that it must be a teaspoonful. About 12 o'clock on Saturday night, she gave each of the children a teaspoonful, and she then went to bed. Both the deceased seemed soothed directly and fell asleep. About 6 o'clock on Sunday morning, the children were still asleep. About 7 o'clock she became alarmed at the condition of the children. They kept opening their eyes and shutting them. She tried to rouse them, but they kept dosing off. About 9 o'clock she sent her husband for Dr. Trail, and while he was away and before the doctor came the boy died. This would be about 9.20 a.m. The doctor ordered the girl to be warmed, and her head to be bathed in cold water. She died at 8.30 on Sunday night. Dr. Trail came again before she died. She never had a drop of the kind in the house before. She was quite sure she only administered a teaspoonful.

Sarah Jane Newton deposed: The last witness sent me for a pennyworth of godfrey on Saturday night. Mrs. Molyneux gave it to me herself. I asked her what a child six weeks old should take, and she said "If it is not a very strong one you can give it a teaspoonful." I told her the child was not so strong, and she said "Then it must not have more than a teaspoonful." I saw Mrs. Makin give the children the cordial, which I got at 8.30. It would be midnight when she administered it as directed. I slept with Mrs. Makin, who awoke me a little after 6 o'clock and said she could not get the children to wake. They simply opened their eyes and shut them again.

By the jury: I am sure they had only one spoonful each. It was said it should be given when the children went to bed.

Betsy Molyneux, wife of Richard Molyneux, Lord Street, Atherton; said: I remember the last witness coming for the godfrey. My daughter supplied it, but I was present. She is in her nineteenth year. The woman Newton did not tell me what sort of a child she wanted the medicine for. Had she done so I should not have given it her, because I should have thought twins would not stand as much. Twins are not reckoned as strong as others.

The Coroner: Did she tell you the child was only six weeks old?—Yes.

And that it was not very strong?—No, she said it was very cross, and they could not get any rest.

Did she ask how she should give it?—Yes, I said a small teaspoonful, but not knowing it was a twin. She said they had had no rest with it for four nights. I told her everybody knew whether their children were strong or weak, and would know what quantity to give.

Did you say "If the child isn't a strong one give it a teaspoonful?"—I cannot say. I don't want to say what's false. I didn't think about twins. I have made cordial for two years.

What is it made of?—I first put half a drachm of opium in a quart of water and boil it to three gills or rather less and then I add two tablespoonfuls of treacle and one of sugar. When it is gone cold I put an ounce of paregoric in. Mr. Wallwork, druggist, weighs the opium of which I always get half drachm at a time. I get the paregoric at the same time in quantities of an ounce. I measure the water before I put the treacle in. I make no other kind of medicine. My mother sold this cordial for near on forty years. This is the first case of the kind.

The Coroner: I advise you not to sell it.

Witness: I will sell no more.

The Coroner: I think it is contrary to law. I would advise you to give it up. If another case of this kind occurred it might be serious for you.

A Juryman: Do you get rid of much of it?

Witness: A great deal, mostly to old people with bad coughs. We have given over selling it twice, but were pressed to start again.

Another Juryman: You have sold it for children all along?

Witness: Yes.

Mr. Mather: You don't prohibit the sale to old people?

The Coroner: I don't prohibit anything, but I say it is contrary to the law for her to vend such drugs. This paregoric is dangerous, unless they know who they are administering it to.

Alexander Forbes Trail, surgeon, said: I was called in to see the children on Sunday morning, arriving about ten o'clock. I found the boy dead, and the girl seemed to be suffering from some narcotic. Before I got there the father told me what they had been giving the children. I saw the bottle, and took a portion of the contents. I have heard Mrs. Molyneux's description of what it contained, and I believe she has told the truth. In a teaspoonful there would be about three-tenths of a grain of opium, and there would be about two grains of the paregoric.

In your opinion these children died from the administration of this godfrey?—That is my opinion.

Do you think narcotics are given in large quantities in this neighbourhood?—Yes, I believe so.

The Coroner said he asked that because the Home Secretary had inquired of him if there were many deaths from narcotics. He had suspected its extensive use.—The witness, continuing, said the parents of many children were occupied during the day, and they liked to have their children sleeping in the night. They went to the medical men to ask for medicine to make the children sleep, and were invariably refused. They were rather advised to regulate the children by means of their food, in nursing, etc. Unable to get what they wanted from the medical practitioners they were more successful with outsiders, and there were few houses where they would not find a bottle of this nature. It was sold by various people in the town and district.

The Coroner supposed there were few instances in which death was so sudden.

Dr. Trail had no doubt many deaths indirectly proceeded from it. This dose he considered excessive.

The foreman asked if a *post-mortem* would throw any light upon the case.

The Coroner did not think it would. It would show in all probability that the deceased died from opium poisoning, and that they were pretty clear about already. A *post-mortem* might show that Mrs. Makin had given a larger dose than was alleged. He, however, believed her; she seemed a very respectable woman.

Dr. Trail said, judging from the quantity of the cordial he took, and that left, he did not think more than one dose was administered.

The Coroner, in answer to the jury, said the parents were anxious no doubt to get the children asleep for the night, and delayed giving the cordial until they went to bed. The danger of these cordials was that they were in the hands of persons comparatively ignorant alike of the strength of the medicine and of the children about to take it. People got into the way of selling it, and did not inquire into the particulars as they might do. He could not help thinking that the constitutions of many children were gradually sapped away, their deaths being attributed to wasting away; the fact being that such stuff as this prevented digestion. The law applicable to this matter was this: Persons dealing in drugs must use reasonable care and skill in their administration. If they did not, and death ensued, they were liable; but in this case the drug was not administered directly by Mrs. Molyneux, but by the mother, and though that would not excuse Mrs. Molyneux entirely, yet it made a great difference in considering whether she had been guilty of such gross carelessness as would render her responsible. He did not think she had been guilty of that carelessness which the law called reckless to such a degree that it amounted to manslaughter. It was within the province of the jury to find a verdict of manslaughter, but he did not think it would result in a conviction, for many circumstances might be urged in mitigation.

The jury at once returned a verdict that the deceased children died from accidental poisoning from an overdose of godfrey.—*Leigh Journal.*

Alleged Poisoning by Oxide of Zinc.

On February 25, at Birkenhead, a cabdriver was found lying in an unconscious condition in an eating-house in that town. It appeared that shortly before that time he purchased of Mr. Fore, chemist, an ounce of oxide of zinc, stating that it was for his horse. He then went into the eating-house, where he ordered a cup of tea. The attendant who supplied it saw him empty some stuff out of a paper into the tea, and asked him what he was doing, to which he replied "I'm going to finish myself." He then swallowed the contents of the cup, and immediately fell down insensible. He was at once conveyed to the Borough Hospital.—*Liverpool Daily Post.*

Poisoning by Oleum Phosphoratum.

An inquest has been held before Mr. Hawkes (borough coroner), at the Angel Inn, Sparkbrook, on the body of Catherine Forrest, thirty-two years of age, single woman, who resided at No. 117, Stratford Road. The deceased was the daughter of Alexander Forrest, accountant, residing at the address given above. For some time past she had been suffering from heart desease, and died on the 18th instant. She was attended by Mr. W. Taylor, surgeon, who prescribed phosphorized cod liver oil, which she obtained from Mr. Thompson, chemist, Stratford Road. When a second supply was sent for, Mr. Ball, the chemist's assistant, went to Messrs. Southall, Son, and Barclay, but he received from one of their assistants, named Withers, phosphorized oil instead of phosphorized cod liver oil. The bottle was labelled correctly by Withers "oleum phosphoratum," but subsequently a capsule label "pure cod liver oil" was attached by Ball. Deceased died after taking three doses from the poisonous mixture.

The coroner, in summing up, remarked that there had been gross carelessness, but he reminded the jury that any verdict of a criminal character arrived at by a coroner's jury would encounter elsewhere violent hostility, and he would not be a party to induce a jury to find such a verdict when he could by any means satisfy himself that justice would be met by a verdict of death from misadventure.

The jury rturned a verdict to this effect, the coroner also, at the request of the jury, censured the two assistants for carelessness.—*Birmingham Gazette.*

[650]. RED DRENCH.—*Agathos* would be obliged by a form for red drench for cattle, horses, sheep, etc., small in quantity, but active.

COSTER'S PASTE. — In answer to a correspondent's inquiry as to the formula of Coster's paste, Mr. James Startin replies in the *British Medical Journal* (Jan. 17):—

"The usual formula, I believed, used is:—

℞ Iodine Pigment . . . . ʒij.
Huile de Cade or Oil of Juniper Tar . ℥j.
Misce. Fiat embrocatio.

"I find the following formula most effectual:—

℞ Pigmenti Iodi . . . . . ʒiii. vel ℥iv.
Creasoti Puri . . . . ℥ss.
Huile de Cade . . . . ℥ss.
Misce.

"In cases of early ringworm, it is an effectual remedy if well brushed into the roots of the hair. The addition of a quantity of iodine makes the preparation more valuable."

Correspondence.

SALE OF POISONS AND PATENT MEDICINES.

Sir,—From the correspondence which has appeared in the daily papers it is evident that this subject is attracting the attention of the public generally as well as the medical profession; and it is to be hoped that the Pharmaceutical Council will take immediate steps to bring before Parliament an amended Pharmacy Act, both for the benefit of the pharmacist and the general good. It appears to me that as the law at present exists that there is nothing to prevent a tailor or any other tradesman or licensed hawker who takes a five shilling licence from selling the so-called patent medicines, however poisonous or injurious they may be, under the protection of a three-halfpenny stamp. A large proportion of these patent medicines are prepared by charlatans, who not unfrequently affix some letters to their names, such as M.B., etc., thereby increasing the gullibility of the ignorant. Now I would ask, Is it fair to a large and educated body of men who have spent years in qualifying themselves for a highly responsible position, and I venture to say are the worst remunerated of any profession, that the chemists of this country should have the responsibility and very doubtful privilege of selling poisons under stringent regulations, and from which they gain little profit and much trouble, when any ignorant person may sell the same if protected by law under a paltry stamp duty? How many hundreds or thousands of children die annually from the effects of soothing syrups and narcotics now legally sold? The medical men can form the best opinion.

It would be well if the formulæ for all patent medicines or preparations had to be submitted to authorized medical inspection, and in case of any being poisonous or of such a nature as to be injurious to the public health that the sale should be prohibited.

The time has now arrived when the retail sale of drugs, medicines and chemical preparations ought to be exclusively in the hands of qualified men. It must be a great injustice to gentlemen who have to pass examinations and spend many years of their lives in order to gain their certificates that they should be at the mercy of any tradesman who can sell drugs with impunity as long as he keeps clear of those poisons enumerated in the schedules.

I must now appeal to country chemists, on whose behalf as well as my own I am prompted to write this letter, and urge them most strongly one and all to unite and try to improve our status and condition, by putting pressure on the Pharmaceutical Council and not being afraid of overdoing it, as all large bodies are proverbially hard to move. The provincial chemists have a great deal in their power if they will only act in unison, and I would call their attention to those gentlemen who now compose the Council, nearly the whole of whom are from the large towns, eight being from London, and out of the twenty-one I can only find two, whose address is Diss and Salisbury, who are likely to know the grievances of a town of some twenty thousand inhabitants where the medical men dispense their own medicines and patent medicines are exchanged for their cost wholesale.

The Birmingham Association is doing good work and acting energetically, but it is the Pharmaceutical Council who must bring forward new legislative measures and get the Act amended, without which being done there will be many who will find their occupation gone. Apologizing for the length of this letter. W. A. BAGNALL.

PATENT MEDICINES AND DISPENSING LEGISLATION.

Sir,—Mr. Symons's letter which appeared in a recent *Pharmaceutical Journal* is thoroughly practical, and represents the true opinion of country chemists in general. Without doubt it is now time for the Council to take in hand the reckless sale of patent medicines containing scheduled poisons by unregistered persons; it is called for by the public, as shown by the press, also the recent verdict of the St. Pancras jury confirms the same. A step further might be judiciously ventured, namely, the dispensing of all prescriptions should be reserved to the duly qualified medical practitioners and chemists and druggists. This, I believe, is the case in Ireland, and why should not the Legislature in England restrict the compounding of all medicines, whether containing scheduled poisons or not, to those who are properly qualified to dispense the same? This would be hailed with satisfaction by the public as additional means for their safety. MAJOR.

J. J. Jackson.—We do not agree with your opinion as to the papers in question, the value of which has been repeatedly vouched for by authorities in this country and on the continent. As to your assumption, it is an incorrect one, and does injustice to the author, as the service has been a voluntary one and has been supplemented by the presentation of a valuable series of illustrative specimens of the drugs mentioned to the Museum, where they have been already found very useful for reference and comparison.

"Delta."—See before, p. 439.

C. Jones.—A permanent gloss can be imparted to leather by coating the surface, freed from grease, with varnish made from a drying oil, after the manner in which "patent" leather is prepared.

J.—By exposing them to the influence of an odorous substance in an enclosed space.

J. A. Wright.—The metallic cyanides are included in the poison schedule. If your preparation comes within the provision of the Pharmacy Act we must decline to suggest any way of evading it.

A. P. S.—Associates not in business are not entitled to vote in the elections of Members of Council. In the election of annuitants on the Benevolent Fund they have each one vote.

Student.—Bentley's 'Manual of Botany.'

THE EFFECT OF INTENSE COLD ON CHERRY-LAUREL.

BY PROFESSOR FLÜCKIGER.

In January, 1879, I submitted cherry-laurel leaves, which were covered with ice, to distillation with water, and ascertained that they nevertheless yielded a small amount both of essential oil and hydrocyanic acid. This experiment is recorded in the new edition of the 'Pharmacographia,' page 256, yet it should be added that the leaves, although frozen, were still green and were not killed by the frost, the temperature being not below $-10°$ C. (14° F.). In the month of December, 1879, as well as in the beginning of the present year, however, we noticed repeatedly, at Strassburg, temperatures of $-25°$ C. ($-13°$ F.), and then the cherry-laurel leaves turned brownish, lost their leathery texture and were in fact killed. Some of them, distilled with water, yielded an aromatic aqueous product which proved devoid of hydrocyanic acid. On repeating this experiment with one pound of the frozen leaves the same negative result was obtained, and the same again when two pounds of leaves were submitted to distillation. In each case the first portions of the distilled liquid were tried for hydrocyanic acid with the usual tests, viz., sulphate of copper and guaiac, the production of sulphocyanate and that of Prussian blue. No trace of hydrocyanic acid was proved to be present by these means. Another distillation, like the former, also performed by using the leaves minutely cut, was carried on for an hour or two, so as to afford a large quantity of water, say about 1½ gallon. It had nearly the usual odour of cherry-laurel water, yet no essential oil made its appearance. The whole quantity of the distilled water was now repeatedly shaken with ether; from the ethereal layers afterwards the ether was cautiously distilled off and the residue exposed to spontaneous evaporation at a temperature not exceeding 20° C. (68° F.). It afforded about 1½ gram of an oily liquid reminding, not exactly of cherry-laurel oil, but a little suggestive of acetic or similar compound ethers, and displaying at the same time a certain pungency; it was of a decidedly acid reaction. Supposing it to be (impure) cherry-laurel oil, I thought it quite in accordance that small crystals began to be formed on the sides of the phial. To investigate the nature of the essential oil I shook it with a saturated solution of bisulphite of potassium, SO_3KH, after having ascertained that this solution immediately combined with true benzylic aldehyde, *i.e.*, essential oil of laurocerasus, yielding crystallized scales of the compound $C_6H_5.COH,SO_3KH$. But such was by no means the case with the oily liquid which had been extracted from the water. And as to the small crystals, which had separated from the same oily liquid, they proved not to be benzoic acid inasmuch as they readily melted at about 60° C. (140° F.). Nor was it possible to ascertain the cause of the acid reaction of the oily liquid; it was due neither to formic acid nor to any other acid of the fatty series. The aqueous residue in the still was duly concentrated and found to be very rich in mucilage and uncrystallizable sugar.

These experiments, which were for the most part performed by Mr. Fels, a pupil of mine, show that the source of hydrocyanic acid and benzylic aldehyde in the laurel leaves is destroyed by intense cold. A minute quantity of an essential oil is still afforded

by the leaves, but it does not agree with the oil as yielded by the living plant. Dried leaves are sometimes said likewise to yield no longer any hydrocyanic acid; I am not able to confirm this statement, having ascertained that fresh cherry-laurel leaves, which I dried for several days at the temperature of the water-bath, on distilling them with water afforded a small amount of the said acid.

I am informed that in December and January past *Prunus Laurocerasus* has been injured throughout northern Italy as far as Bologna and Florence in the same way as with us. It would be interesting to know a little more exactly the area of this action of cold on the shrub, which is so widely spread also in the south of the British Isles.

CONTRIBUTIONS TO THE CHEMISTRY OF SEVERAL VARIETIES OF WAX.

BY EDUARD HIRSCHSOHN, MAG. PHARM.

The reactions I obtained with the different resins, etc., described in the *Archiv der Pharmacie*, can be made use of as a good means not only of distinguishing the various resins, gum resins, and balsams from one another, but also of recognizing the more important commercial varieties of the same by means of chemical reactions. It did not, therefore, appear without interest to subject the varieties of wax more commonly met with in the market to a similar examination.

For this purpose I made use of the samples in the collection of the Pharmaceutical Institute of this town, kindly placed at my disposal by Professor Dragendorff, to whom I take this opportunity of expressing my sincere thanks. The experiments with the same described in the following lines were carried out, with but few exceptions, in precisely the same way and with the same reagents as in my previous investigations.

I was able to avail myself of the following samples:—

(1) *Cera flava*; from a chemist in Dorpat; fine pure sample.

(2) *Cera flava*; produced in 1877 in Rappin in Livonia. Also a very fine sample.

(3) *Cera alba*; in the collection of the Pharmaceutical Institute; fine white pieces.

(4) *Cera alba*; from a chemist in Dorpat; good sample.

(5) *Cera alba*; from the Martiny collection; similar to No. 4.

(6) *Cera africana*; also from the Martiny collection; very similar to European beeswax, but softer and of a greyish yellow.

(7) *Cera mexicana*; from the Martiny collection; is a white beeswax.

(8) *Cera de Orizaba*; also from the Martiny collection, where the following note is appended to it:—

"Received from Schaffner, with the remark that it was in this state offered for sale by the Indians. I have not investigated it more closely, but after a superficial examination I take it for a vegetable wax."

The examination shows it to be a Myrica wax.

(9) *Cera japonica*; in the collection of the Pharmaceutical Institute; usual commercial variety.

(10) *Cera japonica*; from the Martiny collection; similar to No. 9.

(11) *Cera from Myrica quercifolia*; also from the Martiny collection; a pale green mass, tolerably hard and easily powdered.

(12) *Cera from Myrica cerifera*; from the Martiny collection; somewhat darker and more brittle than the foregoing sample.

(13) *Cera from Myrica?* (species not named); from the Martiny collection; similar to No. 12. May be distinguished from No. 11 only by its darker green colour.

(14) *Cera de Bahia*; also from the Martiny collection; very hard grey mass, the freshly fractured surface greenish.

(15) *Cera Brasiliensis*; from the Martiny collection; light yellowish mass, brittle and easily powdered.

(16) *Cera e Lac in baculis*; also from the Martiny collection; chocolate-brown brittle mass, easily powdered.

(17) *Carnauba wax*; obtained in 1878 from Gehe and Co. in Dresden; similar to No. 15.

Alcohol (95 *per cent.*), in the proportion of 1 part of wax to 10 of alcohol, dissolved only a small portion of the samples under examination. On warming to the boiling point, sample No. 8 and 11—13, were completely dissolved, whilst with samples 1—7 and 9 and 10* the greater part of the wax melted, and collected in the form of an oil at the bottom of the test tube. With No. 14—17 on the other hand the undissolved portion remained as a powder. Part of the dissolved wax separated out of the hot solutions on cooling, colourless.

Alcoholic solution of acetate of lead gave with the above cooled alcoholic solutions of samples No. 1—13 and 16 a cloudiness which on heating to boiling completely disappeared in Nos. 1, 2 and 6—13, in Nos. 3—5 and 16 partially only. In Nos. 14, 15 and 17 no change was caused by the addition of the acetate of lead solution.

Solution of ferric chloride (1 part in 10 of 95 per cent. alcohol) added to the alcoholic solution of the wax coloured No. 13 black, with the others it produced either no alteration or a brownish or greenish tint. In No. 11 a cloudiness was produced, insoluble on warming.

Solution of ammonia (sp. gr. 0·96 gave with the alcoholic solutions a more or less opalescent mixture.

Ether, at the ordinary temperature, dissolved Nos. 8 and 11—13 completely, the remainder partially only. Of these Nos. 1—7 and 9, 10 were completely dissolved on boiling and, as with the hot alcoholic solutions, the greater part separated out on cooling, colourless. The addition of an equal volume of 95 per cent. alcohol to the ethereal solutions, obtained at the usual temperature, produced no alteration in Nos. 8, 11—14 and 16, whilst in Nos. 1—7, 9, 10, 15 and 17 a cloudiness appeared.

Chloroform dissolved, at the ordinary temperature, samples No. 1—13 to a perfectly clear solution; Nos. 14—17 were only partially dissolved, but on heating dissolved completely, the greater part separating out colourless on cooling.

Petroleum spirit at the ordinary temperature effected only a partial solution which on boiling became complete. On cooling the wax separated out colourless.

Alcoholic solution of caustic potash (1 part caustic potash in 10 parts 95 per cent. alcohol) on only slightly warming dissolved the Japanese and Myrica wax (Nos. 8—13) completely, and the remainder (Nos. 1—7, 14—17) required to be boiled for some time before solution could be effected. On heating the cooled soap solutions with about 100 parts of water, the soaps from Japanese and Myrica wax dissolved completely, the other soaps only partially.

* Japanese wax dissolved completely on boiling with a larger quantity of alcohol.

Quantitative experiments also were made with some of the samples as follows:—The wax was brought to the finest possible powder with powdered glass and treated with alcohol or petroleum spirit at the ordinary temperature, as long as anything was removed by the solvent. From the solutions thus obtained, the alcohol or petroleum spirit was recovered by distillation, and the residue dried at 110° C.

The following figures were obtained:

	Alcohol 95 per cent.	Petroleum spirit.
Cera Africana . . .	3·50	49·28
Cera de Orizaba . .	10·22	—
Cera Japonica . . .	14·00	69·80
Cera Myrica Quercifolia	16·16	53·62
Cera Myrica Cerifera .	7·16	41·62
Cera Myrica ? .	19·88	68·70
Cera Bahia*	9·70	3·32
Cera Brasiliensis . .	3·25	5·04

The quantitative experiments show that, with the exception of Bahia wax, the solubility in petroleum spirit is much greater than in alcohol.

From the quantitative results it is evident that the behaviour of the samples of wax under examination with chloroform renders admission into two groups possible, viz., such as are completely soluble in that medium, as the Myrica and beeswax, and such as are only partially dissolved by it, as Brazilian and Bahiawax. Further their comportment to ether allows of a similar division, and here the Myrica wax alone is completely dissolved, beeswax and Bahia-wax on the other hand only partially. The effect produced by the addition of acetate of lead solution to the alcoholic solutions can also be made use of, as a means of distinguishing the various varieties of wax, since Brazilian and Bahia-wax are not rendered turbid, whilst the contrary is the case with all the other samples, in some of which the cloudiness disappears on warming, in others it does not.

These peculiarities allow of the several varieties of wax being well distinguished from one another, and the following scheme will, I think, be found to answer that purpose.

A sample of the wax to be examined is heated with ten times as much chloroform to boiling, and, when completely dissolved, cooled in cold water.

I. The chloroformic solution remains clear after cooling.

A. Ether dissolves completely.

(*a*) Alcoholic solution of ferric chloride gives with the alcoholic solution of the wax a precipitate insoluble on heating.

Wax from Myrica quercifolia.

(*b*) Ferric chloride colours the alcoholic solution black.

Wax from an undetermined species of Myrica.

(*c*) Ferric chloride colours brownish but gives no precipitate.

Wax from Myrica cerifera.
Wax from Orizaba.

B. Ether dissolves only a part—

A sample is boiled with ten times the quantity of alcoholic potash solution till saponified and the soap heated with 100 volumes of water.

* Ether dissolved 10·52 per cent. of this sample.

(*a*) The soap is completely soluble.

Japanese wax.

(*b*) The soap is partially soluble.

Beeswax; African beeswax.

II. The chloroformic solution becomes cloudy on cooling.

A. Alcoholic solution of acetate of lead gives with the alcoholic solution of the wax, after a few minutes' standing, a cloudiness.

Wax from stick-lac.

B. Alcoholic solution of acetate of lead gives no cloudiness.

(*a*) The ethereal solution of the wax becomes cloudy on the addition of an equal volume of alcohol.

Brazilian and Carnauba wax.

(*b*) The ethereal solution remains clear.

Bahia wax.

Dorpat, Russia.

THE CLASS OF TROPEINES AND THE ISOMERISM OF ATROPINE AND HYOSCYAMINE.

BY A. LADENBURG.

The success of the author in preparing atropine artificially by treating a tropate of tropine with dilute hydrochloric acid induced him to believe that other similar bases might perhaps be obtained by treating other tropine salts in the same way. This expectation has been fulfilled, and it has been found possible to prepare a whole class of alkaloids, derived as atropine was from tropine, and to them he has given the name of tropeines. Three of these bodies have been described by the author.*

Salicyltropein is prepared by treating salicylate of tropine for some time with dilute hydrochloric acid on a water-bath, and precipitating the solution with potassium carbonate. The oil that separates solidifies after a time in handsome lamellæ, which are filtered, pressed and dissolved in a little alcohol. Upon adding water to this solution an oil separates that quickly crystallizes. The salicyltropeine is thus obtained in white lamellæ, having a silky lustre, melting between 57° and 60° C., difficultly soluble in water, but very freely in alcohol. It is a strong base, and is easily soluble in dilute acids. Analysis gave figures corresponding to the formula $C_{15}H_{19}NO_3$, and it is therefore probably formed similarly to atropine, according to the equation:—

$$C_8H_{15}NO + C_7H_6O_3 = C_{15}H_{19}NO_3 + H_2O.$$

The hydrochlorate of this base crystallizes from water in fine shining needles. An aqueous solution of this salt gives with platinum chloride a precipitate of microscopic needles, difficultly soluble in hot water; with gold chloride a yellow crystalline double salt; with picric acid an amorphous precipitate; with iodide of mercury and potassium a white caseous precipitate, and with tannic acid in neutral solution a white precipitate readily soluble in hydrochloric acid. Iodine in iodide of potassium causes a separation of a brown oil.

Salicyltropeine is a weak poison, but herbivorous animals appear to be little affected by it. It has no action on the pupil of the eye.

Oxytoluyltropeine or Homatropine is readily obtained by a similar treatment of amygdalate of tropine. Upon treatment of the hydrochloric solution with potassium carbonate an oil separates that does not solidify; this is removed with chloroform, and remains fluid after distillation of the solvent. It is further purified by dissolving in dilute hydrochloric acid, and precipitating it as a gold double salt or picrate, both of which compounds can be obtained perfectly pure by recrystallization from hot water. The gold salt, $C_{16}H_{21}NO_3,HCl,AuCl_3$, usually separates as an oil, but quickly crystallizes, and is obtained after recrystallization from hot water in difficultly soluble handsome prisms. It yields the pure hydrochlorate of homatropine upon treating it with sulphuretted hydrogen. The picrate is precipitated in an oily or resinous condition, but soon crystallizes. It dissolves readily in hot water, from which it is obtained in yellow shining lamellæ, having the composition $C_{16}H_{21}NO_3,C_6H_2(NO_2)_3OH$. From the picrate the base is obtained by treating a saturated cold aqueous solution with potassium carbonate in excess, and shaking with chloroform; the chloroform solution is again agitated with solution of potassium carbonate to remove traces of picrate, then dried over potassium carbonate and distilled. The homatropine is always left as an oil, and has not yet been obtained in a crystalline form.

The following are the reactions of homatropine. The acid solution of the hydrochlorate gives with tannic acid no precipitate, with iodide of mercury and potassium a white caseous precipitate, with mercuric chloride a white oil. When treated with solution of iodine in iodide of potassium yellow crystals are formed and a black oil. In a concentrated solution platinum chloride produces an amorphous precipitate, and from the filtrate handsome needles are obtained upon evaporation.

Homatropine has the property of dilating the pupil of the human eye almost as energetically as atropine, and as a series of clinical ophthalmological experiments are said to have demonstrated that in many cases it is to be preferred to atropine, it may possibly attain some therapeutic importance.

Phthalyltropeine has been similarly prepared from phthallic acid, tropine and hydrochloric acid, but only in small quantity, and has been only imperfectly examined. The base, when pure, occurs in white felted needles, having a silky lustre, melting at 70° C., very difficultly soluble in water, but freely soluble in alcohol. Analysis gave results corresponding with the formula $C_{24}H_{32}N_2O_4$. Its reactions resemble those of atropine, from which, however, it differs in being more insoluble and in its platinum double salt crystallizing in beautiful needles.

The existence of the class of tropeines, some of which, like atropine, exercise an energetic mydriatic action, suggested the idea that the other natural alkaloids having a mydriatic action might also belong to them. The hypothesis was tested by a closer investigation of hyoscyamine.

Hyoscyamine in the pure state, according to the author, has not hitherto been known, although Merck of Darmstadt sends a nearly pure product into commerce. The author's experiments were made chiefly with a preparation obtained by himself from hyoscyamus and one obtained from Trommsdorff. All, however, contain the same body. The impure preparation was purified by conversion into a gold salt, recrystallizing from hot water, decomposing with sulphuretted hydrogen, and precipitating a hydrochloric acid solution with a strong solution of potassium carbonate. The separated base was dissolved in a little alcohol and again precipitated by the addition of water. This was repeated until the melting point of the product remained constant.

Hyoscyamine so purified is isomeric with atropine, as shown by the analyses of the base and of the gold salt.

	Calculated for $C_{17}H_{23}NO_3$.	Found.	Calculated for $C_{17}H_{23}NO_3$, $HCl,AuCl_3$.	Found.
C	70·59	70·47	32·48	32·68
H	7·95	8·24	3·82	4·09
N	4·84	4·96	—	—
Au	—	—	31·23	30·89

But that hyoscyamine and atropine are not identical would appear from the following observations made by the author: hyoscyamine forms smaller and less perfect crystals than atropine; it melts at 108·5° C., atropine at 113·5. The gold salt of hyoscyamine when first precipitated is usually oily, but solidifies much more readily than that of atropine, and crystallizes from water in

* *Berichte d. deutsche chemische Gesellschaft*, xiii., 106.

handsome lamellæ that after drying show a beautiful golden lustre, which is not the case with the atropine gold salt. The latter melts at 135° C., whilst the hyoscyamine gold salt commences to melt at 159° C.

The investigation of this subject was then extended to the decomposition products, and the results have been published in a second paper.* Hyoscyamine was heated to 60° C. with an aqueous solution of crystallized baryta, in which way complete decomposition was very quickly effected. The resulting solution was freed from baryta by means of carbonic anhydride, then acidulated with hydrochloric acid and shaken with ether. The acid obtained from this ethereal solution had a great similarity to tropic acid, of which it also possessed the composition, and the following facts favour the identity of the two acids.

Hyoscinic acid melts at 116°—117° C.; the purest tropic acid at 117°—118° C.; both crystallize from water by slow evaporation in tables. Aqueous solution of hyoscinic acid is not attacked in the cold by a 5 per cent. solution of potassium permanganate, but when warmed a distinct odour of bitter almonds is at once given off. The oxidizing solution was added until this smell had disappeared and the colour of the permanganate remained constant on warming; the liquid was then filtered and the filtrate treated with sulphurous acid. The resulting turbid liquid was shaken with ether and the ethereal solution evaporated, when there was left a colourless crystalline acid, which when recrystallized from water melted at 120° and was benzoic acid. Tropic acid behaved similarly. Further 1 gram of hyoscinic acid was boiled during seven hours with 2 grams of barium hydrate in a concentrated aqueous solution, and then precipitated with hydrochloric acid. A well crystallized acid separated, which when recrystallized from dilute alcohol melted at 105°—106° C. and had entirely the appearance of atropic acid. The analysis also corresponded to the formula of atropic acid, $C_9H_8O_2$.

	Found.	Calculated.
C	73·01	72·97
H	5·54	5·41

In the same way Fittig has converted tropic acid into atropic acid, the melting point of which is given by Kraut as 106·5° C.

Notwithstanding this correspondence Herr Ladenburg does not hold that the identity of tropic acid with hyoscinic acid has yet been proved beyond doubt, although very probable. Hyoscine, the base obtained from hyoscyamine by decomposition with baryta, also stands very near to tropine. To prepare the hyoscine the residue after the removal of the hyoscinic acid was evaporated, supersaturated with potash, warmed and then again shaken with ether. The ethereal solution was dried by means of potassium carbonate and the ether distilled off. There remained an oil very quickly solidifying to crystallization. The yield from 12 grams of hyoscyamine,—about 3 grams,—was submitted to distillation; it passed over constant at 229° C., that is at the temperature at which tropine boils. The distilled oil solidified again pretty readily, and was obtained by crystallization from ether in colourless tables, which in the air gradually become slightly yellow coloured. The analysis of this substance gave figures corresponding to a hydrated tropine, perhaps to the formula $C_8H_{15}NO,\frac{1}{2}H_2O$, resembling those previously found by Kraut†. The melting point of this substance, however, is essentially lower than that of pure tropine, namely, 47°—50° C.; anhydrous tropine, according to Kraut, melting at 61·5°. But the author states that he has repeatedly found a melting point of 50° C. in a distilled tropine prepared from atropine, whilst in other preparations he has found a melting point 10° or 12° higher. Probably, he thinks, this lowering of the melting point is dependent upon the amount of hydration, and experiments are being made with a view of clearing up this point. At any rate the melting point of tropine is not a sufficiently defined and characteristic property which can be used in the comparison with other similar bases.

That hyoscine possesses the same composition as tropine, and has not, as stated by Hohn and Reichardt, the formula $C_6H_{15}N$, the author considers to be shown by the analysis of the double platinum salt, which is tolerably easily soluble in water, and can be obtained from it in large orange-yellow prisms.

	Found	Calculated for $(C_8H_{15}NOHCl)_2PtCl_4$
C	27·65	27·67
H	4·78	4·61
Pt	28·00	28·36

The platinum double salt shows also in its other properties very great similarity to the alike constituted tropine compound. Of the latter Kraut says that it forms regular crystals, sometimes, however, monoclinic, when the tropine has been derived from atropine by decomposition with hydrochloric acid, whilst according to Lossen the crystals belong to the rhombic, probably also to the klinorhombic, system. The measurement of the tropine and hyoscine platinochlorides is in progress and the results will be published. It only remains to add that the picrate and the gold salts of hyoscine are obtained and appear exactly like the corresponding tropine salts, so that at present no essential difference has been established between these two bases.

So far as the facts are at present known, there are three possibilities by which the difference between atropine and hyoscyamine, undoubtedly, in the author's opinion, proved to exist, can be explained:—

(1) That hyoscinic acid is different from tropic acid.

(2) That hyoscine is different from tropine.

(3) That the decomposition products of atropine and hyoscyamine are identical, but that the components in the two alkaloids are differently combined, so that their isomerism would be comparable to that between oil of gaultheria and methylsalicylic acid.

At present, however, the author looks upon all three hypotheses as equally improbable, and he expresses his gratification at having discovered a method by which he expects to definitely settle this question. Meanwhile the isomeric relations between atropine and hyoscyamine appear to be the more interesting from the fact that it is claimed that in another investigation the identity of duboisine and daturine with hyoscyamine has been demonstrated.

FATTY MIXTURES.*

BY R. ROTHER.

Emulsions.—In a former paper (*Pharmacist*, February, 1872)† the writer proposed a method for the preparation of emulsions, and advanced certain views of their formation. Subsequently a more extended experience of the process, and a closer observation of the principle involved, did not lead to any material change in its execution or modification of the views. It appears that the underlying principle was correctly conceived, enunciated and applied. On this occasion the writer will, therefore, simply supplement the operation with a few auxiliary suggestions, and further extend and elucidate the theoretical view. An ample flat-bottomed mortar and corresponding pestle should always be used. After a long and successful experience, the writer has adopted the use of powdered gum arabic in all cases where mucilage is designated, employing it in the proper quantity indicated, and abandoning the use of mucilage as a definite preparation ready made: the proneness of mucilage to decompose in the absence of otherwise objectionable preservatives,

* From the *Pharmacist*, January, 1880.

† *Pharm. Journ.* [3] ii. 901.

and the various advantages of powdered gum when properly used, having led to the change. In its application the powdered gum is mixed with from once to twice its weight of water, according to the nature of the oil; if this is thick and viscid, the mucilage must in a measure correspond; the converse is necessary where the oil is thin and mobile. Beyond a certain density, that is with a mucilage which is too thin, no emulsification can be effected. As a general rule, a viscid oil is more easily emulsified than another of an opposite nature; hence, when both a viscid and a mobile oil are compounded in the same mixture the operation is best performed by mixing them previous to their emulsification. However, beyond a certain degree of viscidity, approaching the solid state, emulsification is rendered more difficult. The incipient point of an emulsion is the most difficult stage to attain, and for this reason a dense ready formed emulsion is the most prompt and efficient, and, within certain indefinite limits, constant emulsifier. For this reason the yelk of eggs, with a needless addition of glycerin under the name of glyconine, has of late achieved considerable popularity as an effective emulsifacient. The main point, therefore, consists in getting a perfect emulsion formed at some particular place, and then reaching out from this as a centre, and bringing all of the oil, added by degrees, gradually within the converting vortex. During this operation it is necessary to add small amounts of water from time to time, in order to maintain a certain uniformity, not only in the required viscidity, but also in the relative proportion of the water to the oil. If the mortar is sufficiently large and broad bottomed much oil may be poured in at once, and even partially mixed by several wide sweeps of the pestle, to considerable advantage, providing the central motion of the pestle be immediately resumed. But if the amount of oil added at one time is unduly in excess of the conditions above noted, or if the wide sweep of the pestle be too long continued, the mixture at once assumes a characteristic broken appearance, from which precarious state the emulsion may often be retrieved by the addition of a little water and confining the trituration to a narrow range. However, if the disarrangement has so far progressed that this manipulation fails to recover the normal form, this is promptly secured by adding the whole of the oil to the disintegrated emulsion, mixing all, pouring the mixture back into the graduated measure, and then again adding it as before to a small quantity of new mucilage, and finishing the process in the usual manner. Great facility and speed in the manipulation, as also greater certainty in the result, may be had by slowly revolving the mortar with the left hand towards the movement of the pestle from the right. When sugar or alkalies are prescribed in an emulsion they must not be introduced before the emulsion is finished, since their presence either retards or entirely vitiates the proper result. Strongly alcoholic mixtures interfere with or destroy the emulsion by precipitating the gum. Alcohol, however, does not interrupt or prevent emulsification if diluted so as not to precipitate the gum. Weak alcohol may, therefore, replace water as an adjuvant in the process. Hence, when a strong alcoholic liquid is prescribed in an emulsion it must first be mixed with the aqueous components, and if such are not ordered in sufficient proportion no emulsion can be made.

The fundamental principle of emulsification consists in an extreme mechanical subdivision of the oil akin to pulverization. An emulsified oil bears the same relation to oil in mass as spray, or, more properly, foam does to water. The distinct globules or bubbles are kept asunder by an envelope or superstratum of water. In order to effect this condition, the first requisite consists in rolling the oil out, as it were, in excessively thin sheets and dashing these into shreds, which then coil into perhaps hollow globules with a coating of water. The next requirement is that the watery envelope should contain sufficient tenacity to maintain its form as it adheres to the oily fragments. As the pestle traverses the viscid mucilage the floating oil is drawn into the temporary gap, and immediately after, surrounded on all sides by a wall of tenacious fluid, it causes the oily sheet to be rolled up, broken and folded within itself, still environed by the mucilage. The next stroke of the pestle repeats the operation, and this may be continued as long as the required tenacity endures. Since a dense emulsion permits the more rapid motion of the oil sheet, consequently it facilitates and lessens the process.

Ointments.—Lard is, perhaps, one of the most variable and alterable substances handled by the pharmacist. Variable because of its lack of uniformity of composition as found in the market, probably greatly dependent upon the part of the animal from which it is derived and the manner of obtaining it; alterable because of its great tendency to change, not only in form, through the varying temperature of the seasons, but also in composition from fermentation and oxidation. White wax and spermaceti are also in a measure variable, being always more or less of a rancid character. The various fixed oils used in pharmacy are also of an inconstant and changeable nature. The oil of mustard seed, which was once so good, has of late years become most execrable, doubtless owing to a lack of care exercised in its production, since the oil is mainly consumed in illumination.

During the hot summer months lard becomes more and more granular, then separates into distinct masses suspended in an oily medium, and eventually disintegrates into a slimy sediment of rounded granules of palmitin and an oily superstratum of olein holding palmitin in solution. Ointments prepared solely from lard without hardening additions fare mostly in a similar manner. In order to obviate this very annoying circumstance, the writer deems it advisable that, for summer consumption at least, such lard or ointment should be mixed with from one-sixth to one-eighth their weight of white of yellow wax, or a somewhat larger proportion of spermaceti, and, if necessary, treated with a proper quantity of benzoic acid or tincture of benzoin.

Ointment of potassium iodide almost invariably turns yellow, or even brownish, shortly after being made, from liberation of iodine, caused probably by the presence of oxyoleic acid. The German Pharmacopœia obviates this undesirable change by the incorporation of sodium thiosulphate equal in weight to one-twentieth of the iodide used. The officinal ointment of potassium iodide could therefore be properly prepared by dissolving one troy ounce of potassium iodide and thirty grains of sodium thiosulphate (formerly called sodium hyposulphite) in one fluid ounce of water, and gradually adding the solution to six troy ounces of lard (or lard and hardening as above), with constant stirring until the whole is thoroughly mixed. In all cases where a considerable proportion of some liquid is to be incorporated with a fat the liquid should be added to the fat by degrees and well mixed in before making the next addition. In cases where such mixtures are performed with a fused fat this should first be cooled to the point just short of congelation before the liquid is added.

Ointment of red and yellow mercuric oxide is rapidly discoloured, doubtless by the active agency of the previous ointment. Many remedies have been proposed to counteract this, but the writer has found none so useful as sodium thiosulphate, added in proportion of five grains to one ounce of ointment. It takes a long time for ointment so protected to change, and the alteration is readily traced from the top downward, showing that the absorption of oxygen goes as a cause hand in hand with the decomposition.

In a previous article (*Pharmacist*, August, 1872), the writer, in treating of ointments, dealt emphatically with the fact that glycerin, first thoroughly mixed weight for weight, added half at a time to certain pulverulent substances, compounded in various ointments, gives them the desirable smoothness not otherwise obtained. Since then the writer has, however, found that simply lard, used in the same manner and relative amount as glycerin, yields precisely the same result. It appears that if the dry powder is first well rubbed, even where it cakes somewhat, and then thoroughly triturated in a spacious broad-bottomed mortar with half its weight of lard, a tenacious mass is formed, which latter acts very similarly to the mucilage upon oils, in rendering the powder particles individually invisible and imparting that desirable homogeneity or smoothness. Since in these cases the preliminary mixture is very tenacious, and therefore somewhat difficult to work, it having nearly the consistency of a soft pill mass, more than three or four ounces cannot be handled to advantage. Therefore, in such instances, the whole material, according to the amount, is divided into several batches. Then, when the preparatory mixture has been effected, the remaining lard or mixture is fused and gradually added to and mixed with the first product.

Ointment of zinc oxide is made by triturating two troy ounces of oxide of zinc to a uniform powder, then adding one troy ounce of lard, rubbing the mixture thoroughly, and finally adding by degrees eleven troy ounces of lard (or hardened mixture) previously fused, and then thoroughly incorporating the whole, stirring afterward occasionally, if required, until the ointment stiffens. Tincture of benzoin may also be added if desired.

Ointment of veratria, when made according to the officinal direction, by first dissolving the veratria in alcohol, is difficult to prepare, because veratria, instead of dissolving promptly, agglutinates into masses that firmly adhere to mortar and pestle, and become more and more troublesome to manipulate as the alcohol evaporates. By the above proposed general process for ointments of powdered substances the annoying features of the officinal process are obviated, and an elegant uniform mixture is most easily attained.

Cerate of cantharides has been the fertile cause of much comment as to what process of preparing it is the most advantageous in securing invariably an efficient product. On several occasions within recent years the writer pointed out the result, as a final conclusion, that a comparatively high heat is the prime requisite for the preparation of an invariably active cerate. A water-bath heat, as the Pharmacopœia directs, is wholly inefficient, so much so that an otherwise most active cantharides will frequently not yield a reliable product. The writer has formed the conclusion, after many trials, that a cerate, in order to answer the requirements, must be prepared by subjecting the mixture to a much higher temperature than that of boiling water, and for a longer period. There is apparently no danger of damaging the product, unless a scorching heat is applied, but even in such a contingency no harm to the preparation would result. Every cerate which the writer has prepared at high temperatures has invariably bristled the second day after its preparation with brilliant cantharidin needles, the surest sign of activity next to a practical test.

Suppositories.—In a former article (*Pharmacist*, October, 1872), the writer stated that for making suppositories pure oil of theobroma is not near so good a menstruum as a mixture composed only two-thirds of the oil and one-third spermaceti. This mixture has the property of contracting more, and, whilst preserving a low fusion point, congealing more rapidly. But in that connection the writer pointed out the important fact that for the purpose of compounding soft extracts properly in suppositories the addition of a certain proportion of some dry powder, preferably starch, is almost imperative. Numerous occasions since have invariably borne out this fact and further shown its great advantages. The chilling of the moulds is also considered important. But if these are first dusted, also preferably with starch, so low a temperature will not be needed, and less loss of time incurred.

THE PREPARATION OF GALLIC ACID.*

BY PAUL WEBER, PH.G.

According to the U. S. Pharmacopœia, 36 troy ounces of Aleppo galls, in fine powder, are mixed with a sufficient quantity of water, and allowed to stand for a month, until all tannic acid has been converted into gallic acid through the absorption of oxygen and escape of carbonic acid gas, as the U. S. Pharmacopœia says.

The wording in the formula is very emphatic: "let stand for a month," but the quantity of the product is very variable. Who can determine, whether the conversion from tannic into gallic acid has been completed within a month's time or not? Why not give a mode of preparation which will insure the highest attainable quantity of gallic acid? Or, if a limited amount of time is prescribed, why not note a certain degree of temperature at which fermentation is to go on? Different samples of the same lot of nutgalls will give variable amounts of gallic acid when subjected to different temperatures for the same length of time. To prove this I powdered 25 ounces of nutgall, and divided this into four equal parts, prepared them as the Pharmacopœia directs, and placed them aside, occasionally stirring, for one month.

Sample 1.—6 oz. 2 dr.; temperature constant, 60—64° F.; time one month. Amount gallic acid, 6 dr. 24 grains.

Sample 2.—6 oz. 2 dr.; temperature 72—82° F.; time one month. Amount gallic acid, 8 dr. 15½ grains.

Sample 3.—6 oz. 2 dr.; temperature 96—100° F.; time one month. Amount gallic acid, 9 dr. 84 grains.

Sample 4.—6 oz. 2 dr.; temperature 110—114° F.; time one month. Amount gallic acid, 11 dr. 14 grains.

Of these same galls I powdered again 25 ounces. The first portion, 12 oz. 4 dr., I prepared according to the Pharmacopœia, and set it aside at a temperature of 85—90° F. At the expiration of three weeks, I took a filtered portion, and added to it a solution of Russian isinglass, and obtained a voluminous precipitate, showing that the conversion had not fully set in. After a lapse of four weeks I added again a solution of isinglass, when there was still a copious precipitate, but not quite as dense as the first. After thirty-five days, the precipitation became somewhat transparent in appearance. At the termination of the forty-first day, there was still a turbidity after the addition of a solution of isinglass, so light, however, that I considered the conversion practically completed. I now passed on to the second stage of the process, expressing, boiling the residue with water, and filtering through animal charcoal.

Sample 5.—12 oz. 4 dr.; temperature 85—90° F.; time 41 days. Amount gallic acid, 3 oz. 38 grains.

The second 12 oz. 4 dr. of galls I used for the preparation of tannic acid, and obtained 4 oz. 54 grains. If we now calculate from the amount of tannic acid actually obtained the obtainable amount of gallic acid, we will see that the actual yield of gallic acid very nearly corresponds with the theoretical amount; tannic acid being a glucoside, it will, by the aid of the ferment contained in the galls, and in the presence of water, split up into gallic acid and sugar. The sugar is ultimately converted into grape sugar, and thence into carbonic acid and alcohol.

Now if we calculate the amount of gallic acid obtainable from 4 ℥ 54 grains (or 1974 grains) of tannic acid, the result is 3 oz. 54 grains.

It will be seen from this that the amount of gallic acid obtainable from any given quantity of nutgalls, according to the U. S. process, is very indefinite. The formula for gallic acid should read: Take of nutgalls, in fine powder, 36 troy oz., purified animal charcoal, distilled water, each a sufficient quantity. Mix the nutgalls with sufficient water to form a thin paste, and set aside in a shallow porcelain vessel in a warm place. Stir occasionally, adding a little water from time to time, sufficient to

* Abstract of a thesis presented to the College of Pharmacy of the City of New York. Reprinted from *New Remedies*, February, 1880.

preserve the semi-fluid consistence. Try a small filtered portion, from time to time, with a solution of Russian isinglass. If no precipitate is formed, or only a slight turbidity, then the process is completed. Strain and follow further directions as laid down in the U. S. Pharmacopœia.

CASEIN AND THE ACTION OF RENNET.*

BY O. HAMMARSTEN.

Pure casein may be prepared by precipitating with acetic acid, care being taken to avoid excess of acid, dissolving the washed precipitate in alkali, so that the solution remains slightly acid, filtering from separated fats, reprecipitating several times by acetic acid, and washing with alcohol and ether. The casein thus prepared appears to be a weak acid, dissolving calcium and barium carbonates, and calcium phosphate. Salts appear to keep casein in solution, and this accounts for the fact that, in the precipitation of casein by acids, the amount obtained is not equivalent to the acid employed. Rennet, when it precipitates casein, appears to break it up into two albuminoids: one which is greatest in quantity is combined with calcium phosphate, and appears as cheese; the other (a peptone) remaining dissolved in the whey. For complete precipitation, the presence of calcium phosphate is necessary, and this accounts for the fact that dilute milk cannot be coagulated. The presence of calcium chloride also partly aids curdling, and one part of rennet ferment is capable of curdling 800,000 parts of casein.

THE INFLUENCE OF ELECTRIC LIGHT UPON VEGETATION AND ON CERTAIN PHYSICAL PRINCIPLES INVOLVED.†

BY C. WILLIAM SIEMENS, D.C.L., F.R.S.

The vast development of vegetation proves that dissociation is accomplished freely within the leaf-cells of plants, in which both water and carbonic acid are broken up in order that chlorophyll, starch and cellulose may be formed. It is well known that this reaction depends upon solar radiation; but the question may fairly be asked whether it is confined to that agency, or whether other sources of light and heat, which, in common with the sun, exceed the temperature of dissociation, may not be called into requisition, in order to continue the action of growth, when that great luminary has set or is hidden behind clouds?

About two years ago I mentioned to Sir Joseph Hooker, then President of the Royal Society, that I thought the electric arc might be found sufficiently powerful to promote vegetation, and that I should be willing to undertake some experiments on the subject if he could give me any hope of confirmative results. Sir Joseph Hooker gave me sufficient encouragement to induce me to follow up the subject, and I have since that time gradually matured a plan for conducting the experiment.

The apparatus which has been put up at Sherwood consists—(1) Of a vertical Siemens dynamo-machine, weighing 50 kilos, with a wire resistance of 0·717 unit on the electro-magnets. This machine makes 1000 revolutions a minute, it takes two-horse-power to drive it, and develops a current of 25 to 27 webers of an intensity of 70 volts. (2) A regulator or lamp, constructed for continuous currents, with two carbon electrodes of 12 millims. and 10 millims. diameter respectively. The light produced is equal to 1400 candles measured photometrically. (3) A motor, which at present is a three-horse-power Otto gas-engine, but which it is intended to supersede by a turbine to be worked by a natural supply of water, at a distance of about half a mile from the house.

My object in making these experiments was to ascertain whether electric light exercised any decided effect upon the growth of plants. For this purpose I placed the regulator in a lamp with a metallic reflector, in the open air, about two metres above the glass of a sunk melon house. A considerable number of pots were provided, sown and planted with quick-growing seeds and plants, such as mustard, carrots, swedes, beans, cucumbers and melons. The plants could then be brought at suitable intervals under the influence of daylight and electric light, without moving them, both falling upon them approximately at the same angle. The pots were divided into four groups.

1. One pot of each group was kept entirely in the dark.
2. One was exposed to the influence of the electric light only.
3. One was exposed to the influence of daylight only.
4. One was exposed successively to both day and electric light.

The electric light was supplied for six hours, from 5 to 11 each evening, all the plants being left in darkness during the remainder of the night.

In all cases the differences of effect were unmistakable. The plants kept in the dark were pale yellow, thin in the stalk, and soon died. Those exposed to electric light only showed a light green leaf, and had sufficient vigour to survive. Those exposed to daylight only were of a darker green and greater vigour. Those exposed to both sources of light showed a decided superiority in vigour over all the others, and the green of the leaf was of a dark rich hue.

It must be remembered that, in this contest of electric against solar light, the time of exposure was in favour of the latter in the proportion of nearly two to one, but all allowance made, daylight appeared to be about twice as effective as electric light. It was evident, however, that the electric light was not well placed for giving out its power advantageously. The nights being cold, and the plants under experiment for the most part of a character to require a hot moist atmosphere, the glass was covered very thickly with moisture, which greatly obstructed the action of the light, besides which, the electric light had to pass through the glass of its own lamp.* Notwithstanding these drawbacks, electric light was clearly sufficiently powerful to form chlorophyll and its derivatives in the plants.

These preliminary trials go to prove that electric light can be utilized in aid of solar light by placing it over greenhouses, but the loss of effect in such cases must be considerable. I, therefore, directed my observations, in the next place, to the effect of electric light upon plants, when both were placed in the same apartment. The plants under experiment were divided into three groups; one group was exposed to daylight alone, a second similar group was exposed to electric light during eleven hours of the night, and were kept in the dark chamber during the daytime, and the third similar group was exposed to eleven hours' day and eleven hours' electric light. These experiments were continued during four days and nights consecutively, and the results observed are of a very striking and decisive character, as regards the behaviour of such quick-growing plants as mustard, carrots, etc. The plants that had been exposed to daylight alone (comprising a fair proportion of sunlight) presented their usually healthy green appearance; those exposed to electric light alone were, in most instances, of a somewhat lighter, but, in one instance, of a somewhat darker hue than those exposed to daylight, and all the plants that had the double benefit of day and electric light far surpassed the others in darkness of green and vigorous appearance generally. A pot of tulip buds was placed in this electric stove, and the flowers were observed to open completely after two hours' exposure.

† Abstract of a paper read before the Royal Society on March 4. Reprinted from *Nature* for March 11, 1880.

* Professor Stokes has shown, in 1857, that the electric arc is particularly rich in highly refrangible invisible rays, a circumstance which seems to point to a great loss on passing those rays through glass.

Although the access of stove heat was virtually stopped the temperature of the house was maintained throughout the night at 72° F., proving that the electric lamp furnished not only a supply of effective light, but of stove heat also. No hurtful effect was, moreover, observed on the plants from the want of ventilation, and it would appear probably that the supply of pure carbonic acid resulting from the complete combustion of the carbonic electrodes at high temperature, and under the influence of an excess of oxygen, sufficed to sustain their vital functions. If the nitrogenous compounds which Professor Dewar has shown to be developed in the electric arc were produced in large quantities, injurious effects upon the plants must undoubtedly ensue, but it can be shown that in a well-conditioned electric lamp, with a free circulation of air round the carbon electrodes, the amount of these products is exceedingly small, and of a different nature than is produced in a confined space.

These experiments are not only instructive in proving the sufficiency of electric light alone to promote vegetation, but they also go to prove the important fact that diurnal repose is not necessary for the life of plants, although the duration of the experiments is too limited perhaps to furnish that proof in an absolute manner. It may, however, be argued from analogy, that such repose is not necessary, seeing that crops grow and ripen in a wonderfully short space of time in the northern regions of Sweden and Norway, and Finland, where the summer does not exceed two months, during which period the sun scarcely sets.

The next step in the course of these experiments was to remove the electric lamp into a palm house, constructed of framed glass, which was 28 feet 3 inches long, 14 feet 6 inches wide, and averaging 14 feet 6 inches (8·62 m. × 14·42 m. × 4·42) in height. In the centre of this house a banana palm and a few other small palm trees are planted, the sides of the house all round being occupied with a considerable variety of flowering plants. The electric light was fixed as high as practicable at the south corner of the house, in order that its rays might fall upon the plants from a direction and at an angle coincident with those of the sun during the middle of the day. The temperature of the house was maintained at 65° F., and the electric lamp was kept alight from 5 p.m. to 6 a.m. for one week, from February 18 to February 24, excepting Sunday night. The time was hardly sufficient to produce very striking effects, but all the plants continued to present a healthy appearance. Of three Alicante vines, the one nearest the electric light made most progress, and the same could be said of the nectarines and roses. It was observed that other plants, such as geraniums, continued to exhibit a vigorous appearance, notwithstanding the heat of the place. This experiment is of importance in showing that the electric light, if put into conservatories or greenhouses, does not injure the plants, but rather improves their appearance and growth. The leaves assume a darker and more vigorous appearance, and it seems that the colouring of the flowers becomes more vivid, but a further period of time is necessary to establish this observation absolutely.

I decided to try the effect of electric light as a means of promoting growth in the open air and under glass at the same time.

The regulator was put back into its first position, 2 metres above the ground, with a sunken melon house on one side, and a sunken house containing roses, lilies, strawberries, and a variety of other plants on the other. The space of ground between these, about 1 metre broad and 7 metres long, was covered with boxes sown with early vegetables, including mustard, peas, beans, and potatoes, and in order to prevent cold winds from injuring the plants, low protecting walls were put up across the openings of the passage between the two houses.

Some weeks must elapse before any absolute results can be given, but growth is evidently promoted under all these various circumstances. In order to test this clearly, a portion of the plants both under glass and in the open air are shaded from the electric light without removing them from their position of equal temperature and exposed to solar light during daytime. The effect upon the flowering plants is very striking, electric light being apparently more efficacious to bring them on than daylight. Although the amount of heat given off from the electric arc is not great compared with a gas flame (giving off its products of combustion), yet the rays of intense heat of the arc counteract that loss of heat by radiation from the leaves into space, which during a clear night causes hoar frost. For this reason I expect that electric light may be usefully employed in front of fruit walls, in orchards, and in kitchen gardens, to save the fruit-bud at the time of setting; and in this application electric light will probably be found a useful agent, not only to promote rapid growth, but to insure a better yield of fruit.

The experiments seem to lead to the following conclusions:—

1. That electric light is efficacious in producing chlorophyll in the leaves of plants, and in promoting growth.

2. That an electric centre of light, equal to 1400 candles, placed at a distance of 2 metres from growing plants, appeared to be equal in effect to average daylight at this season of the year, but that more economical effects can be attained by more powerful light centres.

3. That the carbonic acid and nitrogenous compounds generated in diminutive quantities in the electric arc produce no sensible deleterious effects upon plants inclosed in the same space.

4. That plants do not appear to require a period of rest during the twenty-four hours of the day, but make increased and vigorous progress if subjected during daytime to sunlight and during the night to electric light.

5. That the radiation of heat from powerful electric arcs can be made available to counteract the effect of night frost, and is likely to promote the setting and ripening of fruit in the open air.

6. That while under the influence of electric light plants can sustain increased stove heat without collapsing, a circumstance favourable to forcing by electric light.

7. That the expense of electro-horticulture depends mainly upon the cost of mechanical energy, and is very moderate where natural forces of such energy, such as waterfalls, can be made available.

Since writing the above my attention has been drawn to an article in *Nature*, vol. xxi., p. 311, giving interesting observations by Dr. Schübeler, of Christiania, on "The Effect of Uninterrupted Sunlight on Plants in the Arctic Regions." These observations fully confirm the conclusion indicated by my experiments with electric light. Not only are plants able to grow continuously, according to Dr. Schübeler, but when under the influence of continuous light, they develop more brilliant flowers and larger and more aromatic fruit than under the alternating influence of light and darkness, whereas the formation of sugar appears to be dependent chiefly upon temperature.

It would follow from these observations, that with the aid of stoves and electric light, fruit, excelling both in sweetness and aroma, and flowers of great brightness, may be grown without solar aid. Dr. Schübeler mentions that in removing an acacia plant from the dark, and placing it under the influence of the Arctic midnight sun, the leaves opened slowly, and it is interesting to observe that the same effect took place when an *Acacia Lophantha* was placed (in the open air) under the influence of my midnight lamp.

In illustration of the subject of the foregoing paper, Dr. Siemens is reported to have exhibited to his audience a pot of tulips in bud which under the electric light were brought into full bloom in forty minutes.

The Pharmaceutical Journal.

SATURDAY, MARCH 20, 1880.

CORPORATIONS AND THE PHARMACY ACT.

THE decision of the Court of Appeal in respect of the litigation between the Pharmaceutical Society and the London and Provincial Supply Association has once more lent approval to the view which regards the pharmacist as being a simple trader in drugs, who is to face the free trade tendencies of the age without any show of favour on account either of special qualification required from him or of extraordinary necessities for securing the interests of the public. According to this decision, co-operative stores and associations analogous to them are held by the Lords Justices to lie outside the purview of the Pharmacy Act, and in the opinion of some persons the reasons for this holding recommend themselves to common sense. Such, at any rate, is the view put forward by our leading journal, and its enunciation in that quarter goes far to endorse the opinion we expressed last month as to the position in which the question then stood. From a strictly legal point of view the Lords Justices read the Act in such a way that they came to the conclusion that the word "person" as used in that Act is not to be taken to include corporations unless some cogent reason to the contrary is to be deduced from the scope and purport of the Act.

Lord Justice BRAMWELL specifies in detail the several considerations which lead him to regard corporations as being outside the law. He admits that the term "person" may include corporation, but having regard to the fact that when the Legislature made a special interpretation that "person" should be male and female, plural and singular, etc., it did not include "corporation," and that in the way statutes are now drawn "corporation" is always named when it is meant, he expresses himself as reluctant to hold that in any particular statute "person" includes "corporation," unless there is strong reason to do so. In the case in question, he holds there is no such reason, but, as he considers the contrary. Lord Justice BAGGALLAY agrees with him in this, subject, however, to the very important qualification of admitting, as of necessity, that if it be clear from the general scope and purport of an Act of Parliament that a certain act, viz., the selling, dispensing, or compounding of poisons, is or might be within the mischief intended to be guarded against, and further, that if by extending the meaning of the word "person" in such an Act so as to include corporation, the necessary protection against that mischief would be provided, such an interpretation might and ought to be adopted. Lord Justice THESIGER assents only with greater qualification to the view of Lord Justice BRAMWELL, and, as he says, "not without doubt," whether in regard to the providing for the safety of the public, which was the object of the Pharmacy Act, the judgment of the Court below might not be supported upon the ground that the object and scope of the Act peremptorily require corporations to be included within the term "person."

This diverse consideration of what is due to the "interests of the public" constitutes the difference between the several judgments of the three judges. Lord Justice BRAMWELL, with a manifest leaning to free trade in its entirety, seems to think public interests of little account unless they can protect and take care of themselves. Lord Justice BAGGALLAY, retaining still some lingering perception that in the matter of poisons prevention is better than cure, seeks refuge in the belief that the protection intended to be given to the public is sufficiently secured in the case of a corporation keeping open shop for selling, dispensing and compounding of poisons, by the presence of a qualified assistant or manager of the business, since in his view the seller referred to in the first section of the Act is the actual seller, and not the individual or corporation on whose behalf the sale is made. Hence he concludes that so far as the interests of the public are concerned all the requirements of the Pharmacy Act are satisfied by the provision of a qualified assistant. Lord Justice THESIGER, however, is not by any means satisfied that this is the case, and he prefers not to give a definite opinion upon the point whether the individual members of a corporation—as directors or otherwise—would not be liable, and that in this way the mischief intended to be provided against would not be without a remedy, even though a corporation as a separate entity be not liable to the penalty provided for in the Act.

Having regard to these very important qualifications of the assent given by two of the judges to the decision that the appeal should be allowed and the judgment of the Court below reversed, we cannot agree with the statement made by the *Times* that the judgment delivered the other day at Westminster sets this matter at rest. On the contrary, it still remains an open question to be decided, whether the Legislature intended or not to put an absolute veto upon the keeping open shop for the sale of drugs by trading companies. The absence from the Pharmacy Act of any express reference to such companies was considered by Lord Justice THESIGER as being difficult to account for consistently with the existence of such an intention, but when it is remembered that these companies had not, at the time of its passing, engaged in the trade in drugs and poisons no such difficulty will be apparent, nor will it even be necessary to suppose that the absence of any mention of such companies in the Act was a *casus omissus*.

The practical result of the appeal, notwithstanding the encouraging aspects to which we have alluded, is one that fully bears out the opinion we have expressed as to the gravity of the situation. Practically, the Pharmacy Act, 1868, may be said to have become, for the time, a dead letter, except in regard to the use of titles, and to the application of the seventeenth section. But the matter is not yet finally disposed of, and, in the further appeal to the House of Lords, the propriety of thus driving a coach and four through an Act of Parliament passed in the interest of the public, may be made to appear sufficiently questionable to secure its maintenance.

In connection with this view of the subject, it will not be out of place to recall to mind the history of the case upon which judgment has just been delivered for the third time.

The initiative step in this litigation was a proceeding, under the fifteenth section of the Pharmacy Act, against an individual who kept a grocery or general store, under the name of the London and Provincial Supply Association, for having committed an offence under the Pharmacy Act, by selling poisons without being duly qualified and registered as a chemist and druggist. The result was that Mr. Mackness, the proprietor of the business, paid the penalty of £5 and costs, intimating at the same time that in regard to the future it was his intention to take steps to terminate any violation of the law. This took place about the end of the year 1877, and when the result was reported to the Council in February, 1878, a letter had since been received from Mr. Mackness, stating that he had sold his business to the "London and Provincial Supply Association, *Limited*." In this way, the proceedings against a "person" developed into proceedings, under the seventeenth section of the Act, against an association of persons trading ostensibly as a limited liability company. Three summonses were heard before Mr. Newton, at the Marlborough Street Police Court, in March, 1878, and the question whether the word "person" in the Pharmacy Act included a corporation was then raised. Independently of that point, the magistrate decided in one case that the "London and Provincial Supply Association, *Limited*," had complied with the law, because the designation of the company and the place where its business was carried on was put on the label, together with the name of the actual seller of the poison. The summons was therefore dismissed.

The next step was the prosecution of the "London and Provincial Supply Association, *Limited*," under the fifteenth section of the Act, in the Bloomsbury County Court, judgment being given in favour of the defendants upon the ground that no offence was committed by the company so long as the business was conducted on behalf of the company by a duly qualified chemist and druggist.

The appeal from this decision was heard by the Lord Chief Justice and Mr. Justice Mellor, with the result that they reversed the judgment of the County Court Judge, one of the main reasons for doing this being the opinion that no association of persons should be free to do that which in their individual capacity would unquestionably be an offence.

But the Protean tendencies of Mr. Mackness were by no means exhausted by his metamorphosis into a "company, limited," and on the late hearing of the appeal before the Lords Justices he figured as the apostle of co-operation—the representative of the "stores." The policy of Mr. Wills in associating his client's attack upon the Pharmacy Act with the proceedings of co-operative stores cannot be questioned as a matter of advocacy, though the facts of the case are somewhat inconsistent with this ingenious capture of the popular prejudice in favour of stores for his client's benefit.

In this way there has been a further development of the case against a limited liability company into a case between the Pharmaceutical Society and the co-operative stores, and thus a totally false aspect has been given to the action taken by the Society. In the further prosecution of the case by an appeal to the House of Lords it will be desirable to clear away the erroneous impression thus produced and to secure an unbiassed consideration of the question whether or not it is expedient for the safety of the public that the provisions of the Pharmacy Act should be respected.

THE ANNUAL DINNER.

A meeting, convened by public advertisement, was held at 17, Bloomsbury Square, on Wednesday, March 17, to make preliminary arrangements for the Ninth Annual Dinner of the Members of the Pharmaceutical Society and their friends.

At this meeting it was resolved:—(1). That the Dinner be held at Willis's Rooms, on Tuesday, May 18. (2). That the price of tickets be 30*s*. each, and that tickets be obtainable only from the Honorary Secretary.

The following were appointed a Committee to make and carry out the necessary arrangements:—The President, Messrs. Carteighe, Robbins, Taylor and Williams, and Professor Attfield. Mr. Richard Bremridge was appointed Honorary Secretary.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association will be held on Thursday next, 25th inst., at 8.30 p.m., when a paper will be read on the "Preparation of Tinctures," by Mr. W. Elboone. A report on Inorganic Chemistry will be made by Mr. C. H. Hutchinson, F.C.S., on the "Formulæ of some Inorganic Compounds."

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next meeting of the above Association will be held on Wednesday evening next, March 24, at 32a, George Street, when a paper will be read by Mr. W. Smart, "On the Growths and Functions of the Skin."

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The sixth meeting of the session was held in the library of the Association on Thursday evening, March 11, 1880, Mr. Councillor Stead, the President, in the chair.

Mr. C. H. Bothamley, Demonstrator and Assistant Lecturer on Chemistry at the Yorkshire College, delivered a lecture on "Flame." The lecturer commenced by defining flame as gas raised to incandescence by chemical combination, and then proceeded to consider the causes which determine its continuance. A brief sketch was given of the development of the Davy lamp, illustrated by photographs from Davy's original drawings. The structure of flame was next taken under consideration and attention drawn to series of analyses indicating the progress of combustion in various parts of the flame. The analyses showed that of the two principal constituents of a coal gas flame, hydrogen and marsh gas, the hydrogen diminished most rapidly in the early stages of combustion, whereas in the later stages the reverse is the case. The lecturer then discussed the various causes affecting the luminosity of different flames—(1) temperature; (2) the presence or absence of solid particles; (3) the specific gravity of the gases and vapours present; (4) the pressure under which combustion takes place. He pointed out that although the last two causes are generally classed together under the head "density," they are essentially different. In the one case the observed effect is due to a difference in the relative weights of the atoms concerned, their number in a given space remaining the same; in the other it is due to a difference in the number of atoms in a given space, their relative weights remaining the same. The researches of Stein and others have proved that the luminosity of ordinary gas and candle flames is mainly due to the presence of solid particles of carbon as originally supposed by Davy. The causes of the non-luminosity of the flames of mixtures of coal gas with air and various indifferent gases were also discussed. All flames containing carbon require to be raised to a certain temperature before the carbon separates in the solid state. By mixing the coal gas with indifferent gases, with air, or with carbon monoxide, the point of carbon separation is raised to a temperature higher than that actually attained by the flame, which is therefore non-luminous. By the addition of extraneous heat the temperature of the flame may be raised to the required point and it then becomes luminous.

At the close a cordial vote of thanks was accorded to the lecturer on the motion of Mr. T. B. Stead, seconded by Mr. P. Jefferson.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above, held on Wednesday evening, March 10, Mr. F. W. Branson in the chair, a paper was read by Mr. F. W. Collinson upon "Vegetable Foods, their Manufacture and Nutritive Values."

The author first made some general remarks concerning the characters of a food, and the difference between it and a medicine. He then showed how deserving vegetable diet was of its high position as human support, either judged from the composition of the body, or the requirements caused by the waste in physical processes. The various articles of vegetable diet were then enumerated, and divided into two clases, nitrogenous and carbonaceous, their nutritive values compared, and the modes of preparing them for human consumption described.

A discussion ensued supported by Messrs. Branson, Hardwick, Piper, Robinson and others.

A vote of thanks having been proposed by Mr. Piper, seconded by Mr. Phillips and carried, the meeting terminated.

ROYAL INSTITUTION OF GREAT BRITAIN.

Spectroscopic Investigation.*

BY JAMES DEWAR, M.A., F.R.S.,

Fullerian Professor of Chemistry, Royal Institution, etc.

(*Concluded from page* 677.)

When a tube containing cæsium chloride and sodium was observed, in the same way, the two dark lines in the blue were seen very soon after the heating began, and the more refrangible of them broadened out very sensibly as the temperature increased. The usual channelled spectrum of sodium was seen in the green and an additional channelling appeared in the yellow, which may be due to cæsium or to the mixture of the two metals. Indeed the cæsium chloride was not free from rubidium, and the dark lines of rubidium were distinctly seen in the violet. Metallic lithium acts on the chlorides of cæsium and rubidium, giving the same results as sodium.

It is remarkable that these absorption lines of cæsium coincide with the blue lines of cæsium as seen in the flame, not with the green line which that metal shows when heated in an electric spark of high density. It is to be observed, however, that when sparks from an induction-coil without a jar are taken between beads of cæsium chloride fused on platinum wires, a spectrum similar to the flame spectrum is seen, and it is only when a Leyden jar is used that the spectrum is reduced to a green line. In like manner both the violet lines of rubidium are reversed, and both these violet lines are seen when the spark of an induction coil, without jar, is passed between beads of rubidium chloride fused on platinum wires, though only one of them appears when a Leyden jar is used.

Mixtures of carbonate of cæsium with carbon, and of carbonate of rubidium with carbon, prepared by charring the tartrates, heated in narrow porcelain tubes, placed vertically in a furnace, gave sharp results. A small quantity of the cæsium mixture, introduced into a tube at a bright red heat, showed instantly the two blue lines reversed and so much expanded as to be almost in contact. The width of the dark lines decreased as the cæsium evaporated, but they remained quite distinct for a long time. A similar effect was produced by the rubidium mixture, only it was necessary to have the tube very much hotter, in order to get enough of violet light to see the reversal of the rubidium lines. In this case the two lines were so much expanded as to form one broad dark band, which gradually resolved itself into two as the rubidium evaporated. The reversal of these lines of cæsium and rubidium seems to take place almost or quite as readily as that of the D lines by sodium, and the vapours of those metals must be extremely opaque to the light of the refrangibility absorbed, for the absorption was conspicuous when only very minute quantities of the metals were present. The red, yellow, and green parts of the spectrum were carefully searched for absorption lines, but none due to cæsium or rubidium could be detected in any case. It is perhaps worthy of remark that the liberation of such extremely electro-positive elements as cæsium and rubidium from their chlorides by sodium and by lithium, though it is probably only partial, is a proof, if proof were wanting, that so-called chemical affinity only takes a part in determining the grouping of the elements in such mixtures; and it is probable that the equilibrium arrived at in any such case is a dynamical or mobile equilibrium, continually varying with change of temperature.

It is difficult to prevent the oxidation of magnesium

* Lecture delivered at the Weekly Evening Meeting of the Royal Institution of Great Britain, Friday, June 6, 1879.

in the iron tubes, and tubes wider than half an inch did not give satisfactory results. With half-inch tubes, the lines in the green were clearly and sharply reversed, also some dark lines, not measured, were seen in the blue. The sharpness of these lines depended on the regulation of the hydrogen current, by which the upper stratum of vapour could be cooled at will.

(1) The absorption spectrum of magnesium consists of two sharp lines in the green, of which one, which is broader than the other, and appears to broaden as the temperature increases, coincides in position with the least refrangible of the *b* group, while the other is less refrangible, and has a wave-length very nearly 5210. These lines are the first and the last to be seen, and were first taken for the extreme lines of the *b* group.

(2) A dark line in the blue, always more or less broad, difficult to measure exactly, but very near the place of the brightest blue line of magnesium. This line was not always visible, indeed rarely when magnesium alone was placed in the tube. It was better seen when a small quantity of potassium or sodium was added. The measure of the less refrangible edge of this band gave a wave-length of very nearly 4615.

(3) A third line or band in the green rather more refrangible than the *b* group. This is best seen when potassium and magnesium are introduced into the tube, but it may also be seen with sodium and magnesium. The less refrangible edge of this band is sharply defined, and has a wave-length about 5140, and it fades away towards the blue.

These absorptions are all seen both when potassium and sodium are used along with magnesium, and may be fairly ascribed to magnesium, or to magnesium together with hydrogen.

But besides these, other absorptions are seen which appear to be due to mixed vapours.

(4) Thus when sodium and magnesium are used together a dark line, with ill-defined edges, is seen in the green, with a wave-length about 5300. This is the characteristic absorption of the mixed vapours of sodium and magnesium; it is not seen with either vapour separately, nor is it seen when potassium is used instead of sodium.

(5) When potassium and magnesium are used together a pair of dark lines are seen in the red. The less refrangible of these sometimes broadens into a band with ill-defined edges, and has a mean wave-length of about 6580. The other is always a fine sharp line, with a wave-length about 6475. These lines are as regularly seen with the mixture of potassium and magnesium as the above-mentioned line (5300) is seen with the mixture of sodium and magnesium, but are not seen except with that mixture.

There is a certain resemblance between the absorptions above ascribed to magnesium, and the emission spectrum seen when the sparks of a small induction-coil, without Leyden jar, are taken between electrodes of magnesium.

The coincidences of the series of the solar spectrum hitherto observed have, for the most part, been with lines given by dense electric sparks; while it is not improbable that the conditions of temperature and the admixtures of vapours in the upper part of the solar atmosphere may resemble much more nearly those in our tubes.

It became a question of interest to find the conditions under which the same mixtures would give luminous spectra, consisting of the lines which had been seen reversed. On observing sparks from an induction-coil taken between magnesium points in an atmosphere of hydrogen, a bright line regularly appeared, with a wave-length about 5210, in the same position as one of the most conspicuous of the dark lines observed to be produced by vapour of magnesium with hydrogen in our iron tubes. This line is best seen, *i.e.*, is most steady, when no Leyden jar is used and the rheotome is screwed back so that it will but just work. It may, however, be seen when the coil is in its ordinary state and when a small Leyden jar is interposed; but it disappears (except in flashes) when a larger Leyden jar is used, if the hydrogen be at the atmospheric pressure. This line does not usually extend across the whole interval between the electrodes, and is sometimes only seen near the negative electrode. Its presence seems to depend on the temperature, as it is not seen continuously when a large Leyden jar is employed until the pressure of the hydrogen and its resistance is very much reduced. When well dried nitrogen or carbonic oxide is substituted for hydrogen this line disappears entirely; but if any hydrogen or traces of moisture be present it comes out when the pressure is much reduced. In such cases the hydrogen lines C and F are always visible as well. Sometimes several fine lines appear on the more refrangible side of this line, between it and the *b* group, which give it the appearance of being a narrow band, shaded on that side. Various samples of magnesium used as electrodes, and hydrogen prepared and purified in different ways, gave the same results.

In addition to the above-mentioned line, there is also produced a series of fine lines, commencing close to the most refrangible line of the *b* group, and extending with gradually diminishing intensity towards the blue. These lines are so close to one another that in a small spectroscope they appear like a broad shaded band. We have little doubt that the dark absorption line, with wave-length about 5140, shading towards the blue, observed in our iron tubes, was a reversal of part of these lines, though the latter extend much further towards the blue than the observed absorption extends.

Charred cream of tartar in iron tubes, arranged as before, gave a broad absorption band extending over the space from about wave-length 5700 to 5775, and in some cases still wider, with edges ill-defined, especially the more refrangible edge. By placing the charred cream of tartar in the tube before it was introduced into the furnace, and watching the increase of light as the tube got hot, this band was at first seen bright on a less bright background, it gradually faded, and then came out again reversed, and remained so. No very high temperature was required for this, but a rise of temperature had the effect of widening the band. Besides this absorption, there appeared a very indefinite faint absorption in the red, with the centre at a wave-length of about 6100, and a dark band, with a tolerably well defined edge on the less refrangible side, at about a wave-length of 4850, shading away towards the violet. A fainter dark band was sometimes seen beyond, with a wave-length of about 4645; but sometimes the light seemed abruptly terminated at about wave length 4850. It will be noticed that these absorptions are not the same as those seen when potassium is heated in hydrogen, nor do they correspond with known emission lines of potassium, although the first, which is also the most conspicuous and regularly visible of these absorptions, is very near a group of three bright lines of potassium. It seemed probable that they might be due to a combination of potassium with carbonic oxide. Potassium heated in carbonic oxide in glass tubes united readily with the gas, but the compound did not appear to volatilize at a dull red heat, and no absorption, not even that which potassium gives when heated in nitrogen under similar circumstances, could be seen. Induction sparks between an electrode of potassium and one of platinum in an atmosphere of carbonic oxide gave the usual bright lines of potassium, and also a bright band, identical in position with the above-mentioned band, between wave-lengths about 5700 and 5775. This band could not be seen when hydrogen was substituted for carbonic oxide. A mixture of sodium carbonate and charred sugar, heated in an iron tube, gave only the same absorption as sodium in hydrogen. There were also no indications of any absorption due to a compound of rubidium or of cæsium with carbonic oxide.

A mixture of barium carbonate, aluminium filings, and lamp-black, heated in a porcelain tube, gave two absorption lines in the green, corresponding in position to bright lines seen when sparks are taken from a solution of barium chloride, at wave-lengths 5242 and 5136, marked α and β by Lecoq de Boisbaudran. These two absorptions were very persistent, and were produced on several occasions. A third absorption line, corresponding to line δ of Boisbaudran, was sometimes seen, and on one occasion, when the temperature was as high as could be obtained in the furnace fed with Welsh coal, and a mixture of charred barium tartrate with aluminium was used, a fourth dark line was seen with wave-length 5535. This line was very fine and sharply defined, whereas the other three lines were ill-defined at the edges; it is, moreover, the only one of the four which corresponds to a bright line of metallic barium.

Repeated experiments with charred tartrates of calcium and of strontium mixed with aluminium gave no results; but on one occasion, when sodium carbonate was used along with the charred tartrate of strontium and aluminium, the blue line of strontium was seen reversed; and on another occasion, when a mixture of charred potassium, calcium, and strontium tartrates, and aluminium was used, the calcium line, with wave-length 4226, was seen reversed.

In order to command higher temperatures, experiments were made with the electric arc enclosed in lime, magnesia, or carbon crucibles.

In the first experiments thirty cells of Grove were employed; in the latter ones the Siemens arc from the powerful dynamo-machine belonging to the Royal Institution.

The electric arc in lime crucibles gives a very brilliant spectrum of bright lines, a copious stream of vapours ascending the tube. On drawing apart the poles, which could be done for nearly an inch without stopping the current, the calcium line with wave-length 4226 almost always appears more or less expanded with a dark line in the middle, both in the lime crucibles and in carbon crucibles into which some lime has been introduced; the remaining bright lines of calcium are also frequently seen in the like condition, but sometimes the dark line appears in the middle of K (the more refrangible of Fraunhofer's lines H), when there is none in the middle of H. On throwing some aluminium filings into the crucible, the line 4226 appears as a broad dark band, and both H and K, as well as the two aluminium lines between them, appear for a second as dark bands on a continuous background. Soon they appear as bright bands with dark middles; gradually the dark line disappears from H, and afterwards from K, while the aluminium lines remain with dark middles for a long time. When a mixture of lime and potassium carbonate was introduced into a carbon crucible, the group of three lines with wave-lengths 4254, 4434 and 4454 were all reversed, the least refrangible being the most strongly reversed, and remaining so longest, while the most refrangible was least strongly reversed and for the shortest time.

When aluminium was put into the crucible, only the two lines of that metal between H and K were seen reversed. The lines at the red end remained steadily bright.

When magnesium was put into a lime crucible, the *b* group expanded a little without appearing reversed, but when some aluminium was added, the least refrangible of the three lines appeared with a dark middle, and on adding more magnesium the second line put on the same appearance; and lastly, the most refrangible was reversed in like manner. The least refrangible of the three remained reversed for some time; and the order of reversibility of the group is that of refrangibility. Of the other magnesium lines, that in the yellowish-green (wave-length 5527) was much expanded, while the blue line (wave-length 4703) and a line still more refrangible than the hitherto recorded lines, with wave-length 4354, were still more expanded each time that magnesium was added.

The following experiments were made in carbon crucibles:—

With strontia the lines with wave-lengths 4607, 4215 and 4079 were all seen with dark lines in the middle, but no reversal of any strontium line less refrangible could be seen.

A mixture of barium and potassium carbonates produced the reversal of the lines with wave-lengths 5535 and 4933. When barium chlorate was dropped into a crucible the four lines with wave-lengths 4553, 4933, 5545 and 5518 were reversed.

To observe particularly the effects of potassium a mixture of lime and potassium carbonate previously ignited was thrown in. The violet lines of potassium, wave-length 4044, came out immediately as a broad black band, which soon resolved into *two* narrower dark bands having wave-lengths nearly 4042 and 4045. On turning to the red end the two extreme red lines were both seen reversed. No lines of potassium between the two extremes could be seen reversed, but the group of three yellow lines were all expanded, though not nebulous, and other lines in the green were seen much expanded.

Sodium carbonate gave only the D lines reversed, though the other lines were expanded, and the pairs in the green had each become a very broad nebulous band, and D almost as broad a black band. When sodium chlorate was dropped into a crucible, the pair of lines with wave-lengths 5681, 5687, were both momentarily reversed, the latter much more strongly than the former.

When a very little charred rubidium tartrate was put in, the two violet lines were sharply reversed, appearing only as black lines on a continuous light background. Turning to the red end, the more refrangible of the two lines in the extreme red (wave-lengths 7800) was seen to have a decided dark line in the middle, and it continued so for some time. The addition of more rubidium failed to cause any reversal of the extreme red line, or of any but the three lines already mentioned.

On putting lithium carbonate into the crucible, the violet line of lithium appeared as a nebulous band, and on adding some aluminium this violet band become enormously expanded, but showed no reversal. The blue lithium line (wave-length 4604) was well reversed, as was also the red line, while a fine dark line passed through the middle of the orange line. On adding a mixture of aluminium filings and the carbonates of lithium and potassium, the red line became a broad black band, and the orange line was well reversed. The green line was exceedingly bright, but not nebulous or reversed, and the violet line still remained much expanded, but unreversed.

Metallic indium placed in the crucible gave the lines with wave-lengths 4101 and 4509, and both were seen strongly reversed. No other absorption line of indium could be detected.

In some cases a current of hydrogen or of coal-gas was introduced into the crucibles by means of a small lateral opening, or by a perforation through one of the carbon electrodes; sometimes the perforated carbon was placed vertically, and we examined the light through the perforations. When no such current of gas is introduced, there is frequently a flame of carbonic oxide burning at the mouth of the tube. The current of hydrogen produces very marked effects. As a rule, it increases the brilliance of the continous spectrum, and diminishes relatively the apparent intensity of the bright lines, or makes them altogether disappear with the exception of the carbon lines. When this last is the case, the reversed lines are seen simply as black lines on a continuous background. The calcium line with wave-length 4226 is always seen under these circumstances as a more or less broad black band on a continuous background, and when the temperature of the crucible has risen sufficiently, the lines with wave-lengths 4434 and 4454, and next that with wave-length 4425, appear as simple black lines. So, too, do the blue and red lines of lithium, and the barium line of wave-length 5535, appear steadily as sharp black lines, when no trace of the other lines of these metals, either dark or bright, can be detected. Dark bands also frequently appear, with ill-defined edges, in the positions of the well-known bright green and orange bands of lime.

With sodium chloride, the pair of lines (5687, 5681) next more refrangible than the D group were repeatedly reversed. In every case the less refrangible of the two was the first to be seen reversed, and was the more strongly reversed, as has also been observed by Mr. Lockyer. But our observations on this pair of lines differ from his in so far as he says that "the double green line of sodium shows scarcely any trace of absorption when the lines are visible," while we have repeatedly seen the reversal as dark lines appearing on the expanded bright lines; a second pair of faint bright lines, like ghosts of the first, usually coming out at the same time on the more refrangible side.

Potassium carbonate gave, besides the violet and red lines which had been reversed before, the group, wave-lengths 5831, 5802 and 5872, all reversed, the middle line of the three being the first to show reversal. Also the lines wave-lengths 6913, 6946, well reversed, the less refrangible remaining reversed the longer. Also the group, wave-lengths 5353, 5338, 5319 reversed, the most refrangible not being reversed until after the others. Also the line wave-length 5112 reversed, while two other lines of this group, wave-lengths 5095 and 5081, were not seen reversed.

Using lithium chloride, not only were the red and blue lines, as usual, easily reversed, and the orange line well reversed for a long time, but also the green line was distinctly reversed; the violet line still unreversed, though broad and expanded. Had this green line belonged to cæsium, the two blue lines of that metal which are so easily reversed could not have failed to appear; but there was no trace of them.

In the case of rubidium, the less refrangible of the red lines was well reversed as a black line on a continuous background; but it is not easy to get, even from the arc in one of our crucibles, sufficient light in the low red to show the reversal of the extreme ray of this metal.

With charred barium tartrate, and also with baryta and aluminium together, the reversal of the line with wave-length 6496 was observed, in addition to the reversals previously described. The less refrangible line, wave-length 6677, was not reversed.

With charred strontium tartrate, the lines with wave-lengths 4812, 4831, and 4873, were reversed, and by the addition of aluminium, the line wave-length 4962 was reversed for a long time, and also the lines wave-lengths 4895, 4868.

On putting calcium chloride into the crucible, the line wave-length 4302 was reversed, this being the only one of the well-marked group to which it belongs which appeared reversed. On another occasion, when charred strontium tartrate was used, the line wave-length 4877 was seen reversed, as well as the strontium line near it. The lines wave-lengths 6161, 6121, have been seen momentarily reversed.

With magnesium, when a stream of hydrogen or of coal gas was led into the crucible, the line wave-length 5210, previously seen in iron tubes, and ascribed to a combination of magnesium with hydrogen, was regularly seen, usually as a dark line, sometimes with a tail of fine dark lines on the more refrangible side similar to the tail of bright lines seen in the sparks taken in hydrogen between magnesium points. Sometimes, however, this line (5210) was seen bright. It always disappeared when the gas was discontinued, and appeared again sharply on readmitting hydrogen. These effects were, however, only well defined in crucibles having a height of at least 3 inches above the arc.

On putting a fragment of metallic gallium into a crucible, the less refrangible line, wave-length 4170, came out bright, and soon a dark line appeared in the middle of it. The other line, wave-length 4031, showed the same effect, but less strongly.

Reviewing the series of reversals which have been observed, in many cases the least refrangible of binary groups is the most easily reversed, as has been previously remarked by Cornu.

Making a general summation of the results respecting the alkaline earth metals, potassium and sodium, having regard only to the most characteristic rays, which for barium may be taken as 21, for strontium 34, for calcium 37, for potassium 31, and for sodium 12, the reversals number respectively 6, 10, 11, 13 and 4. That is, in the case of the alkaline earth metals about one-third, and these chiefly in the more refrangible third of the visible spectrum, the characteristic rays remaining unreversed in the more refrangible part of the spectrum being respectively 2, 5 and 4.

The curious behaviour of the lines of different spectra with regard to reversal induced a comparison with the bright lines of the chromosphere of the sun, as observed by Young. It is well known that some of the principal lines of the metals giving comparatively simple spectra, such as lithium, aluminium, strontium, and potassium, are not represented amongst the dark lines of Fraunhofer, while other lines of those metals are seen, and an examination of the bright chromospheric lines shows that special rays highly characteristic of bodies which appear from other rays to be present in the chromosphere are absent, or are less frequent in their occurrence than others.

In the following table the relation between the observation on reversals and Young's on the chromospheric lines is shown:—

Lines in Wave-Lengths.	Frequency in Chromosphere.	Behaviour. Reversal in our Tubes.	Remarks.
SODIUM.			
6160, 6154	0	Expanded.	
D . .	50	Most easy.	Principal ray.
5687, 5681	2	Difficultly reversed.	
5155, 5152	2	Very diffused.	
4983, 4982	0	" "	
LITHIUM.			
6705 . .	0	Readily reversed.	Most characteristic at low temperature and low density.
6101 . .	3	Difficultly reversed.	
4972 . .	0	Difficultly reversed.	
4603 . .	0	Readily reversed.	
4130 . .	0	Very diffused.	Described by Boisbaudran.
MAGNESIUM.			
5527 . .	40	Expanded.	
b_1 5183 . .	50	Reversed.	Most characteristic.
b_2 5172 . .	50	"	Most characteristic.
b_4 5167 . .	30	Difficultly reversed.	Most characteristic.
4703 . .	0	Much expanded.	
? 4586 . .	0	Much expanded.	Doubtful whether due to magnesium.

Lines in Wave-Lenghts.	Frequency in Chromosphere.	Behaviour. Reversal in our Tubes.	Remarks.
MAGNESIUM.			
4481 . .	0	Not seen either bright or reversed.	Characteristic of spark absent in arc.
BARIUM.			
6677 . .	25	0	May be either Ba or Sr.
6496 . .	18	Reversed.	May be either Ba or Sr.
6140 . .	25	0	
5534 . .	50	Readily reversed.	Most persistent.
5518 . .	15	Reversed.	
4933 . .	30	,,	Well-marked ray.
4899 . .	30	0	
4553 . .	10	Pretty readily reversed.	
STRONTIUM.			
6677 . .	25	0	May be Sr or Ba.
6496 . .	18	0	,, ,,
4902 . 4895 . 4873 . 4868 . 4812 . 4831 .	...	Reversed.	
4607 . .	0	Readily and strongly reversed.	Most characteristic.
4215 . .	40	Readily reversed.	Well marked.
4077 . .	50	Readily reversed.	,, ,,
CALCIUM.			
6161 . .	8	Reversed difficultly.	Very bright.
6121 . .	5	Reversed difficultly.	
5587 . .	2	Doubtful reversal.	
5188 . .	10	Reversed.	
4877 . .			
4587 . .	2	0	
4576 . .	4	0	
4453 . .	0	Readily reversed.	
4435 . .	1	Readily reversed.	
4425 . .	2	Readily reversed.	
4302 . .			
4226 . .	3	Most easily reversed.	Very characteristic.
4095 (?) .	0	Strongly reversed.	
3968 . .	75	Well reversed.	
3933 . .	50	Rather more readily than the last.	
ALUMINIUM.			
6245 . .	8	0	Strong lines.
6237 . .	8	0	
3961 . 3943 .	0	Strongly reversed.	Very marked.
POTASSIUM.			
7670 . 7700 .	0	Strongly reversed.	Chief rays.
6946 . 6913 .	...	Reversed.	
5872 . 5831 . 5802 .	...	Reversed.	
5353 . 5338 . 5319 .	...	,,	
5112 . .	...	,,	
4044 . 4042 .	3	...	Well marked.
CÆSIUM.			
5990 . .	10	0	
4555 . .	10	Strongly reversed.	Most marked.

The group calcium, barium, and strontium on the one hand, and sodium, lithium, magnesium, and hydrogen, on the other, seem to behave in a similar way in the chromosphere of the sun; but before definite conclusions can be reached regarding the sequence of the reversals, a further series of long and laborious experiments must be executed.

Parliamentary and Law Proceedings.

THE PHARMACEUTICAL SOCIETY v. THE LONDON AND PROVINCIAL SUPPLY ASSOCIATION.

The judgments in this case were delivered on Tuesday, the 16th, in favour of the appellants. The judgments are as follows:—

Lord Justice Bramwell: I am of opinion that this appeal must be allowed. I think the word "person" in sect. 15 of the Pharmacy Act, 1868, does not include a corporation. That the word "person" may include corporation I will not deny, though at the same time, considering the way in which statutes are now drawn, that when "corporation" is meant it is always named, at least that there is no modern instance to the contrary, and that when the Legislature made a general interpretation clause that "person" should be male and female, plural and singular, etc., it did not include "corporation," I should be reluctant to hold that in any particular statute "person" included "corporation," unless there was strong reason so to do. In this case there is, in my opinion, no such reason, but the contrary. Sections 1 and 15 of the Act create an "offence" and provide for its punishment. But for section 15, section 1 would create a misdemeanour punishable by indictment, fine and imprisonment. But offences, certainly offences of commission, are the offences of individuals, not of corporations. A corporation cannot have the *mens rea*. I do not say that a corporation cannot be guilty of an offence of nonfeasance—it certainly can be; and it has been so held as to a misfeasance; but though if the Legislature pleased it might enact that a corporation should in a certain event be taken to have committed an offence, the presumption is that in speaking of "offenders" it speaks of individuals. If a statute were to say that any person publishing a libel should be guilty of an offence, or that no person should publish a libel, a corporate printing company publishing a libel would not be guilty in its corporate capacity; but the individuals publishing would be the offenders. So, for instance, as to the sale of beer or spirits. No doubt, if there was strong reason for saying "person" in this statute meant "corporation," one ought so to hold. As, for example, if the mischief to be prevented could not be otherwise. But that is not so here. For the individual offender may be got at. If the servant or shopman of a corporation sells poison, not being a pharmaceutical chemist and registered under the Act, it will be no answer to an action for the penalty to say that he did it as servant, whether of an individual or a corporation not qualified. If the act is in itself unlawful, it is not the less so because done as servant. If it would be lawful because the servant was qualified, though his employer was not, I think the statute is shown to be all the more reasonable, as in that case a corporation is on the same footing as a partnership, and there is no reason why it should not be. It may be asked, how is the "keeping open shop" to be reached; the servants do not keep it open? No, but the directors or managers do; they are the offenders in that case. I cannot see how they could deny that they kept open this shop. They do—they do it in fact. If they committed a public nuisance by smells, vapours or otherwise in the preparation, or (if supposable) in the sale of their drugs, they and not the corporation would be indictable. I see no reason then for including "corporation" in the word "person." I see many the other way. It is remarkable that in this particular statute "person" never includes "corporation" in any other section. It is manifest that "persons" in the preamble keeping open shops, and "persons" known as chemists and druggists, means individuals; for they are "persons" who it is expedient should possess a competent practical knowledge of their business. A corporation as such cannot possess a competent practical knowledge. Then such "persons" are to be examined. It is manifest "persons" there does not include corporations, why should it in section 1? So "persons" in section 3 who have been assistants cannot include corporations, nor the "person" in section 4 who is to be of full age, nor the "persons" in section 5 who had been admitted pharmaceutical chemists, for no corporation had been, nor the "person" in section 6, for a corporation never could have a certificate of competent skill, nor the "person" in section 10, who is a person that may die. In short "person" in no other section of this Act includes "corporation." Further than this, I am by no means certain that the statute is not levelled at the individual actually acting, and not (at least in all cases) his employer. Who would be liable under section 15 for compounding medicines of the British Pharmacopœia otherwise than according to its formularies? Surely the actual person compounding. Section 16 supposes there may be a qualified assistant, and not a qualified master. Again, section 17 which specially provides that for certain matters the master is liable, seems to suppose that otherwise he would not be. Then section 18 and the following, when they use the word "person" clearly do not mean "corporation." There is this advantage, as I have said, in this construction, that it does not exclude a corporation from the benefit of carrying on this business, nor the public from dealing with them. It is not needlessly in restraint of trade as it otherwise would be, at least not directly. If it does indirectly operate to preclude a corporation carrying on this trade, however qualified all its members may be, it is to be regretted; but then there is no need for making "person" include "corporation," nor for creating the novelty of a corporate offence. It only would operate against a corporation as it would against a partnership. Further, how is this the act of the corporation if it is unlawful? For if it is, it is *ultra vires* of the directors. An assistant hired by them to sell these poisons, if so doing is unlawful, could maintain no action against the corporation. They would have a good defence. Of course, if by their articles of association poisons are expressly to be sold, their sale would not be *ultra vires*; but that does not appear in this case, and at all events the possibility is a reason for fixing the individual and not the corporation. In the result, considering the way in which modern statutes are drawn, that corporations are specified where corporations are meant, that offences are wilful breaches of law or inattention to its commands and so the act of the individual offending, that there is no reason for holding corporations to be within the Act, that there are reasons to the contrary, and that in no other section of this Act does "persons" mean "corporation," I am of opinion it does not in these sections. I am aware that the penalty is recoverable by plaint in the County Court, 15 and 16 Vic. c. 62; but the sum recovered is at the disposition of the Crown, section 14, and it is a "penalty," and the act an "offence," and the person an "offender." I am aware also that there is ground for saying that under section 15 all of several partners keeping a shop must be qualified, though none attend, and the shopman need not be qualified. If so it may be said, so must all the shareholders and directors of a corporation. I do not know. The Act may have a more limited meaning, and be more reasonable. If not, still this furnishes no argument in favour of "person" meaning corporation.

Lord Justice Baggallay: I agree in the opinion that this appeal should be allowed. In modern times when the Legislature has intended that the word "person" or any other word primarily importing an individual in any particular statute shall include a corporation, it has been usual to introduce an interpretation clause, declaring that the word shall have such extended meaning. In the year 1868, the year in which the Act now under consideration was passed, at least four other Acts were passed into which such a clause was introduced; namely, the Sea Fisheries Act, the Fair of Kildare Act, the Regulation of Railways Act, and the Artizans and Labourers Dwellings Act; and in another, the Irish Fairs Act, the word "owner" was declared to have the same meaning. Now the omission from Lord Brougham's Act of any general declaration that the word "person" when used in subsequent statutes should include a corporation, and the absence from the Act now under consideration of any such interpretation clause, to my mind strongly supports the view that the Legislature had no intention that the word "person" when used in the Act should include a corporation. It probably is the fact, as was suggested in argument, that at the time when the Act passed it was not in the contemplation of the Legislature that a corporate body would embark in the business of selling or of dispensing or compounding poisons, and that consequently it had no intention of either including or of excluding a corporation when using the word "person;" but, however, this may be, it must I think be admitted that although an Act may not contain a declaration that the word "person" shall include a corporation, and although it may be clear that the Legislature could not be reasonably presumed to have any intention in the matter; yet, if it be clear from the general scope and purport of the Act that the selling, dispensing, or compounding of poisons by a corporation was or might be within the mischief intended to be guarded against, and if extending the meaning of the word "person" so as to include corporation would enable the necessary protection to be given, such an interpretation might and ought to be adopted. But when I turn to the Act itself I can find nothing to lead me to such a conclusion. The object of the Act is to prevent the selling, dispensing or compounding of poisons by unqualified persons. A corporation cannot of itself sell, dispense or compound; it can only do so by the aid of a servant or assistant, and if that servant or assistant is duly qualified in the manner required by the Act—as is admittedly the case with regard to the dispenser employed by the defendants—the object of the Act is obtained. And in the view I take of the Act, the protection intended to be given to the public is sufficiently secured in the case of a corporation keeping open a shop for selling, dispensing, or compounding of poisons, for in my opinion the seller referred to in the first section is the actual seller, and not the individual or corporation on whose behalf he may act, and this view is supported by the language of the 17th section, which when dealing not with the simple sale of poisons, but with selling particular poisons without the adoption of special precautions, imposes a comparatively small penalty on the seller, but declares that for the purposes of that section the person on whose behalf the sale is made shall be deemed to be the seller, thus implying, that except for the purpose of that section the person referred to in the Act as selling, means the person actually selling, and not the person by whom he is employed. I need not refer to many sections of the Act which are quite inapplicable to the case of a corporation, as they had been pointed out in detail by Lord Justice Bramwell. In the absence then of any declaration in the Act that the word "person" is to include a corporation, and not gathering from the general scope and purport of the Act that there is any necessity in the interest of the public that any such interpretation should be given to the word, I have arrived at the conclusion that such an interpretation ought not to be put upon it, and that this appeal should be allowed.

Lord Justice Thesiger: I also am of opinion, not without doubt, that this appeal should be allowed. The question for determination is whether an incorporated company is subject to the prohibition contained in section 1, and liable to pay the penalty imposed in section 15 of the Pharmacy Act, 1868, or in other words, whether the term "person," used in those sections, includes such a company. In dealing with this question, I start with the axiom that the term "person" is, in legal phraseology, wide enough to include not merely natural persons, that is, individuals, but, artificial persons, such as corporations, aggregate as well as sole. I start at the same time with the undisputed fact that the practice in modern statutes where corporations are intended to be affected is either to expressly name them or to use in reference to them the term "person," with an interpretation clause expressly providing that corporations are intended to be included in the term. As a proper resultant of the apposition between the axiom and the practice, it appears to me that the term "person" when contained in a modern Act of Parliament should never be construed to include corporations, except where, first, the term is expressly interpreted as including them; or, secondly, the context of the Act clearly shows that they are so included; or, thirdly, the object and scope of the Act peremptorily require them to be so included, and the context does not clearly negative a construction to that effect. Neither the first nor the second condition exists in the particular Act under consideration, but for a long time I have doubted whether the judgment of the court below might not be supported upon the third. The object of the Act is that of providing for the safety of the public in the matter of the sale of poisons. The means by which that object is proposed to be attained is, *inter alia*, that of subjecting those who keep open shop for the retailing, dispensing or compounding of poisons to certain conditions and restrictions. Corporations may keep open shop, their doing so without proper safeguards may expose the public to the mischief against which the Act is intended to guard. There is, therefore, a strong presumption *à priori* that they would be made subject to the same conditions and restrictions as those to which individuals would be subjected, or, at least, to some conditions and restrictions that would serve to the same end. Proceeding a step further it may be said that a statutory provision under which a particular thing is made unlawful for any individual to do, except under certain conditions, contains an indication that the thing itself is intended to be entirely prohibited except under those conditions, and consequently cannot be done by a corporation even though the conditions are in their nature such as cannot under any circumstances be complied with by them. Lastly, a penalty, by which the prohibition is to be enforced, recoverable by civil suit, is as applicable to corporations, who may, even under certain circumstances, be the subject of indictment, as it is to individuals. Notwithstanding, however, the force of these considerations, which still press themselves upon me I have come to the conclusion that the whole contents of the Act too clearly point to individuals alone being intended by the term "person" to allow of that term being held to include corporations in the 1st and 15th sections. I do not propose to repeat what has already been said by Lord Justice Bramwell upon this point. He has shown conclusively that the preamble and every section of the Act, putting aside for the moment the two sections whose meaning is in dispute, when using the term "person" or "persons" refer to individuals alone. But in addition to what he has pointed out I find in the first section itself evidence that the words "any person" in the earlier part of that section are limited to individuals and cannot be extended to corporations, for in a subsequent part of the same section the word "person" is again used with such a context as absolutely forbids its application to a corporation, and yet in such a relation to the same word contained in the earlier part of the section as to grammatically require that it should receive the same construction. I do not think that under such circumstances the court ought to strain the language of the Act so as to make it include corporations, even if it were clear that the mischief intended to be provided against would otherwise in the case of companies keeping open shop for the sale of poisons be remediless. But I feel bound to add that I am by no means satisfied, that although a corporation as a separate entity be not liable to the penalty which is sought to be recovered, in this case the individual members of the corporation, whether directors of a company or otherwise, may not be liable, and thus the mischief be remedied. I prefer, however, to give no definite opinion upon this point, for it involves the question whether the Legislature intended or not to practically put an absolute veto upon the keeping open shop for the sale of drugs by trading companies, and the absence from the Act of any express reference to such companies is almost equally difficult to be accounted for upon the notion that the Legislature had that intention as upon the notion that the Legislature did not think of the matter at all, and thereby a *casus omissus* has occurred.

Mr. Bosanquet: My lords, Mr. Lumley Smith is not here, and I am asked to apply to your lordships for leave to appeal to the House of Lords. Leave was given to appeal to this court on the ground of the importance of the case.

Lord Justice Bramwell: Mr. Bosanquet, I am not sure that any leave from us is necessary, and I think it is an objectionable thing for the court to do. You shall have it if it is necessary, but just inquire.

Mr. Bosanquet: I have had no time to look it up, my lord, I have only just been asked to do it. Perhaps you will allow Mr. Lumley Smith to mention it in the course of the day if necessary.

Lord Justice Bramwell: Certainly.

Lord Justice Thesiger: Leave to appeal was granted in the court below.

Lord Justice Bramwell: I think, indeed I know, I may say, that we should grant you that leave, but we do not like to do it unless it is necessary.

Reviews.

MEDICINAL PLANTS: BEING DESCRIPTIONS, WITH ORIGINAL FIGURES, OF THE PRINCIPAL PLANTS EMPLOYED IN MEDICINE, AND AN ACCOUNT OF THEIR PROPERTIES AND USES. By R. BENTLEY and H. TRIMEN. London: J. and A. Churchill. 4 vols. 1880.

We have from time to time called attention to the progress of this work, and it only remains now to say a few words on its completion. The total number of species depicted and described is three hundred and six included in forty-two numbers, the publication of which has extended over more than four years. Of these, two hundred and ninety-eight are flowering plants and eight cryptogams, viz., one fern, one lycopodium, two lichens, one fungus and three algæ. Since allusion has been not unfrequently made in these columns to points of special interest as they arose during the publication of the parts, it is not necessary now to add any criticisms of this nature. The authors apologize for the apparent inequality in the treatment of the different species, on the ground of the varying interest taken in substances at different times, some new remedies especially exciting much attention and thus demanding a full description, though perhaps, not of great permanent value. Now that the work is completed, the authors need not be afraid but that their labour will be appreciated. It is an indispensable work of reference to every one interested in pharmaceutical botany. The botanical descriptions of the species from the hand of Dr. Trimen, and the description of the general characters, composition, properties and uses of its parts and products which are employed in medicine or otherwise, by Professor Bentley, may be thoroughly relied on, and in nearly all cases the coloured drawings and the dissections of the most important parts of the plant give a very correct idea of the species from which the drug is obtained. Moreover, the work, in four handsome volumes, will form a decided ornament to the library shelves or drawing-room table.

Pharmacographia. A History of the Principal Drugs of Vegetable Origin met with in Great Britain and British India. By Friedrich A. Flückiger and Daniel Hanbury, F.R.S. Second edition. London: Macmillan and Co. 1879.

So highly esteemed was the last edition of this remarkable work, that it was speedily bought up, and for some time past there has been considerable difficulty in obtaining even a secondhand copy. Unfortunately, however, owing, we believe, to the publication of a cheaper edition in America, the authors suffered pecuniary loss rather than gain as the reward of years of conscientious and painstaking labour, a result which we sincerely hope will not follow the publication of the present edition. Since the deeply deplored decease of one of the authors, the whole of the labour of revision has fallen on Professor Flückiger, and so well has it been done that only from two or three isolated idiomatic expressions is it possible to tell that anyone but a born Englishman has written the additions; indeed, the condensed and vigorous style so closely resembles that of Daniel Hanbury, that the paragraphs now added might well have been written by him. Although sixty-eight pages of additional matter have been added to the body of the work, the fresh information has been so well intercalated that it is only after the most careful comparison that one discovers the fact that almost every other page contains new chemical facts or historical additions. Nothing that could have been inserted up to the date of going to press seems to have been left unnoticed. The number of journals and publications of all kinds that have to be consulted in order to bring any scientific work up to date is only known to those who have to ransack widely scattered literature in different languages for that purpose. One can only regret that 'Pharmacographia' does not include all the articles used in materia medica in this country. It would then assuredly be adopted as the text-book at all medical and pharmaceutical schools, instead of being used, as at present, only as a reliable work of reference. One or two slight errors have crept in, but not of an important character. Thus Bengal cardamoms are attributed to *Amomum subulatum*, Roxb., whereas it is the Nepal cardamom that is yielded by it. This mistake would appear to have been derived from the Kew Report (1877, p. 27), the author of which evidently misunderstands Dr. King's paper* in the journal of the Linnean Society of London.

* See *Journ. Linn. Soc. Botany*, vol. xvii., p. 5.

Hodthai is not, as the author supposes, identical with *habakhadi;* the former is the produce of *Balsamodendron Playfairii*, the latter of a species of *Balsamodendron* with larger leaves than that plant, and of which a specimen is still growing in Kew Gardens. Sagapenum is stated to have no alliaceous odour, and is removed from under Ammoniacum and placed under Galbanum. Its nearest ally is certainly assafœtida, for sagapenum has a distinct alliaceous odour and a strong alliaceous taste. Nor can we agree with the learned author, who is not the only one who makes the same remark, that the presence of stellate markings is characteristic of Russian and Chinese rhubarb. These spots occur also in *Rheum rhaponticum*, and are by no means found in all specimens of Russian or Turkey rhubarb.

Almost the only new drug introduced is jaborandi. Dr. Flückiger seems to have overlooked the publication of accounts of the spurious drug having occurred in commerce in England and France.

Probably no work was ever published without a few omissions or errors, and those above noticed are of no considerable importance. Without question, 'Pharmacographia' is and must remain for a considerable time the best and most trustworthy work in our language on the drugs of which it treats. Each successive edition, if as well done as the present, can but add to the mine of information it contains.

At the end of the volume a biographical and bibliographical index to the extent of seventeen pages has been added; this comprises a list of the works quoted in 'Pharmacographia.' It adds considerably to the value of the references, and must have cost much more time and trouble to compile than is indicated by the short paragraph devoted to each. The general index has been reduced from three to two columns on each page, and therefore occupies more room, but is more easy of reference.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Practical Chemistry: The Principles of Qualitative Analysis. By William A. Tilden, D.Sc., Lond., F.C.S., etc. London: Longmans, Green and Co. 1880. From the Publishers.

Obituary.

Notice has been received of the death of the following:—

On the 3rd of January, 1880, Mr. Richard Arthur Hall, Pharmaceutical Chemist, Leigh, Lancs. Aged 23 years. Mr. Hall became a Member of the Pharmaceutical Society in 1879.

On the 29th of January, 1880, Mr. John Benjamin Bibby, Chemist and Druggist, Ince, Lancs. Aged 33 years.

On the 6th of February, 1880, Mr. Morris Applebee Gibbs, Chemist and Druggist, Little Newport Street, Leicester Square, London. Aged 59 years.

On the 9th of February, 1880, Mr. Thomas Cribb, Chemist and Druggist, Lisson Street, Lisson Grove, London. Aged 62 years.

On the 9th of February, 1880, Mr. Edward George Thornton, Chemist and Druggist, Lyme Regis. Aged 35 years.

On the 10th of February, 1880, Mr. Edward Wootton, Chemist and Druggist, High Street, Margate. Aged 70 years.

On the 14th of February, 1880, Mr. Michael Andrew McDermott, Chemist and Druggist, Commercial Road, London. Aged 36 years.

On the 18th of February, 1880, Mr. John Croswell, Chemist and Druggist, Tredegar, Mon. Aged 57 years.

On the 19th of February, 1880, Mr. Thomas Robson, Chemist and Druggist, Hartlepool. Aged 77 years.

On the 19th of February, 1880, Mr. Richard Farrant Salter, Chemist and Druggist, Topsham, Devon. Aged 40 years.

On the 26th of February, 1880, Mr. Samuel Arrandale, Chemist and Druggist, Denton, Lancs. Aged 47 years.

On the 1st of March, 1880, Mr. James Thomas Gwatkin, Pharmaceutical Chemist, Grand Parade, Brighton. Aged 66 years. Mr. Gwatkin was one of the Founders of the Pharmaceutical Society, and served it during many years as Local Secretary, which office he held at the time of his death.

On the 6th of March, 1880, Mr. Horatio King, Chemist and Druggist, Post Office Street, Norwich. Aged 54 years.

Dispensing Memoranda.

Reply.

[386]. In answer to *Dubius's* question regarding zinci oleas; I beg to state that I believe the proper consistence to be somewhat similar to what ol. cocoa nucis is in cold weather, and perfectly white, when Hubbock's zinci oxid. is used.

I think that if *Dubius* will, in making zinci oleas, apply a heat of about 120° Fahrenheit, for five minutes, taking care not to exceed that temperature, at the end of that time he will obtain a preparation similar to that I have described it to be.

Having made zinci oleas, I find it rather difficult to make an ointment with it, combined with vaseline; you cannot rub it down fine enough, so as not to appear lumpy in the ointment, and if you apply heat you obtain a very glutinous-like preparation by no means fit to send out, thus showing that care must be taken not to apply too much heat. I would suggest to dispensers, that when they have ung. zinci oleatis ordered, to make their zinci oleas fresh, and before it cools add their lard or vaseline, by so doing they will obtain a very elegant preparation.

EDMUND WHISTON.

Queries.

[394]

℞ Hydrargyri Chloridi granum et dimidium
Pulveris Opii . . . unam tertiam partem grani

Fiat pilula. Mitte decem. Sumat unam quartis horis dolore urgenti.

What size should the above pills be when sent out? and what would be used in a good dispensing establishment to increase the bulk and the excipient?

C. J. B.

[395]. What decomposition takes place in the following prescription?—

℞ Quinæ Disulph.	gr. xij.
Acid. Nit. Dil.	♏xx
Lithiæ Citratis	℈j
Tr. Aurantii	ʒiij
Sp. Chloroformi	ʒj
Aquæ	ad ℥vj

A sixth part at noon and 6 p.m.

I first dissolved the quinine in the acid and some water, the lithia in a mortar with water, and mixed them; I had a thick creamy mixture. The second time I put the quinine in last; there was a precipitate but not so much as in the first case. Attfield and Fownes gave very little information. Would sulphate of lithia and citrate of quinine be formed?

EMBRYO.

[396] "Minor" will be pleased to hear of a good method for silvering ordinary 4 grain pills.

[397].

℞ Camphoræ . . . . . grana triginta.

Fiant pilulæ duodecem. Capiat unam pro re nata.

What is the best excipient to use for the above in order to have pills not exceeding 3 grains?

C. J. B.

[398].

℞ Acid. Sulph. Dil.	ʒj
Acid. Phosph.	ʒvj
Spt. Æther. Chloric.	ʒj
Tinct. Camph. Co.	ʒiv
Ferri Citratis	ʒij
Syr. Aurantii	ʒiv
Aq.	ad ℥xij

Ft. mist.

Would any reader kindly state how the above should be dispensed so as to form a clear mixture, as my customer says it was sent out clear from the place where he had it first made up?

I have mixed the ingredients in every way I can think of, but always get the same thick deposit.

A JUNIOR.

Notes and Queries.

COSTER'S PASTE. — We have received a communication from Mr. Martindale stating that the formula for Coster's paste, quoted in last week's Journal on the authority of Mr. Startin, was incorrect, and that the correct formula is identical with that of the pigmentum iodi et olei picis of the University College Pharmacopœia, as follows:—"Iodine, two drachms; light oil of wood tar, one ounce. Mix carefully, applying heat if necessary; after ebullition, preserve for use." The "light oil of wood tar" has a specific gravity of ·853 to ·867, and is known in commerce as rectified spirit of tar. Mr. Martindale says that the formula was given to Dr. Ringer by Mr. Coster himself. The use of so vague a term as "pigmentum iodi," as in Mr. Startin's note, is condemned by Mr. Martindale.

Correspondence.

PHYSICIANS AND THEIR MANUALS OF DOMESTIC MEDICINES.

Sir,—Much as has been said of late by physicians and surgeons respecting the inability of chemists to prescribe medicines for simple ailments, and the unsuccessful attempt which has been made on the part of surgeons to prevent chemists from handing over their counter any medicines (patents excepted) but those that have been ordered through a prescription by a medical man, there seems to me an important matter, which ought to be brought under their notice at once, namely, the publishing of books for domestic reference in cases of illness, with receipts containing very poisonous drugs. Receipts of a dangerous and poisonous character are copied by mothers and others from these books to suit the ailment from which the patient suffers, taken to the chemist's to be made up, and in many cases even made up by themselves, and given to the patient, in many instances ignorant of the disease for which they are attempting to treat. For example, seeing a book advertised to be published by Messrs. Cassell, Petter, Galpin and Co., entitled the 'Family Physician,' compiled by physicians and surgeons of the principal London hospitals, and knowing that these publishers always bring out books worthy of being read, I commenced taking it in in 6*d*. numbers, for the object of gaining information suitable to my business as a chemist. On page 3, I found the following under "Children in Health and Disease.—Bed-wetting:"—"We have in belladonna a drug which has been of undoubted service in such cases. It should be given in the form of pills, because it is unadvisable to give more liquid to these children than is absolutely necessary. The dose must be small to begin with, and then may be gradually and cautiously increased. A pill containing a ¼ gr. or less of the extract (which should be purchased of some druggist of acknowledged reputation) should be administered every night at bedtime, and if this be found insufficient, the dose may at the end or a week be doubled. If the child complain of thirst, and the pupils of the eyes become dilated, the remedy must not be pushed too far; if delirium occur the belladonna must be withheld." Now, sir, I think you will agree with me that such a receipt is not to be trusted in such hands as this book will reach, neither should such drugs be prescribed, excepting personally by a medical man, who understands the treatment, and can prescribe accordingly. It is not at all unlikely that the chemist who made up the receipt would be called up, and highly censured for dispensing it, should any accident occur.

Birmingham. JOSIAH AUSTIN.

SALE OF PATENT MEDICINES.

Sir,—There seems to be a very general opinion that to meet competition in patent medicines it should be compulsory that all patent medicines containing any of the scheduled poisons should be labelled poison, and the sale restricted to chemists. Permit me to suggest whether this is not a foolish course for chemists to encourage, for this reason. A large majority of the most popular, and presumably, therefore, really useful medicines contain perhaps a small quantity of one or more scheduled poisons. I should suppose that every chemist who has any considerable sale for any of his own preparations can readily find several examples in his own articles. If, therefore, the above became law it would apply to each chemist's preparations as well as those patents that have a large sale. The result would be that the majority of preparations sold by chemists would have to be labelled "poison," to the alarm of the public (at least this is what is intended by the promotion of the above idea, in hope of restricting the sale of patents). A sure result would follow. A class of large advertisers would bring out medicines just free of the law, and largely advertise them as being sold by grocers, etc. As one who has had very considerable experience, I unhesitatingly affirm that if this was done and became a fashion the chemist's trade would certainly suffer seriously. A much better plan would be, when the question is ripe, to try and induce the Government to grant a council composed equally of chemists and medical men to license patent medicines, such medicines only that contain large doses of poisons to be labelled poison. Because a cough mixture contained a small dose of syrup of poppies, though an ordinary bottleful of which would not do the slightest harm, it would be absurd to label it poison.

1, *London House Yard, St. Paul's, E.C.* I. W.

DEATH RATE OF CHEMISTS AND DRUGGISTS.

Sir,—Will you allow me space for a few words on the vital statistics recently given by Mr. Andrews in the Journal (before p. 678). As the writer says that no conclusions are to be drawn from his table they may be passed by; but as he offers no apology for that furnished by some other gentleman, I presume Mr. Andrews considers it correct. I should say that any table of figures that shows that chemists and druggists live twice as long as physicians carries its own refutation on its face.

Does Mr. Andrews know that besides that palpable error the figures also imply that chemists attain to an average of eighty-seven years, and that barristers live one hundred and sixteen years, whilst physicians seem to die at the comparatively juvenile age of fifty-seven?

J. STAINER.

SALVIA SEEDS.

Sir,—In the notes on "Economic Botany of the Western United States," reprinted in the Journal, the properties of *Salvia Columbariæ*, Benth., are noticed. The seed yields the "chia," a mucilaginous substance much used as food by the Indians and Mexicans. The seed is also placed in the eye, where it gives no pain, to form a mucilage, by means of which a foreign body may be removed from that organ. The seeds of our own *Salvia verbenaca* have been used for the latter purpose, the mucilage consisting (as in the case of many seeds) of minute spiral vessels, which form an interesting microscopic object. G. C. DRUCE, F.L.S.

"*Chemist.*"—The publication of names sometimes involves a liability that we think it discreet not to incur.

W. Fowler is thanked for his communication. We shall always be glad to receive similar information.

A Student would probably get the information he desires from a paper on the subject of "Oleomargarine," recently presented to Parliament, which may be obtained for a few pence from Messrs. Hansard. See also on the "Manufacture of Artificial Butter," *Pharm. Journ.* [3], vii. 813.

J. A..—See before, pp. 486 and 644.

"*Dens.*"—There is nothing illegal in the extracting of teeth by any person, but any person not registered under the Dentists Act who in so doing held himself out to be a dentist would be liable to a penalty.

W. Lyle.—See the Fourth Cantor Lecture on the "Chemistry of Bread-Making," published in the *Journal of the Society of Arts* for January 16.

Stamp.—Any statement on the label or otherwise implying that a preparation is secret or occult, or prepared only by a particular person, or that it is useful in the relief of any ailment of the human frame, would render it necessary that such preparation should be stamped. As to the class of preparations of which "salines" and "fruit salt" are typical, it has been recently decided in the appeal court that they come within the exemption in favour of artificial mineral waters.

A. P. S.—Yes, if the preparations come within the provisions of the Patent Medicine Stamp Acts.

B. J. Kent.—(1) See before, p. 638. (2) The second ingredient, which we presume is the one that has caused your difficulty, is "pulv. d'extrait rad. rhei, q.s."

C. C. B.—The presence of spermaceti in oleum anisi may be detected by its insolubility in cold alcohol.

J. B.—The following recipe for mastic varnish is taken from the new edition of Cooley's 'Cyclopædia,' a most useful work to the chemist and druggist:—

"Take of pale and picked gum mastic, 5 lbs.; glass (pounded as small as barley, and well washed and dried), 3 lbs.; finest newly rectified oil of turpentine (lukewarm), 2 galls.; put them into a clean 4-gall. tin bottle or can, bung down securely, and keep rolling backwards and forwards pretty smartly on a counter, or any other solid place, for at least four hours, when, if the gum is all dissolved, the varnish may be decanted, strained through muslin into another bottle, and allowed to settle; if the solution is still incomplete, the agitation must be continued for some time longer, or the gentle warmth applied as well."

"*Ball.*"—A recipe for an aniline marking ink that becomes black after exposure to the air will be found in vol v. of the present series, p. 912.

Mathetes.—The best solvent for india rubber, according to Payen, is one consisting of 6 to 8 parts of absolute alcohol and 100 parts of carbon bisulphide.

Das Blumlein.—*Helleborus viridis.*

T. Horton.—The fruits are those of the olive. Laurel berries have no stone in them.

J. Dingle.—*Cladonia pyxidata.*

C. T.—*Scopolia carniolica.* The Curator of the Society's Museum would be glad of a good herbarium specimen, including root if possible.

C. T. Brookes.—You are recommended to make the inquiry of the Clerk to the Quarter Sessions.

A. B.—Try with care a weak solution of chloride of lime, or, if that is not successful, try, also with care, peroxide of hydrogen.

G. C. R. O.—If you will send a copy of the formula or a reference where it may be found we will give you our opinion.

M. P. S.—The presence of any such large amount of earthy salt as is ordinarily met with in water would probably be of little importance so far as absorption of carbonic acid gas is concerned, but in other respects it might be very objectionable.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Lawrence, Gibbons, Flower, Stenhouse, De Gustibus, etc., Student, Ion, Synthesis, T. W.

"THE MONTH."

Inter arma leges silent. The resumption of the strife in the law courts as to the meaning of the Pharmacy Act has been no doubt the incident of supreme interest during the last few weeks, and like many another conflict it has interfered with the ordinary course of affairs, since the chronicling of its progress necessitated a temporary suspension of the rule with respect to "The Month," and no *résumé* was presented at the end of February. The subject has, however, now been so fully dealt with that it need present no further hindrance to a resumption of these columns.

March is now itself again. Cold winds, bright sunshine and bursting buds herald the near approach of spring, and there is every prospect that the Easter holidays will present some little inducement to dwellers in smoky cities to seek the invigorating air of the country and to search for glimpses of the pale "primrose by the river's brim," the graceful wood anemone in its sylvan haunts, and the fragrant violet under the still leafless hedgerows.

The botanist, in his early perambulations, may even now expect to find a few medicinal plants awaiting him. *Daphne Laureola* and *D. Mezereum*, although neither of them common plants, are sometimes met with in the most unexpected places, where their seeds may have been dropped by birds, and the possibility of finding an unlooked-for treasure always gives a spice of enjoyment to an otherwise uninteresting and perhaps dreary walk. *Helleborus viridis*, in old orchards, and *H. fœtidus*, in thickets, are often met with in this way, and should now be in full blossom. Those who are fortunate enough to reside in localities where they grow, may now expect to find the asarabacca (*Asarum europœum*), the narrow-leaved lungwort (*Pulmonaria angustifolia*) and *Scrophularia vernalis*, in fit condition to collect for the herbarium. The dandelion and the coltsfoot are sure to be found in abundance everywhere; the catkins of the poplar (*Populus nigra*), the diminutive flowers of the elm, and the downy catkins of the willow, are all worthy of examination, for these are not to be found when the botanical session at schools commences.

At various botanical gardens one may expect to find a few flowers representing some of the larger or more important natural orders, thus, *Mandragora vernalis* and *Hyoscyamus orientalis* and the curious *Scopolia carniolica* represent the Atropaceæ; the latter plant, except for the thinner texture, more reticulated appearance and lighter green colour of the leaves and the pale lines on the corolla, might easily be mistaken for belladonna, from which, however, it is distinguished by having a stout creeping rhizome, instead of a root, and by the fruit being capsular instead of baccate. *Jeffersonia diphylla*, *Coptis trifoliata* and *Helleborus orientalis* in the Ranunculaceæ and *Kalmialatifolia* in the Ericaceæ, are frequently also to be found in blossom at this season of the year. At Kew Gardens the sweet orange, the mandarin and the Seville orange trees, as well as the lime, *Citrus Limetta*, and shaddock are now in blossom; the Kola nut and the coca and castor oil plant are still showing their inconspicuous flowers, and several varieties of tobacco, which are to be seen almost throughout the year, may be observed in the Economic House. In the open ground the cornelian cherry is putting forth its bright clusters of small yellow flowers and the *Helleborus niger* and other species, as well as the rare *Scrophularia vernalis*, are in full blossom. But on visiting No. 4 conservatory both the visual and olfactory organs are unexpectedly gratified by a delightful fragrance and a charming display of colour, in vivid contrast with the somewhat bare appearance of the grounds outside, where as yet but little is to be seen in blossom.

At Regent's Park only the Christmas rose and the mezereon are in flower in the Herbaceous Ground, and some of the blossoms of the latter exhibit that pale and sickly hue that flowers as well as human beings are apt to present when there is a deficiency of light and an impurity of atmosphere. In the Economic House there are, however, two or three medicinal plants in blossom. The *Eucalyptus globulus* is just showing flower buds, and the curious calyptrate calyx of the flower is distinctly visible. Last month the Socotrine aloes and the winter bark tree were both in full blossom, and the benzoin tree is now opening its flower-buds. The orange tree is also commencing to flower freely.

When the winter flora of this country is contrasted with that of "sunny Italy" one cannot help feeling a twinge of regret because of the murky skies and want of sunlight which causes such a wide difference in the two countries. A correspondent of the *Garden*, writing from San Remo, mentions among the plants in flower there in January, the marigold (*Calendula officinalis*), the Canadian fleabane (*Erigeron canadense*), the rosemary, *Juniperus oxycedrus*, wild thyme, and other fragrant herbs, and as well as the pretty little *Globularia Alyssum*, with its balls of rich blue flowers. All the above are of some medicinal interest, the last, and perhaps least known here, possessing purgative properties, the leaves having been sold at one time under the name of wild senna.*

The present and final number of 'Medicinal Plants' contains figures and descriptions of the following plants:—*Canarium commune*, *Conium maculatum*, *Coriandrum sativum*, *Cucurbita Pepo*, *Crinum asiaticum*, *Strychnos Ignatii*, *Pinus Abies*, *Avena sativa* and *Hordeum vulgare*. A correct reprint of *Pinus Picea* is also added, a transposition in the text having occurred in that already published in part 38. A systematic list of the contents of the work, an alphabetical index, a list of errata and the preface complete the work.

Of the immense amount of labour involved in a work of this kind, only those who have to bring a work up to date can have any idea. The vast amount of foreign literature scattered in various publications that has to be consulted, and the balancing or reconciling of contradictory or conflicting statements, render the production of a work like the present, one of considerable labour. No other publication can be said to give so complete and yet succinct an account of the medicinal plants of Great Britain, India and the United States and of their products, as this one. It includes no less than eighty-nine natural orders, two hundred and thirty-three genera and three hundred and six species, the information concerning which is brought up to the present time. The plan adopted, by means of which the whole can be arranged in consecutive systematic order by simply paying attention to the number attached to each species, is a most excellent one, and now that the work can be bound, it will be found that the four handsome volumes which it is intended

* *Pharm. Journ.* [1], vol. xvi., p. 426.

to make will have their contents arranged in the most convenient manner possible. No pharmaceutical or medical library will be complete without Bentley and Trimen's 'Medicinal Plants.'

In the *Gardeners' Chronicle* (February 14, p. 201) will be found an illustration of a peculiar pitcher plant, which attracted some attention at a recent meeting of the Linnean Society. The lid of the pitcher is furnished with two stout spines on its under surface, so that the animal which visits the pitchers of other species is considerably inconvenienced by being pricked on the back of the head when it attempts to secure the insects found in the pitchers of this species. Whether the ants which visit these organs have observed this fact, or whether the spines were developed so that the weakest should *not* go to the wall, must be left to the philosophers and naturalists of the future to determine. Sir John Lubbock's interesting studies of the habits of ants would almost lead one to accept the former theory as the correct one. However this may be, ants make an entrance to (or an exit from?) the pitcher by perforating the inner side of the stalk, and thus visit the pitchers to feed on the dead insects found there.

It is remarkable how soon scientific information which appears to have little marketable value at the time of its discovery is turned to account by practical men. A grower of early peaches has conceived and successfully carried out the idea of employing a hive of bees in his conservatory to fertilize the flowers during January. Might not this idea be also carried out with regard to some medicinal plants?

The *Garden* gives an interesting account of the germination of the seeds of *Megarrhiza Californica*, a plant which is used by the Indians in dropsy, and possesses cathartic properties. It seems that the seed coat opens towards the apex and a stout necklike body, similar to that of many monocotyledons, is protruded. This curves over and its apex swells into a tuber, the plumule or stem being developed from a niche in the neck or tigellum-like growth as in *Crinum*. The fleshy tuber is produced at the bottom of the pot in which the seed is sown; it forms fibres and when the requisite power to nourish the young plant is obtained this begins to be developed.*

In the *Scientific American*, Mr. W. Weaver, of Bogota, has advocated the introduction of cinchona cultivation in North California and Oregon, the mountains of which he considers eminently suitable for the experiment. The natives of the cinchona producing districts in South America, too, are at last waking up to the importance of replanting cinchonas, and, according to *New Remedies* (quoted from the *American Mail*), 150,000 trees have recently been planted in the states of Cundinamarca and Tolima and Santander.

Dr. Schroder, after investigating the effect of the smoke and fumes of chemical and metallurgical works, has arrived at the following conclusions:—The deleterious action of these fumes depends upon the acid gases, especially sulphurous and hydrochloric acids; the former turns the whole surface of the leaves brown, while the latter appears to principally attack the edges. Annual crops are less affected than trees. The walnut tree is the most sensitive; then follow the red beech, birch, lime, poplar, alder, ash and plane.

* See *Pharm. Journ.* [3], vol. vii., p. 393.

In a recent number of the *Pharm. Zeitung*, Dr. J. Biel, of St. Petersburg, calls attention to a false white quebracho bark which came to Hamburg. The first lot of white quebracho bark received in Hamburg was a very small quantity and the second lot consisted of three serons. Dr. Biel therefore supposes that what is being used in Germany at present is not the true drug, and therefore sounds this warning note, lest a drug which promises well should be unjustly condemned before it has had a fair trial. The false bark he describes as follows:—From the size of the finger to 2 inches broad, 2—5 millimetres thick, mostly in quills inrolled on both sides, and of different lengths, furnished with a yellowish white periderm presenting numerous deep longitudinal furrows and some transverse ones. The inner surface is dark brown with a fibrous fracture, the outer a horny fracture; the taste bitter but not aromatic. Viewed in transverse sections the outer layer consists of tabular cells disposed regularly in layers; the next portion of a spongy nature and nearly as thick as the outer, consisting of tangentially arranged thin-walled cells with numerous groups of stone cells, which latter form an easily seen uninterrupted ring as the inner limit of the outer layer. The middle layer or mesophlœum is composed of loose parenchyma cells partly filled with dark brown contents, and contains stone cells aggregated in groups of from 10 to 20; with these are mixed a few bundles of liber tissue. The inner bark or liber consists almost entirely of liber cells, traversed by medullary rays, whose cell-contents are of a dark colour.

At a meeting of the Obstetrical Society last month, Dr. J. W. Anderson, of Jamaica, read a paper "On an Infusion of Leaves of the Cotton Tree (*Gossypium Barbadense*) as a galactogogue." The use of the root-bark as a parturient has long been known in the United States, but the leaves of the castor oil plant, which are much more easily obtained in this country, are even better known as a valuable galactogogue than those of the cotton tree, and a new remedy of this kind seems scarcely needed unless it possesses advantages over those hitherto in use.

In the *Lancet*, Drs. Ringer and Murrell describe the effects of a remedy for neuralgia, which seems to be one of considerable promise. It has recently been introduced into this country by a gentleman residing in Fiji, who states that it has been used by the aborigines for several centuries, the secret of its preparation having been an heirloom in the family of a chief for two hundred years. One of the most remarkable circumstances connected with the remedy is that it does not produce toxic symptoms in large doses frequently repeated, neither the pupil, the secretions of the mouth and skin, nor the sensation of the skin supplied by the fifth nerve being affected by it. This drug, which is called Tongu, consists of a mixture of a hard fibrous bark, a fibrous root and a few fragments of leaves, neither of which appears to possess any marked taste.

It will be remembered that some months since *Xanthium spinosum* was brought forward as a remedy for hydrophobia but discarded on account of apparently possessing no sensible properties. This plant, however, according to Dr. Bancroft, has escaped from abandoned cotton plantations at Brisbane, and killed cattle which ate it. He states that the animals die with symptoms of pure debility, without convulsions, tetanus, or any excitement. The plant would seem therefore to deserve chemical investigation. He further states he has found the active principle of *Piper Novæ-Hollandiæ* to kill frogs with symptoms of a mixed narcotic and convulsive character.

Baron Mueller and L. Rummel describe, in the *Zeitschrift Oëst. Ap. Ver.*, a new glucoside obtained from *Gastrolobium bilobum*, an Australian plant, which possesses poisonous properties. It is called "gastrolobin," and is described as a blackish, brittle hygroscopic substance, with an odour and taste resembling that of sassafras, soluble in hot water and alcohol, and precipitated by a watery solution of acetate of lead. It is easily decomposed by mineral acids and partly by organic acids, and is soluble in ammonia with an intense yellow colour. It is not, however, as yet certain that the glucoside is the principle to which the poisonous properties of the plant are due. A poisonous principle has been found also in other species of this genus, and of the allied genera, *Oxylobium* and *Gompholobium*, and also in *Isotropis striata*, Benth.

Some papers lately read before the Berlin Chemical Society promise to be subversive of previously existing ideas respecting several of the solanaceous alkaloids. According to Herr Ladenberg, who recently succeeded in reforming atropine from tropine and tropic acid obtained from it by decomposition, hyoscyamine, daturine and duboisine are one and the same alkaloid, whilst atropine, if not also identical, appears to yield the same decomposition products, and can hardly be distinguished chemically from it. Herr Kraut also, has published some experiments which he thinks render it probable that belladonnine is an isomer with atropine, and he suggests, that it too may prove to be identical with hyoscyamine. Herr Ladenburg has further found that by the treatment with dilute hydrochloric acid of different salts of tropine, the base obtained by decomposing atropine or hyoscyamine with baryta, a class of alkaloids may be produced artificially, to which he has given the generic name of tropeines. One of these, obtained from the amygdalate of tropine, promises to be of therapeutic importance, it having powerful mydriatic properties, and being said to be preferable for use in some ophthalmic cases to atropine.

Dr. Purjesz, of Pesth, in the *Centralblatt für prakt. Augenheilkunde*, relates a case of poisoning by 2½ grains of sulphate of atropine which was entirely cured in three hours by the administration of a centigramme of muriate of pilocarpine every five or ten minutes until 16 centigrammes had been taken.

The deposit sometimes occurring in syrup of lactophosphate of lime has recently been examined by Professor Wayne (*Druggists' Circular*, March), who states that it consists of lactate of lime, resulting from the phosphate of lime at first dissolved in the lactic acid becoming subsequently decomposed by it. The syrup in this condition is therefore no longer a solution of phosphate of lime in lactic acid, but only a magma of lactate of lime with free phosphoric acid. This change, it is said, sometimes takes place quickly, and a similar one also occurs in syrup of lactophosphate of iron. It is not prevented by the addition of hydrochloric acid, but the lactate of lime or iron formed then remains in solution.

It has been found by Herr Tausch (*Chem. Zeitung*, March 4, p. 156) that commercial samples of hydrochlorate of morphia, when heated to 130° C., become brown under partial decomposition. Pure hydrochlorate of morphia, however, can be heated to that temperature without such change taking place. The decomposition and discoloration appear to be dependent upon the presence of resinous contaminations, and Herr Tausch concludes from his experiments that the commercial salt is almost always impure. Both the hydrochlorate of morphia and the free base lose their water of crystallization at 100° C.

A note in the *Chemical News*, by Mr. R. H. Ridout (Feb. 13, p. 73) on the products of the slow oxidation of phosphorus is not without an application to a common form of specialty terminology that reveals anything but the real nature of the preparation. Four or five years since a country practitioner having in consultation with a London specialist been recommended to use an injection of "ozonized water," unsuccesfully tried in various places to obtain a supply. Mr. Ridout being applied to, although aware of the general impression that ozone is insoluble in water, made an experiment by aspirating a current of air over moist phosphorus. An abundant evolution of an oxidizing body was thus produced, which was passed through caustic soda to free it from phosphorus vapour and then through recently distilled water; but after this action had been continued for six hours the water was found to contain not a trace of any oxidizing agent. After this evidence of the insolubility of ozone in water an application was made to the specialist for a sample, which proved to be a solution of potassium permanganate.

Dr. Vasowicz, in *La Ruche Pharmaceutique*, has detailed some experiments made with a view to ascertain the correctness of the statements of Dr. Jehn that oil of peppermint is coloured red by hydrate of chloral. He shows that in those cases in which the oil was of ascertained purity no coloration took place; in those in which it was not possible to ascertain the exact purity a yellowish coloration occurred.

The cupric pellets for testing sugar, suggested by Dr. Pavy, and referred to before (p. 604), have since been the subject of some correspondence in the *Chemical News*. Mr. Langbeck has pointed out that Schiff (*Annalen*, cxii., 369) has attained the same end by the mixture of a concentrated aqueous solution of sulphate of copper (250 parts) with a solution of tartarated soda (280 parts), well washing and drying the light blue salt that separates, and preserving it in small glass tubes protected from daylight. When required for use the salt is dissolved in a sufficiency of soda ley, sp. gr. 1·14, and if it has been properly prepared 3·686 grams of it is reduced by 0·5 gram of glucose. On the other hand Mr. Glassford remarks that the difficulty of preserving Fehling's solution is entirely overcome by keeping the cupric sulphate and alkaline tartrate in solution in different bottles and mixing when required.

Ammoniacal glycyrrhizin appears to be steadily making its way upon the continent. According to the *Journal de Pharmacie* the French Minister of War has just ordered its definite introduction into the military hospitals, where a preparation containing 4 decigrammes of glycyrrhizin in a litre of water is to take the place of the old *tisane de reglisse*.

A writer in the *Grocer* (February 21), calls attention to the presence in the market of a "spurious pearl tapioca," manufactured in Germany from potato starch. It is said to be a clever imitation, in size and colour, of tapioca from cassava, but differs from it in changing when boiled into a soft and pappy compound, without consistency.

The *Canadian Pharmaceutical Journal* recommends the trial of the "cold blast" for the purpose of drying herbs and drugs. Quartered apples thus preserved are said to be much superior, both in appearance and flavour, to those dried by heat or in the sun.

A writer in the *Boston Medical and Surgical Journal* points out that the distressing symptoms such as headache, impaired appetite and derangements of the stomach and liver, which sometimes follow the administration of tincture of chloride of iron, disappear when half a grain of chloride of ammonium is added to each minim of the tincture.

In the *Philadelphia Medical Times* Professor H. C. Wood recommends a simple but apparently very effectual remedy for hæmorrhoids. This consists in the injection of ½ to 1 ounce of a saturated solution of chlorate of potassium with a few drops of laudanum. This is only used as an adjunct to the usual systematic treatment, and of course under medical supervision, but the results obtained are stated to be surprising.

The *Allg. Hopfer Zeitung* points out that one of the best remedies for relieving the pain of burns and scalds is oil of peppermint, applied by a camel's hair pencil. It is said to give prompt relief and to lead to a rapid cure without scars. This accords with what is already known of the similar action of turpentine and creosote. Either of these agents should not be applied where the skin is destroyed, if the object be to relieve pain.

Dr. Lush, in the *British Medical Journal*, Nov. 22, 1879, gives the following lotion as almost, if not quite, a specific for the intense burning irritation which often attends chronic eczema of the palms, especially if the patient has a rheumatic tendency:—

Sodæ Bicarb.	ʒij.
Pot. Bicarb.	ʒj.
Glycerini	1·5 dr.
R. Opii	2 dr.
Aq.	18 dr.

M. Arloing, of Paris, has recently shown that formate of sodium lowers the temperature of the body in a marked manner and suggests that it might be employed in some cases where the salicylate of sodium is contra-indicated, the formate not congesting the kidneys nor modifying the temperature of the body so profoundly.

According to the *Gardeners' Chronicle* (February 14, p. 211) the value of camphor in Japan has considerably increased of late. Although the production is very large, it could easily be increased were proper means adopted, the method in practice at present being very wasteful, large tracts of country being denuded of valuable trees. The export of Japanese wax, however, continues to diminish, being now less than one-fourth the quantity taken in 1876. This is attributed partly to the introduction of kerosene oil, partly to the damage done to the trees during the civil war in the south of Japan, and partly to the fact that manufacturers in Europe are already abandoning its employment in favour of cheaper substitutes, so that the consumption is rapidly falling off.

M. Pasteur, whose name is inseparably connected with the history of the lower organisms, and who recently has been pushing his investigations in the direction of their physiological importance, has presented to the Academy of Sciences another important memoir that appears to throw light upon the nature and propagation of zymotic disease. (*Comptes Rendus*, vol. xc., p. 239.) This time he has taken for his subject the *choléra des poules*, a disease that is occasionally very disastrous in the poultry yard. He believes it to be produced by an extremely minute organism, having prodigious powers of multiplication in a suitable medium. In filtered yeast water, a medium favourable to the development of many microscopic organisms, it speedily dies; but in a broth of fowls' flesh it flourishes, and by successive minute impregnations of fresh quantities of such liquor, the organism was obtained by a species of cultivation free from contamination with other organisms. A few drops of this liquor on a piece of bread is said to be capable of setting up the disease and inducing almost invariably a fatal termination, the organisms entering the system by the intestinal canal, and multiplying enormously, while the excrements become charged with them and capable of setting up the disease in other fowls. Guinea pigs inoculated with the organism only suffer inconvenience from a local abscess, but the discharge from this abscess is fatal to fowls and rabbits. Although in its normal form this organism almost invariably produces death in fowls, M. Pasteur states that by a special treatment, the particulars of which for the present he keeps secret, it can be so modified that the disease produced by it is, as a rule, no longer fatal; whilst a bird that has once suffered from the modified form of the disease is only in rare cases susceptible to reinoculation even with the most virulent form of the organism. The apparent analogy of this phenomenon with that of cow pock and small pox is plausible, and M. Pasteur considers it to form a link between maladies known to have a living virus and those virulent maladies in which a living virus has not yet been detected.

Considerable interest has been awakened by Dr. Siemens's paper, recently read at the Royal Society, on the "Influence of Electric Light upon Vegetation." Horticulture will receive a new stimulus as the result of his experiments, and forced fruits and vegetables will probably be produced, not merely equal in size, but in flavour, to those grown in the summer months. At the last meeting of the Society specimens of strawberries grown partly under electric light showed an extraordinary advantage in point of size and colour over those grown without it. One of the conclusions arrived at by Dr. Siemens, to the effect that plants do not appear to require a period of rest during the twenty-four hours, but make increased and vigorous progress if subjected during daytime to sunlight and during the night to electric light, is a rather startling one, and suggests that further experiments are necessary to show whether such treatment would not ultimately destroy the vitality of the plants and render them entirely unfit for reproductive processes. Such a result seems to be the case with many vegetables, which by prolonged and forced cultivation have ceased to produce seed and in some cases flowers. It seems not improbable that the attacks of fungi in coffee plantations, in potatoes and other plants, may be due to the vitality of the plants being impaired by excessive demands on their vitality and that they are consequently unable to resist the onset of those parasitic diseases. The failure of the lavender crop during recent years is in all probability due partly to this cause, and partly to the fact of the matters removed from the soil by the plants not being always returned to it in the form of the dead leaves, as nature dictates. Although Dr. Siemens's results are more especially of value to horticulturists' yet the fact of the practical identity of solar and electric light as regards vegetation is particularly interesting from a pharmaceutical point of view. In this country where the intense light of tropical regions is otherwise unattainable, it will be possible to investigate in a scientific manner the influence of light in promoting the formation of the different alkaloids in the cinchona plants, the poppy, etc.

The revived interest in the subject of the artificial production of the diamond, provoked by Mr. Mactear's experiment, has been intensified by the communication made by Mr. Hannay to the Royal Society at its last meeting in February. Mr. Hannay, continuing his researches in respect to the solubility of solids in gases, recently referred to in these columns (*ante*, p. 504), made numerous experiments with different forms of carbon in vapours that he thought most probable to act as solvents, in the hope that from one of them the carbon might be redeposited in a crystalline form. These experiments, Mr. Hannay says, were unsuccessful, but it was noticed that when a gas containing carbon and hydrogen was heated under pressure in presence of certain metals its hydrogen was attracted by the metal and the carbon was set free. Ultimately the operation was conducted in the presence of a "stable nitrogen compound," and under these conditions Mr. Hannay says that "when the whole is near a red heat and under very high pressure the carbon is so acted upon by the nitrogen compound that it is obtained in the clear, transparent form of the diamond." At any rate, there seems to be no doubt that some minute crystalline fragments submitted with the paper as the product of such an operation were really identical with the natural diamond. The stable nitrogen compound used was not specified, but Professor Dewar pointed out the analogy between such a reaction and the production of graphite by heating a cyanide in caustic soda to a low red heat. These statements, so interesting to scientific men, are probably not altogether comfortable to diamond owners, but it will be somewhat reassuring to them to learn that the cost of producing diamonds artificially still far exceeds the market value of the product.

How to effect the dissociation of the "elements" —and especially of the metalloids—is a problem still occupying the attention of scientific men. According to *Nature* (March 11), M. Pictet, who two years since liquefied oxygen, starting with the fact that none of the metalloids, with the exception, perhaps, of oxygen, has yet been detected in the sun, infers that their absence is due to dissociation, and proposes to attempt to reproduce the conditions under which this takes place. This he would do by means of an enormous parabolic mirror, in the focus of which the sun's rays should be concentrated upon the metalloids which it is sought to decompose. Some of the data for working out this problem are known, and assuming that to dissociate bromine would require "a hundred times as much heat (at the temperature of its dissociation point) as water vapour requires (at its dissociation point) to split it up," M. Pictet calculates that a gram of bromine would need 350 calorics to resolve it into its elements, and that to dissociate one gram per minute would require that the solar rays should be concentrated by a mirror of at least 35 square metres of surface. At the focus would be a chamber or crucible of zircon or lime, or other refractory substance, into which the vapours to be operated upon would be led, and which to avoid loss of heat would be kept hot from without by oxyhydrogen flames. From this chamber the products of dissociation—if any—would be withdrawn by aspiration through metal tubes containing metallic gauze and cooled by refrigeration from without to $-50°$, a proceeding which it is supposed would hinder at least a considerable portion of the constituents from recombining.

The publication of the results of a series of experiments by Professor Krafts (*Comptes Rendus*, xc., 183) that appeared to be somewhat antagonistic to the important statements made by Professor V. Meyer last summer, with respect to the density of chlorine, has induced the latter chemist to communicate to the Berlin Chemical Society (*Berichte*, xiii., 394—408) a series of notes confirmatory and explanatory of Professor Kraft's experiments. It will be remembered that Meyer, working with chlorine obtained by decomposition of platinous chloride, found that when it was heated to 1567 C.° it underwent a diminution of density equal to one-third. Krafts, working with free chlorine, failed to obtain the same result, and it now appears that at any temperature at present used the change is limited to chlorine in the nascent state. Iodine behaves similarly to a certain extent, for at about 600° C. the vapour density corresponds to the formula I_2; at 800° it undergoes considerable diminution; and at from 1027° to 1567° C., it exactly and permanently corresponds to the formula $\frac{2}{3}I_2$. But it is curious that though pure iodine was used in these experiments there was no permanence in the normal vapour density corresponding to that experienced when free chlorine was used. Nevertheless there is the fact that the investigation of Deville and Troost of the boiling-point of zinc was carried out with an iodine thermometer and based upon the ascertained permanent vapour density of iodine at a temperature of 1040°. The explanatory hypothesis apparently favoured by Meyer is that iodine vapour produced under certain conditions may remain, as he found free chlorine to do, permanent in its density, and that perhaps those conditions may be induced by the way in which Deville and Troost operated, which differed in the iodine being gradually heated. Bromine appears to behave similarly to iodine, but great difficulty was met with in dealing with it in the free state in consequence of the explosive rapidity with which it vaporized at a yellow heat. In operating upon it in the nascent state, a new salt, platinum tetrabromide, $PtBr_4$, was used. It is well, in view of certain inferences that have been drawn from these experiments, to quote Professor Meyer's cautious description of the result as "the dissociation of the chlorine to molecules of the size of $\frac{2}{3}Cl_2$." He also remarks that the power chlorine has of existing at the same temperature both as Cl_2 and $\frac{2}{3}Cl_2$, according as free or nascent chlorine is operated on, is analogous to the case of oxygen and ozone.

Professor A. Sacchi has recently reported to the Royal Academy of Sciences at Naples the probable presence of a new metal in the lava ejected from Vesuvius in the year 1631. This metal he proposes to call "vesbium," after the ancient name for Vesuvius mentioned by Galen. It appears allied to vanadium and molybdenum, although not answering to the special tests for either of these metals. As the professor has as yet only 3 grams of vesbic acid, he makes no definite claim as to the existence of vesbium until he has obtained a sufficient quantity to insure purity of the salts and exactness of results.

The vacancy in the Pharmacy section of the French Academy of Medicine, caused by the death of M. Poggiale, was on the 3rd ult. filled up by the election of M. Jungfleisch. The other candidates were MM. Méhu, Baudrimont and Prunier.

If the argument that pharmacists should take a prominent part in the preparation of a national Pharmacopœia required an illustration it could be found in the admirable draft report on the Revision of the United States Pharmacopœia, just issued by the committee of pharmacists appointed by the American Pharmaceutical Association. It can be safely said that a report so valuable and practical from the pharmaceutical point of view as the one prepared by Mr. Rice, the chairman of this committee, could hardly have emanated from a committee of medical men. In France, too, where the Government has decided that the Codex shall be revised, the commission nominated to undertake the work includes several pharmacists, and, more than that, the commission itself has submitted to the Society of Pharmacy for consideration a list of the members of various sub-committees, many of them pharmacists, whom it proposes to entrust with divisions of the work.

Since the last appearance of the "Month" another veteran German pharmacist has passed away, in Dr. August Wiggers, Professor of Pharmacy in the University of Gottingen. The deceased was in his 77th year, and his jubilee was celebrated about two years since. From France, too, the death is reported of M. Baudrimont, Professor of Chemistry to the Faculty of Sciences, Bordeaux, at the age of seventy-four years.

That a considerable amount of responsibility rests upon dispensing chemists is evident from the character of some of the prescriptions which are sent to these columns.

The one No. 385 is a fair example of one class, where ol. sinapis sem. ʒvij is ordered in a two ounce liniment, and the difficulty is further increased by the fact that the writer of the prescription, when applied to by the dispenser, failed to explain what it really was he did mean. The particular oil which should be used, therefore, was left to the discretion of the chemist, whose first duty would be to protect the patient from injury, and in the next place to protect himself from censure.

Referring to the only oil of mustard in the B.P., Mr. Talbot will see that the sole officinal preparation in which it is ordered, is the lin. sinap. comp., where the proportion is 1 vol. in 41. Presuming that the ol. sinap., B.P., was intended, it may safely be assumed that the writer was not aware of the character of the article ordered; it would, therefore, be safer to use the expressed oil, which generally has a little pungency, and is said to possess some value as an external application in rheumatism. The presence of the spirit would indicate that the volatile oil was intended, but the proportion of this is unusual, and as it possesses such powerful vesicating properties, to dispense the liniment with the volatile oil would be very injudicious, unless under special circumstances which are not, in this instance, indicated by the prescriber.

It will be seen on referring to the lists of some wholesale houses that there is an ol. sinap. express., as well as an ol. sinap. ess., and probably the writer of the prescription is better acquainted with the contents of the wholesale price lists than he may be with his Pharmacopœia.

The query No. 386, with regard to zinci oleas has been very correctly answered by Mr. Baldock, and nothing further than a reference to his remarks need be said with regard to this question. In Mr. Baldock's answer the name has been inadvertently printed oleate of lime. Oleate of zinc when properly made is usually of the character of a stiff ointment whose consistence varies with the percentage of zinc

"Dubius" asks, No. 387, with regard to infusion of buchu, "Should the remainder of the leaves, after decantation, be pressed to obtain the mucilage, or should the liquid merely be allowed to run from the leaves without pressure?" The directions of the Pharmacopœia on this point are very clear, "Infuse in a covered vessel for one hour and strain." The infusions of the Pharmacopœia are directed to be made in covered vessels for different periods of time, and when the full time has elapsed the infusion should be strained from the dregs; but in no case should the dregs be pressed, neither in any case should any of the infusion be poured off for use previously to the straining of the whole. The instructions are concise, but clear.

When tr. nuc. vom. and acid. nit. mur. dil. are mixed together in relative proportions something like No. 388, there is at once turbidity, resulting from some of the resin of the nux vomica being thrown out of solution. In an hour or so it becomes darker and loses a little of its opacity; afterwards there is a separation of the resin as a flocculent matter; this is followed by chemical action with slight disengagement of gas, and the formation, judging from the smell, probably of nitric ether. Again, in a day or two, the mixture assumes a colour very like the original, the flocculent matter aggregating into particles and floating in the liquid. These successive changes probably result in the formation of nitric ether, and the re-solution of some of the separated resin after all action has ceased. This combination of medicines in so concentrated a state is unsuitable for prescriptions; the presence of gas formed by the combination may result in the bursting of the bottle, and the dispenser does good service by pointing out the chemical incompatibility involved.

The ingredients of prescription No. 389 may be well combined by the use of glycerine of tragacanth as an excipient. It has on previous occasions been recommended as very suitable, and perhaps one of the best, for a mixture of aloes with sulphate of iron in a pill mass.

In using glycerine of tragacanth as an excipient great care should be taken to use only just sufficient, with a good deal of manipulation; an excess tends to make the pills very soft, from which they cannot afterwards be recovered.

The writer of prescription No. 390 orders liq. quinæ ammon. gr. iv. ad ʒj; this is four times the strength of tr. quinæ am., B.P., for which preparation it may be presumed the liquor was intended. The proportion of quinine is not held in solution in the relative proportions of liq. ammon. and proof spirit ordered in the B.P. The excess, therefore, of quinine may be rubbed to a powder and suspended by mucilage, and more especially is mucilage needed in this combination as the ammonia neutralizing the hydrochloric acid used to dissolve the strychnia will throw that active ingredient out of solution, and if not suspended by means of mucilage, or some such agent, the whole may be taken in the last dose of the mixture.

The change mentioned by W. Symons in No. 391 as occurring in a mixture of mag. sulph. with mag. carb. pond. etc., has not been observed, and, therefore, cannot now be explained. As some time seems necessary to produce the effect, it may, on a future occasion be adverted to in these columns.

It is sometimes difficult for a dispenser to know what the writer of the prescription intends. He can only gather his intention from what he writes, and his mode of writing it. In No. 392, the prescriber directs glycerol. plumbi diacet. ℥ij, to be applied to the parts as directed every night and morning. With regard to the sodæ biborac. ℥ij which follows, he may have given private instructions to the patient how to deal with that substance, but in the absence of knowledge beyond that given in the writing, there is only one course open to the chemist, that is to send the sodæ bibor. separately. Many dispensers are so favourably placed that they experience no difficulty with regard to what physicians mean, and, therefore, dispense their prescriptions with a previous knowledge of their intentions; but without any such previous knowledge the dispenser has no other course before him but to send out the two separately. The prescriber may very probably say that the dispenser should have mixed them, as he intended them to have been mixed; but had they been mixed in the presence of these directions, he may with much greater force have said, that he did not intend them to be mixed, and wrote his prescription accordingly. Mr. Baldock's view may be the correct one, that the sodæ bibor. with the glycerole should have been sent out of the consistence of an ointment, but there is ample room for doubt, and it was to discuss such doubtful questions as this now before us, that called the Dispensing Memoranda into existence, and as long as prescriptions such as these create a reasonable doubt in the mind of the dispenser, so long will these pages continue to supply a want to many of our less favoured brethren in pharmacy.

The mixture No. 393 contains dec. senegæ, and the question is, should dec. senegæ, P.L., be used or the inf. senegæ, B.P.? As there is no dec. senegæ in the B.P., it may be assumed that the writer of the prescription means the decoction of the London Pharmacopœia, which would be the proper preparation to use.

The pills, No. 394, may be made into a mass with conf. rosæ can., using as small a quantity as possible to make the pills of a suitable consistence. It is impossible to say what size the pills should be, much would depend on the manipulation of the dispenser.

In the prescription, No. 395, there is no decomposition apparent, either by separation or precipitation, if dispensed in the following manner:—The citrate of lithia should be dissolved in half the fluid, and the dissolved quinine added to the other half, and then mixed; the result will be an opaque mixture, mainly if not wholly due to the tincture of orange peel.

In answer to "Minor," No. 396, if pills be of firm consistence they may be silvered without difficulty by first moistening their surfaces with mucilage and then shaking them in a gallipot with silver leaf.

In No. 397 C. J. B. requires an excipient for camphor pills. This subject has been referred to on a former occasion, and will be found on p. 166, vol. ix., series 3 of this Journal. Castor oil has been recommended for this purpose, and glycerine of tragacanth is a very suitable excipient.

"Junior," in No. 398, gives a prescription which has been dispensed and sent out clear; there results from a mixture of these ingredients a reddish precipitate of phosphate of iron from the ammonio citrate. The precipitate is redissolved in a considerable excess of sulphuric acid, but that is not admissible. It is one of those incompatibilities which should, when possible, be brought under the notice of the prescriber.

WHAT IS MATTER?*

BY C. G. KNOTT, SC.D. EDINBURGH UNIVERSITY.

Matter and energy are the two recognized existences in the physical universe. The latter is the active principle, being that in virtue of which change is possible; the former is to be regarded as being purely passive, merely the vehicle by means of which energy works and through which its workings are evident. And yet, so far distinct as they are, it seems barely possible to separate them even in thought. Matter without energy may be imagined, but can never be realized; and it is doubtful whether energy without matter of some form can even be conceived. We know of matter only by means of transformations of energy; we recognize energy only through its affections of matter. Hence, in discussing the ultimate nature of matter and the experimental grounds for any belief regarding it, we shall find it impossible to escape from the consideration of energy; indeed, we shall ere long find that one of the most ingenious modern theories concerning the structure of atoms makes matter, *as we know it*, a form of energy. Our many sensations so impress us with a belief in the existence of matter, that it is not surprising that speculation as to its ultimate nature should have been rife from the very beginnings of philosophic thought. By experience, and by experience alone, can we obtain that knowledge of the various properties of matter which is indispensable to the formation of a truly philosophical theory; so that the true order of inquiry is first to become acquainted with these properties and then discuss their bearing severally and together upon the great question, what is matter? Now, it is evident that many properties of matter are dependent upon the peculiar circumstances in which the portion of matter under consideration is placed. Thus iron, which is tolerably hard under ordinary temperatures becomes soft and plastic at a white heat; glass, which is ordinarily thought of as being rigid, inflexible and brittle, may be made to assume the form of delicate elastic threads or fibres; and gold, which is usually opaque, may be obtained so thin as to be transparent. Such characteristics are not persistent; indeed, the only properties of matter which seem to be persistent are gravitation and indestructibility, and of these, gravitation should perhaps be regarded as being not a property of matter, but an affection of matter imposed upon it by energy conditions. Still, from the non-persistent properties of matter much is to be learned. The changes above specified lead at once to the consideration of internal structure, and so to the wide question concerning the ultimate nature of matter. At the very outset, there are two rival theories, the one of which regards matter

* Abstract of a Lecture delivered before the North British Branch of the Pharmaceutical Society, February 26, 1880.

as being ultimately coarse grained, while the other maintains that matter is continuous though heterogeneous. In other words, is matter indefinitely divisible, or, if the division could be performed far enough, should we at length come to a point beyond which we could not go,—in fine, should we reach the atom? The latter was the view taken by Epicurus, Lucretius, and the early atomists: and in some form or other, the atomic theory has been held by the great majority of scientific men down to our own day. By both physics and chemistry we have been led to the hypothesis of the molecular or "particular" structure of matter; and further than the molecule we have not as yet been able to penetrate except in thought, though the presumption is that a molecule has an atomic structure. Let us then glance at a few of the arguments furnished us from the domain of molecular physics.

All matter, as we know it, must exist in the solid, liquid or gaseous condition. Consider, then, a block of solid marble. We may divide it into two, then the one half into two smaller fragments, and so on, but not indefinitely. Marble is not a homogeneous structure, and at length we obtain two fragments which have no resemblance to each other and which are neither of them marble. We have reached the limit of divisibility of marble, though not of matter. We thus pass from huge blocks to finest dust, and we may, in imagination at least, reverse the process and reconstruct or build up a solid mass from the most impalpable powder. This latter process is carried on in nature on an extensive scale, and in the formation of crystals we find an interesting argument in favour of the molecular structure of matter. The symmetrical pyramidal form of a pile of equal spherical balls is very similar to some of the forms assumed by natural crystals, and the inference is that these have been constructed in a somewhat analogous manner, namely, by the aggregation of the molecules which make up the crystal and which in virtue of the action of their molecular forces assume a stable configuration. This implies the similarity of the molecules of a given portion of homogeneous matter. Passing to the consideration of liquids, we meet with many striking illustrations. For example, comparing water and mercury, we know by experiment that water is not indefinitely divisible, but of mercury we are not so sure. Water in fact is coarse-grained, a molecule of water having the same relation to an average-sized drop that a good-sized plum has to the earth. At a certain point in our subdivision of water we get as far as we can go, further sub-division being a decomposition of the water molecule into its component molecules of hydrogen and oxygen. This decomposition is most easily effected by means of a strong electric current, whose energy is employed in pulling apart the components of the water molecule. By collecting and mixing the gases so evolved, we may by heating the mixture recover this energy in the sound and heat of an explosion. Electrolysis, indeed, furnishes endless examples, and gives a means for estimating the sizes of molecules. The effect of heat upon a solid is in general to make it expand and rise in temperature, and at length transform it into a liquid, which in its turn goes through an analogous succession of changes till it is finally made to assume a gaseous form. According to the molecular theory of matter, the molecules of a gas are perfectly free from each other and move about in all directions with considerable velocities. They are constantly coming into collision with each other and impinging upon the walls of the vessel which contains them. In these impacts we find a sufficient explanation of the phenomenon of fluid pressure; and, with the assumption that heat has the effect of increasing the average velocity of the moving molecules, we are able to deduce at once the well-known laws connecting the pressure volume and temperature of a gas. The assumption regarding the effect of heat is one which receives countenance from other phenomena. Thus a liquid is believed to differ from a gas only in the much smaller velocities of its component molecules which are in closer proximity; while in a solid the molecules are so closely wedged together as to admit of no translatory motion at all. Vibratory motion in each individual molecule is of course still possible, and to it the effects due to temperature are referred. Upon this hypothesis, then, the gradual transition from solid through liquid to gas by the agency of heat receives a simple and beautiful explanation; while the laws of Boyle and Charles, and the principles established experimentally by Graham, which regulate the diffusion of gases and liquids, are direct physical consequences of the so-called kinetic theory of gases. In spectrum analysis we discover evidence that a free molecule has definite fundamental modes of vibration, which give definite wave-lengths of light, exactly as a tuning fork gives a musical note of a definite pitch; that the molecules of different kinds of matter have different periods of vibration, and may thus be distinguished by their characteristic rays; and that heat is the great agent in starting and sustaining these vibrations. Molecules then must be of a structure which is physically capable of vibrating; but what of the atom in this respect? It is quite clear that the hard incompressible sphere of the early atomists could never vibrate; but, apart from this, such an atom in its very nature is inconceivable. An atom which owed its indivisibility to its hardness would require to be infinitely hard so as to resist any force, however great. To Sir William Thomson, however, we are indebted for the conception of an atom, which has the property of indivisibility without the inconceivable property of infinite hardness, and has in addition the power of vibrating. This atom is the *vortex-atom.* A vortex is produced when any portion of a fluid is set rotating round an axis, as, for example, in eddies, whirlpools, waterspouts, whirlwinds, and cyclones and storms generally. Professor Helmholtz, of Berlin, proved more than twenty years ago that if, in a frictionless fluid, a vortex-filament, *i.e.*, a column rotating round an instantaneous axis, exists, it must either return into itself so as to form a *vortex-ring*, or extend through the fluid till it reaches the bounding surface, and also that where such vortex motion does exist it must always exist, and where it does not exist it never can by physical means be made to exist. It is upon this indestructibility of vortex motion that Sir W. Thomson has based his theory of the vortex-atom, which is simply a vortex column returning into itself after it may be several knottings. The simple vortex-ring is frequently formed by the smoke emanating from a funnel or a cannon's mouth, and may be very simply produced, as was done first by Professor Tait of Edinburgh, by projecting smoke-rings from a hole in one side of a box filled with sal-ammoniac by impacts on the cloth or india-rubber sheeting which forms the opposite side. In this case we can form vortex-rings because the fluid we are dealing with is *not* a frictionless fluid. By such an apparatus curious properties of vortex-rings may be demonstrated, such as their rebounding after collision like elastic solids, their spreading out indefinitely as they approach a plane surface, and the tendency which the foremost of two rings has to expand and slacken speed, and permit its contracting and accelerated successor to shoot through it. According to Thomson, then, an atom is a vortex-ring existing in a homogeneous frictionless continuous fluid filling space—an atom which must therefore exist always, and cannot be cut, cannot even be got at to be cut; hence matter, as we know it, is simply a form of energy, being a rotatory condition of a finer, more ethereal, but still material substratum. The authors of the 'Unseen Universe' have speculated upon the possibility of this homogeneous matrix of matter being after all not quite frictionless, so that, finally, in accordance with the doctrine of dissipation of energy, our material universe—

"Shall dissolve;
And, like the baseless fabric of [a] vision,
Leave not a wrack behind."

INDIAN DRUGS.

SOME observations on Indian drugs made at a recent Evening Meeting of the Society by Dr. M. C. COOKE were of sufficient importance to justify a further expansion in the pages of this Journal of the views then propounded. Unfortunately there is a habit of alluding to *Indian* drugs and other products in so vague a manner as to lead to the impression that only a small district, or a few neighbouring ports, constitute the locality from whence the products are derived, instead of that immense variety of states, climates and peoples, included in the term British India.

At all exhibitions where the products of India have been represented, it has been abundantly evident that even the same substance varies extensively, according to the different districts from whence it is sent. It is under such circumstances most instructive to compare the productions of different localities the one with the other. Confining ourselves to drugs, we would note the drugs of Bombay, Madras, Calcutta, Lahore, and also of the independent states, as each having a special interest of its own, which cannot but enforce the conclusion that an important feature in connection with Indian drugs is the *locality* from whence they are derived, a feature which should never be forgotten when attaching labels to a collection of drugs from India. The following seem to be some of the aspects in which this question of locality may be viewed. Primarily, the source of the principal imports. Many drugs in extensive use in India are not products of any part of the country, but are imports, such as asafœtida, olibanum, much of the senna, etc. If the locality whence a drug has been obtained in India is always associated with it, there will be less difficulty in conjecturing and ultimately tracing its source. One of the most important centres is Bombay. A great number of drugs are met with commonly in Bombay which are rare or unknown in Calcutta or Lahore. The most of these are imports from Aden.

Moreover, the trade between Bombay and Aden, as well as Zanzibar and other African districts, must not be lost sight of in the examination of a collection of Bombay drugs. Take olibanum, for example; that met with in collections of drugs from other parts of India is universally dark, dirty, broken, poor, and small in quantity, whilst from Bombay the finest tears ever met with in commerce may be obtained. The Arabian origin of many of the Bombay drugs is also a circumstance which cannot be overlooked.

There is another element which adds an interest to Bombay drugs, and that is the intimate political relationship which for a long time subsisted between Bombay and Sind. It is not unnatural to expect to find Sind drugs in Bombay, and such products as mastic, googul (or bdellium), boojkund (the galls of *Pistacia*), and others, will be recognized in every collection. There is yet another advantage possessed by most of the collections of Bombay drugs which have come under our notice, that the native names which accompany them are to a very large extent Arabic or Persian. It may seem useless, at first sight, to retain the native name in a collection of drugs in this country; but a little reflection will show that such is not the case.

Drugs from India have an interest historically, and by retaining even the modern Arabic and Persian names we link the articles themselves with old authors; they become commentaries on the 'Ulfaz Udwiyeh,' and through a Persian channel communicate with the Greeks. It is through a knowledge of drugs from India and Persia, with their Arabic and Persian names, that we are most likely to acquire an accurate knowledge of Dioscorides and Theophrastus.

In Madras the interference with native produce is very limited; there are no great channels of communication and no foreign imports of importance; hence the Madras drugs are chiefly native, except in the case of such imports as are common throughout India. Instead of imported senna, as at Bombay, we meet with the growth of Southern India. We look in vain for the Koraraima cardamom, with its hole through the centre, but Mysore cardamoms are plentiful. We have the lesser galangal, as we have it also in Calcutta, but not alone the product of a single species of *Alpinia*, but of two or three native species. Thus, without instituting comparisons, we may affirm that Madras drugs have an individuality, an importance of their own, which renders it advisable to study them as Madras drugs, and not merely as illustrations of the Pharmacopœia of India. The native names attached to products from this locality are chiefly Tamil and Telugu, the preservation of which is by no means of equal moment to the preservation of Arabic names. Possibly they may be forgotten with advantage.

From Calcutta the drug collections are unfortunately less valuable to the student than those from Bombay or Madras. Commerce at Calcutta concentrates and radiates in a puzzling manner. One can never estimate the probabilities as to whence any given substance may be derived. The aloeswood, for instance, may have come down from Nepal, or it may have come through the Tenasserim provinces, or it may have come round by sea from Malacca. Then again we cannot deny the fact, whatever may be its cause, that Calcutta drugs are inferior in quality to those from the other Presidencies. Whether the fault lies with the collectors, or whether there is a general inferiority in the markets, we cannot tell, but the constant recurrence of the same circumstance tends to the conclusion that it is not the collectors' fault. Very few, if any, of the drugs derived from Calcutta are not obtainable also from Madras or Bombay, if we except those from eastwards of Calcutta. At present Burma, Chittagong, Tenasserim, and the Malay Peninsula contribute but little to the drugs of that city. The wood-oils and cardamom seeds (*Amomum xanthoides*) being amongst the rare exceptions. This may not always be the case, when British Burma is more developed. Still the drugs of Bengal possess interest with the pharmacologist in the fact that they are not identical in quality with those of other Presidencies. Some may possess superior quality, and others,—feculas, for example,—may be derived from a different botanical source. The native names in Hindustani, or Bengali, if not in themselves so desirable as Arabic or Persian names, possess this value, that when a drug with a known Arabic name is once identified with one having a Hindustani name the very wide area over which Hindustani is known would enable us to obtain information concerning it, under its Hindustani name, from nearly any part of India.

It is not with any intention of depreciating one Presidency at the expense of another, that these observations are made; but for the purpose of showing that the pharmacologist who really desires to make acquaintance with the drugs of India must not be content with seeing and knowing such drugs only as are derived from one centre, but should endeavour to see and compare them with those of all the important centres, notably from the three Presidencies and from the north-west.

This leads us to allude to Lahore as another important place, to be taken into account in obtaining a knowledge of Indian drugs. One of the highways to India is through the passes in the north-west. Hence it is not too much to expect that a collection of drugs from Lahore should contain imports from Cabul, Candahar, Herat and Persia, as well as from Cashmere, Bokhara and Thibet. We have seen drugs from Lahore of a most interesting kind, never sent to Europe from any other locality in India. Here we come into contact with another current of imports, quite distinct from that which flows into Bombay, not to mention the indigenous products of the Punjab and the Himalayas. Here, again, we are glad to recognize Arabic and Persian names predominating, as at Bombay.

As an illustration, by the way, we would allude to "salep," which has a great value in India, although it has little in this country. More or less, salep is known and appreciated throughout India, but even the casual observer would at once recognize a great difference in the drug as derived from places widely separated from each other. It may be affirmed thst there are at least six distinct varieties of salep, and yet we are unable with certainty to refer any one of them to its botanical source. It is by no means improbable that several species of orchidaceous plants may be collected in any given locality as salep, and yet, without picking or sorting, certain of these saleps have an individual character. Whence do they come? The question would require a different answer according to the locality in which it was propounded. At Lahore, the presumption would be in favour of the Himalayas, at Madras it would revert to the Nilghiris, at Calcutta it would be difficult to answer, and at Bombay the mind would at once concern itself with the imports. The Turks and Persians also know and appreciate salep. Does it travel down the Persian Gulf to Bassora, with the blue galls, or Aleppo galls as they are termed, or down the Red Sea to Aden, and thence to Bombay? This example must yield some force to our suggestion as to the importance of taking the locality into consideration in connection with products obtained from such an immense expanse of country as British India.

THE MEDICAL REGISTRAR.

The Medical Register for 1880, which has just been issued gives fresh evidence of the zeal and activity of the present Registrar to the Medical Council. During 1879 there were 551 names removed that were improperly on the Medical Register, and as there were 654 similarly removed in 1878, it would seem that careful supervision did not come before it was wanted. The number of names added by registration during 1879 was 996, and the number of deaths reported was 548. The total number included in the Medical Register for 1880 is 22,516.

REGISTRATION OF FIRMS.

In a Bill that was introduced into the recent House of Commons by Mr. Sampson Lloyd, having for its object the consolidation of the existing law of partnerships and the introduction of a system of limited partnerships corresponding to the Continental *Société en commandité*, there is a provision for the registration of firms which, if passed, might prove to be a considerable assistance in carrying out the Pharmacy Act. It provides that every limited partnership or firm carrying on business in England or Ireland under a "firm name" which does not consist of the full usual names of all the partners, and every person carrying on business under a "firm name" consisting of or containing any name or addition other than the full usual names of that person, shall be registered. The registration is to include the "firm name," the nature of the business, the place or places of business, and the full name, usual residence, and other occupation, if any, of the person or persons carrying on the business.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The fifth evening meeting of the session was held in the Society's rooms, 119A, George Street, Edinburgh, on Wednesday, March 10, Mr. J. B. Stephenson in the chair.

A paper on "Dialysed Iron: its manufacture and value," was read by William Inglis Clark, Sc.D., Edinburgh, which he illustrated by experiments and diagrams.

DIALYSED IRON.

BY W. INGLIS CLARK, D.SC., ETC.,
Pharmaceutical Chemist.

In selecting the subject of dialysed iron for this evening, I was influenced by the consideration that no paper bearing on its manufacture or possible value had been presented to this branch of the Society, while my own experiments might assist in the scientific development of the question of its value as a remedial agent, and at the same time prove interesting to the younger members who attend these meetings.

A glance at the Year-Books of Pharmacy will show that the manufacture of dialysed iron has received attention from many observers, and that only a moderate amount of care is necessary, in order to produce a satisfactory article; but I do not suppose that many of those here present will have found time or occasion to practise the various published processes, and I may be, therefore, excused if I tread on what may be, to some, old and familiar ground, and recapitulate the various methods of manufacture.

What is Dialysed Iron?—It is a very basic oxychloride of iron prepared by the process of dialysis. This certainly does not agree with published statements which represent it as a solution of pure peroxide of iron in the colloid form; but, as I can readily show you, the purest forms of this preparation contain notable quantities of chlorine. It is only necessary to precipitate with ammonia, filter and neutralize with nitric acid, when the chlorine can be at once tested for by argentic nitrate.

The salts of iron are distinguished for their tendency to become basic, that is to form salts in which more or less oxide is united to or dissolved in a normal salt, and those who have manufactured liq. ferri perchlor., B.P., and the tincture from it will know how difficult it is to prevent the production of the oxychlorides or basic chlorides of iron. Indeed, the darkening of tr. ferri perchlor. is owing to this cause, the ferric chloride suffering decomposition, part of the hydrochloric acid being acted on by alcohol to form various chlorinated substances, along with aldehyde, and the oxide thus set free dissolving in the remainder of the ferric chloride to form a dark red oxychloride. Should this action proceed too far, eventually a very basic insoluble chloride or even hydrate is deposited and the tincture becomes colourless. We have in this case a natural formation of a basic iron salt, such as is aimed at in the preparation of dialysed iron, and it will be noticed that the ferruginous taste of the tincture will have perceptibly diminished, in proportion as the hydrochloric acid has been appropriated by the alcohol and the ratio of the oxide to ferric chloride has increased.

Preparation.—It has been long known that by dissolving freshly precipitated ferric hydrate in ferric chloride, a very basic solution is obtained, and that with patience and care the resulting salt might be approximately represented by the formula $Fe_2Cl_6 23Fe_2O_3$, while Graham showed that by dialysing such a solution he could obtain a liquid the composition of which indicated the formula $Fe_2Cl_6 95Fe_2O_3$. Dialysed iron, viewed apart from its method of manufacture, may be regarded as a solution of a very large amount of ferric oxide in a very small amount of ferric chloride, and if it were possible, by simple addition of ferric hydrate to the chloride, to approximate to Graham's figures, the resulting liquor would be identical with dialysed iron. The difficulty which meets us in such a simple method of manufacture lies in the presence of ammonium chloride, which prevents the solution of the oxide after a certain limit is reached. The source of this is the action of a minute trace of ammonia, present in the precipitated hydrate, on the hydrochloric acid of the ferric chloride. I have obtained a very soluble form of hydrate by the precipitation of dialysed iron with ordinary town water. This is soluble in pure distilled water, and very readily in a trace of ferric chloride, but it must be regarded as being a basic chloride and not a pure hydrate.

In an able article, by Emil Scheffer (*Pharm. Journ., Amer.*, 1878, p. 79), on dialysed iron, the nature of the ferric hydrates obtained under different circumstances is discussed. He showed that there were three stages in the preparation of ferric chloride by ammonia, and that the composition and physical properties of the precipitates varied therewith. I must refer you to the paper itself, but I shall briefly touch on the points above mentioned.

On adding ammonia to a solution of ferric chloride the first effect is to throw down a precipitate, which, if time be allowed, will dissolve again, but on further addition a point is reached when all the iron has been precipitated and the supernatant liquid is *acid.* More ammonia may be added till the liquid is *neutral*, and any further addition will make it *alkaline.* On examining the precipitates at these three points, we find that those obtained from the acid or neutral liquids are basic chlorides, and are soluble in pure distilled water, after being well washed, but that that from the alkaline liquid is a hydrate containing ammonia, and is insoluble in pure water. As the neutral point is reached the solubility of the precipitate rapidly diminishes, showing that the presence of ferric chloride is essential to solution. I have verified all Mr. Scheffer's results, and place before you a solution of a precipitate obtained from an almost neutral solution. This was carefully washed upon a vacuum filter for nearly a week, transferred to this bottle along with some distilled water, and after some weeks began to dissolve. Now, after twelve months, it is not entirely dissolved, but you will perceive that it is absolutely free from ferruginous taste, and would pass as a typical specimen of dialysed iron. For some time I thought that this process would be practicable for manufacturing purposes, but the difficulty in adjusting the amount of ammonia to be added, in washing away the ammonium chloride, and finally in dissolving the highly basic chloride, relegated this to the interesting but impracticable methods.

In practice, dialysed iron is always prepared from liq. ferri perchlor., B.P., and I shall, with your permission, discuss this process at some length.

Dialysis of Simple Liquor.—In *Pharm. Journ.*, September, 1878, we read, referring to perchloride of iron, "Lot B. shows that an ordinary acid solution of iron simply undergoes diffusion without decomposition, when put to dialyse." Seemingly then it is impossible to make dialysed iron by simple dialysis of liq. ferri perchlor., but this is by no means borne out by my experiments. A sample of liquor was analysed for use. It contained in 10 c.c. chlorine 3·9227 grams, and Fe_2O_3 2·82 grams, showing an excess of chlorine equivalent to HCl ·1781 gram. It was therefore a solution of ferric chloride with slight excess of acid, and was an ordinary commercial sample. For a dialyser, in experimental work, I alway use a bell jar with parchment tied over the mouth, the whole being suspended so that the parchment is about $\frac{1}{8}$ inch below the surface of distilled water. In this I placed 10 c.c. of the liquor previously diluted with water to 50 c.c., and after complete dialysis, I found that 1·85 gram or 65·6 per cent. of Fe_2O_3 had passed through the septum, leaving 34·4 per cent. which had not diffused. Thinking that dilution might cause dissociation in the dialyser, I started a second experiment, using 10 c.c. undiluted in it. Dialysis gave 1·817 gram Fe_2O_3 = 64·4 per cent., showing plainly that dilution was not the cause of the decomposition. In order that the liquor might be strongly acid, I now added to 10 c.c. of it 5 c.c. ac. hydrochlor., B.P., and found the loss to be 2·015 grams, Fe_2O_3 = 71·46 per cent. By boiling the liquor with an equal volume of hydrochloric acid, the loss was 70·5 per cent., and after varying the amounts of free acid I find the loss to vary from 63 per cent. to 81 per cent., but in no case to exceed the latter figure.

In order to reconcile these results with the published ones before referred to, I thought it possible that my liquor had been over heated in preparation, and rendered basic, a consideration which was, however, hardly possible since, as we have seen, it contained excess of acid. To decide this point, I prepared a solution of ferric chloride, oxidizing the ferrous salt by means of potassium chlorate, so as to avoid the use of nitric acid, and slowly, and at a low temperature, evaporating to the required B.P. strength. On dialysing this, 90 per cent. of the iron passed through, leaving dialysed iron inside. In order to determine the effect of further evaporation on this sample, I reduced it to half its bulk, making it up to its original volume with water, and on now dialysing only 68·9 per cent. of iron diffused. From this we see, as might have been expected, that if there be a deficiency of acid the loss of iron is much reduced.

I next took crystallized ferric chloride, obtained in nodular masses from a concentrated liquor, heated it in a flask with receiver, and obtained first a distillate of hydrochloric acid, water, free chlorine and ferric chloride, and subsequently scales of ferric chloride apparently contaminated with oxide. The first distillate on being placed in a dialyser passed entirely through; but the scales dissolved in water, and immediately filtered from a trace of oxide which had mechanically passed over, on dialysis suffered decomposition and only partly diffused. A sample of neutral ferric chloride, obtained by passing chlorine over metallic iron, on being placed in a dialyser, passed through to a large extent; but towards the end of the process precipitation took place inside the dialyser, and the remaining liquid was colourless.

From all these experiments we learn—

a. That ferric chloride may under some circumstances diffuse without partial decomposition.

b. That ordinary acid solutions, such as liq. ferri perchlor., B.P., invariably decompose when placed in a dialyser, and that the amount of decomposition is increased by deficiency of hydrochloric acid or evaporation, while it is but slightly diminished and not prevented by large excess of hydrochloric acid.

In order to examine this decomposition, I placed 10 c.c. of the same liq. ferri perchlor. fort. in the dialyser, and analysed the diffusate after various periods of time. The following table indicates the results, and shows that throughout the whole period of the experiment the salt which diffused away was more acid than ferric chloride, and was never more basic than that with which I started. This is the more interesting as Professor Redwood has since shown that when ammonio-citrate of iron is dialysed, the salt which passes through becomes more basic than that which was originally placed in the dialyser.

Table showing composition of diffusate from 10 c.c. liq. ferri perchlor. f. containing:—

Fe_2O_3 = 2·820 grams.
Cl = 3·922 „

	Fe_2O_3.	Cl.
Diffusate in ½ hour . .	·380	·7685

From the table, by calculation, it can be seen that the ratio of acid to base was much higher during the first half-hour than at any subsequent time, but that throughout it was always greater than that required by the formula Fe_2Cl_6.

Dialysis of Partly Neutralized Liquor.—We can now see that for the profitable production of dialysed iron, some means of preventing the loss of so much iron by diffusion must be adopted, and such is the addition of an alkali or an alkaline carbonate. Some recommend sodium carbonate on account of the rapid diffusive power of the sodium chloride which is formed; but I find ammonia more convenient, and the increase of time in the manufacture is insignificant. In using ammonia two methods may be employed. We have seen that ferric oxide is soluble in ferric chloride, and in practice I find that 1 part of B.P. liquor will dissolve the oxide from at least 6 parts, so that we may either take 6 parts of liquor, dilute with water, precipitate with ammonia, wash and dissolve in 1 part of the same, or to 7 parts, diluted with water, add the amount of ammonia (previously determined) necessary to precipitate the 6 parts. In either case we get a dark red solution which may be dialysed with but slight loss of iron.

It will be evident to everyone that by washing away the saline matters from the precipitate in the one case, we have greatly shortened the process, for it is the removal of the ammonium chloride by diffusion that is tedious and nearly six-sevenths will be contained in the wash water. I append a table showing the progress in two dialysers of equal quantities of liquor which had been treated in the above manner, and from it we learn that by precipitating and washing three-fourths of the liquor, with subsequent solution in the remaining one-fourth, the time necessary to produce dialysed iron is only one-half of what it is when washing is not made use of.

The dialysers were suspended in one-half litre of distilled water which was changed at the hours specified. The liquor used contained in 10 c.c.:—

Chlorine . . . . 4·1892 grams.
Fe_2O_3 . . . . 2·9714 „

In the series marked M, 7·5 c.c. were precipitated, washed and the precipitate dissolved in 2·5 c.c., and diluted with water to 40 c.c., while in N, the ammonia equivalent to 7·5 c.c. was added to the 10 c.c., and the whole made to 40 c.c.

Loss of Iron.—I have already said that the loss of iron is greatly diminished by the partial neutralization of the liquor with ammonia, and I append the ascertained loss for different amounts of ammonia:—

Table showing Loss of Iron.

NH_3=Liq. Ferri.	Per cent. of total iron lost.	Per cent. of Fe_2Cl_6 lost.
None.	64—80	Av. 72
25 per cent.	47	62·6
50	26	52
75	9·04	36·1
87·5	1·73	13·9

I have also determined the loss of iron (*a*) when the precipitate of half the liquor has been washed and then dissolved, as compared with the simple addition of ammonia (*b*).

In the former case (*a*) the loss was 26·3 per cent., while in the latter (*b*), it was 25·6 per cent. I was led to examine this because of the extraordinary diminution in the percentage of iron lost as the liquor is neutralized. As will be seen from the table, when 25 per cent. is neutralized, 62·6 per cent. of the iron as ferric chloride is lost, while with 87·5 per cent. neutralized, the loss is only 13·9 per cent., or one-fifth of the proportionate loss. Judging from the dissociation of iron ammonia alum (Thompson, *Journ. Chem. Soc.*, Dec. 1879), I thought it possible that the accumulation of ammonium chloride in the liquor might be the cause of the reduction in the loss, and if this were so, in the cases previously referred to, the loss of iron in *a* should have been much less than that in *b*, a conclusion which was not borne out by fact. In like manner the addition of ammonium or potassium chlorides should cause a great increase in the loss of iron. I therefore added to 10 c.c. of liq. ferri as much chloride of ammonium or potassium as would have been produced by neutralizing 7·5 c.c. with ammonia or potash, with the following results:—

10 c.c. of liquor = . . .	loss of Fe = 72	per cent.
10 c.c. + NH_4Cl 8·8 grms. .	„ „ = 72	„
10 c.c. + KCl 12.3 „ .	„ „ = 70	„

The only explanation of the reduced loss seems to me to be in the increased ratio of the ferric oxide to chloride in the liquor, although this is not proportional to the reduction in loss.

Strength of Solution.—In order to have as rapid dialysis as possible, the liquor in the dialyser must be concentrated, for dialysis proceeds proportionally to the percentage of chlorine in the dialyser, if the liquids outside be similar. Thus, if we add 1 grm. chlorine as ammonium chloride in each of two dialysers, the one with 100 c.c. of water, the other with 1000 c.c., dialysis would go on ten times faster from the former than from the latter. This has a bearing on the question of "precipitation and washing *v.* addition of ammonia;" for when washing is not resorted to, there being a greater amount of crystalloids present, a much larger quantity of water enters the dialyser than in the other case, and we get a very dilute, slow dialysing liquor.

Is Change of Water Necessary?—In any dialyser the rate of dialysis is proportional (approximately) to the difference between the percentage of chlorine in the dialyser and in the external water; and it is evident that if the outside water be strongly charged with chlorine it will exercise an influence on the rapidity of dialysis, more especially when the percentage in the dialyser becomes very small. Let us calculate its effect. If 6 parts of liq. ferri perchlor. fort. be precipitated, and the precipitate dissolved in one part, the resulting solution will measure about 10 parts (with the included water) and the percentage of chlorine will be at least 3·5. Now I found on the large scale, with about 17 pints of the strong liquor dialysing from five dialysers, each 15 inches square, into 100 gallons of water, renewed as stated, that the outside water contained of chlorine:—

First day	·114	per cent.
Second day	·074	„
Third day	·047	„
Fourth day and fifth day	·057	„
Sixth day to thirteenth day . . .	·0023	„

There the ratio after the first day must have been roughly as 3 per cent. to ·114 per cent.; *i.e.*, 26·3 to 1 so that by leaving the same water in for another day, we retard dialysis by one twenty-sixth, as compared with fresh water. At the thirteenth day the liquid in the dialysers would contain about 1 per cent. chlorine and outside = ·0023 per cent., *i.e.*, as 435 to 1, or dialysis would be retarded $\frac{1}{435}$ by not changing the water. We thus see that if without expense we can have a constant flow of water there is an advantage, more especially at first, but not to the extent that might be expected from the various published statements as to the necessity of using distilled water, especially at starting. The difference between distilled and Edinburgh water for such dialysis as I have referred to is:—

	Dialyser.		Water.
Distilled . . .	3 per cent.	to	0000
Edinburgh . .	3 „	„	00001

Hot Dialysis.—From Graham's researches we find that dialysis is twice as rapid at 120° F. as it is at 60° F., and we would therefore shorten the time if we could use hot water for dialysis. Such I have successfully used on the large scale, and my method of working is as follows:—Mix 3 pints liq. ferri perchl. with 2 gallons of water, add just sufficient ammonia to impart a faint ammoniacal odour after stirring. Wash the precipitate well, and squeeze as strongly as possible, then add to it in a capsule 10 oz. liq. ferri fort. Warm slightly, with stirring, and when dissolved place in a dialyser, 15 inches square, consisting of two frames of wood, 4 inches deep, fitting outside each other and stretching the parchment tight. A number of these dialysers are placed on a wooden frame, supporting the edges only, and to the under side of which cork is fastened. By this device, no trouble is experienced by the toppling over of the dialysers. Warm water is passed below the dialysers, and in a few hours a jelly results. In the course of two or three days this dissolves up, and sometimes in less than a week such a quantity as I have referred to is perfectly tasteless, but usually a fortnight is required. It is advisable to use cooler water towards the end of the process. The points to be attended to, are:—

Avoidance of excess of ammonia in precipitating the liquor.

Thorough washing and squeezing of the precipitate.

Complete solution before placing in the dialyser.

Care, lest evaporation from the dialyser dry up the contents.

Strength of Liquor.—By the use of hot dialysis it is easy to get a liquor containing 10 per cent. of ferric oxide, but I think that the commercial article should be made the same strength as the tr. or liq. ferri perchlor., B.P., *i.e.*, 2 grains in 1 fluid drachm. I need hardly remind you of the necessity of igniting the residue of oxide, before weighing, and of allowing it to cool in a desiccator, for the various papers (*Pharmaceutical Journal*, various) have fully insisted on these points. I may, however, draw attention to the care which must be exercised in igniting the residue, after evaporation, for containing as it does some ferric chloride, the first increase of heat volatilizes this, and in so doing, bursts the little fragments of oxide, scattering them if the vessel be uncovered. A better and safer plan is to precipitate with ammonia, filter, wash, ignite, cool in desiccator, and weigh the precipitate.

I have hitherto referred only to the manufacture of dialysed iron, touching on such details as seemed to warrant attention, but I must now bring forward some experiments which are of interest with regard to the value of this form of iron when given internally. It has been claimed for dialysed iron that the absence of astringent properties, free acid and ferruginous taste, render it of special value among the preparations of iron. On the other hand, dialysed iron is precipitated by mere admixture with town water, and even when administered diluted with distilled water it must be entirely precipitated by the time it reaches the stomach. This, at first sight, appears a serious objection, for unless in solution, the iron cannot be assimilated, and on this ground dialysed iron has been pronounced worthless. It is, however, held by many that the stomach contains sufficient hydrochloric acid to redissolve the precipitated ferric oxide, and that this actually happens when it is administered, while the testimony of physicians would seem to show that it is capable of absorption. In a recent paper, Professor Redwood has attacked this view of the behaviour of dialysed iron, and expresses a belief that even when so dissolved in the stomach it cannot be assimilated, because of the colloid and non-diffusing form in which it dissolves. This belief is based on his experiments, which have shown that if the dialysed iron be mixed with excess of ordinary water, the whole of the iron is precipitated, and that if this be collected, washed, and dissolved in hydrochloric acid, a pseudo-solution is obtained, which is not capable of dialysis, and cannot therefore be absorbed into the system. He further points out, that according to this experiment, the ferric oxide from dialysed iron is different from that obtained from ferric chloride. I have made many experiments on this point, but still some curious results await explanation. When the precipitate from dialysed iron is treated with strong hydrochloric acid in successive drops, we get—

a. A dark red clear solution.

b. A precipitate, redissolving, on standing, to a clear liquid, turbid by reflected light, and increasing in turbidity as more acid is added, till a point is reached—

c. When a precipitate falls (*d*), and a clear, bright yellow liquid (*e*) remains. Large excess of hydrochloric acid dissolves up the precipitate *d* by the aid of heat, and it is also soluble in cold distilled water. If these successive liquids be placed in dialysers, *a* will diffuse a notable amount of iron, the proportion varying with the amount of acid that had been added. *b* being the same liquid as *a* with excess of acid, I have always found much iron to pass through even in a few minutes. From my experiments I find that the precipitate falls, especially on heating, before sufficient hydrochloric acid has been added to convert the iron into Fe_2Cl_6. If the filtrate *e* from the precipitate be dialysed, nearly the whole of the iron diffuses through.

It would thus seem that a soluble oxychloride at first results, which by further addition of acid becomes decomposed, with an insoluble oxychloride and ferric chloride. The precipitate from ferric chloride by ammonia on addition of hydrochloric acid at first gives a non-diffusive dark red solution, but it undergoes no further decomposition on addition of acid; showing that some difference actually occurs in the two oxides.

The experiments above recorded were all made with strong, or but slightly diluted hydrochloric acid, and they were performed before the appearance of Professor Redwood's paper on the subject, so that the results therein described seemed irreconcileable with my own work. In order to imitate the precipitation of dialysed iron in the stomach I had prepared mixtures containing dialysed iron, sodium chloride, etc., and on treatment with hydrochloric acid I had invariably got diffusible iron. In some of the experiments I used no heat at all, while in others I boiled the liquid with the result above mentioned. In order to see the effect of adding hydrochloric acid to dialysed iron, I took 5 c.c. liq. ferri perchlor. f., precipitated with ammonia, washed the precipitate, and dissolved it in 5 c.c. of the same liquor. Complete dialysis showed a loss of 26·3 per cent. of iron. To the contents of the dialyser were now added 10 c.c. ac. hydrochlor., B.P.; a slight momentary precipitation occurred, and on continuing dialysis, exactly 26·3 per cent. of iron passed through again. Allowing for the diminution in iron when the acid was added, 35·7 per cent. passed through on continuing dialysis. In this case the acid was 1·3 times what was requsite to produce Fe_2Cl_6. We thus see that in the cold, if the acid be only mixed in the dialyser, a large amount of iron is rendered diffusible.

I also took 50 c.c. Wyeth's dialysed iron, mixed it with 10 c.c. ac. hydrochlor., B.P., or slightly less than is requisite to change it into Fe_2Cl_6, boiled for one minute, placed in a dialyser, found the separation of insoluble basic chloride, previously described, and in twenty-four hours found the oxide of iron which had diffused to weigh 1·815 gram. If the dialysed iron contained 5 per cent. oxide of iron, the percentage which diffused was thus over 72 per cent. Two explanations of the difference in my results with those of Professor Redwood have suggested themselves.

1st. I found that the more completely a sample of dialysed iron had been dialysed, the more difficult was it to form a diffusible compound without using excess of acid. I had prepared samples, stopping the operation while traces of chlorine could still be directly tested for in the liquor, or as soon as such direct testing indicated no chlorine, and by comparing these with very colloid forms I found that in the former cases the action of hydrochloric acid was much more rapid and complete than in the latter, the solution of the precipitate taking place without the deposition of a basic precipitate. This would indicate that the advantages of dialysed iron would be most found in those samples which approached most nearly to an ordinary oxychloride, and yet were free from astringent properties.

2nd. I found that dilution of dialysed iron (for I have not had time since the publication of Professor Redwood's paper to use the precipitate) materially modified the action of hydrochloric acid on it, and at first noting the decomposition at the boiling point, I found that the precipitation of the basic chloride with accompanying formation of diffusible chloride occurred at the following points of dilution:—

	Wyeth's iron	+	Ac. Hydrochlor. B.P.	+ Water
1	5 c.c.	+	0·55 c.c.	+25 c.c.
2	5 c.c.	+	1·00 c.c.	+50 c.c.
3	5 c.c.	+	2·05 c.c.	+100 c.c.
4	5 c.c.	+	5·0 c.c.	+235 c.c.
5	5 c.c.	+	1·0 c.c.	+80 c.c. = no precip.

From this we see that ·55 c.c. containing about half the amount of acid required to form Fe_2Cl_6 with the iron was able to produce a diffusible chloride when diluted to 25 c.c., while 5 c.c. were needed to accomplish the same when dilution was carried to 240 c.c. This shows that ·76 per cent. of HCl is necessary to form the diffusible chloride and basic precipitate at the boiling point, whatever be the relation of acid to the dialysed iron present. In the cold the same order of decomposition is found, and the same amount of acid will suffice if time be allowed.

I have also made the following experiments:—

(*a*). 5 c.c. Wyeth's dialysed iron were diluted with distilled water to 40 c.c.; 10 c.c. hydrochloric acid, one-tenth of B.P. strength, were now run in, making the whole 50 c.c.; the HCl = ·762 per cent. This was boiled for two minutes, and after two days' dialysis ·086 grm. Fe_2O_3 = 34·4 per cent. had diffused.

In the following seven experiments the dialysed iron was mixed with the distilled water and dilute hydrochloric acid run in. The mixture was immediately placed in a dialyser, and the distilled water into which diffusion took place was kept at 100° F. for two or three hours. After that the whole was allowed to cool, the water frequently changed, and after two or four days the iron estimated as Fe_2O_3. I give the results in a tabular form for comparison:—

	Wyeth's iron	+ HCl B.P. Per cent.	Water to.	Fe_2O_3 diffused. grm.	Per cent.	Time.
b.	5 c.c.	1 c.c. = ·762	50 c.c.	·056	= 22·4	2 days.
c.	20 „	1 „ = ·381	100 „	·0635	= 6·35	2 „
d.	10 „	1 „ = ·381	100 „	·044	= 8·8	2 „
e.	20 „	1 „ = ·1905	200 „	·0375	= 3·75	2 „
f.	10 „	1 „ = ·1905	200 „	·026	= 5·2	2 „
g.	40 „	1 „ = ·0952	400 „	·0335	= 1·67	4 „
h.	10 „	1 „ = ·0952	400 „	·0235	= 4·7	4 „

Some very interesting facts are derivable from these results. In *a* and *b* we see that the action is much more complete at the boiling point than at a lower temperature. In *c* the hydrochloric acid present was only equivalent to the formation of Fe_2Cl_6 with half the iron, while in *d* it was sufficient for the whole of the iron.

In *c* 6·35 per cent. of iron diffused
In *d* 8·8 " " "

So that by doubling the acid 1·23 times as much iron was rendered diffusible. In *e* and *f* the hydrochloric acid was also equivalent to 50 and 100 per cent. of the iron.

In *e* 3·75 per cent. of iron diffused
In *f* 5·2 " " "

So that by doubling the acid 1·38 times as much iron diffused. In *g* and *h* the acid was equivalent to 25 and 100 per cent. of the iron.

In *g* 1·67 per cent. of iron diffused
In *h* 4·7 " " "

By quadrupling the acid 2·81 times as much iron diffused.

Now in *g* and *h* we have mixtures which contain a less percentage of HCl than is normally present in the stomach, and yet 1·67 per cent. and 4·7 per cent. of the iron were capable of diffusion, an amount which might easily account for the benefits said to be derived from the use of dialysed iron. It is instructive to note that with the same volume of dilute acid (·0952 per cent. HCl) a much higher percentage of iron is capable of absorption when the amount of dialysed iron present is small than when it is large. This points to the advantage of giving dialysed iron in small doses often repeated, under which circumstances the most favourable conditions for absorption are obtained. It will be noticed that I have assumed Wyeth's article to contain 5 per cent. of Fe_2O_3. I have found the amount to range from 4·35 per cent. to 4·95 per cent., and of course if less than 5 per cent. were present the percentage of diffusible iron must be greater. Again I did not allow diffusion to proceed to the fullest extent, but stopped it after two or four days, and therefore the amounts given are actually less than what might be obtained. It may be urged that no substance would remain so long in the stomach, but the amount of absorbing surface must be far greater than that used in my experiments, while the quantity of substance to diffuse would be much less, so that my figures may be considered, at least approximately, indicative of what might occur in the stomach.

The dilution of the dialysed iron, coupled perhaps with the use in Professor Redwood's case of some very colloid preparation, may, in my opinion, account for all the differences which seem to exist between our results.

Even supposing, however, that the iron remains in a colloid non-diffusing form, it does not follow that it cannot be assimilated, else how can gelatine, starch and other colloids be digested, unless they pass through an intermediate crystalloid state? The value of dialysed iron, in my opinion, is far more surely to be tested by noting the increase of red-blood corpuscles, than by purely chemico-physical research, for we know too little of the processes involved in nutrition; but if we assume that assimilation of mineral substances is accomplished by dialysis only, then it may be interesting to test the value of liq. ferri perchlor. by this gauge. We have seen that the B.P. liquor only diffuses about 72 per cent. of iron, while a liquor prepared by the chlorate of potash oxidation process lost about 90 per cent. Again, I find that the evaporation of such a liquor to half its volume, with subsequent dilution with water, reduces the dialysing power from 90 per cent. to 68·9 per cent. According to our test a liquor which has been so evaporated (even though acid has been added afterwards, as seems to be shown by my experiments, though in a modified degree) cannot possess the same medicinal properties as it had before evaporation. Pursuing our examination, I find that a solution of oxide in hydrochloric acid diffuses more than 90 per cent., while crystals of perchloride obtained from the liquor show a similar diffusing power. Such solutions must be more active than the B.P. liquor. It may be in your knowledge that many medical men prefer the old E.P. tinct. ferri mur., prepared from oxide, to the B.P. preparation. If such is more diffusible, (this I have not ascertained), the reason for the preference would be plain, and so also we should expect a freshly prepared sample of the tincture to be more efficacious than one which had become basic by standing. I thought it would be interesting in this connection to to see if iron, which had once diffused, would diffuse entirely a second time. I find it does not. I placed liq. ferri perchlor. fort. in a dialyser, and diffused for some time into a limited amount of water. The solution so obtained was placed in a dialyser, but failed to pass entirely through, leaving an appreciable quantity of dark red solution inside.

I have said nothing of the use of dialysed iron in cases of arsenical poisoning, for this is too well known to require comment, but I trust that, in having thus fully entered into the chemical relations of this substance, I may have assisted, however little, in determining its value as a chalybeate.

The paper was fully illustrated by diagrams and by experiments bearing out the results arrived at.

Mr. Nesbit (Portobello) said he had always been much interested in this preparation, and had some years ago prepared it by the process now recommended by Dr. Clark. He thought the name a very misleading one. Almost every medical man he had spoken to on the subject had been under the impression that it was what its name implied—a solution that would pass through a septum, and not a colloid. They, however, all concurred in the opinion that it possessed the tonic properties of iron in a mild form. He had, since Professor Redwood's first paper appeared, made some experiments on its diffusion when mixed with acidified solutions of pepsine of the strength of gastric juice. The results were somewhat different from those of Dr. Clark, but the experiments had been made under different circumstances. In the first place, he had not found vegetable parchment so satisfactory a dialyser as animal membrane, and as the latter was what it must pass through before entering the circulation, he considered it the most suitable material to use. In the second place, he had not boiled the dialysed iron with the hydrochloric acid, as that would induce a chemical combination which it might not undergo in the stomach. The following experiments were made with Wyeth's dialysed iron containing 5 per cent. Fe_2O_3:—(1) 100 grains were diluted with distilled water and 6·8 grs. HCl added—the quantity required to form the iron present into Fe_2Cl_6. The solution, which was perfectly transparent, was dialysed for eight hours at 100° F.; when the diffusate was tested it gave no trace of iron, but abundant evidence of hydrochloric acid. An excess of acid was now added to the colloid; after twelve hours a considerable quantity of iron had passed through the membrane. (2) To two ounces of acid solution of pepsine of the strength of gastric juice were added 100 grains of hard boiled white of egg, and ℥ss (an ordinary dose) of dialysed iron. On adding the latter, the liquid became turbid, and after standing a short time a considerable precipitate was deposited. On digestion at 100° F. for four hours the white of egg remained altogether unacted upon. (3) The last experiment was repeated with the same materials, but adding the dialysed iron after the white of egg had been completely dissolved in the solution of pepsine. The liquid was dialysed for four hours at 100° F., but without a trace of iron being found in the diffusate. After these experiments, he entertained great doubts of the usefulness of the preparation, as it not only appeared to be incapable of digestion, but might even retard that process. At the same time it was not the province of the pharmaceutist to decide as to its effect on the human frame; that must be left to the physician and physiologist. Dr. Clark had alluded to gelatine, a colloid, and yet used largely as an aliment. He had not made any experiments on that substance, but had always understood that doubts existed as to its nutritive value. He assumed, however, that on entering the stomach it would, by the action of the gastric juice, be chemically changed, and thus rendered capable of absorption.

Mr. Napier suggested that the discrepancy between the diffusibility of colloid iron as brought out by Professor Redwood and Dr. Clark might be due to a difference in the condition of the iron in the original dialysis, and that the presence of hydrochloric acid and muriate of soda in the stomach, under vital conditions, might also materially affect this property. He had had occasion to try the effects of this preparation on himself, and while he had found it quite non-irritant to the mucous surfaces, and not sensibly affecting the circulation, its action as a tonic was at best feeble. A microscopic examination of the increase of blood corpuscles would best determine its therapeutic value. It would be a matter of great regret were a preparation brought forward with so fair promise to have to be put aside as useless. Perhaps, as Dr. Clark was not quite satisfied as to the absolute accuracy of his results, it might be hoped he would prosecute his investigations and favour the Society at no distant date with some further results.

The President remarked that he had always taken a great interest in this preparation. He confessed to somewhat of a prejudice against it; from the first, he thought it too good news to be true that a preparation could be deprived of all sensible and chemical qualities, whilst its medicinal were retained. He considered the article as still upon its trial, and thought the question of its therapeutic value was to be settled more on the results obtained under its administration than on facts and inferences connected with its chemical nature—useful and suggestive as these undoubtedly were. Fortunately the effects of iron were not so equivocal as to require the counting of the blood corpuscles on the microscopic field as evidence of their reality. He mentioned a case which had come under his personal observation, in which it was desirable to get iron rapidly and in large quantities into the system. Under dialysed iron for two months this case had made little or no improvement; but under Blaud's pills, which contain $2\frac{1}{2}$ grains of sulphate of iron each, it subsequently underwent a rapid and wonderful improvement.

On the motion of Mr. Napier, seconded by Mr. Nesbit, a hearty vote of thanks was awarded to Dr. Clark for his communication.

Provincial Transactions.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

Mr. Robert Gibson, of Manchester, delivered an address before the Society on Wednesday evening, February 25. There was a large and enthusiastic attendance. The subject of Mr. Gibson's address was "Commercial Success," which he treated in a manner suited to instruct, entertain and leave lasting impressions for good upon the minds of all who listened to it.

The chair was occupied by Mr. William Sinclair, who along with Mr. G. S. Shepherd, proposed the usual votes of thanks.

The annual meeting was held in the rooms on March 9, Mr. Giles presiding. The following gentlemen were elected office-bearers for the ensuing year:—President, Mr. John Gordon; Vice-President, Mr. R. D. Presslie; Secretary, Mr. A. Strachan; Treasurer, Mr. J. Paterson; Librarian, Mr. C. Coutts; Auditor, Mr. Wm. Giles.

The Treasurer's report showed a balance of £28 4*s*. 0½*d*. standing to the credit of the Society. The Lecture, Library and Price List Committees were reappointed.

THE REGISTERED CHEMISTS' ASSOCIATION OF LIVERPOOL.

The fifth annual dinner of this Association was held on the 16th inst. After the dinner the loyal toasts were duly honoured. The President, Mr. A. Redford, then gave the toast of the evening, "The Registered Chemists' Association of Liverpool." He considered such meetings as the present not only enjoyable but useful in their tendency to improve the business relationships of the members by better personal acquaintance with each other. Although in the Liverpool Chemists' Association an admirable organization for scientific and educational purposes existed, yet a Trade Association like that, where questions that affect chemists as traders can be thoroughly considered, and by which united efforts may be put forth, was well worthy of institution and maintainance; and its objects could only be attained in proportion as the chemists of the town join its membership, and work together. After referring to the necessity of combination against vexatious attacks by analysts (happily not known in Liverpool), against injurious legislation by an ill-informed or mis-informed parliament, he touched upon the past work of the Association, and coming to the recent agitation upon the "patents" question, expressed the belief that the position taken up from the first by the committee and endorsed by the trade, had assisted in other places to stem the tide of panic, and to maintain their relations to one another as honourable traders. He believed that the ethical outcome of some men's faithfulness to the general interests, to the probable disparagement of their individual gains, must be morally most invigorating. He could not believe that the system of amalgamating the most heterogeneous pursuits together in one huge establishment could long affect them, but fighting the for "selfishness" under the banner bearing the device of the "hand-in-hand," with the motto "union in strength," and alive to the need of adopting well-considered reforms, they need not fear but that public sentiment will support those who with true and noble aims reach forward to the most perfect ideal of duty and utility. He coupled with the toast the names of Mr. R. Parkinson, Treasurer, and Mr. B. Dickins, Hon. Secretary, who briefly responded.

The toast of the Liverpool Chemists' Association was given by Mr. J. Woodcock, who desired to pay the highest tribute to the zeal and ability of the officers of that Association then present with them; the President, Mr. Charles Symes, Ph.D., and Mr. M. Conroy, F.C.S., the Hon. Secretary. He said that it was incumbent upon all who desired the culture and improvement of their class to encourage and countenance both the societies, as the scientific element was of the utmost possible advantage to the pharmacist.

Mr. C. Symes, Ph.D., in responding to the toast said:—He would like to see more of the registered chemists joining and taking an active part in the Association. It might possibly be assumed that the papers read and the subjects discussed at its meetings were too scientific or not sufficiently practical for the purposes of business men. But was that so? He thought all they attempted to do was to keep pace with the times. He felt sure he should carry the meeting with him when he said that they lived in days of unusual competition; days in which the influences of education were felt on every side. Now he had learned to believe in the good which trade association could accomplish; he looked with satisfaction on the power for good which exists in such organizations as the Trade Association of Great Britain and the Registered Chemists' Association of Liverpool; and at the temperate yet firm and unflinching manner in which that power had been exercised. But he could not close his eyes to the fact, that if the competition referred to was to be met and successfully combated, if they were to show themselves equal to the educational progress of the times, then (while they held firmly to their trade principles) they must not ignore the higher development wrought out by the Pharmaceutical Society, the scientific advancement promoted by the Conference and the efforts in the joint direction put forth by the Liverpool Chemists' Association and other bodies of a kindred nature. It was thus they could keep abreast of chemical discovery, raise their status and make themselves masters of the position. Thus they could best demonstrate to the public and the medical profession that they were worthy their confidence, and that the remuneration they ask in exchange for the duties they perform is the minimum of their just due and that it should be increased rather than be diminished.

Mr. M. Conroy, F.C.S., also responded, and expressed his wish that more were added to the list of members. The society was healthy and flourishing.

The toast of "The Pharmaceutical Society and The Chemists and Druggists' Trade Association of Great Britain," was given by Mr. J. Fingland, and responded to by Mr. Shaw, who spoke of the strong financial position of the older Society, and of the usefulness of the Benevolent Fund. In connection with the Trade Association he alluded to the loss it sustains in Mr. Haydon's removal to another office, and much regreted parting with so efficient a worker.

Mr. W. Wright gave "The Wholesale Trade," and Messrs. J. J. Evans and R. Sumner responded. Mr. Sumner remarked that there was now a very much better appreciation of quality of goods sent than formerly existed, and that by reason of greater ability and knowledge on the part of retail chemists.

Mr. M. Bell, on behalf of Messrs. Raimes and Co., also thanked the company for their reception of the toast.

"The Chemists and Druggists of Birkenhead and Kindred Associations," was proposed by Mr. J. A. Turner. His speech was altogether too humorous to epitomize. Mr. A. Stewart responded. He said that their Association, although not yet twelve months old, had done good service in restraining some from lowering prices. He advocated the formation of such Associations in every town in the kingdom.

Mr. Hocken then gave the toast of the President, Mr. A. Redford, which was drunk with musical honours. After responding, the President then gave the Vice-President, Mr. C. Symes.

Mr. W. P. Evans gave "The Ladies," responded to by Mr. F. J. Mackinlay; and Messrs. J. Fred. Swift and J. T. Pugmire, who had much assisted the enjoyment of the evening with music, were similarly thanked.

Mr. H. Jackson (Messrs. W. and H. Jackson) gave an impressive recitation, and Mr. A. H. Mason "The Vicar of Bray."

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on March 18. Mr. Warren De La Rue, President, in the chair. The following certificates were read for the first time:—J. M. Dennis, R. Grimwood, W. F. Haydon, F. B. Last, H. Liepmann, A. J. Smith, J. W. Stanley.

Professor Tidy was then called upon to read his paper on—

River Water.—The author discusses the subject under three heads:—1. Analytical details of river waters. 2. The various sources of impurity to which river water is subject and the means whereby purity is maintained by nature or may be effected by art. 3. The extent to which statistics warrant us in condemning or in approving the supply of river water for drinking purposes.

1. Analytical details of river waters—River Thames.—The author gives tables showing the composition of the Thames water as supplied to the metropolis, from January, 1876, to December, 1879. The details given, are total solid matter, oxygen required to oxidize the organic matter, organic carbon and nitrogen, as determined by Dr. Frankland, nitrogen, as nitrates and nitrites, lime, magnesia, chlorine, sulphuric anhydride, hardness before and after boiling. The solid matter is at its highest in February, 21·63 grains per gallon, descending regularly to August, 18·24 grains per gallon, whence it again rises. Boiling reduces the hardness to less than one-third. From September to January, the chlorine is under 1 grain per gallon; from February to August, it is over 1 grain per gallon. The quantity of solid matter is no gauge as to its organic purity, as judged by the oxygen required. The testimony of the results obtained with the oxygen process agree remarkably with those obtained by the combustion process, as has already been pointed out by the author; the same story being thus told by two absolutely independent experimental witnesses. The author regrets the frequency with which cases occur, where conclusions of great importance sanitarily are based on experimental determinations as incapable of arrangement or of interpretation as they are outside the sphere of scientific accuracy. The nitrates and nitrites do not accord with the results indicating the organic matter; it may be that the organic nitrogen of one month becomes the inorganic nitrogen of the next. The author has estimated the gases dissolved in filtered Thames water on twenty-seven different occasions. The oxygen in solution during the winter months (2·19 cubic inches per gallon) was found to be very nearly double the amount held in solution during the summer months (1·19). The author intends to turn his attention to a further examination of this part of the subject. Some analyses of unfiltered Thames water from Hampton are then given. River Lea.—Monthly analyses (1877—1879 inclusive) of the water from this river are given. The total solid matter is again highest in February, 23·34 grains per gallon, sinking to a minimum in September, 17·99 grains per gallon. The chlorine is slightly higher than in the Thames. As far as organic matter is concerned, this river is slightly purer than the Thames, the results of the oxygen and combustion processes again exhibit a remarkable correspondence. River Nile.—Monthly analyses of this river taken during one year at Cairo are given, the total solid matter ranged from 9·5 to 14·3 grains per gallon; the chlorine from 0·645 to 1·395; the oxygen required from 0·08 to 0·27. All the samples but that of May were thick. During April, May and June, when the Nile is lowest, the water is worst as regards total solid matter, 12·73 to 14·33; chlorine, 0·64 to 1·39, etc.; the month of July is the transition month, the river rapidly rising; during September and October, the condition of maximum flood persists, during the fall the river attains its maximum purity. The Severn.—Analyses of samples of water collected from the Severn at various spots, in January, 1878, from Worcester, above the sewage outfall down to Tewkesbury, a distance of sixteen miles, together with analyses of the river Teine, are given. The Severn water contains about 16 grains of solid matter per gallon, the chlorine being double the amount of that present in the Thames. The quantity of chlorine varies remarkably at different spots, probably from the influx of brine springs from the new red sandstone. The Shannon.—The samples were collected in October, 1879, the river being about two feet above summer level. This river was selected because it drains a larger area than any single river in the British Islands; because though uncontaminated with animal impurity, it contains a large quantity of dissolved peaty matter and because it is a type of the Irish rivers which so often pass through lakes in their course to the sea. The analyses include samples taken at the extreme ends of one of the lakes, Loch Derg. The solid matter varied from 15·3 to 20·2 grains per gallon, there was but a trace of nitrogen as nitric acid, the chlorine was remarkably constant, about 1·0 grain per gallon.

2. The various sources of impurity to which river water is subject, and the means whereby purity is maintained by nature or may be effected by art. (The pollution produced by trade refuse is not considered in the present paper). Flood water.—During the first few days of a flood the drainage, called by the author "primary flood water," materially affects the river for the worse, as all the soluble and some of the insoluble matters accumulated in the soil during the period when the rainfall was insignificant, pass into the river. The river becomes

heavy in total solid matter, excessive in dissolved organic matter, and turbid. The velocity of the river is increased and carries down accumulations, organic and mineral, from the higher reaches of the river. The author then gives analyses of the Thames water before and after two heavy floods, November 18, 1875, and January 11, 1877; the rise in the total solid matter is not so great as was expected. The rise in the organic matter was well marked, the high flood water requiring 0·173 grain of oxygen per gallon against 0·064 grain ten days before. Further analyses of ordinary floods are given, which show similar results. Primary flood water is therefore inferior to normal river water as regards organic purity and general clearness. By "secondary flood water" the author implies the water that comes down after some considerable period of flood, when the drainage area has been washed clean, the river passing slowly from a state of maximum impurity to one of maximum purity. The total solid matter of a secondary flood water being only 17·28 grains against 22·84 grains in primary flood water, the oxygen required being reduced to about a sixth, the hardness by three degrees, whilst the suspended matters are too small to be capable of estimation. Although the Thames when at or below summer level is brighter and clearer than at any other time, the water is not of such good quality as during the period succeeding a flood. The author then discusses the influence of floods as exhibited in the river Nile, and shown in the analyses already referred to, the influence of the geological nature of the drainage area, of the time of year at which the floods occur, of the interval between one flood and the next, and of the exact time occupied by a given rainfall on the flood water carried into the river. He then takes up the subject of peat. Peat exists for the water analyst as old peat or recent peat, the latter giving a yellowish-green, the former a coffee-brown tint, the colour passing through all gradations, according to the age and quantity of peat present. The author then insisted on the value of the "two foot tube," *i.e.*, a tube 2 feet long, 2 inches in diameter, with white glass ends, as a most valuable adjunct to analysis; thus 0·4 per 100,000 of organic carbon would have a very different significance to the chemist if the tint exhibited by a large bulk of the water was brown, indicating vegetable matter, to what it would if the water was colourless. Professor Tidy has never known in practice a case where the water of a river became colourless simply through the bleaching of peat, and thinks that it is quite possible to compare the depths of colour in two waters, though the tints are different. The oxidation of peat has been carefully studied by the author in the Shannon. He has analysed the water at various places, the most notable instance of oxidation being at the falls of Castle Connell; a short distance above the organic carbon being 0·84 parts per 100,000, a short distance below 0·593 per 100,000. Another instance of this diminution of carbon was noticed in the North of England, where the water is peaty, and is delivered from a storage reservoir to the supply reservoir, 6820 yards distant, by two channels, one a closed iron pipe, the other an open brick conduit. The water delivered by the iron pipe has distinctly a peaty tint, the same water delivered from the conduit is clear and nearly colourless. The water in the storage reservoir contained 0·46 organic carbon per 100,000, that from the iron pipe 0·49, that from the open conduit, 0·23. This, says the author, is a perfect experimental proof of the oxidation of peat. The quantity of peat can also be considerably reduced by admixture with water containing much suspended mineral matter, which causes a precipitation of the peat. Thus the entrance of the turbid river Malcaire brings down the organic carbon in the Shannon from 0·914 to 0·61. This action was also confirmed by shaking up a peaty water with turbid Malcaire water in the laboratory. Thus the quantity of peat in running water is kept in check, (1) By the inherent power which water possesses of self-purification, owing to the oxidation of the peat by the oxygen held in solution in the water, the process being enormously helped by certain natural and physical conditions whereby the more complete aeration of the water and the intimate contact between the oxygen and peat is effected; (2) By mechanical precipitation by admixture with coarse mineral suspended matter. From peat the author passes to animal impurity. He agrees entirely with Dr. Frankland as to the vital importance of this subject. No one, says Professor Tidy, should be required to drink his own excreta, much less the excreta of his neighbours. The two important questions are, does the water of a river, having been once polluted by admixture with sewage, again after a moderate flow assume its original state of purity? and, secondly, if such a natural process of self-purification exists what are the conditions requisite for its fulfilment, and what are the circumstances affecting these conditions? The author answers the first question in the affirmative, and considers that this self-purification depends upon three things: "a." The subsidence of the coarser suspended impurities. "b." On the presence of animal life after the water has assumed a certain degree of purity. "c." The oxidation of the organic matter, the dissolved oxygen being derived partly from the air and partly from plant life. The rapidity of this oxidation depends on the degree of dilution of the sewage, the distance of run, the velocity of the current, the temperature, and certain natural or artificial physical conditions, such as the mixing of the water and air at locks, weirs, etc. The author then proceeds to enumerate the proofs of this oxidation. From analogy we should expect water to purify itself, as the air which is constantly receiving masses of organic *débris* eliminates by oxidation, etc., its sewage matter. Are men never to drink water because it has been once contaminated by sewage? As well might we say that air which has once received scales from a person suffering from scarlet fever or the infected breath of a measly patient must never be breathed again. If oxidation purifies in the one case may not oxidation be expected to act in the other? The proofs of this oxidation are threefold. A. The naked eye inspection of rivers receiving sewage.—The sewage at the outfall is probably offensive; as it passes down the river it blackens from the formation of sulphide of iron; further on this black colour decreases, disappears, and the river at last exhibits no signs of odour, colour or turbidity. Again, soon after the sewage has been turned into the river the sewage fungus appears, all other vegetable life being absent, no fish are seen, the banks are black. A short distance further on the fungus vanishes, vegetation is luxuriant, fish abound, the river clears and no trace of black deposit can be seen. Thus the river Soar at Leicester is black with sewage; at Loughborough thirteen miles distant the river is perfectly clear and fish are abundant. The Irwell at Manchester is polluted with every form of filth; in nine miles the offensive character of the stream has entirely disappeared, and so on in many cases. Such examples prove the power of self-purification possessed by rivers. B. Analysis.—The Thames at Lechlade may be taken as pure river water; after flowing a distance of 110 miles and receiving the sewage of many towns, etc., the water at Hampton contains rather less organic carbon and nitrogen that at Lechlade; what has become of this sewage if it has not been oxidized? The same is true of many other rivers, the Severn, the Wear. The author then refers to the diametrically opposite conclusions in the sixth report of the Rivers Commission, in which Dr. Frankland states that organic matter is not appreciably oxidized by the flow of a few miles. Professor Tidy does not for one moment question the accuracy of the results, but strongly dissents from the conclusions, and submits that analyses indicating a reduction of organic carbon and nitrogen between two spots are of much greater value than any analyses indicating the reverse; because Dr. Frankland cannot that say the organic matter found at B when he collected his second sample was the same as that at A where the first sample was taken, and between the two spots A and B a fresh quantity of organic matter may have been introduced. Thus to take an illustration. Six passengers enter a carriage at station No. 1; at station No. 3 six passengers are still in the carriage, but unless there is evidence to show that they are the same six passengers there is nothing to prove that the whole of the six passengers who got in at station 1 did not get out at station 2, and six fresh passengers get in. But if at station 3 only two passengers are found it is absolutely certain that at least four must have got out at station 2. The author then criticizes experiments in which Dr. Frankland shook up a mixture of water with 10 per cent. of sewage and thus imitated the flow of a polluted stream for 96 and 192 miles; the author contends that these experiments did not imitate at all accurately the flow of a stream, and the results obtained are therefore valueless. C. The author set up an apparatus which did to some extent represent the action of running streams; it consisted essentially of a series of about twenty V-shaped wooden troughs lined with glass, the troughs were placed one over the other and were inclined alternately in opposite directions, so that the water flowed from a cistern into the upper trough and thence gradually down the twenty troughs into a cistern beneath, from which it was pumped up into the higher cistern. After many difficulties from the smoky atmosphere in London, the author, with the assistance of Mr. Hart, obtained results with various mixtures of New River water with sewage from Abbey Mills, which proved satisfactorily a decided decrease of organic matter after a run of one mile. After two or three runs the offensive sewage smell disappeared; the last traces of sewage matter seemed to be the most difficult to oxidize. From these considerations the author concludes by paraphrasing a well-known passage in the sixth report of the Rivers Commission, p. 138, "I am led to the inevitable conclusion that the oxidation of the organic matter in sewage when mixed with unpolluted water and allowed a certain flow proceeds with extreme rapidity and that it is impossible to say how short a distance such a mixture need flow under favourable conditions before the sewage matter becomes thoroughly oxidized. It is certain to my mind that there is no river in the United Kingdom but what is many times longer than is required to effect the destruction of sewage by oxidation." Some of the methods for purifying water are then considered. A water which is impure from the presence of sewage should be unhesitatingly rejected. In urging the claims of rivers as one of the sources for water supply, the author means always rivers free from sewage, *i.e.*, rivers, the purity of which at the suggested intake can be proved by chemical analysis. Having such a water, however, much may be done by art to improve it by storage, subsidence and filtration; these methods are considered in detail. Pure sand of uniform medium fineness is recommended as the best filtering medium on the large scale, the rate of filtration should be 2 gallons per hour per square foot, the filter bed should be changed about every two years.

3. How far do statistics warrant us in condemning or in approving the supply of river water for drinking purposes? —In the opinion of the author, peaty waters have not been proved to produce diarrhœa. As regards animal pollution, the author admits that disease has been produced by drinking impure and polluted water, but the argument against the use of a river water is based, (1) on the existence of germs, (2) on the supposition that the oxidation process which might affect organic matter would probably leave organized bodies untouched. Germs would probably be destroyed by oxidation and endosmose after a run of ten or twelve miles in a river. If they are not destroyed as organic matter they ought as organized bodies to increase, and as we pass down the river each town should exhibit an increasing death rate from the multiplication of the disease germs. Statistics, however, show a very different state of things. A disease usually spreads up not down a river. From an examination of numerous statistics it is seen that the death rate of towns in which the water is obtained from wells is practically identical with that in towns supplied by rivers, and that in London as regards mortality there is very little to chose between districts supplied by well water and those supplied by river water, so that it is clear that the *materies morbi* is subject to the same laws of destruction as ordinary organic matter. As a matter of sentiment, the author would prefer well water. If all the mischief be laid to an undiscoverable germ, a terrible doubt is cast on the value of all chemical analysis. There is no well-authenticated case where river water, having received sewage, the dilution being considerable and circumstances favourable for oxidation, has after a flow of ten to twelve miles been manifestly the cause of an outbreak of disease. In all well-proved cases of outbreaks of disease resulting from the use of drinking water, such water would have been unhesitatingly condemned on analysis by the chemist. The author protests most strongly against the startling statement in the report of the Rivers Commission, "that the supply of deep well water would confer on the metropolis *an absolute immunity* from epidemics of cholera." Regarding all the above facts, the author submits the two conclusions: —1. That when sewage is discharged into running water, provided that the dilution of that sewage with pure water be sufficient, the whole of the organic impurity will be got rid of after the run of a few miles. 2. That facts indicate that, whatever may be the actual cause of certain diseases, the *materies morbi* that finds its way into the river at the sewage outfall is destroyed, along with the organic impurity, after a certain flow.

The above paper of about 130 pages contains a large number of tables of analyses, etc.; it was listened to with great interest by a crowded meeting of the Society.

The President said that the large assemblage that evening evinced the great interest taken by chemists in this vital question of a suitable water supply. This interest had been increased by the forcible yet courteous way in which Professor Tidy had supported his views. He would call on Dr. Frankland for any remarks he would like to make.

Dr. Frankland said that at that late hour it was quite impossible to do justice to the discussion of this important paper. He did not know any subject of greater moment to the health of towns. He had listened to many statements founded on opinions, surmises and casual observations, but they had made but little impression, as they lacked the quantitative element. The present paper differed entirely from such statements. Professor Tidy had furnished a large number of facts which deserved serious consideration; as far as he could see there was no fundamental difference between the facts of Professor Tidy and previous results of his own, but considerable explanation was necessary to understand how such diverse opinions could be drawn from identical facts. He would therefore propose that the discussion be deferred until after the paper had been printed.

The discussion was th n adjourned *sine die.*

The cordial thanks of the meeting were given to Professor Tidy for his paper, and the Society adjourned to April 1, when the following papers will be read:—"On β Orcinol," by Dr. Stenhouse and Mr. Groves; "Preliminary Note on the Action of the New Diastase Eurotin on Starch," by R. W. Atkinson; "Note on the Products of the Combustion of Coal Gas," by L. T. Wright; "On Polysulphide of Sodium," by H. C. Jones; "On the Reflection from Copper and on the Colorimetric Estimation of Copper," by T. Bayley; "On Pyrene," by Watson Smith and G. W. Davies; "Analyses of the Ash of the Wood of two varieties of the Eucalyptus," by Watson Smith.

The anniversary meeting takes place on Tuesday, March 30.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, March 11, Mr. R. H. Parker, Vice-President in the chair.

Mr. H. Allen read a paper on "Wind and Weather," illustrated by numerous diagrams and charts. After a description of the atmosphere and its various changes, together with the methods of observing those changes, the author proceeded to notice its general circulation, and the extent to which the latter is modified by the form and motion of the earth, the distribution of land and water, and the inequalities of the surface. The general characters of the climate of different parts of the earth were then described; after which the irregularities to which the weather of Great Britain is subject were discussed, and the paper concluded with an account of the means at the disposal of the meteorologist for foretelling these irregularities.

A vote of thanks was accorded to Mr. Allen for his paper.

A Report on Materia Medica was made by Mr. R. H. Parker on "Coca." The geographical source of *Erythroxylon coca* together with the mode of cultivation and collection of the leaves were referred to in detail, and the varied opinions as to its position in the vegetable kingdom. A minute botanical description of the plant in general and of the leaves in particular was given. The difference was noticed between the apex of the fresh leaf as seen in this country, and that of the dried leaf as imported, the former being blunt and emarginate with a small apiculus in the notch at the apex, while the latter is almost invariably more or less acute and apiculate. The proximate principles of coca leaves, cocaine, hygrine, cocatannic acid and coca wax were described and the medicinal properties of the drug discussed at some length. The report concluded with a description of the microscopic structure of the fresh leaf grown at the Royal Botanic Society's garden, an epitome of which is as follows:—The epidermal layer of the upper surface consists of tubular cells of oblong outline, beneath which are several layers of closely packed small elliptic cells filled with chlorophyll and starch; the epidermal layer of the under surface is composed of tubular cells with sinuous outline, upon which project numerous and regularly disposed hemispherical or half oblong cells, very minute and appearing in the transverse section as tent-like projections; these occur on the under surface only and form a feature peculiar to this leaf. Beneath the epidermal layer is a very loose tissue composed of irregularly branched cells filled with chlorophyll and starch. The microscopic structure of the two longitudinal ridges characteristic of the bark of the coca leaf is very different from that of other portions of the surface of the leaf and closely simulates the structural arrangement of the vein tissue. This appearance scarcely lends support to the theory that these ridges are formed by pressure produced by the peculiar character of venation.

The Sale of Patents.

Sir,—I saw some time ago in the advertisement columns of one of our trade journals that a handsome present would be given to any one selling a certain number of a much-advertised patent medicine. Thinking it was only a Yankee "notion," I did not take much notice of it; but when, a few days ago, I saw a pamphlet setting forth that a prize (*sic*) would be given to chemists retailing so many of another patent, I thought it was time something was said about the matter.

There has been a great deal said and written lately about "The Future of the Drug Trade," and surely this is a sign of degeneracy. We ought to be above the Cheap Jack who offers a joint of mutton to his customers.

Are we to pass the high-class examinations we do just to sell any quack medicine that is puffed, and then to be rewarded with a prize like so many school-boys?

We heard the examinations were going to raise the status of chemists and druggists, but they have not done so yet, if we are not above this sort of thing.

Articles which require such desperate efforts to make them popular we could evidently do without, since they cannot recommend themselves, and a chemist in the majority of cases might easily substitute his own preparations for So and So's "cough elixir," "liver pills," etc., etc., with more satisfaction to his customers and a larger profit for himself.

If chemists would combine to do this we should soon have the patent medicine trade a thing of the past, and should no longer be offered such insults.

Ferrum.

"Detection of Traces of Bismuth."

Sir,—On reading the paper under the above heading, by Mr. J. C. Thresh, in the *Pharmaceutical Journal* for February 14, I was surprised to find that he mentions as a discovery of his own a test for bismuth which is contained in a text-book issued in 1874 by Bloxam, entitled, 'Laboratory Teaching,' on page 22 of which the test claimed to be discovered by Mr. Thresh is written as follows:—"To confirm the presence of bismuth add to the original solution (or to the solution of the oxide precipitated by ammonia in hydrochloric acid, even after dilution) a little solution of iodide of potassium; this will produce a red or yellow colour if bismuth be present (or even in a strong solution a brown precipitate of iodide of bismuth)."

As this work is intended as a text-book for beginners of practical chemistry, this may be the reason why Mr. Thresh has overlooked it.

52, *Alexandra Road, Kilburn Park, N.W.* J. Woodland.

The above has been submitted to Mr. Thresh, whose reply is as follows:—

Sir,—Before reading Mr. Woodland's letter I must acknowledge that I was not aware that the potassium iodide test mentioned by me in the paper entitled "Detection of Traces of Bismuth," had previously been published, no mention of such a method being found in any of the more advanced treatises on practical chemistry to which I have access.

But Mr. Woodland appears somewhat to mistake the import of the paper, which certainly was not to laud a new test for bismuth discovered by myself, but had special reference to the detection of traces of bismuth in complex mixtures. The whole of the paper relates to experiments made to determine the reliability of the method under most varied circumstances, and knowing the exceeding difficulty of ascertaining in all cases whether a reaction has before been observed, chemical literature being now so enormous, special care was taken in wording the article to avoid as far as possible any pointed allusions to the originality of the test.

As showing under what circumstances potassium iodide may be employed for detecting traces of bismuth in presence of any or all of the commonly occurring metals, any slight value which the paper may have originally possessed does not appear to me to be in any way decreased by the fact which Mr. Woodland has kindly pointed out.

Buxton, March, 1880. John C. Thresh.

J. Gillett and "*Chemist*."—We refer you to the Secretary of the Pharmaceutical Society for any further information you may require upon the subject referred to in your letters.

C. Ellisson.—Copies of the Manchester Price List may be obtained from Mr. Silverlock, printer, Blackfriars Road, S.E.

R. Calvert.—At present it is impossible to say.

Communications, Letters, etc., have been received from Messrs. Pattison, Conroy, Parsons, Tebbutt, F. Smith, Fletcher, Chichester, Amicus, Alpha, E. L.

JAPANESE BELLADONNA.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

In January last, I received from Professor Flückiger, of Strassburg, a specimen of a root labelled "Japanese belladonna," and which, in his opinion, "seemed to contain atropine."

The root was totally different in character to true belladonna; but, having at that time no clue to its botanical source, I put it on one side for future investigation.

My attention was again called to this belladonna root by a sample received, a few days ago, from Messrs. Hearon, Squire and Francis, who informed me that it was offered at a drug sale in London early this month, but that no one bid for it.

Just at this time I had occasion to refer to a figure of *Scopolia carniolica*, Jacq.,* and was struck by the remarkable resemblance between the root of this plant, as figured by Jacquin, and the Japanese belladonna.

On turning to the recently published work by Franchet and Savatier on Japanese plants, I found that an allied species, *S. japonica*, Max., occurs in Japan, and that no other solanaceous plant there described would be likely to have a stout rhizome like that of scopolia, most of the solanaceous plants of that country being either annuals, or suffruticose perennials like dulcamara. On referring to Maximowicz's description of *Scopolia japonica*,† I found that he considered it to be the *Atropa Belladonna* of Japanese botanists. Although Franchet and Savatier record it only, on the authority of Tschonaski, from near streams on the highest mountains of Nikoo, and on that of Tanaka, from an unknown locality, yet it is well known that the Japanese cultivate several solanaceous plants, and probably this one among them since it is figured both in the 'Sô mokou Zoussetz,' vol. iii., fol. 17 (under the name of *Hashiri dokoro*), and in the 'Phonzou Zoufou,' vol. xxi., fol. 22 (under *Ro outo*). It would seem, therefore, to be a well known plant, and may reasonably be supposed to be as hardy as the *S. carniolica* of English gardens, and the root might well be an article of commerce in Japan.

I entertain no doubt, therefore, that the Japanese belladonna root which has lately been offered for sale in Europe is the root of *Scopolia japonica*, Max. This species differs from the European one (*S. carniolica*) chiefly in its more acute leaves, which have constantly longer petioles, in the style being curved or declinate instead of straight, and in the teeth of the calyx being sometimes very unequal. The fruit is unknown. In size, the Japanese plant equals robust specimens of the European species.

The rhizome, as met with in commerce, varies in length from 2 to 4 or 5 inches, and on the average is ½ inch in diameter, cylindrical or slightly compressed, rarely branched, knotty, and more or less bent and marked on the upper surface with circular, disc-like scars where the leafy stems have arisen. It is the slightly alternate disposition of the nodes from which these stems arise which gives the rhizome its knotty character. No rootlets remain attached to the rhizome, but each node is surrounded with one or more indistinct rows of dots or scars, apparently indicating their presence. The rhizome is externally of a brown colour, not white when abraded, as in belladonna, of a pale brown colour internally, speckled with

Japanese Belladonna Root.—The left hand figure represents the root, the right hand one the twisted rhizome, and the central one a transverse section of the rhizome with the vascular bundles more marked than usual.

numerous very minute dots, which appear under a lens to be white and starchy, and scattered through a resinous or horny looking structure. The bark is so similar in colour and so closely applied to the meditullium as not to be readily distinguishable by the naked eye. The odour is slightly mousy and narcotic, and the taste hardly any except a slight bitterness. From portions which were mixed with the rhizome, it would appear to terminate in a genuine root of some length and thickness.

The recent investigations by Ladenburg (see below), concerning the relationship of the solanaceous alkaloids to each other, seem to point out that the active principle of this drug might be worth examination, as well as that of its European congener.

A few remarks on the genus *Scopolia* may perhaps not be out of place here. It was founded by Jacquin on the peculiarity of the fruit, which is a capsule. The capsule, with the calyx and pedicel, fall off together, and after a time, the capsule dehisces transversely, like that of henbane. In colour of the flower and in foliage the plant so closely resembles belladonna, that were it not for the fact that belladonna has a baccate fruit and no rhizome, even a good botanist might be led to call it an *Atropa*. The genus is named after Antoine Scopoli, an Idrian physician and professor of botany, who appears to have been the first to notice the European species.

The Japanese scopolia has the leaves often more or less deeply dentate, or even repand-dentate, in which character it presents an analogy to *Solanum nigrum* in this country, the leaves of which may sometimes be found quite entire and sometimes coarsely-toothed.

NOTE ON DUBOISINE.*

BY A. LADENBURG.

Recently a new alkaloid has come into commerce, derived from an Australian plant, *Duboisia myoporoides*. The plant is at present generally referred to

* *Berichte d. deutschen chemischen Gesellschaft*, xiii., 257.

the Solanaceæ, notwithstanding that morphologically it is far removed from *Atropa* and *Hyoscyamus*. Upon the preparation and properties of this alkaloid few communications have been published, and among these it appears to me that only that by Gerrard* is of importance. That author describes the alkaloid as a yellow oil, which in its chemical and physiological aspects approaches to atropine; indeed he appears to consider the identity of the two possible, notwithstanding that he has observed some differences between them. Among the known properties of duboisine is its powerful mydriatic action, which alone is remarkable, and this has already procured for it a considerable place in the pharmacopœia, or, better still, an important *rôle* in ophthalmic clinics. But although the action of duboisine upon the human pupil is very similar to that of atropine, it is at present chiefly used when individuals who have an idiosyncrasy against atropine, or who have become intolerant of it, have to be ophthalmically examined. From this use of duboisine a difference in this base from atropine must be assumed, and a chemical examination of duboisine appeared to me desirable, in order to ascertain whether in its composition it was allied to atropine, and whether it belonged to the class of tropeines.†

I procured from Merck, in Darmstadt, two grams of sulphate of duboisine, and received it in the form of a brown resin, evidently the evaporation residue of an aqueous solution. This was hygroscopic, and readily soluble in water. From this solution there was precipitated by potassium carbonate an oil that did not solidify. The reactions were similar to those of atropine, but the precipitates almost throughout were resinous. According to the method adopted for the purification of this kind of alkaloid in the case of hyoscyamine,‡ I directed my principal attention to the gold salt, and this I soon succeeded in bringing to the solid state by fractional precipitation, *i.e.*, by removing the resin first precipitated and the oil that separated after longer standing. The gold salt so obtained was recrystallized from hot water, and finally obtained in the handsome lustrous crystals so characteristic of the gold salt of hyoscyamine. After drying, the melting point was 159° C., and the composition corresponded to the formula—

$$C_{17}H_{23}NO_3,HCl,AuCl_3.$$

	Found.	Calculated.
C	32·23	32·48
H	4·00	3·82
Au.	31·00	31·23

The gold double salt in warm aqueous solution was decomposed by sulphuretted hydrogen, filtered from the gold sulphide, and the colourless solution strongly concentrated. This was after cooling treated with potassium carbonate in excess, when a precipitate was formed that at first was amorphous and gelatinous, but after some time was transformed into beautiful small needles. These were removed by filtration, washed with a little water, and dissolved in chloroform, in which they were very soluble. The solution was twice shaken with water, to remove potassium carbonate, and then evaporated in an exsiccator. There remained a well crystallized tolerably hard mass, the melting point of which was found to be 106·5° C., whilst that of pure hyoscyamine is 108·5° C. The analysis corresponded to hyoscyamine, the loss depending probably upon traces of admixed potassium carbonate.

	Found.	Calculated.
C	70·17	70·59
H	7·82	7·95

The qualitative reactions of this base are identical with those of hyoscyamine. I have not yet published the latter; but the following will serve for both alkaloids:—A dilute hydrochloric solution gives with picric acid a yellow oil that almost momentarily solidifies to handsome regular tables. Platinum chloride produces no precipitate. Iodine in potassium iodide causes at once a separation of a crystalline periodide. Tannic acid produces a slight turbidity; iodide of mercury and potassium a white amorphous precipitate.

I believe through the foregoing investigation the identity of duboisine and hyoscyamine to have been proved.

NOTE ON DATURINE.*

BY A. LADENBURG AND G. MEYER.

It is assumed on the ground of an investigation by Von Planta† that daturine is identical with atropine. Planta's experiments show, however, only that both alkaloids have the same composition, which alone is not sufficient to establish their identity. For instance this author states that the gold salt of daturine melts between 90° and 100°, whilst he places the melting point of the gold salt of atropine quite correctly at 135° C. He mentions also that the melting points of the free bases nearly correspond, being respectively 88° and 90° C. But as it has recently been proved that atropine first melts at 113·5 a renewed examination of daturine appeared to be desirable.

Daturine was obtained in a tolerably pure condition from Merck, in Darmstadt, as a scarcely crystalline white powder, melting at 90° to 95° C. The attempt to purify it, like atropine, by dissolving it in a little alcohol and pouring this solution into water gave a jelly-like mass, which changed only slowly into an aggregation of fine needles, an appearance which is never observed in atropine. The melting point of this preparation lay above 100° C. A repetition of the experiment gave only so small a yield that this method of purification was given up as impracticable.

A larger quantity of the alkaloid was now converted into the double gold salt, which at first separated out oily, but very quickly solidified. After recrystallization from hot water it was obtained in shining golden yellow lamellæ, having quite the appearance of the gold salt of hyoscyamine and also possessing the same melting point, 159° C. Analysis of this gold salt gave—

	Calculated for $C_{17}H_{23}NO_3HClAu\,Cl_3$	Found.
C	32·48	32·52
H	3·82	3·99

The gold salt was freed from gold by means of sulphuretted hydrogen, and the resulting hydrochlorate in tolerably concentrated solution was precipitated by potassium carbonate. The precipitate was taken up by chloroform and this upon evaporation left behind a hard crystalline mass which after drying on a water-bath melted at 105-106° C. To purify it further it was recrystallized from hot toluol,

* *Berichte d. deutschen chemischen Gesellschaft*, xiii., 380.
† *Ann. Chem. Pharm.*, lxxiv., 252.

from which it separated on cooling in needles. After longer drying at 100° C. the preparation melted at 105-108° C. The melting-point of hyoscyamine lies at 108·5° C.

Analysis gave—

	Calculated for $C_{17}H_{23}NO_3$	Found.
C	70·58	70·47
H	7·96	8·33

In the quantitative reactions also no difference was shown between daturine and hyoscyamine. Picric acid produced in the acid solution an oily precipitate, quickly solidifying to right-angled lamellæ. Tannin produced only a slight turbidity, but after neutralization a thicker and whiter precipitate was formed. Iodine in iodide of potassium produced a scarcely crystalline brown powder and iodide of mercury and potassium formed a white cheesy precipitate, whilst platinic chloride, mercuric chloride and potassium ferrocyanide gave no precipitates in dilute solutions.

We believe, therefore, that we are warranted in affirming the identity of daturine with hyoscyamine and duboisine.

It is interesting to notice that there occur in nature only two strongly mydriatic acting alkaloids, atropine and hyoscyamine, which are isomeric with one another and stand extraordinarily near to each other.

NOTES ON THE LIVER-ROT IN SHEEP.

BY F. PORTER SMITH, F.R.G.S.,

Medical Officer of Health, Shepton Mallet.

Whilst the wool of the sheep was undoubtedly the first product of this useful animal to attract the attention of man, the carcase has of late years become the main object of the sheep-breeder. In many foreign countries the flesh is disliked, or at least rarely eaten. The Calmucs and Cossacks seldom touch it, and the Mongols make a wine from it. In some parts of America, and in Spain, mutton is scarcely considered fit for food. The occurrence of the liver-rot, coe, or bane, is likely to create a prejudice against what is practically the most important meat element in the diet of the sound, and especially of the sick members of our highly civilized country. Apart from these latter considerations, the study of the diseases of such an animal as the sheep, so widely spread all through the land, must tend to throw light upon the epidemic diseases of mankind. It speaks little for the oversight of the Government of the day that, while an expensive network of sanitary agencies is stretched all over these islands, nothing scarcely has been done to closely investigate the origin, extent and means of prevention of this bane of the farmer. Epizootics have long been a recognized subject of study, but there is a new world of facts to be adventured upon in this branch of practical agriculture. As early as the year 1532, in the "Book of Husbandrye," by Sir Anthony Fitzherbert, the principal features of the liver-rot were well known, and its effects on the health of the sheep carefully described. At that period, from the absence of draining, the liver-rot must have been much more (proportionably) destructive than it is now. Thanks to the more general and more intelligent adoption of systems of drainage, the estimate of a writer of some thirty-five years ago that "more than a million sheep and lambs *die* of it annually," must have been too high for the average of later years. In some seasons this number has been much exceeded. In the winters of 1830-31 it was more than doubled, and in some of the midland, eastern and southern counties, where the pestilence was most rife, the existing race of sheep was almost entirely swept away. In no season for the last thirty-five years, have I had any difficulty in procuring coed livers from both "urban" and "rural" unsanitary carcases.

The disease is not confined to this country. Just as the "measle," or trichina, is as common in the pig-market of Central China as in Somersetshire, so the Mongol, the Norwegian, the Spanish, the North American, and the Australian flocks are scourged with this pest, even in *natural* pastures.

Recent discoveries have led to the assignment of several forms of minute vegetable and animal growths as the probable causes of human diseases, little suspected to be connected with "foreign residents" in the blood or other parts of the body, of which we have only a gross instance in the too familiar disease "worms." The liver-rot, as it occurs in sheep, is due to the presence in the gall-bladder, and bile-channels of the liver, of a small parasitic creature, called the "fluke," from its resemblance (on a small scale) to a fish of that name, more commonly called a flounder. The liver-fluke (*Distoma*) is met with in the sheep in two forms, the *larger* (*Distoma hepaticum*), or liver-fluke proper, in shape very like a small sole, full at each end of the body, which is, when full-grown, from three-quarters to an inch and a half long, and the *smaller* (*Distoma lanceolatum*), which was formerly thought to be the juvenile stage of the other, a little more than a quarter of an inch long, and tapering at each end, like a surgical lancet. They have two suckers, or mouths, at the head-end, hence the name "Distoma," or "double-mouthed." The body is soft, gelatinous, semi-transparent and somewhat white in colour. With the bile of the liver, on which they seem to feed, and the variegation of the surface, caused by the bunches of eggs at the indented edges, these flukes have been compared to small leaves. Each fluke is both male and female in itself, and more than a thousand flukes have been positively counted in one liver. It may be easily inferred how universal must be their powers of propagation by the minute yellow eggs, or spawn (two hundred of which would only measure an inch) which fill the biliary channels of the rotting liver. This organ instead of having a thin, bevelled edge is rounded off at the margin, pale, shrunken, easily torn through, somewhat greasy in tecture, and sometimes covered with a callus on the upper surface. But the most serious changes are wrought in the biliary channels, or ducts, where the flukes are found, and not in the veins as is often asserted. These ducts become enlarged and toughened, and are stuffed with flukes, and the excrement and eggs of the creature, mixed with slime. In some livers the flukes die, and an earthy callus is all that is left to show where a whole nest of them once finished their biography.

The effects of these bile-suckers upon the health of the infected animals are very striking at first; if well fed the animals put on fat rapidly, but this does not deceive the butcher who turns up the eyelid and finds it pale and dirty-looking, if not slightly yellow. The membrane of the eyelid should be ruddy and worked with veins, filled with bright red blood, and the little caruncle, or bunch of flesh, at the corner of the eye should be plump and florid. The skin, when the wool is parted, is seen to be pale, sallow, jaundiced often, and very loose upon the muscles beneath, which are wasted and unhealthy-looking. The legs become dropsical and very weak, and as the disease goes on fat disappears, the appetite fails, the bowels are either costive or very loose, and the belly eventually becomes potted full of water. The wool comes off easily, and the skin becomes mottled, bruising with the slightest blow. The actual course of the disease to death is by emaciation, varied by jaundice, general dropsy, diarrhœa, and other complications, which finish up the poor animal in from two to six months from the commencement of a disease, which, in a more elevated being, a sailor might put down for scurvy, and a rabid teetotaller as the effects of unlimited three-pennyworths of gin and brandy. In fact "heavy wet" has a good deal to do with "liver-rot" in sheep, though not all of the blame can be properly set down to this single cause. The fluke is first found in the upper part of the small gut, where the main gall-passage is found, and the creature seems to pass by some instinct up this route to the liver. After wet seasons, from November to April, the eggs of the fluke are met with in the droppings of sheep. These are brought down in the bile from the infected liver, and are capable of retaining their vitality for a long period. Flukes themselves are found under the same circumstances at all periods. Being full of myriads of eggs, they probably die, and add to the store of eggs which are the omnipresent germs of the disease. It is probable that the sheep itself is not capable of perfectly hatching these germs in its own body into full-grown flukes. Some eggs seem to be directly hatched, and the small creatures, variously described as young tadpole-like, or ciliated, make from the ditches, ponds, etc., where the sheep drink them down with the water. In other cases aquatic insects, mud-snails, etc., swallow these eggs, and partly hatch them in their minute bodies, which are eaten with the herbage by the sheep, and the creatures are further developed in the food-canals of the animal. It is probable that in healthy sheep the stomach is able to digest and destroy most of these germs, but if the food be poor, watery and too same in its character, and the sheep consequently suffer in its nourishment, these germs get the upper hand, and the animal becomes a mere nurse for these pests. It is true that the wet weather produces a direct effect on the disease by weakening and chilling the animal, and by promoting the growth of inferior herbage, such as the carnation-grass, which fails, from its watery nature, to nourish the animal. But wet weather means sunless days. The eggs or germs, or those mud-snails which harbour or hatch the germs, cannot bear strong sunlight. On those lowering dark days called "blights" the growth of aphides, bugs, and small insects of all kinds is something enormous. On the appearance of the sun they crawl for shelter to the under-surfaces of leaves, blades, etc., and a continuance of clear sunny weather cooks these eggs, or germs, or destroys these thin skinned creatures, so that with the vigour of brighter days, and the checking of the numbers and strength of these germs, the sheep escape, or fight out fairly their battle with these pests. The liver-rot is in ordinary seasons confined to wet land, does not spread in dry seasons, or during hard frosts, and seldom shows itself in dry sandy soils, except after a prolonged rainy season. Autumn and winter are the seasons in which the liver-rot prevails most, that is some time after the fluke-germs have been inoculated into the system of the infected animals. It would appear that the fluke-germs may lie dormant in some animals, until some favourable circumstances conspire to develop the active disease of the liver. The liver-rot does not seem to originate in higher lands, if well drained, although it may be conveyed there in the sheep, or by some other means. Ground much trodden down by close and overstocked feeding seems to be more liable to the disease. It is generally believed that at night, or while the dew is on the grass, the infection spreads much more than by day. It has been therefore strongly recommended that the sheep should be folded early in the evening, and not be released until the dew is gone off. Overcrowding should also be avoided, and the droppings carefully collected and burnt in cases of actual infection. The practice of allowing sheep to graze on the wayside, where rushes and other plants often indicate the damp nature of the soil, is also to be avoided. The rapidity with which sheep are tainted is very remarkable. "A farmer in the parish of Woraghy (Lincolnshire) took twenty sheep to the fair, leaving six behind in the pasture on which they had been summered. The score sent to the fair, not being sold, were driven back to join the other six left. In the course of the winter every one of the score (distinctively marked) died of the liver-rot, but ths six left behind in the field all lived and did well. The loss of the score can only be accounted for on the belief that they had gone over some infected ground." A second case is still more conclusive of infection. "A sheep, belonging to a lot of twenty, having broken its leg in Burgh fair, in Lincolnshire, the nineteen others were placed in a common at the end of the town until a cart could be got to remove the lamed animal. The nineteen all died of the liver-rot, while the one lamed remained sound." Common sense seems to suggest that, as there is proof and possibility of infection, so that no land can be kept free from the disease, whether well-drained, or well-situated on higher ground or lighter soil, the greatest care should be taken in preventing access in any way to the infection. There is no proof of contagion, that is infection, by mere contact of one diseased animal with another.

Hares, rabbits, oxen, deer, horses and asses are all liable to be attacked by liver-rot, but the disease is less virulent than in the case of the sheep. The size of the cow seems to render it less liable to suffer from the flux and irritation caused by the fluke, whilst in the case of the smaller animals, such as the hare, the struggle is more equal, and more fatal. To the question how the flukes work the destruction of the animal, it is not easy to reply. They have been supposed to excite a serous secretion from the lining of the gall-channels, which, by its amount and loss to the system, greatly impoverishes the blood. This interference with the proper formation of healthy bile, a necessary element in the assimilation of the food and the regular action of the bowels, seems enough to account for the loss of flesh and strength in the infected animal, without mentioning the permanent irritation set up in the largest organ of the belly. As preventive measures have incidentally been mentioned, such as draining, fencing of stagnant ditches, provision of pure running water, isolation, use of dry artificial food, etc., the question of what positively curative measures can be adopted only remains. That many animals will still die, even when removed to a healthy pasture, follows necessarily from the facts alluded to in the history of the fluke-disease. The thoroughly infected animals carry the enemy with them, only to flourish in the new situation, but many of them will recover. The use of salt, placed in lumps (of rock salt) where the sheep can conveniently lick it, or added to their water, or artificial food, has been attended with marked benefit. The salt seems to destroy the flukes already in the liver. The use of hyposulphite of soda, sal-ammoniac, sulpho-carbonate of soda, and other corrective or antidotal substances is also worth a trial. Of all mere physic I have most confidence in the chlorate of potash, a cheap and comparatively tasteless substance, which has been very beneficial in liver-rot. That in the mixed plants of natural and mountain pastures there are herbs of a curative influence, such as the cow-wheat, yellow rattle, buck-bean, wild liquorice, wild thyme, gentian, wild camomile, etc., which are the medicines of the grazing animal, just as grass is for the dog or cat, there can be no doubt. Whilst these plants find no favour with the farmer, who looks jealously for clover s and pure grasses, they may afford a beneficial and alterative diet to the animal. We wonder at the perversity of the cow or sheep which grabs at the leaves of the bushes in the hedgerow of the field, or the wayside, or consumes the twigs, leaves and bark of the chance-fallen tree in the pasture, but these new dishes may have their place in the modern, too much restricted diet of these animals. The hardihood of the ass is, at least, associated with some such similar promiscuous and perverse browsing on thistles, brambles, and other "unclean" feeding. The mixing of condiments, such as ginger, of drugs, such as gentian, with ground cake, and the use of "cattle-foods," "pig-spices," etc., are all plans worthy of trial. But to sit still until State-aid and red tape regulations shall have regulated away this baneful disease, which is no new thing among us, would be unworthy of the restless, enterprising, blood-resisting English yeoman. Let our cattle societies commission their standing veterinary counsel to investigate this liver-rot, ere the plague has passed away from our midst for a time, only to return again to punish indifference and relapse.

As the fluke has been found in the human liver, it is desirable that all mutton should be selected, inspected, and carefully cooked, say by thorough roasting. It is a pity, however, that any panic should seize our minds on this subject of mutton-eating. The *Lancet*, our highest medical sanitary authority in this country, says distinctly that "the flesh of sheep which have been affected with this verminous disease, cannot be said to be positively dangerous as food, though it must be greatly reduced in nutritive properties." This is meant to apply, beyond doubt, to animals greatly affected by the disease. The livers should be certainly not consumed as food, but destroyed by burning, or some other similar effective means, as they swarm with the flukes and their eggs. In fact all livers should be avoided by delicate feeders during the present epidemic.

That other forms of chill, rot, etc., are affecting grazing animals of all kinds at the present time, as the result of the past wet seasons, there can be no doubt. The disease called "ergot," or the "spurred" condition of any sort of grain, is very common in wet seasons. These black seeds result from the infection of the grain by a parasite, which in late sunless seasons happens to ripen nearer to the critical period of the growth of the corn, than in normal years. The seeds of the grasses are also affected by "ergot," and these ergotized seeds produce foot-rot, "slipping" of the young, and also certain symptoms likely to be confounded with the liver-rot, or foot-rot.

The ray-grass (commonly mis-called "rye" grass), nearly related to the darnel grass, is not always safe as a herbage. The bitter vetch, the meal of which is often mixed with pigs' food, sometimes produces "red water," but curiously enough not in sheep fed upon the meal. Darwin, in his 'Origin of Species,' 1879, page 13, makes the curious observation that white sheep are injured by feeding on certain plants and grain, whilst dark sheep escape the bad effects.

The moral of all these odds and ends of remarks upon this large subject, the well of which is deep, and I, perhaps, have little to draw up the truth from it with, is that there is much scope for study, dealing with, and, I believe, stamping out of this pest—this curse of the sheep-farmer, the liver-rot.

A METHOD FOR THE PROXIMATE ANALYSIS OF PLANTS.*

BY HENRY B. PARSONS.

At the request of my friend and former instructor, Professor Albert B. Prescott, of the University of Michigan, I have prepared the following scheme for the analysis of plants. This method will appear, in substance, in his new proximate 'Organic Analysis,' now nearly completed.

The plan submitted is the outgrowth of a quite varied experience in the proximate analysis of plants; no claim to originality is made, the sole aim being to arrange in one simple scheme those methods best suited to insure accuracy.

It must be premised that no one method is applicable in all cases, and that the operator will so modify and adapt the proposed processes as to best attain the truths he seeks. If the present scheme shall serve merely as an example, to be improved upon as discoveries multiply, it will at least have served to stimulate to the more thorough study, this side the Atlantic, of a much neglected, yet very important, branch of analysis. The American student, when first entering upon the study of plant analysis, is perplexed and disheartened, owing to the lack of any elementary treatise in which he may find directions for the quantitative estimation of the various plant constituents. The works of Rochleder and Wittstein, while giving most valuable assistance in the investigation of special constituents and their separation from large quantities of the crude herb, still fail to give clear and practicable directions for the quantitative estimation of each constituent. Von Müller's latest enlarged edition of Wittstein's 'Plant Analysis' gives a scheme, most excellent in many respects, yet cumbered with tiresome methods of extraction and manipulation, which serve to unnecessarily lengthen the time required for making the analyses without increasing the accuracy of results obtained.

Too many American analyses of plants have been summarized thus: "The plant contains gum, resin, tannin, a volatile oil, and a peculiar bitter principle, to which may be ascribed its medicinal activity." The foreign journals bring occasionally most excellent examples of accurate examinations of vegetable substances; as instances may be cited the examination of ginger, by J. C. Thresh,* and of ergot,† aloes,‡ and other articles, by Professor Dragendorff. To these sources the student must look for his best models, until a more thorough and systematic training is given American students in proximate organic analysis.

In the following plan now presented, the use of the apparatus for repercolation is strongly urged for the extractions with benzole, alcohol, and other volatile solvents. A very simple and inexpensive apparatus has been described by various American and foreign chemists.§

"In any convenient water-tight vessel is a worm of block-tin pipe, having an internal diameter of 9 mm., and a length of about 2·5 metres. The lower (external) part of this worm is fitted, by an ether-soaked velvet cork, to a glass percolator having a diameter of 4 c.m., a length of 20 c.m. to the constriction, and 5 c.m. below. Within this percolator is a smaller tube, flanged at the top and bottom, and suspended by fine platinum or copper wires. This tube has a diameter of 2·5 to 2·8 c.m., and a length of 14 c.m.; the bottom is covered by filter paper and fine washed linen,|| tied on by linen thread. The weighed sample of the finely powdered herb is placed within this tube for extraction. A light glass flask, weighing about 30 grams, is fitted by an ether-soaked cork to the outer percolator." Having introduced the solvent into this glass flask, the connections are made secure, and heat is applied, by a water-bath, to the flask. If the liquid is too slowly volatilized, the addition of a little common salt to the water in the bath serves to remove the trouble.

Next in importance is the use of a good tared filter. The form originally presented by F. A. Gooch¶ leaves little to be desired. It may be made by perforating with fine holes the bottom of an ordinary platinum crucible, and fitting it accurately to a perforation made in a large rubber cork; this cork connects it with a receiving vessel, which, in turn, is connected with a Bunsen's pump. Fine asbestos suspended in

|| In place of the linen and filter paper may be substituted fine brass or platinum wire gauze. Asbestos suspended in water may then be poured in to form a fine felt. The tube can then be dried and weighed, and the amounts extracted may be found by the loss of weight of the tube and substance. A little experimentation will show the operator how to prepare and use the tube. It is but an adaptation of the Gooch's filter here recommended.

¶ 'Proc. Amer. Acad. Sci.' [13], 342, 1878; *New Remedies*, [7], 290, Oct., 1878; *American Chemical Journal*, [1], 317.

water is poured into the crucible, the air exhausted from the receiving vessel, and thus a firm thin layer of asbestos is deposited on the bottom of the crucible. After ignition and weighing, the crucible is ready for the reception of any precipitate which it is desired to separate and weigh.

The use of these two pieces of apparatus will eliminate two grave sources of error, viz., incomplete extraction of soluble matters, and inaccuracies introduced by the use of tared paper filters.

The other necessary apparatus is simple, and includes one or more platinum crucibles and evaporating dishes, accurate burettes and graduated cylinders, a good balance, sensitive to at least ·5 milligram, and the ordinary glass and porcelain ware found in all laboratories.

It is assumed that whoever attempts the analysis of a plant is informed as to the normal constituents to be sought, that he has had considerable experience in inorganic analysis, and in the identification of the principal classes of proximate constituents which he now undertakes to estimate quantitatively. Accordingly tests for identification will not be here presented; they should, however, never be omitted. The necessity of recording in detail all physical and chemical peculiarities, with every weight that is taken, is self-evident.

A Method for the Proximate Analysis of Plants.

I. *Preparation of Sample.*

The air-dry specimen should be carefully examined, and all extraneous substances removed. The entire sample should then be ground, or beaten in an iron mortar, until it will all pass through a sieve having from forty to sixty meshes to the linear inch. After thoroughly mixing this sample, take of it 100 grams, which should be further pulverized until it will all pass through a sieve having from eighty to one hundred meshes to the linear inch. From this smaller portion remove all iron, derived from mill or mortar, by use of a magnet. Then place in a clean dry bottle, which should be labelled and securely corked. This small sample is for the analysis; the larger portion should be reserved for the separation of those proximate principles which seem, from the analysis, to be worthy of more extended investigation.

II. *Estimation of Moisture.*

Dry rapidly, at 100 to 120° C., 2 or more grams of the sample; the loss of weight equals moisture, and occasionally a little volatile oil. In some cases it is best to dry at a lower temperature, and at other times the drying should be conducted in a stream of hydrogen or carbonic anhydride.

III. *Estimation of Ash.*

In a weighed crucible gently ignite 2 or more grams of the sample until nearly or quite free from carbonaceous matter; the heat should not be permitted to rise above faint redness, or loss of alkaline chlorides may occur. Weigh this residue as crude ash, and in it determine—

a. Amount soluble in Water.—This portion may contain chlorides, sulphates, phosphates, and carbonates of potassium and sodium, also slight amounts of chlorides and sulphates of calcium and magnesium.

b. Insoluble in Water; Soluble in dilute Hydrochloric Acid.—The residue from *a* should be treated with a slight excess of hydrochloric acid, and evaporated in a porcelain dish over a water-bath until all free acid has been expelled; it should then be again moistened with hydrochloric acid, water added, and be filtered from any remaining insoluble substances. This treatment removes carbonates (with decomposition) and phosphates of calcium and magnesium, sulphate of calcium, and oxides of iron and manganese.

c. Insoluble in Water; Insoluble in dilute Hydrochloric Acid; Soluble in concentrated Sodic Hydrate.—Boil the residue from *b* with a solution containing about 20 per cent. of sodic hydrate. This treatment removes combined silica of the ash. The residue still insoluble is sand and clay which adhered to the specimen; this residue should be separated, washed thoroughly, and weighed.

Always determine the amounts removed by the above treatment by weighing the dried, undissolved residues. The ash, as thus estimated, usually includes a little unconsumed carbon, together with more or less carbonic anhydride (CO_2), most, or all, of which was not originally present in the plant, but was produced by the combustion of the organic matter. For most purposes it is unnecessary to estimate and exclude from the ash this carbonic anhydride; where great accuracy is desired, a complete quantitative analysis should be made, the amount of each base and acid being determined, and in the statement of results only those should be included which existed originally in the plant. For this purpose it is necessary to burn from 20 to 100 grams of the sample; for further directions consult text-books on agricultural and inorganic analysis.

IV. *Estimation of Total Nitrogen.*

In ½ a gram or more of the sample determine total nitrogen by combustion with excess of soda-lime, as directed by Professor S. W. Johnson and E. H. Jenkins.* If later in the analysis no other nitrogenous substances are discovered, calculate the total amount of nitrogen to albuminoids by multiplying by 6·25. When other nitrogenous compounds are present, their contents of nitrogen should be determined directly or by difference; after proper deductions have been made, the remaining nitrogen should be calculated to albuminoids.

V. *Estimation of Benzol Extract.*

In a suitable apparatus for repercolation completely exhaust 5 grams of the sample with pure coal-tar benzol (sp. gr. ·85—·88, boils at 80—85° C., leaves no residue when evaporated). The extraction requires from four to six hours' continued action of the solvent. Carefully evaporate this liquid to dryness in a weighed dish, and record its weight as total benzol extract. This extract may contain volatile oils and other aromatic compounds, resins, camphors, volatile or non-volatile organic acids, wax, solid fats, fixed oils, chlorophyll, other colours, volatile or fixed alkaloids, glucosides, almost no ash.

To the weighed extract add water, again evaporate on the water-bath, and complete the drying in an air-bath at 110° C. In absence of other vaporizable substances the loss of weight approximates the amount of volatile oil. If the presence of a volatile alkaloid is suspected (from a characteristic odour or an alkaline reaction), add a drop of hydrochloric acid to prevent its volatilization. Camphors are partially dissipated by this treatment; hence, when they are present, this evaporation should be dispensed with.

Treat, now, the residue with a moderate amount of warm water, all to stand until cool, then filter through fine paper by aid of a Bunsen's pump. In half of the aqueous filtrate determine total organic matter and ash; test the remaining half for alkaloids, glucosides, and organic acids by salts of lead, silver, barium and calcium. Care must be taken not to mistake a slight amount of suspended matter, frequently resinous, for other substances actually soluble in water.

The still undissolved residue should be again removed from filters and dishes by solution in benzol, the benzol solution being again evaporated to dryness. Treat this residue with warm, very dilute hydrochloric acid, allow to cool, and filter through paper. The filtrate should be tested for alkaloids and glucosides. The amount extracted by acid, if any, may be determined by weighing the still undissolved residue. Treat this residue with several considerable portions of 80 per cent. alcohol (sp. gr. ·8483 at 15·6° C.), allowing at least an hour for each treatment. Filter through paper and determine by evaporation the matter dissolved; this usually consists of chlorophyll with one or more resins, which may sometimes be separated by use of petroleum, naphtha, chloroform, or

* 'Report Conn. Agric. Exp. Station,' 1878; *Chemical News*, July 18, 1878, p. 28; *Amer. Chem. Journ.*, 1, p. 77.

similar solvents. Purified animal charcoal removes chlorophyll and some resins from alcoholic solution, while certain other resins are not removed. If camphors were present in the plant the greater portion will be found in the alcoholic liquid.

The substances undissolved by 80 per cent. alcohol may be fixed oil, solid fat, wax, and very rarely a resin; their separation may be attempted by refrigeration and pressure, or by use of ether, chloroform, etc.

Recapitulation.

1. Loss by evaporation, with precautions : *volatile oil.*
2. Soluble in water : *alkaloids, glucosides, organic acids.*
3. { Insoluble in water. Soluble in dilute acids. } : *Alkaloids,* possibly *glucosides.*
4. { Insoluble in water. Insoluble in dilute acids. Soluble in 80 per cent. alcohol. } :
   - *a.* Removed by animal charcoal : *chlorophyll, some resins*
   - *b.* Not removed by animal charcoal: *some resins.*
5. { Insoluble in water. Insoluble in dilute acids. Insoluble in 80 per cent. alcohol. } : *wax, fats, fixed oils.*

It is frequently advantageous to extract the plant with petroleum naphtha (sp. gr. ·66–·70, boils at about 50° C., wholly volatile) before treatment with benzol; by reference to the accompanying table of comparative solubilities it will be seen that this treatment may serve to separate fixed and volatile oil and some resins and colours from certain solid fats, wax, other resins and colours.

Where benzol of sufficient purity cannot be had, pure chloroform is the best substitute. The use of ether is objectionable in this place, as its solvent properties are less distinctly marked than are those of naphtha, chloroform and benzol; in other words, more plant constituents are sparingly soluble in ether than in the above mentioned solvents. Consequently, many substances which should properly be extracted by 80 per cent. alcohol, would be sparingly dissolved if ether were used, while benzol, chloroform, and naphtha would have no perceptible solvent action upon them; tannic acids may be cited as instances illustrating this point.

* "Para cellulose" soluble in ammonia-cupric oxide after boiling with dilute HCl.
† Glucosides reduce Fehling's solution after boiling with dilute acids; same with sucrose.
An ? shows that some marked variations or exceptions occur.
Sp.=sparingly soluble. Sol.=soluble. Ins.=insoluble.

VI. *Estimation of Eighty per cent. Alcohol Extract.*

That part of the plant not dissolved by benzol should be dried at 100° C. and then completely exhausted by eighty per cent. alcohol (sp. gr. ·8483 at 15·6° C.). This requires from twelve to fourteen hours' continuous treatment with the solvent. Remove, dry, and weigh any crystals or powder that may separate upon concentrating and cooling the alcoholic percolate. Make the clear liquid to a definite volume by adding more eighty per cent. alcohol. In an aliquot part of this liquid determine *total organic matter* and *ash:* in another equal portion determine *total organic matter* and *ash soluble in water,* and, by difference, *total organic matter insoluble in water.*

The remaining clear alcoholic liquid should be evaporated carefully to dryness, pulverized, and treated with several considerable portions of absolute alcohol (sp. gr. ·7938 at 15·6°C.).

A. SOLUBLE IN ABSOLUTE ALCOHOL.

a. Soluble in water.

a[1]. *Precipitated by subacetate of lead.*

Tannin and most organic acids; some extractives; some inorganic acids of the ash. Weigh in Gooch's filter, ignite cautiously, and again weigh; loss equals organic matter precipitated.

a[2]. *Not precipitated by subacetate of lead.*

Alkaloids, glucosides, some extractives and colours.

Determine by difference between *a* and a^1.

b. Insoluble in water.

b^1. *Soluble in dilute hydrochloric acid.*
Alkaloids, glucosides (rarely), some extractives. Determine by difference between *b* and b^2.

b^2. *Insoluble in dilute hydrochloric acid.*

b^3. *Soluble in dilute ammonic hydrate.*
Most acid resins, some colours. Determine by difference between b^2 and b^4.

b^4. *Insoluble in dilute ammonic hydrate.*
Neutral resins, some colours, albuminoids (in some seeds). Redissolve in alcohol, evaporate and weigh.

B. Insoluble in Absolute Alcohol.

c. Soluble in water.

c^1. *Precipitated by subacetate of lead.*
Some colours, extractives, albuminoids (rarely), organic acids, and inorganic acids of ash. Weigh in Gooch's filter, ignite cautiously, and again weigh; loss equals organic matter precipitated.

c^2. *Not precipitated by subacetate of lead.*
Alkaloids, glucosides, sucrose, glucose, some extractives. Determine by difference between *c* and c^1. Remove Pb by H_2S, H_2SO_4, Na_2CO_3, or other means, and titrate for sucrose and glucose.

d. Insoluble in water

d^1. *Soluble in dilute hydrochloric acid.*
Some alkaloids and glucosides. Determine by difference between *d* and d^2.

d^2. *Insoluble in dilute hydrochloric acid.*
Few resins, some extractives, and colour substances. Dissolve in alcohol, evaporate and weigh in a tared dish.

In some cases it may be preferable to use the following method for analysis of the eighty per cent. alcohol extract; it is more desirable when the plant examined contains a considerable amount of sugars, tannic acid, etc.

Alcohol Extract, dilute to 200 c.c. with eighty per cent. alcohol.

1. In 20 c.c. determine total organic matter and ash.

2. In 20 c.c. determine total organic matter and ash that are soluble in water, and, by difference, total organic matter insoluble in water.

3. Evaporate the remaining 160 c.c. to dryness, treat with water, filter, and make the filtrate measure 160 c.c. Reserve the insoluble matter on the filter for examination. (10).

4. In 20 c.c. of the aqueous solution determine tannin gravimetrically by A. Carpeni's method;* precipitate by ammoniacal acetate of zinc, use a Gooch's filter, wash the precipitate with very weak ammonia, dry at 120° C., weigh, ignite cautiously, again weigh. The loss by ignition equals tannic acid, in absence of certain interfering substances.

5. Precipitate 20 c.c. by normal acetate of lead, and determine, as before described, the amount of organic matter after drying at 100—120° C. This precipitate will contain, if the substances are present in the plant, tannic, gallic, and most other organic acids, some colours, rarely albuminous substances, some extractives, and most inorganic acids of the ash. Determine, by difference, the amount not precipitated by this treatment.

6. In 20 c.c. determine in like manner the amount precipitated by basic acetate ("subacetate") of lead. This reagent precipitates a greater number of acids, colours and extractives than are precipitated by the normal acetate, hence it is frequently possible to estimate such substances by subtracting the amount precipitated by one reagent from the amount precipitated by the other. To the filtrate add a slight excess of dilute hydrochloric acid, boil gently for half an hour, and determine in the liquid total glucose by use of Fehling's solution.

7. Precipitate 20 c.c. by subacetate, exactly as in 6, and use the precipitate as a duplicate to check the amount there estimated. To the filtrate add a very slight excess of solution of carbonate of sodium, filter from the carbonate of lead, wash well with water containing a little alcohol, and in the filtrate estimate actual glucose. If the glucose thus found is appreciably less than that in 6, subtract it from that amount; this glucose may be due to the presence in the plant of sucrose or some glucoside. If due to sucrose, the amount of the latter may be found by multiplying this residual glucose by ·95; if to a glucoside, a fit subject for an extended investigation is presented. The properties, formula, and decomposition products of the newly-found glucoside should be carefully studied.

8. Precipitate 20 c.c. with subacetate of lead, as in 6 and 7, employing the precipitate as material from which to separate organic acids, after removal of lead by sulphuretted hydrogen. Acidulate the filtrate with sulphuric acid, add an equal volume of alcohol, allow to stand two hours, filter, wash the precipitate with fifty per cent. alcohol, and evaporate the filtrate until all alcohol has been dissipated. Test the acid solution for alkaloids, glucosides, sugars, extractives.

9. Reserve the remaining 40 c.c. for duplicating any unsatisfactory determination.

10. The residue mentioned in 3 as insoluble in water may contain resins, albuminoids (especially from seeds), colours, alkaloids, glucosides. Dilute acids remove alkaloids and some glucosides, dilute ammonic hydrate will remove some resins, colours and glucosides. Any still insoluble residue probably contains albuminous or resinous substances.

VII. *Estimation of Cold Water Extract.*

That part of the plant remaining insoluble after treatment with alcohol should be dried at 100° C. and completely extracted by cold water. When the plant contains considerable mucilaginous matter, this is best removed by placing the substance in a flask or graduated cylinder, and then adding a measured volume of cold water. Allow to macerate, with frequent agitation, for from six to twelve hours; then filter through fine washed linen, and evaporate an aliquot portion of the solution. In this residue determine total organic matter and ash. This residue usually contains little but gum; in analysis of fruits and fleshy roots pectin bodies, salts of organic acids, rarely a substance resembling dextrin, and small amounts of albuminous substances and colouring matter. Usually the separation of these substances is very difficult. The unevaporated liquid should be used for such qualitative reactions as are necessary to show the nature of the substances extracted. The insoluble residue should be well washed with water, transferred to a crucible, and completely dried at 110° C. This residue should be then weighed.

VIII. *Estimation of Acid Extracts.*

The dried residue insoluble in cold water should be transferred to a beaker containing 500 c.c. of water and 5 c.c. of concentrated sulphuric acid (sp. gr. 1·84). Boil for six hours, on a gauze support, adding water to keep the volume of liquid unchanged; if the substance be very starchy, a longer boiling may be necessary. This treatment will convert starch and its amorphous isomers to dextro-glucose, and will occasionally remove some salt of an organic acid, and usually traces of albuminous and indeterminate substances.

The total amount extracted may be found by washing, drying at 100° C., and weighing the yet insoluble residue, and subtracting the weight from the one taken after extracting with cold water. The amount of starch and isomers may be found by determining in a given volume of the acid filtrate the amount of glucose, using Fehling's solution; the glucose thus found multiplied by ·9 equals starch and isomers. The total extract minus starch and isomers equals acid extract not starch. This includes a small amount of ash, which may be approximately determined by evaporating and igniting a known volume of the solution.

* *Chem. News*, July 9, 1875, page 19, from *Gaz. Chim. Ital.* 1875, No. 3; *Proc. Am. Ph. Ass.*, 1875, p. 341.

Where it is wished to separate the extracted matter from the sulphuric acid, boil the liquid with an excess of powdered barium carbonate until no acid reaction remains. Filter, and evaporate to dryness. The residue consists chiefly of hydrated dextro-glucose ($C_6H_{12}O_6.H_2O$), with some ash.

IX. *Estimation of Alkali Extract.*

Wash well and dry at 110° C. the residue from treatment with acid, and record its weight. Boil this residue, for two hours, with 500 c.c. of a solution containing 20 grams of sodic hydrate to the litre. Filter through fine washed linen, and wash the residue thoroughly with hot water, alcohol and ether. Transfer it to a weighed crucible, dry at 110—120° C., and weigh the residue as crude fibre and ash; this weight subtracted from the previous one shows the total alkali extract. The extract is largely albuminous matter and various modifications of pectic acid, Fremy's "cutose," and various colouring, humus, and decomposition compounds in small amounts. Most of the extracted substances may be precipitated by excess of an acid with or without the presence of alcohol.

X. *Cellulose.*

The crude fibre from IX. should be treated with from 50 to 100 c.c. of U.S.P. solution of chlorinated soda, and allowed to stand twenty-four hours. If not then bleached white, slightly acidulate with hydrochloric acid, and set aside for another day. Filter through fine linen, or Gooch's filter, wash with hot water, dry at 110—120° C., and weigh, ash free, as cellulose. The loss of weight by this treatment state as lignose and colour.

Remarks.

It is advisable to determine always, in addition to what has already been directed, the amounts extracted directly from the sample by water, ether, alcohol of various precentages, methylic alcohol, naphtha, chloroform, carbon disulphide, etc. In each extract estimate total organic matter and ash, determine qualitatively, and quantitatively when possible, its constituents, by treating with such solvents and reagents as are indicated. Each extract being composed of certain distinct substances, it is necessary to account for them in every case.

The amounts present of some constituents may be found by subtracting the weight extracted by some one solvent extracted by some other. It will be seen that this is a method of limited applicability, which can only be applied in those cases where the difference between the solvent action of the two liquids is very sharply defined. Certain special methods for the estimation of single constituents may be used, care being taken that all interfering substances be first removed. The methods of preparation of known substances as given in Husemann's 'Pflanzenstoffe,' and to a considerable extent in Watt's 'Dictionary,' may serve as suggestions for work. Treatment with benzol, eighty per cent. alcohol, and water, removes from nearly all the plants the constituents of greatest chemical and medicinal interest, but in analyses of grain, fodder, and food materials those compounds extracted by dilute acids and alkalies have great value. There are substances in plants, seemingly isomers of starch and cellulose, which have properties more or less resembling those of cellulose, and are changed by boiling with dilute acids to glucose. In absence of an established nomenclature it has seemed best to use the terms "starch isomers," or "amylaceous cellulose" for these substances,* while those constituents, not albuminous, which are removed by dilute alkali have been termed "alkali extract." These substances have been investigated by various chemists, but no definite and authoritative nomenclature has yet been adopted. Thomsen gives the name "holz-gummi,"† *wood-gum*, to a white substance extracted from plants by dilute sodic hydrate, while Fremy regards these various compounds as modifications of pectic acid, pectin, and "cellulose bodies."* Starch also may exist in some seeds (as of sweet corn) in a form soluble in water.†

It will be seen that the field for investigation is limitless, and almost unoccupied as yet, and that there is great need for improved methods for proximate analysis. The analyst will find that a study of any common plant will require of him much more than unthinking, mechanical habits of manipulation, while every careful investigation will reveal to him some constituents deserving more full and accurate study.

NEW ORIGINAL FORMULAS FOR BOUQUETS.‡

BY G. DUBELLE, PH.D.

The growing importance for new perfumes has already called forth a considerable amount of formulas in publication, but all the writers fail to present the subject in a form suited to the increasing demand. It is the aim of the writer to publish occasionally new and well approved receipts for the use of our manufacturing perfumers and druggists.

WATTLES.

Of the tree known as the wattle in the colony of Victoria, there are three species, all of the genus Acacia, from which the bark used in tanning is obtained. These are :—*Acacia pycnantha*, commonly known of the "broad leaf," "golden" and "green" wattle ; *Acacia decurrens*, or black wattle ; *Acacia dealbata*, or silver wattle. The first named has a thick, glossy ovate leaf, the bark being thinner and smoother than that of either of the others. It is chiefly found in the south-western part of the colony and along the coast as far as the colony of South Australia. Its bark is generally considered superior to any other, but the habit of the tree is not so advantageous, it being of slower growth and not attaining such large dimensions as the black and silver species.

The black wattle is found over all the western district of Victoria, in the north-east, and also in the district of Gippsland. It is of vigorous, robust habit, and for commercial purposes is equal to the broad-leaf species. From the rapidity of its growth, and the ease with which it can be stripped during the proper season, the board considered that, for all practical purposes, it was desirable to cultivate this species either alone or with the broad-leaf wattle. The silver wattle, for tanning purposes, is generally discarded.

Wattles grow on almost any soil, but their growth is most rapid on loose sandy patches, or where the surface has been broken for agricultural or other purposes. Where the soil is hard or firm it is recommended that plough-furrows should be made at regular distances of five or six feet apart, into which the seed should be dropped. The outer covering of the wattle seed is peculiarly tough, hard and horny in character, thereby forming a protection which renders the seed comparatively impervious to ordinary germinating influences. It will, therefore, be found necessary to employ a more direct agency than simply covering the seeds with earth. Water of a little less than boiling temperature should be poured on them, and they should be allowed to soak until soft. As the seeds are small and ought to be sown near the surface, a very light sprinkling of earth is sufficient. For all practical purposes it would be enough to drop the seeds about one foot apart along the furrows, in which case about 7200 seeds would suffice for an acre of land. The wattle seed is cheap, and can be bought for 8*s.* or 10*s.* per pound. There are about 40,000 seeds of the black wattle to the pound. Those of the broad-leaf are one-fourth heavier, and consequently there are not more than about 30,000 to the pound. The seeds could, therefore, be dropped more plentifully with little additional expense, and the seedlings thinned out at discretion, thereby increasing the chances of a regular plantation. On loose sandy soil, on which *Acacia pycnantha* can best be raised, it might not be even necessary to break up the soil in any way; but it should be born in mind that any opening up of the surface would materially accelerate the germination of the seed and subsequent growth of the seedlings. On such open sandy soil the furrow line might be dispensed with and the seeds scattered broadcast. When the young trees attain the height of three or four feet the lower branches should be pruned off, and every effort afterwards made to keep the stems straight and clear, in order to facilitate the stripping and induce an increase in the yield of bark. In all instances where attention is paid to the cultivation of wattles as a source of income, care should be taken to replace every tree stripped by successional sowings, in order that there should be as little variation in yield as possible.

The wood of the wattle is of considerable value for industrial purposes. It can be readily utilized for cask staves, for axle spokes, for axe and pick handles, and many other articles requiring a tough and durable grain. When dried, it forms the best fire-wood known for culinary and all domestic purposes, also for ovens and furnaces. It emits a clearer and greater heat than any other firewood. The wattles may be utilized also for fencing, the trunks making top-rails of the best description. The commercial uses of the wattles are multifarious, as, in addition to the value of the bark and the wood, a good profit may be derived from the sale of the gum which exudes from the tree. Recently the price of Australian gum has increased thirty per cent. in the continental and English markets.

The character of the soil appears to affect, to some extent, the quality of the bark, this being clearly proved to the members of the board during their inspection of the North Gippsland district. A sample of bark from trees growing on a limestone formation was greatly inferior in tannin to that of bark obtained from another section of country, although the climate was in every way calculated to produce better results. From bark growing within five miles of the Buchan River, 42 per cent. of tan material was obtained, while the bark taken from the limestone formation on both sides of the stream only yielded 29 per cent. Continuing the examination still further, the board found that the samples of bark obtained from the Goulburn and western districts were about equal in point of tanning strength, both being a little inferior to the best bark obtained from Gippsland. The bark in each instance subjected to analysis was of the black or "feather" leaf species. The bark of the golden leaf or broad leaf wattle was also tested, and the result proved that its strength exceeded all the other barks by fully 5 per cent.

The size of the trees varied considerably in many districts, soil and position evidently effecting the difference. One of the largest black wattles met with in the western district gave a mean diameter of 24 inches, its age being ascertained to be eighteen years. This may be taken as the maximum size attained by this species ; and, although even larger trees may be occasionally met with, the wattle is at its prime when about ten years old, and possessing a trunk 9 or 10 inches in diameter. After that the trees lose their healthy, vigorous habit, and are usually attacked by disease and wood insects.

The Pharmaceutical Journal.

SATURDAY, APRIL 3, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE DENTAL ACT AND REGISTRATION.

A FEELING of discontent seems still to pervade a section of the dental body, and to indicate a disposition in favour of agitation, which, we think, is scarcely suited to the position of affairs. The *Monthly Review of Dental Surgery*, in dealing with the subject of dental organization, very fairly states that up to the time of the passing of the Dentists Act the practice of dental surgery was carried on without let or hindrance by whomsoever thought fit to undertake it, with or without qualifications, and with or without competent knowledge of the subject. This state of things was permitted by the law, and though some persons sought to acquire the qualification of special knowledge to fit them for carrying on dental surgery as a profession, others practised it only as a trade. Worse than all there was no recognized distinction between the thoroughly qualified dentist and the uneducated pretender, so that the public was unable to judge as to the competence of a dental practitioner.

So long as this state of things prevailed, it was but reasonable that the better class of dental practitioners should have been dissatisfied; but now that an Act has been obtained providing means for distinguishing between the two classes by establishing a register of all persons who can rightfully take or use any of the titles recognized as designating dental practitioners, the case is altered, and there would seem to be good reason "to rest and be thankful" during such time as may be requisite for perfecting the internal organization of the dental body.

Such reason may at least be found in the consideration that a sudden change from the state of affairs depicted by the *Monthly Review* as prevailing before the passing of the Act to one more consistent with desires of thoroughly educated dentists is scarcely possible. As a necessary consequence of the previous condition, there would be numerous interests established by usage which could not be sacrificed and made away with, however little they might be entitled on other grounds to recognition. The state of the Dental Register at the outset could not be expected to be perfect; it would be almost impossible to hope for such agreement as to the "proper claims" to be placed upon the register, as would cover all cases, and from some points of view no doubt there would be many who did obtain registration while destitute of "proper claims" as they might be determined from the higher standard of professional qualification.

The remedy for such defect in the measure designed to effect the organization of the dental profession is to be looked for from lapse of time and from the efforts of those best able to promote the establishment of a satisfactory professional standard. A further reason for the exercise of patience in seeking for the attainment of this desirable end is also to be found in the fact that the requisite educational provisions for the attainment of this end have been made in a manner so satisfactory that in the opinion of Mr. ERICHSEN, the L.D.S. diploma may be considered amply sufficient as a guarantee of the professional position and competence of any man who holds it.

But, as we have already remarked, these views do not appear to be generally entertained, and even now, when the Dental Act has only been in operation for a year, there is a movement for its repeal or amendment on the part of the Association of Surgeons practising Dental Surgery. This body has presented to the Executive Committee of the General Medical Council a memorial pointing out that more than 500C persons have been registered as dentists, whilst the highest estimate formed by those who were interested in the passing of the Dentists Act was that not more than 2000 persons could be registered in Great Britain and Ireland. Reasoning upon this basis, it is urged by the memorialists that the result has not been obtained which it was the object of the Act to secure, namely, the registration of persons "specially qualified to practise as dentists," and it is inferred that the registration is deceptive because no doubt a very large proportion of the persons actually registered do not possess the qualifications indicated as being desirable by the preamble of the Act.

The view here put forward is evidently to be ascribed to the belief that those only were interested in the passing of the Dentists Act who held the most exclusive opinions as to what was necessary for being "specially qualified to practise as dentists." But however much such a belief may recommend itself to respect from a purely abstract point of view it is not acceptable from a practical point of view, for the fact is that there were many others interested in the passing of the Act and they could not be ignored though representing interests possibly of a humbler order than those which mere abstract consideration would lead one to have regard for.

The result which appears to be objected to by the Association of Surgeons practising Dental Surgery is no doubt due to the absence of any interpretation of the terms "dentisty or dental surgery" as stated in the memorial now referred to, but we must also add that it seems equally clear those terms do not at the present time admit of being so strictly interpreted as to enable the General Medical Council to remove from the register the names of persons who may not be felt to be "specially qualified" as dentists according to the estimate of those who take the highest standard of dentists' qualifications. Such a proceeding would at once be possibly productive of injustice to a numerous class of persons who have long been in the habit of extracting teeth and carrying out other dental operations of a minor character that might be held to constitute practising dentistry and to require registration.

If it be now intended that the due interpretation of the terms "engaged in the practice of dentistry or dental surgery," which is earnestly prayed for in the memorial of the association, should be one that would leave the chemist and druggist free to extract teeth and perform the operations of dentistry as heretofore, we contend that the agitation for this amendment of the Dentists Act is not well timed. The desire for this "due interpretation" is expressed either too late or too soon: too late as regards the reasons which led chemists and druggists to seek an amendment of the Dental Bill while it was before the House of Cammons, and too soon as regards that advancement of the practice of dentistry to a higher standard which may be looked for in the future.

Though the Dentists Act has nominally united the dental profession, it has by no means harmonized its discordant elements, and that probably was more than could reasonably have been expected under the circumstances; but we are far from sharing the opinion of those who regard the liberality of its provisions as a defect, though it leaves much to be done by the individual, as well as associated efforts of those who desire more thorough improvement. As is well pointed out by the editor of the *British Journal of Dental Science*, one great point has been attained by the passing of the Act, viz., that no one can henceforth assume the title of dentist without passing a certain amount of medical and technical education, tested by examination and verified by the possession of a diploma.

Meanwhile it may be well that the British Dental Association, taking a lesson from the action of the Pharmaceutical Society in carrying out the duties imposed upon it by the Legislature, should undertake the duty of investigating charges of incorrect registration and the task of bringing them before the Medical Council or some other tribunal, as the case may require. But whatever is done in this direction should be done in a liberal spirit, with a due regard, not only to the necessary internal organization and advancement of the dental body, but also to all the *bonâ fide* interests that were affected by the passing of the Act. By the maintenance of such a spirit in their proceedings we venture to think dental reformers will do more to improve the position of the body and to advance its true interests than by striving to enforce one-sided and selfish views or by taking part in "the civil war" referred to by the President of the Association of Surgeons practising Dentistry as having begun among dentists.

PERSIAN AND NATIVE OPIUM IN CHINA.

According to the report of Mr. Arthur Davenport, Her Majesty's Consul at Shanghae, Persian opium has in that district greatly interfered with the price and consumption of Malwa opium, which it much resembles in consistency, though lower in price. It appears that the greater proportion of the Persian opium imported into China in 1877 was in irregularly shaped pieces and adulterated with sugar, but since then a marked improvement has been observable, both in its manipulation and its freedom from saccharine matter. The Persian drug is said to resemble Malwa opium, not only in consistency, but in flavour when smoked, and accordingly its price has fluctuated in sympathy with that of Malwa. It is not, however, a favourite in the Shanghae local market, its largest consumption occurring in the Chinkiang and Tientsin districts. Upwards of two thousand chests were entered at the custom house during the year previous to the report, and the quantity would probably have been larger had not the drought which caused the failure of the opium crop in India extended to Persia also.

Both in Szechuen and Yunan the Chinese native crops of opium have been abundant, that in Szechuen being estimated as equal to fifty thousand chests of foreign opium and that in Yunan to fifteen thousand chests, the former amount alone equalling the yield of the entire Malwa crop when grown under the most favourable circumstances. But in other districts the laws prohibiting the cultivation of the poppy have been enforced more rigidly, though in one case where the peasants had neglected to obey an order to root up their crops of growing poppies, upon the military attempting to perform the duty they were resisted and compelled to retire.

THE EVENING MEETING.

The next Evening Meeting of the Pharmaceutical Society will be held on Wednesday, the 7th inst. The papers announced are—"The Volumetric Determination of Alkaloids," by Mr. J. C. Thresh; "The Histology of Araroba, or Goa Powder," by Mr. T. Greenish; "Experiments on Taraxacum Root," by Mr. J. B. Barnes; "The Composition of Tonga Root, a Reputed Remedy for Neuralgia," by Mr. A. W. Gerrard; and "The Action of Potassium Chlorate on Ferrous Iodide," and "The Quantitative Estimation of Syrup of Iodide of Iron," by Mr. R. H. Parker. As, however, it is not probable that there will be sufficient time on Wednesday next to read and discuss the whole of these papers, it has been arranged that the meeting at its close shall be adjourned to Wednesday, April 21st.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION

A meeting of this Association will be held on Thursday next, the 8th inst., at 8.30 p.m., when a paper will be read by Mr. C. Thompson on "Robert Boyle." A report on Physical Chemistry will be made by Dr. Senier on "The Solubility of Solids in Gases."

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The eleventh general meeting of the thirty-first session was held at the Royal Institution, on Thursday evening, March 11, the President, Dr. Symes, in the chair.

The minutes of the previous meeting were read and confirmed.

Mr. M. Conroy exhibited some so-called copaiva capsules, which, upon examination, he had found to be filled with olive oil, and did not contain a trace of the balsam. He understood that some quantities of these capsules were in the market at present, and advised pharmacists to examine their stock.

The following paper was then read, entitled—

The Estimation of Copper.

BY ARTHUR G. HADDOCK.

The estimation of copper is an operation which the analyst is frequently called upon to perform, and though apparently a simple one, it often happens that the results obtained by different analysts vary very considerably. As these discrepancies are probably due, not to want of manipulative skill, but in most instances to the employment of different methods of analysis, some of which may be faulty, and as the subject is one of great importance, I have thought that some profit and interest might be derived from a critical examination of some of the methods generally employed.

I will first describe a method, which is a very good one, for the detection of copper in articles of food, or in the stomachs and viscera of animals. Take 1000 grains of the substance, place it in a flat fire-clay dish, such as a scorifier, and heat gently until perfectly dry, then incinerate over a charcoal fire until the organic matter has completely burned away, leaving nothing but a grey or reddish-white ash. Dissolve this in nitric acid, with the aid of a gentle heat, filter from any insoluble residue which may remain, neutralize the clear solution with ammonia, supersaturate it with acetic acid, and filter again if necessary. To the acetic acid solution add a few drops of potassium ferrocyanide, when, if a trace of copper is present, the solution will assume a red colour, and if there is any appreciable amount a precipitate of a mahogany colour will be immediately formed. If this is well stirred, and left for twenty four hours, we obtain a complete separation of the copper as ferrocyanide, which may be thrown upon a weighed filter, washed, dried, and its weight ascertained. It has the composition Cu_2FeCy_6, when dried at 100° C., and contains 37·28 per cent. of its weight of copper. It is a matter of importance that the burning of the organic matter should be done over charcoal and not over a Bunsen's burner, as a sufficient amount of copper to give the reaction with ferrocyanide is invariably volatilized, or carried mechanically from the brass tube of the burner into the sample.

For the estimation of copper in ores and in manufactured products many processes have been suggested, some of which, though very ingenious, are impracticable, and others, though very convenient and expeditious, are not sufficiently accurate to be of very great use.

Lovel has proposed as a method to place the copper solution in a flask which is furnished with a very tight stopper, to supersaturate with ammonia, then place in the solution an accurately weighed slip of pure copper, fill the flask with recently boiled distilled water, and quickly replace the stopper. When the solution is quite colourless the operation is at an end, and the copper is taken out, dried, and again weighed, the loss of weight which it has sustained representing the amount of copper which was originally in the solution. The rationale of the method is that the blue cupric compound takes up another equivalent of copper to form a cuprous compound, which is colourless. If care be taken, it is possible to obtain very fair results as follow:—

Took 10 grs. $CuSO_45H_2O$ containing 2·545 grs. Cu; obtained 2·56 grs. Cu.

Took 10 grs. $CuSO_45H_2O$ containing 2·545 grs. Cu; obtained 2·565 grs. Cu.

It is imperative that the stopper should fit very tightly, and that the water should be boiled to expel all dissolved air. The objections to this process are, the time required, the necessity of removing all foreign substances which might be precipitated by metallic copper, and the extreme delicacy which is required in the manipulation.

Plessy and Moreau have published a modification of the process, which consists in boiling a weighed strip of copper with the cupric solution rendered slightly acid with hydrochloric acid, until the solution is quite colourless, and the loss of weight sustained by the copper indicates, as before, the amount of copper in the solution. I have obtained good results with this process, working with the pure chloride.

Cassaseca dissolved the ore in acids, added ammonia in excess, filtered, and determined the copper colorimetrically by comparing the tint with that given by a copper solution of known strength. This method is only applicable for spent ores, to give a rough approximation as a guide to workmen, and is valueless to analysts.

Pelouze recommended the destruction of the colour of the cupric-ammonium solution by a standard solution of sodium sulphide as a method. The copper is precipitated as sulphide, and from the quantity of sodium sulphide required to completely effect this, the amount of copper present can be calculated. Precipitated zinc sulphide may be used as an indicator of the end reaction. As the presence of other metals, as lead, zinc, bismuth, and antimony, are stated not to interfere, I thought this would prove a good process, and some years back made a number of experiments with it, but I am sorry to say with such indifferent success that I had to abandon it. My failure to obtain correct results I attribute to the difficulty of distinguishing the end of the reaction and to the fact that the blue colour rapidly reappears, owing to the absorption of oxygen by the copper sulphide.

Several methods, such as Mohr's, Fleitmann's, Terreil's and Schwartz's have been proposed, all of which are based either upon the oxidizing action of cupric salts, or the reducing action of cuprous salts. Thus Mohr's method consists in adding metallic iron to the cuprous salt, and estimating the amount of ferrous salt formed by standard solution of potassium permanganate.

Schwartz's method depends on the reduction of a ferric salt by cuprous oxide, and the amount of ferrous salt produced estimated with permanganate solution.

Terreil reduces cupric sulphate with ammonium sulphite, with the addition of a little hydrochloric acid, boils off the sulphurous acid, and oxidizes directly with potassium permanganate.

Fleitmann precipitates the copper in the metallic form with zinc, and after washing it thoroughly dissolved it in an acid solution of ferric chloride, and then titrates with permanganate solution. Care should be taken that no nitric acid is present in the solution.

The objection to all these methods is that the cuprous salts are so very unstable and readily oxidizable that they are not adapted for practical working.

But the process perhaps more generally used than any other is the one which depends upon the destruction of the colour of a cuproammonium salt by means of cyanide of potassium. The ore is dissolved in acids, supersaturated with ammonia, and a standard solution of potassium cyanide added slowly from a burette. The colour of the solution gradually fades, and finally disappears. When this occurs the operation is finished. It is usual to leave a slight blue shade in the solution, and not wholly destroy the colour, as this will disappear after the lapse of a few minutes. This method is a very convenient one in many cases, but unfortunately is open to a number of very serious objections. It is often exceedingly difficult to tell exactly when the colour is completely destroyed, and also the amount of cyanide required to produce a given effect varies according to whether it is added quickly or slowly; if run in quickly, it will take as much sometimes as ·5 c.c. less than if run in slowly, with vigorous stirring. Again, the quantity of ammoniacal salts present exercises a great influence, as also excess of ammonia. It is necessary that there should always be, as nearly as possible, the same amount of acids and ammonia added to obtain an accurate result. The presence of excess of salts makes the copper estimation too high. Also, the presence of other metals, as arsenic, zinc, lead, etc., affect the accuracy of the test, as has been shown by Mr. R. T. Thomson, in the *Chemical News*, vol. xxxiii., page 152. These must therefore be separated, and it is well known in the case of zinc, which is contained in most copper ores, that its sulphide is invariably precipitated, to a greater or less extent, along with copper sulphide, by sulphuretted hydrogen in an acid solution, and the separation of it in small quantities from a large excess of copper is a difficult operation. With regard to the uncertainty of the finishing point of the reaction M. Fleck recommends, instead of ammonia, to use carbonate of ammonium to supersaturate the acid, and to add a drop of potassium ferrocyanide solution. He states that when the operation is exactly finished, the liquid assumes a red colour. Crookes, in 'Select Methods,' mentions this improvement in the process. In the course of my experience, I have never yet been able to obtain this reaction.

The cyanide process as carried out by Steinbeck obtained the prize offered by the directors of the Mansfeld copper mines, as being the most expeditious, the most accurate, and the cheapest process (taking these qualifications combined), which was submitted to them. To avoid the interference of other metals he precipitated the copper in the metallic salt from its acid solution by means of zinc. The well-washed precipitated metal he dissolved in nitric acid, supersaturated with ammonia, and titrated with cyanide in the usual way. He states that lead does interfere with the readings. A great objection to this process is the extreme difficulty of obtaining pure zinc wherewith to precipitate the copper. This metal in the pure state seems to be commercially unknown. I have made many attempts to procure it, but without success. Dr. Steinbeck, in an elaboration of his process, admits that varying amounts of ammonium salts interfere with the accuracy of the test, and especially particularizes ammonium chloride.

Although the Mansfeld committee gave the prize to Dr. Steinbeck, they were so pleased with a process devised by M. Luckow, that they awarded him an extra premium. His method consists in the separation of the copper in the metallic state from its nitric or sulphuric acid solution by the electric current. He dissolves the ore in one or both of the acids mentioned, evaporates to dryness in a beaker and takes up the residue with nitric acid—sp. gr. 1·2 diluted with six times its volume of water—with which he half fills the beaker. A few drops of a strong solution of tartaric acid are also added to prevent peroxidation of any lead which may be present. He then places in the solution a spiral of platinum wire of such size that the convolutions of the spiral touch the sides of the beaker. He also suspends in the solution a strip of platinum foil, sufficiently broad to almost touch the spiral, and long enough to project about an inch out of the liquids. The foil has a wire attached to it which is connected with the zinc end of a Bunsen battery, and the spiral is connected with the copper end. Metallic copper immediately begins to deposit on the surface of the platinum foil, and in the course of a few hours is entirely removed from solution. In order to ascertain when the operation is finished, the solution is diluted with a little weak nitric acid, and if, after the lapse of about ten minutes no more copper is deposited on the clean part of the platinum foil, it may be assumed that a complete separation has been effected. The foil is then removed from the solution, or, as a little of the copper might redissolve in the nitric acid adhering to it when removed from the beaker, it is better to remove the solution from the foil by allowing a stream of water to displace the acid liquor in the beaker, which may run over the sides, and continuing this until the overflowing fluid is no longer acid. The foil is then disconnected from the battery, washed well with cold water, and finally with alcohol, dried at 100° C. and weighed. The copper is now removed with nitric acid, and the foil again weighed, when the difference, will, of course, be the weight of the copper.

This process yields excellent results, if carefully worked, and I think that with slight modifications in detail, it is the best which has been proposed for general work. Indeed, in brass and alloys which contain zinc, it is almost the only method by which an accurate separation and estimation of these two metals can be effected. The modifications to which I refer were given by Mr. E. W. Parnell in a paper which he read before this society about four years ago. That paper, I am sorry to say, was not published. Instead of working with a nitric acid solution, he used dilute sulphuric acid to which a few drops of nitric acid had been added, and instead of precipitating the solution contained in a beaker, upon platinum foil, he placed it, after first removing lead, in a platinum dish connected with the zinc end of a battery, and immersed in it a spiral of platinum wire connected with the other pole. The copper then deposits on the dish in a beautifully bright and coherent condition. I find the addition of the small quantity of nitric acid absolutely necessary, and it is also desirable that a weak current should be used, or the metal is apt to deposit in a pulverulent condition, in which state it is extremely difficult to wash thoroughly. Two small Bunsen elements are quite sufficient. I also find that it is almost impossible to remove the last trace of copper from solution, and when a drop taken out, and placed on a porcelain plate, gives only a slight brown coloration with sulphuretted hydrogen water, I consider it finished and remove the dish. The solution is emptied quickly from the dish after being disconnected from the battery, and the dish washed with cold water until the washings are no longer acid, rinsed finally with alcohol, dried at 100° C., until the weight remains constant and weighed. The weight of the dish alone is subtracted, and the difference is the weight of the copper. The small quantity of copper remaining in the solution is precipitated with sulphuretted hydrogen, filtered off, washed, ignited and weighed as oxide. This is calculated into metallic copper, and added to the weight of the copper in the dish.

If zinc is required to be estimated, the solution is now boiled to expel sulphuretted hydrogen, and sodium carbonate is added in excess; the precipitate filtered off, washed, ignited, and weighed as oxide. This method can, of course, only be adopted if iron is absent.

Although M. Luckow states to the contrary, it is my experience that the presence of arsenic interferes with the accuracy of the determination. It seems to be thrown down with the last portions of the copper, as an alloy with it.

An exceedingly good method for the separation of arsenic from copper is given by Abel and Field in the *Journal of the Chemical Society*, January, 1862. The alloy or metal is dissolved in acids, the solution filtered, and supersaturated with ammonia. Sulphuretted hydrogen is now passed in to complete saturation, when the copper is perfectly separated, leaving the arsenic in solution. The sulphide of copper is filtered off, well washed, and may then be dissolved in nitric acid, evaporated with sulphuric acid to separate lead, and the copper deposited by the electric current. The solution containing the arsenic is acidified, and the sulphide of arsenic which precipitates is filtered off, washed, dissolved in nitric acid, the solution supersaturated with ammonia, and magnesium mixture added. It is allowed to stand for twenty-four hours, then filtered on to a weighed filter, dried at 100° C., and weighed as $MgNH_4AsO_4.\frac{1}{2}H_2O$.

The precipitation of copper by sodium or potassium hydrate gives very good results if careful attention is paid to details. The solution should be moderately concentrated, and the sodium hydrate added when boiling hot, care being taken to avoid too great an excess. It may be done either in a beaker or a smooth porcelain dish. Stirring should be avoided, as the precipitate is liable to become so firmly attached to slight scratches on the vessel that it cannot be removed by mechanical means. After boiling for a few minutes the oxide is allowed to settle, and the supernatant fluid carefully decanted on to a filter; more hot water is then added, and the precipitate washed by decantation several times before being thrown upon the filter, as this will greatly facilitate the subsequent washing. When quite free from alkali, the filter and its contents are dried, and the oxide removed as perfectly as possible from the paper, and placed in a crucible. The filter paper is strongly ignited on a crucible lid, and when cold, a drop of nitric acid is added, and it is again ignited. The resulting oxide is then added to the main bulk in the crucible, and the whole strongly ignited, cooled under a desiccator, and weighed as oxide. This process in my hands has yielded excellent results, and in ores and substances where the amount of copper is small it is more convenient than the battery process, and I generally employ it.

The precipitation of copper as sulphide, and subsequent ignition, and weighing as oxide, is open to the objection that some sulphate may be formed, and thus make the result too high. Mr. Forbes recommends the addition of carbonate of ammonium after ignition, and states that on re-ignition the sulphuric acid is abstracted, by, I suppose, a double decomposition, leaving the oxide. This is so, no doubt, to a certain extent, but after taking all precautions, I have several times found that some sulphate has escaped decomposition.

Copper may be precipitated from solution as sulphide by means of sodium thiosulphate, and the precipitate may be dried and ignited with an equal weight of sulphur, and weighed as sub-sulphide, Cu_2S. This process gives very good results, but is rather inconvenient. In igniting the mixture of sulphide and sulphur great care must be taken to prevent its boiling over the sides of the crucible, by using at first a low heat which is afterwards increased. The ignition is better conducted in an atmosphere of hydrogen.

I will conclude by giving the processes which I find to be the most accurate and convenient for general estimation of copper.

The battery process is the most accurate, and is the one which must be employed if the solution contains zinc, and the percentage of that metal is also required.

In the case of ores containing small quantities of copper, the battery process may be conveniently substituted by precipitation with sodium hydrate, in a solution from which other metals have been removed, and weighing finally as oxide.

In testing slags it is necessary to powder them very finely, and to fuse with sodium carbonate and potassium nitrate, to get them in solution, as they often contain silicate of copper, which cannot be removed by treatment with acids.

The paper was ably discussed by the President, Messrs. T. F. Abraham, Kehlstadt, Watt and Williams.

Mr. Haddock replied to the questions raised in the discussion, and a hearty vote of thanks having been passed to the author, the meeting closed.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The sixth meeting of the present session was held on Wednesday, March 17, in the rooms of the North British Branch, Mr. D. Maclaren, President, in the chair.

A letter was read from Mr. Fisher, Secretary, resigning office, he having left the city. It was resolved to record in the minutes the great regret the Association felt in losing Mr. Fisher, and their high appreciation of his valuable services as Secretary during the present session. A paper was then read by Mr. C. P. Henry, entitled "Our Examinations."

The author first stated how the examinations originated, and after referring to the incorporation of the Pharmaceutical Society in 1842, and the establishment of the North British Branch in 1851, he gave a short account of the lamentable condition of the drug business at that time. Contrasting the position of the chemists and druggists of those times with the present, he thought the examinations should get the credit of being the main cause of the improvement. He next referred to the process of development which the examinations had undergone since their institution, and regretted that there was no check on the Council, or opportunity for appeal on the part of those most interested, in regard to the additions which were every now and again being made. He thought the time had now come when it should be made compulsory that the Preliminary examination should be passed before the business could be entered, and that while the Minor might remain as at present, the Major might well be abolished as "a useless burden, conferring a mere ornamental title, and serving no useful end." Referring to the examinations themselves, he thought they should be made more practical, candidates having at present to acquire a vast amount of non-essential knowledge. He regretted that the syllabus for the Minor examination was so indefinite, and suggested that it would be a great help to perplexed candidates if they had a more extended syllabus, which would let them know more definitely what knowledge to acquire. He also thought that such vague expressions as "etc." which occurred so often in the present syllabus should be abolished, and suggested that text-books might be named for the different subjects. He observed that more justice was done to the Major candidates, and still more to the Modified, the names of plants and substances requiring recognition being given without any "etc." being added. He thought that in common fairness this should be done with all the examinations. Seeing that nervousness was a great hindrance to many candidates in passing the examinations, he advocated written, as far as practicable, in preference to oral examinations, as a remedy. Other advantages of the former system would be a more equal and fair examination, and fewer examiners would be necessary, with the effect of lessening the cost and reducing the fees. He thought the clause as to age of candidates should be abolished as unnecessary and unjust. He condemned the present regulations as to passing all the subjects at one time, as it had the effect of producing "cramming," which defeated the object of the examinations, and advocated shorter hours of business to enable candidates to prepare for the examinations in such a way as that the knowledge acquired should be permanently retained.

Discussion of the paper followed, in which Messrs. Maclaren, Hutton, Robertson, Aitken and Hill took part, and in which general concurrence with the views of Mr. Henry was expressed, some gentlemen differing from him as to the age of candidates, the passing of subjects seriatim, and the abolition of the "Major," and an additional suggestion being made that the time had come when the Modified examination should be abolished.

A hearty vote of thanks was awarded to Mr. Henry for his paper, and Mr. Hill having agreed to act as interim secretary, the meeting was brought to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

The anniversary meeting of this Society was held at the Society's rooms, Burlington House, on Tuesday, March 30, Mr. Warren De La Rue, President, in the chair.

The President, in his annual address, contrasted the condition of the Society during the past year with its position in 1869, when also he was President. The number of Fellows has increased from 522 to 1034, the income from £1122 to £2720, the number of papers read from 31 to 75. The Journal has also increased both in value and importance, especially in the addition of the abstracts which form such a complete compendium of the progress of chemistry. As regards the library, £500 had been spent in purchasing new books, and a card catalogue is being prepared to increase the facility for finding books. The President then referred to the rapid progress of chemistry which he had specially noticed on returning to the chair. Much of the aspect of chemical thought has changed. The elements once looked upon as most stable are now considered to be at any moment liable to be dissociated. Some months back, spectroscopic evidence was brought forward, which tended to show that the so-called elements were in reality compound bodies, and now V. Meyer has succeeded in dissociating chlorine, bromine and iodine. As regards the spectrum itself, specific functions and properties can no longer be attributed to various parts of it; for Captain Abney has shown that every part acts actinically, and holds out a prospect of producing permanent photographs of the spectrum in its natural colours. The artificial production of the diamond has also been said to have been effected, but Mr. Hannay's communication on this subject is so vague that it is impossible to pronounce any opinion upon it. The joint observations of Hannay and Hogarth on the solubility of solids in gases promise results of great interest. Remarkable observations have been made by Cailletet, Ansdell, etc., on the behaviour of various substances, mixtures, etc., under great pressure. The researches of Gladstone, Landolt and others on the refractive indices of carbon compounds have been greatly extended by Brühl. The President then alluded briefly to the great diligence of organic chemists in the investigation of carbon compounds, and especially to the elucidation of the constitution of alkaloids and the carbohydrates; the synthesis of isatin and Baezer's researches in the indigo group must, it would seem, result, ere long, in the discovery of a method for the artificial manufacture of indigo. Ladenburg has prepared atropine from tropine and tropic acid, and thus probably the first steps have been taken towards the synthesis of an alkaloid. Much light has been thrown on the constitution of the bases of the pyridine and picoline series, of the nicotine and cinchona alkaloids, and of starch. Recent facts seem to show that our present symbolic system is inadequate to represent the constitution of carbon compounds. A new element, scandium, has been separated, corresponding to Mendelejeff's ekaboron, thus verifying his sagacity and the importance of the periodic law. The President then referred to the objects and position of the Research Fund, and expressed a hope that all whose fortune allowed would contribute largely to this fund and thus promote the advancement of a science which may have contributed greatly to their own prosperity. He thanked the Drapers' and the Goldsmiths' companies for their donations to the fund. During the past year death has removed fourteen Fellows.

At the conclusion of the address, Mr. F. A. Abel proposed a vote of thanks to the President for his interesting address, and for the zeal with which he had performed the duties of President during the past year. It had been a special pleasure to see Mr. De La Rue again in the chair. Some of the older members would recall with gratitude the great exertions which had been made by Mr. De La Rue on behalf of the Society at a critical period of its history, when he was appointed Treasurer; and the present prosperous condition of the Society was in a great measure due to his efforts at that time. He hoped that the example set for a second time by the President would prove an incentive to others to subscribe liberally to the Research Fund.

Dr. Gladstone, in seconding the vote of thanks, said that he had listened with great interest to the successful *résumé* of chemical progress given by the President. The experiment of re-electing a former President for twelve months had proved a great success, and he hoped it would form a precedent. The small attendance was an indication, not only of the holiday season, but also of the peaceful prosperity which now reigned in the Society.

The President, in reply to the vote of thanks, said that as an original member he had taken great interest in the Society and had been very glad to take up the management of the finances; the prosperous career of the Society was, however, due more to its own innate life than to any efforts of his. He had returned to the chair with some sense of his own inefficiency, owing to the enormous changes which had recently taken place in chemistry. He thanked the Council, officers and the fellows of the Society for the kind way in which they had supported him during his year of office.

The Secretary read the third report of the Research Fund Committee. Grants to the amount of £495 have been made during the year. The assets consist of £4000 stock and a balance at the bankers of £152. A detailed list of the grants is given. A donation of £105 from the Drapers' Company and £100 from the President form important items in the income. The Committee point out the desirability of obtaining further additions to the fund, as without such contributions the income from investments would have been quite inadequate. Results of investigations have been published by Dr. Tilden, Professor Thorp, Dr. Wright, Mr. F. D. Brown, Dr. Armstrong, Dr. Bedson, Messrs. Hartley and Huntington. Dr. Japp has forwarded a paper which will be read at the next meeting. Preliminary reports have been received from Dr. Dupré and Messrs. Bolas, Burghardt, Jago, Shenstone and Williams.

The Secretary then read the Treasurer's report. The expenses on account of the Journal amount to £1870; on account of the library, £601; house expenses, £191; various other items, including £720 for purchase of stock and a balance of £929 at the bank, make up a total of £4684. On the other side are, balance at the bank in March last, £1964; subscriptions, etc., £2151; sale of Journal, £295; dividends, £217. The assets consist of £6988 stock; balance at the bank, £927; cash in hand, £2.

Votes of thanks were then passed to the Treasurer, the Auditors, the Officers and Council and the Editor, Sub-Editor and Abstractors of the Journal. A ballot was then held for the election of Officers and Council. Messrs. Grosjean and Kingzett being appointed Scrutators. The following were elected:—President, H. E. Roscoe; Vice-Presidents, F. A. Abel, C.B., B. C. Brodie, Warren De La Rue, E. Frankland, J. H. Gladstone, A. W. Hofmann, W. Odling, Lyon Playfair, A. W. Williamson, J. Dewar, J. H. Gilbert, N. S. Maskelyne, V. Harcourt, R. Angus Smith, J. Young; Secretaries, W. H. Perkin, H. E. Armstrong; Foreign Secretary, Hugo Müller; Treasurer, W. J. Russell. Other members of the Council M. Carteighe, C. Graham, C. W. Heaton, H. McLeod, E. J. Mills, J. M. Thomson, W. C. Roberts, W. A. Tilden, W. Thorp, T. E. Thorpe, J. L. Thudichum, R. Warington.

A special meeting was then held, at which the by-law relating to the number of members required to be present for the election of Fellows was altered; the number 32 being substituted (by-laws page 12, line 4) for 40.

SOCIETY OF ARTS.

The Chemistry of Bread-Making.*

BY PROFESSOR GRAHAM, D.SC.

Lecture I.

Some six years ago I had the honour of addressing an audience in this room upon a subject closely allied to that which will engage our attention on this and each succeeding Monday evening before the great festival of the Christian year. I refer to the course delivered by me on

* Cantor Lectures: Delivered November and December, 1879. Reprinted from the *Journal of the Society of Arts.*

the "Chemistry of Brewing." The Council of the Society of Arts has again honoured me by a request to give a Cantor course on some application of science to the arts, and in selecting the chemistry of bread-making I have been guided by a consideration of the vital necessity of food to the existence of man. As cereals are, of all the fruits of nature, the most important to man for their invaluable store of flesh-forming and heat-giving principles, the right method of preparing these for his use is one well worthy of the most attentive study. Although the cultivation of the cereals is beyond our present province, which is limited to the study of the phenomena of bread-making, I shall incidentally have to refer to the effect of climate—and more especially to the influence of the weather at the ripening and harvesting periods—on the character of the wheat garnered; and I shall show that unfavourable climatic conditions not only seriously affect the quantity, but also the quality of the grain.

It may be thought by some that there is little need for a scientific study of bread-making, since man has already attained a considerable degree of excellence in its manufacture. This is true, but much remains to be done ere all inferior productions shall have given way to the loaf of unsurpassable excellence, and it is chiefly to science that we must look for a rapid development. It is true that in London we can, if we search for it, obtain bread of excellent quality, yet we all know there is much that is inferior throughout the country; nor can our average of wheaten bread equal the average wheaten bread of France and Germany. This is, doubtless, partly due to the more favourable climatic conditions of those countries, but inasmuch as we import the best qualities of wheat from some of the most favoured countries of the Old and New Worlds, the inferiority of our average bread cannot arise chiefly from our less favourable harvesting conditions, but rather from the less skill and knowledge possessed by many of our millers and bakers.

A fuller knowledge of the chemical phenomena of bread-making must not only be of great value to the baker, but also to the consumer of bread. In this respect we are all interested in the phenomena of fermentation, and later in this course I propose to direct your attention to the digestion of bread, which is a process of fermentation, and to the conditions requisite for its due fulfilment.

The historic aspect of our subject is lost in obscurity. Probably, soon after man learned to till the earth, and reaped a rich cereal harvest from his toil, the grinding of corn, and its admixture with water and salt, and then its heating, would be resorted to. Thus unleavened bread is made, and the earliest attempt to prepare ground cereals for man's use has not ceased to be practised. The oatcake of Scotland, and her peas and barley bannocks, the Passover bread of the Jews, the damper of the Australian shepherd, the American corn bread, are existing examples of that method of bread-making. In many parts of Spain wheat flour is simply mixed with water and baked, not even salt being added. There, not only the most primitive of all methods of bread-making is still pursued, but even the separation of the grain from the straw is carried out, as in Biblical times, by the treading out of the corn in the fields by oxen; and although the bread is deficient in salt, it is rich enough in fine, gritty sand.

The next step, and the most important one in the history of bread-making, whereby leaven was employed to lighten the product, is also of considerable antiquity. It is probable the Chinese may have been the first to make leavened bread. Be this as it may, we know that the Egyptians, in the time of Moses, understood the art, and from them the Greeks acquired the secret, and through the Greeks the Romans spread the knowledge wherever their all-conquering and colonizing armies went. Leaven, although a great improvement on unfermented bread, acts slowly, and gives rise to so much of high-coloured products that it has, to a great extent, been replaced by yeast. The introduction of this important factor in bread-making probably took place soon after the art of making beer had obtained some degree of success, because the evolution of gas in the leavening process must have suggested the trial of yeast, which also evolves gas in the conversion of saccharine matter into beer. I have, however, been unable to find any authentic statement of its introduction in place of leaven. The preparation of leaven is still practised, and thus we have the unleavened, the leavened and the yeast-fermented breads of the present day. But it is chiefly yeast-fermented breads which will occupy out attention throughout the course, although, incidentally, the spontaneous ferments of the leaven process will be considered.

Before we proceed to study the phenomena of bread-making, it will be needful to consider the constituents of the chief cereals, and to compare them, not only amongst themselves, but also with the more important articles of food employed by man. In the following table you will find a statement of the component parts of these cereals, wheat, barley, oats, rye, maize and rice:—

Average Composition of the Grain of Cereals.

	Old Wheat.	Barley.	Oats.	Rye.	Maize.	Rice.
Water	11·1	12·	14·2	14·3	11·5	10·8
Starch	62·3	52·7	56·1	54·9	54·8	78·8
Fat	1·2	2·6	4·6	2·0	4·7	0·1
Cellulose	8·3	11·5	1·0	6·4	14·9	0·2
Gum and Sugar	3·8	4·2	5·7	11·3	2·9	1·6
Albuminoids	10·9	13·2	16·0	8·8	8·9	7·2
Ash	1·6	2·8	2·2	1·8	1·6	0·9
Loss, etc.	0·8	1·0	0·2	0·5	0·7	0·4
	100·00	100·00	100·00	100·00	100·00	100·00

Bearing some of these numbers in mind, if we take the following table, prepared by Messrs. Lawes and Gilbert, with reference to the articles of food most used by man, we find that the ratio of carbon to nitrogen, in the case of flour, is 38 to 1·7, in meat as 30 to 2, in potatoes as 11 to ·3. We therefore notice that in the case of these cereals we have a considerable quantity of flesh-forming albuminoid matters, more especially in the case of wheat. I shall have again to refer to the subject of diet at a later period of the course.

Average Composition of Articles of Food. (Lawes and Gilbert.)

Foods.	Dry Substance.	Carbon.	Nitrogen.	Nitrogen to 100 Carbon.
Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Meat (fresh)	45·0	30·0	2·0	6·6
Bacon (dried)	85·0	61·0	1·4	2·3
Butter	85·0	68·0	0·0	...
Milk	10·0	5·4	0·5	9·3
Cheese	60·0	36·0	4·5	12·5
Flour (wheaten)	85·0	38·0	1·72	4·5
Bread	64·0	28·5	1·29	4·5
Maize	87·0	40·0	1·75	4·4
Oatmeal	85·0	40·0	2·0	5·0
Rice	87·0	39·0	1·0	2·56
Potatoes	25·0	11·0	0·35	3·3
Vegetables (succulent)	15·0	6·0	0·2	3·3
Peas	85·0	39·0	3·65	9·4
Sugar	95·0	40·0	0·0	...

We may conveniently divide the constituents of the cereals into three great classes. In the first place, those constituents which, by being burnt up in the system, produce heat. They are the materials that we call carbohydrates: the starch, the gums and the sugars; it is from the oxidation of these carbohydrates, and also from the fat in our food, that the greater portion of the force that man exerts is derived. The next great division it will be convenient to take is the albuminoids, or flesh-forming elements of the cereals; and lastly, the ash, which, although not great in quantity, is still most important in its bearing on the physiological phenomena which go on in the cells of animal life, and also because it is from the mineral matter of the ash that the bone structure of man is built up. Now, the mineral matter of the ash of wheat has been the subject of very lengthened investigations by numerous chemists. The series which, perhaps, on the whole, are most complete and trustworthy, are those made by Messrs. Lawes and Gilbert and those by Messrs. Way and Ogston.

Composition of Wheat Grain Ash.

	Lawes and Gilbert.	Way and Ogston.
Phosphoric acid	49·68	45·01
Phosphate of iron	2·36	0·82
Potash	29·35	31·44
Soda	1·12	2·71
Magnesia	10·70	12·36
Lime	3·40	3·52
Sulphuric acid	...	0·34
Carbonic acid	...	0·02
Chlorine	0·13	0·13
Silica, etc.	2·47	3·67
	99·21	100·03

We find from the former chemists' statements that the ash of wheat contains, in 100 parts, 49 of phosphoric acid; Way and Ogston say 45, so that nearly one-half consists of phosphoric acid. There is also a small quantity of phosphate of iron, but the next important constituent concerned is potash. That amounts to about 30 per cent. Lawes and Gilbert state, as the average of nine analyses, that they have found it to be 29·35; whereas the average of twenty-six analyses of various samples of wheat, by Way and Ogston, gives 31·44 of potash Thus phosphoric acid amounts to nearly one-half, and potash one-third of the whole of the ash. The next important constituent is magnesia, amounting, according to Lawes and Gilbert, to 10·7, and to Way and Ogston, to 12·3. Lime, soda, and a small quantity of silica make up the remainder of the 100 parts. Phosphoric acid, a small quantity of iron, potash and magnesia, are the characteristic constituents of the ash of wheat.

I will now proceed to examine somewhat fully the chief chemical and physical properties of the organic constituents of cereals, beginning with starch. I have here a table that indicates in our chemical language the composition of what we term the carbohydrates.

Formulæ of Carbohydrates.

$$\left.\begin{array}{l}\text{Starch}\\\text{and}\\\text{Dextrin}\end{array}\right\} = (C_{12}H_{20}O_{10})_n$$

$$\left.\begin{array}{l}\text{Cane Sugar}\\\text{and}\\\text{Maltose}\end{array}\right\} = (C_{12}H_{22}O_{11})_n$$

$$\left.\begin{array}{l}\text{Dextrose}\\\text{Lævulose}\end{array}\right\} = (C_{12}H_{24}O_{12})_n$$

We use that expression in order to indicate that hydrogen and oxygen are found in the carbohydrates, in precisely the same ratio as they occur in water. These two elements, hydrogen and oxygen, do not exist in starch or sugar as water, but they exist in the same proportion as they do in water, and that expression has been applied to all these bodies. In the case of starch and dextrin you will notice the formula given here ($C_{12}H_{20}O_{10}$) has a small "n" added outside of it. The simplest formula which would represent our knowledge of the centesimal ratio of the carbon, hydrogen and oxygen would be $C_6H_{10}O_5$, but we shall hereafter see so small a formula is insufficient to explain a number of reactions we know of in reference to starch. The formula of starch must, therefore, be written $(C_6H_{10}O_5)_n$. I have thought the formula $(C_{12}H_{20}O_{10})_n$—in which even the value of n is probably high—would best express to those not well conversant with chemical science the correlation of the various carbohydrates in the table.

The next subdivision of this important class of bodies embraces cane sugar and maltose; indeed, I might also have included sugar of milk.

They are isomeric, that is to say, that they have precisely the same ratio of carbon, hydrogen and oxygen in their molecular composition, but they differ from the previous sub-groups in having one of oxygen and two of hydrogen more in the formula given. The last subdivision of this group embraces the glucoses, the simplest formula expressing their molecular composition being $C_{12}H_{24}O_{12}$. Here also, we notice an increase of two of hydrogen and one of oxygen over the cane sugar group, which differs from the starch group in the same manner.

It is to the first on our list of the carbohydrates that I have now to direct your attention. Starch is found in various vegetable structures, and for much the same purpose as fat is stored up in animals, for the future use of the organism.

It is thus found in pith. The sago of commerce is obtained by cutting down the sago plant and rasping the pith, and from that extracting the starch. It also occurs in bulbs, in tubers, such as the potato, in rhizomes, and in roots; and it also occurs in seeds, either in what is called by the botanist the albumen of the seed, although it is not albumen from a chemical point of view, but it is called so because it is convenient to consider the stored-up starch in ordinary grain by that name. If you take the caryopsis of wheat, the small embryo will be found at the bottom, surrounded by a large mass of starchy matter. It contains, not merely starch, but also albuminoid bodies, and this, in botany, is called the albumen of the seed, for the reason that in the case of an ordinary hen's egg, the white of the egg surrounding the embryo is called albumen, and in both cases the albumen serves for the future growth of the young embryo. Starch is also found very largely in the fleshy cotyledons of some seeds, as, for instance, the ordinary bean, horse-chestnut, or pea, where practically the whole mass is made up of the two thick fleshy leaves that constitute the two halves of the whole seed, the young embryo being at the bottom. We see, therefore, that in all structures that are intended for the future growth of the plant, or, as in the case of seeds, for the reproduction of the new plant, that we have stored-up starch.

(*To be continued.*)

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above, on Wednesday, March 17, Mr. F. W. Branson in the chair, a paper was read by Mr. Stewart Hardwick, on "Assimilation in Plants." The author first proceeded to notice the movement of water in the tissues, and explained the manner in which the ash constituents were taken up by the roots. The laws governing transpiration were next alluded to, and evaporation shown to take place from the external surface of the cell walls, which in their turn removed water by imbibition from the cell sap. The elements necessary for plant life were enumerated, and the processes of assimilation and metastasis reviewed. In conclusion, the author described the movements of food material in the tissues, and proved there could be no such thing as a continuous uniform motion of the so-called nutritive cell-sap.

After an interesting discussion, a vote of thanks having been proposed by Mr. Naylor, seconded by Mr. Wallis and carried, the meeting terminated.

Review.

THE RISE AND DEVELOPMENT OF ORGANIC CHEMISTRY. By C. SCHLORLEMMER, F.R.S., Professor of Organic Chemistry in the Owens College, Manchester. Manchester: J. E. Cornish. London: Simpkin, Marshall and Co. 1879.

"This little work" is a *résumé* of past achievements in a science of which its author is an acknowledged master. It consists of twelve chapters.

The opening chapter contains an account of the organic processes and compounds known in ancient times; such as acetic acid and some acetates, the use of paper steeped in infusion of galls as a test for green vitriol, the distillation of turpentine, soap making, and the fermentation of grape juice. The origin of the word chemistry is then discussed and the rise of alchemy and iatro-chemistry traced until Boyle rescued chemistry from being simply the tool of the alchemist and physician and placed it as a separate and independent science. The theory of phlogiston, the discoveries of Scheele, and the work of that circle of chemists which we associate with the name of Lavoisier are briefly explained.

Thus at the commencement of the present century chemistry had reached a stage when it became evident more and more that a distinction should be made between the chemical processes involved only in vegetable and animal life and those which take place in the mineral kingdom. This led to the theory of vital force, and thus Berzelius, in 1827, says "that the elements present in living bodies obey laws totally different from those which rule inanimate nature." The brilliant series of discoveries commencing with the synthesis of urea by Wöhler, in 1828, which have completely overthrown the vital force theory, are then fully considered. Although, however, the great distinction between inorganic and organic chemistry was thus broken down, still it has always been found convenient to treat nearly all carbon compounds as a separate branch of chemical science; moreover, it is shown in a later chapter that carbon possesses properties peculiar to itself which amply justify this separation.

The announcement by Wöhler and Liebig in 1837, that in a number of reactions, in the case of benzoic acid, oil of almonds and allied bodies, there always remained intact a certain group of atoms which they termed a "compound element" or radical, is discussed and its important bearings pointed out. This compound element they named benzoyl. The discovery of radicals, afterwards called residues by Laurent, was then only a matter of time, and Liebig at a later date even proposed that organic chemistry be defined as "the chemistry of compound radicals." The quotation from Liebig on pp. 20 and 21 respecting the characters essential for recognition as a compound radical is very valuable and, as Professor Schlorlemmer points out, it holds good at the present day.

The "empirical law of substitution" of Dumas, and the modifications urged by Laurent and afterwards adopted by Dumas, are then explained. We presume that when the author, in view of Laurent's discoveries, says on p. 23 "thus Dumas's third law did not hold good," he means that the whole of Dumas's law requires modification, because the third part is but a qualification of the first and second parts. It was held by the French chemists that in cases of substitution the place occupied by the element substituted was a more important matter than the particular element employed in deciding the characters of the resulting compound. This gave rise to the "theory of types" of Dumas, which was attacked by Berzelius and afterwards by Liebig. The march of discovery, however, soon convinced the latter of the correctness of the views of the French chemists, and these views were much advanced by the researches of Bunsen, Kolbe and Frankland, Hofmann and others.

The next great step was the idea of the introduction of radicals into the types, after which the compound ammonias were discovered by Wurtz and Hofmann, types were extended by Williamson, Gerhardt and Kekulé, and the theory of valency began to be perceived.

In chapter v., the author points out the properties of carbon which distinguish it from all other elements, and leads up to his definition of organic chemistry as "the chemistry of the hydrocarbons and their derivatives." Organic analysis is dealt with in chapter vi., also the calculations of empirical formulæ, the determination of molecular weights, etc. There are many hints in this chapter of considerable value, and which are, at least, not easily accessible elsewhere.

The "law of the linking of atoms," or more correctly, we should think, the theory of the linking of atoms, developed by Kekulé and independently by Couper, is then explained, so far as it relates to the paraffins. The methods employed for determining the constitution of compounds is illustrated by the "history of lactic acid," and the present views respecting isomerism are discussed.

In chapter ix., an account is given of the views of Kekulé, Körner and Ladenburg, respecting the probable arrangement of the carbon atoms in the benzene molecule. These are illustrated by drawings of glyptic formulæ. The reply of Kekulé to some objections urged against his theory is illustrated, when it is shown that the objections apply rather to a fault in the usual method of expressing his idea graphically, than to a fault in the idea itself. He shows, taking into consideration the probable motion of atoms, that the double carbon attractions, as they are usually illustrated graphically by double lines, while they express the state of things during a first moment of time do not express the condition during a second moment. During the second moment they change places with the single carbon attractions, while during the third moment the original state is again resumed, and so on.

Chapters x. to xii. are devoted to very interesting explanations of organic synthesis. Amongst the bodies included are:—paraffins, fats, vegetable acids, benzene, benzoic acid, salicylic acid, vanillin, alizarin and indigo.

It may be worth while to point out a few of the little errors which we have observed:—"Berzrlius" p. 25, for "Berzelius"; p. 41, "hydroyl" for "hydroxyl"; p. 42, "C_2H_4O" for "C_2H_6O," and "Gerhalt" for "Gerhardt"; p. 44, the words "like the" in the third line from the top are superfluous; p. 61, "formulæ of fatty acids" for "formula of fatty acids," and again, lower down, "general formulæ" for "general formula;" p. 64, "hudrogen" for "hydrogen"; p. 72, "oxyproponic acid" for "oxypropionic acid"; p. 73, "H_2O" in equation for "$2H_2O$"; p. 86, "normal iodine" and "butyl iodine" for "normal iodide" and "butyl iodide;" p. 90, reference note "Ber. dent. cheas. Ges." for "Ber. deut. chem. Ges.," and "Journ. Cheas. Soc." for "Journ. Chem. Soc.; p. 120, "isation" for "isatin;" and p. 112, "quininone" for "quinone."

We have derived considerable pleasure from the perusal of this book and believe that, as its quality requires no praise, its usefulness will be equally well appreciated by chemists. It will be found of greatest value to those who take an interest in theoretical chemistry and to those who desire to study the various methods of reasoning which have directed, supplemented, and even anticipated experiment, and have thus so powerfully contributed to the science of organic chemistry as we know it to-day. To those engaged in organic research, especially in the case of beginners, it will be found most useful, and finally to those whose interest is entirely of a technical nature, it will be of value as containing the latest methods of synthesis of substances having pharmaceutical and industrial utility.

THE SALE OF DRUGS BY UNREGISTERED PERSONS.

Sir,—Such a crisis has arrived that it behoves the chemists and druggists throughout the land to be up and doing, or else their legitimate business will no longer yield th em a livelihood, and it is a question whether it would not be for their best interests to allow the recent decision in the case of the Pharmaceutical Society *v.* the Provincial Supply Association to rest without an appeal to the House of Lords, and at once to commence an agitation for an amendment and extension of the Pharmacy Act, so as to make it compulsory for any shopkeeper who sells drugs to keep a qualified person for the purpose, and that his shop should be registered for the sale of drugs, not poisonous, within the meaning of the present Act, the permit to be obtainable from the Pharmaceutical Society.

Such establishments would be entirely distinct from those of the registered and pharmaceutical chemists, inasmuch as they would not be allowed to compound medicine, but merely to sell drugs not poisonous.

Moreover, the sale of patent medicines should be restricted to the establishments of registered chemists and druggists, pharmaceutical chemists, and establishments registered for the sale of drugs.

In my opinion, the public require no less protection than that the sale of drugs should only be entrusted into the hands of men qualified by their education to judge of their quality and understand their doses and modes of administration.

I feel sure that the great body of registered chemists would join heart and hand with their pharmaceutical brethren, and, with the Council of the Society at their head, a Bill might be framed which would not infringe upon the principles of free trade and yet give to the chemist a better reward than he now has for performing his responsible duties, and at the same time satisfy the public that their safety is more cared for under the new regulations than it ever has been before.

6, *Belgrave Terrace,* FRANK TEBBUTT.
North Croydon.

PHYSICIANS AND THEIR MANUALS OF DOMESTIC MEDICINES.

Sir,—Your correspondent, Mr. Austin, has done good service in directing attention to the character of the information imparted to the public by so-called "Manuals of Domestic Medicine."

As an illustration of the conscientious motives which inspire the compilers of these works, it may be of interest to your readers to state that I not long since received a letter from an M.D., L.R.C.P., and Fellow of several learned societies, besides author of numerous medical treatises, informing me of his intention to publish a book on the treatment of certain complaints. "His attention had been called to certain pharmaceutical preparations bearing my name," and he was prepared "to give an extended notice of them" in his forthcoming work—for which, by the bye, he predicted a vast circulation—if I would, in return, confer upon him a trifling *solatium* in the shape of a ten pound note.

The preparations referred to were as much adapted for the diseases his book was to describe as for making door mats; but that of course was a trifle of no consequence.

His generous proposal, I need scarcely say, is still "awaiting my reply."

Surely those who have any influence in maintaining the decencies of medical literature will not suffer these "Domestic Manuals" to run riot with the good name of the profession. The practice of advertising somebody's wares, under the guise of genuine information, has so long been regarded as the distinguishing feature of the "religious" journals, whose special mission it seems to be to combine piety and puffing, that it will ill become the dignity of medical authorship if it seeks to appropriate it.

73, *Highbury Hill, N.* F. W. FLETCHER.

THE SALE OF PATENT MEDICINES.

Sir,—Upon reading the letter of "Ferrum" in a recent week's issue, one cannot help but endorse his references with regard to the "patent medicine farce" now being pushed with such vigour and enticing rewards. It is a deplorable fact that many who call themselves "chemists and druggists," either through incompetence or "wilful neglect" recommend some of the "thousand and one" dubious remedies, costing them from 6*s.* to 9*s.*, etc., per dozen, about whose composition they know nothing, whilst they (with a little knowledge and forethought), might put forward something of their own preparing with greater confidence, and probably with far better results.

There are obvious reasons why this should be done, viz., if a person asks you to recommend something, say in the way of "liver pills," if you recommend Cockle's or King's, your customers find that they can procure these, not only at a rival chemist's, but also at the "co-op." or your bookseller's, whereas, if they have found benefit from your own compounds, they must needs re-apply to you for them, thereby ensuring their regular patronage. If this were done we should soon relieve our cases and shelves of a large amount of "riff-raff," increase our takings and raise our profession in the estimation of the general public.

J. ROBERTS THOMPSON.

DR. CLARK'S PAPER ON DIALYSED IRON.

Sir,—In my remarks on Dr. Clark's paper on Dialysed Iron, in Journal, p. 784, I am made to say that "Dr. Clark was not quite satisfied with the absolute *accuracy* of his results." As this word is fitted to imply *inaccuracy* in work on his part, will you allow me to say that I had not such an idea when I spoke. My only allusion being to a remark which Dr. Clark had made as to the *inconclusiveness* of the results on the question before us.

ALEX. NAPIER.

Socius.—*Helleborus fœtidus.*

G. D. Druce.—(1) *Leskea sericea*, of Wils. Bry. Brit. (2) *Dicranum majus.* (3) *Funaria hygrometrica.* (4) *Hypnum squarrosum.* (5) *Anomodon viticulosus.* (6) *Hypnum cuspidatum.* (7) *Tortula subulata.* (8) *Tortula ambigua.* (9) *Hypnum striatum.* (10) *Hypnum pumilum.*

Amicus.—*Syrupus Tussilaginis.*—The following formula is given in the Codex:—"Dried coltsfoot flowers, 100; boiling water, 1000; white sugar, q.s. Pour the boiling water on the petals, macerate during six hours in a closed vessel, strain, press and filter. Add the sugar in the proportion of 190 parts to each 100 of the infusion, and make a syrup by simple solution in a covered water-bath.

J. R. Y.—Your question seems to indicate a confusion of terms. If you refer to concentrated preparations, the process of percolation is usually employed, which does not involve the application of heat.

"*Azote.*"—The provision in the Weights and Measures Act relating to the sale of drugs by "apothecaries' weight" is only permissive, and there is no doubt that the use of the avoirdupois weight for the purpose is legal. As to the interpretation of symbols used in prescriptions see a letter from Professor Redwood, in vol. viii., p. 477 of the present series of this Journal.

Inquirer.—The use of methylated spirit in making such a preparation, which is capable of being used internally as a medicine, or the sale of a preparation so made, would, under the 29 and 30 Vict. cap. 64, sect. 8, render you liable to a penalty of £100.

Erratum.—On p. 788, vol. i., line 30 from bottom, for "tubular" read "tabular;" line 27, for "tent" read "teat;" line 21, for "bark" read "back;" line 16, for "venation" read "vernation."

"*Alpha.*"—The formula for syrupus calcis lactophosphatis approved by the Paris Society will be found in vol. vii. of the present series of this Journal, p. 1041. Several other formulæ have also been given at various times.

"*Chemist and Druggist.*"—Carbolic acid is not included in the Schedule of Poisons.

Sigma. — Ringer's 'Handbook of Therapeutics,' or Naphey's 'Modern Medical Therapeutics," would probably best suit your purpose.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mee, Mackay, Dranbridge, Jacque, Junior, K., C. L. S.

VOLUMETRIC DETERMINATION OF ALKALOIDS BY SOLUTION OF THE IODIDES OF BISMUTH AND POTASSIUM.*

BY J. C. THRESH, F.C.S.

So far as I am aware, the only solution hitherto employed for volumetric determination of alkaloids is that proposed by Mayer (*Am. Journ. Pharm.*, xxxv., 28), consisting of a solution of mercuric chloride and potassium iodide, but the results obtained by use of this reagent are only approximately accurate when the solutions are of a certain strength, and in the absence of ammonia, acetic acid, and many other substances.

From the known want of some reliable mode of estimating alkaloids volumetrically, and from observations of the character of the precipitates produced in solutions of alkaloids by the iodide of bismuth and potassium reagent, and the exceeding delicacy of the test, I have been led to make a series of experiments to ascertain the applicability of such a solution for alkaloidal determinations, and the circumstances under which its action is reliable.

M. Yvon (*Répertoire de Pharm.*, ii., 335, Abs. Y. B. P., 1874, 232), who published a form for preparing a solution of iodide of bismuth and potassium for detection of alkaloids, at the conclusion of his paper says that "since the nature of the precipitate produced by the reagent varies and the composition of the reagent itself also changes that it will be impossible to use the double iodide as a volumetric test." As, however, M. Yvon's experiments did not appear to me to be conclusive on this point, and as only in one case, afterwards to be referred to, did any attempt appear to have been made to determine the nature or composition of the precipitate produced by this double iodide when added to an alkaloidal solution, it was determined to clear up, if possible, both these points.

The results I now have the pleasure of laying before this meeting, and although the experiments have not led up to a method of volumetrically estimating alkaloids applicable under all circumstances, yet there are special cases in which the method may prove to be of considerable service. But apart from this as an account of the examination of an hitherto unexplored domain, it is hoped that the paper will not be altogether without interest.

In the first experiments, a solution of bismuthic chloride, to which excess of potassium iodide had been added, and containing 2 milligrams of bismuth in each cubic centimetre, was employed. Solutions containing strychnine, quinine, morphia and cinchonine, were prepared, each containing, in 1 c.c., 2 milligrams of alkaloid.

When the bismuth solution was run in to measured quantities of solution of quinine, it was found that at a certain point the fluid became tinted by the reagent, but that the clear supernatant fluid became cloudy upon addition of more bismuth solution. When filtered it also precipitated upon addition of quinine. Reading off from the instant when the fluid became of a decided orange tint, results very concordant were obtained. Readings taken by running the alkaloid into the bismuth solution, so long as a distinct precipitate (not a mere turbidity) was produced, gave nearly the same results. The mean of five experiments showed that 210 bismuth precipitated 140 quinine. The molecular weight of quinine, $C_{20}H_{24}N_2O_2$, being 324, the above ratio corresponds to a double iodide, containing 7 molecules of Bi I_3 to 3 of $C_{20}H_{24}N_2O_2.HI$, or—

$$7\,(BiI_3)\,3\,(\bar{Q}HI).$$

This formula requiring 139 parts of quinine to 210 of bismuth.

With cinchonine also very approximate results were obtained, the mean quantity of this alkaloid precipitated by 210 of bismuth being 210. The formula—

$$3\,(BiI_3)\,2\,(C_{20}H_{24}N_2OHI)$$

requires 205 of alkaloid to 210 of bismuth. When the cinchonine was run into the bismuth solution, the results were not so concordant, and agreed with no simple formula. With strychnia, the mean quantity corresponding to an atom of bismuth (in milligrams) was 466 milligrams. This would apply most nearly to a formula—

$$3\,(BiI_3)\,4\,(C_{21}H_{22}N_2O_2HI),$$

which requires 445 of alkaloid to the atom of bismuth.

When it was attempted to titrate the solution of morphia, it was found that the fluid became coloured long before it ceased to precipitate with the reagent, and the results obtained were not to be depended upon.

Next a volumetric solution containing 10·5 milligrams of Bi (and excess of KI) in each c.c. was prepared, and with this results corresponding closely amongst themselves, but differing totally from the previous ones, were obtained. Now 4 atoms of bismuth almost exactly precipitated 3 molecules of quinia. With a solution of bismuth oxide and potassium iodide in dilute hydriodic acid the same proportions were found to hold.

A portion of the quinine and bismuth precipitate was then collected for analysis, but upon attempting to wash it, it so readily decomposed that it was obvious the results could not be satisfactory. After the supernatant fluid has been removed from the precipitate, and water has been placed upon it, the latter, although it remains uncoloured, is found to contain hydriodic acid and quinine, but no bismuth, and by continued washing the salt becomes paler and paler in colour until ultimately very little besides oxide of bismuth is left behind.

A solution containing ·162 gram quinia was found to be entirely precipitated by bismuth reagent corresponding to ·135 gram bismuth. The filtrate was tested in various ways and found to contain the merest trace of bismuth and no alkaloid. The precipitate was collected upon a tared filter, rapidly washed with a little cold water by aid of a filter pump, dried at 212° and weighed. The compound weighed ·750 gram, and when heated to about 250° fused into a transparent ruby fluid, but the weight remained constant. In a second experiment ·519 gram bismuth and ·606 quinia yielded 2·922 grams of the orange coloured compound. Calculated into percentages we have—

	1.	(2)
Bi.	18·07	17·8
$\bar{Q}$	21·6	20·75
I	60·33	61·45

The formula

$$4(BiI_3)\,3(\bar{Q}HI)\,8HI$$

requires—		
	Bi	17·7
	Q	20·6
	I	61·7

* Read at the Evening Meeting of the Pharmaceutical Society, April 7, 1880.

A number of similar determinations were made with solutions of different strengths and containing various amounts of potassium iodide, and it was found that by varying the amount of this latter salt, orange coloured compounds containing most varied proportions of bismuth, quinine, and iodine were obtainable. One such compound agreed most closely with the formula

$$5(BiI_3)\ 4(\bar{Q}HI)\ 3HI$$

and in every case the molecule contained more or less HI. Evidently these precipitates are mixtures of definite compounds of simpler constitution, but still complex, as is shown by the facility with which they suffer decomposition. In colour they vary from a pale brick red to a deep and beautiful scarlet, the greater the proportion of iodine the deeper the colour.

Seeing that Mr. F. W. Fletcher, at the British Pharmaceutical Conference, in 1878, had given

$$(BiI_3)_2\ C_{20}H_{24}\quad .HI$$

as the formula of a double iodide prepared by him, I attempted to arrange the strengths of my solutions so as to precipitate this compound. Mr. Fletcher having informed me that he obtained the iodide by mixing together solutions of potassium iodide, bismuthic nitrate, and quinine, in the proportions calculated from the formula, I mixed together solutions of bismuth and quinine in the above proportions, and then ran in the iodide from a burette, but found invariably that more iodide was required to completely precipitate the bismuth and alkaloid than the formula indicated, no matter what was the state of dilution or whether the iodide was added slowly or at once. The mean of two determinations, (volumetric and gravimetric) gave

Bi	23·8
$\bar{Q}$	18·4
I	57·8
	100·

which is almost absolutely identical with that required by the formula

$$(Bi\ I_3)_2\ (\bar{Q}HI)\ HI.$$

A specimen of Mr. Fletcher's compound, kindly furnished me by that gentleman I found exhibited instantaneously signs of decomposition when agitated with cold water, the filtrate precipitating freely with silver nitrate and with alkaloidal reagents. Most likely the salt when freshly precipitated has the formula above given, but upon washing, the proportions of HI and $\bar{Q}$ are decreased and its composition will approximate to that given by Mr. Fletcher.

To ascertain what proportion of potassium iodide to bismuth would give the best results, volumetric solutions containing the two in various proportions were tried and the results proved that the following solution gave in the majority of cases the most reliable indications and was most convenient for use:—

Bismuthic Oxide	4·68 grams.
Potassium Iodide	20· „
Hydrochloric Acid (B.P.)	80· c.c.
Water add to	1 litre.

The bismuth oxide is dissolved in the acid, diluted to 300 c.c., and the iodide of potassium dissolved in sufficient water to measure 700 c.c. mixed with it. If the iodide is added to the strong acid solution, a precipitate of bismuthic iodide falls upon the addition of the water, and if too much water is added first oxychloride is precipitated. Made as above directed the fluid is perfectly bright, of a rich dark orange colour, and is apparently permanent, but whether it retains its strength unimpaired for a length of time I cannot yet say. Half a c.c. added to 100 c.c. of water containing a trace of potassium iodide gives a perfectly bright pale orange tinted fluid. The tint is of such depth that when a few drops of the liquid are drawn into a glass tube 2 mm. in diameter, the colour is readily perceptible.

When the reagent is dropped into pure water a distinct turbidity is at once produced, the fluid remaining colourless until a certain amount has been added, but singularly enough the presence of ·1 per cent of potassium iodide entirely prevents this decomposition.

The following are the results of my experiments with this solution. In all cases, unless otherwise stated, the alkaloids were first dissolved in slight excess of hydrochloric acid:—

Solutions of Quinine. $C_{20}H_{24}N_2O_2$.

Quantity taken in grams.	Dilution, etc.	c.c. of Bi. Sol.	Mol. bi. / Mol. alk.	Quinia calculated from results.
·065	10 c.c. Water, temp. 49° .	15·	1·5	·065 gram.
·130	20 c.c. Water	29·5	1·475	·128 „
·130	20 c.c. Water	30·	1·5	·130 „
·130	50 c.c. Water, temp. 65° .	31·	1·55	·134 „
·086	13 c.c. Water	19·5	1·48	·084 „
·130	20 c.c. Water and excess of HCl . .	29·	1·45	·125 „
·130	100 c.c. Water and excess of HCl . .	32·	1·6	·138 „
·194	50 c.c. Water and excess of H_2SO_4 .	47·2	1·57	·204 „
·097	15 c.c. Water and excess of acetic acid . . .	22·5	1·5	·097 „
·131	40 c.c. Water and excess of acetic acid . . .	31·5	1·56	·136 „
·065	10 c.c. Water and excess of HNO_3 .	14·5	1·45	·063 „

The point read off was that at which the reagent ceased to give a distinct precipitate with a drop of the fluid filtered through paper. The precipitates in nearly all cases, it may here be remarked, are flocculent and settle somewhat rapidly, especially towards the end of the reaction, and as a consequence the use of filter paper may generally be dispensed with, by substituting a very small pipette having its contracted extremity plugged with a little cotton wool. A few drops of the supernatant fluid are drawn by careful suction into the tube, and are thus completely filtered by the wool. If the point to be read off is that at which the fluid becomes tinted, this is ascertained without further trouble. When the end of the reaction is that at which further addition of reagent ceases to cause a precipitate, the few drops of fluid are transferred (by blowing) to a small test-tube, and a single drop or fraction of a drop of the bismuth solution dropped in from the pipette. The tube and pipette are rapidly rinsed with a little water. I prefer a small test-tube to a watch glass, because a slight opalescence is frequently produced long after excess of the reagent has been added, and this is more readily distinguished in the tube from the slight but distinct precipitate produced towards the end of the reaction.

When free acetic acid is present from 1 to 2 c.c. of the bismuth solution is decolorized; this may be prevented by adding a little potassium iodide to the alkaloidal solution previous to running in the reagent, but it is apparently unnecessary. Within certain limits the state of dilution of the quinine solutions does not materially affect the results, neither does the presence of excess* of hydrochloric or nitric acids. Excess of sulphuric acid causes the readings to be somewhat too high.

The mean value of the ratio, $\frac{Bi}{Alk}$ is $\frac{16 \cdot 635}{11} = 1 \cdot 51$, and the results in the fifth column are calculated from the formula—

$$3(BiI_3)\,2(\overline{Q}HI)\,x(HI).$$

Solution of Strychnia.

Strychnia.	Dilution.	c.c. of Bi. Sol.	$\frac{Bi.}{St.}$	Result.
·167	25 c.c. Water . .	20·	·8	·160
·134	40 „ . .	16·5	·825	·132
·067	10 „ . .	8·3	·83	·067
·200	100 „ and excess of nitric acid	26·	·86	·208

The mean value of the ratio $\frac{Bi}{St}$ is $\frac{3 \cdot 315}{4} = \cdot 83$, corresponding to—

$$5(BiI_3)\,6(\overline{St}HI),$$

from which formula the results are calculated.

Solution of Cinchonine.

Alkaloid.	Dilution.	$\frac{Bi.}{Alk.}$	c.c. Bi. Sol.	Results.
·071	11 c.c. Water . .	1·5	16·5	·071
·129	20 „ . .	1·475	29·5	·127
·129	50 „ with excess of H_2SO_4	1·53	30·7	·132
·258	150 c.c. Water with excess of acetic acid	1·57	63·	·270
·039	10 c.c. Water with excess of acetic acid	1·5	9·	·039

The mean value of $\frac{Bi}{Alk}$ is $\frac{7 \cdot 575}{5} = 1 \cdot 515$, and the results are therefore taken from the formula—

$$3(BiI_3)\,2(\overline{C}HI)\,xHI.$$

Cinchonidine. $C_{20}H_{24}N_2O$.

Quantity.	Dilution.	Bi. Sol.	Ratio.	Results.
·062	10 c.c. water	15·5	1·55	·064
·123	20 „	32·	1·6	·131
·154	50 „	43·	1·72	·176
·062	10 „ and little KI.	15·5	1·55	·064

Mean value of $\frac{Bi}{Alk} = 1 \cdot 6$.

In these determinations it was noticed that when the readings were taken at the point where the fluid becomes coloured, the ratio $\frac{Bi}{Alk}$ was almost exactly 1·5. Thus in the fourth determination the liquid acquired an orange tint with the 15th c.c. of the bismuth solution, but another ½ c.c. was required to complete the precipitation. Most probably the formula is—

$$3\,(BiI_3),\ 2\,(\text{Cinchonidine HI}).$$

Quinidine Solution.

Quantity.	Dilution.	Bi. Sol.	$\frac{Bi}{Alk}$	Results.
·072	10 c-c. water	14·5	1·45	·070
·072	10 „	14·	1·4	·067
·144	50 „	28·	1·4	·134

Mean value of ratio $\frac{Bi}{Alk} = 1 \cdot 42$.

Results calculated from formula,

$$3\,(BiI_3),\ 2\,(\text{Quinidine HI}).$$

It was afterwards noticed that the crystals of quinidine employed were slightly effloresced, hence probably the cause of the results appearing uniformly too low. The molecular weight was taken as 360 ($C_{20}H_{24}N_2O_2 + 2\,H_2O$).

Morphia Solution.

Alkaloid.	Dilution.	$\frac{Bi}{Alk}$	c.c. Bi. Sol.	Results.
·057	10 c.c. water	1·1	9	·051
·114	20 „	1·	20	·114
·114	40 „	1·	20	·114
·108	50 „	·95	18	·103
·091	30 „ with excess of H_2SO_4.	1·06	17	·097

The end of the reaction is in this case more difficult to hit, since the fluid after it becomes coloured continues for some time to precipitate copiously with each further addition of the bismuth solution. The value $\frac{Bi}{Alk} = \frac{5 \cdot 11}{5} = 1 \cdot 02$ indicates that the formula of the precipitate corresponds to

$$(BiI_3)\ (\overline{M}HI).$$

Solution of Atropia. ($C_{17}H_{23}NO_3$).

Quantity.	Dilution.	$\frac{Bi}{Alk}$	Bi. Sol.	Results.
·060	10 c.c. water	1·06	11·	·064
·119	30 „ with little H_2SO_4. .	1·03	21·5	·124

Taking the atomic weight of atropia as 289, the formula of the precipitate is probably

$$(Bi\,I_3)\ (\overline{At}\,HI),$$

since the ratio $\frac{Bi}{Alk} = 1 \cdot 045$ is nearly unity.

Brucia.

Quantity.	Dilution.	c.c. Bi Sol.	$\frac{Bi}{Alk}$	Results.
·093	20 c.c. water	9·	·9	·093
·139	30 „ with excess of acid. .	13·	·89	·135

The results are calculated from the somewhat improbable formula—

$$9\,(BiI_3),\ 10\,(\overline{Br}\,HI).$$

Aconitia. ($C_{54}H_{40}NO_2$.) (734.)

	Quantity.	Dilution.	c.c. Bi Sol.	$\frac{Bi}{Alk}$	Results.
English	·050	20 c.c. water	5·	1·47	·049
Foreign	·090	40 „	9·	1·47	·088

* In the experiments quoted, 1 c.c. strong H_2SO_4 was added to the 50 c.c. quinine solution, ½ c.c. HNO_3 to 10 c.c., and ½ c.c. HCl to the 20 c.c.

Results calculated from the formula—

3 (BiI_3), 2 ($\overline{A}$HI).

The end of the reaction was easily read, no precipitate being produced after appearance of colour.

Emetine. $(C_{30}H_{44}N_2O_8.)$

·084	20 c.c. water	12 c.c.	1·6	·089

3 (BiI_3) 2 ($\overline{E}$HI).

No turbidity after appearance of colour.

Codeia. $C_{18}H_{21}NO_3$, H_2O. (317.)

·118	20 c.c. water	19	1·02	·120
·165	30 „	25	·96	·159

Became coloured long before it ceased to precipitate.

Results calculated from formula—

(BiI_3) (Codeia. HI).

Apomorphia. $(C_{17}H_{17}NO_2.)$

·100 (as hydrochlorate).	50 c.c. water	16·	·97	·097

Precipitated long after production of colour. Flocculæ very large, and settling rapidly.

Formula—

(BiI_3) (Apomorphia HI).

Narcotine. $(C_{22}H_{23}NO_7.)$ (413.)

·059	20 c.c. water	7·	·98	·058
·088	30 „	10·	·94	·083

No precipitation after fluid became tinted.

Formula of precipitate, and from which results are calculated—

(BiI_3) ($\overline{Nt}$HI).

Narceia. $(C_{23}H_{29}NO_9.)$ (463.)

·116	20 c.c. water	11·5	·99	·115
·169	50 „	16·	·94	·160

The values ·99 and ·94 are calculated on the assumption that the crystals of narceia contain two molecules of H_2O.

Formula of precipitate—

(BiI_3) ($\overline{Nc}$HI).

Became coloured about 1 c.c. before it ceased to precipitate.

Theine. $(C_8H_{10}N_4O_2$, 2 $H_2O.)$ (202.)

·136	20 c.c. water	31 c.c.	·92	·125
·068	10 „	16 „	·95	·066

Caffeine. (As Citrate ?)

·103 (citrate).	20 c.c. water	23 c.c.	1·15

The value 1·15 is found upon assumption that this so-called citrate has the formula :—

$3(C_8H_{10}N_4O_2)$, $(C_6H_8O_7)$, (774).

The theine and caffeine precipitates differed entirely from those of the other alkaloid in being pulverulent, dense, and settling almost instantaneously towards the end of the reaction. In both cases the fluid became coloured some time before a precipitate ceased to form on addition of more of the reagent.

Bebeeria Sulphate.

·144 gram required 22 c.c. of the bismuth solution for complete precipitation. The precipitate did not settle so as to leave the supernatant fluid clear, and was of a dull lemon-yellow colour, quite different from that produced by any other alkaloid. Assuming the molecular weight of the sulphate—

$(C_{28}H_{42}N_2O_6.\ H_2SO_4)$

to be 720, the ratio $\frac{Bi}{Alk} = 2·9$, a much higher number than was found in any other case.

The concordance of these results leave in most cases little to be desired, and are more trustworthy than those obtainable by any gravimetric method. In every case it was observed that at a certain point, varying with the alkaloid and in a lesser degree with the state of dilution, the fluid being titrated assumed an orange tint, and at this stage precipitated upon the addition either of more reagent or of an alkaloidal solution. By continuing the addition of the *titre*, however, ultimately no further precipitate is produced by it. This stage, at which both alkaloid and reagent produce precipitates, appears to vary with the solubility of the alkaloid and bismuth compound. Thus in solutions of quinine in which the bismuth and potassium iodide will produce a distinct turbidity when the fluid contains only 1 of alkaloid in 200,000 ; the points at which the colour first appears and at which the reagent ceases to precipitate differ only by ·5 to 1 c.c. according to dilution of fluid. With morphia, however, which in solution can only be detected by the reagent when more than 1 in 40,000 is present, the two points may differ by several c.c.

To ascertain the applicability of the method the following experiments with cinchona barks and preparations of quinine were conducted, the volumetric solution employed being a little stronger than that previously used and standardized by aid of pure quinine disulphate, with the followng results, the end of the reaction being taken as that at which an orange tint was assumed by the fluid.

Quinine Disulph.	Bi. sulph.	Quantity of Disulph. precipitated by 1 c.c.
·089 gram	14 c.c.	6·36 mm.
·226 „	36 „	6·28 „
·178 „	28 „	6·36 „

Mean quantity of disulphate, represented by 1 c.c. of the reagent = 6·33 mm.

·470 gram ferri et quiniæ cit. B.P. was dissolved in 50 c.c. of water, acidulated with hydrochloric acid and titrated. 14 c.c. of the bismuth solution were required, corresponding to ·065 grm or 13·83 per cent. of anhydrous quinia. A solution of ·313 gram in 50 c.c. of acidulated water required the addition of 9 c.c. bismuth solution to precipitate the alkaloid. This represents ·042 or 13·42 per cent. quinia.

A dilute tincture of quinia when titrated gave results much too high ; another portion, 2 drachms, was therefore placed on the water-bath until all the spirit had evaporated, diluted with acidulated water and filtered ; 22·5 c.c. of the reagent were required to effect complete precipitation, and represent 2·2 grains of quinine disulphate.

One fluid ounce of vin. quinæ was then similarly treated, but without filtration, and required 11 c.c. of bismuth solution to tint the fluid. This corresponds to 1·08 grain of quinine disulphate.

Two fluid drachms of a so-called concentrated decoction of cinchona, when diluted, were precipitated by 7 c.c. of the reagent. A similar quantity of the decoction to which ·1 gram of quinine disulphate had been added, required 23·5 c.c. (23·5—7 = ·104 disulphate).

To an acidulated solution containing about 1 gram of citrate of iron and ammonia, ·1 gram of the quinine salt was added, and the mixture titrated.

15 c.c. of reagent were used, corresponding to ·096 quinine.

In all these cases there was little difficulty in reading off to ½ a c.c., the point at which the orange tint appeared in the fluid. In the dark coloured citrate of iron solution, the brown colour disappeared gradually upon addition of the reagent, until when excess of the latter had been added, the characteristic tint was readily discernible. In all the solutions containing iron the precipitates were finally of a dull, dark red colour, and subsided very slowly.

Messrs. Woolley, Sons and Co., having placed at my disposal several samples of assayed cinchona barks, attempts were made to determine the alkaloids volumetrically. In devising methods for assaying drugs, however, the chemist has two distinct processes to work out. First, a method for thoroughly extracting all the active principle of the drug, and, second, for obtaining or measuring the amount of this principle in a state of purity.

When to the acid decoction of cinchona bark, obtained by boiling the bark in acidulated water, the bismuth solution was added, the results were obviously much too high, and the character of the precipitate was somewhat changed, refusing to settle even after standing some time. When, however, the barks were exhausted by De Vrij's process, the titration could be readily effected, and the results obtained agree very closely with the results obtained gravimetrically.

In each case the finely powdered bark was mixed with ¼ part of slaked lime and 2·5 parts of water, and the whole thoroughly dried upon the water-bath. The residue was then heated to ebullition with 10 parts of alcohol (sp. gr. ·795), and when cold the supernatant fluid filtered, and successive quantities of alcohol percolated through the residue until in all 20 parts of tincture were obtained. The filtrate was finally acidulated with very dilute sulphuric acid, the spirit distilled off, the residual fluid filtered when cold, diluted by washing with acidulated water to 50 c.c., and titrated.

Red cinchona bark, labelled, "total alkaloid 4·75 per cent."—3·13 grams of this bark gave ·134 alkaloids equal to 4·28 per cent.

Pale cinchona bark, labelled, "total alkaloids, 3·48 per cent."—5 grams required for complete precipitation bismuth solution corresponding to ·180 cinchona alkaloids, or 3·62 per cent.

Yellow cinchona bark, labelled, total alkaloids 1·95 per cent., quinia, ·77 per cent. The fluid extract of 5 grams contained, as determined by titration, ·098 alkaloids, corresponding to 1·96 per cent. The extract of other 5 grams was rendered alkaline, and shaken with successive small quantities of ether, then acidified, and warmed to expel the ether dissolved. The alkaloids insoluble in ether = ·043 gram or ·86 per cent.

Yellow cinchona bark, labelled, total alkaloids 2·55 per cent., quinia 2·28 per cent. Total alkaloids as determined in 5 grams corresponded to 2·44 per cent. The extract from other 5 grams after treatment with ether, gave ·006 alkaloids insoluble in ether, equal to ·12 per cent. The ethereal solution was evaporated to remove the ether and the residue dissolved in acidulated water, and titrated. The quinine thus determined corresponded to 2·36 per cent. of the bark used.

Another solution of bismuth and potassium iodide was then made for morphimetric purposes. Standardized with a sample of hydrochlorate of morphia, the mean of three experiments gave 1 c.c. = 5·93 mgs. of hydrochlorate or 4·78 mgs. of pure alkaloid.

			Mlgrs. of salt precip. by 1 c.c.
·171 morp. hyd.	required	29 c.c.	5·9
·106 "	"	18 "	5·9
·159 "	"	26·5 "	6·

Whilst attempting to devise a process for volumetrically determining the morphia in opium the following notes were taken.

Small quantities of the common inorganic salts ($NaCl$, Na_2SO_4, etc.), had no influence upon the results. Large excess, however, causes the results to be too high, a solution of 6 grams $NaCl$ and ·088 gram morphia not giving a permanent precipitate until 11 c.c. of the *titre* had been added.

The presence of mucilaginous matter also entirely vitiates the results.

To obtain most concordant results, the determination should be conducted as rapidly as possible after the fluid has become tinted, and to the small portions removed by filtration to ascertain the end of the reaction only a very small drop of the reagent must be added. When this filtrate is mixed with an equal quantity of the *titre* (after excess of the latter has been previously added) a slight turbidity slowly forms.

A number of preparations of aconite root were next examined, and in all cases the determinations were easily and rapidly made, and when repeated with the same preparations, the results were closely concordant. By extracting the coarsely powdered roots of aconite and belladonna with alcohol, removing the spirit by evaporation, dissolving the residue in acidulated water, filtering and titrating the filtrate, the amount of alkaloid was readily found. This would prove a very simple method of ascertaining the quality of these drugs and of the preparations made therefrom.

Whilst experimenting with the alkaloids it was though desirable to ascertain the delicacy of the reagent with each. The results are tabulated below. It was found that a strong solution when treated with the bismuth solution, and afterwards diluted, exhibited a very evident turbidity long after a similarly dilute solution to which the reagent was directly added. Thus a solution containing 1 part of quinine in 100,000, when diluted after addition of a few drops of the reagent until 500,000 parts contained 1 of alkaloid, was sensibly as turbid as a solution of 1 in 200,000 to which the bismuth was added directly; moreover not the slighest opalescence could be detected in a solution of 1 in 500,000 when the reagent was dropped into it. It is essential in all cases to add to the fluid* to be examined a drop or two of potassium iodide solution and of dilute acid, otherwise the test solution may suffer decomposition and lead to erroneous conclusions.

With solutions of the strength indicated below the turbidity was such as to be evident in 1 c.c. of the fluid held in a test-tube, and viewed by reflected light.

Quinine	1 in 200,000
Strychnine	1 " 250,000
Cinchonidine	1 " 125,000
Morphia	1 " 20,000
Atropia	1 " 25,000

* About 10 c.c. In very dilute solutions an excess of KI or HCl entirely prevents the formation of a precipitate.

Brucia	1 in	40,000
Quinidia	1 ,,	150,000
Aconitine (E. and F.)	1 ,,	40,000
Codeia	1 ,,	17,500
Apomorphia	1 ,,	12,500
Narcotine	1 ,,	50,000
Narceia	1 ,,	20,000
Bebeerine	1 ,,	6,000
Theine	1 ,,	4,000
Caffeine	1 ,,	3,000

In all cases, except with theine and caffeine, the opalescence appears immediately upon the addition of the reagent. With theine and caffeine the precipitate does not make its appearance for a minute or so; in appearance, however, it is quite characteristic.

Infusions of hemlock, tobacco, and other substances containing volatile alkaloids, are freely precipitated, but no quantitative experiments have as yet been made with them or with any of the volatile alkaloids.

I have only to add three notes :—

1st. That for the four cinchona alkaloids the ratio BiI_3 : Alk. HI is $\frac{3}{2}$, for the opium alkaloids unity, and for the nux vomica alkaloids less than unity. This possibly indicates some analogy in structure of the individual members of each group.

2nd. That the amount of alkaloid in any organic substance (tinctures, extracts, roots, etc., in all the experiments I have hitherto made, and many of which are not recorded in the paper) was readily determined in the acidulated aqueous solution of the alcoholic extract. Such a solution is devoid of all mucilaginous substances, containing only those matters soluble in both alcohol and water.

3rd. That the recorded experiments were purposely made with small quantities of alkaloids, as a volumetric method of estimating such expensive compounds, to be of practical value, must yield good results when working with very small quantities.

[*The discussion on this paper is printed at p.* 825].

THE HISTOLOGY OF ARAROBA OR GOA POWDER.*

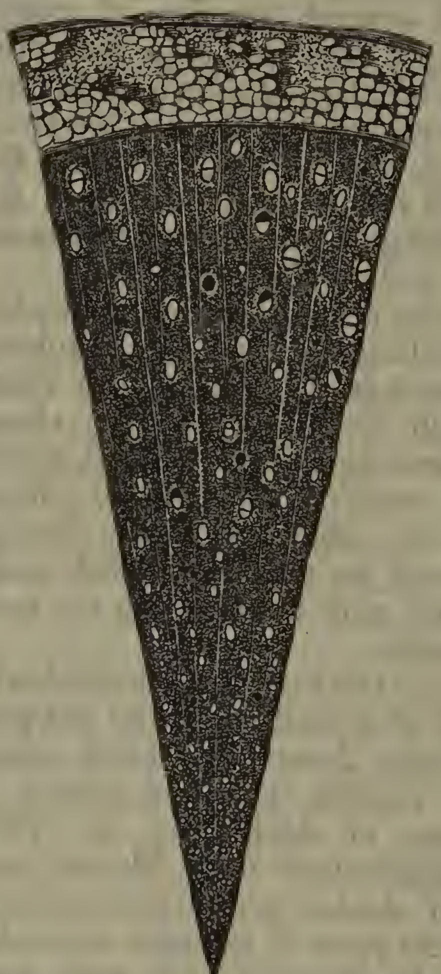
BY THOMAS GREENISH, F.C.S.

Within the last few years much interest has attached to a drug imported from Brazil, and to which the native name "Araroba" is applied, and sometimes also "Goa" powder, from Goa, a Portuguese possession of that name on the Malabar Coast, through which it was imported into British India.

Its chemistry has been investigated by Professor Attfield and subsequently by Liebermann, the botanical characters of the tree whence it is produced have been described and illustrated, and so much of its history as has reached this country can be gathered from various papers in the *Pharmaceutical Journals* of the last five years.

The object of this paper is to deal with the histology of araroba, a substance at the present time employed chiefly, if not exclusively, for the production of chrysophanic acid.

As met with in commerce araroba is in the form of a powder more or less agglomerated; mixed with it, and covered by it, are splinters of the wood in which this substance originates. The powder has an intensely bitter taste, and somewhat of a resinous adhesion to the fingers; it is said that the colour is originally of a fine yellow, resembling sulphur, and that this by exposure gradually changes to a rhubarb colour, and then darkens to that of aloes. Occasionally in the commercial powder lumps are met with, which, when broken, show internally a canary colour, whilst the external parts are dark brown. A sample dried at 100° to 110° C. lost 1·98 per cent.



No. 1.—Segment of Araroba.

The drawing No. 1 represents a segment of a transverse section of the wood yielding araroba, from an authentic specimen deposited in the Society's Museum, and the fragments of wood found in the powder, from sections of which the other drawings were made, correspond with this in structure.

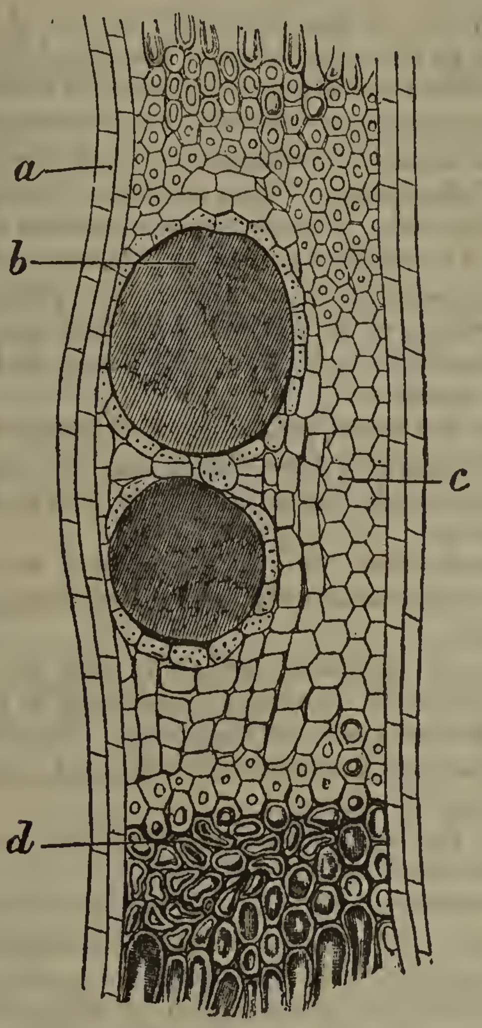
The bark externally is more or less covered with lichen, which gives it a somewhat grey and black patchy appearance. The epidermal tissue is for the most part thrown off by a suberous layer composed of a large number of cork cells compressed together and forming a layer of dense tissue; within this is a cellular tissue containing starch grains, and amongst these cells are sprinkled sclerogen or stone cells—cells much thickened by secondary deposit, and therefore, equally with the cork cells, capable of great resistance to external or internal destructive influences. The granular protuberances seen in a section of the bark are due to these sclerogen cells being left intact, whilst those containing the starch grains have to some extent given way.

With reference to the bark little need be said, as it does not appear to enter into the composition of araroba. Within the bark is the woody column traversed from the medulla to the bark by narrow medullary rays coloured by the araroba, and the round spots show the porous vessels, most of them also filled with the same substance.

The drawing No. 2 shows a small part only of the woody column of this segment, enlarged as seen

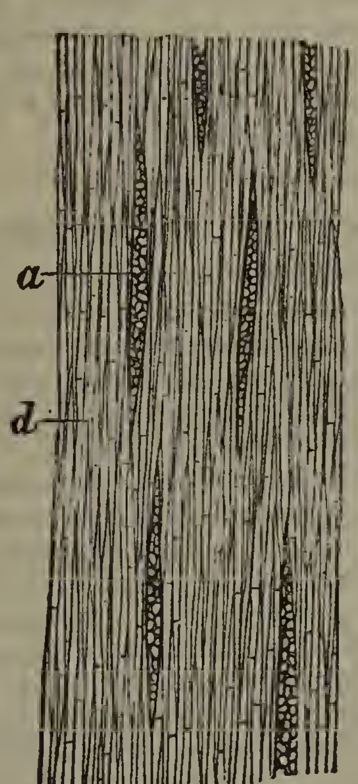
* Read at the Evening Meeting of the Pharmaceutical Society, April 7, 1880.

under the microscope and bounded on either side by the medullary rays. The whole segment of No. 1



No. 2.—Transverse section of Araroba, enlarged.—*a*, medullary rays; *b*, porous vessels; *c*, parenchyma of wood; *d*, libriform cells.

being only a repetition of this section, an explanation therefore of the cellular structure of this portion will give the cells comprising the whole. It exhibits four distinct forms of cells. There are the medullary rays *a*, on either side; they are usually two cells wide, narrow, thin walled, and elongated in a radial direction. *b* represents porous vessels, surrounded by the parenchyma *c* of the woody tissue, having some of its cells thickened and dotted, and *d* the libriform cells. This comprises the whole of the cell tissue of the wood yielding araroba.



No. 3.

The drawing No. 3 is a longitudinal section through the medullary and libriform cells, showing the latter disposed in their length as elongated pointed cells; the several cells composing these tissues were isolated and identified.

The first question that presented itself was, what tissues are involved in the formation of araroba? Under the microscope, either alone or in any fluid that does not change its nature, araroba presents the character of an amorphous powder; by heating it in a test-tube in a solution of caustic alkali, which dissolves about 80 per cent., it was hoped that some indication would be obtained, in the deposit, of cell tissues, but the result was not satisfactory. Recourse was then had to boiling in repeated portions of benzol, but with no better success. Adopting, however, the microchemical method, allowing the caustic alkali to run under a cover glass on the slide of moistened araroba, whilst under the microscope, and by this means dissolving away gradually the soluble portion of the powder, fragments of those cells just referred to as composing the several tissues were found and identified without difficulty.

In this manner broken portions of libriform cells and of porous vessels, also of cells of the parenchyma of the wood were discovered. Those of the medullary rays were too fragmentary to be distinguished satisfactorily; being a very delicate tissue it was scarcely expected otherwise. In no single instance were cork cells present or any of the sclerogen cells before referred to as forming part of the bark; starch, although found in the cells of the parenchyma of the bark, has not been detected in any sample of araroba examined. It is fair to infer, therefore, that the bark does not form any portion of the araroba, although in some samples of it pieces may be found just in the same manner as pieces of the wood; also that from the fragments of the cells in the araroba which were obtained by the process just mentioned a conclusion may be arrived at that the whole of the cell tissue, comprising the woody column, from within the bark to the medulla, is involved in the decomposition which results in the formation of araroba.

The next question that occurred was, what was the physical condition of this substance immediately resulting from the destruction of tissue? The araroba was found to have permeated more or less and imbued with colour all the tissues, even those which retained their form, but it filled many of the porous vessels, as shown in No. 2, and whilst examining under a high power the deposit in one of these vessels remains of cell tissue were visible, so disposed as to convey the impression that the deposit must have once been in a fluid condition; and subsequent examination of sections from different pieces of wood, taken at random from a parcel of powder, presented other indications leading to the same conclusion.

It will be observed that the libriform cells *d* on one part of the section, pressing closely upon each other, are in their outline sharply polygonal, whilst at the other they are separating, and show indications of having been subjected to some solvent action; the cells have lost their polygonal outline and are gradually becoming loose and shapeless, and this is seen rather on the outside in contact with the powder than in the interior of the wood. It is difficult also to understand how the porous vessels in the interior of the wood could have been so densly filled, unless the araroba had been in a fluid or semi-fluid condition. That its presence in these porous vessels is not due to decomposition of the vessels themselves is evident from the fact that when the contents are removed by solution and the cell wall examined it is found to be intact. Did the araroba consist of finely comminuted cell tissue the action of caustic alkali would little affect it; but the solution of about 80 per cent. proves that the cell tissue has been changed to some other substance soluble in caustic alkali. So far as these investigations go they point to a fluid condition of araroba, whilst its presence in the clefts and hollow places of the wood, and the fact of more being found in old trees than in younger ones, must dispose at once of the idea of its being a secretion.

The most interesting point of the inquiry next suggested itself, the cause of this formation. On this point there is no satisfactory evidence; but araroba has its analogies in the gums and resins, and to the student of materia medica these obscure changes in plant organism are of especial interest. Kützing first observed structure in tragacanth, but erred in considering it to be a fungoid growth. Mohl confirmed Kützing's observations that it possessed structure, but proved that the gum was due to a metamorphosis of the cell membrane, and the remains of cell tissue may very readily be seen under the microscope.

From the investigations of Wigand, Karsten and Wiesner, most of the natural resin which exudes from the coniferæ is due to a similar change in the starch and the cell membrane. The gums of which gum arabic may be taken as typical owe their origin to a similar change from an obscure cause in the interior of the tree. In one instance the medulla and medullary rays with the starch are involved and in another the bast cells of the bark.

This change has sometimes been called a degradation of cell tissue, but the word, restricted to its application in geology, is not a suitable term. If this had been a degradation, or rubbing down, of cell tissue the result would be nothing more or less than a mass of cell *débris*; but this is a disorganization or destruction of organic structure, resulting in the formation of a substance of a totally different character.

Last autumn in the forest of Thuringia resin was seen exuding from a large number of coniferæ and also gum from the cherry trees. A specimen which was brought home well illustrates a natural exudation of the cherry gum, and there seems little doubt but that the same natural law which governs the changes resulting in the formation of gums and resins governs also those which result in the formation of araroba, and that this substance was, equally with those named, originally in a fluid condition.

While engaged in the investigation of this subject, a new edition of the 'Commentary on the Austrian Pharmacopœia' was sent to the Society by the author, that eminent histologist who has done so much in the examination and illustration of the materia medica of this and other countries, Professor Vogl, of Vienna, and I found that he had been engaged in the examination of araroba, and had arrived at the conclusion that the change to a fluid form, which had taken place in this instance, was the same as that occurring in another of the tropical leguminosæ, *Ferreira spectabilis*, which he had several years previously examined, a tree that furnishes the resinous substance termed pedra-harz.

[*The discussion on this paper is printed at p.* 825].

NOTE ON THE FRUIT OF ADANSONIA DIGITATA.*

BY F. L. SLOCUM.

A short notice of the so-called "cream of tartar fruit" is contained in the *Amer. Journ. Pharm.*, 1877, p. 254, and it is there stated to be probably distinct from the fruit of the Baobab, *Adansonia digitata*. Opportunity was afforded by Professor Maisch to examine some of the pulp covering the seeds of the latter. When examined under the microscope, the dry pulp is seen to be destitute of crystalline structure. It readily falls to a yellowish-white powder, and has a pleasant acidulous taste. The pulp of the cream of tartar fruit is of a darker colour and more acid taste. The pulp is soluble in hot or cold water, and the solution has an acid reaction.

Examined for bases, potassium was found, and probably traces of calcium and phosphates, the two latter requiring confirmation, which, for want of time, had to be postponed for the present.

The examination for acids resulted in proving the presence of malic acid only, combined as an acid malate of potassium.

The aqueous solution, agitated with six volumes of strong alcohol, gives a copious precipitate of pectin, which forms the largest part of the pulp. The pectin, when dissolved in strong hot hydrochloric acid, yields a bright magenta-coloured solution.

Distilling the aqueous solution with water, ether and alcohol gave no volatile compounds.

The concentrated aqueous solution left in the still, had, in each case, a dark brown colour, and deposited a white amorphous powder. On agitating this residue with ether, it was dissolved; on evaporation of the ether, it either separates as white, silky needles, or as a white amorphous mass. After the removal of pectin and after the evaporation of the alcohol, the remaining solution yields, with alkaline solution of copper, a very copious precipitate of cuprous oxide, showing a large percentage of grape sugar. No traces of tartaric acid were found.

Summing up the constituents, we have pectin, grape sugar, malic acid and potassium as acid potassium malate, a crystalline principle not further investigated, and probably traces of calcium and of phosphates.

AN IMPROVED NITRATE OF SILVER CAUSTIC.†

Dr. Sawostizki called the attention of the Moscow Surgical Society to an improvement in the preparation of sticks of nitrate of silver. It consists in melting together five parts of nitrate of silver with one part of nitrate of lead, forming an argentum plumbo-nitricum. Sticks formed of this are preferable to those of the ordinary nitrate, as they are not easily broken and can be pointed just like a lead pencil.

A NEW METHOD OF ADMINISTERING KOOSSO.‡

Of all the remedies for tape-worm none is more certain or efficient than koosso, and many efforts have been made to bring it into such pharmaceutical shape that, while its properties as a tænicide remain unimpaired, it might be administered without repugnance. Dr. Corre, some years ago, proposed the following method, which has been successfully used in many cases:—One half ounce of fresh powdered koosso is treated with 1 ounce of hot castor oil, and afterwards with 2 ounces of boiling water by displacement; express, and by means of the yolk of an egg combine the two percolates into an emulsion, and add 40 drops of sulphuric ether, flavouring with some aromatic oil.

This is to be taken at one dose early in the morning, after a previous fast of about eighteen hours. The worm is usually expelled dead after six or eight hours.

THE SALE OF PATENT MEDICINES CONTAINING POISONS.

THE appearance of a denunciatory letter in one or more of the daily journals respecting the sale of poison, marked on the one hand by a laudable solicitude for the public health and on the other by confused and erroneous notions as to the law on the point, has now become a frequently recurring phenomenon. Efforts have been repeatedly made by persons acquainted with the subject to correct the numerous erroneous assumptions and misstatements put forth in such letters, but these have generally provoked their reiteration in a more dogmatic form, so that it has almost become question whether it would not be wiser in future to leave them uncontradicted and trust that the excitement temporarily produced will follow the usual rule as to nine days' wonders. But there is after all so much reality in the evil upon which these maladroit attacks are made, and the interests of the public and of chemists are so closely in accord as to its removal, that we feel warranted in alluding to the latest epistolatory outburst in the hope that it may be utilized in helping to form a correct public opinion on the subject and so facilitate the attainment of a most desirable end.

In a letter that appeared in the *Standard* and the *Daily Telegraph* of Wednesday last, Dr. HUBBARD, of Notting Hill, states that a summons to a deathbed on one day and on the next to an inquest where the verdict returned was "Death from an overdose of chloral taken through misadventure," added to previous similar experiences, induced him to put to the test the laws regulating the sale of poisonous drugs in this country. What those laws require, according to Dr. HUBBARD's impression at the time of writing the letter, is indicated by the statement that no chemist and druggist or vendor of drugs of a poisonous nature can sell such to any person not known to him, unless that person be introduced by some one known to the vendor, and then under specified conditions which, in fact, are those applicable only to substances included in Part 1 of the Poison Schedule. Dr. HUBBARD does not seem to have been aware that all "drugs of a poisonous nature" are not poisons according to law, and that some which are so do not come under the more stringent regulations, whilst the whole of them are entirely exempt from regulation if sold under the guise of a patent medicine. It is not, however, with this misapprehension that we propose now to deal,—in fact it was ably corrected in one of the newspapers on the following day,—it is rather to the experience of Dr. HUBBARD that we would here refer.

Dr. HUBBARD states that he took one of his daughters, a child under twelve years, and sent her, by herself, into the shops of different chemists and grocers carrying on business in his neighbourhood, telling her to ask for a bottle of solution of chloral and a bottle of chlorodyne, and that these articles were supplied to the child by each of the shopkeepers without question or the slightest hesitation, with one exception, when a grocer not having the solution of chloral in stock was anxious to be allowed to procure it on the child's order by the evening. The result was that a quantity of poison was thus easily obtained sufficient, in Dr. HUBBARD's opinion, to poison fifty people.

Such is Dr. HUBBARD's experience, and apart from certain moralizings upon it with which the remainder of his letter is occupied it is certainly a striking one and we think might be turned to account. But one of the first essentials is that much prevalent misconception and mystification should be cleared away, and that it should be clearly understood that nothing appears to have been done, according to the foregoing statement, which is not allowed by the present law. One of the "poisons" obtained stands revealed by its name as a well-known "patent medicine," and we have reason to believe that the other belongs to the same category, and as long as the clause in the sixteenth section of the Pharmacy Act, 1868, which exempts the making and dealing in patent medicines from the provisions contained in the previous part of the Act, remains the law of the land, so long will it be legal for the grocer, or the huckster, or the bookseller, or anyone else, to sell such patent medicines containing powerful poisons in whatever quantities and to whomsover he may please.

There is no doubt a growing force of public opinion that would be favourable to the repeal of this provision, and this every now and then becomes manifest in an outburst of indignation directed against the body of chemists and druggists which is in no wise responsible for the evil and is powerless to act in the removal of it except with the aid of that public opinion which, influenced by uninformed leaders, frequently imputes to the body a desire to perpetuate it from interested motives. It is well known that the subject has long been under the consideration of the Council of the Pharmaceutical Society, and there is little doubt that the Council would cheerfully take its part when an opportune moment shall arrive in assisting to remedy the present anomalous state of the law relating to the sale of poisons. It must not be lost sight of, however, that there are many conflicting interests involved in this question, all of which would have to be carefully considered, and cannot be lightly over-ridden even in the public interest. Nevertheless, it must be conceded by any impartial person that it is high time the inconsistency should be abolished which demands, that before a chemist shall be allowed to sell or dispense poisons under their recognized names he shall become qualified after a long and expensive training, whilst any ignorant person may sell the same poisons under a fancy designation that reveals little or nothing of their nature or the danger involved in using them, provided that they be covered by the magic stamp supplied by the Inland Revenue authorities.

It is almost disheartening that whilst so much depends upon the public mind being correctly informed upon this subject, some of those who in the public press assume to themselves this function seem to be even more than usually liable to err when they attempt to descant upon it. Their lamentable errors provoke the time-honoured query, *Quis custodes ipsos custodiet?* Thus, strange as it may seem to the writer of an editorial article in the *Daily Telegraph*, having for its subject Dr. HUBBARD's letter, it is not a fact that "highly necessary "and valuable laws are shirked in the instance of "certain patent medicines and seductive drugs," the fact being that there is no law to shirk except that which requires that the package shall be covered by a stamp of the proper amount, a provision that the revenue authorities may be trusted to see carried out, and which it is not pretended there is any attempt to evade. We assert again, that in the sales of the "poisons" referred to by Dr. HUBBARD the grocers and others effecting them were acting strictly within the limits of their rights, and lamentable on public grounds as the recent enormous development of this traffic may be, there is nothing in it that is at present illegal.

We are sure that the chemists and druggists throughout the country would welcome the help of the public press in an effort to place the law relating to the sale of patent medicines containing poisons on a more satisfactory footing. But in order that real help may be rendered it will be necessary that writers should inform themselves of the real facts of the case. They will not find that there is either law or custom necessitating the enclosing of poisons "in "phials of a distinctive colour, and in the case of "white liquids tinging them with some coloured "ingredient." But they will find that the sale and dispensing of scheduled poisons is carried on by chemists and druggists throughout the country with scrupulous adherence to the rather stringent provisions of the Pharmacy Act, whilst side by side with this trade there has grown up an enormous traffic, fostered by competing "stores" and tradesmen of every description, by which these same poisons are scattered broadcast, and the existing legislation on the subject has been rendered almost useless.

SECRET ALLIANCES.

PRESCRIPTIONS written by medical men in such a fashion as to be intelligible only to a certain few dispensers possessing the key to the terminology adopted are not unknown in this country and have frequently furnished subject for inquiry and comment in this Journal. Although various more or less plausible attempts have been made to justify their existence, it has generally been assumed that they are the outcome of certain beneficiary arrangements made between the medical men who write them and the dispensers who make them up, and the practice has been frequently and strongly denounced as unfair to the pharmaceutical body and dangerous to the public. Across the Atlantic the same opinion obtains, and we learn from *New Remedies* that an attempt is being made by the Californian Pharmaceutical Society to put a stop, by legislative enactment, to the custom of payment by apothecaries to physicians of a percentage on prescriptions. A Bill has been for this purpose introduced into the Legislature, which, if passed, would make any agreement between an apothecary and a physician to give or receive any money or other reward in consideration of an order to procure medicine only of such apothecary a misdemeanour punishable by a fine of not less than fifty dollars. A fine of fifty dollars would also be imposed upon any physician who made use of arbitrary signs, names, or numbers, or who wrote his prescription in such a manner as not to be intelligible to any competent pharmacist. Further, a like fine would be imposed upon any pharmacist who refused to give to another competent pharmacist, upon application, the name of any preparation so designated. The Bill appears to have aroused some opposition, and some of the medical journals have spoken adversely respecting it.

THE CASE OF THE LONDON AND PROVINCIAL SUPPLY ASSOCIATION.

IT will be seen with satisfaction, from the report of the General Purposes Committee, presented to the Council at its meeting on Wednesday last, that there has been no delay in seeking a reversal of the judgment recently pronounced in the case of *The Pharmaceutical Society* v. *The London and Provincial Supply Association*, the Solicitor to the Society having taken immediate steps for appealing to the House of Lords from the decision of the Court of Appeal.

ALLEGED POISONOUS VIOLET POWDER.

AT an inquest held before Mr. PAYNE, in Southwark, on Tuesday last, medical evidence was given to the effect that the death of a child had been caused by blood poisoning consequent upon the application of so-called violet powder which contained a very large percentage of sulphate of lime. The jury returned a verdict in accordance with this view, and added an opinion "that these powders "ought not to be sold without being analysed before-"hand, and then under proper supervision."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, April 7, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Greenish, Hampson, Hills, Mackay, Rimmington, Robbins, Savage, Shaw, Squire, Symes, Williams and Woolley.

The minutes of the previous meeting were read and confirmed.

WEIGHTS AND MEASURES ACT.

The PRESIDENT read the reply from the Board of Trade to the communication sent from the Council, which had been received since the last meeting, and which has already been published in the Journal, p. 713. He said he thought it was very satisfactory as far as it went, and the diagram which had accompanied it would be engraved and also published. He understood that the fee for verifying measures bearing not more than fifty graduations would be 4*d*.

Mr. SYMES drew attention to the last paragraph in the letter just read. At the previous meeting he argued as a reason why the Council should not press the matter further that the Act was more or less permissive, when he was contradicted, and told that the Act was not at all permissive. He took it that the last clause of this letter distinctly stated that the local authorities might not at present deem it necessary to get these standards.

The PRESIDENT said he should be sorry for an idea to go forth that the Act was permissive. It was not permissive, but compulsory on all persons in the kingdom to use a certain description of weights and measures. Whether it was permissive or not so far as procuring standards was another matter; but the Act did not allow anyone to use in his business a measure which had not been verified by authority. It would be misleading, therefore, to say that the Act was permissive.

Mr. BOTTLE drew attention to a previous paragraph in the letter, which said that the Board of Trade could give no authoritative opinion on the legal construction of the Act.

The VICE-PRESIDENT thought that rather showed that the Council had better leave the matter where it was.

Mr. SAVAGE remarked that while local authorities might receive the standards, it was optional with them whether they would use them or not. At Brighton the local authority had applied for the standards, and afterwards decided not to use them.

The PRESIDENT said the Act was compulsory on traders, and the magistrates at Brighton or anywhere else might at any moment put it in force.

Mr. MACKAY said it was perfectly certain that all chemists came under this Act of Parliament, and he should be sorry if the publication of Mr. Symes's remarks led any chemists to suppose that they might go on with their old measures, whereas at any moment the local authority might go in and test the accuracy of those measures.

Mr. SYMES said he had evidently been misunderstood. He never suggested that the Act was permissive; all he said was that according to the information that had as yet been obtained, the local authorities were not compelled to obtain standards, and that he still adhered to.

Mr. HAMPSON said he supposed the local authorities would employ inspectors to see whether weights and measures were stamped. The position of Mr. Symes was perfectly tenable; if the local authorities did not use the standards, and did not employ inspectors, certainly the Act would not be in operation.

Mr. ATKINS thought no inspector would go round to inspect weights and measures under the new Act unless he had the standards in his possession and used them, and no magistrate would convict otherwise. The first thing would be for the local authorities to adopt the Act; up to that point it was permissive. The standards having been obtained, after a certain time the inspector would go round and give notice that he was prepared to test the weights and measures; but until that preliminary step had been taken, he was quite sure that no magistrate would convict.

Mr. GREENISH took it that whether local inspectors were appointed in Dover, Brighton, or elsewhere, it would be incumbent on every chemist using dispensing measures to see that they were verified.

Mr. RIMMINGTON did not think Mr. Greenish was quite correct. Unless notice had been given that the Act would be put into operation there was no likelihood of anyone being interfered with.

Mr. WOOLLEY said that in Manchester the inspector of weights and measures told him that no action would be taken in Manchester until the trade had been all properly advised beforehand.

Mr. MACKAY said the inspector in Edinburgh was to give the Local Secretary information when he was prepared to verify, but he looked to the Local Secretary to advise chemists and druggists as to the fact. No inspector would undertake to give information to every one.

Mr. FRAZER said in Glasgow the inspector was going to send a printed notice to every chemist and druggist when he was prepared to verify the weights and measures.

The PRESIDENT said that was probably by private arrangement. The law was published and was binding on every one without further notice. He would also state that measures could now be bought verified. The Westminster inspector had been for a week or two prepared to verify the measures. The Marylebone inspector had also called on him, saying that he was in a position to do so. What was legal in one district would be legal in another, and he hoped all chemists would prepare themselves to obey the Act.

Mr. SHAW said there was a great deal of uncertainty with regard to the character of this Act. A short time ago he saw that an Alderman of Bath had moved a resolution in the town council that it was not desirable to procure standards for the verification of apothecaries' weights and measures. If such a resolution were passed it would seem to imply that no action would be taken, but at the same time the sellers might be liable if any one thought fit to prosecute them for using measures not verified. He produced patterns of stencil plates which were about to be used in Liverpool for marking measures.

Mr. SYMES proposed moving that it was not expedient to take any further action in this matter.

The PRESIDENT remarked that no one proposed to take any. The Council had simply to pass on to the next business.

NOMINATIONS FOR COUNCIL AND AUDITORS.

The Secretary reported that there had been *thirty-seven* nominations to fill the fourteen vacant seats on the Council, and the following *nineteen* nominees had signified their willingness to accept office if elected:—

Andrews, Frederick, 23, Leinster Terrace, Hyde Park, W.
Atkins, Samuel Ralph, Market Place, Salisbury.
Butt, Edward Northway, 13, Curzon Street, Mayfair, W.
Frazer, Daniel, 113, Buchanan Street, Glasgow.
Gostling, Thomas Preston, Market Hill, Diss.
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Hampson, Robert, 205, St. John Street Road, E.C.
Hills, Thomas Hyde, 338, Oxford Street, W.
Mackay, John, 119, George Street, Edinburgh.
Postans, Arthur William, 35, Baker Street, W.
Radley, William Valentine, 7, Hampton Road, Southport.
Sandford, George Webb, 47, Piccadilly, W.
Savage, William Dawson, 4, Park Road East, Brighton.
Schacht, George Frederick, 7, Regent St., Clifton, Bristol.
Shepperley, George, Long Row, Nottingham.
Spink, Harry N. B. 3, Marsham St., Westminster, S.W.
Squire, Peter Wyatt, 277, Oxford Street, W.
Symes, Charles, 14, Hardman Street, Liverpool.
Wills, Geo. S. V., 116, St. George's Rd., Southwark, S.E.

Six nominations for Auditors had been received, and the following *five* had signified their willingness to accept office if elected:—

Hodgkinson, William, 127, Aldersgate St., London, E.C.
Lescher, Frank Harwood, 60, Bartholomew Close, London, E.C.
Stacey, Samuel Lloyd, 300, High Holborn, London, W.C.
Thompson, Henry Ayscough, 22, Worship Street, London, E.C.
Watts, William Manning, 32, Lower Whitecross Street, London, E.C.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Amoore, Lewis Perigoe ....Twickenham.
Arnfield, John Cash ....Shrewsbury.
Goodall, William Anthony ......London.
Howse, Charles Turk ....London.
Remfry, Samuel Alfred ....London.
Williams, Thomas Henry ......Yeovil.
Wise, Joseph Norman ....Stanwix.

Chemists and Druggists.

The following registered Chemists and Druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Kay, James Petrie ....Aberdeen.
Potts, Robert Alfred ....London.
Stacy, Frederick ....Upper Norwood.
Venables, George ....Pussellawa, Ceylon.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Barnes, Edward......................Godalming.
Crowther, William Fearne ......London.
De Carle, Horace Edward ......London.
Evison, William ....Waltham, Grimsby.
Homes, Joseph Peter ....Oldbury.
Howell, William ....King's Lynn.
Jepson, Alfred ....Pontypridd.
Jones, Charles ....Loughborough.
McConnal, Alan ....Dudley.
Marsden, William...................Manchester.
Ratcliffe, George ....Waterloo.
Smith, Joseph ....Weymouth.
Stephenson, Robert ....Bradford.
Street, Walter Charles............Louth.
Thomas, Thomas Gratton ......Bagillt.
Thompson, Harry...................Bedford.
Whitlamsmith, Walter............Preston.
Wise, James ....St. Neots.

Modified.

Parkin, Charles.....................Doncaster.

ASSOCIATES.

The following, having passed their respective examinations, and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Carruthers, Robert ....Dumfries.
Coleman, Edward ....Kidsgrove.
Davies, John ....Haverfordwest.
Hay, Henry Scott...................Insch.
Hutcheon, William ....Montrose.
Knott, Henry Archer ....Walthamstow.
Lonnon, Frederick ....Plymouth.
Parker, William Marris ....Walcot.
Pigott, Samuel ....Manchester.
Price, Frederick ....Liverpool.
Pringle, George......................Pathhead.
Thornley, Frederick ....Devizes.
Webb, William Henry............Hereford.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Bates, Edward ....Bicester.
Brown, Ernest Ansell ....Margate.
Burton, Edmund ....Totnes.
Chaston, Alfred Edward ....Winchester.
Clark, Harry ....London.
Davies, Edward Charles James..London.
Davies, Rees ....Swansea.
Farquhar, Robert Forbes.........Aberdeen.
Hamnett, Thomas ....London.
Maillard, William Job............Brecon.
Neve, Annie ....London.
Nichol, Henry Walter ....Bedford.
Pearce, Thomas Ellery............Tavistock.
Rees, Rice William ....Swansea.
Skyrme, Henry Edward ....Cardiff.
Smyth, Thomas Spring............London.
Thompson, Arthur ....Buxton.
Tupholme, Frank ....London.
Wright, George Cornelius W....Leeds.

RESTORATION TO THE REGISTER.

The name of the following person, who had made the required declaration and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:—

John Thomas Watts, High Street, Hampton Wick, Middlesex

ADDITION TO THE REGISTER.

The Registrar reported that—

John Bennett, 10, King Street, Derby,

having made the statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and the declaration having been supported by a duly qualified medical practitioner, his name had been placed on the Register.

HONORARY MEMBERS.

The Council went into committee to select names for election next month as Honorary Members. One name was selected and ordered to be exhibited in the Library until the next meeting of Council.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was read, and sundry accounts recommended for payment. An application for a subscription to the Parochial Schools Building Fund had been made, but the Committee had decided not to recommend it being granted, the Vice-President stating that the view taken by the Committee was that benevolent objects did not come within the proper scope of the Society's expenditure.

The report and recommendations of the Committee were received and adopted.

PAYMENT FOR PAPERS READ AT EVENING MEETINGS.

Mr. MACKAY desired to make some remarks on one of the items of expenditure just passed, viz., "Contributions to the Journal." There was a considerable amount of "haze" about this subject still in the north, as would appear from some correspondence he would read between a gentleman who had read a paper at a meeting of the North British Branch and the Editor of the Journal. From this it appeared that the Editor looked upon papers read before the Society as part of the Society's Transactions, the publication of which was one of the objects of the Journal, and that he never thought of paying for such papers when published in the Journal. Now that seemed scarcely consistent with the fact that six papers were announced to be read that evening downstairs; for which payment would be made in the ordinary way. What he was desirous the Council should do, if possible, was to lay down some general rule. It was not consistent that payment should be refused for a paper which showed a considerable amount of research, and which had been obtained in order to render an evening meeting in Edinburgh more attractive, simply because it had been read there, and yet similar papers should be paid for if read in London. Having referred to the discussions which took place in January and February, 1879, he again expressed his desire that some intelligible and consistent rule should be laid down.

Mr. Symes was about to address the Council, when

Mr. Hampson suggested that it was desirable some motion should be proposed before any further discussion took place.

Mr. Williams thought this question ought not to be settled by any vote of the Council without consultation with the Editor. It would be better to refer it to the Library, Museum and Laboratory Committee to confer with the Editor and report.

Mr. Greenish said Mr. Mackay's complaint was that there was a difference made between papers read at the North British Branch and those read in London. He would ask if the Editor had any option with regard to papers read at the North British Branch, or whether he was not obliged to publish them as part of the Transactions.

Mr. Mackay said this was one of the mysteries which he could not understand. In Edinburgh, they could not tell where the papers were to go, or how they were to be judged. In London there was a committee to consider papers submitted, but there was no such committee in Edinburgh. If it were thoroughly understood that all papers must be submitted to the London committee if they were to be paid for, well and good; but it was felt by gentlemen in the north that their labour was not recognized in the same way as that of other persons who provided material for the Evening Meetings in London. A further question was whether the Council should go beyond the North British Branch, and extend the same rule to provincial societies. The Journal was now going on very well, and he thought could well afford to pay for what was deemed worthy of appearing in its columns.

Mr. Symes hoped this question would be considered from a wider point of view than that of Edinburgh only, and include papers read at provincial meetings. Those who had to obtain papers for provincial societies ought to be able to offer to gentlemen who took pains and trouble the same recompense which those in London received.

Mr. Mackay said he would move that the whole matter be referred to the Library, Museum and Laboratory Committee.

Mr. Shaw said he claimed the same privilege for Liverpool, Manchester and other places in the country as was claimed for Edinburgh.

The President said the two matters were quite distinct. A paper read before the Society became the property of the Society, but papers read before provincial associations were not the property of the Pharmaceutical Society, and the Editor was not bound to publish them, or even at liberty to do so, unless sent by the authors. It was quite within the discretion of the Editor when he received a paper from Liverpool, for instance, to accept it and pay for it; but according to his, the Editor's, view he was debarred paying for a paper read in Edinburgh, because it was the property of the Society already.

Mr. Mackay also pointed out the distinction between provincial associations and the branch in Edinburgh, which was really part of the Society.

Mr. Greenish remarked that all papers read in London had to be previously approved by the Committee, but the Committee had no control over either the length or quality of the papers read before the North British Branch. He should like to see this matter settled once for all, for it was by no means encouraging to members of Council to bring forward papers at the Evening Meetings if there were these constant discussions raised about the payment. He could only say that any payment allotted for a small paper he was about to read would hardly pay him for the expense out of pocket in preparing it, to say nothing of the time.

Mr. Mackay then moved and Mr. Williams seconded—

"That the Library, Museum and Laboratory Committee be requested to consider the desirability of payment for papers read at the Evening Meetings of the Society in Edinburgh when published in the Society's Journal, as contributions thereto."

The Vice-President thought it would be better to refer the whole matter to the Committee, including payment for papers read at provincial associations. There was a strange muddle about the whole arrangement, under which there was a pretence that no payment was made for providing papers for the Evening Meetings in London, though in some way the authors were always paid. He had always contended that it was a legitimate expense in connection with the Evening Meetings, and did not approve of charging it on the Journal.

The President said there was another motion being prepared which would deal with the question of papers read at provincial meetings.

Mr. Mackay again explained the difference between Edinburgh and other provincial towns.

Mr. Symes said there was no doubt a difference, but he did not agree that it was quite so wide as had been represented. The provincial associations were more or less connected with the Society, and the Council should do all they could to encourage that connection.

The motion was then carried unanimously.

Mr. Symes moved and Mr. Shaw seconded—

"That the Library, Museum and Laboratory Committee be requested to consider the desirability of payment for papers read before provincial associations when published in the Society's Journal, as contributions thereto."

The motion was agreed to unanimously.

Reports of Committees—*continued.*

BENEVOLENT FUND.

The report of this Committee included a recommendation and the following grants:—

£5 to a registered chemist and druggists, formerly in business.

£10 to a registered chemist and druggist, suffering from paralysis induced by a stroke of lightning. Applicant had a grant of £10 in September last.

£5 to the widow of a pharmaceutical chemist and member, who has had two previous grants, amounting to £25.

£5 to the widow of an annuitant, and an unsuccessful candidate at the last election. She has had several previous grants.

£5 to a registered chemist and druggist (subject to the approval of a member of the Society resident in the locality).

£10 to the widow of a late member (subject to similar conditions as above).

£10 to the daughter of a late member. She has received twelve previous grants of £10 each.

£15 to the widow of a recently deceased registered chemist and druggist.

Some applications stood over in consequence of grants having been recently made to the applicants, and in the case of an annuitant whose conduct had more than once been under consideration, and who had refused to comply with the requirements of the Council, it was recommended that the annuity be suspended.

The Council went into committee to consider some of the cases mentioned in the report. On resuming, the report and recommendations of the Committee were unanimously adopted.

Benevolent Fund, 1879.

The Secretary presented the following statistics with regard to the Benevolent Fund:—

		£	s.	d.	
161 subscribers	at 2s. 6d. =	20	2	6

LIBRARY, MUSEUM AND LABORATORY.

The Librarian's report had been received and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
February	Day	336	22	9	14
	Evening	198	14	6	10 nearly.

Circulation of books.	Town.	Country.	Total
No. of entries	141	93	234

Carriage paid . . . . . . £1 14s. 1d.

The following donations to the Library had been reported, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Madsen, H. P., Sur la Solubilité des Calculs Urinaires dans les Solutions de Benzoate de Lithium et de Boro-citrate de Magnésium, 1879.
From the Author.

American Pharmaceutical Association, Committee on the Revision of the United States Pharmacopœia, Report by C. Rice, Chairman, 1880.
From Mr. Charles Rice.

Royal Society of New South Wales, Journal and Proceedings, 1878, vol. 12.

New South Wales, Department of Mines, Annual Report for 1877.
From the Royal Society of New South Wales.

Hogg, J., Arsenic and Arsenical Domestic Poisoning, 1879.

Carr, H., Poisons in Domestic Fabrics in Relation to Trade and Art, 1880.

Our Water Supply: A Discussion for and Against the Fitness of Thames and River Water for Domestic Use, 1880.
From Mr. Jabez Hogg.

Flückiger, F. A., Pharmacognostische Notizen aus Alexander Trallianus, 1880.
From the Author.

Boe, F. de le, Practice of Physick, 2nd ed., 1717.

Royal College of Physicians of London, Pharmacopœia, Translated by T. Healde, 3rd ed., 1788.
From Mr. C. Biddiscombe.

Wernitz, I., Über die Wirkung der Antiseptica auf ungeformte Fermente, 1880.
From Professor Dragendorff.

The Librarian had also reported that one of the missing books had been returned to the Library, viz.:—

Bloxam, C. L., Metals, 2nd ed., 1871.

The Committee recommended the purchase of the following works for the Library:—

Russian Pharmacopœia, 3rd ed., 1880.
Monatshefte für Chemie, etc.
La Farmacia Moderna, Rivista Bimestrale.
Cooley, A. J., Cyclopædia of Practical Receipts, 1880. (A second copy for reference.)
Frankland, E., Water Analysis, 1880.
Schorlemmer, C., Rise and Development of Organic Chemistry, 1879.
Schmidt, E., Ausführliches Lehrbuch der pharmaceutischen Chemie, 1879-80. Bd. 1. Bd. 2 when published.
Schwanert, H., Lehrbuch der pharmaceutischen Chemie, 1880. Bd. 1. Bd. 2-3 when published.

The Curator had reported the average attendance in the Museum to have been:—Morning, 14; Evening, 3.

The following donations to the Museum had been received:—

Specimens of Loxa Bark unusually rich in quinine.
From Messrs. Benton and Schloss, through Dr. Paul.

Fruits of the Cotton Tree.
From the North British Branch.

Mikania Guaco, Tayuya Root and Baycuru Root.
From Dr. Symes.

A Mounted Gourd and Bombilla used in drinking Paraguay Tea.
From Messrs. T. Christy and Co.

Herbarium Specimens of *Mentha Canadensis*.
From Professor Asa Gray.

Specimens of *Adonis vernalis*.

From Messrs. Corbyn, Stacey and Co.

Specimens of Nux Vomica Bark, Chiquiqui Bark and Pods of *Cassia moschata*.

From Messrs. Morson and Son.

Bark of *Cinchona officinalis*, var. *pubescens*, and "China cuprea."

From Mr. J. E. Howard, F.R.S.

The Professors had attended the Committee and reported on their respective classes.

Professor Redwood had submitted for inspection some proof sheets of the 'Progress of Pharmacy.'

A proof copy of the Journal Index had been submitted, and the Committee recommended that one thousand copies be bound similar to the Calendar, and that the price to non-subscribers be 2*s.* 6*d.*

At an adjourned meeting the draft annual report had been considered, and ordered to be printed for the use of the Council.

A letter from the Professors had also been read suggesting certain alterations in the mode of teaching, but its consideration had been deferred.

The Secretary had reported that the Catalogue of the Library was nearly completed, and the Committee recommended that the published price be fixed at 2*s.* 6*d.*

Several letters had been received with reference to the exhibition of apparatus and preparations at the approaching Annual Meeting.

Mr. Symes said it occurred to him that there were many people who would be willing to send articles of interest to pharmacists, who might not see the Journal, to whom a special circular should be sent.

The Secretary said he had received two applications besides those mentioned in the report of the Committee.

Mr. Greenish thought that in so far as the number of applications received was a test, the exhibition seemed likely to be a failure, and the Committee felt much discouraged with regard to it.

Mr. Churchill thought if a circular were sent to manufacturers of chemical apparatus there was no reason why it should be a failure.

Mr. Squire thought the principal question was whether there would be any time to see these things.

Mr. Symes said that point had been already decided, and it was no use to try to throw cold water on the scheme now. It might succeed or it might not, and the Council would judge by what took place whether it should be repeated. He did not think it necessary to send circulars out, and probably other applications would come in during the present month.

Mr. Greenish said he had no desire to throw cold water on the scheme, he only reported the feeling of the Committee, arising from the small number of applications received from persons desirous of having space. It appeared to him there was no such thing as pharmaceutical apparatus; each individual obtained what suited his own requirements.

Mr. Woolley said there had been a very valuable arrangement of pharmaceutical apparatus exhibited at Manchester, sent from London. Each pharmacist had different requirements, but still they liked to see various apparatus, in order to be able to make a selection.

Mr. Robbins hoped it would be convenient to Mr. Symes to attend the next meeting of the Committee. There were many difficulties in the way, and he did not like sending out circulars to manufacturers inviting them to send apparatus, at considerable expense, when there might be very little opportunity of inspecting what was sent. He hoped it would not be supposed that the Committee were not doing their best in the matter.

The Vice-President said the only plan hitherto adopted for enlisting interest amongst manufacturers was an advertisement in the *Pharmaceutical Journal*; but that evidently had not been sufficient, and he saw no reason why an application should not be made to persons who had things to exhibit. It might be true to say that there was no apparatus specially used in pharmacy, but there was apparatus used in pharmacy extensively if not exclusively. He was in monthly receipt of a circular from a maker of gas-heating apparatus, which was very interesting, and such as he had purchased thoroughly answered the purpose designed. He should be glad to see the various articles which such an ingenious man manufactured. He thought with a little judgment a circular might be prepared and sent to some dozen or twenty persons, which would result in a very useful exhibition.

Mr. Hampson thought that as the Committee had this matter in hand it should do its best to make the exhibition a success; and he was anxious it should be so, because he believed it would be the forerunner of many successes. The credit of the Society was at stake in this matter, and he believed if the least encouragement were offered to exhibitors there would be many applications for space.

Mr. Savage said it was quite right of Mr. Greenish to state the facts, but these should rather be a stimulus to greater effort. The suggestion of a circular seemed a very good one, but the question of the time when the articles should be exhibited was of importance.

Mr. Williams said the Committee had no wish to do anything but forward this matter as far as possible. All the members of it felt that if they were to have an exhibition at all it ought to be one creditable to the Society, but when they came to look at the matter there were many difficulties in the way. The greatest difficulty of all was the question of time; if there were going to be an evening meeting, when the members could meet and inspect the things, it would be very simple, but the evening of the Annual Meeting was devoted to South Kensington and the previous evening to the dinner and, therefore, he feared the whole thing would fall through. There would be no objection to leaving the things on view for several days, but the question was, would there be any one to see them. It seemed to him doubtful whether it was fair to call on manufacturers to go to the expense of sending apparatus or pharmaceutical products, when really there would be no opportunity of their being properly and efficiently exhibited. Everything sent would be displayed in the best possible way, but it would not be right, in his view, to send round a circular specially inviting exhibits when they knew there would be but a scant opportunity of their being properly examined.

Mr. Atkins asked what amount of time there would really be for this exhibition, and also what space.

The President said the Museum table was allotted for the purpose.

Mr. Atkins said if the Committee issued many circulars there might be a sort of white elephant sent in the shape of some large piece of apparatus which there would be no means of exhibiting. Although he hesitated at the time, yet when the resolution was passed he felt all ought to be done that was possible to make it a success, and although the exhibition might be a comparatively small one, it might be made the starting point of more important ones in the future. Still it would be absurd to send out circulars to a large number of manufacturers, unless the Committee were prepared with adequate accommodation. But, after all, the great point seemed to be the time. A few days ago he attended a conversazione, and in one large room there was a very large audience listening to some beautiful music, whilst in an adjoining room, where some scientific apparatus was exhibited, some of which had been brought a considerable distance, and great trouble taken, there were not half-a-dozen people present the whole time.

Mr. Greenish said he hoped it would not be thought that he desired to throw cold water on the exhibition, for it was his intention to exhibit some apparatus himself.

Mr. Symes was very glad to hear this, for it did seem to him that the Committee had somewhat exceeded its duty. It was requested to consider the best means of carrying out this exhibition, not the worst; but it seemed to him it had rather reconsidered the desirability of carrying it out at all. He was astonished to hear Mr. Greenish say there was no pharmaceutical apparatus. If he had said that he (Mr. Symes) did not exist, he might believe him; but he could not believe that there was no pharmaceutical apparatus, for it was only by means of such things that he existed himself. He was not on this Committee, but should be very glad to assist in any way he could with a view to making the exhibition a success. It must not be supposed that it was for his special benefit; the resolution was carried by the Council for the benefit of the whole trade. He presumed the advertisement would be continued in the Journal and also in any other journal relating to pharmacy sufficiently important to attract the attention of manufacturers who did not take in the Journal of the Society, and if it pleased the Council to decide that circulars should be sent out, he should be glad to give the Secretary the names of half-a-dozen persons to whom one might be sent. The Council was told, on the one hand, that the exhibition would be so meagre there would be nothing to be seen, and on the other, that the house might be filled with white elephants. All he asked was that the Committee should make an effort to get a small but efficient exhibition of apparatus which would be interesting to pharmacists. He believed it would be inspected by many of the members, some of whom would no doubt prefer doing so to listening to the speeches at the Annual Meeting. He admitted the time was rather short, but there was no reason why the exhibition should not be open the day before, when the Trade Association held its annual meeting and a great number of chemists were in town.

Mr. Frazer thought the instance mentioned by Mr. Atkins was hardly appropriate, because at a conversazione all sorts of people were collected together, but here they would be all pharmacists, and he apprehended the exhibition would be specially interesting to them.

The President said the advertisement would continue to appear, and the Committee at its meeting next week would no doubt do its best in other ways to get together a good collection.

The report and recommendations of the Committee were received and adopted.

The Council then went into committee to consider the draft annual report, and after a few amendments it was remitted to the Committee to add anything which might appear necessary before the next Council meeting.

Local Secretaries.

On the motion of Mr. Savage, seconded by Mr. Bottle, Mr. J. R. Gwatkin was appointed Local Secretary for Brighton, in place of Mr. Gwatkin, deceased, and Mr. Frank Adams for Stoke-on-Trent, in place of Mr. A. F. Adams, retired.

House.

The report of this Committee was received and adopted.

Conversazione.

This Committee reported that it had held two meetings during the month, and interviews and correspondence had been had with the authorities of the South Kensington Museum. A letter had been received from the Lords of the Committee of Council for Education, granting the use of the Museum for the purpose of holding a Conversazione. The Committee also reported terms which the contractor was willing to accept so that refreshments might, on this occasion, be supplied at the expense of the Society, and which it was recommended should be accepted. The report and recommendations were unanimously adopted.

General Purposes.

The Committee reported that it had received reports from Professors Redwood and Bentley as to the prize examinations at the end of the first course.

Professor Redwood had reported that thirteen students in his class had competed, six of whom had obtained sufficient marks to entitle them to recognition.

Professor Bentley had reported that fourteen students in his class had competed, to five of whom he recommended the award of some distinction.

The Committee having opened the envelopes marked with the mottoes named by the Professors, in order to ascertain the names of the competitors, recommended that the following awards be made:—

Chemistry and Pharmacy.

Bronze Medal	William Elborne.
Certificate of Merit ...	Robert Wright.
" "	David Hooper.
" "	James Williams.
" "	William Fowler.

One student, Mr. E. C. J. Davies, recommended by the Professor for a certificate, being third on the list, was ineligible, not being an apprentice or student of the Society.

Botany and Materia Medica.

Bronze Medal	David Hooper.
Certificate of Merit ...	Robert Wright.
" "	William Elborne.
" "	William Fowler.
" "	John Thomas.

The report also included the usual report from the Solicitor with regard to cases placed in his hands, and enclosed a cheque for the amount of penalty and costs paid in two cases.

Another case of alleged infringement had been reported, and the Committee recommended that the Solicitor be instructed to take proceedings.

The Society v. the London and Provincial Supply Association.

The Solicitor also had stated that he had taken immediate steps for appealing to the House of Lords from the decision of the Court of Appeal in the case of the Society *v.* The London and Provincial Supply Association.

The report and recommendations were received and adopted.

The President drew attention to a set of apothecaries' weights which had been purchased for the Society, from ½ grain to 10 oz., and which Mr. Chaney, of the Standards Office, Westminster, had kindly verified.

Mr. Williams moved—

"That the thanks of the Council be given to H. J. Chaney, Esq., of the Standards Department, Board of Trade, for verifying and stamping a set of apothecaries' weights for the Society."

Mr. Squire seconded the motion, which was carried unanimously.

The Sale of Patent Medicines containing Poisons.

The President read a communication which had been received from the Stockport Chemists and Druggists' Association, enclosing a resolution to the effect that the Association desired to press on the Council of the Pharmaceutical Society the necessity of obtaining powers so that licences for the sale of patent or proprietary medicines should be only granted to persons on the register of the Pharmaceutical Society.

PHARMACEUTICAL MEETING.

Wednesday, April 7, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT, IN THE CHAIR.

The minutes of the previous meeting having been read and confirmed,—

The President drew attention to various specimens of drugs and preparations which were placed on the table, and suggested that, as there were several papers to be read, Mr. Holmes should give any information about them which might be desired at the close of the meeting. There was one matter which Mr. Williams would mention relating to poison bottles.

Mr. WILLIAMS said the bottles on the table had been invented or suggested for general use by Dr. Brushfield, of Brookwood Asylum, Surrey. The doctor stated that he found in practice that nurses who had been using fomentations, and persons with hard hands, did not always readily detect in the dark the feel of the ordinary fluted poison bottles. These now exhibited were conical in shape, and could not possibly be mistaken, even in the dark, for an ordinary bottle containing medicine for internal use.

At the request of the Chairman, Professor Attfield gave an abstract of a paper on—

THE VOLUMETRIC ESTIMATION OF ALKALOIDS BY SOLUTION OF THE IODIDES OF BISMUTH AND POTASSIUM.

BY J. C. THRESH, F.C.S.

The paper is printed at p. 809, and gave rise to the following discussion—

Mr. LUFF wished Mr. Thresh were present to answer some questions he should like to put to him, but perhaps Professor Attfield, who had evidently given his attention to the paper, might be able to dispel some of the illusions which had arisen in his own mind. He was not quite sure whether the object of the paper was to determine the compositions of the various precipitates produced by a solution of iodide of bismuth with the alkaloid, so that from their formulæ a process might be devised for estimating alkaloids volumetrically, or whether it was simply intended to show that very accurate results might be obtained by starting with known quantities of pure alkaloids. The paper seemed to start with the former object, and then to turn off and terminate with the latter. If the process were to be of general utility, and no doubt such a one was much wanted, the formulæ of the precipitates must be accurately known in order that the quantity of alkaloids could be calculated from them. As far as he could make out, in only one instance had Mr. Thresh made an analysis of the precipitate, the double iodide of bismuth and hydriodate of quinine; but in his estimations of the different samples of quinine, he abandoned that formula altogether, and selected an entirely different one, for what purpose he could not imagine, but was loth to suppose it was because it was the only one which would agree with his results. Again, one of the formulæ given, from which he calculated results, contained "x" number of molecules of hydriodic acid. He did not know what that meant, unless it were that any number could be taken which would agree with the results obtained. Towards the conclusion he mentioned that assays of various preparations might be made by means of the solution, and particularly stated that the strength of different preparations of aconite might be determined. In order to do this, he mentioned that he had made various experiments with different aconitine preparations, and had also made two assays of samples of aconitine. These two were remarkably exact, only erring in the third place of decimals; but unfortunately they were calculated from a formula which was entirely wrong, it being given as $C_{54}H_{40}NO_2$, whereas the true formula of aconitine was $C_{33}H_{43}NO_{12}$. The molecular weight used also was 734, instead of 645, and yet with a molecular weight nearly 100 too high he got results which only erred in the third place of decimals. If Mr. Thresh would not think it impertinent, he would advise him to make careful quantitative analyses of these various precipitates, for in that way he would lay a basis on which he could construct a process, which there was no doubt was much wanted for volumetrically determining alkaloids.

Professor ATTFIELD said as far as he could see Mr. Thresh had not proposed to himself to do what Mr. Luff fancied. The author had not primarily set himself the task of ascertaining the composition of the various precipitates which were obtained on adding the volumetric reagents to solutions of alkaloids. In the earlier part of the paper it was clearly stated that the precipitates first obtained were not constant in composition, because varying quantities of reagent were required for constant quantities of alkaloid. From the fact that solutions of known composition had been used, both as regarded bismuth reagent and the quinine, the author thought he could approximately give the composition of the precipitates obtained. That was all. The precipitates did, no doubt, vary from each other considerably, according to the varying conditions of precipitation. But the author said he thought he had arrived at such conditions of experiment that one variety of precipitate was constant in composition; at all events, he got constant quantities of the reagent used for constant quantities of pure salt employed; and that being so, he considered he could recommend the use of the liquid as a volumetric reagent for the precipitation of alkaloids generally. That seemed to be the primary object of the experiments. Then Mr. Thresh went on to confirm these results by applying his reagent to solutions of cinchona bark and other drugs which had been examined gravimetrically, and found the volumetric solution gave figures corresponding fairly closely with those previously obtained by recognized methods of analysis. Hence the inference that the reagent would be valuable in estimating the alkaloidal strength of those drugs. He (Professor Attfield) did not understand that the author pretended to go further that that. No doubt he could go very much further, and possibly when he had read Mr. Luff's remarks he would be induced to continue the investigation, for obviously the chemistry of this matter was one of great interest.

Mr. MOSS said Mr. Luff had already said a good deal which had occurred to himself, but he did not quite come to the conclusion that Mr. Thresh intended these formulæ to represent definitively the precipitate obtained by the process he had described. He thought he put them down as representing approximately the composition of the precipitate which would be produced, using that preparation of volumetric solution and of alkaloid. It was perhaps rather a pity that he had published these formulæ, because they could not be in many instances correct, and the one to which Mr. Luff referred where he put "xHI" puzzled him a good deal. Of course they knew that x meant an unknown quantity, and when he went on to say that from that formula he calculated results, his speculation rose into wonder. If he could get results on which he could depend from data which he did not know, it would often be extremely useful. But whatever opinion might be entertained as to the merits of the paper, and he believed there was great merit in it, there could be no difference of opinion that Mr. Thresh had occupied himself usefully and industriously, and had put a great deal of work into it. He had shown that a certain quantity of the volumetric solution corresponded to a definite quantity of alkaloid; and he might prosecute his researches further and perhaps evolve a process which would enable them to determine the quantity of alkaloids in all kinds of vegetable solutions and infusions.

A vote of thanks was passed to Mr. Thresh for his paper.

The next paper read was on—

THE HISTORY OF ARAROBA.

BY THOMAS GREENISH, F.C.S.

The paper is printed at p. 814.

Previous to the discussion the CHAIRMAN read the following extract from a letter that had been received from Professor Thisleton Dyer on the subject of the paper:—

"The paper on Goa powder is an illustration of a very curious and interesting class of phenomena. The mode of formation of the very curious body known as *eagle wood* appears to me to be analogous. I do not myself see any great objection to the use of the term 'degradation,' for the introduction of which I believe I am partially responsible. The conversion of the cellulose walls of the cells of the medullary rays of *Astragalus* into mucilaginous tragacanth involves a complete destruction of the organic structure of the tissues concerned and their replacement by a substance which is incapable of playing any part in the vital economy of the plant, but which, on the contrary, by its disruptive effects, is positively injurious. The formation of tragacanth, like that of cork and gum, implies the death, and is the commencement of the decay of the tissue involved."

Mr. Greenish also read the following passage in a letter from Professor Bentley:—

"Is not 'araroba' one of the secondary products of metastasis rather than an ordinary degradation product? The term degradation is certainly a bad term, owing to the poverty of our language as compared with the German, but surely even in our language it means something more 'than a rubbing down of cell tissue.' Of course, what is intended is that which you have stated, a change in the organized structure of the plant, so that the substances thus produced can never be reconverted into materials capable of forming cells, walls or protoplasm, or in other words, '*constructive materials.*'"

Mr. Balmanno Squire said he could not discuss this subject pharmaceutically, but he was interested in the therapeutics of chrysophanic acid, and was indebted to the Society for nearly all the information he had about it. A little while ago it was only a quack or secret remedy in India, but owing to the researches of Professor Attfield it was discovered that chrysophanic acid was the proper name for its chief constituent; Mr. Holmes had shown its botanic origin, and now they had an explanation of how it came to exist in the tree to which Mr. Holmes and some Portuguese physician had traced it. It was formerly used in India for ringworm, for which it was now scarcely used at all, being now employed for a disease of another character entirely. It had now attained a world-wide reputation, chiefly through the light thrown upon it by the Society, for he had lately received a very excellent paper upon it from Australia. Dr. Neumann, of Vienna, said it was one of the most valuable remedies which had been introduced during the last ten years, and through the increased demand for it its price had been much reduced, for formerly it was sold for about 10*s.* 6*d.* an ounce. It was originally attributed to Africa, but now it turned out to belong to America, and to be due to a degradation of tissue; so he supposed it had come almost to its last legs, and its popularity might perhaps begin to wane. In Vienna of late, and also in Paris, pyrogallic acid, which had a nearly allied composition, had been tried as a substitute. It had much the same therapeutic effect, but was not so active nor valuable, though it produced the same irritant effect on the skin. Another attempt had been made by Dr. James Thomson, in Scotland, and also in Vienna, by Dr. Jarrisch, to use alizarine for the same purpose, but not so successfully. One fact connected with the use of pyrogallic acid was rather discouraging, however. A German physician rubbed a patient suffering from psoriasis all over on one side with chrysophanic acid and on the other with pyrogallic acid, the result being that the patient died; this the physician attributed to the powerful deoxidizing effect of the pyrogallic acid on the tissues in the presence of an alkali; his theory being that when it got absorbed into the blood, the patient became asphyxiated, as the blood could not be oxygenated in the lungs. This was the only fatal case on record. Chrysophanic acid had no drawback of that kind, and the researches of Mr. Ashburton Thomson established that it was by no means a dangerous drug taken internally. He had administered it in two or three hundred cases, and found that it only acted as an emetic and purge, and to produce these effects it required to be given in fairly large doses—10 to 20 grains.

Mr. Symes said he had brought several samples of araroba as it occurred in commerce, one being rather interesting as it was an old specimen, and yet being light in colour. He had it in the paper in which it came from the brokers, which was dated May 20, 1847, and yet it was not so dark as the others, tending to show that exposure to the air was necessary in order to produce the dark colour. He had not noticed the bitterness which Mr. Greenish had referred to, but it was rather a dangerous thing to taste, as it tended to produce sore throat. The amount of moisture was stated at 1·98, but he had never met with any containing so little, unless it had been kept in a very dry place. On the contrary, it was remarkable how much moistnre it would contain, and yet remain in a tolerably dry substance; he found it on arrival contain from 5 to 30 per cent. The paper gave an excellent *résumé* of the histology of araroba; and not only with regard to it, but many other substances they were certainly in comparative ignorance of the manner of production and the physiological influences which were at work. Mr. Greenish considered it was due to a metamorphosis of tissue, a breaking up of the cell, and had found cell tissue in the araroba. He (Mr. Symes) had taken lumps of chrysorobin which were deposited in the plant, and, when free from all exterior powder, had never found in the interior of them any cell tissue. Mr. Greenish also said that it must originally have been in the fluid condition, and he believed that was so; he had sliced and mounted sections of the wood, and in one he could see that the whole plant was thoroughly infiltrated with this fluid; but then they had to assume that that whole structure broke up into a fluid which had to traverse from one part of the plant to the other. First they were told that it was a breaking up of cell tissue, and secondly that it was a fluid which deposited itself in a cell tissue, and he could scarcely reconcile the two together. He thoroughly believed it had been in a fluid state, and that it deposited in something more than cells was quite clear, because masses of the comparatively pure substance could not possibly deposit in cells, and that was the form in which it was obtained. These lumps were not wood, they were masses deposited he believed in intercellular spaces in the plant. He had found Mr. Greenish's method of applying a solution of potash to the sections under the microscope very good, but as solution of potash darkened them considerably the structure was not well made out, and as the chrysarobin was very soluble in glacical acetic acid, he found subsequent treatment with that acid would dissolve out a further portion of the araroba, and leave the section more transparent, and the structure more distinguishable. Professor Attfield had made an exceedingly elaborate analysis of the araroba, and first separated what he called chrysophanic acid, but which was now known as chrysarobin. Benzole dissolved out from the pure substance about 80 per cent. of a bright yellow powder, but Liebermann and Seidler had further investigated this substance, and said it was not chrysophanic acid, but chrysarobin, and gave a process for preparing chrysophanic acid from it. He had a specimen there of the pure acid, which was obtained by putting chrysarobin in a solution of potash, and passing a current of air through it. It took about forty-eight hours to dissolve, and was then precipitated by hydrochloric acid, washed, dissolved and reprecipitated and crystallized out again from alcohol. The characteristics were perfectly distinct. He had prepared about one ounce of it, and sent some to one of the skin hospitals with the desire that they would compare its results with those of chrysarobin. They knew very well that the latter produced certain effects, and the question was whether pure chrysophanic acid would produce the same. He should be very pleased to hand over what he had there to Mr. Squire if he would kindly experiment with it. The distinctions given by Liebermann and Seidler were that strong sulphuric acid dissolved chrysarobin with a yellowish-brown colour, whilst the chrysophanic acid on the other hand dissolved with a bright red colour; but after a short exposure to the air they both became red so that that test was not very satisfactory. They also stated that in a weak solution of potash chrysarobin was comparatively insoluble, whilst chrysophanic acid dissolved with a red colour. That was a more marked test, but that was not quite satisfactory either, as after a short time there would be a reddish solution in both cases. He found that a more decided test was strong nitric acid. This dissolved very little chrysarobin, giving a brown colour, whilst the chrysophanic acid dissolved very largely with a bright canary colour.

Mr. HOLMES thought Mr. Greenish was probably correct in saying that the araroba appeared at first to be a fluid secretion. They all knew that the descending sap, which contained active principles or matters which had been formed by the plant, descended through the inner bark, and passed along the medullary rays, and from them to the porous vessels, and was so distributed in the surrounding tissue of the duramen. He had examined Dr. Symes's section of the wood, and had observed that the walls of the porous vessels and of the parenchymatous tissue immediately surrounding these vessels, which in a transverse section of the stem appeared as yellow dots from the quantity of araroba they contained, were not all disintegrated. He supposed, therefore, that the descending sap which contained the elements of araroba passed along the medullary rays and filled the porous vessels and surrounding tissue, and that the cause of there being large lumps of araroba in the wood was simply due to the same reason that balsam of copaiba would collect in enormous quantities in the trunk of the copaiba tree. It was well known that large cavities were often formed in trees by the pressure of liquid within them, and he had read that travellers had occasionally heard loud reports like a cannon caused by the fluid in the trunk bursting open trees; the solid lumps of araroba, one or two inches across, were, he imagined, formed in that way, from the fluid after a time becoming solid. He agreed with Dr. Symes that these solid lumps, as far as he had been able to observe, contained no sign of cellular tissue at all. With regard to the old specimen, which Dr. Symes showed, he had found that if araroba were at all moist it appeared to absorb ammonia from the air, and the slight trace of alkali thus obtained caused it to develop the purple colour, which alkalies always produced in this drug. He imagined that this old specimen was, in the first place, exceedingly dry, and not being exposed to air and moisture, had not absorbed ammonia, and so retained its colour.

Mr. WILLIAMS said the araroba which now came into the market appeared to contain a great deal more water than it formerly did. He remembered when 5 per cent. used to be considered quite sufficient, but he was sorry to say that the last he purchased contained 38 per cent. of moisture. A small sample dried incautiously at rather an elevated temperature, though far below that of boiling water, was very much darkened, and the chrysophanic acid yielded was so dark that it had to be reworked once or twice before it was fit for sale.

Mr. MOSS could not see any objection to the use of the term "degradation" in the way Professor Dyer would use it. Surely, in the English language, at all events, the meaning of a word depended, to a considerable extent, on the connection in which it was used, and in his mind "degradation" as applied to the rubbing down of rocks, and the breaking up and impoverishment of cell tissues, conveyed two very different ideas, which were, he thought, quite correct in each case.

Mr. POSTANS thought the meeting was much indebted to Mr. Greenish for this paper, and also for the beautiful diagrams by which it was illustrated. It was a curious thing that this Goa powder should have had so many names; even in India where it had been known for many years, and formerly sold at an enormous price, it had several appellations. The extended use of this drug was largely due to the excellent paper of Professor Attfield, which had been already alluded to. In that paper, however, he spoke of chrysophanic acid as a natural constituent of Goa powder, whereas it would appear evident now that it was an oxidation product. This could be seen by referring to the 'Year-Book of Pharmacy' for 1879, p. 62.

Mr. GERRARD said that in accordance with the suggestion made by Professor Attfield he had worked a considerable quantity of the residue of araroba after the chrysophanic acid had been removed for alkaloid, but, applying the usual reagents, he found no trace whatever of any alkaloid.

Mr. HANBURY said it might be worth mentioning that care should be taken by those who had occasion either to sift or powder araroba, for some time ago one of the men employed by his firm who was engaged in grinding a quantity had such an attack of inflammation of the eyes that for nearly two days his sight was in danger.

Professor ATTFIELD said there could be little doubt that the substance called Goa powder when first produced in the wood contained no chrysophanic acid as such, but that this acid was produced by the action of the air, and probably of moisture, on a substance which might be called chrysorabin, or which might be termed potential chrysophanic acid. It might be that Goa powder, as Mr. Squire hinted, might cease after a time to be popular, and it might be that the question of the mode of formation of the substance might also lose interest. But the interest attaching to the formation of such things in plants could not subside, and he thought that no class of men could better investigate this question than pharmacists,—whether they did so on this wood, or any other, whether they had to go to the Malabar coast or to Brazil, or found it amongst their forests at home—because it seemed to him to involve a knowledge of chemistry, microscopy and structural botany such as pharmacists commonly possessed. If pharmacists, especially those who had been educated during the last thirty years, would turn their attention to this matter, surely the question of formation—whether conversion of one tissue into another, or the production of a secretion, or the conversion of a fluid like honey into a granular substance like solid honey—might shortly be set at rest. He might add that of the different samples of Goa powder he had examined since Mr. Kemp of Bombay first put the article into his hands, some chiefly contained chrysophanic acid, others potential chrysophanic acid.

Mr. GREENISH, in reply, said his view of "degradation" was this, that when degradation applied to a sandstone rock he should find minute pieces of that rock as a deposit, and examining that under the microscope each particle would be a particle of the sandstone. Such was not the case with this; it was a total disorganization of the structure, and soluble in caustic alkali, whereas cell tissue was not. Dr. Symes assumed that he took the rough powder for examination, but that was a mistake; he used the interior portion of the lumps which Dr. Symes mentioned, and he had always found cell tissue. Mr. Holmes seemed to suppose that he believed the araroba of commerce to be deposited in the cells he had shown in the drawing, but that was not the case. The whole wood would be saturated with it, and the cell tissue more or less disorganized, but the lumps known to commerce were really found in clefts in the trees. When the tree was sawn asunder, and split up it was found in clefts and hollow places, not in cells. Still its being found in the cells was a curious feature, and was an argument in favour of its having been originally in a fluid form, for in no other way could it find its way into the centre of the wood. He did not think it was due to fungi, although in one sample he found in some of the sections a mycelium of fungus running through the medullary rays. His idea was that the starchy matters in the medullary rays first underwent decomposition, and the result following that was the fungus. He hoped some day to be able to separate that fungus from its means of nutrition, and force it into fructification, and then to be able to identify the fungus. With regard to the name, he believed it had the same derivation as arrowroot, which some authorities give as derived from an Indian word, "ara," meaning mealy or flowery, arrowroot meaning a mealy root. In the same way he believed the same native word "ara" was applied to the mealy part of the interior of the araroba plant.

A vote of thanks having been passed to Mr. Greenish for his paper, the Chairman said it was too late to take another paper that evening, but an extra meeting would be held on the 21st.

Mr. HOLMES called attention to one or two samples on the table, in particular to some Chian turpentine, which had been recently recommended in the *Lancet* by Dr. Clay, of Birmingham, as a remedy for cancer, in which disease it was given in conjunction with sulphur. In an editorial article in a subsequent number of the same journal it was stated that Chian turpentine was a honey-like liquid at first, and that it was difficult to procure. Several samples had been brought to him (the Curator) during the past few days for identification, and two of these he had found to be Venice turpentine. He thought it might interest some of the gentlemen present to see genuine specimens of the true Chian turpentine side by side with the false drug. The Venice turpentine was more honey-like in appearance than the Chian, and he believed that possibly some persons might have been misled by the article in the *Lancet*, which mentioned this character as distinctive of Chian turpentine. He also drew attention to the drug called "tonga," which has been recommended for neuralgia, and a specimen of which had been presented by Mr. A. W. Gerrard. Mr. Holmes said that he had been asked by that gentleman to examine it. He had done so, and had come to the conclusion that the active ingredient was the stem of a plant of the Arum family, belonging to the genus *Raphidophora*, and probably *R. pertusa*, var. *vitiensis*. He hoped to lay the details of his examination of this drug before them on a future occasion. There was also a specimen of Japanese belladonna root, concerning which he wished to mention that in preparing the note upon it which appeared in the Journal he had overlooked the fact that *Scopolia japonica* had been investigated in the University of Tokio, Japan, and found to contain solanine, and not atropine.

The meeting was then adjourned.

NORTH BRITISH BRANCH.

The sixth meeting of the session was held in the Society's rooms, 119A, George Street, Edinburgh, on the evening of Wednesday, March 24, Mr. J. B. Stephenson in the chair.

The minutes of the former meeting were read and confirmed.

The Honorary Secretary announced the following donations:—

To the Library:—*The Chemist and Druggist* with *Australasian Supplement*; 'First Report of the Pharmacy Board of Victoria'; 'The Pharmaceutical Register for 1879,' from the Pharmacy Board of Victoria; *The Journal of the Chemical Society* for March, from Mr. Mackay.

Dr. F. W. Moinet then read a paper entitled "Food and Work," which he illustrated by diagrams, and at the close of his lecture he received a hearty vote of thanks.

It is intended to print Dr. Moinet's paper in the next number of this Journal.

Parliamentary and Law Proceedings.

THE SALE OF FOREIGN PROPRIETARY MEDICINES.—PROSECUTION BY THE INLAND REVENUE AUTHORITIES.

On Wednesday last, at Marlborough Street Police Court, before Mr. Newton, Mr. Augustus Leamont, French chemist, of Wardour Street, was summoned by the Inland Revenue authorities, for selling foreign medicines without having a wrapper with the stamp provided by the Commissioners of Inland Revenue. A gentleman from the Solicitor's Office of the Inland Revenue Department prosecuted, and in opening the case said the proceedings were taken under the 52 Geo. III., cap. 150, for selling a bottle of foreign medicine and a box of foreign pills without having a proper stamp affixed, by which he had incurred two penalties of £10 each, the object of the prosecution being to warn chemists against selling foreign medicines without the stamps to which they were liable.

Mr. George Crisp Farmer, an officer of the Inland Revenue, proved purchasing a bottle of medicine at the defendant's shop, for which he paid 5*s*., and subsequently a box of pills, neither of the medicines bearing stamps.

The defendant said the medicines were sold by his new clerk by mistake without stamps.

Mr. Newton said if that were so the sooner the defendant changed his clerk the better.

The solicitor said that about a year and a half ago the Commissioners had their attention called to the fact that a large quantity of foreign medicines were being sold without stamps, and the medicines in question were bought as tests.

Mr. Newton said the defendant was responsible for the acts of his clerk. As the two purchases were made so near to each other he was afraid the defendant was in the habit of committing this offence. He should order him to pay 40*s*. and costs in one case, and 2*s*. costs in the other.—*Times*.

THE SALE OF DRUGS BY UNREGISTERED PERSONS.

Sir,—I fear that Mr. Tebbutt's hope of an extended and amended Pharmacy Act has very little prospect of realization when we find one of the judges in the late appeal case saying that the general feeling is against restriction, and rather suggesting that everyone should do what is right in his own eyes. To my mind there is more likelihood of the final appeal being heard at Tottenham Court Road, the legal reasoning in the late case, if thoroughly followed out, tending to the formation of an Universal Supply Association where the legal affairs of a nation of shopkeepers will be managed by those who know not the law. Nay, more, though the voice of the country is now against the Conservative Government, its members need not be long out of employment, as some Civil Service Store may be found willing to undertake the duties of the Foreign and other offices, and no doubt, sir, the former would be glad to engage the service of some nobleman of high political standing.

But, seriously, why do not the shopkeepers change this? It is said that one Conservative candidate owed his defeat in no small measure to a report that his printing had been done by the "stores," whilst in another quarter political capital has been made out of a statement that an eminent Conservative nobleman is a director of a Civil Service Store, so that I think the point should be for the "nation of shopkeepers" to unite and vote only for candidates who insist that civil servants shall do a fair day's work for their fair day's pay, and that their hours of business shall be at least as many as those of the majority of the traders who help to pay them. If they do not like this they had better live by shopkeeping at stores prices.

ALPHA.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Moore, White, Stokes, Walker, Brown, Elliman, Euretes, Scilla, No Surrender, A. J. S., A. Y. Z.

THE ALKALOIDS OF POMEGRANATE BARK.*

BY C. TANRET.

In March, 1879,† the author announced that in pursuing his chemical investigation of pomegranate bark he had established the fact that pelletierine, the alkaloid previously isolated by him, is accompanied in the bark by three other alkaloids, two of which, like pelletierine, are liquid and one is crystallizable, all four being volatile. In the present communication the author describes the principal properties of these alkaloids and the method adopted by him for their separation.

In the first place a mixture of the salts of the alkaloids is prepared by mixing the powdered bark with a milk of lime, exhausting with water, shaking the resulting liquor with chloroform and neutralizing the latter with dilute acid. A solution of the mixed alkaloids is thus obtained in which one or other of them predominates, according to the source of the bark. Two of the four alkaloids are displaced from their salts by bicarbonate of soda and two are not. This solution is therefore treated with an excess of bicarbonate of soda and shaken with chloroform, and this in its turn is agitated with dilute sulphuric acid. The resulting solution contains the sulphates of two alkaloids to which the names of "methylpelletierine" and "pseudopelletierine" have been given. Caustic potash is then added to the first liquor, and upon repeating the treatment with chloroform and acid, there is obtained a solution of the sulphates of "pelletierine" and "isopelletierine."

Methylpelletierine.—In isolating this alkaloid the author has adopted a method of fractional saturations. The mixture of sulphates obtained by treatment with bicarbonate of soda is partially decomposed by an alkali, then shaken with chloroform and this afterwards with an acid. The methylpelletierine is concentrated in the first portion set free, and after this treatment has been sufficiently repeated a point is reached at which the rotatory (dextro) power of the product is no longer augmented, and the salt so produced the author considers to be pure. To obtain free methylpelletierine a concentrated solution of one of its salts is decomposed by an alkali, and the alkaloid liberated is dehydrated over fragments of potash and distilled in a current of hydrogen.

This alkaloid is liquid. Analysis of its hydrochlorate, which has a rotatory power of $\alpha_D = +22°$, gave results corresponding with the formula $C_{18}H_{34}N_2O_2$. It dissolves in twenty-five times its weight of water at 12° C., is very soluble in alcohol, ether and chloroform, and boils at 215° C.

The salts of methylpelletierine are extremely hygrometric.

Pseudopelletierine is a crystalline alkaloid, and is obtained by concentrating the liquid from which the methylpelletierine has been removed, treating it with caustic potash, and shaking with ether. Upon evaporation of the solvent crystals are left, which can be obtained quite pure by repeated recrystallization. The composition of this alkaloid is represented by the formula $C_{18}H_{30}N_2O_2$.

Pelletierine.—The solution of sulphates obtained by the action of caustic alkali is evaporated over sulphuric acid, and when the residual mass is dry it is exposed to the air upon folds of blotting paper. It soon partially deliquesces, leaving on the surface of the paper scarcely hygrometric crystals, consisting of sulphate of pelletierine. The salt which penetrates the paper, and which if care be taken at the time to prevent its exposure to the air has no rotatory power, is the sulphate of isopelletierine.

The pure alkaloid is obtained by the same process as methylpelletierine, the precaution being used of distilling at a low pressure, ebullition at the ordinary temperature altering it rapidly.

Pelletierine is a liquid and colourless alkaloid when just obtained in a current of hydrogen, but it is remarkable for the rapidity with which it absorbs oxygen and resinifies. Its density at zero is 0·988. Analyses of its chloroplatinate and hydrochlorate lead the author to assign to it the formula $C_{16}H_{30}N_2O_2$. The alkaloid is soluble in the cold in twenty times its weight of water, of which it dissolves its own weight. It is soluble in all proportions of ether, alcohol and chloroform. At the ordinary pressure it boils at 195° C., distilling then with partial decomposition. Under a pressure of 10 centimetres the boiling point is lowered to 125° C.

Sulphate of pelletierine has a rotatory power of $\alpha_D = -30°$. If the free alkaloid be heated to 100° the rotatory power disappears.

Salts of pelletierine lose a portion of the base when heated either dry or in solution.

Isopelletierine is isolated in the manner just described. It is a liquid alkaloid, without action upon polarized light. Analysis of the hydrochlorate gave results corresponding to the same formula as pelletierine, of which it may be considered an isomer. Its density, solubility in water, and boiling point are the same as those of pelletierine.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 582.)

CURCUMA Sp.? AMOMACEÆ. *The rhizome. Vernacular*: AMBÉ-HALDI, JANGLI-HALDI (Hind., Beng., Bomb.); KASTURI-MANJAL (Tam.)? KATTU-MANNAR (Malay)?

History, Uses, etc.—This rhizome is the *zédoaire jaune* of Guibourt, who tells us that the plant which produces it has been well described and figured by Rumphius. It is his *Tommon bezaar* or *Tommon primum*, which has been wrongly referred by most writers to the *Curcuma Zedoaria* of Roscoe (Confer. Guibourt, 'Hist. Nat.,' 6ème éd., tome ii., p. 214). It would appear also that it is identical with the cassumunar described by Pereira and the turmeric coloured zedoary of Ainslie. (Confer. Pereira, 'Mat. Med.' vol. ii., part i., p. 236). Lastly it would appear to be the same as the Cochin turmeric noticed by Flückiger and Hanbury ('Pharmacographia,' p. 580). The porperties of this drug are very similar to those of turmeric, but its flavour is not so agreeable; in Bombay it is used medicinally in combination with other drugs as an external application to bruises, sprains, etc.

The plant grows wild in the Concan. I have not seen it in flower. The foliage is like that of the *C. Zedoaria*, Roscoe; pale yellowish green with a purple stain down the midrib of the leaf. A good deal of the drug is sent from Bombay to Europe, where it appears to be used as zedoary. A European chemists' firm in Bombay, writing home for zedoary root, was supplied with this article. The name cassumunar is probably a corruption of the Malay Káttu-mannar.

Description.—Central rhizome oblong or conical, often more than 2 inches in diameter, external surface dark grey, marked with circular rings and giving off many thick rootlets; lateral rhizomes about as thick as the finger, with a few fleshy rootlets; at the ends of some of the rootlets are orange yellow tubers about the size and shape of an almond in its shell. Internally the central and lateral rhizomes are of a deep orange colour like turmeric. The odour of the fresh root is like turmeric, but more camphoraceous.

Microscopic Structure.—Similar to that of turmeric.

Commerce.—The Bombay market is supplied from the Malabar Coast. Value, unpeeled Rs. 24—25 per kandy of 5¼ cwt.; peeled Rs. 24—27. I have the plant in cultivation, but it has not yet flowered. Can it be the *C. zanthorrhiza* of Roxburgh?

CURCUMA AROMATICA, *Salis.* AMOMACEÆ. *The rhizome. Vernacular*: KACHOORA (Hind., Beng., Bomb.).

History, Uses, etc.—This plant affords the round zedoary of Guibourt, which he tells us is the zerumbet of Serapion, Pomet and Lemery. The following is his description of the drug. "The round zedoary is greyish-white externally; heavy, compact, grey and often horny internally, having a bitter and strongly camphoraceous taste, like that of the long zedoary, which it also resembles in odour. The odour of both drugs is analogous with that of ginger, but weaker unless the rhizome be powdered, when it develops a powerful aromatic odour similar to that of cardamoms." ('Hist. Nat.,' 6ème éd., tom. ii., 213.) The round zedoary is one of the two zurambáds (zerumbets) described by Mahometan writers, the other being the nar-kachoora of India, which does not appear to be known in Europe.

Description.—Guibourt's description already given agrees exactly with the kachoora of India, but it is often cut into transverse slices instead of into halves and quarters.

Microscopic Structure.—This is essentially the same as that of turmeric, but the resin and essential oil in the cells are of a yellowish-white colour, and the greater portion of the starch grains are ovoid or pyriform instead of narrow and elongated as in turmeric.

Chemical Composition.—Zedoary contains, according to Bucholz (*Rèpert. Pharm.*, xx., 376), volatile oil, a bitter soft resin, a bitter extractive matter, gum, starch, etc. The oil is turbid, yellowish-white and viscid, has a camphoric taste and smell, and consists of two oils, one lighter, the other heavier than water. Trommsdorff obtained from the root a substance which he called zedoarin, but did not further describe it (Watt's 'Dict. of Chem.' vol. v., p. 1066).

Commerce.—The Bombay market is supplied with Kachoora from the Madras Presidency. Value, Rs. 20—30 per kandy of 7 cwt.

CURCUMA Sp. AMOMACEÆ. *The rhizome. Vernacular*: NAR-KACHOORA (Hind., Bomb.).

History, Uses, etc.—This drug is one of the two zurambáds of Arabic and Persian writers on materia medica and the nar-kachoora of India. Strange to say it is not noticed by recent writers on Indian materia medica, though it is a well-known drug and to be found in all the shops. Meer Muhammad Husain states that the plant blossoms from the centre of the leaves like turmeric, which it also resembles in foliage. Can it be the *C. viridiflora* of Roxburgh and tommon-giring *seu* giri of Rumphius (Amb. 5, 169)?

Description.—The drug consists of small globular central tubers, from which spring numerous lateral rhizomes about the size of the little finger. It is of a dark grey colour externally and marked with circular rings; internally it is very hard and horny, of a greyish-orange when cut in thin slices; odour camphoraceous, taste bitter and camphoraceous.

Microscopic Structure.—The minute structure of this rhizome hardly differs from that of the zedoary. The starch contained in the parenchyme cells has been altered by heat and appears as a finely granular mass nearly filling the cell. The resin cells are about as numerous as in the zedoary, but the contents are of a dull orange colour. The vascular system consists of scalariform and spiral vessels, most numerous at the junction of the central and cortical portions of the rhizome.

Commerce.—This drug is said to reach Bombay from Cawnpore. Value, Rs. 4—5 per maund of 41 pounds.

ALPINIA OFFICINARUM, *Hance.* AMOMACEÆ. *The rhizome. Vernacular*: CHOTA-KULIJAN, CHOTÉ-PANKI-JAR (Hind., Beng., Bomb.); SHITTA-RATTAI (Tam.).

History, Uses, etc.—Although this drug has been long known its botanical source was only discovered in 1870, when a description of the plant was communicated to the Linnean Society of London by Dr. H. F. Hance, made from specimens collected by M. E. C. Taintor near Hoihow in the north of Hainan (Confer. *Journal of the Lin. Soc.*, 1873, xiii., 6). Galangal is not much used in Hindu medicine. In Sanskrit works it is called "kulinjána," evidently a corruption of the Arabic khúlanján. Mahometan writers suggest that the drug may be the root of very old plants of *Piper Betle*, but they are evidently in doubt about its being produced by that plant (Confer. 'Makhzan,' article "Khulanján"). Meer Muhammad Husain describes galangal as tonic, stomachic, carminative, stimulant and aphrodisiac. He tells us that if given to young children it makes themt alk early, and that a paste of the powdered drug made with oil or water will remove freckles. The Persian name is khusrodáru. Galangal is one of the ingredients of Warburg's tincture. It is not used in English medicine, but there is a considerable demand for it in Russia. Irvine ('Med. Topog. of Ajmeer,' p. 171) says that the natives add kuliján to bazar spirit to make it more intoxicating.

Description.—The dried rhizomes are about as thick as the little finger or often less. They have evidently been cut into short lengths (2—3 inches) while fresh; many of the pieces are branched, and all are marked by numerous circular ridges of a light colour. The external surface of the rhizome is of a deep reddish-brown; the interior pale red, hard and tough; the odour is aromatic and the taste hot and spicy.

Microscopic Structure.—The bulk of the rhizome consists of a uniform parenchyma traversed by fibro-vascular bundles. Some of the parenchyme cells are full of resin and essential oil, but most of them contain large starch grains of an elongated or club-shaped form.

Chemical Composition.—Galangal contains from one-third to one-half per cent. of an essential oil which is the odorous principle. According to Vogl its formula is $C_{10}H_{16}O$. Brandes extracted from galangal with ether a neutral, inodorous, tasteless crystalline body, kampferide, which requires further examination. The resin, which is probably the acrid principle, has not been examined.

Commerce.—Galangal arrives in Bombay from Canton and other Chinese ports. The imports are about 400 quintals yearly. Value, Rs. 3 8a. per maund of 37½ lbs.

The Great Galangal, though not so much used as the lesser, is well known in Bombay as baré-pán-ki-jar, malabáree-pán-ki-jar or kost-kuliján. The native dealers all state that it is imported from the Malabar coast. This drug is generally considered to be produced by the *Alpinia galanga*, Swartz, a native of Java. It is easily distinguished from the lesser galangal by its larger size, orange-brown exterior and yellowish-white interior. It is also less aromatic and pungent. Value, Rs. 50 per kandy of 7 cwt.

Hedychium spicatum, *Smith.* Amomaceæ. *The rhizome. Vernacular*: Kafur-kachri, Kápoor-kachri (Hind., Beng., Bomb.); Shimai-kich-chilik-kizhangu (Tam).

History, Uses, etc.—I have not met with any account of this drug in native works on materia medica, which seems strange, as it is very well known and a considerable article of commerce in India and China and is also exported to Europe. Two kinds of kapur-kachri are found in the Bombay markets, viz:—Chinese and Indian. The latter was supposed by Royle to be the sittarittee or lesser galangal of Ainslie ('Mat. Ind.,' vol. i., p. 140), but Moodeen Sheriff states that the sittarittie of the Tamils is the true lesser galangal, which statement appears to be correct. Kapur-kachri is used in perfumery, and to preserve clothes from insects. The Indian is preferred.

Description.—Indian kapur-kachri occurs in slices mostly circular, but sometimes the section is made in a sloping direction. The slices are half-an-inch or less in diameter and vary much in thickness; they are white and starchy and when freshly pared exhibit a faint line dividing the cortical from the central portion. The edges of each slice are covered by a rough reddish-brown bark, marked with numerous scars and circular rings; here and there rootlets remain attached. The odour is like that of orris root but more powerful and strongly camphoraceous. The taste is pungent, bitter and aromatic. Chinese kapur-kachri is a little larger than the Indian, white and less pungent. The bark is smoother and of lighter colour.

Microscopic Structure.—The rhizome consists of a delicate parenchyma, most of the cells of which are loaded with large ovoid starch grains; a few contain a yellowish resin and essential oil. The epidermis is composed of several rows of compressed, nearly empty reddish-brown cells. From the unaltered condition of the starch it appears that the rhizomes are not exposed to heat.

Commerce.—The Indian drug is said to be imported from the Malabar coast. The other kind comes from the Chinese ports. Value, Chinese, Rs. 4½ per maund of 37½ pounds; Indian, Rs. 5. The Arabs and Persians are the chief consumers.

Kämpferia rotunda, *Linn.* Amoinaceæ Bhuichampa of India.

This does not yield any of the zedoaries of commerce. It is commonly cultivated in gardens on account of the beauty and fragrance of its flowers, which appear in the hot weather before the leaves spring up. The fresh tubers are pounded and applied by the natives to wounds, bruises and swellings. The root consists of several central, almost globular rhizomes, from which proceed numerous thick, fleshy rootlets, all of which terminate in small round tubers. The substance of the rhizomes is of a pale straw colour and has a bitter pungent camphoraceous taste much like that of the true zedoary.

(To be continued.)

FOOD AND WORK.*

BY FRANCIS W. MOINET, M.B.,

Lecturer on Materia Medica, Edinburgh School of Medicine.

During the past few years a great deal has been said and written about food and cooking, and not without reason, as the importance of a knowledge of the food we eat, and how to cook it properly, can hardly be overestimated. This has been of late, I am glad to say, in some degree appreciated, although not to the extent it deserves. Thus it is now an offence by law to expose for sale or sell articles of food or drugs which are adulterated, even although the substances used for adulteration may be comparatively harmless to health, as milk and water; because it is a fraud on the public, as the article sold is not what it is represented to be, while the price asked is for the pure article. Still more worthy of punishment is he who defrauds the public with articles which are injurious to health. That the Adulteration Act was necessary we have had ample proof; that it will be beneficial in the future may taken for granted. Schools of cookery have also been established in various places, where those willing can learn how to cook properly, because cooking requires to be learned as much as reading or writing does. It is a great mistake to imagine that a knowledge of cooking comes naturally to a woman; practical proof of this almost every householder must have had in many so-called good plain cooks.

With a knowledge of cooking the power of conferring a great benefit is obtained, as good cooking implies:—1st, Economy; 2nd, It tends to promote appetite and digestion, and thus helps to preserve health of body and comfort of mind, as the dependence of good temper on good digestion is a well-known fact; while the importance of health as affecting the national prosperity cannot be overlooked, as its absence tends to promote pauperism, drunkenness and crime, and as a result increased taxation.

It is also, doubtless, a promoter of temperance and as such is now recognized in the many comfortable establishments where good and cheap food can be got and a comfortable place to eat it in. These must be a great boon to working men who frequently have to pursue their avocations at a considerable distance from home and otherwise would have to eat their food, not always the most suitable, in considerable discomfort.

How does it promote temperance?

By the well-cooked food promoting and satisfying the appetite and enabling the man to feel up to his work and so preventing that crave for stimulants which often proceeds from a stomach deranged by badly-cooked food, and, therefore, insufficient to support unaided the wear of the body.

The importance of a knowledge of cooking, especially among the working class, is very great, because they cannot get rid of their cooks if they are inefficient, as we can, since the law does not look upon that as a sufficient cause for divorce, and it is on account of this want of knowledge

* Read at a meeting of the North British Branch of the Pharmaceutical Society, March 24, 1880.

that we find a far greater proportion of the labouring classes suffering from derangement of the stomach than among the wealthier classes.

Besides when we consider and compare the number of times the wife of a working man has to cook, say in the course of a year, to the frequency with which she requires to write a letter, we will find it will probably be two or three hundred times to one. I, therefore, think in view of its importance to so large a portion of the community that a good case is made out for rendering it compulsory.

Having thus acknowledged the importance of cooking, because unless our food is properly cooked it is very apt to be a poison instead of food, I pass on to the subject of my lecture, viz., food and work, or rather the relation between food and work. Every one knows that without food no work could be done; even life itself would fail, for what is life but work. But behind this general relation, which is felt and appreciated by all as a law of existence, lie many other interesting and important relations, which at first sight are not so apparent and to which I wish to draw your attention this evening. But when I use the term work, I do not mean simply paid or manual labour; I employ the word in a more comprehensive sense to signify the general wear and tear of the body in our usual daily avocation of business or pleasure; and to make the subject clearer to you, we will first notice the general relation between food and work, or the function which food plays in the animal economy.

1st. *The Composition of the Body.*—I do not intend to detain you with a chemical analysis of the tissues of the human body, but simply give you a list of the elements, oxygen,* carbon, hydrogen, nitrogen, phosphorus, sulphur, chlorine, fluorine, silicon, calcium, potassium, sodium, magnesium, iron, manganese, copper, which in different combinations compose the various structure of the human body, the bones, muscles, nerves, fat, blood, brain, etc. These compounds are very numerous, depending on the number of the elements and the proportion in which they are present; just as you can get any number of tunes from the keys of a piano by various combinations, so out of comparatively few elements you get a great number of compounds, which collectively make up the human body.

As the food we eat or drink—the latter term applying only to the condition of the article used whether fluid or solid—is the only source from which these elements forming the constituents of the body are derived, it naturally follows that no article of food can satisfy the requirements of life which fails to comply with this condition. But as comparatively few articles of food contain all these elements, or in their proper proportion, it follows that we must combine different articles of food together to make a satisfactory meal, *i.e.*, a meal not only sufficient to satisfy the appetite, but also capable of supplying the different elements required by the tissue to replace what has been spent on work. Hence the reason and necessity of living on a varied diet, which experience taught our ancestors long before the scientific facts on which it is founded were discovered. For with the exception of milk, which is a perfect food, no ordinary article of diet contains all the necessary elements. But this is not only a necessity, but also a great advantage, as our food would be very apt to pall on our palates were it always the same, so nature liberally supplies us with a great variety to choose from, which are nearly equally capable of nourishing the body, and at the same time suiting different tastes, which to some individuals is a matter of importance, either from habit or natural peculiarity, still more valuable to the invalid whose recovery sometimes depends not on medicine, but on diet.

Another reason of this variety in nature is that all animals and vegetables are not found to flourish under the same conditions of climate and soil; hence in different countries the food supply is often obtained from different sources, plants and animals, especially the former.

* 'Food,' by A. H. Church, M.A. Oxon.

Having seen, then, what our bodies are composed of, and that as a natural result our diet must contain these elements in suitable proportion, and that if, excepting milk, no article of food contains all these elements, our diet must, to nourish us properly, consist of more than one article of food, we have now to notice the function of food, *i.e.*, how it nourishes the body, and enables it to perform its work, as work of some kind or other is necessary for health, and not only to health, but also to happiness. This is a wise provision of Providence in making what is essential to a useful existence a promoter of health and happiness.

The function of food may be described as twofold. Food is essential to the body to fulfil two distinct objects:—1st, to afford material to replace what is spent in labour, physical or mental, muscular or brain; 2nd, to supply fuel which is spent in force.

Because the tissues of the body are constantly changing, the old material being replaced by new, supplied from the food we eat, and as labour increases the destruction of old material, it necessitates a fresh supply to make up for it; hence why, as a rule, the harder the labour the more food is required. To render the second function of food, viz., to supply fuel which is spent in force, more clear to you, we will compare the human body to a steam engine, a common, but a good comparison,—the first function being simply to repair what is lost by wear and tear. In the steam engine the fuel is burnt, and its latent energy is set free in the form of heat, which is employed to convert water into steam, which sets the machinery in motion, the motion and power of the engine being the result of the burning of the fuel. What happens in the body is almost the same. A considerable proportion of our food, especially the fatty and starchy matters, after being digested and assimilated and stored up in the various tissues, are slowly burnt or oxidized by the oxygen which has been carried from the lungs by the blood, the fat is decomposed into carbonic acid and water, which are given off by the lungs and the kidneys and skin. By this oxidation, or burning, heat and force are generated to keep up the temperature of the body and keep the vital functions going, and to supply physical and mental energy, all the internal and external work of the body being performed by the combustion of the stored-up fat in the tissue. Hence the necessity of a regular and constant supply of food to warm the body and supply mental and physical energy, and repair the waste of the tissues. This brings us naturally to consider next whether this twofold function of food is performed by the same or any article of food. In some cases it is; but as most articles of food do not contain the substance required in suitable proportion to perform both of these functions, you require to take more than one article of food to make up what the other lacks, and in this way you get a diet sufficient to fulfil both of these functions. It is for this reason that articles of food, or their nutritive principle, have been classified according as they contribute especially to the growth and nutrition of the body, or to the production of heat and force, into two great classes:—I. Heat producers; II. Flesh formers, or non-nitrogenized and nitrogenized compounds, *e.g.*, organic constituents of food.

Heat-Producing.

Sugar Starch Gum Lignus Oils and Fats	composed of	Carbon Hydrogen Oxygen

Flesh-Forming.

Albumen Gluten Fibrin Casein Legumin	composed of	Carbon Hydrogen Nitrogen Oxygen Sulphur and Phosphorus

Of these compounds those which contain nitrogen are used principally for building up the muscles, while those which contain no nitrogen are burnt up in the body to yield heat and force. And you will notice that the flesh-forming compounds are not obtained solely from animal food, as gluten and legumin are obtained from the vegetable kingdom, from cereals and peas and beans respectively; while the heat-producers, with the exception of some oils and fats, are obtained solely from the vegetable kingdom. So that for perfect health our food must contain sufficient of both of these two classes of compounds to repair the tissues and to supply heat and force (the mineral substances being contained in these compounds, also partly supplied by the water we drink). As to the relative proportion in which they should be present in our food, there is no hard and fast line; this would be an impossibilty unless we were to weigh and analyse every article we eat. We judge by experience what will satisfy the appetite and enable us to feel up to our work. Besides it must vary considerably according to circumstances,—1st, the amount of work or exercise; 2nd, the climate. Thus you are aware how physical or bodily exercise compels us to eat more than when idle, our increased hunger or appetite being nature's method of indicating to our minds that our bodies require food to replace what has been expended in force and to repair the waste of the tissues. Then the colder the climate more food is required, especially of the heat-giving varieties, as more requires to be spent in keeping up the warmth of the body. Cold is also more conducive to physical work than warm weather, so that for this reason also more food is required in a cold climate.

This use of the fatty or non-nitrogenous articles of food (or heat-producers) you will often see exemplified in a painful manner in those suffering from fever or protracted illness. In these cases the sufferers are not capable of eating or digesting a sufficient quantity of food to keep the machinery of the body in motion, and repair the waste. To make up for the deficient supply nature draws on the store of fatty substances, which is laid up in the tissues for such an emergency; because if more such food is taken than is required it accumulates in the tissues and the individual grows fat or stout, and gradually as this stored-up fat is consumed to make up for the diminished supply, we find the patients becoming thinner and thinner, until often they are literally nothing but skin and bone, as first the fatty and then even the muscular tissues in such a case are slowly burnt up to keep the vital spark alive, until the flickering flame of life slowly expires as a lamp when the oil has run low. There is no doubt, therefore, that the fatty and starchy substances form the most important of these two groups in relation to the production of heat and force, as without a constant supply of these the body would soon cease to exist.

This is the reason why cod liver oil is so much employed and with such good results for delicate persons, for those who cannot take enough food to nourish them and for those who are suffering from diseases which entail a drain upon the system.

But why, you may ask, is cod liver oil more useful than other oils and fats, and in smaller quantity?

The answer to this must be looked for in its chemical composition.

Analysis of Cod Liver Oil.—Olein, 80 per cent., palmitin (margarin), 15 per cent., acetic, cholic, butylic, phosphoric and sulphuric acids, traces of iodine, bromine and chlorine, salts of lime, magnesia and non-colouring matter. The olein and palmitin are the chief constituents of many oils and fats and are present in as large a quantity, and yet they are not so useful. Winckles tried to explain it by saying that in cod liver oil the fatty acids were in combination with propylene instead of glycerine; disproved.

Hence, we must look for another explanation. Some have attributed its action to the iodine, bromine and phosphorus; but the amount which the oil contains is much too small to be medicinally active, while the therapeutic effects of the oil are quite different from those of these metalloids. The same may be safely said of the magnesia, lime and iron. Others have attributed it to the biliary principles (Bucheim), especially the acids. This latter is probably the true explanation. Thus fats when swallowed are partially emulsionized and saponified by the pancreatic and biliary secretions. But all fats are not absorbed with the same facility, and the presence of certain substances is necessary for this. This absorption of fat is accomplished by the bile. It was long since shown by Wistinghausen that in capillary tubes moistened with bile oil will rise much higher than in tubes not so moistened, or moistened with water or a saline solution. He also showed that oil will pass through membrane, saturated with bile much more readily than through similar membranes saturated with water (confirmed by Haussmann). So that as the presence of bile is necessary for the absorption of fats, it is for this reason that cod liver oil which contains it is more readily absorbed, and, therefore, more fattening than other oils and fats and in smaller quantity.

The necessity, then, of our requiring both flesh-forming and heat-producing articles of food to keep us in health is the foundation or reason of many of the combinations of articles of food which constitute our different meals, and which experience taught long before the scientific facts were discovered on which the requirement was based, *e.g.*, meat and vegetables, bread and cheese, porridge and milk, bacon and beans, etc., and so on from these more homely combinations up to the wonderful dishes of the professional cook. Thus meat and cheese, which are purely nitrogenous articles of food, or flesh-formers, would not form a sufficient meal by themselves; hence you add vegetables or bread to get the necessary amount of heat-producers to fulfil the two functions of food which I have mentioned; and this law we find has been unconsciously at work in forming the staple dishes of many races of people, regulated, however, by the climate, their source of food supply and amount of exercise.

The following table will give you some idea of the relative amount of flesh-formers and heat-producers in certain articles of food, showing the amount of heat-producing elements they contain for every ten parts of flesh-formers. Thus in the tropics, where little exercise can be taken, the waste of tissues is small, so that little nitrogenous food is required and only a moderate amount of fat is taken, the need of heat-producers being comparatively small, so that starchy products, as millet and rice, are the principal articles of food.

	Flesh-forming.	Heat-producing.
Milk*	10	40
Beans	10	22
Fat Mutton	10	27
Fat Pork	10	30
Beef	10	17
Hare	10	2
Veal	10	1
Wheaten Flour	10	44
Oatmeal	10	50
Barley	10	57
Potatoes	10	115
Rice	10	123

But gradually as you come north there is a marked increase both in the fatty and nitrogenous articles of food, until in the Arctic zone oily substances and animal food are the staple articles of existence, the amount of them that an Esquimaux will eat being something almost incredible, being necessary to resist the severe cold. But you will now notice that the vegetable kingdom alone can supply all that is necessary for the human body both of flesh-forming and heat-producing substances, and you

* Dr. Stevenson Macadam.

must not for a moment imagine that animal food is the only source of flesh-formers, as the world's population is supported to a large extent on vegetable products, especially in tropical regions, as we have already seen, while in colder climates, where vegetable products are hardly to be obtained, flesh and fat are indispensable. Thus man is clearly omnivorous; while men may be advantageously almost vegetarians in one climate, mixed eaters in another (as with us), and almost exclusively flesh eaters in a third, as in the Arctic regions. But, as you are aware, there are some people who live exclusively on a vegetable diet (vegetarians) in our country, believing that such a diet is right in principle. But only those are pure vegetarians who exclude milk, butter, eggs and cheese, as these are the very essence of animal food.

In regard to this theory of diet, without going into the question minutely, there are one or two facts which I will lay before you, from which you may judge the soundness of the theory.

We have already seen that man is capable of deriving all that is required for living and working from the animal or vegetable articles of food, either separately or combined. The question, therefore, is whether a purely vegetable diet or a mixed diet of vegetable and animal food is the better suited for our existence. To judge the question we have some facts to go upon.

1. We are so physically constructed as to be able to derive our nourishment from either animal or vegetable food.

2. That in the Arctic regions hardly any vegetables are to be obtained.

3. Man alone has the intelligence to obtain food from all sources and to render it by cooking fit for nourishment.

It apparently follows, therefore, from these facts, that while we are suited for either diet, or rather a combination of both, we may also select to some extent our diet according to our individual taste and habit of body and other circumstances, as work and climate, as experience has taught us that for the enjoyment of good health our diet must be regulated by the circumstances I have mentioned. These facts go far to prove, to my mind, at least, that a mixed diet of animal and vegetable food is for the majority the better and more natural diet in this northern climate, but certain deviations or variations are necessary in certain circumstances, according to certain individual peculiarities. Thus some people are so constituted, or have become so, that a vegetable diet is more conducive to their health and comfort than a meat one, in which case it is evidently their duty to live accordingly; but, not content with living thus themselves, they think with their limited vision that it must be best for others also, and take up and try to expound the advantages of vegetarianism, quite forgetting the old and true proverb that what is one man's meat is another man's poison. So that while some few find a vegetable diet best suited for health, our knowledge points strongly to the fact that under all circumstances the mixed diet is the more natural and of the two the better suited to support health and strength.

Having thus noticed the function of food and the general relation between food and work, we will now consider briefly certain circumstances which must also be taken into account, viz., how the relation between the two is affected by the amount of work, kind of work, age of the worker, and the circumstances under which the work is done. To state it properly we will commence with the infant.

The Infant.—Its work is simply to live and grow. But the child is father to the man, and just as a child's health greatly depends on the parent's health, so does the man's greatly depend on the child's. Hence nothing is more important than proper feeding for a child, and parents and guardians should understand their responsibility in this respect. Milk is a perfect food and the natural food for children; but many mothers and nurses think they can improve upon nature, and under the stupid idea that solid food is more nourishing, give them food quite unsuited for their digestive organs; the consequence is that the infant mortality directly due to improper feeding is something almost incredible. Then during youth it should be wholesome and nourishing, but plain, simple and varied as much as possible. Alcohol in any form should be avoided, as it is not only unnecessary, but may induce a habit the danger of which I need not dwell upon. Then in manhood it behoves us also to be careful in our diet in relation to our work, as carelessness in this respect is as little to be commended as extravagance or epicureanism, physical work requiring more food than mental, especially nitrogenous compounds. But it is a popular mistake, and an extravagant one, to imagine that physical work requires a large amount of animal food. We have seen that flesh-forming materials can be obtained from the vegetable kingdom, and for hard mechanical labour there is no doubt that a mixed diet is more nutritious and wholesome than one principally composed of animal food. This should be borne in mind, because at the present day there is as a rule too much animal and even other food consumed in this country, considering the climate, even among the working class, to whom it is an unnecessary extravagance, while to the rich it is a hurtful one; as the effects of such indulgence are injurious not only to the individual but also to the children.

But it should also be regulated by the climate.

Then, again, it is certain, although contrary to the popular belief, that while a good supply of food is essential during the period of growth and development and active middle life, a diminished supply is not less essential to health and prolongation of life during declining years, when physical exercise is small and the digestive power becomes somewhat feeble.

But you may be asking yourselves why I do not give you some more particular directions. Simply because they would be quite useless. The facts which I have given are quite sufficient for any one to follow out in practice without further details, and if more attention were paid as to the function of food and the value of different articles of food, and the importance of such a knowledge to the health and pocket were considered, a reformation would result fraught with material advantage to a great class of our community.

CEMENTS.*

Quite as much depends upon the manner in which a cement is used as upon the cement itself. The best cement that ever was compounded would prove entirely worthless if improperly applied. The following rules must be rigorously adhered to if success would be secured:—

1. Bring the cement into intimate contact with the surfaces to be united. This is best done by heating the pieces to be joined in those cases where the cement is melted by heat, as in using resin, shellac, marine glue, etc. Where solutions are used, the cement must be well rubbed into the surfaces, either with a soft brush (as in the case of porcelain or glass), or by rubbing the two surfaces together (as in making a glue joint between two pieces of wood).

2. As little cement as possible should be allowed to remain between the united surfaces. To secure this the cement should be as liquid as possible (thoroughly melted if used with heat), and the surfaces should be pressed closely into contact (by screws, weights, wedges, or cords) until the cement has hardened.

3. Plenty of time should be allowed for the cement to

* Quoted in the *Druggists' Circular* from the 'Workshop Companion.'

dry or harden, and this is particularly the case in *oil* cements, such as copal varnish, boiled oil, white lead, etc. When two surfaces, each half an inch across, are joined by means of a layer of white lead placed between them, six months may elapse before the cement in the middle of the joint has become hard. In such cases a few days or weeks are of no account; at the end of a month the joint will be weak and easily separated, while at the end of two or three years it may be so firm that the material will part anywhere else than at the joint. Hence, where the article is to be used immediately, the only safe cements are those which are liquefied by heat and which become hard when cold. A joint made with marine glue is firm an hour after it has been made. Next to cements that are liquefied by heat are those which consist of substances dissolved in water or alcohol. A glue joint sets firmly in twenty-four hours; a joint made with shellac varnish becomes dry in two or three days. Oil cements, which do not dry by evaporation, but harden by oxidation (boiled oil, white lead, red lead, etc.), are the slowest of all.

Aquarium Cement.—Litharge, fine, white, dry sand, and plaster of paris, each 1 gill; finely pulverized resin $\frac{1}{3}$ gill. Mix thoroughly and make into a paste with boiled linseed oil to which drier has been added. Beat it well, and let it stand four or five hours before using it. After it has stood for fifteen hours, however, it loses its strength. Glass cemented into its frame with this cement is good for either salt or fresh water. It has been used at the Zoological Gardens, London, with great success. It might be useful for constructing tanks for other purposes or for stopping leaks.

Casein Mucilage.—Take the curd of skim milk (carefully freed from cream or oil), wash it thoroughly and dissolve it to saturation in a cold concentrated solution of borax. This mucilage keeps well, and as regards adhesive power far surpasses the mucilage of gum arabic.

Casein and Soluble Glass.—Casein dissolved in soluble silicate of soda or potassa, makes a very strong cement for glass or porcelain.

Cheese Cement for mending China, etc.—Take skim milk cheese, cut it in slices and boil it in water. Wash it in cold water and knead it in warm water several times. Place it warm on a levigating stone and knead it with quicklime. It will join marble, stone, or earthenware so that the joining is scarcely to be discovered.

Chinese Cement (*Schio-liao*).—To three parts of fresh beaten blood are added four parts of slaked lime and a little alum; a thin, pasty mass is produced, which can be used immediately. Objects which are to be made specially water-proof are painted by the Chinese twice, or at the most three times. Dr. Scherzer saw in Pekin a wooden box which had travelled the tedious road *viâ* Siberia to St. Petersburg and back, which was found to be perfectly sound and water-proof. Even baskets made of straw became, by the use of this cement, perfectly serviceable in the transportation of oil.

Pasteboard treated therewith receives the appearance and strength of wood. Most of the wooden public buildings of China are painted with schio-liao, which gives them an unpleasant reddish appearance, but adds to their durability. This cement was tried in the Austrian Department of Agriculture, and by the "Vienna Association of Industry," and in both cases the statements of Dr. Scherzer were found to be strictly accurate.

Faraday's Cap Cement.—Electrical Cement.—Resin, 5 ounces; beeswax, 1 ounce; red ochre or venetian red in powder, 1 ounce. Dry the earth thoroughly on a stove at a temperature above 212°. Melt the wax and resin together and stir in the powder by degrees. Stir until cold, lest the earthy matter settle to the bottom. Used for fastening brass work to glass tubes, flasks, etc.

Cement for Glass, Earthenware, etc.—Dilute white of egg with its bulk of water and beat up thoroughly. Mix to the consistence of thin paste with powdered quicklime. Must be used immediately.

Glass Cement.—Take of pulverized glass, 10 parts; powdered fluorspar, 20 parts; soluble silicate of soda, 60 parts. Both glass and fluorspar must be in the finest possible condition, which is best done by shaking each, in fine powder, with water, allowing the coarser particles to deposit, and then to pour off the remainder, which holds the finest particles in suspension. The mixture must be made very rapidly, by quick stirring, and when thoroughly mixed must be at once applied. This is said to yield an excellent cement.

Gutta-Percha Cement.—This highly recommended cement is made by melting together, in an iron pan, 2 parts common pitch and one part gutta-percha, stirring them well together until thoroughly incorporated, and then pouring the liquid into cold water. When cold it is black, solid, and elastic; but it softens with heat, and at 100° Fahr. is a thin fluid. It may be used as a soft paste, or in the liquid state, and answers an excellent purpose in cementing metal, glass, porcelain, ivory, etc. It may be used instead of putty for glazing windows.

Iron Cement for closing the Joints of Iron Pipes.—Take of coarsely powdered iron borings, 5 pounds; powdered sal-ammoniac, 2 ounces; sulphur, 1 ounce; and water sufficient to moisten it. This composition hardens rapidly; but if time can be allowed it sets more firmly without the sulphur. It must be used as soon as mixed and rammed tightly into the joint.

2. Take sal-ammoniac, 2 ounces; sublimed sulphur, 1 ounce; cast iron filings or fine turnings, 1 pound. Mix in a mortar and keep the powder dry. When it is to be used, mix it with twenty times its weight of clean iron turnings, or filings, and grind the whole in a mortar; then wet it with water until it becomes of convenient consistence, when it is to be applied to the joint. After a time it becomes as hard and strong as any part of the metal.

Kerosene Oil Lamps.—The cement commonly used for fastening the tops on kerosene lamps is plaster of paris, which is porous and quickly penetrated by the kerosene. Another cement which has not this defect is made with three parts of resin, one of caustic soda and five of water. This composition is mixed with half its weight of plaster of paris. It sets firmly in about three-quarters of an hour. It is said to be of great adhesive power, not permeable to kerosene, a low conductor of heat, and but superficially attacked by hot water.

Cement for uniting Leather and Metal.—Wash the metal with hot gelatine; steep the leather in an infusion of nut galls (hot) and bring the two together.

Cement for Leather Belting.—One who has tried everything says that after an experience of fifteen years he has found nothing to equal the following: Common glue and isinglass, equal parts, soaked for ten hours in just enough water to cover them. Bring gradually to a boiling heat and add pure tannin until the whole becomes ropy or appears like the white of eggs. Buff off the surfaces to be joined, apply this cement warm, and clamp firmly.

Litharge and Glycerine Cement.—A cement made of very finely powdered oxide of lead (litharge) and concentrated glycerine unites wood to iron with remarkable efficiency. The composition is insoluble in most acids, is unaffected by the action of moderate heat, sets rapidly, and acquires an extraordinary hardness.

Cement for attaching Metal to Glass.—Copal varnish, 15; drying oil, 5; turpentine, 3. Melt in a water-bath and add 10 parts slaked lime.

Paris Cement for mending Shells and other Specimens.—Gum arabic, 5; sugar candy, 2; white lead, enough to colour.

Porcelain Cement.—Add plaster of paris to a strong solution of alum till the mixture is of the consistency of cream. It sets readily, and is said to unite glass, metal, porcelain, etc., quite firmly. It is probably suited for cases in which large rather than small surfaces are to be united.

Soft Cement.—Melt yellow beeswax with its weight of turpentine, and colour with finely powdered venetian red. When cold it has the hardness of soap, but is easily softened and moulded with the fingers, and for sticking things together temporarily it is invaluable.

Soluble Glass Cements.—When finely pulverized chalk is stirred into a solution of soluble glass of 30° B. until the mixture is fine and plastic, a cement is obtained which will harden in between six and eight hours, possessing an extraordinary durability, and alike applicable for domestic and industrial purposes. If any of the following substances be employed besides chalk, differently coloured cements of the same general character are obtained : 1. Finely pulverized or levigated stibnite (grey antimony, or black sulphide of antimony) will produce a dark cement, which, after long burnishing with an agate, will present a metallic appearance. 2. Pulverized cast iron, a grey cement. 3. Zinc dust (so-called zinc grey), an exceedingly hard grey cement, which after burnishing will exhibit the white and brilliant appearance of metallic zinc. This cement may be employed with advantage in mending ornaments and vessels of zinc, sticking alike well to metals, stone, and wood. 4. Carbonate of copper, a bright green cement. 5. Sesquioxide of chromium, a dark green cement. 6. Thénard's blue (cobalt blue), a blue cement. 7. Minium, an orange coloured cement. 8. Vermilion, a splendid red cement. 9. Carbon red, a violet cement.

Sorel's Cement.—Mix commercial zinc white with half its bulk of fine sand, adding a solution of chloride of zinc of 1·26 specific gravity, and rub the whole thoroughly together in a mortar. The mixture must be applied at once, as it hardens very quickly.

Steam Boiler Cement.—Mix two parts of finely powdered litharge with one part of very fine sand, and one part of quicklime which has been allowed to slake spontaneously by exposure to the air. This mixture may be kept for any length of time without injuring. In using it a portion is mixed into paste with linseed oil, or, still better, boiled linseed oil. In this state it must be quickly applied, as it soon becomes hard.

Turner's Cement.—Melt 1 pound of resin in a pan over the fire, and when melted, add $\frac{1}{4}$ of a pound of pitch. While these are boiling add brick dust until, by dropping a little on a cold stone, you think it hard enough. In winter it may be necessary to add a little tallow. By means of this cement a piece of wood may be fastened to the chuck, which will hold when cool; and when the work is finished it may be removed by a smart stroke with the tool. Any traces of the cement may be removed from the work by means of benzine.

Wollaston's White Cement for large objects.—Beeswax, 1 ounce; resin, 4 ounces; powdered plaster of paris, 5 ounces. Melt together. To use, warm the edges of the specimen and use the cement warm.

BORACIC ACID AS A PRESERVATIVE.*

BY H. ENDEMANN.

Boracic acid has, for the last ten years, held a place amongst our antiseptics, and has frequently been recommended for the preservation of meats and vegetable substances. The original discoverer, Gahn, sold in Europe two mixtures.

The one was a mixture of one part of boracic acid with one part of alum; the other, one part of boracic acid with two parts of alum. These were called respectively "aseptine" and "double aseptine."

Provisions in part preserved by boracic acid are generally within the time of from one to two months covered with a black crust, provided they are kept in the ordinary oak provision barrels. Alum prevents this.

This observation, long ago published, I found verified in my own investigations. It was, at first, my intention not to preserve without salt, but to limit the quantity of the salt to be used by the addition of certain antiseptics. In the following, without going into the details of the numerous experiments, I shall give the results of those which are directly of interest to the question discussed in this paper.

It was found that fresh beef, packed with 1 per cent of boracic acid and a salt pickle of 50 per cent., remained sweet and wholesome for several months, even if kept at an average temperature above 80° Fahr. It was likewise found that previously salted beef could not be preserved by the addition of boracic acid. From this it was evident that the process of salting removed from the beef certain substances, in the absence of which preservation became impossible. These substances proved, on further investigation, to be the phosphates. It was, therefore, not the boracic acid which had been the cause of the preservation, but, rather, substances which are produced by the action of the boracic acid—the acid phosphates.

I could cite a long list of materials which cannot be preserved with boracic acid, owing to the want of phosphates. In all these cases, however, preservation would be possible if, with the boracic acid, a phosphate were to be added: a somewhat roundabout way, which can be improved, as I shall explain further on.

During my investigations regarding the disinfecting properties of various substances I had found that it is very difficult to develop bacteria in a fluid containing acid phosphates, and also that many acids are powerful disinfectants, destroying the life of bacteria completely, even if present only in small quantities. One part of HCl in sixty-four parts of Cohn's fluid, well stocked with bacteria, destroyed these completely.

I was led, therefore, to make experiments in which boracic acid was replaced by equivalent quantities of other inorganic acids, and thus ascertained that exactly the same results could be reached as with the use of boracic acid.

The best results were reached by the use of phosphoric acid, and mixtures of phosphoric acid and hydrochloric acid.

Phosphoric acid, even in dilute solution, acts powerfully on fresh meat, covering it with a white layer of coagulated albumen, which, however, on standing gradually disappears. Mixtures, however, where the PO_5 is partly replaced by HCl, do not act in a like manner; and, even if some precipitation should take place, will soon allow the meat to recover its original appearance.

Meats thus treated keep exceedingly well, and at least fully as well as when preserved, under similar circumstances, with an equivalent quantity of boracic acid.

Less favourable results were obtained by the use of sulphuric, nitric, and acetic acids, which is easily explained by the instability of these acids.

The preservation by means of boracic acid cannot, therefore, be considered as involving a new principle; it is merely a variation of, but by no means an improvment on, the time-honoured vinegar pickling. The insipid taste of free boracic acid and the acid phosphates prevents its easy detection, and brings consumers to the belief that the meat is fresh.

This peculiarity is the only one recommending the use of boracic acid.

A French commission, appointed to investigate the influence of boracic acid on the human system, found that it could be taken for a considerable time without producing any injurious effects. Yet it is certainly neither a regular constituent of the body, nor is it contained in our food, and it is, therefore, doubtful whether the results reached by the commission must be considered as conclusive, as, in the course of time, constitutional difficulties may supervene, if such preserved provisions are taken for a considerable period.

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE SALE OF PATENT MEDICINES CONTAINING POISON.

AMONG the letters that we publish this week is one from Dr. HUBBARD, in which he describes more clearly than before the real objects with which he addressed himself to the public through the medium of the daily papers. From that letter it is evident that the sale of poisonous drugs of which he spoke in his former letter was simply that mischievous practice carried on under the protection of the Patent Medicine Act, and the exemption made by section sixteen of the Pharmacy Act, which has lately been so often referred to in this Journal by correspondents or by speakers at the Council and other meetings.

It is certainly a great anomaly that while the educated and experienced pharmacist is not allowed to sell dangerous drugs otherwise than in accordance with certain formalities, and under conditions which are intended to prevent accident or misuse, still the same drugs can be sold without any such precautions and by any persons, ignorant or otherwise, so long as they are sold anonymously under the guise of secret nostrums with a patent medicine stamp.

Nor is it less surprising that there should have been so little effort on the part of medical men to protest against and oppose the continuance of a practice so dangerous to the general community and so antagonistic to their own interests. Though the cultivation of business and the acquisition of fortunes upon the basis of human credulity may not be a proceeding that in all cases calls for the interference of the Legislature to protect willing dupes from any damage possibly resulting from their own folly, there are certain lines of demarcation beyond which this species of commercial enterprise cannot and should not be allowed. The law steps in to prevent the country bumpkin from being damaged by his willingness to place his property in the hands of too plausible performers of the "confidence trick," and it is difficult to understand why it should not in like manner protect the enthusiastic invalid from injury to his health, or perhaps from loss of life, resulting from his belief that certain much vaunted, but poisonous, nostrums are gifts of the "healing hand," from which he may safely hope for relief. And of some preparations that are sold as patent medicines and as specific remedies it is not too much to say that their use is never unattended with peril. It is true that the composition of these articles has not been disclosed, and to some extent their exact ingredients can only be conjectured or in some instances detected by chemical analysis; but in regard to most of them there is little question what are the poisonous substances contained in them, and there should we think be as little question that such preparations ought not to be obtainable with the same ease as a box of purgative pills and with no greater precaution against misuse than would suffice in the case of such a simple medicine.

Dr. HUBBARD very justly urges that the reduced cost of a licence to sell patent medicines is injurious to general safety, because it gives to grocers and other dealers facility for distributing as patent medicines articles of the most dangerous character that should never be used except under competent supervision. While such a state of things exists, it would be of no avail for the chemist and druggist acquainted with the nature of these poisonous preparations to seek to apply to their sale the same rules and precautionary measures that he observes in selling the same poisonous drugs under their proper names. In the first place, he is not, under existing circumstances, justified in treating any such article as a preparation containing prussic acid, morphia, atropine, or what not, although he may have good reason for suspecting the presence of these or other poisons, and then such a course of action would be open to uncertainty. Neither can the chemist and druggist well decline to supply such articles without the risk of giving offence.

As a remedy for the various evils resulting from the sale of patent medicines containing poison, it seems, therefore, that the only feasible course is to require the disclosure of the constituents that are of a poisonous nature and to make the sale of the preparations containing poison subject to the limitations of the Pharmacy Act. This might be done without detriment to the proprietary interests of the manufacturers, and without making known the secrets of preparations which are in certain instances supposed to constitute in some degree the value of patent medicines, and as there is such cogent reason for adopting some such regulation of the sale of patent medicines containing poison, it is to be hoped, in the interest of the public, that the attention now directed to the subject by Dr. HUBBARD may be productive, as he desires, of something more than a "nine days' wonder."

DANGEROUS "VIOLET POWDER."

ATTENTION has again been directed to violet powder, or rather to that preparation which is sold under this name, consisting of or containing calcium sulphate, and according to the medical evidence given at the inquest referred to in this Journal last week, the use of this powder has been attended with a fatal result. This evidence, however, is far from being so conclusive as might be desired, and it seems to amount to little more than an expression of opinion by the medical man that "violet powder" containing sulphate of lime is highly dangerous and unfit for use. Moreover, the coroner, in summing up, appears to have regarded "violet powder" containing a large percentage of calcium sulphate in the same light as "violet powder" also containing a considerable amount of arsenious acid, for he referred to the cases which occurred some years ago as being analogous to the case he was then dealing with.

Although we have never admitted the propriety of selling under the name of violet powder an article consisting wholly or in part of calcium sulphate, we cannot altogether concur in the justice of the remarks made by the coroner in the recent case; first, because there is not, so far as we know, any evidence that calcium sulphate is injurious, and secondly, because there are some reasons for believing that it does not exercise any injurious influence when used as a dusting powder. Chief among these is the opinion expressed by Professor Redwood, as based upon his own experience, and in the absence of any positive evidence in the opposite direction that opinion is entitled to considerable respect.

The jury at the late inquest does not appear to have taken this into account, but to have adopted the opinion of the medical witness, and added as a rider to the verdict, "that these powders ought not to be sold without being analysed beforehand, and then under proper supervision." For our part we fail altogether to perceive the utility of this suggestion, or to understand what good purpose analysis or supervised sale would serve, if the article in question be really objectionable or dangerous to use. Of course, we are now assuming that the "violet powder" referred to in this case was not arsenical, like that which caused so many deaths some years ago.

The question then is whether calcium sulphate is generally injurious when applied to the skin of infants, or likely to be so in some instances. If that be the case its sale for such purposes ought to be stringently prohibited, and nothing short of such a course would satisfy the requirements of the case.

Apart from this question, we still perceive nothing to alter the view we have previously expressed in regard to the sale as violet powder of any other preparation than the perfumed starch which has by long usage acquired a prescriptive right to be designated by that name, and to that extent we agree with our correspondent, Mr. H. Brown, as to the propriety of applying that name only to perfumed starch, on the ground of expediency as well as honesty.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

We learn from Mr. Haydon that at the late election of the General Committee of this body, out of fifty-three nominations forty-two were irregular, and consequently only ten members could be declared duly elected. At the meeting of the General Committee to be held in London next month additional members can be added if it be considered advisable to do so.

FATAL MISTAKE IN DISPENSING.

The *Medical Times and Gazette* reports a fatal accident which has occurred in Bombay through the misreading of a prescription. The Italian consul, having a pain in his leg, placed himself under medical treatment by a fellow countryman, who ordered for him a preparation containing morphia, which was administered, and the same evening the consul died. In the course of the inquiry that followed it was found that the doctor ordered two grains of morphia, and wrote the word "grana" in full. This the dispenser mistook for "grammes," and made up the prescription accordingly.

THE PROPERTY IN LABELS.

Among our legal notices will be found a report of the decision of the Master of the Rolls in reference to an application for an injunction against a perfumery company for using labels that were alleged to be imitations of those used by the plaintiff, Mr. Rimmel. The case is important, since the ruling of the Master of the Rolls affirms the principle that a manufacturer's goods can be protected against imitation even when his name and trade mark have not been copied.

LEGISLATION RELATING TO THE SALE OF POISONS IN THE STATES.

A considerable amount of legislation regulating the sale of poisonous substances now exists in the United States. Some of these Acts have been already quoted in this Journal, and several more or less resemble our own Pharmacy Act, especially in defining what is legally a "poison." But the Act enacted on behalf of the people of Michigan leaves this point very indefinite, and shows originality in other aspects, as will be seen from the following quotation, in which the italics are ours:—"Every "apothecary, druggist, or other person who shall sell "and deliver at retail any arsenic, corrosive subli- "mate, prussic acid, *or any other substance or liquid* "*usually denominated poisonous,* without having the "word 'poison,' and the true name thereof, *and the* "*name of some simple antidote,* if any is known, "written or printed on the label attached to the vial, "box or parcel containing the same, shall be punished "by a fine not exceeding one hundred dollars."

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting will be held on Thursday, April 22, at 8.30 p.m., when the paper on "Robert Boyle," postponed from the last meeting, will be read by Mr. C. Thompson. A Report on Pharmacy will be made by Mr. H. R. Arnold, on "Emulsifying Agents."

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on April 1, Professor H. E. Roscoe, F.R.S., President, in the chair. After a few remarks from the President on taking the chair for the first time, the following certificate was read for the first time:—J. Taylor.

The President called upon Mr. Groves to read a paper on—

Betorcinol and some of its Derivatives. By J. STENHOUSE and C. E. GROVES.—Some thirty-two years ago, in the course of an examination of lichens, a quantity of crude usnic acid from *Usnea barbata* and *Cladonia rangifernia* was submitted to destructive distillation. In the distillate a crystalline substance was found of the composition $C_8H_{10}O_2$, homologous with and closely resembling orcinol; it was therefore named β orcin. It was somewhat hastily inferred that the usnic acid in the above lichens was the source of the β orcin. Subsequent attempts to prepare β orcin by distilling pure usnic acid, however, completely failed. A quantity of *Usnea barbata* was therefore obtained and the crude usnic acid extracted and submitted to destructive distillation. On adding to the distillate solution of chloride of lime a crimson red coloration proved at once the presence of the orcinol-yielding body. On purifying the usnic acid no trace of the orcinol was obtained after destructive distillation. The source of the β orcin, or, as the authors now name it, betorcinol, was therefore not usnic acid. To prepare betorcinol, $C_8H_{10}O_2$ or $C_6H_2Me_2(HO)_2$, *Usnea barbata*, carefully freed from other lichens, is exhausted with milk of lime, the solution precipitated by hydrochloric acid and the precipitate boiled with lime and water; the clear solution is neutralized with hydrochloric acid and evaporated, when the crude betorcinol crystallizes out. It is purified by crystallization from benzene and from water. Melts at 163° C. It is less soluble than orcinol, gives a bright crimson colour with hypochlorites, orcinol a purplish-red. The ammoniacal solution is rapidly coloured on exposure to air, whilst the corresponding orcinol solution is but slowly changed. Tetrachlorobetorcinol, dichlorobetorcinol, the corresponding bromine derivatives and a mononitroso compound, were prepared and examined. The acid which yields the betorcinol was separated after some trouble from the usnic acid by taking advantage of its greater solubility in cold ether. It melts at 186° and decomposes at a somewhat higher temperature, carbonic anhydride and betorcinol being formed. It has the formula $C_{19}H_{20}O_7$, having the same relation to betorcinol that evernic acid, $C_{17}H_{16}O_7$, has to orcinol. As, however, it cannot be at present definitely asserted that it is a dimethylevernic acid, the authors have provisionally named it *barbatic acid*. Hesse obtained an acid from an usnea growing on calisaya bark melting at 172° which he termed usnetic acid. This is probably not identical with barbatic acid, but the authors suggest that it may be an ethereal salt of barbatic acid, as Hesse used alcohol in extracting and purifying his substance.

The President, after complimenting the authors on the completeness and clearness of their communication, called on the Secretary to read a paper—

Note on Chemical Equilibrium. By M. M. P. MUIR.—The object of this paper is to describe a few measurements of the variations caused in chemical changes by modifications in the condition of these changes, and to attempt to generalize some of the conditions of chemical equilibrium, looking at the phenomena from a dynamical point of view. The influence of the manner of mixing on the changes which occur when potassium permanganate, oxalic and sulphuric acids react in the presence of sulphate of manganese is illustrated by numerical results, showing that during the earlier part of the reaction the velocity of the chemical change is greater when permanganate is slowly added, and the liquids are not thoroughly mixed until after three minutes. The disturbing influence of a secondary change upon the primary is illustrated by a few numbers representing the relative velocities of the solution of ferric oxide by sulphuric acid alone, in the presence of zinc, and when aided by the passage of an electric current. In the two latter cases, the velocity of the change is considerably greater than in the former; the nascent hydrogen appears to decompose the product of the primary change, ferric sulphate, and to set free sulphuric acid in contact with ferric oxide, the latter being rapidly acted upon. Attention is drawn to the work of Professor Willard Gibbs, wherein the conditions of equilibrium of a system of heterogeneous substances are deduced from a consideration of the great principles of the conservation and dissipation of energy, and a rough attempt is made to connect the so-called "chemical induction" with the commonly occurring phenomena of chemical action, and to trace analogies between chemical and electrostatic induction. The general conclusions arrived at are, that chemical changes are always complex; that each change consists of at least two parts, a direct and a reverse change; that during the progress of either of these, secondary changes may be induced, which will, in their turn, modify the primary changes; that systems not in phases of absolute stability tend to undergo changes by contact with very minute quantities of matter in phases other than their own; that such systems will always tend to pass into that phase the passage to which is attended with the maximum loss of entropy; but that this tendency may, to a certain extent, be prevented by the action of impressed force.

Dr. Armstrong thought that it would have been desirable to make a series of observations, and take the mean results; apparently, only single observations had been made, and the slight differences might, to some extent, be due to experimental errors.

The President commented on the difficult nature of such investigations, but agreed with Dr. Armstrong that it would have been better to have made a series of observations.

The Secretary then read a communication from Japan, entitled—

Preliminary Note on the Action of the New Diastase, Eurotin, on Starch. By R. W. ATKINSON, Professor of Chemistry at Tôkiô.—M. Korschelt described in the 'Transactions of the German Asiatic Society,' in some detail the Japanese brewing process (*Ding. Polyt. Jour.*, 230, 76), and mentioned the occurrence of a soluble ferment, which he named eurotin, in the fermenting material employed, having the property of dissolving starch, and converting it into sugar. A brief description of the process was given by the author in *Nature*, 1878. The fermenting body is termed "koji," and is prepared as follows:—Washed rice is soaked in water till soft, it is then steamed for some hours until the starch has gelatinized; when lukewarm the mass is sprinkled with spores of the fungus *Eurotium oryzea*. The grains are then well mixed, and exposed in trays to a temperature of about 25° C. In three days the mass is cemented together by the silky filaments of the mycelium, and forms the "koji," which is used instead of malt in the brewing process. When extracted with water koji yields a solution reducing the Fehling test; when digested with water for about ten minutes the solution gives about 12–14 per cent. of glucose. Alcohol also dissolves out sugar, so that probably some sugar is present in the substance before treatment with water. Korschelt has shown that the cold aqueous extract of koji has properties resembling those of malt, and when added to gelatinized starch renders it limpid and forms sugar. He also concluded that the temperature of 45°–50° was the most favourable to this change. The author of the present paper has examined more minutely into the chemical reactions of the brewing processes of the Japanese, and has come to the conclusion that the starch breaks up in this process into glucose and dextrin, instead of maltose and dextrin as in our mashing operations. Korschelt assumed that maltose was formed, but gives no estimation of sugar or polariscopic determinations. The author then describes the process, and gives analyses of the mash on different days. A mixture of koji, steamed rice and water is made in the cold; on the 5th to 7th days the mash is warmed by introducing tubs filled with hot water. The principal points in the analyses are given in the following table:—

	1st day	3rd day.	5th day.	7th day.	10th day.	14th day.	17th day.	19th day.	24th day.	28th day.
Alcohol, per cent.	—	—	—	5·2	8·61	9·20	5·80	9·44	12·41	13·23
Dextrose, per cent.	—	7·35	12·25	5·4	0·99	0·50	2·06	1·16	0·27	0·0
Dextrin, per cent.	—	5·12	5·69	7·0	2·81	2·57	3·89	2·74	0·47	0·41
Starch and cellulose .	38·2	26·5	21·49	15·64	15·67	16·15	19·25	132·5	10·22	8·69
Rotatory power .	—	124°	106°	135°	100·7°	116°	160°	132·3°	48·2°	36°
Sp. gr. of mash .	—	1·15	1·18	1·08	1·05	1·04	1·03	1·02	0·99	0·98

It is to be noted that between the 14th and 17th days two further additions of steamed rice and water were made, and again on the 18th day a fourth addition of steamed rice ferment and water took place. The mash was then pressed, and during the interval the small quantity of dextrin underwent fermentation, and the specific rotatory power of the filtered liquid became almost *nil*. The filtered liquid (Saké) which contains the water used to rinse out the fermenting tuns contains 11·14 per cent. alcohol, glycerin and resin, 1·99, fixed acid, 0·13, volatile acid, 0·02, water, 86·72. The fermentation is probably spontaneous; the size of the ferment cells is a little less than that of the beer yeast. The author endeavoured to obtain the sugar formed by solution in alcohol, but no crystallizable sugar separated. Experiments made by mixing cold extract of "koji" with gelatinized starch invariably gave a rotatory power lower than that calculated from the amount of dextrose and dextrin, assuming only these two substances to be present. The author leaves the detailed consideration of these reactions for a future communication; at present he is satisfied to have shown that the diastase of "koji," unlike that of malt, yields glucose and dextrin when it acts on gelatinized starch.

Dr. Armstrong said that the paper was very suggestive and interesting, but he was sorry that more details of the methods and especially of the polariscope used were not given. He must differ from the author, and did not think he had proved that glucose was formed. The author seemed to think that the formation of dextrose and dextrin was due to the eurotin, an unorganized ferment resembling diastase, and to neglect the action of the organisms present, which are, as is well known, capable of converting starch into dextrose.

Mr. Groves called attention to the large amount of alcohol present and suggested that it might be due to the particular organisms present.

The Secretary then read a note on—

The Products of Combustion of Coal Gas. By L. T. Wright.—Some years ago the author was much struck by the powerful odour, suggestive of ozone, which he noticed when coal-gas was consumed in a Bunsen burner in an atmosphere charged with the nitrogen oxides evolved from fuming nitric acid. During some experiments on the estimation of sulphur in gas the author passed the products of combustion of a Bunsen burner through solutions of iodine, and noticed that after the iodine solution had been bleached and the current of gas stopped, free iodine reappeared after some time in the solution. This reaction was attributed to nitrous acid and was completely prevented by adding sodium bicarbonate to the iodine solution; the sulphur could then be determined by burning half a cubic foot of gas. In 1877 the author proved that nitrous acid was produced by the combustion of coal-gas in ordinary air but that if the gas and the air were both freed from ammonia no nitrous acid was formed (*Chem. Soc. Journ.*, 1879, Trans. 42). The futility of the ordinary methods of washing gases was also proved. The author has never had the least difficulty in obtaining a blue reaction with paper moistened with iodide of potassium and starch when coal gas is burning in a Bunsen burner. Since reading Mr. Ridout's paper on "The Production of Ozone," read before the Society a few weeks back, further experiments have been made, and the author concludes that ozone is not formed by the combustion of coal-gas, and that while ordinary gas burned in air usually gives the blue colour with starch and iodide of potassium, no such reaction is obtained when ammonia and its compounds are completely removed previous to combustion.

The Secretary then read a paper on—

Polysulphides of Sodium. By H. Chapman Jones.—These bodies were usually prepared by the direct union of sodium and sulphur; the author establishes the existence of Na_2S_5 which on heating gives off sulphur and leaves Na_2S_4, it being extremely difficult to obtain the substances pure. The body Na_2S_5 seems to be the highest sulphide procurable; in a body containing more sulphur than the pentasulphide, the excess of sulphur seems to be merely dissolved. An aqueous solution of Na_2S_5, when gently warmed evolves sulphuretted hydrogen; the pentasulphide cannot, therefore, be satisfactorily prepared by boiling a lower sulphide with excess of sulphur; on boiling the above solution no sulphur is precipitated, $Na_2S_2O_3$ and SH_2 being formed. The author has examined the action of cadmium carbonate and other cadmium salts on the pentasulphide and concludes that the precipitate consists of cadmium sulphide and sulphur, the latter being removable by carbon disulphide. The pentasulphide is believed by the author to be a tetrathiosulphate. He hopes to be able to prepare the di- and tri-thiosulphates, and has obtained on several occasions a substance (giving a dark green solution having an absorption band) which may be one of these bodies. In conclusion the author gives some properties of a black residue which is uniformly left when sulphur is burned, but has not examined the substance as Dr. T. Cross (*Berl. Ber.*, 1879, 788) is already investigating the subject.

The next paper was read by the Secretary on—

The Reflection from Copper, and on the Colorimetric Estimation of Copper by means of the Reflection Cuprimeter. By T. Bayley.—The author has shown that the light reflected from metallic copper contains all the elements of white light, but that the region of the spectrum to the red side of the D line is more intense than in the spectrum of the reflection from a white surface of equal illumination; the light transmitted by dilute solutions of cupric salts is deficient in those rays which the spectrum of reflection has in excess. It follows that if we look at a copper surface through a sufficient thickness of cupric sulphate solution, the metal appears silver white, for the solution absorbs the excessive rays which make the copper red. Upon these facts the construction of the "reflection cuprimeter" is based. The direct light from the sky is reflected from a mirror of copper and through two vertical tubes closed at the bottom by plates of glass. The sheaves of light are concentrated by lenses on two layers of tissue paper moistened with glycerine. The level of the liquid in the tubes can be adjusted by means of an aspirator. A standard solution of copper is made by dissolving 1 gram of copper in nitric acid, adding excess of sulphurous acid and diluting to a litre. It was found that a depth of 8·01 centimetres of this solution gave the silver-white tint to the copper reflector. Iron does not interfere if reduced to the ferrous state. The degree of accuracy is shown by analyses. The apparatus is made by Messrs. Jackson, 65, Barbican.

The next paper was—

On Pyrene. By WATSON SMITH and G. W. DAVIES.—The crude material was obtained from Dr. Schuchardt and consisted of a dark brown crystalline mass. This was purified by solution in petroleum spirit and crystallization. Crystals were light yellow, melted at 149°. A drawing of the crystals and a determination of the angles of the faces are given. The crystals are monoclinic. Analysis gave the formula $C_{16}H_{10}$. Vapour density was found to be 6·912, calculated 6·999. The authors used Victor Meyer's method and a lead bath. They recommend smoking the glass, dipping into the melted lead, in a luminous gas flame; this prevents cracking and adherence of the lead.

Analyses of the Ash of the Wood of two Varieties of the Eucalyptus. By WATSON SMITH.—The two varieties were the red and blue gum trees, *E. rostrata* and *E. globulus.* The wood is remarkably hard and gives rise to a powerful aromatic odour when planed. Sp. gr. of *E. rostrata* is 0·8112, of *E. globulus* 0·752. Ash respectively 2·25 per cent. and 2·01 per cent.; K_2O and Na_2O, 12·9 per cent. and 25 per cent., CaO, 43·8 per cent. and 35·08 per cent., with small quantities of iron alumina, etc. The author suggests the use of a decoction of the leaves of *E. globulus* as tea.

On the Action of Organo-Zinc Compounds on Quinones. Second Notice. By F. R. JAPP.—In a previous communication the author described a compound of the formula $C_{16}H_{14}O_2$–C_2H_6O, but failed to isolate the substance $C_{16}H_{14}O_2$; in the present paper this body has been isolated and its more important reactions studied. The alcohol was absorbed by sulphuric acid after being sealed up some months in an N-shaped glass tube. Analysis gave the formula $C_{16}H_{14}O_2$. The substance melted at 80°. In the reactions the compound $C_{16}H_{14}O_2C_2H_6O$ was employed. By oxidizing a solution in glacial acetic acid with chromic anhydride a mass of orange-coloured needles of phenanthrene quinone was obtained. By distillation with zinc dust, redistilling the distillate and treating the product with picric acid, the double compound of phenanthrene and picric acid was obtained in long orange needles, melting at 143°, from which phenanthrene was obtained, melting at 95°–96°. On treating the compound $C_{16}H_{14}O_2C_2H_6O$ with caustic alkali it dissolves, yielding a potassium salt in satiny flat needles, soluble in water; from this solution CO_2 precipitates the body $C_{16}H_{14}O_2$, which thus behaves like a phenol. The author then considers the question as to the constitution of the quinones and comes to the conclusion from the action of zinc ethyl and other considerations that Graebe's views are correct and that phenanthrene quinone has the structure of a peroxide, thus

$$\begin{array}{l} C_6H_4\text{—}C\text{—}O \\ \;\;|\qquad\;\; \| \quad\; | \\ C_6H_4\text{—}C\text{—}O \end{array}$$

and is not, as suggested by Fittig,

$$\begin{array}{l} C_6H_4\text{—}C=O \\ \;\;|\qquad\;\; | \\ C_6H_4\text{—}C=O \end{array}$$

Dr. Armstrong objected to the conclusions arrived at by Dr. Japp and thought that though his argument was very ingenious it was not conclusive; in fact, that it was just as likely that a substance having the constitution assigned by Fittig would give

$$\left\{\begin{array}{l} C_6H_4C(OEt) \\ \qquad \| \\ C_6H_4C(OZnEt) \end{array}\right. \quad \text{as} \quad \left\{\begin{array}{l} C_6H_4C \left\{\begin{array}{l} Et \\ OZnEt \end{array}\right. \\ \qquad\;\; | \\ C_6H_4CO \end{array}\right.$$

In fact, the probabilities were in favour of the first supposition, when the behaviour of phenanthrene quinone with nascent hydrogen was considered.

The Society then adjourned to April 15, when the following papers were to be read: "On the Lecture Illustration of Chemical Curves," by Dr. Mills, and "On the Analysis of Organic Bodies Containing Nitrogen," by W. H. Perkin.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, March 25, Mr. H. Allen, Vice-President, in the chair.

Mr. W. Elborne, in a preliminary note on the "Preparation of Tinctures," drew attention to a new apparatus which he had devised for the preparation of the tinctures of the British Pharmacopœia with a minimum of loss. The author will communicate the results of his experiments in a paper to be read on May 13.

A Report on Inorganic Chemistry was then read, dealing with the subject of—

THE FORMULÆ OF SOME INORGANIC SUBSTANCES.

BY C. H. HUTCHINSON, F.C.S.

The introduction of some simple form of apparatus for the achievement of a particular branch of scientific research has often been the precursor of important discoveries in that branch. An example of this fact may be now seen in the beautifully simple apparatus which Professor V. Meyer has invented for the determination of vapour densities, and by means of which he and C. Meyer and Züblin have already accomplished much important work, extending from the verification of doubtful vapour densities to the probable dissociation of some "elements."

As the apparatus has been already described to the Association by Dr. Senier (see *Pharmaceutical Journal*, May 17, 1879), I can pass immediately to an account of some of the results which have been obtained by means of it; all of these are not new, but are worth collecting, since they have been arrived at under conditions differing from those originally employed, and, coming from such skilful hands, dispel at once any doubts which may have existed with regard to them.

The substances chosen for examination have been chiefly those about the formulæ of which doubt may have arisen, or which for various reasons have never been experimented with in the form of vapour. Pentasulphide of phosphorus is such a one, for although several determinations of its pentachloride have been made, the pentasulphide has not been thoroughly examined on account of its high boiling point. It seemed interesting, therefore, to determine whether this substance could be volatilized unchanged, or whether its composition in the state of gas was represented by $3P_2S_3+S_6$ or $P_2S_3+S_2$. Accordingly the vapour density was taken at a red heat in a lead-bath, the bulb of the glass apparatus being protected by means of a layer of clay 2 to 4 mm. thick, which prevented the shape of the glass vessel being in the slightest degree altered. The apparatus was filled with nitrogen, a proceeding which was adopted in nearly all the estimations which will be here enumerated. Two determinations* gave the numbers 7·63 and 7·67, and since the calculated vapour density of P_2S_5 is 7·67 the experiment shows that this substance does not suffer dissociation when volatilized at this temperature.

In a similar manner they have also obtained the vapour density of indium chloride, for the volatilization of which a temperature just short of bright red heat is necessary, a temperature which the glass bears quite well if it be covered with the coating of clay. The numbers found in their determination were 7·87, which accord very well with the calculated density of $InCl_3$ (7·6).

The method of weighing such deliquescent substances as this was as follows:—The bottle to be introduced into the density apparatus was weighed in a stoppered bottle, then taken out and connected to a glass rod by means of a piece of india-rubber tubing passed over its closed end, and when thus conveniently held filled with the powdered substance by being pushed into it, in the bottle in which it was stored; after removing the particles adhering to the outside by wiping with silk the bottle was replaced in the stoppered bottle and again weighed.

* *Deut. Chem. Ges. Ber.*, 12, 609.

Since the specific weight of the vapour of no copper compound is known the determination of the vapour density of cuprous chloride is of considerable interest. The temperature at which this substance volatilizes is so high that it was necessary to employ a porcelain apparatus instead of the usual glass one; this was constructed in the same shape and about the same size, differing, however, in the fact that the narrow tube ended at 200 mm. from the bulb, and to it was joined by means of a piece of india-rubber tubing the ordinary glass gas delivery tube. The bottle in which the substance to be experimented upon was weighed consisted merely of a piece of the stem of an ordinary clay tobacco-pipe, 2 to 3 c.m. long, closed at one end by a clay plug fused into it. The source of heat was a Perrot's gas furnace.

The determinations showed that the usually accepted formula for this substance, viz., Cu_2Cl_2 was correct, the numbers obtained being 7·05* and 6·93,† instead of that calculated for this formula, 6·84.

Mitscherlich, forty-five years ago,‡ showed that the formula of arsenious acid is As_4O_6 and not that which has been customarily adopted. Some chemists, and Kolbe among them, seem to have been of the opinion that arsenious acid would have a density corresponding with the formula As_2O_3 if estimated at a sufficiently high temperature.

In order to settle this point two determinations were made,§ one at a moderate red heat, the other at a temperature of about 1560° C. The vapour density obtained in the first experiment was 13·80, in the second 13·78; both of which numbers correspond with that calculated for As_4O_6, 13·68.

Similarly the formula for antimonious oxide is Sb_4O_6, instead of that usually accepted, as shown by the numbers 19·6 and 19·98 obtained‖ at a temperature of about 1560° C., which agree with 19·9, that calculated for Sb_4O_6.

The vapour density of mercuric sulphide (cinnabar) has also been determined by Mitscherlich, who obtained the numbers 5·95, 5·99. On this result he could not, however, place much confidence, since the glass of this apparatus was considerably attacked. The work was therefore repeated in Zurich, a porcelain tube being employed, the vapour density found being 5·39,¶ the density calculated for a mixture of $Hg+Hg+S_2$ is 5·34. It is noteworthy that at the temperature employed by Mitscherlich, 669° C., the sulphur existed as S_2 and not as S_6.

The only work which has been published with regard to the vapour density of stannous chloride is a short note by Rieth,** where he records the numbers 7·47 and 6·88, which points to the formula $SnCl_2$, the corresponding number being 6·53.

The Messrs. Meyer thought it desirable to repeat this work, which they accordingly undertook and at temperatures of about 619° and 697° C. obtained the numbers 12·85 and 13·08. These seem to show that the formula should be doubled, since the density calculated for Sn_2Cl_4 is 13·04. The difference between their results and those obtained by Rieth they attribute to the probability of decomposition having taken place at the temperature employed by the latter.

Dr. Carnelly, however, suggests†† that the Meyers' results were obtained at a temperature too near the boiling point of stannous chloride, 617°–628° C., so that the formula suggested by Rieth's work may after all be the correct one.

No determination of the vapour density of zinc chloride having been made, this substance was next chosen, and volatilized in the porcelain apparatus, which is not acted upon by the gas at temperatures below the melting point of iron. The temperature employed was about 907° C.; the resulting numbers were 4·53 and 4·61. The number calculated for $ZnCl_2$ is 4·7.

Two determinations of the vapour density of ferric chloride, one at the boiling point of sulphur,* the other at 619° C., gave respectively 11·14 and 11·01, these numbers agreeing with that calculated from Fe_2Cl_6, viz., 11·23.

Since only the density of cadmium itself is known it was considered desirable to determine the vapour density of one of its salts, the bromide being chosen. This acts on glass at a temperature of 800° C.; the estimation was therefore conducted in the porcelain apparatus. At a temperature of about 923° C. the density 9·22 was found; at a temperature of about 914° C., 9·28. The vapour density calculated for $CdBr_2$ is 9·40.

The task of determining the vapour density of the alkali metals has also been undertaken by Victor Meyer, but so far without success, he finding, as others before him, that these metals exert a powerful action on the apparatus employed. Thus Mitscherlich in 1834† found that Bohemian glass tubes were destroyed by the vapour of potassium. Rieth, in 1871,‡ was met by the same difficulty, and gave up the experiments after finding that determinations in copper tubes were likewise untrustworthy. Dewar and Dittmar,§ endeavoured to effect the determination in iron vessels, but, as was pointed out by Dewar and Scott later on,‖ this method is impracticable, since iron absorbs the vapours of the alkali metals, an alloy being produced. Victor Meyer attempted to obtain a determination in his porcelain apparatus¶ in an atmosphere of nitrogen, but found that the porcelain under the action of the sodium vapours was converted into a black mass. His next experiment was with a Bohemian glass apparatus which had been coated with silver inside; a red heat, however, quickly turned the silver bottle with its charge of sodium into a lump of alloy, the vapours from the sodium being so rapidly absorbed by the silver that no gas escaped from the apparatus; a platinum vessel proved itself equally unsuitable for the determination. The only substance not tried which is likely to withstand the action is carbon; there are, however, difficulties in the way of preparing an apparatus from this substance.

These negative results were published by Victor Meyer on account of the publication by Dewar and Scott of the vapour densities of the alkali-metals** obtained by operating in a wrought iron apparatus of the same construction as Meyer's and by means of which they obtained results corresponding with the formulæ K_2, Na_2. In their next paper, however,†† they state that the vapours of the alkali metals, as before quoted, are absorbed by iron, and therefore these results were not trustworthy. They then repeated their experiments in a platinum apparatus, finding numbers agreeing with the formulæ K_1, Na_1, though these are not more trustworthy than the last, since they state that the platinum apparatus was so strongly acted upon as to be useless after two or three experiments.

As a continuation of their work on the vapour densities of gases at high temperatures, Professor V. and Herr C. Meyer determined to examine the specific weights of the elements at the highest yellow heat attainable in their gas furnace.‡‡

Since the accuracy of their results depended entirely on the non-decomposability of the nitrogen molecule at

the temperatures employed, it was considered advisable to check its behaviour at widely differing temperatures against that of a gas whose molecules were even less likely to divide. The gas chosen was that from mercury, since as this substance has a monatomic molecule, the probability of a further division is as small as possible. Two estimations gave the following results:—At a temperature of about 440° C., 6·86; at about 1567° C., 6·81; calculated for Hg 6·91.

These experiments showed the nitrogen to be trustworthy, and accordingly the density of oxygen was chosen for the next determination. Since, however, the nature of their apparatus required the substance to be introduced in the solid form, it was necessary to choose some compound which at the temperature employed would part entirely with its oxygen, and the residue of which would not be in the least volatilized.

Silver oxide, answering these requirements, was chosen, the results obtained being at a temperature of about 1392° C., 1·06, 1·04; at about 1567° C., 1·04, 1·06; the calculated density of O_2 is 1·105.

The results of this and other experiments were to show that the elements oxygen, nitrogen and sulphur, possess the usually ascribed formulæ at the temperatures employed—O_2, N_2 and S_2.

In the case of chlorine, however, different results were obtained. The substance chosen for examination was platinous chloride, which is more convenient to handle than either platinic or gold chloride, not being deliquescent. The results, which are tabulated below, show that at a temperature of about 800° C., the dissociation of chlorine commences, medium numbers being obtained at 1000° C.; whilst at 1200° C., the numbers become again constant, corresponding with $\frac{2}{3}$ Cl_2, thus:—

Approximate temperature.	Observed density.	Calculated density.
620° C.	2·42 2·46	Cl_2 : 2·45
808° C.	2·21 2·19	
1028° C.	1·85 1·89	
1242° C.	1·65 1·66	
1392° C.	1·66 1·67	
1567° C.	1·60 1·62	$\frac{2}{3}$ Cl_2 : 1·63

In order to satisfy themselves that the porcelain apparatus had not been acted upon, a piece of one of the tubes was cut off, and after the external glaze had been removed by grinding, it was dried and weighed, and then heated to a temperature of about 1567° C. in a stream of chlorine gas; on again weighing, the weight was found to have remained constant.

The next substance examined was, as one might naturally expect, iodine.* The substance employed in this case was the carefully purified solid halogen. The results of fourteen experiments in the porcelain apparatus are tabulated below:—

Approximate temperature.	Observed density.	Calculated density.
253° C.	8·89 8·83	I_2 : 8·78
450° C.	8·84 8·85	
586° C.	8·73 8·71 8·71	
842° C.	6·68 6·80 6·80	
1027° C.	5·75 5·74	
1570° C.	5·67 5·60 5·71* 5·81*	$\frac{2}{3}$ I_2 : 5·83

On comparing this table with that already given for chlorine, it will be seen that the density corresponding with $\frac{2}{3}$, the accepted formula, is reached at a much lower temperature in this case than in that; the chlorine requiring a temperature of 1200° C., whereas 1000° C. is sufficient to produce a constant $\frac{2}{3}$ density in the case of iodine.

That the iodine had no action on the porcelain tube was proved by comparing the results obtained in it with those obtained in a platinum apparatus.† In this case the iodine vapour comes in contact with nothing but platinum and nitrogen, as no substance such as asbestos or sand is necessary to break the fall of the small bottle, a precaution which has to be taken in the glass and porcelain apparatus. The results thus obtained are included in the table given above, being those found at a temperature of about 1570° C. marked with an asterisk.

It was not considered desirable to determine chlorine in this way on account of the action which that gas exerts on platinum at a high temperature.

With the object of obtaining the vapour density of bromine it was at first decided to work with platinous bromide. Professor V. Meyer and Herr Züblin found, however, that platinic bromide may easily be prepared in the following manner:—Platinum sponge is heated with bromine and aqueous hydrobromic acid in sealed tubes to a temperature of 180° C., the filtered liquid is evaporated to dryness, the residue dried at 180° C., the platinic bromide thus obtained extracted with water to separate from traces of platinous bromide, again evaporated to dryness and the residue dried at 180° C.* Operating with this substance at a temperature of about 1570° C. they obtained the numbers 3·78 and 3·64, which agree with those calculated for the formula $\frac{2}{3}$ Br_2, viz. 3·64.

Experiments were then instituted with free bromine, which at a temperature of 100° C. gave the density 5·38, corresponding with the density of Br_2 5·52. But when attempting to perform the experiment at a yellow heat, they were met with the difficulty that the bromine volatilized with explosive violence; by sealing small quantities in capillary tubes they were, however, enabled to obtain the following results, the difference between them probably referable to the explosive manner in which even these small quantities are volatilized:—

4·30; 4·14; 3·94; 3·99; 3·78; 4·20; 4·14.

These numbers lie between those calculated for Br_2 5·52 and $\frac{2}{3}$ Br_2 3·64.

This difficulty of the too rapid vaporization of bromine and other volatile substances such as water, they have not yet been able to overcome; they hope, however, soon to be able to publish a table of the densities of bromine at differing temperatures in order to show at what temperature this substance first exists as $\frac{2}{3}$ Br_2. These experiments they are not yet able to undertake on account of other substances which are now the objects of examination.

I will now draw your attention to objections which have been raised to this latter part of Meyer's researches.

Professor Seelheim's criticism shall be the first to be considered. He suggested that the determination of the vapour density of chlorine might have been rendered inaccurate owing to the volatilization of platinum which is known to take place in an atmosphere of chlorine.

Professor Meyer replied† that he had exposed platinum at a temperature of 1570° C. to the action of a stream of dry chlorine gas and found that in the course of one hour it lost about 1 per cent. Now in the case of his determinations, which only occupied a few seconds, the platinum left by the chlorine only weighs about 0·07 gram, and this is not subject as in the experiment above referred to, to the action of a stream of chlorine, being almost instantaneously separated from the chief bulk of the gas by the bottle containing it. He therefore considers that the volatilization of the platinum does not practically occur, an argument which is supported by the fact that after weighing the platinum left in the bottle after the experiment, he found it now suffered no loss.

In the *Compt. Rend.*, 90, 184, Professor Crafts published an account of some experiments he has been carrying out with a modification of Meyer's apparatus, the modification consisting of two graduated and calibrated U tubes kept at constant temperature by a bath of cold water, connected with Meyer's apparatus in such a manner that by means of a fine tube a measured volume of a gas

* *Deut. Chem. Ges. Ber.*, 13, 394.
† *Ibid.*, 12, 1398.

* *Deut. Chem. Ges. Ber.*, 13, 404.
† *Ibid.*, 12, 2022.

could be transferred from the one U tube to the heated bulb of the apparatus, the amount of gas displaced by it being collected and measured in the other U tube.

The apparatus being filled with air and heated to the highest temperature of the Perrot's furnace, two experiments showed that 10 c.c. of chlorine displaced 10·37 c.c. and 10·24 c.c. of air, and the apparatus being filled with chlorine 10 c.c. of air were found to displace 9·98 and 10 c.c. of chlorine. Operating with a platinum vessel instead of the porcelain one used in these experiments, he found that 10 c.c. of chlorine displaced 10·43 c.c. and 10·50 c.c. of air. If the expansion observed by the Meyers had taken place, the quantity of air collected should have been 15 c.c., that of chlorine, 6·6 c.c.; his experiments, therefore, with free chlorine do not verify those of the German chemists with nascent chlorine.

Working with iodine, he obtained the densities 6·01 and 5·93, which correspond very nearly with 5·83, the calculated density of $\frac{2}{3}$ I_2.

Bromine was found to be intermediate, giving the numbers 4·39 and 4·48, instead of 5·57, the normal density.

Professor Meyer, referring to this observation of Professor Crafts,* states that he had observed this property of chlorine some months before the appearance of the latter chemist's publication, and† describes his method of experimenting, which was as follows:—

The heated apparatus was filled with dry chlorine by means of a narrow platinum tube, reaching down to its bottom; after this had had time to be heated to the temperature of the furnace, it was displaced by air passed through the same tube, its amount being estimated by titration of the iodine displaced from a solution of potassium iodide. By filling the apparatus with dry air, and allowing it likewise to attain the temperature of the furnace, and then displacing it by means of carbonic anhydride and collecting in a measuring tube over potassium hydrate solution, the contents of the porcelain apparatus were determined; corrections were then made, so that the volumes of gas compared were only those contained in the strongly heated part of the apparatus.

The results of the comparisons thus instituted showed that free chlorine is not dissociated at this temperature (yellow heat); the numbers obtained were 2·57, 2·63, 2·64, that calculated for Cl_2 are 2·45.

It might be interesting further to state that the explanation of the difference between the observations of V. Meyer on the one hand,‡ and Troost and Deville on the other, may perhaps lie in the different conditions attending the respective experiments, and therefore both observations may be correct.

Troost and Deville, who used iodine in their classical researches on vapour densities, first assured themselves that the expansion of this substance is regular. Meyer, as has been shown, found the expansion to be irregular.

In the experiments of the latter, the iodine was almost instantaneously raised to a high temperature, in contact with another gas; in the former case, the iodine being introduced into the apparatus was slowly heated to the required temperature, and whilst under experiment was not in contact with another gas.

The differences in the results produced by such a different procedure in the case of destructive distillation is well known; the influence, too, of a foreign body in promoting the dissociation of complicated molecules or molecular groups is well illustrated by the interesting researches of Horstmann,§ on the vapour of acetic acid, in which he showed that although the vapour density of this substance, when heated alone, is only normal at a temperature considerably above its boiling point, the theoretical value may be obtained even at the temperature of a room, if the vapour be experimented upon when mixed with a considerable amount of air.

In order to satisfy themselves that oxygen or nitrogen has no special influence in promoting the dissociation of iodine, Professor Meyer and Herr C. Meyer took its vapour density in an atmosphere of hydrochloric acid, the result verifying the former observations, being 5·98 at a temperature of about 1570° C., instead of 5·83 calculated for $\frac{2}{3}$ I_2.

What the products of the dissociation of chlorine, bromine and iodine may be, we do not yet know; that a change has taken place similar to that in the sulphur molecule at different temperatures is scarcely probable, or proof of the heteromorphic nature of these substances would surely, ere now, have been found in some one of the many compounds containing them, whereas all those examined have been shown to contain (to take the case of chlorine) either 35·4 or a multiple of this number, and never a multiple of its part. We must therefore wait for a solution of this problem at the hands of those who, by their accuracy of thought and skill in experimental research, grace the science of chemistry with those discoveries to which it owes its very existence.

For convenience of reference, I here append a table of the substances whose formulæ have been considered in the foregoing report.

Cu_2Cl_2 .	$CdBr_2$	As_4O_6	P_2S_5	Hg
Fe_2Cl_6 .	...	Sb_4O_6	..	O_2

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the above held on March 24, Mr. F. W. Branson in the chair, a paper was read by Mr. W. Smart, on "The Growths and Functions of the Skin."

The author first described the anatomical structure of the skin, illustrating his remarks by reference to diagrams; then followed an explanation of its physiology and the functions of absorption and excretion, also the part played by it in the regulation of temperature. The sensibility of the skin relative to the estimation of weight and temperature under varied conditions was commented on. The origin, development, and structure of various skin modifications, as hair, nails, teeth, etc., were then considered, and the paper was concluded by an excellent exhibit of microscopic slides of the tactile corpuscles, sweat glands, etc.

After the discussion, a vote of thanks was proposed by Mr. Wallis, seconded by Mr. Lund, and carried unanimously.

The last paper of the session will be read on Wednesday next, April 21, by the President; subject, "Chalk: its Origin and Distribution."

Parliamentary and Law Proceedings.

The Use of a Perfumery Trade Mark.

In the Chancery Division of the High Court of Justice, April 9, 1880, before the Master of the Rolls, the case Rimmel *v.* Thompson came on for hearing. This was a motion by the plaintiff, the well-known perfumer, for an injunction to restrain the defendants, who trade under the name of "The Crown Perfumery Company," from

* *Deut. Chem. Ges. Ber.*, 13, 394.
† *Ibid.*, 399.
‡ *Ibid.*, 401.
§ *Ibid.*, 3, 78, and 11, 1278.

* Dr. Carnelly (*Deut. Chem. Ges. Ber.*, 12, 1836) considers that the density corresponding to the formula was obtained at a temperature too near the boiling point of stannous chloride.

using certain labels on perfumery and other articles sold by both parties, and being an imitation of labels used by the plaintiff. The labels used by the defendants were stated to be for the Brazilian market, and were, according to his Lordship's opinion, an improper imitation of those used by the plaintiff. The defendants now gave an undertaking not to use the eight labels complained of or any imitation thereof, and the costs of the motion were made costs in the action.—*The Times*.

Reviews.

Cooley's Cyclopædia of Practical Receipts and Collateral Information in the Arts, Manufactures, Professions and Trades, including Medicine, Pharmacy and Domestic Economy; designed as a Comprehensive Supplement to the Pharmacopœia and General Book of Reference for the Manufacturer, Tradesman, Amateur and Heads of Families. Sixth Edition. Revised and greatly enlarged by Richard V. Tuson, M.I.C., F.C.S., etc. London: J. and A. Churchill. 1880.

"Cooley" is a work well known to a large number of chemists and druggists, who are in the habit of consulting it in the thousand and one difficulties with which they meet in carrying on their business. Comprehensive as the rather long title is, in the original author's opinion it did not express completely the design of the work, and it must be admitted that it raises no expectations that are not fairly fulfilled. This opinion finds confirmation in the fact that Cooley's 'Cyclopædia' has now passed through five editions, and indeed were it not that in its sixth edition it comes to us in a much altered form a commendatory reference to so well established a favourite might seem superfluous.

The new edition has been issued in sixteen monthly parts, and now that it is completed it makes two thick volumes of 900 pages each, instead of one of 1200 pages. A considerable proportion of this increased size is due to the insertion of a number of fresh articles on medical subjects, notices of new additions to the materia medica, and several fresh wood cut illustrations. We notice also many new recipes and formulæ. The work is moreover brought well up to date in other subjects, such as electric lighting, liquefaction of gases, weights and measures legislation, etc.

The revision of such a work must have been a task of no slight dimensions, and it appears on the whole to have been admirably performed. But it must be confessed that a considerable number of errors have been overlooked. Thus in the Paris Society's formula for dialysed iron the specific gravity of the solution of ammonia to be used is given as 1·169. We mention this error particularly because, although not so stated, the paragraph in which it occurs appears to have been copied from this Journal (where a similar slip occurred and was the subject of a correction), and the mistake would probably not have been perpetuated had the rule which Mr. Cooley laid down for himself been followed,—"Secondary channels of information have been scarcely ever relied on when original authorities were within my reach." In another case where this Journal is quoted as the authority we have "Carnauba wax" uniformly turned into "Carnanba wax," an error for which we must decline any responsibility. Then in the list of "Eclectic Remedies," there are "Baptis*t*in," and "*In*glandin" (? "Juglandin"), and in the list of "Vapours" we find "Vapor Pini Plumilionis," "Vapor creosoti, B.P., and "Fir-woo*d* oil." In the article on "Mixtures, Arithmetic of," under *b*, a not very lucidly expressed rule is obscured by a wrong figure in the illustration. These errors are typical of others that occur, and are mentioned not because of their importance, but because they may easily be eliminated. They are only slight blemishes in a book that has no rival in the amount of information it contains which is specially applicable in the every-day business of the chemist and druggist.

The Society of Arts Artizan Reports on the Paris Universal Exhibition of 1878. London: Sampson Low, Marston, Searle and Rivington. 1879.

A few weeks before the opening of the last International Exhibition in Paris, a suggestion was made by the Prince of Wales to the Council of the Society of Arts that it should undertake the duty in co-operating with a Committee to be appointed from the members of the Royal Commission, of sending a number of selected artizans to Paris, with a view to the preparation by them of a series of reports on the articles representing their respective trades in the great building in the Champs de Mars. The suggestion was acceded to, and at the solicitation of the Committee that was formed the movement received active assistance from the municipal authorities and chambers of some of the larger towns, as well as of private firms, and eventually two hundred and eight artizans visited the Exhibition under the auspices of the Committee. The reports received from these delegates numbered one hundred and sixty-eight, and of these about forty have been printed at the expense of those by whom the reporters were sent. From the remainder a selection of about as many more has been made, to form the material of a bulky octavo volume, which has been issued under the editorial supervision of Mr. H. Trueman Wood, the secretary of the Society of Arts.

The branches of industry reported on in this volume are, pottery and glass, art workmanship, mechanical engineering, agriculture and horticulture, the building trades, cabinet work, watch and clock making, jewellery and optical instruments, printing, textile fabrics, leather and india rubber, and mining and metallurgy. It will be seen therefore, that the book contains nothing having a special bearing upon pharmacy, for only the barest mention of microscopes and spectroscopes occurs in the report on optical instruments. But notwithstanding this, and although marred here and there, as might be expected, by attempts at fine writing, crudeness of expression, and inopportune moralizing, the reports selected are important as the intelligent expression of the results of the observation of picked workmen upon the objects belonging to their respective crafts, and frequently, also, of the conditions under which they were produced. They will therefore be welcomed by all those who take an interest in the relative progress of the British artizan in his competition with the foreigner, whilst to many who enjoy a hobby, in glass, pottery, or other departments—as many pharmacists do—they will have a special value.

Potable Water. How to Form a Judgment on the Suitableness of Water for Drinking Purposes. By Charles Ekin, F.C.S. London: J. and A. Churchill. 1880. From the Publisher.

Obituary.

Notice has been received of the death of the following:—

On the 15th of December, 1879, Mr. Gavin Stiell, Pharmaceutical Chemist, Dunfermline. Aged 68 years. Mr. Stiell had been a Member of the Society since 1841, and for several years acted as its Local Secretary in Dunfermline.

On the 6th of March, 1880, Mr. John Page, Chemist and Druggist, Blackfriars Road. Aged 61 years. Mr. Page had been a Member of the Pharmaceutical Society since 1870.

On the 12th of March, 1880, Mr. Samuel Smith, Chemist and Druggist, Mabgate, Leeds. Aged 84 years.

On the 20th of March, 1880, Mr. George Rossiter, Chemist and Druggist, Tiverton. Aged 64 years.

On the 21st of March, 1880, Mr. William Smith, Pharmaceutical Chemist, Western Road, Brighton. Aged 51 years. Mr. Smith had been a Member of the Pharmaceutical Society since 1853.

On the 24th of March, 1880, Mr. Thomas Hall, Pharmaceutical Chemist, Westgate, Grantham. Aged 74 years. Mr. Hall had been a Member of the Pharmaceutical Society since 1849.

On the 31st of March, 1880, Mr. Robert Gibson, Chemist and Druggist, Soho, W. Aged 40 years.

On the 1st of April, 1880, Mr. Richard Hind Harburn, Chemist and Druggist, Bishop Auckland. Aged 48 years.

On the 8th of April, 1880, Mr. Jonathan Henry Adams, Pharmaceutical Chemist, Stoke-on-Trent. Aged 62 years. Mr. Adams had been a Member of the Pharmaceutical Society since 1853.

On the 11th of April, 1880, Mr. Thomas Hartley Pickup, Pharmaceutical Chemist, Blackburn. Aged 62 years. Mr. Pickup carried on business as a chemist and druggist in Preston upwards of forty years, and during that time took an active part in municipal affairs. He was elected an alderman, and in 1869 and again in 1870 he was chosen mayor, an office that he filled with great credit. In 1874 he was appointed on the commission of the peace for the borough. Mr. Pickup became a Member of the Pharmaceutical Society in 1845, and for many years served it as Local Secretary.

Correspondence.

The Sale of Patent Medicines containing Poison.

Sir,—I have read with much interest your paper upon this very important subject. I have had numerous private letters from town and country correspondents, some thankful and flattering, and others setting me right upon some trifling inaccuracy or omission which are unnecessary to allude to, as they are completely wide of the mark and object. From many remarks and letters, I find I am much misunderstood.

The objects in taking the course I did, and the letter I wrote, were two.

1. To show that the restrictions put upon chemists by section xvii of the Pharmacy Act of 1868 are inoperative, and worse than useless so long as the provisions of that section are rendered for all practical purposes null and void by section xvi, in dealing with patent medicines.

2. To show how injurious to general and domestic safety, and encouraging bad habits to the weary minded and wakeful, and leading to very serious consequences, disasters, and accidents of the most unfortunate kind,—the greatly reduced licence giving grocers and others every facility to scatter broadcast even to little children (!!) potent poisons, the nature of which they are utterly ignorant of.

In consequence of this absurdly ridiculous state of things, chemists and druggists are, in my experience, hampered, perplexed, and not unfrequently offend their best friends, and for bringing these points as I may say to the surface and public opinion, I am sadly abused by some. I trust my humble efforts may prove more than "a nine days' wonder."

Henry W. Hubbard,
L.R.C.P., Vice-President, St. Mary's Hospital.
26, *Elgin Road, Notting Hill, W.*

The Dispensing and Vending of Poisons by Corporations.

Sir,—I fail to see the advantage of adopting the suggestions of Mr. Tebbutt in a recent Journal. On the other hand, I think it is clearly the duty of the Society to appeal to the House of Lords, whatever it may cost.

If the Sale of Poisons and Pharmacy Act of 1868 will not bear its intentions scrutinizing any better than its wording, surely it is high time the question was definitely settled, and the Act amended to include corporations if the decision is against us.

I still believe that as corporations cannot be examined therefore they cannot be registered, and consequently cannot legally dispense or vend poisons.

Our present position *re* poisons is a very one-sided arrangement; the public get all the protection now, but can they reasonably expect qualified men to keep shops in small towns on such terms and prices as the stores do business at?

If the present state of affairs continues, and the stores increase their trade, there will not be enough business to support a chemist in scores of small towns throughout the country, and the public will have to go a long way to find a chemist.

The Irish Pharmacy Act (if I am not mistaken) prohibits the sale of poisons by corporations.

If our Act fails on being put to the test, the sooner all registered chemists are aware of the fact the better it will be for everybody concerned.

Judging by the recent decision, there is nothing to prevent any grocer, draper or hairdresser from turning his shop into a limited company, by distributing a few shares amongst his assistants, then engaging a registered chemist and conducting all branches of our business. But the question arises, if corporations are exempt, need they employ a qualified person at all?

No Surrender.

The Sale of Patent Medicines containing Poisons.

Sir,—Whilst the subject of the sale of poisons by unregistered persons is so freely discussed in your columns, I write to communicate an unusual application for poison which I received at the uncomfortable hour of 5 o'clock on Sunday morning last. On answering the night bell, a young man, respectably dressed, but of vacant appearance, applied for some laudanum to give his father, and on inquiring for what purpose, he said that his father was suffering mentally from a family trouble, and that he was then so violent they had to procure assistance to hold him in bed, and he thought if he gave him a good dose of laudanum to procure sleep, he would soon be well again. I inquired if he had had medical advice, and he replied in the negative, so, of course, I refused to supply him, and cautioned him not to give his father narcotics without medical authority. He left the shop and I have not since seen or heard of him, so do not know what steps he took, but probably on the morrow he was able through the protection of the patent medicine stamp to procure the laudanum from some grocery stores and dose his father (or himself) *ad libitum*.

I may add the young man was quite unknown to me, and did not live in the neighbourhood.

Leamington. Edward Thornton.

Sir,—Is not the time arrived when the Pharmaceutical Council may suitably combine with members of the medical profession in an attempt to obtain for registered chemists and druggists the exclusive sale of proprietary medicines, or at any rate of such as contain poisonous ingredients? The facility with which such poisonous substances as chlorodyne and solution of chloral can be obtained from grocers, hucksters, etc., should make it evident that such a course would be conducive to the safety of the public, and the present is an auspicious time for chemists to bring the subject prominently before the notice of their local representatives in Parliament.

It is an old adage that "new brooms sweep clean," and is it not likely that a new Parliament, with the pressure that individuals in each locality could put upon its members, would be able to pass such a measure as proposed? Would it not, then, be well if the Council, in view of such legislation, should instruct the Secretary in London to forward to the local secretaries a circular setting forth the objects which they seek in legislation, with a list of cases illustrative of the importance of such legislation in the interests of the public, and requesting them to bring the matter in such way as they may deem best before their local representatives in Parliament? Such a united effort might be crowned with success.

Scarborough. CHAS. FRYER.

Sir,—Please except me from the Hubbardian stigma, as no chloral solution has ever been supplied without medical authority by

GEORGE ADAMS, M.P.S.

Clarendon Road, Notting Hill.

Election of Council.

Sir,—The important privilege of electing fourteen members of Council now devolves upon the Pharmaceutical Society, and it is to be earnestly hoped that every elector will conscientiously and wisely discharge the duty of voting for those gentlemen whose knowledge, experience, and interests are such as to guarantee a faithful performance of the onerous duties attaching to the office.

There are now no burning questions at issue, although the competition arising from co-operative societies is such as to cause the deepest concern, and is doubtless felt as much by the well-to-do members of our Society as by those in humbler positions. Happily the question of counter practice is at rest, and it therefore seems a pity that a name should have been put in nomination which is liable to bring this subject to the front again, especially one which is likely to arouse the suspicion and distrust of the Society of Apothecaries, which is now friendly towards us. Surely Mr. Shepperley has the interests of his brethren sufficiently at heart to perceive on reflection that it is incumbent upon him to withdraw from the contest.

A MEMBER.

Volumetric Estimation of Alkaloids.

Sir,—As unfortunately I could not be present at the last evening meeting, to read my paper on the "Volumetric Estimation of Alkaloids," perhaps you will allow me space to reply to some of the remarks of Messrs. Luff and Moss.

Neither of these gentlemen can, I think, have carefully gone over the paper or they would have seen that in the formula $3\,(BiI_3)\,2\,(\bar{Q}HI)\,x\,(HI)$, the value of "$x$" cannot by any possibility affect the results, and that if known, the knowledge would be of no practical service whatever. All the double iodides examined were found to contain more or less HI, and their formulæ therefore could be expressed in the form—

$$a\,(BiI_3)\,b\,(\bar{Q}HI)\,c\,(HI)\,;$$

but as for my purpose it was only necessary to know the value $\frac{a}{b}$, the value of "c" in the special case was not determined but put as "x."

That such an exceedingly simple matter should have so excited the wonder of Mr. Moss, and have proved such a stumbling block to Mr. Luff, is certainly surprising.

Again Mr. Luff says he is *loth to suppose* that I employ a certain formula, simply because it is the only which agrees with my results. Surely when it is ascertained that a certain amount of quinine is precipitated by a certain quantity of bismuth, it follows as a consequence that the precipitate thus produced will contain the two in that proportion, and as in the cases referred to, 3 atoms of bismuth were found almost exactly to precipitate 2 molecules of quinia, the inference is that the double iodide contains $3\,(BiI_3)\,2\,(\bar{Q}HI)$. Since also in all the specimens examined the molecule had been found to contain more or less HI, it was most likely that this precipitate also contained it, hence the addition of x (HI).

From the nature of these precipitates their accurate gravimetric analysis is almost impossible, but as I have shown that in most cases their composition, so far as regards the ratio of the bismuth to the alkaloid, can be readily determined by synthetic methods.

The formula above given was therefore employed, simply because it agreed with the results, and undoubtedly expressed the proportion of quinine precipitated by any given quantity of bismuth in my volumetric solution. Of course the formulæ could have been dispensed with, and perhaps, from a practical point of view, it would have been better to have avoided their use; but it will at once be evident to anyone that the formulæ for the quinine precipitate so closely corresponds to the results calculated from, say the three first experiments, from which the "titre" might have been standardized, that it is a matter of indifference in which manner the results of the other quinine determinations are calculated.

The formulæ of all the alkaloids were taken from the 'Pharmacographia' (first edition), and accepting the formula for aconitia given by Dr. Wright and quoted by Mr. Luff, the formula for the bismuth and aconitia iodide will be incorrect. This, however, does not affect the fact that in both the experiments 1 c.c. of "titre" precipitated 10 milligrammes of alkaloid.

With regard to the error in this case being in the third decimal place, Mr. Luff must know that by such an expression chemists understand the error to be between ·001 and ·009 per cent., whereas the difference (or error) between the amount of alkaloid precipitated, as determined by experiment, and the theoretical amount calculated from the formula is 2· per cent. Had I elected to express the quantities in kilograms, according to Mr. Luff the error would then have been in the sixth (!) decimal place.

Should time allow I should like to follow out the suggestion of Mr. Moss, and "evolve a process which would enable them to determine the quantity of alkaloids in all kinds of vegetable solutions and infusions," but since many substances interfere with the reaction, special methods would have to be devised to remove such substances from the infusions. It would also be necessary to know what alkaloid was present, and what quantity of it corresponds to 1 c.c. of the "titre."

The method given for aconite and belladonna roots may prove to be applicable in many instances, and some of the experiments alluded to are part of a series which I am conducting to ascertain whether such is the case or not.

Buxton. JOHN C. THRESH.

Poisonous Violet Powder.

Sir,—A poison is usually defined as a substance capable of destroying life when taken into the system either by the mouth or by absorption, and that in small quantity. I think this definition covers most of the ground of a debatable point; but the term "small quantity" does not always hold good. In the case of violet powder in which calcium sulphate enters into its composition, it is questionable how far the term "poisonous" is correct. I am inclined to think it is a misnomer.

When arsenious acid is added, either by mistake or to increase the weight of violet powder, the whole aspect is changed, and the word "poisonous" then possesses its full and true meaning. That such "violet powder" was sold it is now useless to deny, because one sample contained the enormous proportion of 38·5 per cent. of arsenious acid.

It would be idle to characterize such gross carelessness in manufacturing as other than akin to a criminal offence, and a most disreputable trade proceeding. The hackneyed word "mistake" is no excuse.

I am unwilling to blame any person in particular as to the continued manufacture of spurious violet powder by wholesale dealers; but, I add most emphatically, that if Professor Redwood and others, in 1878, had not by their opinions expressed, and absolutely advocated, that selenite powder was good, useful, and even better than pure starch as a dusting powder for infants, we would long ere this have had the question settled. It is now revived, and I ask the advocates of the selenite powder to give an explanation of the cause of death of the child in Mrs. Marshall's care, other than that testified to at the inquest, lately held by Mr. Payne. The violet powder was purchased from a druggist in Waterloo Road; after using it for a day or two great irritation ensued. The child died, and it was the opinion of the medical man in attendance that blood poisoning caused the infant to succumb. The blood poisoning was the result of great local skin irritation, induced by the application of selenite violet powder.

Here the facts end, and it is now for the advocates of adulterated violet powder, and Professor Redwood in particular, to make good their position as to the innocuous nature of selenite of the kind and quality used in the manufacture of the Waterloo Road poisonous dust for infants.

I know it has been said that in the case of ordinary starch powder irritation has been set up.

Not in the hands of a good and clean nurse, be it observed, but only in those cases where fermentative changes have been induced by inattention to cleanliness. I think the small amount of perfume in most powders is wholly inadequate to cause excoriation or blistering of the skin, but I can well understand Professor Redwood's harmless selenite lighting up all kinds of skin mischief, if once chafing has taken place.

If there is a doubt about the matter, and I think there is not a thread to hang from, why do chemists sell, or put up, the selenite rubbish? Surely the price of violet powder is quite equal to the cost of its manufacture when made from pure starchy matters without adding selenite. The finest builders' alabaster may be obtained for 30*s.* a ton, but pure precipitated calcium sulphate costs 3*s.* a pound, and it is evident that common selenite is used instead of starch wholly on account of its cheapness. Why then, do chemists permit a fraud to be practised, first upon themselves, and then to be the means of perpetrating it upon their customers? In every aspect of the case the whole proceeding is wrong, very mischievous, and fraudulent.

It is a question which does not admit of unbiassed discussion, because wherever fraud is practised or intended, all men of honour should wash their hands clean from such chicanery, and not support, even for trade interest, that which is wrong and decidedly unjust. I therefore say that every chemist throughout the length and breadth of the land should no longer deal in spurious violet powder, and the public should insist upon genuine nursery powder made from starch. I hope this letter may be the means of once more causing an awakening upon a subject which has been tampered with by leaders of the pharmaceutical body, and their apathy towards, or advocacy of, a system of sophistication has caused countless misery to infants, and I close by asserting, in direct opposition to Professor Redwood's opinion, that his statement in regard to the usefulness of selenite compared with starch has no foundation in fact, and let us hope every man who cares for the comfort of our infant population will denounce in unmeasured terms all sophisticated violet powders. I leave other matters concerning the topic in hand for a future occasion, and await replies.

Northallerton. HENRY BROWN.

NOTE ON A RARE FORM OF COLCHICUM AUTUMNALE, L.

Sir,—In the article last published for "The Month" the remark is made that "the botanist, in his early perambulations, may even now expect to find a few medicinal plants awaiting him." To those there mentioned I will add *Colchicum autumnale* as now to be found in full bloom!

The specific names of many of our common plants are in more or less distinct relation to their habits, character or uses, and there is little doubt that colchicum was christened "autumnale" in recognition of its conspicuous appearance at a season when little floral beauty remains to be seen. One feels almost inclined to carp at the paradoxical freak of Nature, which has induced a plant so truly autumnal to put forth flowers in early spring, but the occurrence is so rare that, in the present threshed-out condition of British botany, it is with a feeling of gratitude for the presentation of an object so interesting that we proceed to examine and record it.

On the 15th of March I was rambling a few miles from home, and endeavoured to shorten my return by taking a cut across some country which had not previously been explored. Having surmounted a few obstacles, I entered a large pasture and welcomed the appearance of a great quantity of daffodils, whose bright golden flowers enliven too few of our British fields. Welcome, indeed, they are

"That come before the swallow dares, and take
The winds of March with beauty."

Here and there among the herbage, scarcely raised above the soil, was dotted a pale pink blossom, like a little crocus. This was soon recognized to be the flower of colchicum, by some accident appearing in the spring.

The structure and growth of this singular plant in its normal condition have often been described and commented on. In the spring-flowering form the corm is large, plump, and in the same condition in which we usually find it in October. The perianth tube is radical, perianth small, with narrow segments, pale and "washed out" in point of colour. Stamens imperfect, the anthers shrivelled, and not containing pollen. I find no mention of this form in any record to which I have access, and one of the most distinguished of our botanists tells me he has never met with it. In Sir J. Smith's 'English Botany,' vol. 20, tab. 1433, there is a figure of a monstrous colchicum, found in Wiltshire nearly a century ago, which bore an abortive, misshapen flower in the position normally occupied by the fruit. That is quite a distinct plant. It is referred to by Pereira, Hooker and Arnott, and others.

My supposition is that this spring-flowering form will not prove to be a permanent variety. I think it probable that the young corms were seriously impeded in their development by the unusually wet and cold summer of last year, and that many of them therefore were not prepared to flower before the first frosts of winter compelled them to postpone the effort.

It may not unjustly increase the indictment of offences already preferred against 1879, if we add to it that of having utterly upset the equilibrium of plant-life in the common colchicum.

Clifton. JAS. W. WHITE.

A.G.—(1) The process given by Gmelin for preparing oleate of zinc is to precipitate it from sulphate of zinc by a boiling solution of oleate of potash. (2) Professor Clay's prescription was—"Chian turpentine, six grains; flowers of sulphur, four grains; to be made into two pills to be taken every four hours.

"*Melanion.*"—(I) The subject is not a recent addition. (2) No doubt the candidate would be expected to "work out sums."

"*Inquisitor.*"—We cannot advise you, in the direction you require. The only advice we can give you is that you study the subjects of examination carefully, and that when you meet with difficulties you should consult some older member of the trade, who may be acquainted with your circumstances, as to the best way of overcoming them.

G. B. O. R. (who should have sent his name and address).—Fox's lungs is a term applied to syrup of poppies in some districts.

W. H. R.—Possibly the cautious use of a depilatory might effect the required result, but we do not think the subject is one that can be properly advised on in these columns.

A. Y. Z. should apply to the Secretary, 17, Bloomsbury Square.

B. M. Stoakes.—Possibly a powder of the so-called "Australian fever bark" (*Alstonia scholaris*).

R. W. Hogg.—See a paper by Mr. Siebold on "Urinary Examination," in vol. iv. of the present series of this Journal, p. 249.

Scilla, Hirwain.—Systematic botany is treated of incidentally in the work mentioned, but the principal subject is physiological botany.

EXPERIMENTS ON TARAXACUM ROOT.*

BY J. B. BARNES, F.C.S.

Dr. Symes's able paper on taraxacum, read at the November meeting last year, has been the means of directing my attention to this subject.

Whatever doubts may exist as to the medicinal value of taraxacum, I think as long as its preparations have a place in the Pharmacopœia it is desirable to endeavour to improve them. I have, therefore, made some experiments with this object in view, and hope that further discussion may result in some advance being made.

I quite agree with Dr. Symes that the activity of the succus cannot be very great; the extract, although it does contain inulin, is, notwithstanding, when prepared in accordance with the directions of the Pharmacopœia, a more concentrated preparation; but now that we have the resin of podophyllin, euonymin, etc., in competition with this popular drug it is desirable to have a still more concentrated preparation than those now in use.

Experiment No. 1.—In order to exclude inulin (which in the autumn is so very abundant and necessary to the development of the plant, gives considerable trouble, and causes much waste in preparing the succus, and is not completely separated from the extract), clean fresh taraxacum root in thin slices, with the milky juice exuding, was covered with rectified spirit for two hours, strained and washed with more spirit, and the clear liquor evaporated over a water-bath to dryness, the result being a bright canary-coloured hygroscopic powder possessing an intensely bitter taste and perfectly soluble in water.

Experiment No. 2.—The above preliminary operation being wasteful of spirit, one pound of clean fresh thinly-sliced root was macerated with an equal weight of spirit of wine for two days, the liquid poured off, the marc pressed and the product filtered, the spirit recovered by distillation, and the solution evaporated over a water-bath to the consistence of an extract, which is bitter and of a light brown colour. The quantity obtained was one ounce and a half.

Experiment No. 3.—The above operations were repeated, three pounds of another sample of fresh root being now employed, but the evaporation was continued to dryness and the product powdered, the result being a yellowish hygroscopic powder, a sample of which is on the table. It possesses a bitter taste, but not so intense as that obtained in experiment No. 1, the pressure having extracted a something, probably sugar, and other matters in addition. A small quantity of inulin was pressed out, which, however, was readily separated by filtration; the quantity of dry extract obtained was three ounces and a quarter.

Experiment No. 4.—One pound of the fresh thinly sliced root was macerated in distilled water for twelve hours, thrown on a filter, washed with water and the liquid evaporated over a water-bath; a dark brown extract possessing a sweet taste was obtained.

Experiment No. 5.—Half a pound of dried taraxacum root, reduced to powder, was macerated for twelve hours in half a pound of rectified spirit and percolated with a further portion of spirit. After distilling off the spirit an oily looking substance was observed floating upon the surface of the liquid. It was separated by filtration and dissolved in ether; the latter having evaporated, there remained a semi-solid, tasteless, greenish, oily substance. The liquid extract upon further evaporation yielded a golden-coloured, bitter, solid extract, so very hygroscopic as to defy my efforts to reduce it to powder.

In all these experiments upon taraxacum root with spirit, albumen and inulin are necessarily separated; it is clear that No. 1 gives the best result, presuming bitterness and brilliancy of colour to be the standard of efficiency.

Commercially, Nos. 2 and 3 show the most satisfactory result, the waste of spirit being reduced almost to nil and the yield satisfactory.

No. 4 shows that cold water does not separate the bitter principle of taraxacum. These results are so clear that there does not appear to me any difficulty in arriving at the conclusion, that an alcoholic extract of taraxacum root is superior to the extract of the Pharmacopœia.

A tincture made by percolating the dried root with rectified spirit, so as to obtain it of the strength of one in two, would I think be an improvement on the preserved juice; it resembles tincture of nux vomica in colour and has a very bitter taste.

When water is added to this tincture it becomes opaque, and after the addition of dilute hydrochloric acid, in a few hours a pale brown precipitate soluble in ether, chloroform, and petroleum spirit is formed, upon the evaporation of which there remains the greenish oily substance above described.

[*The discussion on this paper is printed at p.* 860].

* Read at an Evening Meeting of the Pharmaceutical Society, April 21, 1880.

THE COMPOSITION OF TONGA: A REPUTED REMEDY FOR NEURALGIA.*

BY A. W. GERRARD, F.C.S.

A paper was published in the *Lancet* of March the 6th of this year, by Professors Sydney Ringer and William Murrell, giving details of the use of tonga in eight cases of neuralgia, six of which were promptly cured, one was much improved, and in the other a week's trial of the remedy failed. The drug was brought to Professor Ringer by a gentleman residing in Fiji, named Mr. Ryder, with the following account: "It has been used several years by the aborigines of the Fiji Islands, and a European, who married a chief's daughter, learnt the secret from his father-in-law, in whose family the knowledge of the composition of this remedy had been an heirloom for upwards of two hundred years." Mr. Ryder described the drug as a mixture, and knew nothing of its botany, and the name tonga, I am informed, was invented by himself, the drug previously bearing the name "Neuralgia Medicine."

Tonga, as first placed in my hands, consisted of small loose bundles about the size of a small Florence flask, containing in the interior a mixture of bark, leaf and woody fibre; the outer covering or wrapper consisted of the inner bark of the cocoa-nut tree; the following instructions were given for its use:

"The bundle, without being unfastened, to be steeped in half a tumbler of cold water for ten minutes; then squeeze the liquid from the bundle back again into the tumbler, and take a claret-glass of the infusion three times a day about half-an-hour before each meal; dry the bundle and hang it up in a dry place to prevent its getting mouldy; it will

* Read at an Evening Meeting of the Pharmaceutical Society, April 21, 1880.

answer for twelve months. Hot drinks and exposure to cold winds should be avoided whilst taking the medicine."

Mr. Ryder and his friends have tried the remedy extensively, and found it very successful, curing by the second or third day. It has also been used in Sydney with much success.

A supply of about eight pounds of the drug was placed in my hands by Professor Ringer; it had been removed from its envelope of cocoa-nut tree fibre. The drug, upon separation into its various parts, was found to consist of about an eighth per cent. leaf, two per cent. fibre, and the remainder portion bark. These proportions are not constant, on account of the rough mode of preparation.* The leaf is cut or broken into small pieces which precludes a description of its form; its colour is deep green; taste slightly bitter and astringent. The fibrous portion is of loose structure chopped into irregular lengths, varying from one half to two inches, and torn into shreds. No bark is attached, and there is nothing I can find in its structure to indicate with certainty whether it is root or stem. Its colour is dull greyish-brown, odour peculiar, and may be termed urinous, and taste of the same kind. The bark is found in irregular-sized pieces, much broken and partly in coarse powder, the majority of pieces consisting of inner bark rarely beyond a line in thickness; its colour is not uniform, but varies from pale brown to purplish-black; many pieces are brownish-yellow, due, I think, to undetached portions of outer bark; its taste is slightly sweet and astringent.

Examination of Bark.—Sixty grammes of bark in fine powder was divided into six parts, and treated respectively to exhaustion with hot benzole, benzine, ether, chloroform, alcohol, and water; the resulting solutions were allowed to spontaneously evaporate, except those of alcohol and water, which were evaporated over a water-bath. The benzole, ether, and chloroform gave no residues worthy of examination; benzine gave a slight residue, consisting of an essential oil and a pale, fat-like substance. The amount being small, they were not further examined.

Alcohol yielded an extract of pale brown colour, sweet and slightly astringent taste, and mostly soluble in water. The filtered watery solution of this extract, when tested for alkaloid, gave negative results, but readily reduced when warmed the alkaline cupric tartrate. The bulk of this alcoholic extract was dissolved in water, and treated to excess with basic lead acetate, filtered and excess of lead removed with H_2S, filtered from lead sulphide and evaporated, when a pale yellow tenacious residue was obtained, which by its chemical reactions I identified as glucose.

The watery extract of the bark was examined, and during evaporation became pectinous. A portion treated with alkaloidal reagents gave negative results, but, like the alcoholic extract, readily reduced alkaline cupric tartrate; and further examination proved that, excepting the pectin, the watery extract does not differ essentially from that prepared by alcohol.
