Examination of Fibre.—The fibre portion of tonga being, unfortunately, very small in quantity, I have been obliged to limit myself to work upon ten grammes. Five grammes were exhausted with water, and the infusion, upon concentration and addition of the necessary reagents, gave strong evidence of the presence of an alkaloid. The semi-fluid aqueous extract, now treated with excess of alcohol, almost entirely passed into solution and, upon evaporation of the alcohol was deposited as a brown crystalline residue of a deliquescent character; the crystals, upon examination, proved to be mainly chloride of potassium commingled with an alkaloid salt. The potash salt was removed by treatment with tartaric acid and alcohol, and the filtered alcoholic solution when evaporated left a pasty crystalline mass of an alkaloid salt, having the following reactions:—Moderately strong solutions gave white precipitates with potash, soda, and ammonia, hydrates and carbonates, also with mercuric chloride, tannic acid, potash mercuric iodide, phosphomolybdate of soda and nitric acid; with potash bismuth iodide it gave a red precipitate; strong sulphuric acid changed it brown, evolving an odour of hawthorn flowers. When the solution is treated with caustic alkalies, the alkaloid is evolved, bluing red litmus paper; the odour of the vapour is peculiar, and suggestive of decomposed potatoes. The vapour passed into dilute nitric acid gave a solution having the above alkaloid reactions. The remaining five grammes of fibre was worked out with alcohol, and yielded results parallel to the above.

The leafy portion of tonga being only a fractional percentage and its separation tedious, I did not consider it worthy of examination, neither do I think it takes any part in the action of the drug.

To summarize: the preceding results show that the drug called tonga is composed mainly of a mixture of fibrous material, probably a root, and the inner bark of plants, the botanical sources of which are unknown; the main constituents of the bark being pectin, glucose, a little essential oil, and fat; the fibre containing a volatile alkaloid, which is probably the active principle, and may for the present be named tongine, also some chloride of potassium.

I trust we may soon command botanical specimens and larger supplies of this interesting drug, and be able to substantiate the reputation it bears, and prove it a valuable addition to our materia medica.

[*The discussion on this paper is printed at p.* 861].

* Since writing the above, Messrs. Allen and Hanbury have kindly placed at my disposal further samples of tonga, one of which is without leaf, and in which the fibrous portion consists of compact transverse sections broken longitudinally—additional evidence of its want of uniformity.

THE ACTION OF POTASSIUM CHLORATE ON FERROUS IODIDE.*

BY R. H. PARKER.

When a solution of potassium chlorate is mixed with syrup of iodide of iron, a nearly colourless solution is obtained, which on standing a few hours acquires a reddish-brown colour and an evident odour of iodine. This change is followed by the subsidence of a red precipitate and deeper colour of the supernatant liquid; in a few days the solution becomes supersaturated with iodine and crystals of this element are deposited. Sodium chlorate produces a similar decomposition.

As far as I have been able to search, recorded information fails to give a satisfactory explanation of the reaction; the following attempt was, therefore, made to solve the problem.

A number of experiments were started simultaneously as follows:—Varying quantities of potassium

* Read at an Evening Meeting of the Pharmaceutical Society, April 21, 1880.

chlorate (0·2 to 2·0 grams) were mixed with 10 c.c. of syrup of ferrous iodide diluted with 30 c.c. of water and allowed to stand at ordinary temperatures; some of the bottles were completely filled in order to exclude atmospheric air, and the contents of one were heated nearly to boiling as soon as prepared.

After standing for a period of from four to six weeks the supernatant liquid, treated with slight excess of sodium thiosulphate (hyposulphite) to remove iodine, failed to give any blue colour with ferro or ferridcyanide of potassium, indicating complete precipitation of iron.

Assuming that the sugar present exerted a retarding influence on the reaction, a similar series of experiments was conducted on an aqueous solution of ferrous iodide. This method did not appear to expedite the process; the saccharine solution was, therefore, again resorted to.

It was observed that the liberation of iodine was more rapid in presence of increased proportion of chlorate, but that the rate of decomposition was most accelerated by heat, while in all cases the total amount of iodine set free was approximately the same. The iron remaining in solution during the gradual precipitation continued entirely in the ferrous condition, while the precipitate at all stages of the process, washed and disolved in dilute hydrochloric acid, consisted entirely of a ferric compound. This precipitate was carefully examined for acidulous radicals by boiling it, after washing, in a strong solution of pure potassium hydrate and accurately neutralizing the diluted filtrate with nitric acid. The solution so obtained gave no precipitate with argentic nitrate, proving the compound was not basic chloride or iodide. Another portion mixed with potassium iodide and starch solution gave no immediate blue colour with a dilute acid; the absence of iodate was thereby demonstrated. The precipitate is, therefore, ferric hydrate or hydrated oxide. It was found that the addition of sodium thiosulphate at the commencement of the reaction, so as to absorb the free iodine as soon as liberated, rendered the precipitate much more manageable; in fact, without this modification it was impossible to collect the whole of the precipitate for quantitative examination. Assuming that the body produced in this way was identical with that thrown down in the absence of thiosulphate, its study was resumed with this method of preparation.

The physical characters of this iron compound seem to indicate that it is ferric oxide, with probably not more than one molecule of water. Its colour is bright red, it is very dense, its bulk is not materially diminished by desiccation, and its tint and pulverulent character are preserved even after ignition. On the other hand, ferric hydrate is dull reddish-brown, very bulky, shrinks much on drying and when ignited, assumes the form of hard fragments of dark steel-grey colour.

The potassium chlorate being the probable source of the oxygen required for the conversion of the iron from the ferrous to the ferric condition, the formation of potassium chloride was expected. The filtrate after precipitating the iron and removing the iodine by ebullition, gave abundant evidence of the presence of a chloride.

From the qualitative evidence thus obtained, the reaction would appear to be in accordance with the following equation:—

$$2FeI_2 + KClO_3 + H_2O = Fe_2O_3,H_2O + 2I_2 + KCl.$$

It now remained to prove the accuracy of this theory by quantitative estimation.

In the presence of large excess of chlorate the reaction was found to be complete after a few minutes' boiling. Two parallel estimations were conducted by boiling 10 c.c. of the B.P. syrup with 2·0 grams $KClO_3$ and 60 c.c. v.s. thiosulphate. In the first case the precipitate was washed, dried at 105° C., weighed, ignited and again weighed. In the second case the precipitate was washed, dissolved by heating with HCl and a little HNO_3, precipitated by excess of AmHO, washed, dried at 105° C., weighed, ignited and again weighed.

		Weight at 105°	Weight after ignition	Ratio
1	10 c.c. syrup	0·2260	0·2012	1 : 0·890
2	10 c.c. „	0·2292	0·2031	1 : 0·887

These results corroborate the qualitative evidence of the absence of acidulous radicals in the precipitated iron compound; the ratio of its weight at 105° C. to that after ignition indicates that it contains at least one molecule of water, the ratio of Fe_2O_3,H_2O to Fe_2O_3 being 1 : ·898.

The very close approximation of the amounts of ferric oxide and free iodine obtained to the actual amounts operated on are detailed in the subsequent note on the estimation of the syrup, and eliminated the necessity of searching for iodine in state of combination.

The amount of KCl produced now remained for investigation. An attempt was made to find the minimum amount of chlorate required to completely decompose a given quantity of iodide. This could not be arrived at definitely, because with only small quantities of chlorate such protracted boiling was required to complete the decomposition; thus, according to the equation, 10 c.c. of B.P. syrup should require ·1545 $KClO_3$. For complete precipitation—

10 c.c. syrup + 2·0 $KClO_3$ required 3 minutes' boiling.
10 c.c. „ 1·0 „ „ 10 „ „
10 c.c. „ ·5 „ „ 30 „ „
10 c.c. „ ·2 „ not complete after 40 minutes' boiling.

The syrup was in each case diluted, and an excess of sodium thiosulphate added.

The next method adopted was to use a large excess of chlorate, boil off most of the iodine, make up to a known volume, filter and titrate one portion for free iodine with v.s. $Na_2S_2O_3$, and another for total iodine and chlorine with v.s. $AgNO_3$.

This method did not give correct results, because the filtrate appears to contain an iodide, which would of course be calculated as a chloride.

As yet, therefore, the amount of KCl produced is an open question, but is still under investigation.

It is doubtless superfluous to point out the importance of physicians bearing this reaction in mind, but the fact of having seen potassium chlorate prescribed in combination with syrup of iodide of iron is perhaps an adequate apology for so doing.

[*The discussion on this paper is printed at p. 861*].

THE QUANTITATIVE ESTIMATION OF SYRUP OF IODIDE OF IRON.*

BY R. H. PARKER.

The study of the reaction detailed in the foregoing note suggested its application as a method for esti-

* Read at an Evening Meeting of the Pharmaceutical Society, April 21, 1880.

mating syrup of iodide of iron. The ordinary volumetric and gravimetric processes for determining the amount of iron present are rendered more or less inconvenient or entirely inapplicable by the presence of sugar. The British Pharmacopœia does not mention its quantitative analysis, but, tacitly assuming that no loss occurs during its preparation, says "it contains 4·3 grains of iodide of iron in 1 fluid drachm," which is a theoretical deduction from the amount of iodine taken and the volume of syrup produced.

Numerous attempts were made to obtain a solution or syrup of iodide of iron of known strength by using definite quantities of iodine, but with all precautions some loss was incurred from decomposition of the iodide. Syrups carefully prepared by the author and commercial samples were therefore used to test the value of contemplated processes.

In order to save time, definite quantities of syrup were apportioned by diluting one volume to four with water and measuring the resulting solution with a bulb pipette. The dilution reduced to a minimum the adhesion of the liquid to the surface of the pipette, and this method was found almost as accurate as the more tedious one of making two weighings for each quantity taken, and determining the sp. gr. of each sample examined.

The first idea followed was to render the process directly volumetric, by boiling a known quantity of syrup with $KClO_3$ and a known excess of volumetric solution of thiosulphate, estimating the amount of the latter used up by titrating the filtrate with vol. sol. iodine, and from this result calculating the quantity of iodide of iron present, thus—

Take 20 c.c. diluted syrup (1 in 4), 1·0 gram $KClO_3$ and 30 c.c. v.s. thiosulphate, boil gently for five minutes, cool, make up to 50 c.c. with water, filter and titrate 20 c.c. of filtrate with v.s. iodine, checking the result with another 20 c.c. filtrate.

The amount of iodine absorbed by the filtrate does not indicate the exact amount of thiosulphate undecomposed, and consequently the amount of iodine liberated by the chlorate cannot be precisely ascertained. This follows from the fact that tetrathionate of sodium (produced by the action of iodine on sodium thiosulphate $2Na_2S_2O_3 + I_2 = Na_2S_4O_6 + 2NaI$) is decomposed* by ebullition according to the following equation :—

$$Na_2S_4O_6 = Na_2SO_4 + SO_2 + S_2.$$

Still, it was hoped that the decomposition would prove sufficiently definite to enable the actual amount of iodine liberated from the syrup to be calculated from the results obtained by this process.

Concordant results in estimations by this process were only obtained by scrupulously observing the same conditions in each case. Discrepancies were found to result from the presence of different quantities of chlorate and thiosulphate, also from varying periods of ebullition.

A careful study of the decomposition of the tetrathionate during ebullition was made by boiling together definite quantities of v.s. iodine and v.s. thiosulphate under all the conditions found to give discrepant results, each point being attacked by a series of experiments conducted *cæteris paribus*.

The results obtained were calculated into a percentage of error upon the quantity of iodine taken, as indicated by the final titration with v.s. iodine. The experiments, which are much too lengthy to produce here in detail, established the following conclusions :—

In somewhat concentrated solutions, containing excess of thiosulphate, the evolution of SO_2 and precipitation of sulphur commence with boiling heat.

In dilute solutions, *e.g.*, a mixture of the volumetric solutions, especially when only slight excess of thiosulphate is present, ebullition may be continued for five, or even ten minutes, without the appearance of sulphur or odour of SO_2; longer ebullition gave evidence of the change.

When the thiosulphate is very nearly adjusted to the amount of free iodine taken, the error from five minutes' boiling is very slight. The presence of a considerable excess of thiosulphate gives a result indicating a large error of deficiency, which is increased by continued ebullition. The presence of potassium chlorate and the iron precipitate exert an influence in the opposite direction, the calculation indicating a larger quantity of iodine than the amount taken. These bodies would favour the evolution of SO_2; but their influence beyond that does not seem quite clear, for thiosulphate alone is not decomposed by a few minutes' ebullition with $KClO_3$ and Fe_2O_3,H_2O.

By the light of these conclusions we are prepared to find that the application of the direct volumetric process to syrup of iodide of iron gives unreliable results; but that if several estimations are made, each time reducing the amount of thiosulphate used until an insufficiency is indicated by the appearance of iodine in the vapour after five minutes' boiling (wet starch paper being turned blue in the steam) a tolerably close approximation to the actual amount of iodide of iron present may be obtained, as indicated by the results detailed at the end of this paper.

This process being not altogether satisfactory, another method was devised, viz., the separate determinations of iron and iodine, collecting the former and weighing as Fe_2O_3, distilling the latter into solution of KI, and titrating with v.s. thiosulphate. This method gave exceedingly good results, and was finally adopted as follows :—

Estimation of Iron.—Into a 200 c.c. flask put 2·0 grams $KClO_3$, 60 c.c. v.s. thiosulphate, and 40 c.c. diluted syrup (=10 c.c.), boil gently for five or ten minutes, pass while hot through a very fine filter, rinse the flask and filter once with boiling water, wash the precipitate from the filter into the flask, dissolve it by heating with dilute HCl, precipitate with excess of AmHO, wash the precipitate, dry, ignite, and weigh as Fe_2O_3.

Estimation of Iodine.—Deliver 20 c.c. diluted syrup into a plain glass retort containing 2·0 grams $KClO_3$. The neck of the retort should pass quite to the bottom of a flask containing about 2·0 grams KI and enough water just to cover the end of the retort; the flask must be immersed in a jar of cold water. Distil until nearly all the iodine has passed over, change the flask and water surrounding it, and continue the process until the distillate passes over colourless. Mix the distillates, and titrate with v.s. thiosulphate.

In order to form an idea of the extent of loss incurred by this iodine estimation, several trials were made by distilling 40 c.c. v.s. iodine, and titrating the distillate, with the following results :—

* Gmelin's 'Chemistry,' vol. iii., p. 99.

39·86 c.c., 39·43 c.c., and 39·5 c.c., or a loss per cent. of 0·35, 1·42 and 1·25 respectively.

The results of the examination of various samples of syrup of iodide of iron are tabulated below.

No. 1. Prepared by the author; particular attention was paid to the weight of sugar taken and the final weight of the syrup. The solution of FeI_2 was heated for five or ten minutes after the froth became white; the flask and filter were washed as completely as the small quantity of water permitted. The product was light straw coloured, sp. gr. 1·398, and crystallized slightly on keeping.

No. 2. Prepared by the author; the solution of FeI_2 was filtered as soon as the froth became white. This was done in order to see whether much loss of iron resulted from ten minutes' subsequent heating. The product contained a trace of iodine.

No. 3. Commercial sample of syrup prepared by adding a liquor ferri iodidi to simple syrup. It was perfecly colourless, sp. gr. 1·374. The estimation of the iron in this case presented a difficulty not encountered in examining any of the syrups prepared by the B.P. process. The iron when first precipitated was in an extremely fine state of division and passed through the closest filter paper. By repeatedly returning the filtrate to the filter until it passed quite bright, the whole of the iron was at last collected, dissolved and the process completed in the usual way.

No. 4. A commercial sample prepared by the B.P. process. Light straw coloured.

No. 5. A commercial sample prepared by the B.P. process and exposed to light until very nearly colourless, sp. gr. 1·380.

The table indicates the results obtained, using in each case 10 c.c. of syrup (*i.e.*, 40 c.c. diluted syrup).

	Fe_2O_3.	I_2.	I_2 Theory from Fe found.	Error I_2 per cent. from Fe found.	Deficit per cent. of Iron.
1.	0·2031	0·6519	0·6411	1·7 +	1·1
2.	0·1993	0·6273	0·6328	0·87 −	3·0
3.	0·1897	0·5592	0·6023	7·0 −	7·6
4.	0·1800	0·5680	0·5715	0·6 −	12·4
5.	0·1770	0·5562	0·5620	1·0 −	13·8
6.	0·1876	0·5702	0·5956	4·2 −	8·7
7.	0·1768	0·5525	0·5614	1·5 −	13·9
8.	0·1757	0·5469	0·5579	1·9	14·5
9.	0·1838	0·5659	0·5836	3·0	10·5
10.	0·0628	0·1758	0·1994	11·8	69·4
11.	0·2016	0·6358	0·6401	0·65	1·9
Theory B.P.	0·2055	0·6444			

It will be observed that the amounts of Fe_2O_3 and I_2 obtained in No. 1 approach very nearly the B.P. theory, but the iodine is *above* what theory demands from the Fe_2O_3 found. No. 5 is very deficient in strength; probably long exposure to light causes loss of iron; but what becomes of it is not evident, since the bottle contained no deposit.

The apparently anomalous error of iodine in No. 3 was checked by another sample (No. 6) obtained from the same source, and prepared in the same manner. This deficiency in available iodine indicates that the syrup made with a "liquor" differs materially from those prepared by the B.P. process; the physical difference in the Fe_2O_3, H_2O already referred to, points to the same conclusion.

In the earlier stages of the investigation, while endeavouring to obtain a solution of iodide of iron of known strength by adding excess of reduced iron to v.s. iodine, it was observed that after standing a day or so bubbles of gas were disengaged from the sediment and eventually the solution appeared to be very deficient in iron. Following this observation, two parallel series of experiments were conducted, using in one case iron wire, and in the other reduced iron, thus:—

3 grams iodine and 3 grams iron wire with a little water were heated gently and at the close of the reaction boiled for ten minutes. The solution was diluted so that 40 c.c. = 0·6 iodine. The iron and iodine were determined after standing nine hours. 80 c.c. of the solution was kept seven days in contact with a few pieces of bright iron wire. It was then quite colourless and was again estimated.

In the second case, precisely similar steps were taken, using 3·0 grams reduced iron (50 per cent. Fe). The solution was examined after nine hours, 80 c.c. set aside with 1·0 gram reduced iron for a week and again estimated.

		Fe_2O_3.	I_2.	Loss Iodine per cent. from Fe found.	Loss Iron per cent.
Theory		0·1889	0·600		
Iron wire	9 hours	0·1800	0·5446	4·7 −	4·6
	7 days	0·1786	0·5395	4·8 −	5·4
Reduced iron	9 hours	0·1545	0·4623	5·7 −	18·2
	7 days	0·1140	0·3320	8·2 −	39·6

The solution made with iron wire lost after nine hours 4·7 per cent., and after a week 5·5 per cent.; while that made with reduced iron indicated at the end of nine hours a deficiency of 9·4 per cent., and after seven days 39·7 per cent. The use of a large excess of reduced iron, therefore, causes a serious deficiency of strength of the resulting solution, especially if kept in contact for any great length of time.

The precise nature of the change which occurs on keeping solution of iodide of iron in contact with iron does not seem quite clear, and is a point requiring further investigation. It is stated that ferric oxide is deposited, and iodine liberated, which recombines with the metallic iron present, but Berzelius regarded the deposit as a basic salt.* According to the former theory, the solution should continue of unvarying strength; this is disproved by the results tabulated above. It should be noticed in this table, that the available iodine decreases in very nearly the same proportion as the iron.

After distilling the iodine from the solution kept for a week over reduced iron, the filtered residue in the retort was found to be quite neutral, free from iron and uncombined iodine, but gave abundant evidences of chlorides and iodides. This would indicate the absence of hydriodic acid and formation of chloride and iodide of potassium.

If hydriodic acid were formed by keeping the solution of ferrous iodide it is probable that the iodine estimations would be too high, compared with the amount of iron found, for according to Kerner,† hydriodic acid dissolves Fe_2O_3 on heating, forming ferrous iodide and free iodine; in which case, the total iodine would be distilled by continued ebullition; this, however, does not occur, for, as previously noticed, the available iodine

* Gmelin's 'Chemistry,' v., p. 249.

† Gmelin's 'Chemistry,' v., p. 249.

diminishes in very nearly the same ratio as the iron estimations fall, while an undecomposed iodide remains in the retort.

In order to discover the relation which the iodine estimations made by the first mentioned process bear to the results obtained by distillation, the following experiments were conducted upon the same sample of diluted syrup:—

40 c.c. diluted syrup, 2·0 grams $KClO_3$ and 60 c.c. v.s. thiosulphate, boil ten minutes, filter, dissolve, precipitate Fe_2 6 HO, wash, dry and ignite = (1) 0·1763; (2) 0·1776, Fe_2O_3.

40 c.c. diluted syrup, 4·0 grams $KClO_3$, distil into 2·0 grams KI = 0·5561 I_2.

The same repeated, distilling into 3·0 grams KI = 0·5563 I_2.

20 c.c. diluted syrup examined according to the first volumetric process, using 30 c.c. v.s. thiosulphate; the iodine indication, × 2 = 0·5762 I_2.

The same repeated, using 25 c.c. v.s. thiosulphate = 0·5763 I_2.

The same repeated, using 22 c.c. v.s. thiosulphate = 0·5556.

The same repeated, using 20 c.c. v.s. thiosulphate; after five minutes' boiling, iodine was detected in the steam, showing that the actual amount of iodine present lay between 20 and 22 c.c. Another experiment, using 21 c.c., would probably have given even a closer approximation to the amount indicated by the distillation process than that already obtained.

This proves what has previously been alluded to, that when the amount of thiosulphate used is nearly adjusted to that of iodine present the error incurred is not large.

[*The discussion on this paper is printed at p.* 861].

CHIAN TURPENTINE.

BY WILLIAM MARTINDALE.

This drug, the oleo-resin from *Pistacia terebinthus*—having until lately fallen into desuetude—since the appearance in the *Lancet** of an article recommending its use in cancer of the female generative organs, has been much in request. Owing to the small demand for it very little has of late years come into the market, and it has been stated that much of what has been supplied to the trade is factitious. There is little doubt with the demand now created plenty of the genuine article will be forthcoming in time.

The history of its use in medicine seems to be lost in antiquity. It was always more prized by the Greeks than the pinaceous oleo-resins. It has principally been obtained from the Island of Scio; here, as well as on the other islands of the Archipelago, Cyprus, Asia Minor and Syria, the tree is cultivated and flourishes to the greatest perfection. It attains the height of 40 feet or more in favourable localities, but in others it grows as a stunted straggling shrub, and is found as far east as Afghanistan and west as the Canary Islands. The yield of the oleo-resin from a large tree, 4 or 5 feet in circumference, is only about 10 or 11 ounces yearly. A great part of it exudes spontaneously, but more of it is obtained by making incisions into the trunk and branches in the spring, from which the turpentine continues to flow during the whole summer. It is collected in the morning, after the coolness of the night has somewhat solidified it, from the stem and flat stones placed at the foot of the tree to receive what may have run down.

* *Lancet*, vol. i., 1880, p. 477.

Chian turpentine has been omitted from the British Pharmacopœias, but was official in the London Pharmacopœias. Royle states that it used to be taken chiefly to Venice, where it was in request for making the far-famed Theriaca. Pereira, Guibourt and Hanbury describe it, and their descriptions are rather conflicting. It has a very firm honey-like consistence, yet is slightly brittle and becomes more so with age and exposure to the air, and even then it alway takes the form of the vessel in which it is kept. It is translucent, small pieces appear yellow or brownish-yellow, but in mass it has a greenish-brown colour. It has, when fresh, a distinctive odour, slightly like the pinaceous turpentines, but much more agreeable and aromatic, according to some, resembling citron and jasmine; but there is always a background smell like that of mastic which becomes more developed and distinct with age, when it has lost the more volatile portion, the essential oil. According to Pereira the turpentine-like odour is combined with the odour of fennel, and Guibourt says, when kept in a covered glass vessel the odour is strong and agreeable, analogous to that of fennel or the resin of elemi. I have only seen one sample which had an odour at all resembling fennel. It probably loses this rapidly. A specimen, bearing Guibourt's name, in the Society's Museum, has now no trace of it, but the mastic odour is very persistent. If the fennel odour be very evident in it, I should fear the sample was not genuine, as in a statement made in the *Lancet** the writer says what is sold as Chian turpentine "is either greatly adulterated, or a wholly factitious article manufactured from black resin, Canada balsam, and the essential oils of fennel and juniper." The taste of genuine Chian turpentine resembles that of mastic; it is agreeable and free from the characteristic bitterness and acridity of the pinaceous turpentines.

From its mode of collection, even the genuine Chian turpentine is always contaminated with impurities, earthy dust, etc. Testing a number of what I have reason to believe are genuine samples, as well as some not genuine, I find they are all (mechanical impurities excepted) entirely soluble in ether and absolute alcohol. Still the genuine oleo-resin, as stated by Guibourt, leaves a little glutinous resin undissolved when treated with alcohol slightly diluted (I used rectified spirit, sp. gr. ·838); yet this can scarcely be identical with the beta-resin or masticine of mastic, which is left undissolved when mastic is treated even with absolute alcohol. The alcoholic solution of Chian turpentine reddens litmus paper. The pimaric acid of Canada balsam is not soluble in cold absolute alcohol, but admixture with other ingredients might render it so. I am unacquainted with any definite test for its purity.

In judging of its genuineness, we must rely on its taste, odour and physical characters as above described. It should, more especially, be not too fluid. The drug was considered by Dioscorides to be diuretic, stomachic and laxative.

In administering it for cancer (an application of it

* *Lancet*, vol. i., 1880, p. 541.

Mr. J. Tweedy has shown to be not new,*) three formulæ have been employed by Professor Clay:—pills, ethereal solution, and an emulsion made from the latter. The pills consist of 3 grains of Chian turpentine and 2 grains of sulphur in each. Sulphur is a novel excipient, and not a very good one, as the pills lose their shape. The excipient generally used and recommended in books for the purpose is calcined magnesia. Three grains of Chian turpentine and 1½ grain of light magnesia make a pill which retains its shape tolerably well; but it is perfectly indigestible, barely losing one-tenth of its weight in passing through the body.

Some years ago† I was asked to prepare tar in a pilular form. The excipients mostly used for this—light magnesia and beeswax — have both the disadvantage of making the pills indigestible, and knowing the peculiar action lycopodium has of absorbing these oleo-resins, I succeeded in making a very good pill with 2 parts of tar and 1 of lycopodium. I, at that time, also made some pills with 2 parts of American turpentine and 1 part of lycopodium, which kept their shape. Chian turpentine, although harder, I find requires a little more lycopodium to enable the pills to keep their shape; 3 parts with 2 of the powder make fairly good pills; but these also are not digested. Sugar is a no better excipient than sulphur in enabling the pills to retain their shape. The sulphur pills are digested, and perhaps no better formula can be devised. With any excipient the pills should not be made too hard. I have seen some pills of Chian turpentine coated which retained their shape well; but I should be inclined to doubt their digestibility.

The other formulæ used are an ethereal solution of 1 ounce of Chian turpentine dissolved in 2 fluid ounces of absolute ether, the resulting solution measuring slightly over 3 fluid ounces, and an emulsion is prepared from this as follows:—

℞ Ethereal solution of Chian turpentine	fl. ℥ss.
Solution (mucilage) of tragacanth .	fl. ℥iv.
Syrup	fl. ℥j.
Sublimed sulphur	grs. 40.
Water . . . . to	fl. ℥xvj.

Mix.

The sulphur appears to have been added because it was not wished to lose anything contained in the pills which had previously been proved to be of such service. Mix it as you will, the sulphur will separate from such a mixture and aggregate the resin in masses first to the top and then at the bottom of the bottle. By using mucilage of acacia in place of mucilage of tragacanth, a satisfactory mixture may be obtained by first putting the mucilage into the bottle, adding the turpentine solution, shaking, and diluting with a little water; rub the sulphur with the syrup and pour into the bottle, fill up gradually with water, shaking after each addition of a little; or a good emulsion can be made, using either mucilage of tragacanth or mucilage of acacia, by omitting the sulphur altogether. This, as pharmacists, we are not warranted in doing, but the substituting of mucilage of acacia for mucilage of tragacanth is a deviation from the strict letter of the prescription which, with the leave of the prescribers, I have had recourse to.

The Pharmaceutical Journal.

SATURDAY, APRIL 24, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE EXHIBITION AT THE SOCIETY'S ROOMS.

It is now six years since an exhibition of objects specially interesting to pharmacists was held at Bloomsbury Square, on the occasion of the Conference meeting in London, and as it is considered that the approaching anniversary of the Pharmaceutical Society will be an opportune time for renewing the effort, the Secretary has, by direction of the Council, issued a circular announcing that an exhibition will be held on the 18th, 19th and 20th of May, and inviting persons desirous of exhibiting to give early intimation to him what they propose to show, and what space will be required for the purpose.

Already a considerable number of applications have been received in reply to this circular, and there seems to be every reason to anticipate that the exhibition will be a feature of considerable interest for those attending the Annual Meeting of the Society. In order to promote the success of the undertaking, by making it known as widely as possible, it will not be out of place to call attention to the matter here, and to remind our readers that as the time allowed for sending in applications for space is short, and as the available space is but limited, those who desire to exhibit should not delay making known their intention. There are now but fourteen days within which this can be done, so as to allow of the arrangement of such exhibits as may be sent and the preparation of a catalogue preparatory to the Annual Meeting.

We understand that the classification of the exhibits will be, as far as possible, of such a nature as to place them under one of three groups, viz., 1. Apparatus; 2. Drugs and Chemicals; 3. Educational Appliances.

A similar exhibition to that now contemplated has been for several years carried out in connection with the annual meeting of the German Pharmaceutical Association, and it has invariably proved very successful. As these meetings are held at different places every year, it is necessary to hire a building for the exhibition, and a small charge is made for the space occupied by exhibits at the rate of about five shillings per square yard. Members of the Association are admitted without payment, but persons who are not members are charged a shilling admission.

While speaking of the exhibition now proposed to be held in connection with the Annual Meeting, it may be admissible to recall to mind the proposal made some years ago by Mr. Schacht to establish a pharmaceutical laboratory or a permanent collection of pharmaceutical apparatus at Bloomsbury Square, and to offer the suggestion that the forthcoming exhibition may pave the way towards a realization of that project. At the time when this subject was under the consideration of the Council several letters were received from correspondents warmly advocating Mr. Schacht's proposal, and amongst others who took this view we may refer to Dr. Symes, Mr. Tanner and Mr. Barnard Proctor.

One of the chief objections to the adoption of this plan was founded upon the argument that a collection of pharmaceutical apparatus, such as furnaces, stills, etc., etc., would not be of much utility for purposes of instruction unless practical operations were constantly being carried on with them, and that if this were done the Society would necessarily have to enter upon the manufacture and sale of preparations. This was admitted on all hands to be an undesirable course for the Society to take; but at the same time it was not admitted that such a proceeding would be necessary, and Mr. Proctor contended that valuable and useful assistance might be gained from the inspection of even a "dummy laboratory" having "furnaces without fire and stills without steam."

Another objection had reference to the probable difficulty of deciding what particular form of apparatus would be best for the different purposes to which it was to be applied, and though the real existence of this difficulty was acknowledged, Mr. Tanner made it a ground for supporting Mr. Schacht's suggestion, inasmuch as he considered that the possession of a museum of apparatus would afford opportunity for the comparative trial of different forms of apparatus and for deciding which of them was best suited for certain purposes.

Certainly the great difference of opinion manifested when this subject was being discussed sufficiently shows that it is one of considerable difficulty. If the establishment of such a museum of pharmaceutical apparatus were undertaken, it would also involve considerable expense for its maintenance, and in addition to that, further continual outlay would be requisite, in order to keep pace with the improvements introduced and for the substitution of perfected forms of apparatus in the place of those which had become antiquated or obsolete in process of time. We have, however, called attention to this matter, because it has on a recent occasion been again referred to by Mr. Schacht, and because there is some connection between it and the exhibition that is to be held during the ensuing month.

COUNTER PRACTICE IN FRANCE.

Some months ago, the *Répertoire de Pharmacie* contained an account of a case in which M. de Bossy, a pharmacist at Harfleur, was prosecuted for the illegal practice of medicine, and was condemned by the tribunal of Havre to the payment of a fine. The offence with which M. de Bossy was charged consisted in his having administered an emetic to a child suffering from croup, and in his having done so without the order of a medical man. It was admitted that in all probability the action taken by M. de Bossy was the means of saving the child's life under the circumstances, and it was urged on his behalf that what he had done was excusable on account of the urgency of the case; but the tribunal refused to listen to this defence as constituting any justification of the accused, because there was at Harfleur a medical man, to whom it was held that M. de Bossy ought to have applied for directions before he ventured on his own account to render any assistance to the child at the solicitation of its parents.

M. de Bossy has since appealed against the decision of the tribunal, and it is on the whole satisfactory to learn from the report in the last number of the *Répertoire* that the judgment against him has been reversed by the higher court at Rouen. But the satisfaction to be derived from this result is somewhat qualified by the circumstance that the reversal of the judgment was, in the first place, based upon the evidence proving that upon the day M. de Bossy gave the emetic the medical man residing at Harfleur was not in the town, and only as a secondary consideration upon the fact that the case was one of great urgency, involving a question of humanity that would not admit of delay on the part of M. de Bossy.

Notwithstanding the heartburnings and discord there have been among ourselves in regard to the matter of counter practice, we may congratulate chemists and druggists in this country that they are not likely to be exposed to the trouble and annoyance experienced by the Harfleur pharmacist, and that in this respect at least we are not under the necessity of admitting that they manage these things better in France than we do.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION.

In stating the result of the late election of members of the General Committee of the body last week, we should have mentioned that the nominations only referred to the election of "additional members," and we have been requested by Mr. Haydon, the Secretary, to make this correction. At his request we also publish on another page a list of the members of the General Committee as it now stands, which will, we trust, prevent the trade from being misled in any way.

Messrs. Allen and Hanburys write to us in reference to a report, which they find is being circulated, to the effect that they are selling patent medicines below the recognized retail prices, and they request us to make known that this report is entirely and absolutely without foundation.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London on Wednesday, April 21, 1880, the report of the College of Preceptors on the examination held on April 6, was received.

Three hundred and fifty-six candidates had presented themselves for examination, of whom *one hundred and fifty-two* had failed. The following *two hundred and four* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically).

Adams, Joseph Henry ....Newcastle-on-Tyne.
Aikman, John ....Edinburgh.
Armstrong, John ....Langholm.
Atherton, Albert George.........Tunbridge Wells.
Atkinson, Walter Alexander ...Long Benton.
Bailes, Henry Cochrane ....Newcastle-on-Tyne.
Barker, George......................Mirfield.
Barnaby, William Arthur ......Lincoln.
Beach, Thomas Edgar............Bridport.
Beardmore, Alfred Edmund ...Wolverhampton.
Bell, Edward Wightman.........Doncaster.
Bellamy, Robert Arthur ....Bedale.
Birss, Robert, junr. ....Aberdeen.
Blain, William Rushton ....Bolton.
Blond, James Le ....Hamilton.
Bostock, Henry.....................Hyde.
Bowie, George ....Aberdeen.
Boyden, Alfred E. ....Burnley.
Braden, Frank ....Nottingham.
Breeze, Alfred Dennant ....Devonport.
Brigham, George ....Hull.
Browne, John ....Lowestoft.
Brunyee, Arthur ....Thorne.
Burden, Arthur Clarke ....Ryde.
Burt, John Aurens ....Castle Eden.
Campbell, Charles.................Manchester.
Cass, John William ....Guisborough.
Cheshire, Frederick ....Lexden.
Clark, William Alfred...........Southampton.
Coats, Richard Ridley............North Shields.
Cockle, William Henry ....Lynn.
Copland, William..................Huntly.
Crarer, Edward.....................Blairgowrie.
Crook, George ....Southport.
Crowther, Horace Woodward...West Bromwich.
Cryer, Joseph ....Liverpool.
Cullwick, Geo. Hamar Jones ...Birmingham.
Davidson, George ....Aberdeen.
Davies, Daniel E...................Carmarthen.
Dempsey, Arthur ....Edinburgh.
Dick, James ....Newcastle-on-Tyne.
Doble, Henry Tregellas ....London.
Doble, Richard Dennis ....Tavistock.
Dobson, George Edwin ....Bridlington.
Dodsley, Charles Edward ......Mansfield.
Dorman, James.....................Stranraer.
Drummond, Robert Gordon ...Broughty Ferry.
Duffus, William ....Aberdeen.
Dukes, Henry John ....Stafford.
Duplock, Walter ....Petersfield.
Edmondson, Thomas ....Keswick.
Elborne, Herbert ....Southampton.
Eley, Herbert ....Derby.
Evans, Hugh Thomas ....Carnarvon.
Evans, Owen ....Carnarvon.
Evans, William Lloyd............Barbourne.
Fawcitt, Thomas ....York.
Fell, Frederick William ....Preston.
Fletcher, Francis Round ....Netherton.
Forbes, James A. B. ....London.
Forsyth, William ....Elgin.
Fresson, Alfred Reginald ......Stevenage.
Ganson, John ....Aberdeen.
Gee, Edgar Frederic...............Neath.
Goodliff, George ....Huntingdon.
Gould, Charles William ....London.
Groves, Ernest ....Richmond, Surrey.
Hall, Charles Hurd ....London.
Harris, Henry Thomas ....Worksop.
Harrison, Arthur John ....Nottingham.
Hatrick, William Lindsay ......Pollokshields.
Haworth, Walter...................Levenshulme.
Heald, Alfred Francis ....Burnham, Bucks.
Heyworth, Samuel ....Bradford.
Hinde, Albert Henry ....Lowestoft.
Hodgson, George ....Doncaster.
Holloway, Charles Terry.........London.
Horsey, Herbert Vaughan ......Southampton.
Hubbard, Emily ....Downham Market.
Hughes, Hugh Griffith ....Chester.
Humphrey, Albert Edward......Portmadoc.
Jackson, Alfred ....Widnes.
Jackson, Richard Herbert ......Hull.
James, Morgan William ....Llandovery.
Jaques, George ....Leeds.
Jarvis, Leonard Vickery ....Norwich.
Jeffery, Elias.........................Falmouth.
Johnson, Frederick David ......Beverley.
John, William ....Narberth.
Jolley, S. Herbert ....Heaton Norris.
Jones, John ....Stockport.
Knight, George......................London.
Lang, John West..................Southport.
Lay, William George ....Clevedon.
Leech, John Frederick ....Tideswell.
Leslie, George ....New Pitsligo.
Lewis, Alfred Wheatcroft ......Swansea.
Lewis, James Adam...............St. Clears.
Lewis, Thomas Wright ....Bloxwich.
Little, Andrew ....Old Aberdeen.
Lloyd, Edwin Henry ....Ashby-de-la-Zouch.
Lowe, William Baillie.............Forres.
Luis, Ellia Raphael ....Edinburgh.
Machattie, Adam ....Keith.
McIntosh, James ....Elgin.
McKenzie, James...................Macduff.
McKenzie, James...................Perth.
McLeod, James......................Ayr.
Malone, Joseph Peter ....Rochdale.
Marsden, Charles Edwin.........Huddersfield.
Marshall, John ....Accrington.
Martin, John Pearson ....Maryport.
Mason, Edgar ....York.
Mason, Hubert Huxley ....Clevedon.
Matthew, Edwin ....Hadleigh.
Matthews, Harry James.........Warwick.
May, Samuel Augustus ....Jersey.
Medd, Frank Edward ....Gloucester.
Metcalfe, James ....Bradford.
Metcalfe, Percival William......Bradford.
Milne, Alexander ....Montrose.
Mitchell, James ....Aberdeen.
Morrell, Frederick ....London.
Morris, John Hall ....Bolton.
Morriss, Edward Stow............Sleaford.
Morse, Frederick Bartho.........London.
Mulliner, Thomas Chas. Mills...Southsea.
Munro, John Joyner ....Strichen.
Negus, John Henry ....Northampton.
Nicholson, Richard Thomas ...Maidstone.
Nicol, George Harry ....Dumfries.
Nowers, Lawrence Edward......Lydd.
Ogle, John Henry...................London.
Oliver, John Robert...............Lynn.
Oram, Frank.........................Totnes.
Padley, Frank Robert ....Birmingham.
Parker, Edwin ....Stoke-on-Trent.
Parker, William ....Wainfleet.

Parsons, Henry Imber............Barnstaple.
Parsons, Stanley Bernard ......London.
Paterson, George ....Aberdeen.
Pellew, Albert ....Woodbridge.
Peterkin, James ....Elgin.
Phillips, David......................Llandilo.
Plant, Frederick ....Buxton.
Potts, Robert ....Newcastle-on-Tyne.
Redfern, Edward ....Rhyl.
Richmond, Paul Henry ....Wigtown.
Rickards, Henry William ......London.

Stephens, David ....Llandilo.
Stevens, Walter Rowland ......Wye.
Stokoe, James Clarke ....Clare.
Swain, Eliza ....London.
Taylor, Charles......................Tregoney.
Taylor, William ....Turriff.
Taylor, William Chadwick C....Saltburn-by-the-Sea.
Thomas, Evan ....Pwllheli.
Thomas, Evan Jenkyn............Newquay.
Thomas, Daniel Griffith ....Cardigan.
Thomas, Tom ....Halifax.
Thompson, George ....Knaresborough.
Thorpe, John..........................Leigh.
Thorpe, William ....Sleaford.
Todd, William Carter ....Preston.
Tregellas, Clifton Pari............London.
Tucker, Thomas ....London.
Turner, Robert Michael ....Oundle.
Turner, Samuel......................Buxton.
Waddington, Alfred Henry......Bradford.
Wade, Herbert ....Oldham.
Walker, Charles Herbert.........Hull.
Watson, John Robert ....Newport, Mon.
Watt, Robert..........................Huntly.
Webster, Robert ....Selby.
Welch, Frederick ....Colchester.
Westover, John Turton ....Bridgnorth.
Wheeldon, Frederick John ......Manchester.
Wheeler, William Robert ......Fant Holme.
Wilkes, Thomas James ....London.
Wing, John William ....Colsterworth.
Wood, Fred ....Ely.
Woodward, Charles Frederick...Wellingborough.
Wright, Joseph Pretty ....Burton-on-Trent.

The questions for examination were as follows:—

Time allowed: Three hours for the three subjects.

I. LATIN.

1. Translate into English the following passages:—

A. Post ejus mortem nihilo minùs Helvetii id, quod constituerant, *facere conantur*, ut e finibus suis exeant. Ubi jam se ad eam rem paratos esse arbitrati sunt, oppida sua omnia, numero ad duodecim, vicos ad quadringentos, reliqua privata ædificia incendunt, frumentum omne, præterquam quod secum portaturi erant, comburunt, ut, domum reditionis spe sublatâ, paratiores ad omnia pericula subeunda essent; trium mensium molita cibaria sibi quemque domo efferre *jubent*.

B. Postridie ejus diei Cæsar, præsidio utrisque castris quod satis esse visum est, *reliquit*; omnes alarios in conspectu hostium pro castris minoribus constituit, quò minùs multitudine militum legionariorum pro hostium numero valebat, ut ad speciem alariis *uteretur*: ipse, triplici instructâ acie, usque ad castra hostium *accessit*.

2. Give the present, perfect, infinitive, and supine of the verbs in italics.

3. Decline throughout—*mortem, eam rem, omne frumentum*.

4. Translate the following sentences into Latin:—

(i.) The soldiers were fortifying the camp.
(ii.) On the next day they began to seek help from Cæsar.
(iii.) The Helvetii determined to depart from their own territories, in order that they might obtain possession of all Gaul.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

5. Divide 203 litres of soup among 18 men and 22 women, giving each man double a woman's share.

6. What number must be added to $\frac{3}{7}$ of $\frac{5}{9}$ to make $\frac{1}{2}$ of $\frac{6}{9}$?

7. Divide the product of 4·255 and ·032 by ·00016.

8. If $\frac{7}{12}$ acre of land cost £118 13*s.*, what will $10\frac{6}{7}$ acres cost?

9. If 7 fires consume 4 tons 10 cwt. of coal in 30 days of 10 hours each; how much will be consumed by 12 fires in 20 days of 14 hours each?

III. ENGLISH.

10. Of what inflexions are nouns capable? Write down those inflexions which are used to distinguish the feminine gender from the masculine.

11. Define Active Voice and Passive Voice. Show that verbs may be active without being transitive, and transitive without being active.

12. Enumerate the Personal Pronouns, simple and compound.

13. Parse fully each word in the following sentence:—

"Is this a dagger that I see before me?"

14. Write a short composition on one of the following subjects:—"Reading," "Waste of Time," "The University Boat-Race"; or give a short outline of one of Shakspere's Plays.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	17	16	1	Lancaster	9	3	6
Birmingham	20	12	8	Leeds	17	11	6
Bristol	6	3	3	Lincoln	9	5	4
Cambridge	10	5	5	Liverpool	14	7	7
Canterbury	4	2	2	London	45	26	19
Cardiff	5	1	4	Manchester	26	18	8
Carlisle	9	4	5	Newcastle-on-T.	13	7	6
Carmarthen	9	8	1	Northampton	5	2	3
Carnarvon	7	4	3	Norwich	13	7	6
Cheltenham	2	2	0	Nottingham	15	7	8
Darlington	7	3	4	Oxford	2	0	2
Dundee	7	4	3	Peterborough	3	2	1
Edinburgh	13	5	8	Sheffield	5	3	2
Exeter	9	6	3	Shrewsbury	5	2	3
Glasgow	9	5	4	Southampton	6	5	1
Hull	13	6	7	Truro	3	2	1
Inverness	5	4	1	Worcester	2	0	2
Jersey	1	1	0	York	11	6	5

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificate of the University of London.

Thomas, William ....Burnley.

Certificates of the University of Oxford.

Bird, Frederick Charles John...Bath.
Drew, Walter Clark................London.
Gilbert, Charles George ....Walthamstow.

Certificates of the University of Cambridge.

Jeans, Edward ....Mansfield.
Puckey, Courtenay ....Herne Hill.
Taylor, Francis William ....Newport Pagnell.
Thomas, John ....Oswestry.

Certificates of the College of Preceptors.

Birch, John ....Heywood.
Elliott, Alfred ....Stowmarket.
Fox, Frederick William ....Lincoln.

EXAMINATIONS IN LONDON.

April 14, 1880.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Ashmead, John Stubbings ......Clifton.
Cox, Frederick John ....Newark.
Powrie, Percival Chamberlain..Mossel Bay.

MINOR EXAMINATION.

Twenty candidates were examined. *Twelve* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Ashton, Henry ....Lynn.
Ballinger, Arthur Joseph ......Coventry.
Bamforth, Joseph.................Manchester.
Bayfield, Gabriel Thomas ......Norwich.
Bennett, Charles Joseph ....Widnes.
Bentley, John Thomas............Hull.
Blagg, Eli ....Hanley.
Bolton, Frederick William ......London.

April 15, 1880.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, and Taylor.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Carruthers, Robert ....Dumfries.
Howell, Edmund ....Oxford.
Williams, William ....St. Clears.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Fifteen* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Brooker, Algernon ....Exeter.
Burnett, William ....Hull.
Callander, William Wright......Exeter.
Evison, Alfred ....Alfreton.
Fletcher, James Edward.........Saltley.
Goodchild, Alfred Clarke ......London.

April 16, 1880.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present, on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Twelve* failed. The following *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Guy, Daniel ....Lee Green.
Hagon, Albert ....Cardiff.
Hall, Alfred Lee ....Winchcombe.
Hardwicke, Arthur ....Sheffield.
Hebblethwaite, George Arthur.Hull.
Hill, John Staniforth ....Blackpool.
Holloway, Edwin Arthur ......Leominster.
Horne, John ....Wednesbury.
Hughes, Henry Milner ....Newcastle-on-Tyne.
Jackson, Henry Lawson ....Crediton.
Jones, Hugh Robert...............Bangor.

April 21, 1880.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Five* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Jones, William Harris............Abergavenny.
Shepherd, John William ....Settle.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Eleven* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Morgan, William ....Saint Clears.
Morse, Charles Henry Stafford..Bishop's Stortford.
Nethercott, Walter John.........Stroud.
Parsons, James Vincett ....Icklesham.
Phethean, James ....Bolton.
Radford, James Alfred ....Birmingham.
Ratcliffe, Joseph William ......Sutton Bridge.
Richards, Randolph Hutchings..London.
Seward, George Halifax ....London.
Williams, Charles Adrian ......Plymouth.

April 22, 1880.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Dr. Greenhow was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Two* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Thompson, John Tatham.........Scarborough.
Williams, James Edward ......Louth.
Wimpenny, James McMillan...Waterloo.
Winfrey, Richard ....Long Sutton.

MINOR EXAMINATION.

Twenty candidates were examined. *Twelve* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Shipman, Joseph James ....Chesterfield.
Steward, Alfred ....Great Yarmouth.
Thompson, George ....Epworth.
Tutton, James ....Northampton.
Waring, Edwin Scholey ....Greetland.
Wellington, Frederick............South Petherton.
Williams, John.....................Carnarvon.
Wright, Eli ....Tipton.

MODIFIED EXAMINATION.

One candidate was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Mickle, Edward.....................Liverpool.

PHARMACEUTICAL MEETING.

Wednesday, April 21, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT, IN THE CHAIR.

An adjourned Evening Meeting of the Society was held on Wednesday last, in order that four papers which were announced for the meeting on the 7th inst., but were then postponed through want of time, might be read. The chair was taken at half-past eight o'clock. The first paper read was entitled—

Experiments on Taraxacum Root.

BY J. B. BARNES, F.C.S.

The paper is printed on p. 849, and gave rise to the following discussion:—

Mr. Greenish congratulated Mr. Barnes on having produced a very practical paper, one which emanated from the laboratory rather than from the desk. In his first three experiments he had no doubt Mr. Barnes adopted the true principle in making a succus taraxaci, viz., adding spirit as early as possible, as soon as the juice was exposed to the air, so as to prevent fermentation being set up and the formation of a saccharine principle. It was known that in other instances of a similar character if fermentation took place there occurred not only a conversion of the starchy matter into sugar, but whatever bitter principle the root contained would also be decomposed. The results were extremely satisfactory, though he should have liked to know the quantity of root operated on in experiment 1 and the amount of product. He did not think Mr. Barnes's conclusion that cold water did not separate the bitter principle was quite borne out by experiment 4, because the root having been exposed to the action of cold water fermentation would have been set up and sugar formed unless spirit were added. Mr. Barnes had evidently got a large quantity of inulin, which decomposed and fermented, and this would account for the sweet taste. Even if he had tried spirit, after twelve hours' maceration in cold water, he would probably not have separated any bitter principle. Mr. Barnes's earlier experiments quite agreed with his own, and if care were taken in obtaining the taraxacum in good condition, and the spirit were added as soon as possible, he thought a preparation would be obtained far superior to anything which could be got from the dry root.

Mr. Moss agreed with Mr. Greenish that Mr. Barnes's statement about the power of cold water to separate the bitter principle did not necessarily follow from the observation that the product of experiment 4 possessed a sweet taste. He did not, however, quite agree with Mr. Greenish's reason, though he differed from Mr. Barnes. The bitter powder prepared by experiment No. 2 was not so bitter but that the taste would be masked by a considerable quantity of the sweet matter of taraxacum root. It must be there in the product of experiment 4, though it could not be tasted. That powder also was somewhat crystalline to the taste, and he should suppose that possibly some chloride of potassium had been dissolved out by the spirit; if so it would account for the hygroscopicity. Mr. Barnes had referred to the resins of podophyllin and euonymin, and the speaker had hoped he had experimented with a view of getting a similar preparation from taraxacum. If he added the spirituous tincture to water it was quite possible he might get a resin precipitated which would compare better with those he had named than the spirituous extract he had obtained. Of course, the resin thus obtained would not be so uniform as many substances having names with the same termination, but it would be more uniform than the extract, decoction or succus, because the diluting matters which occurred in all those preparations would be eliminated.

Professor Redwood said there were two objects contemplated in preparations of vegetable substances possessing medicinal properties, one of which was that of administering the substance in an available form, but as nearly as possible in the condition in which it occurred in nature. This object was especially kept in view in the preparation ordered in the Pharmacopœia under the name of succus taraxaci. This was a desirable object to carry out, as some vegetable substances appeared to produce more satisfactory effects when administered in their natural state than when the active principles in their isolated condition were used. Nevertheless it had been a great step in advance to be able to isolate the active principles from vegetable substances, and that appeared to be the direction of Mr. Barnes's researches. Whether the resinous substance which was thus isolated were the most valuable medicinal constituent of taraxacum still remained to be proved, that must be left for medical men to determine. It was very desirable to have preparations which could be tested in this way, and so far the paper was very valuable, as it showed the means of obtaining this active principle in an approximately pure condition, so that its value as compared with the succus could be ascertained. The two preparations, however, were quite distinct, as were the processes for their production.

Mr. Gerrard asked if the passage of 32 ozs. of rectified spirit over a pound of powdered taraxacum entirely exhausted it of its bitterness. It seemed to him scarcely sufficient for the purpose. He should also like to know what percentage of loss occurred, and whether Mr. Barnes recovered the spirit absorbed by pressure, or used the displacement method. Of course, in percolating a pound of powdered root with 32 ozs. of spirit nothing like 32 ozs. would pass through.

Mr. Barnes said he did not add any more spirit; he simply passed the 32 ozs. through the powder. No doubt there would be some of the bitter principle remaining.

Mr. Postans said Mr. Greenish had anticipated several things he should have said; but he could not help saying a word for the old succus of the Pharmacopœia. The demand for it was something enormous, and that, too, by medical men, so that as pharmacists they were bound to supply it. He took it that in the Pharmacopœia it was intended where possible to have a liquid and a solid preparation, a succus and an extract. It occurred to him, as he had mentioned on a former occasion, that as the Pharmacopœia ordered that the succus should be heated to 212° before evaporation, it might perhaps have been a more elegant way of getting rid of the various matters to use the succus of the Pharmacopœia to which spirit had been added, and evaporate it at a low temperature. The result was very similar to that which Mr. Barnes had presented to the meeting. Pereira said that 100 lbs. of taraxacum root would yield about half their weight of juice, and in the months of April and May rather more; but Squire said that 100 parts of root yielded 30 parts of succus and 8 of extract. Mr. Barnes, in his experiment No. 2, took one pound of root, which yielded $1\frac{1}{2}$ oz. of extract, prepared by treating the fresh roots with rectified spirit; one pound of the expressed juice would yield something over $1\frac{1}{4}$ oz. He hardly looked upon Mr. Barnes's extract as really alcoholic, because there was clearly a good deal of water in the succus, whether it were expressed or the root itself were treated with spirit. The real alcoholic extract was obtained when the dried root was treated with alcohol.

Mr. Urquhart wished to say just one word as a medical man. There were two forms of administering medicine, the solid and fluid; the latter had been chiefly employed for taraxacum, and the succus had hitherto been found unfailing in its action. A great many experiments would have to be tried, therefore, before it would be set aside.

A vote of thanks was passed to Mr. Barnes.

The next paper read was one on—

The Composition of Tonga: a Reputed Remedy for Neuralgia.

BY A. W. GERRARD, F.C.S.

The paper is printed at p. 849, and gave rise to the following discussion:—

Mr. Holmes said that he had little to add to the observations he made at the last Evening Meeting, viz., that he believed that the so-called root was the stem of a species of *Rhaphidophora*, probably *Rhaphidophora vitiensis*, Seem. He had placed on the table microscopical slides, both of that plant and of tonga, for comparison. With regard to the bark found in the tonga, he believed that it would be found to belong, in all probability, to a tree of the natural order Sapotaceæ, several plants of that group having a bark of a singularly sweet and slightly astringent taste, *e.g.*, monesia bark. He believed Mr. Greenish had examined the bark under the microscope, and might be able to give some information on the point.

Mr. Jackson said all he had seen of this drug hitherto was a small quantity, about half a teaspoonful, which was submitted for examination at Kew, some time back, but there was not sufficient to determine the botanical structure of any portion. There was no leaf at all, and only a small portion of wood or root; he could not really say which. He was much interested in seeing these specimens wrapped up in the sheathing bark of the leaf stalks of the cocoa nut.

Mr. Greenish said that he, like many others, had been much interested in this tonga, which he found was a very expensive article. He sent to Mr. Tanner and asked him to be good enough to send him some typical specimens for examination. Three specimens were sent, viz., the bark, the root and the leaf. In the bark there were very dark and light portions. He had made sections of the dark part, and found that it consisted not of the primary, but the secondary layer. The cortical portion seemed to have been removed. The whiter portions were evidently the inside portions of the same bark,—what might be termed the tertiary layer. The secondary dark rind had the stone cells very prominent, and the inside portion had the bast cells which belonged to the tertiary layer. There was no doubt that these two portions belonged to each other, and to a dicotyledonous plant. That which was called the root had a large amount of fibrous material, but it was evidently from a monocotyledonous plant and had nothing whatever to do with the bark. The leaf again was that of a dicotyledonous plant, and might possibly belong to the bark; he could not say. But really, when the root of a monocotyledon and the leaf of a dicotyledon were found mixed together in that sort of bag, and varying very much in their relative proportion, it required a large amount of faith to believe in the value of such a remedy for neuralgia. Mr. Holmes had mentioned an arum as the probable source of the root, and he believed Mr. Holmes was guided to some extent by the starch, but he had examined the starch grains, and compared them with those of the arum, and they certainly differed very considerably. He could not say what starch it was, but it was very much smaller, and of a different form.

Mr. Holmes said he had placed a specimen of raphidophora under the microscope and the starch seemed to him as nearly as possible of the same size and character as that of the tonga. He was quite willing to admit that the starch of *Arum maculatum* was much larger and possibly different in shape, but he knew of no other starch which the tonga starch approached so nearly in character. If the bark belonged to a plant of the order of Sapotaceæ, as he supposed, the leaf could not belong to the same plant, because plants of that order had usually thick leaves, very different in character to those mixed with the tonga.

A vote of thanks was passed to Mr. Gerrard.

The Chairman said that the next two papers would be read and discussed together. The subjects were—

The Action of Potassium Chlorate on Ferrous Iodide; and

The Quantitative Estimation of Syrup of Iodide of Iron.

BY R. H. PARKER.

The papers are printed on pp. 850 and 851, and gave rise to the following discussion:—

Mr. Naylor said the reaction which Mr. Parker had embodied in this communication was evidently a combination of a process which had been long known and of one which, perhaps, was less known. The action of alkaline chlorates upon ferrous salts was very well known indeed, and Stelling had devised a method of estimating the chlorine in chloride of potassium, based on the reaction of alkaline chlorates upon ferrous oxide. The other reaction was not so well known, viz., the change which a ferrous iodide solution underwent in the presence of water. He believed there was very good evidence still to believe that when ferrous iodide was dissolved in water, and the aqueous solution allowed to stand for some time, hydriodic acid was formed. This could be readily shown by making first of all a perfectly neutral solution, which when kept for some time in a bottle acquired an acid reaction, and it became in time still more acid; in fact, it went through all those changes which Mr. Parker had so minutely recorded. He had satisfied himself that it was hydriodic acid which was formed, because if to it were added first a little starch no free iodine was manifested, but if then a little iodic acid were added the hydriodic acid and iodic acid at once gave free iodine, which was recognizable by the blue iodide of starch being formed. Mr. Parker might have shown more intelligibly the different stages of the decomposition, by substituting two equations for his one.

Professor Attfield said the meeting ought not to separate without recognizing the large amount of time, trouble and thought which the author had evidently devoted to this subject. He would have said even more in his praise, but being an old laboratory student it would not be becoming in him to do so. With regard to the fundamental reaction to which Mr. Parker had drawn attention, he had only given the equations respecting the commencement and, probably, the end of the reaction, and he would no doubt admit that there were in all probability many stages before the end was reached; and that in the course of those stages probably some ferrous chloride was produced, and also some iodide of potassium.

Mr. Fletcher wished to ask one question. In the equation which Mr. Parker had given he represented two molecules of iodide of iron and one of chlorate of potassium eventually giving free iodine and chloride of potassium. He did not wish to dispute the accuracy of that reaction, but should like to ask how it was that whilst he had an excess of chlorate of potassium present, free iodine could exist in the solution. It appeared to him that probably the extraordinary deficiency Mr. Parker had found in some of his iodine estimations was accounted for by the fact that the excess of chlorate which was of course in his retort was acting on the iodine, and forming iodic acid, and consequently he would never get the theoretical amount of iodine. As regarded syrups, Mr. Parker mentioned that in each case when made by himself according to the B.P. formula the syrup was straw coloured. He did not know whether that was the experience of pharmacists generally, but as a manufacturer he could say that if they sent out syrup of iodide of iron straw coloured, they would soon have it back on their hands.

Mr. Parker, in replying, said that hydriodic acid could not be formed in the syrups to any large extent, because old samples of syrup and solution were only feebly acid; and since HI was decomposed by boiling with $KClO_3$ (probably with liberation of the whole of the iodine) it was evident that the iodine estimations of such samples would be in *excess* of that required by the Fe_2O_3 found, which was never the case; indeed the results detailed in the paper proved that the longer the solution of FeI_2 was kept, the greater is the *deficiency* of available iodine. With reference to Mr. Fletcher's remarks Mr. Parker said that free iodine did not react on $KClO_3$ forming KIO_3, except in the presence of nitric acid, which was required for the intermediate production of HIO_3. This he had proved by distilling 40 c.c. of a solution of iodine with 2·0 grams $KClO_3$; the distillate contained as much iodine as could be obtained by distilling the iodine solution alone. As to the colour of syr. ferri iodidi, Mr. Parker had found that all samples prepared in strict accordance with the pharmacopœial process possessed a slight tint which might be called light straw coloured or very light green, according to fancy, but it was never absolutely water-white. If, however, the solution of FeI_2 were kept for some hours with excess of iron, or if some reduced iron were added, a water-white solution might be obtained; but a considerable loss of iron was thus incurred, and a constitutional change in the iodide appeared to take place, since in such liquors the available iodine was deficient to an extent varying from 4 to 12 per cent., according to the length of time the solution had been kept, whereas, from the tinted syrups it was easy to obtain within 1 per cent. of the total iodine. In his opinion it would be preferable to send out a very slightly tinted syrup of full strength rather than a beautifully water-white preparation which might be from about 8 to 70 per cent. deficient in iron. Mr. Parker drew special attention to the fact that solution of ferrous iodide cannot be kept without considerable loss of iron, because of its important bearing upon the extemporaneous preparation of the syrup by adding a "liquor ferri iodidi" to simple syrup. Such specimens were frequently very weak; one which he had examined during the last few days he had found to be nearly 70 per cent. deficient, while a syrup prepared by himself of the "light straw coloured variety" gave Fe_2O_3 99·3 per cent. and iodine 98·7 per cent. of the theoretical amount. Finally Mr. Parker pointed out that the iodine estimation 1·7 + in the table was an error due to defective apparatus and that the B.P. theory for Fe_2O_3 should have been stated as 0·2030 instead of 0·2055.

The President, in proposing a vote of thanks to Mr. Parker, said he had shown great industry and care in preparing this paper, and also a great love of his work—a quality which promised well for the future. He was glad that the session closed with so earnest and good a paper as Mr. Parker had given them.

The Chairman then drew attention to some glass measures sent by Messrs. Toogood, some bearing the Westminster and some the Marylebone mark.

NORTH BRITISH BRANCH.

The seventh and last meeting of the session was held in the Society's rooms, 119a, George Street, Edinburgh, on Wednesday evening, April 14, Mr. J. B. Stephenson, President of the Branch in the chair.

The minutes of the former meeting were read and confirmed.

The Honorary Secretary announced the following donations:—

To the Library:—*The Australasian Supplement to the Chemist and Druggist*, 'The First Report of the Pharmacy Board' and the 'Pharmaceutical Register for 1879,' from the Pharmaceutical Society of Victoria; *The Journal of the Chemical Society* for April, from Mr. Mackay.

The Honorary Secretary read a letter from Mr. D. B. Dott, expressing that, on account of family bereavement, he had to ask to be excused for not being able to read a paper "On the Solubility of some Alkaloidal Salts," which had been announced for this meeting.

Mr. J. F. King, city analyst, then read a paper on the "Edinburgh New Water Supply: its Composition and Action upon it of Different Filtering Materials as regards Removal of Colour." The paper, which was illustrated by copious diagrams, will be printed in a future number.

The President then formally closed the session in a few remarks, enumerating the papers which had been read at the various meetings, and thanking the members for the great honour they had shown him in continuing him in the chair for three years, and for the uniform indulgence and assistance he had received.

On the motion of Mr. Blanshard a cordial vote of thanks was awarded to Mr. King, and a no less hearty one, on the motion of Mr. Nesbit, was given to the President for his conduct in the chair.

Provincial Transactions.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Law and Parliamentary Committee of this Association was held at the Queen's Hotel, Birmingham, on Wednesday the 14th inst., at 1 p.m.; Mr. Thomas Barclay (Birmingham), President, in the chair.

Present—Messrs. Andrews (London), Arblaster (Birmingham), Bell (Hull), Churchill (Birmingham) Cross (Shrewsbury), Hampson (London), Holdsworth (Birmingham), Jervis (Sheffield), Maltby (Lincoln), Symes (Liverpool), and the Solicitor of the Association.

The Secretary said that the case which had previously been before the Committee in which a member had been threatened with an action for damages for the alleged improper mixing of nitric acid and mercury by one of his assistants had been settled by arrangement.

The President said the Executive at its last meeting passed a resolution suggesting that the Law and Parliamentary Committee should appoint a sub-committee to deal with urgent cases.

It was moved by Mr. Symes, seconded by Mr. Bell, and unanimously resolved:—"That the President and the Members of the Executive residing in Birmingham, with power to add to their number, be appointed a sub-committee to deal with urgent cases."

Communications from members asking for legal advice and assistance were placed upon the table and dealt with by the Committee.

The President said that the next item on the agenda paper was to consider the applications for the secretaryship, to interview several of the candidates for the appointment, and if deemed advisable to provisionally appoint a new secretary.

The Secretary said that acting under the direction of the Executive he had inserted an advertisement in the *Pharmaceutical Journal* and in the *Chemist and Druggist*. Twenty-three applications had been received. One gentleman had subsequently withdrawn his application. A sub-committee, consisting of the resident officers of the Association and Mr. Churchill, had perused the applications and instructed him to communicate with some of the applicants requesting them to meet the Committee on that day. The applications, testimonials, etc., of the candidates were then placed upon the table and perused by the Committee, and the candidates present had an interview with the Committee.

After a deliberation of upwards of four hours it was moved by the President, seconded by the Vice-President, supported by Messrs. Bell, Symes, and others, and unanimously resolved:—"That Mr. W. F. Haydon be reappointed Secretary to the Association."

It was moved by Mr. Churchill, seconded by Mr. Symes, and unanimously resolved:—"That Mr. G. R. Templeman be provisionally appointed Assistant Secretary to the Association, the engagement being terminable at three months' notice from any date, security to be given to the extent of £500."

The Secretary reported having drafted the Fourth

Annual Report of the Executive Committee, to be presented to the members of the Association at the forthcoming Annual General Meeting, and having caused it to be printed and a copy forwarded to all the members of the Executive with a request that they would amend it in any way they deemed desirable and return the amended draft to him.

The amended drafts were laid on the table and each clause of the Report carefully considered and finally approved.

SECOND ELECTION OF GENERAL COMMITTEE.

The following is a list of the gentlemen who are reported by the Scrutineers, Messrs. Laundy and Co., to have received the highest number of votes in the respective districts in which nominations have been made. In cases where an equal number of votes have been given for two or more candidates they are marked equal.

England.

District 1.—Anthony, J. L., High Street, Bedford.
,, 2.—Welch, Charles, 161, King's Road, Reading.
,, 3. Robinson, Messrs. Cox and Robinson, Stony Stratford; Turner, John, Aylesbury; Griffith, Robert, Slough — equal
,, 4.—Throssell, John, Fitzroy Street, Cambridge.
,, 5. Hornby, C. H., Lower Hillgate, Stockport; Bates, W. I., Mill Street, Macclesfield — equal.
,, 6. Singleton, Henry, Winsford, Cheshire; Goode, Charles, 9, High Street, Congleton — equal.
,, 8.—Prockter, John, Penzance, Cornwall.
,, 9.—Thompson, Andrew, English Street, Carlisle.
,, 10.—Greaves, Abraham, Chesterfield.
,, 11.—Frost, George, Corn Market, Derby.
,, 12.—Symons, W., 26, Joy Street, Barnstaple.
,, 13. Wood, W., Bedford Street, Plymouth; Turney, S. B., Union Street, Plymouth; Codd, F., Duke Street, Devonport — equal.
,, 14.—Delves, George, High Street, Exeter.
,, 15.—Groves, T. B., St. Mary Street, Weymouth.
,, 16.—Elliott, Robert, High Street, Gateshead.
,, 17.—Harrison, Jno., 33, Bridge Street, Sunderland.
,, 18.—Robinson, James, Northgate, Darlington.
,, 19.—Cole, F. A., 34, St. Botolph's Street, Colchester.
,, 20. Smith, N., Cheltenham; Jeffrey, T. A., Leamington Pl., Cheltenham — equal.
,, 21.—Stafford, William, Northgate Street, Gloucester.
,, 22.—Barker, C. D., 51, White Ladies Rd., Clifton, Bristol.
,, 25.—Pollard, Henry, High Street, Ryde, Isle of Wight.
,, 26.—Chave, W., Broad Street, Hereford.
,, 27.—Durrant, G. R., Old Cross, Hertford.
,, 28.—Turner, W. M., St. Ives, Hunts.
,, 29.—Green, Robert, Hare Street, Woolwich.
,, 30.—Barnaby, Henry, Star Hill, Rochester.
31.—Bing, E., St. George's Street, Canterbury.
,, 32.—Cotterell, W. H., Dover.
,, 33.—Bagnall, W. H., New Street, Lancaster.
,, 34.—Sharples, George, 7, Fishergate, Preston.
,, 35.—Farnworth, William, King William Street, Blackburn.
,, 36.—Thomas, Richard, Manchester Road, Burnley.
,, 37.—Dutton, Francis, Town Hall Square, Bolton.
,, 38.—Ashton, William, Lord Street, Southport.
,, 39.—Robinson, Ralph, Yorkshire Street, Rochdale.
,, 40.—Hargreaves, H. L., High Street, Oldham.
,, 41. Woolley, G. S., 69, Market Street, Manchester; Slugg, J. T., 242, Stretford Road, Manchester; Benger, F. B., 7, Exchange Street, Manchester; Brown, W. S., Market Street, Manchester; Williams, F. P., 257, Oldham Rd., Manchester — equal.
,, 43. Symes, Dr Charles, Hardman Street, Liverpool; Woodcock, Joseph, Shaw Street, Liverpool; Shaw, John, Gt. George Place, Liverpool.
,, 44.—Clark, W. B., Belvoir Street, Leicester.
,, 45.—Robson, W., Cleethorpe's Road, Great Grimsby.
,, 46.—Maltby, Joseph, High Street, Lincoln.
,, 47.—Pilley, Henry, Strait Bargate, Boston.
,, 48. Hampson, Robert, 205, St. John's Street Road, London, E.C.; Andrews, Frederick, 34, Leinster Terrace, Hyde Park, London, W.; Greenish, Thomas, New Street, Dorset Sq., London; Urwick, W. W., 60, St. George's Road, London, S.W.; Owen John, 51, Holloway Road, London, N.; Pattison, George, 139, St. John's Street Rd., London; Preston, Alfred, 88, Leadenhall Street, London; Slipper, James, 86, Leather Lane, London; Humpage, B., Turnham Green, London — equal.
,, 49.—Young, John, High Street, Newport.
,, 50. Wigg, W. C., 17, High Street, King's Lynn; Atmore, George, 17, High Street, King's Lynn — equal.
,, 51.—Robinson, James, Oxford Hill, Norwich.
,, 52.—Poll, W. S., Regent Road, Great Yarmouth.
District 53.—Bingley, John, Wood Hill, Northampton.
,, 54.—Carr, W. G., Berwick-on-Tweed.
,, 55.—Proctor, B. S., Newcastle-on-Tyne.
,, 56.—Shepperley, George, Long Row, Nottingham.
,, 57.—March, W., Market Place, Newark-on-Trent.
,, 58.—Prior, G. T., Broad Street, Oxford.
,, 59.—Cross, W. G., jun., Mardol, Shrewsbury.
,, 60.—Hillier, Henry, Bridge Street, Bath.
,, 61.—Prince, Henry, Fore Street, Taunton.
,, 62. Blackshaw, Thomas, Burslem; Prince, G. A., Longton; Pickburn, G. H., Kidsgrove — equal.
,, 63.—Averill, John, Market Square, Stafford.
,, 64. Fleeming Wm., Queen Square, Wolverhampton; Brevitt, W. Y., Pennfields, Wolverhampton; Lowe, R. H., Wolverhampton — equal.
,, 65.—Anness, S. R., Westgate Street, Ipswich.
,, 66.—Whaley, Edward, Kingston-on-Thames.
,, 67.—Cortis, A. B., South Street, Worthing.
,, 68.—Vizer, E. B., Church Road, Brighton.
,, 69.—Rossiter, F., George Street, Hastings.
,, 70. Barclay, Thomas, Bull Street, Birmingham; Arblaster, C. J., New Street, Birmingham; Southall, William, Bull Street, Birmingham.
,, 71.—Walker, George, Coventry.
,, 72.—Davis, Henry, Warwick Street, Leamington.
,, 73.—Severs, Joseph, Stricklandgate, Kendal.
,, 74.—Orchard, E. J., Salisbury.
,, 75.—Hollier, Elliott, Market Place, Dudley.
,, 76.—Johnson, T. S., Malvern.
,, 77.—Thompson, Thomas, King Street, Richmond, Yorks.
,, 78.—Middleton, Joseph, Clevedon Terrace, Middlesboro'.
,, 79.—Whitfield, John, 113, Westborough, Scarboro'.
,, 80.—Davison, Ralph, Holgate Hill, York.
,, 81.—Bell, C. B., Spring Bank, Hull.
,, 82.—Greenwood, John, 20, Parliament Street, Harrowgate.
,, 83. Reynolds, Richard, 13, Briggate, Leeds; Stead, T. B., Upperhead Row, Leeds.
,, 84.—Silson, R. W., Church Street, Manningham, Bradford.
,, 85.—Jessop, Jonathan, Halifax.
,, 86.—Robinson, J. R., Westgate, Dewsbury.
,, 87.—Cardwell, James, Bread Street, Wakefield.
,, 88.—Hall, George, King William Street, Huddersfield.
,, 89.—Badger, Alfred, Eldon Street, Barnsley.
,, 90. Cubley, George A., High Street, Sheffield; Jervis, William, Broomhill, Sheffield.

Wales.

,, 91.—Roberts, M., High Street, Bangor.
,, 92. Roberts, Peter, St. Asaph's; Round, W. T., Ruthin — equal.
,, 93.—Jones, Thomas, Bala.
,, 94.—Davies, T. J., Great Darkgate Street, Aberystwith.
,, 95.—Francis, Thomas, Notts Square, Carmarthen.
,, 96.—Drane, Robert, 8, Queen Street, Cardiff.

Scotland.

,, 97.—Kermath, W. R., St. Andrews, N.B.
,, 98. Mackenzie, James, 45, Forrest Road, Edinburgh; Laird, G. H., 40, Queensferry Street, Edinburgh; Raimes, Richard, Jun., Leith Walk, Edinburgh.
,, 99.—Borthwick, A. J., Market Place, Selkirk.
,, 101. Davison, Thomas, Buchanan Street, Glasgow; Kinninmont, Alex., Portland Street, Glasgow; Greig, William, 59, Glasford Street, Glasgow; Currie, John, 479, Sauchiehall Street, Glasgow; McAdam, Robert, Virginia Street, Glasgow.
,, 103. Burn, D. H., Arbroath; Kerr, Charles, 56, Nethergate, Dundee.
,, 104. Strachan, Alex., George Street, Aberdeen; Ritchie, David, Market Street, Aberdeen; Paterson, James, Aberdeen — equal.
,, 105. Bartlett, E., Banff; Sangster, W., Dufftown — equal.
,, 106. Dewar, P. J., Dingwall, Ross-shire; MacRitchie, David, 28, High St., Inverness — equal.

The following "additional members of the General Committee" have also been elected:—

Holdsworth, T. W.	Birmingham.
Churchill, W. J.	Birmingham.
Jones, S. U.	Leamington.
Wade, John	London.
Pearman, H.	Newport, Mon.
Phillips, J.	Wigan.
McNeill, J. H.	Crewe.
Shaw, H. W.	Doncaster.
Storrar, D.	Kirkcaldy.
Ellinor, George	Sheffield

LIVERPOOL CHEMISTS ASSOCIATION.

The twelfth general meeting of the thirty-first session was held at the Royal Institution, on Thursday evening, April 8, the President, Dr. Charles Symes, in the chair.

The minutes of the previous meeting having been read and confirmed, some interesting miscellaneous communications were made by several members.

A paper on "Resorcin and the Dyes prepared therefrom," was read by Mr. Albert Kehlstadt, Ph.D. The author described the production of resorcin, dealt fully with its chemical and physical characters, and passed on to illustrate the formation of the many beautiful dyes prepared from it.

Mr. M. Conroy exhibited a small sample of volatile oil of gentian root (about half a drachm) which he had obtained by distilling 3 cwt. of root. Not a particle of oil separated from the distilled water, and the small quantity of oil exhibited had been prepared by abstracting the oil from the distilled water by washing with ether, and the subsequent recovery of the ether by distillation, at as low a temperature as possible. The oil obtained by this means possesses a powerful odour of the root, is brown in colour, and of the viscosity of castor oil. The sample was too small to enable him to fully examine it, but he hoped soon to be in the possession of more and would then be in a position to do so.

Dr. Symes exhibited and described the working of "An Improved Form of Apparatus for Continuous Extraction." The apparatus consisted of a conical glass percolator which fitted air-tight into a receiving vessel contained in a water-bath. As the percolate passes into the receiver, the menstruum is volatilized by the heat of the water-bath and driven back into the percolator, passing by means of a tube through the centre of the material in the percolator. The percolator lid being dish shaped and filled with ice answers the purpose of an effectual condenser. The apparatus was exhibited working alcoholic extract of cinchona, and the process seemed very complete.

Interesting discussions followed each communication and votes of thanks having been passed to the authors, the meeting closed.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The sixth meeting of the session was held in Anderson's College, 204, George Street, on Wednesday, April 14, Mr. A. Kinninmont, F.C.S., President, in the chair.

The minutes of the previous meeting were read and adopted.

The President then reviewed the work of the session about to close, and in doing so commented upon the various papers read during that period by Messrs. Clarke, Kinninmont, Hunter and Dr. Whittaker.

After the President's remarks it was agreed to hold the annual general meeting about the middle of May, for the election of President and office bearers for the ensuing session, to receive the treasurer's report, and to transact any other business that may require attention.

Mr. John Currie moved a vote of thanks to the President, for his address, which was duly awarded by the members; and there being no other business the meeting closed.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

A meeting of the members of this Association was held on the 13th inst., the chair being occupied by the President, Mr. Fitzhugh, F.C.S. There was a good attendance.

Mr. Warriner, in a short paper, introduced the question of "Present Rates charged for Carriage of Goods," and after considerable discussion the following Committee were appointed—Messrs. White, Warriner, Rogerson, Wilford and Shepperley—to consider and inquire into the present high rates charged for carriage of drugs in hampers, and put themselves into communication with any whom they might think proper, with a view to the reduction of the present high rates and to report thereon to another meeting.

The Honorary Secretary, Mr. R. Jackson then read a circular from the Manchester Chemists' Association respecting the sale of proprietary medicines containing poisons by unregistered persons. In the discussion which followed, it was felt most desirable that such medicines should be sold only by chemists and druggists, but it was suggested that if all proprietary medicines which contained such poisons had to be labelled poison, it would entail considerable trouble if diarrhœa and cough mixtures were under the same regulation. Eventually, however, a resolution similar to the one sent from the Manchester Association was adopted, and the Honorary Secretary was requested to forward it to the Council of the Pharmaceutical Society.

The next subject for discussion was the Thursday afternoon closing movement, which is being adopted by many of the different trades in the town. Several speakers argued in favour of the movement, but it was strongly opposed by others, and several chemists having branch post-offices attached to their business stated they were unable to close in consequence. The proposal to close, therefore, fell through, although a majority of the meeting were in favour of it.

A vote of thanks to the chairman closed the proceedings.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on April 15, Professor H. E. Roscoe, President, in the chair. The following certificates were read for the first time:—E. Rawson, Kamze Lal Dey Rai Bahadour, Tarapwsanna Roy, of Calcutta, and R. G. Watts. The following gentlemen were balloted for and declared duly elected Fellows of the Society, Professor McLeod and Dr. Wright being appointed scrutators:—M. Bechler, A. W. Black, E. C. Copas, W. J. Dibdin, A. C. Fryer, E. C. Graham, C. H. Gimingham, R. Grimwood, W. F. Haydon, H. Liepmann, F. B. Last, W. Robinson, W. Regester, J. W. Stanley, H. H. Slater, A. J. Smith, H. C. Stephens, C. P. Scheibner, J. R. Skelton.

The following papers were read:—

On the Lecture Illustration of Chemical Curves. By E. J. Mills.—The author has contrived for lecture illustration an apparatus extremely concrete in its effect, in which a chemical action or process constructs its curve under the eyes of the observer. It consists of eighteen tall glass cylinders, of about 270 c.c. capacity, which are filled with water and inverted in as many glass troughs, the cylinders being supported at equal distances from each other in a sort of test-tube frame; each inverted cylinder has a 100 c.c. stoppered retort, so arranged that its beak can be made to dip under the mouth of the cylinder, the whole forming a series of gas generators and pneumatic troughs, arranged at equal distances from each other. With this apparatus the author has examined the action of dilute sulphuric acid on zinc and sodic hydrate on aluminium, the two factors which were varied being the strength of the solution and the time during which the action was allowed to take place. Thus equal pieces of clean zinc were placed in each of the retorts, the strength of the acid rising in successive retorts by 3 per cent.; thus various amounts of hydrogen were evolved and collected in the inverted cylinders; the surfaces of the water in the eighteen cylinders were then found to assume a curved line, representing the course of the action. This the author designates a quantity curve. Similarly, by measuring the time during which the action was allowed to proceed by equal increments, another curve was obtained—the time curve.

The errors in the method are pointed out, but a sufficiently accurate general impression will be conveyed of the true curve, as the eye neglects the small variations.

After a few remarks by Mr. W. Thorp, who had seen the experiments in Dr. Mills's laboratory, and who confirmed the care taken to insure identity of conditions as to the zinc, temperature, etc.,

The President called on Mr. W. H. PERKIN to read his paper on—

The Analysis of Organic Bodies containing Nitrogen. (Continued.)—In the previous portion of the paper the author proposed to absorb the oxides of nitrogen formed during the combustion of nitrogenous substances by potassic chromate instead of decomposing them by metallic copper. In the combustion of uric acid, oxide of copper was used; as some of this was reduced, it might be argued that the good results were partly due to the metallic copper and not to the chromate; therefore, to test the process still further, combustions were made with plumbic chromate instead of oxide of copper, and it was found that the potassic chromate did not satisfactorily absorb the nitrous fumes. A quantity of precipitated manganic oxide was now made into a paste with a saturated solution of potassic chromate and the mixture dried and heated somewhat strongly to drive off most of the water of hydration. The efficacy of this mixture was tested by its power of absorbing the red fumes evolved when plumbic nitrate is heated. When the mixture was heated to a dull red heat some of the nitrogen oxides passed, but if kept at a lower temperature the absorption was complete. The mixtures used consisted in one case of 1 part of chromate to 2 of manganic oxide, in others of 2 parts of chromate to 1 of manganic oxide; both mixtures seemed to answer equally well. Combustions with dinitrobenzene and ethylorthotoluidine gave very satisfactory results. The author recommends potassic chromate containing 10 per cent. of potassic bichromate, as the commercial precipitated manganic oxide may contain potash; powdered pyrolusite will not act satisfactorily. In making combustions about six inches of the mixture are placed in the front part of the tube (the oxygen process being used); the whole of the tube is then heated and dried with air in the usual way. The temperature of the mixture is then allowed to fall to about 200—250° C. (in the combustion furnace used by the author about one-fourth of the burners were kept alight and were half turned down); the combustion is then proceeded with in the ordinary way. By re-heating the mixture strongly and passing a current of air the oxides of nitrogen are removed and the mixture is ready for a second combustion. Thus the same mixture has been used seven times. If the organic substance contains sulphur a greater length of the mixture must be used, the back part being strongly heated to absorb the sulphur dioxide and the front part maintained at 200—250° to absorb the oxides of nitrogen.

The President said that all present could appreciate the value of this convenient method. The author had hit on a blot in our methods of organic analysis, and apparently completely removed it.

Dr. Wright commented on the great boon the author had conferred on analysts by the introduction of this method.

The President then called on Professor McLeod to communicate some results obtained—

On the Volatilization of Solids in Vacuo. By W. DOUGLAS HERMAN.—Professor McLeod requiring some pure phosphorus endeavoured to obtain some by distilling ordinary phosphorus in an atmosphere of carbon dioxide, but without success. He then wrote to Mr. Herman, who had been investigating the question, inquiring where his paper on the subject was published. In reply Mr. Herman forwarded the present communication, with a request that he would read it. The paper, however, was incomplete, and Professor McLeod therefore gave an abstract of the paper with a short account of some experiments he had himself made, and exhibited some illustrative specimens. Mr. Herman sealed up some phosphorus in glass tubes containing air and in vacuous tubes. On distillation in the light the phosphorus in the vacuous tubes condensed in minute yellow crystals. When, however, the distillation was conducted in the dark most beautiful colourless transparent adamantine crystals were obtained. The phosphorus was dried with filter paper. The author states that when these crystals were exposed to daylight they became rough and opaque, at the same time yellow or red. As regards the opacity, Professor McLeod has obtained somewhat different results. Mr. Herman also observed that when phosphorus was heated in sealed tubes to 140°, it became surfused, and remained in the liquid state for some months after cooling. This phosphorus turned red in the sunlight; it was interesting to note that the red amorphous phosphorus could therefore be obtained from solid, liquid and gaseous phosphorus by the action of light alone. In one case a crystal of phosphorus was obtained 8 mm. long. Mr. Herman also made some most interesting experiments with sulphur. Sulphur sealed up in vacuous tubes distilled over at the temperature of boiling water, *i.e.*, 11° below its melting point, and condensed in minute drops of liquid sulphur, forming a cloud on the glass. After a time minute crystals appeared, and began to grow, the liquid disappearing *pari passu* until the whole was converted into crystals. Similar experiments were made with iodine, selenium, ammonium chloride, etc. Professor McLeod then gave an account of the experiments he had made. He had sealed up phosphorus in glass tubes, carefully absorbing all moisture by melting the phosphorus in a bulb, connected with a second bulb containing phosphoric anhydride. He had obtained most beautiful crystals, some of which were exhibited. They resembled in appearance diamonds, being perfectly colourless, with an adamantine lustre, perfectly transparent, and from their high refractive index, sparkling with prismatic colours. Professor McLeod had not been able to confirm Mr. Herman's statement that these crystals became opaque in daylight, and thought that this was due to the presence of a trace of water containing a trace of air, as from experiments he had made by distilling some phosphorus, as above described, and then exposing it to the action of boiled water and light, the crystals became red, but remained transparent; if, however, unboiled water was used, a white coating was formed similar to that on the ordinary phosphorus kept under water and exposed to light.

The President had listened with great interest to the lucid explanation given by Professor McLeod. As to the specimens, they would speak for themselves. He hoped Mr. Herman would finish and publish his paper, and especially complete the interesting observations about the volatilization of sulphur.

Mr. WARINGTON then communicated a paper—

On the Determination of Nitric Acid as Nitric Oxide by Means of its Reaction with Ferrous Chloride.—The author has previously communicated some results on the determination of nitric acid by Crum and Frankland's process; with small quantities of nitric acid and in the presence of sugar and other organic matter, the results were always low. Schloessing's method was therefore examined; it consists in boiling the solution of the nitrate in a flask until all air has been expelled, and then boiling with strong solution of ferrous chloride and hydrochloric acid for ten minutes, the nitric oxide is collected over mercury, oxidized into nitric acid and titrated. An atmosphere of carbonic anhydride was then used to displace the air; in this way results were obtained equal to 95 per cent. of the nitrogen taken. When cane sugar, gelatin, etc., were added, the results came too low, but by increasing the quantity of ferrous chloride good results were obtained. Another modification largely used consisted in collecting the gas over caustic soda. As the quantities of nitric acid to be determined by the author were extremely small, being equal to 5 to $\frac{1}{3}$ milligram of nitrogen, it seemed to him best to estimate the nitric oxide given off by gas analysis. A chloride of calcium bath was also introduced for heating the nitrate, the best temperature being 130°—140° C. It was found that however long the mixture was boiled, bubbles of gas were being constantly evolved, due to the introduction of air with the hydrochloric acid. However, with small quantities, 5 and 1·4 milligram of nitrogen, gas = 99 per cent. of the nitrogen was obtained. On analysing this gas, it was found to contain only 95—87 per cent. of nitrogen. It was noticed when sugar was present that much brown fluid distilled over, and on examination it was found that a marked diminution of the gas took place by allowing it to stand over caustic soda, and especially with caustic soda and the brownish distillate, as much as 42 per cent. of nitric oxide being thus absorbed with the caustic soda alone, so the author cannot help thinking that many analyses in which the gas has been collected over caustic soda are in rather a perilous condition. If the gas is analysed at once before much absorption has taken place, the error is not large. The author then described the apparatus which he found to be most convenient. It consists of a double necked globular receiver; from one end passes the delivery tube, through the other a tube for a stream of carbonic anhydride, and a somewhat long vertical tube, furnished with a stoppered funnel at the top for introducing the hydrochloric acid. The air is first cleared out by passing carbonic anhydride for thirty minutes, the acid is then introduced and the solution evaporated to dryness, by the chloride of calcium bath at 130°—140°; the nitric oxide swept out by carbonic anhydride, and analysed. In this way with 1·4 milligrams of nitrogen results = 92—94 per cent. were obtained. Sugar and organic matter have no effect on the results. The author mentioned, in conclusion, that a strong solution of ferrous chloride was extremely useful for absorbing nitric oxide.

Dr. Armstrong suggested the use of the Sprengel pump, instead of a stream of carbonic anhydride to get rid of the air.

The next paper was taken as read —

On the Six Possible Isomeric Dibrom-toluols and other of the Bromo and Bromo-nitro Derivatives of Toluol related thereto. By R. H. C. Nevile and A. Winther.—In the table given by R. Körner in his memoir on 'The Isomerism of the Aromatic Compounds containing six Atoms of Carbon,' the rule is laid down that in introducing one of the halogens, or the nitro group into anilin it takes the para position. Körner's paper deals only with the substitution of the second hydrogen atom in mono-derivatives of benzol, and consequently in this case only with anilin. But it appears to the authors that the rule is of more general application, and that if bromine, or the other halogens, or the nitro group be caused directly to act upon aniline or its homologues, toluidin, xylidin, etc., or probably other amido compounds, the acid group nearly always, if possible, takes the para position to the amido group; if the para position be occupied by any other group, it then takes one of the ortho positions, but under no circumstances can one of the above acid groups be directly introduced into a position meta to the amido group. The authors think that the above rule will also hold good with diamido compounds. Some experiments of Wrobleosky (*Jahrs.*, 1870, 528, and 1871, 450), appear to point to conclusions at variance with the above theory, the authors have therefore repeated his experiments and established the correctness of the above theory against the experiments of Wrobleosky. They obtained a bromo-nitro-toluidine, m.p. 180°·3, having the constitution $\underset{1}{CH_3}\ \underset{2}{NH_2}\ \underset{3}{Br}\ \underset{5}{NO_2}$, the constitution of Wrobleosky's substance, m.p. 139°, being $\underset{1}{CH_3}\ \underset{2}{NH_2}\ \underset{3}{NO_2}\ \underset{5}{Br}$ and ordinary nitro-ortho-toluidine $\underset{1}{CH_3}\ \underset{2}{NH_2}\ \underset{5}{NO_2}$. The authors next consider the dibromotoluol, in which both the bromine atoms are meta to the CH_3 group, and promise a further communication on the dibromotoluol 1, 2, 6, and the tribromo and tetrabromo toluols. The paper is lengthy, and contains detailed accounts of the preparation and analyses of the numerous compounds investigated.

The Society then adjourned to May 6, when the following papers will be read:—"On the Action of Sodium on Ethereal Salts of Phenylacetic Acid," by Dr. Hodgkinson; "Estimation of Nitrogen in Carbon Compounds," by C. E. Groves; "On Sage Oil," by M. M. P. Muir. It was also announced that the discussion on Dr. Tidy's paper on "River Water," will take place on May 20. (The paper will be printed early in May.)

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[394]. In answer to C. J. B., I beg to inform him that one grain of manna to each pill will make them the proper size and consistence.

T. Drawbridge.

[398]. "Junior" will do well to remember in the dispensing of "doctors' prescriptions" not to rely entirely on the order in which they are written; but by using discretion with regard to the nature of the drugs contained in such prescriptions, especially if highly concentrated, will ensure against such unsightly mixtures now complained of.

But if he will reverse the *modus operandi*, and put all ingredients (except tinct. camph. co.) in the bottle, and nearly fill up with aqua, lastly adding tinct. camph. co., "Junior" will obtain a clear mixture *sine* deposit.

Fred. Ellis.

Queries.

[399]. A short time ago I had the following prescription handed me to be made up:—

℞ Acid. Nitric. Dil. . . . . ʒiij.
Extract. Taraxaci Liquid. . . . . ℥iv.
M.

In my experience in several large dispensing establishments and in various towns, it was the usual practice to give "Battley's liquor taraxaci" in such a case as this. I did so in this instance, and the medical attendant expressed surprise.

Can any of your correspondents say if I was right?

D. G.

[400]. I had the following to dispense:—

℞ Acid. Carbolic. . . . . ʒj.
Aqua . . . . Hss.
Ft. lotio.

Lotion for external use. To be applied to the parts, and covered with tinfoil.

Does the prescriber intend the bottle of lotion to be covered with tinfoil, or the parts on which it has to be applied?

Junior.

[401]. I have just had the following prescription to dispense:—

℞ Chlorodyn.		ʒij.
Tr. Senegæ		℥ss.
Vin. Antim.		ʒj.
Mist. Scillæ	ad	℥jv.

M. sig. ℥ss ter in die.

Will you kindly inform me in the next issue of the Journal what is mist. scillæ, and give the formula, if there is one. I may say that it is a Scotch prescription, and has been dispensed in Aberdeen.

K.

---

[402]. When pulv. cretæ co. c. opio is prescribed, which should be used, the P.L. preparation, or the pulv. cretæ aromat. c. opio of the B.P.?

JACQUE.

---

[403]. E. L. will be glad of the editor's opinion in the following cases:—

℞ Acid. Citric.		℈j.
Quinæ Disulph.		gr. v.
Ext. Taraxaci		ʒss.
Ext. Sarsæ Liq.		℥j.
Aq.	ad	℥vj.

Ft. mist. Dose, ℥ss.

---

[404].

℞ Inf. Gent. Co. Conc.		℥j.
Inf. Chirettæ Conc.		℥j.
Inf. Pruni Virgin.		℥j.
Acid. Phosphoric. Dil.		ʒij.
Tinct. Nucis Vomic.		ʒiss.
Syrup		℥ij.
Aq.	ad	℥viij.

Ft. mist. Dose, ℥ss.

In the above mixtures a decomposition takes place; in the first from the presence of acid. cit. and quinia, and in the second from the nux vomica and acid. phosphoric.

What can be done in order to make nice clear mixtures in both instances?

E. L.

---

[405]. Will you kindly inform me whether any decomposition takes place in making up the enclosed prescription rolled on the machine by means of mag. carb. pond.?

℞ Plumbi Acet.	gr. iij.
P. Opii	gr. j.
Conf. Rosæ	q. s.

Fit. pil. iij.

CYMRO.

---

[406]. What is the best mode of dispensing the following and what appearance should it present?—

℞ Quinæ Sulphat.		gr. xxiv.
Potass. Iodid.		gr. xxiv.
Potass. Citrat.		ʒij.
Pulv. Tragac. Co.		ʒiss.
Vin. Colchici.		ʒij.
Tinct. Card. Co.		ʒiv.
Aq. Chlorof.	ad	℥viij.

M. ft. mist.

C. L. S.

Notes and Queries.

[645]. LOVERS' EVANESCENT INK.—"A. J. Hurn" asked in the *Pharmaceutical Journal* of December 27, 1879, for the formula of this ink. Let him try the following:—"Finest potato starch, 13·5 kilos., and powdered iodine, 1 kilo., are mixed and then rubbed through a sieve, then mixed with 4 litres of water and 1 litre of rectified spirit. The resulting black powder is allowed to stand for fourteen days, then dried and exposed to the air. The dry powder contains 10 per cent. of iodine. The iodide of starch becomes soluble when heated with stirring in an enamelled saucepan over a gentle fire. As soon as the powder is dry the operation is finished, it then emits a pungent smell. From time to time during the heating it must be ascertained whether the powder has become soluble, by heating some of it with water in an iron spoon. At a strong heat it yields a red solution with loss of iodine. In order to purify the powder and make it thoroughly soluble, of a violet tint in cold water, a concentrated solution is made by heating, so that it shows 7–8°. This solution is allowed to deposit for several days, decanted and precipitated with rectified spirit. The precipitate is strained, and dried in the drying closet. If excess of spirit is used in the precipitation, a gummy matter is thrown down, the presence of which is superfluous." A certain firm claims to be the sole manufacturers of the ink. They advertise that writing executed with it gradually fades away and cannot be restored by any chemical, and state "that the time it takes to fade depends on the paper that is used; if written with a perfectly clean steel or quill pen on unglazed paper the evanescence will be more rapid than when written on glazed paper. On some papers it will disappear in a day, whilst on other kinds it will take more than a week." I tried this ink, six weeks ago, on various sorts of paper, and I still find the writing quite visible. It can easily be restored to a jet black by exposing the writing to the fumes of iodine. Perfection has not yet been obtained in the production of this useful ink; there appears to be some chemical either absent or not present in a sufficient quantity to induce a rapid evanescence.

[651]. PRESERVATION OF EMULSION OF ALMOND OIL.—Can any reader of the Journal inform me of anything to prevent emulsion of almond oil from spoiling, when made with mucilage or alkali?

W. M. P.

---

[652]. CHILI PASTE.—Can any reader furnish formula for Chili paste, such as used in hydropathic institutions?

J. W.

---

[653]. FLEXIBLE CEMENT.—"Euretes" wishes for a recipe for a flexible cement which would maintain its adhesive virtues at a temperature of 212° F. and when immersed in boiling water.

---

[654]. TINCT. CHLOR. MORPH. SCOTIS.—Would any reader give me the formula for tinct. chlor. morph. Scotis?

F. MOORE.

"SOLIDIFIED" BROMINE.—The utility of bromine as a disinfectant agent is now well recognized; but, owing to its liquid condition and difficulty of transportation, it has hitherto been but little used for such purposes. Chlorine, which is a gas, is always available by means of the solid commercial chloride of lime; but a similar method of binding bromine in a compound, which would readily yield it up, has heretofore been a desideratum. A manufacturer of Charlottenburg (Prussia), Mr. Frank, has conceived the idea to cause bromine to be absorbed by so-called "kiesel-guhr," that is, the siliceous marl which Ehrenberg has shown to consist of the microscopic shells of infusoria, and which is also used to absorb nitroglycerin, thus forming the well-known dynamite. The inventor has given to the mixture the inappropriate name "solidified, or solid bromine." In this condition, it is easily applied for disinfecting purposes.—*Pharm. Handelsbl.*

THE ELECTION OF THE NEW COUNCIL.

Sir,—The evident intention of the letter of "A Member" (of the Council?) is to damage, if possible, Mr. Shepperley's candidature.

It is written with such an air of self-satisfaction, and in such a solemnly grandiose style, that it reminds one of a recent celebrated political manifesto, and I hope sincerely that its aim and object may be as completely frustrated.

The insinuations in it, that Mr. Shepperley has not the knowledge and experience necessary for such a position, are rude and ungentlemanlike in the extreme.

May I ask what Mr. Shepperley has done to merit such treatment as to be asked by this egotistical "Member" to retire from the contest for filling up the vacancies on the Council of the Society? There can be but one answer, and that is, nothing.

Through no seeking of his own, and unfortunately for himself, he happened to be chosen for the attack on chemists' privileges by the Nottingham Medical Defence Association; he was thus necessitated either to pay the penalty for the so-called infringement of the Apothecaries Act, 1815, or defend the trade interests attacked at law. This, thanks to the generous aid rendered by the Chemists' Trade Association, he did successfully, to his own comfort and to the immense benefit of the entire trade, few will question; and, in the language of the "Member's" letter, "happily the question of counter practice is at rest."

The craven fear of the Society of Apothecaries shown by the writer is mean and servile. It is absurd to think that the election of Mr. Shepperley to a seat on the Council would in any way influence the members of an honourable corporation to pursue a different course of action with reference to the counter practice of chemists and lead them to recall their expressed intention of not in the future lending their aid to any more similar prosecutions.

However, Mr. Shepperley's address, which is explicit and straightforward, is before the members, and is one which I believe will command their sympathy and support.

I confidently expect to see that the result of his appeal to the country members will be answered by them in such a manner as will make "A Member" feel that his dictation and unsought-for advice are not acceptable to the majority of our members and associates.

GEORGE JAMES GOSTLING.

Sir,—In accordance with the laws which govern the Society, it is perfectly legal for any member to be elected to the Council, provided he is not a member of the Board of Examiners. In view of this prohibition, which appears to be directed against the entire control of the examinations being in the hands of one body, it seems somewhat anomalous that Mr. Wills should be nominated for election as a member of Council. It is true he is not a member of the Board of Examiners, and is not therefore actually disqualified by law, but, as a professed teacher of candidates for the Society's examinations, is it desirable that he should be elected to take a seat in a body which has as a part of its duties the control of examinations and the appointment of examiners?

Would it not be thought strange if one of the professors at Bloomsbury Square should aspire to a seat on the Board?

A MEMBER.

Sir,—I have been shown a circular, signed by Mr. G. S. Wills, asking for the votes of the members of the Society in the approaching Council election. How far circulars issued by candidates in support of their own claims are a desirable innovation in these elections is a matter I do not wish to enter upon, nor do I desire to question Mr. Wills's qualifications for the office he seeks. Of Mr. Wills personally I know nothing whatever, save what he himself tells us in his weekly advertisement and in his circular: but from the former source I gather that his business consists in preparing students for the examinations of the Society; and this being so, I would ask, is it proper, is it decent, that he should seek to belong to the body whose duty it is to select the members of the examining board?

I do not learn from the circular that Mr. Wills is dissatisfied with the conduct of past Councils, or that there is any new policy he wishes to be the means of inaugurating, so that I trust second thoughts will induce him to withdraw from a position which, to say the least, is offensive to good taste.

AN OLD MEMBER.

VOLUMETRIC ESTIMATION OF ALKALOIDS.

Sir,—Mr. Thresh's letter in your last issue does not touch the point which excited my wonder.

x is so ordinary an expression in chemical papers that its presence in the formula referred to only gave rise to speculation when it was found to distinguish this and another among upwards of a dozen. Wonder supervened on reading that "the results in the fifth column are calculated from the formula, $-3(BiI_3)2(\bar{Q}HI)xHI$;" in other words, that calculations are made from a formula one of the elements of which (x) is of a value unknown to the author. This is the inconsistency which I criticized by a *reductio ad absurdum*, and which Mr. Thresh's letter has done nothing to remove. Will the author show us by an example how he uses the formula? The inference is that the formula actually used was $3(BiI_3)2(\bar{Q}HI)$, but making the calculation on this basis I find that 15 c.c. of the volumetric bismuth solution is equivalent to ·0648 gram quinia and not ·065. A comparison of the third and fifth columns of the table on page 810 indicates other differences of a similar character.

Before seeing Mr. Thresh's letter I had formed the opinion that the formula in question was put down to remind him of an unknown proportion of HI being associated in the precipitate, and that in arranging the materials for his paper the inconsistency of the formula with the expression immediately preceding escaped observation.

E. Yewdall.—Thanks for your note, concerning the subject of which we are making inquiries.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Yewdall, Castle, Carter, A.P.B., M.P.S., Cymro.

"THE MONTH."

In the earlier part of the month the proverbial "April showers" and gentle zephyrs seemed to betoken the approach of an old-fashioned, or perhaps it would be more correct to say an ideal April. The cold north-easterly winds have, however, checked the bursting buds, dried up the earth, and seem to have plunged us back again into the middle of March. The almond, which generally at this time of year presents masses of delicate pink blossom in the London gardens, is hardly noticeable from the sparseness of flowers. Still, according to the calculation of an Isle of Wight correspondent, the flowers in blossom are at least twenty per cent. more abundant than last year, and a "dropping May" will perhaps make up for the loss of time occasioned by the recent cold weather.

Among the plants in flower in the Isle of Wight, this correspondent mentions the woodruff, berberry, *Vinca major*, *Viburnum Lantana* and *Symphytum officinale*, which are certainly in advance of the neighbourhood of London. There also figures on his list the curious root parasite, *Lathræa squamaria*, remarkable for the absence of chlorophyll in its leafless stems and for its singular, branched, tooth-like roots, to which, following the doctrine of signatures, the old herbalists attributed the property of curing toothache. From the appearance of its root it has received its English name of toothwort and its more appropriate German name of scale-root (*schuppenwurz*). The French name is a singular one, "*clandestine.*" From the genus *Orobanche*, to which it is closely allied, it is distinguished by having a four-toothed calyx. The yellow bark of the berberry is still used by herbalists in jaundice. The comfrey root is used to make a mucilaginous demulcent drink, and by bone-setters to form a plaster-like splint; hence its old name of "consolida major" or "great consound."

The leaves of the wayfaring tree (*Viburnum Lantana*) yield a yellow dye, and its astringent berries are used in Switzerland in the manufacture of ink, while the rind of the root furnishes bird-lime. The cellular structure of the young woody shoots is also worth examination under the microscope. Although abundant in calcareous soils this plant is often absent for miles where the soil does not contain lime. Those who are fond of critical botany will find the genus *Barbarea* an interesting one. One of the forms or sub-species is distinguished most readily, according to one of our best field botanists, by the bitterness of its root. The pretty little whitlow grass, *Draba verna*, also presents a large number of varieties.

Those who live in the eastern counties, especially in the neighbourhood of Bardfield, will find the true oxlip, *Primula elatior*, Jacq., in blossom. Few who have not seen this plant in flower can believe that it is a distinct species. Those who have once seen it growing, however, rarely entertain a doubt upon the subject. This plant forms a notable instance, therefore, of the impossibility of conveying in a short botanical description a good idea of the features which distinguish one plant from another. It is distinguished from the common hybrid forms of the primrose by its drooping flowers turned to one side, their peculiar tint, and especially the linear oblong capsules equalling in length the calyx. Indeed Darwin states that the last-mentioned is almost the only botanical character by which it can be distinguished. The fertility of its pollen, and the quantity of the seed it produces, however, show that it cannot be a hybrid. The possibility of chemical differences existing in plants which present hardly any botanical difference can scarcely be questioned. Thus the Japanese mint, except in taste, agrees closely in botanical characters with some varieties of *Mentha arvensis*. The bergamot is by most botanists considered to be only a variety of the Seville orange, while homœopathists declare that the form of *Anemone Pulsatilla*, called *Pulsatilla nigricans*, is much more effective as a medicine than the form common in this country. The cause of these differences is one of the problems of plant life that well deserves the attention of vegetable physiologists.

The botanical student may now fairly begin in earnest his rambles in search of materials. In the woods the Ranunculaceæ are well represented by the delicate wood anemone and the goldilocks (*Ranunculus auricomus*), while the showy marsh marigold is decking the boggy meadows, and in the north the handsome *Trollius europœus*, with its golden cups, is almost as ornamental as a garden flower; the dull hellebores, too, have not quite finished flowering in copses and orchards. The Cruciferæ are well represented by the three British scurvy grasses, the cuckoo flower, the yellow rocket, and a number of garden plants.

In the Herbaceous Ground at Kew there is abundance of material for study in blossom. The curious *Epimedium* in the Berberidaceæ, with its large horn-shaped nectaries and quaternary flowers, should not be overlooked, for its duration is short. A singular Japanese plant *Stylophorum japonicum*, which seems to form a link between the genera *Chelidonium* and *Papaver*, is now in blossom. The leaves bear a strong resemblance to those of *Chelidonium*, while the base of the pistil is enlarged to form a capsule, reminding one of that of the poppy, were it not surmounted by a style. *Uvularia grandiflora* with its singular perfoliate leaves forms a noticeable object in the Melanthaceæ, and a pretty little plant in the Ericaceæ, *Andromeda tetragona*, offers an excellent illustration of the tetrastichous arrangement of leaves. In this singular plant, the small leaves are so closely placed that the plant has the aspect of a Lycopodium, and presents an instance of the curious fact that plants growing in similar situations, although belonging to very different natural orders, have often great similarity of leaf-shape; *e.g.*, willows, oleander and willow herb, and *Isnardia palustris* and *Peplis Portula*. Of rare British plants at present in flower at Kew may be noticed *Draba incana*, *Arabis Turrita*, *Corydalis solida*, *Epimedium alpinum*, *Leucojum æstivum*, *Doronicum Pardalianches*, *Andromeda polifolia*, *Veronica alpina*, *Euphorbia palustris*, *Muscari racemosum* and *Rubus arcticus*.

Of the purely medicinal plants the *Podophyllum peltatum* is full of buds, and the large handsome yellow flowers of *Adonis vernalis* are in full bloom. The latter plant has recently been brought into notice in this country as a substitute for digitalis, over which it is said to have the advantage of not being a cumulative poison. *Rheum undulatum* and asarabacca are also in blossom, and in the Economic House the orange, lemon, tobacco, and one of the Indigo plants (*I. anil*) are sparingly in flower.

At a recent meeting of the Société Botanique de France, M. Poisson read a paper on "The Adaptive Character of Plant Hairs," and stated that in most climbing plants, as Darwin had shown with regard to the hop, *Galium aparine* and *Rubus australis*, the ridges alone of the stem are furnished with stiff hairs whose tips are bent downwards, while, in the intervals between the ridges, on the upper surface of the leaves, and on the inflorescence, etc., the hairs have a forward or horizontal direction. That these hairs are adapted to enable the plant to climb, is, he considers, evident from the fact that in the dwarf varieties of the haricot beans, which do not climb, these hairs have not a downward direction, and that in the Loasaceæ and other families, it is the species which climb that alone present this form of hair. Of course, there are exceptions, such as *Dioscorea*, in which the leaves are glabrous, and the stem hairs not bent downward. M. Poisson proposes to turn to account the fact that, in the majority of cases, climbing or twining plants have recurved hairs, by using it as a means of judging from incomplete herbarium specimens whether the specimen is a climbing plant or not. It may also be of service in determining such a point in drugs of unknown origin.

The recent researches on chlorophyll by Pringsheim are well summarized and reviewed by Professor Ray Lankester, in *Nature* for April 18. It will be remembered that Pringsheim's experiments went to prove that the true function of chlorophyll is to protect the protoplasm of the cell from excessive oxidation, more especially those portions coloured by the chlorophyll, so that the protoplasm of the chlorophyll corpuscles is able to decompose carbonic acid and synthesize the elements of starch, the rays of light allowed to pass through the chlorophyll being those which are most efficient in exciting this process. Unlike hæmoglobin—which possesses the same property of combining with and setting free oxygen when separated from the blood corpuscles as it does when diffused through them—chlorophyll, when separated from the protoplasm which it colours, does not possess the property of decomposing carbonic acid. The fact that the cells containing most chlorophyll form a dense layer on the upper side of the leaf, and so serve to a certain extent to screen the lower side of the leaf where the stomata are usually more abundant, seems to favour this view. Mr. Sidney Vines suggests that it might be possible, if Pringsheim's view be correct, to excite the protoplasm of fungi, by an artificial chlorophyll screen, to decompose CO_2. Professor Lankester suggests that it would be worth while to try it on an etiolated green plant with an artificial chlorophyll screen. Seakale and celery are abundantly grown and *Lathræa* and *Monotropa* are easily obtained, and there is an excellent laboratory at Kew Gardens, so that it may be hoped that this point will soon be settled.

In the *Journal of the Royal Society of New South Wales*, the Rev. G. E. Tenison-Woods contributes some interesting data as to the annual growth of trees. He mentions the fact that a blue gum tree (*Eucalyptus globulus*), known to have been planted eighteen years previously, when cut down was found to have thirty-six concentric rings, *i.e.*, two for every year. As this tree, as well as the stringy bark tree (*Eucalyptus obliqua*) and others, shed their bark twice every year, he concludes that the sap rises twice a year in these trees.

In the *Journal de Pharmacie*, Professor Planchon gives a continuation of his valuable papers on the plants yielding curari. In the April number the microscopical appearance of the stem of *Strychnos Gubleri*, a new species, is figured, and also a leaf, which evidently differs from that of *S. toxifera* in not having the long scattered hairs with which the leaves of the latter are clothed. It yields the curari of the Orinoco.

In the same journal, M. Petit proposes the name kusamine for the new alkaloid which he discovered some time since in a Japanese root used in medicine and described in this Journal (before p. 23). The root yields 2 per cent. of the alkaloid, which has a very bitter taste, is crystalline and non-poisonous.

At a recent meeting of the Edinburgh Odonto-Chirurgical Society, Mr. W. Bowman Macleve introduced to the notice of the members a new anæsthetic, or rather a combination of two well-known anæsthetics. It consists in putting a sponge containing about half a drachm of dichloride of ethidene in the way-tube or supplementary bag of the nitrous oxide inhaler, leaving sufficient space on each side of the sponge for the free passage of the nitrous oxide into and out of the bag. The sensation is said to be more profound and agreeable than when nitrous oxide alone is used; there is complete absence of sickness, while the lividity which renders the administration of nitrous oxide so repulsive to the onlooker is present only, if at all, slightly on the lips. It also produces muscular relaxation rather than the rigidity induced by nitrous oxide.

Bromide of ethyl, or hydrobromic ether, has during the last few years attracted attention in the United States as an anæsthetic and now appears to be coming into notice in this country. It was, however, first introduced in this country as an anæsthetic by Mr. Nunneley, of Leeds, as long ago as 1865, but the cost of preparation then seems to have precluded its general adoption. It is said, according to a paper in the *British Medical Journal*, April 10, p. 565, to possess the following recommendations. It produces more rapid anæsthesia than chloroform and is eliminated more rapidly, and the heart and respiration are less affected than with ether or chloroform, and its odour is more agreeable than that of ether. It is also much less inflammable. Another correspondent of the same Journal, however, states that the odour is disliked by patients, and that it causes giddiness, nausea and headache, which is directly opposed to the statements of others. It also differs from ether in not causing excessive secretion of mucus. According to Dr. Marion Sims, however, bromide of ethyl does not answer well in long operations, nor when disease of the kidney exists. It requires to be given rapidly like nitrous oxide. This body is much more stable than hydriodic ether, which it is almost impossible to keep long free from discoloration. Until, however, a ready means of testing the purity of anæsthetics is available, it is difficult to say how far the disagreeable symptoms may be due to impurities.

In *La France Médicale*, M. Terrillon is reported to have found bromide of ethyl valuable also for producing local anæsthesia; refrigeration is stated to be produced more rapidly than with ether, and the spray may be continued for a long time without causing the irritation of the wound produced by ether.

In the *Lancet*, a few weeks ago, Dr. Hewan called attention to salicylate of quinine as a remedy for rheumatic gout and rheumatism, and gave so good an account of the results obtained that it is now easily obtainable in London.

Chian turpentine also is in great demand, but very scarce. In view of the great variation of the samples to be met with in commerce, it seems highly desirable that the particular kind which Dr. Clay found so successful should be submitted to a careful examination. A specimen of the kind used by that gentleman appeared to be not free from the suspicion of containing Canada balsam, of which it possessed the odour to a certain degree.

Dr. Underwood, in the *British Medical Journal*, gives another instance of the excellent effect of chloride of ammonium in neuralgia. The dose given was 20 grains every three hours.

In a paper in the *Practitioner* for April, attention is called to citrate of caffeine as a diuretic. The author considers it to be "a diuretic of no little value in cardiac dropsy, one too which succeeds at times when digitalis and other diuretics fail." It appears in some cases, however, to cause nausea and headache. Possibly the effervescing preparation of this salt, lately introduced, might be free from this disadvantage.

In the same periodical Dr. T. P. Atkinson recommends the use of boracic acid in diseases having a septic origin, and quotes from Drs. Cossar Ewart and Malcolm Simpson statements to prove that it renders the bacilli of diphtheria innocuous.

Dr. J. Allan, in the *British Medical Journal*, gives an account of a new use for apomorphia. After the use of other means without effect in a case of hysterical coma, which had lasted several days, he injected subcutaneously one-tenth of a grain, and in a few minutes the patient was able to walk home with her friends.

In the same journal a remarkable case of poisoning by 22 grains of strychnine is mentioned, in which the man recovered after the administration of hydrate of chloral, which seems to demonstrate that this substance is the best antidote known for the effects of strychnine.

In the *Medical and Surgical Reporter*, Dr. Traill Green recommends chlorate of sodium for use in medicine in preference to the potash salt. It has the advantage of being soluble in little more than its own weight of water, and is stated by Dr. Green to manifest a more decided remedial effect than the potassium salt.

A curious fact, noticed by Schlaefke, in *Graefe's Archiv*, is worthy the attention of pharmacists, who, if ignorant of it, might be blamed for badly prepared medicaments. It is, that if calomel be applied to the eye, and iodide of potassium administered internally, severe inflammation of the conjunctiva is liable to arise.

Dr. F. Biermann (*Pharmac. Zeit.*, No. 3) recommends oil of fennel for removing or masking the odour of iodoform. From five to eight drops of the essential oil are sufficient to disguise a gram of iodoform.

According to the same paper much of the fennel seed met with in the German market last winter was adulterated with previously extracted fennel, owing to the fact that only a small quantity of fennel of a good appearance was produced last year.

A. Poehl, who has examined the volatile oil of jaborandi, states that the pilocarpene $C_{10}H_{16}$, which distils over between 170° and 176°, is so similar in properties to carvene that he considers them identical.

According to observations of Frickinger (*Dingler's Polytechnic Journal*), Bohemian glass is attacked by sodium tartrate, potassium carbonate, and solution of camphor in alcohol.

Dr. Hieronymus, in the *Pharm. Zeit.*, has pointed out that *Iodina rhombifolia*, belonging to the natural order Aquifoliaceæ, is known in the Argentine Republic under the name of "quebracho flojo," and that the wood and bark are often mixed with those of the red quebracho. Another tree, *Machœrium fertile*, belonging to the Leguminosæ, commonly called "tipa," is also used for tanning purposes under the name of quebracho.

The quarterly *Handels-Bericht* of Messrs. Gehe and Co. for April contains, as usual, some interesting notes. It states that in the absence of quebracho blanco bark (*Aspidosperma Quebracho*), only small specimens of which have yet been received in Germany, it has been necessary to be content with the quebracho colorado wood, of which an extract and a tincture are said to have been in considerable demand. But what is more interesting is the statement that good results have been obtained with these preparations in cases of dyspnœa, as well as in bronchitis, pulmonary phthisis, defective action of the heart, and spasmodic asthma. This is said to be confirmed in the experience of Dr. Penzoldt, who first called attention to the therapeutic properties of the white quebracho bark, who also says it is free from some of the inconveniences attending the use of that remedy. The red wood, however, does not appear to possess the antifebrifuge properties accredited to the white bark. It is also stated that frequently what has been supplied as real quebracho blanco bark has been in fact "copalchi bark."

Referring to coca leaves, Messrs. Gehe say that notwithstanding the war in South America there has been a sufficient supply, but they utter a caution that through insufficient drying and careless packing a considerable proportion have become brown, in which state the leaves are inactive. On the other hand, in the case of jaborandi, they say that the true leaves from *Pilocarpus pennatifolius* are usually brownish and stalky when received, but even in this condition are to be preferred to some beautiful green leaves, free from stalks, which have been recently imported as jaborandi from the province of Matto, in South Brazil. The presence of pilocarpine in the latter leaves is at least doubtful, and they are thought to be probably derived from another Rutaceous genus, or perhaps from the *Serronia Jaborandi*, belonging to the Piperaceæ.

During this year Siam benzoin has been met with somewhat more frequently than usual, though its high price prohibits its use for the preparation of benzoic acid, the enormous demand for which has also caused a rise in the price of Palambang benzoin.

Herr Ladenburg has communicated to the French Academy (*Comptes Rendus*, xc., 874), a *résumé* of his researches upon the Solanaceous alkaloids which contains a few interesting details besides those already mentioned in these columns. He says there can be extracted from belladonna at least two alkaloids, that known as atropine and first obtained in a state of purity by Meyn, and hyoscyamine, the properties of which were described in a paper recently published in this Journal.* The second alkaloid, hyoscyamine, is contained in belladonna in small quantity, and is difficult to isolate, but Herr Ladenburg says it is

* See before, p. 751.

that which is known in commerce as "light atropine," because of its light specific gravity. *Datura Stramonium* he finds to contain principally hyoscyamine, which is identical with the alkaloid hitherto known as daturine, and another alkaloid which is probably atropine, although it has not yet been separated in the pure state. An impure atropine, said to be derived from stramonium, is met with in commerce as "heavy daturine." Henbane contains also two alkaloids, hyoscyamine, and another which is not atropine and of which the composition and properties have not yet been ascertained. Lastly, only one alkaloid has yet been extracted from duboisia, and that is identical with hyoscyamine. Herr Ladenburg therefore thinks it probable that hyoscyamine and the "light daturine" of commerce are capable of rendering the same service as duboisine in ophthalmic maladies.

When hydrochlorate of morphia is heated in twenty times its weight of alcohol a momentary solution takes place, followed by a separation of a heavy granular crystalline mass. As the solution cools more of these crystals are deposited, and eventually the solution solidifies with formation of a dense mass of fine crystalline needles. Upon again applying heat the acicular crystals, which can be readily recognized as hydrochlorate of morphia, redissolve, but the greater part of the granular crystals remain undissolved. If wood spirit be used as the solvent a clear solution is obtained without heat, but after a few minutes a deposition of the granular crystals commences. These crystals have been examined by Hesse (*Annalen*, 202, p. 151), who has found them to have the composition represented by the formula $C_{17}H_{19}NO_3,HCl$; they, therefore, consist of anhydrous hydrochlorate of morphia. When this salt is recrystallized from a little hot water the ordinary hydrated hydrochlorate is deposited upon cooling.

Many kinds of beet sugar, and even well-filtered "thick juice," have been observed to possess the characteristic smell and taste of vanilla. In order to ascertain the nature of this phenomenon, Dr. Lippmann (*Chemiker Zeitung*, No. 12, p. 192) neutralized a concentrated sugar solution and then agitated it with ether. After separation and evaporation of the ether there remained some oily drops, smelling strongly of vanilla, which, however, did not solidify. This residue was treated with bisulphite of soda, heated in a water-bath with sulphuric acid to drive off sulphurous acid, and repeatedly exhausted with ether; after several recrystallizations small white stellate groups of needles were obtained, corresponding in properties and composition with vanillin. A satisfactory explanation of the origin of this vanillin has not yet been offered, but it has been suggested that it is due to the action of lime upon the cellular tissue of the beet during the manufacture.

The evaporation of solutions in ether, chloroform, benzol and carbon bisulphide, according to Liebermann (*Ber. Deut. Chem. Ges.*, 12, 1294), can be rapidly effected in an ordinary desiccator charged with crude paraffin. The paraffin is said soon to deliquesce, but to retain its absorptive property until it has absorbed three times its weight of carbon bisulphide or twice its weight of ether. Experiment has shown that paraffin under suitable conditions will absorb its own weight of carbon bisulphide in four to five hours, of ether in eight to nine hours, and of chloroform in nine to eleven hours. The absorbed solvents may be recovered by distillation.

The curious reaction by which when permanganate of potassium and peroxide of hydrogen are brought into contact in a strongly acidulated liquid they lose all their active oxygen and become converted into the state of protoxide was noticed by Brodie. P. Thenard observed, however, that when the reaction took place at a temperature below zero, although the mixture became decolorized there was no evolution of oxygen as long as the liquid remained cooled. M. Berthelot has been investigating this phenomenon (*Comptes Rendus*, xc., 656), and attributes it to the formation of a colourless compound, permanent at a temperature of $-12°$ and below, but decomposed with evolution of oxygen upon approaching the ordinary temperature. After excluding the possibility of this colourless compound being a higher oxide of manganese, persulphuric acid, or dissolved ozone, he has arrived at the conclusion that it is a higher oxide of hydrogen which, following the old atomic weights, he represents as HO_3 and calls "tritoxide of hydrogen."

The *Chemical News* (April 2) mentions a patent taken out by Messrs. Rickman and Thompson for the manufacture of ammonia from the nitrogen of the atmosphere and the hydrogen of water, which if it realizes the expectations formed concerning it will exercise an important influence on the future of artificial manures. The operation is carried on in a closed brick furnace, having the ash pit closed to regulate the current of air. The deoxidizing material used is the dust of steam coal. In the presence of this at a full red heat the vapour of water is decomposed and the hydrogen combines with the nitrogen from the regulated current of air. But ammonia is decomposed at a bright red heat, therefore, to prevent loss by accidental excess of temperature 5 to 8 per cent. of salt is mixed with the coal. This chloride of sodium being decomposed at a full red heat in the presence of nascent ammonia, chloride of ammonia is formed which is volatilized without decomposition. It is estimated that with a consumption of 20 to 28 lbs. of the mixture of coal dust and salt per hour from 2 to 3 lbs. of ammonium chloride will be obtained.

A paper recently read before the Society of Telegraph Engineers on the effects produced by the immersion of steel and iron wire in acidulated water (*Nature*, April 22), besides its interest in respect to telegraphy, is not without a bearing upon a practice sometimes followed in cleaning iron vessels. Professor Hughes has found that when iron or steel wire is immersed in acidulated water it rapidly becomes brittle, only a few minutes' immersion in water containing 10 per cent. of sulphuric acid producing a very marked effect. This he believes to be due to the absorption of hydrogen in the nascent state, the same result following the exposure of the wire to hydrogen set free by the electrolysis of water. Upon heating the iron wire so rendered brittle to a cherry-red it is restored to its primitive flexibility in a few seconds. Rods of iron a quarter of an inch thick are equally affected when subjected to the action of a sufficient quantity of nascent hydrogen. Iron or steel thus "hydrogenized" is rendered more negative, and whilst in this condition remains free from oxidation. No similar effect has been perceptible in experiments made with copper and brass.

It is generally assumed that gluten exists already formed in various cereals as one of their constituents. But some experiments made by Messrs. Weyl and

Bischoff (*Ber. Deut. Chem. Ges.*, 13, 367) render this problematical, and point to the probability of gluten being formed by the action upon albuminous matter of a ferment contained in the grain in the presence of water. The principal albumenoid in wheaten flour was found to be a substance resembling the myosin of muscle, and this the authors think must be the mother-substance of gluten. As to the identification of the hypothetical ferment nothing certain has been made out, but the gluten-forming constituent appears to lose its activity in the conditions which usually affect the activity of ferments; thus flour kneaded with solutions of sodium chloride or sulphate, or magnesium sulphate, or thoroughly heated previous to kneading it with water, yielded little or no gluten. It may be remarked that the presence of a nitrogenous ferment in the perisperm of the wheat grain was long ago announced by M. Mége Mouriès, but that ferment, which he named "cerealine," was stated to dissolve gluten, and a process for making "whole meal" bread was based upon the preliminary removal of it from the grain.

An allied subject was recently brought before the French Academy (*Comptes Rendus*, xc., 369), by M. Scheurer-Kestner, who called attention to some inedited researches of his father upon the formation of a digestive ferment during panification. He stated that if a paste be prepared by adding a suitable quantity of water to 550 to 575 parts of flour, 50 parts of yeast and 300 parts of finely chopped fresh beef previously boiled for an hour in the water, and be left to ferment at a moderate temperature for two or three hours, at the end of that time it will be found that the meat has completely dissolved and disappeared in the paste. When such dough is baked a bread is obtained which remains unalterable, becoming neither putrescent nor mouldy for years. Mutton, veal or bacon may be substituted for beef, bacon having the advantage of being the least insipid. It was pointed out in the discussion that a similar combination of meat with farinaceous food is met with in "Spratt's biscuits."

Yet more concerning the dissociation of the halogen elements. Messrs. Crafts and Meier, whose criticism of Professor Victor Meyer's results was referred to in the last "Month,' have contributed another paper to the French Academy (*Comptes Rendus*, xc., 690) on the density of iodine at high temperatures. It will be remembered that Professor Meyer found that, commencing at a temperature of about 1000°, the density of the vapour of iodine became reduced until it equalled about two-thirds of its normal density, at which point it remained constant at the highest temperature of a Perrot furnace, estimated at 1570°. Messrs. Crafts and Meier give reasons for supposing that the real temperature was below 1400°, and state that at this point they have observed a density inferior to two-thirds, which Professor Meyer thinks to be the limit of dissociation. In fact, they say that starting at 600° they observed an uninterruptedly progressive diminution of density up to the limit of their observations, and suppose that at a still higher temperature the density might become one-half of the normal density. In other words, if the cause of diminution be a dissociation it may be admitted that the molecule I_2 tends to separate into two atoms.

In reference to a remark made in the recent notice of the second edition of 'Pharmacographia' in this Journal (before p. 766), to the effect that a cheap edition of the work had been published in the United States, a note has been received from Dr. F. A. Castle, the Editor of *New Remedies*, stating that the reviewer is mistaken, no republication of the work having taken place there. It appears that a New York publisher had a correspondence with Professor Flückiger on the subject, but nothing further was done.

Some very good excipients have from time to time been named in these columns. In the employment of any one, the dispenser is guided by several considerations. Sometimes a prescription for pills is mainly composed of powders, having little or no adhesive properties; in this case mucilage of tragacanth may be had recourse to, and more especially if sulphate of iron form one of the ingredients; but if the pills are to be silvered this excipient requires to be used with great judgment, or the covering cannot satisfactorily be accomplished. In many such cases conserve of roses answers the purpose better. Again, conserve of roses may not be admissible when the quantity required to form a suitable mass would make the pills inconveniently large; manna is sometimes preferable to any other, and in the case of sulphate of iron it is sometimes very useful, but the quantity of an excipient necessary to form the mass must be an item of consideration. In choosing an excipient the ingredients prescribed must also be taken into consideration, and the quantity of excipient which these will admit of; moreover, if the pills are to be silvered when finished a firm surface is required for the silver leaf to cover the pill satisfactorily.

The first prescription requiring notice is that of No. 399, where ext. tarax. liq. is ordered. This preparation has on several occasions been referred to. It is not official, and in some establishments suc. tarax. is used, and at others either a preparation of the dried root or a solution of the extract. D. G. is referred to some remarks in "The Month," *Pharmaceutical Journal*, [3], vol. viii., p. 145, No. 10.

Some medical men, and more especially does it apply to those who once dispensed their own prescriptions, have acquired a habit of using the proprietary preparations of some particular maker, and when they discontinue the dispensing of their own medicines, the habit will still adhere to them of ordering preparations which either never had a place in the national pharmacopœia, or have been superseded by others more reliable and more elegant. In cases such as these the prescriber should be referred to, and definite instructions be obtained as to the preparation required when ext. tarax. liq. is ordered in a prescription.

The prescription No. 400 refers to the directions, which are somewhat ambiguous. Carbolic acid lotion is ordered with a direction written thus:—"To be applied to the parts, and covered with tinfoil." "Junior" asks if the bottle or the part to which the lotion is applied is to be covered with tinfoil. There is ample room for a difference of opinion on this point, but it seems very probable that the bottle is to be covered with tinfoil to guard against accident. From the cases recorded of accidental poisoning, arising through mistakes as regards the bottle, it would appear that in many places where medicine is dispensed, mixtures for internal administration and lotions or liniments for external use are put into bottles of the same colour or shape, and it is probable that the prescriber has in this instance added the covering with tinfoil as a preventive of accident; at the same time on the face of it as written, the tinfoil applies to the covering of the parts to which the lotion has been used. If "Junior" does not use poison bottles, he would do well to cover the bottle with tinfoil, and as the directions are for the guidance of the patient, most probably verbal instructions have been given with regard to covering, or otherwise, the parts after the application of the lotion.

The mist. scillæ of No. 401 is most probably some hospital or private formula. It is not unusual to find a hospital preparation in a prescription for a private patient, or a preparation that is kept as a matter of convenience for dispensing in the surgery of a private practitioner, and hence these "misturæ" as met with in prescriptions. When not official reference should be made to hospital formulæ, and many of these find their way into Beasley. There is one among the London Hospital formulæ as follows:—Mist. scillæ: vinegar of squill, 40 minims; pimento water, 1 ounce. But a dispenser would very properly object to the introduction of pimento water into a private prescription through an indefinite preparation. In most of the formulæ either oxymel or vinegar of squill forms the squill ingredient. It would, therefore, be more safe to use oxymel of squills in the proportion of about ʒj to ℥j water as a mist. scillæ for this prescription.

"Jacque" inquires (No. 402), when pulv. cretæ co. c. opio is prescribed, what should be used, the P. L. preparation or the pulv. cretæ arom. c. opio, B.P.? The dispenser must assume that the P. L. preparation is intended. The Pharmacopœia preparation, pulvis cretæ compositus c. opio ceased to be official on the publication of the B.P., and to supply its place a preparation was introduced of the same strength as regards the opium, but in other respects differing in composition, and named pulvis cretæ aromat. c. opio. If the writer of the prescription chooses to ignore the existence of the B.P., with its alteration of formulæ and names, the dispenser must follow him.

In the preface to the B.P. it is stated that, in accordance with the Act, "The British Pharmacopœia, when published, shall for all purposes be deemed to be substituted throughout Great Britain and Ireland for the several above-named Pharmacopœias;" but so strong is the force of habit, that in writing prescriptions the preparations of former pharmacopœias are still occasionally ordered and are required to be kept in every dispensing establishment.

In No. 403 there is no appreciable decomposition from the addition of the quinine dissolved in the citric acid; but if there were, it would not be perceptible in a mixture such as the one in question containing not only ext. tarax., but also ext. sarsæ liq. If a slight separation occurred immediately on the addition of the quinine, a brisk shake of the bottle would produce a homogeneous mixture.

The addition of tinct. nucis vom. to a mixture containing acid, as in No. 404, has been referred to in "The Month" on several occasions. E. L. will find one [3], vol. ix., p. 796, No. 255. The tinct. nuc. vom. being an alcoholic tincture, on its addition to water there is an opalescence, and a separation of resin is determined by the presence of an acid, most of the flocky matter rising to the surface of the liquid. It cannot be altogether avoided, but it may be retarded by the addition of a little mucilage.

No appreciable decomposition will take place in the pill mass, No. 405, if rolled out on the machine with mag. carb. pond. Each particle of the plumbi acet. and p. opii would be covered by the conf. rosæ. But mag. carb. is not the best powder for pills. Ingredients for pills could be named in which the use of magnesia would be attended with inconvenience. Starch powder is more suitable and not incompatible with the usual ingredients which go together to form a pill mass. More than this, magnesia sometimes hangs to a pill and makes an otherwise very moderately sized pill look like a bolus; but this will not occur with starch, and "Cymro" is recommended to lay aside magnesia and let starch take its place.

The prescription No. 406 presents no special difficulties. The pot. iodid. and pot. citras should be dissolved in a part of the aq. chlorof., and the quinine (not dissolved) being rubbed down and suspended in the mucilage made with the pulv. tragac. comp. and the remaining part of the aq. chlorof., this with the addition of the vin. colchic. and tr. card. co. being added to the other ingredients, a mixture, rather thick from the pulv. tragac. co. and pale pink from tr. card. co., will result. There is no apparent incompatibility, and an elegant mixture is formed. There will, of course, be a certain amount of deposit, and a label to "shake" should therefore accompany the bottle. In making such a mixture as this, and the same applies very generally to mixtures, solutions of salts should not be thrown together in a concentrated form, but should each be well diluted before being mixed.

The cultivation of a habit of observation and a little more self-reliance on the part of young dispensers would carry them over most of these difficulties, and would at the same time enable them to grasp those general principles which have from time to time been inculcated in these columns for their guidance in combining the several ingredients of a prescription. A careful study of the prescriptions which are commented on in "The Month," with now and then a practical application of the lesson, should enable a youth, less fortunately situated than some of his elder brethren, to turn out medicines from physicians' prescriptions that would satisfy the writers, and do credit to the often quoted "West End" establishments.

EDINBURGH NEW WATER SUPPLY: ITS COMPOSITION AND ACTION UPON IT OF DIFFERENT FILTERING MATERIALS AS REGARDS REMOVAL OF COLOUR.*

BY J. F. KING, F.C.S.,

City Analyst, Edinburgh.

Edinburgh, like most other cities of similar size, ha for many years been rapidly growing both as regards ex tent of boundary and population.

One result of this extension and by no means the most unimportant is that the water supply, which was abundant twenty years ago, was found some few years back to be totally insufficient. In consequence of this scarcity of the necessary element the authorities of our city determined at that time to introduce an additional supply, and the present abundance which we now enjoy is the happy result of that determination. Time would fail me, and indeed it is hardly within the legitimate limits of this short paper, to enter into a description of the different sources from which it was proposed that Edinburgh should

* Read at an Evening Meeting of the North British Branch of the Pharmaceutical Society, April 14, 1880.

obtain her new supply of water. Suffice it to say that these were very numerous and the great difficulty the authorities had to contend with was not where to obtain a source, but rather to select the best from the many that were suggested. As the result of much patient inquiry and acting under high professional advice they chose as being, everything considered, the most suitable supply for Edinburgh that which in now known as the Moorfoot water. This water, which is derived in great part from the river Esk, is collected for the use of the city in a magnificent natural reservoir, situated near the Moorfoot Hills, skifully selected and rendered suitable for use by the well known civil engineers, Messrs. J. and A. Leslie. This splendid sheet of water, known as Gladhouse reservoir, is no less than four hundred acres in extent. It holds 1700 million gallons, and could, therefore, supply the city for one hundred and eighty days at a rate of 30 gallons per head per day, without receiving a fresh supply.

This reservoir, which took at least three years to make, is the largest in Scotland if not in Great Britain. I should say that there is another reservoir known as Portmore which holds 250 million gallons, so that the stowage of these two together is no less than 1950 million gallons.

The water as it leaves Gladhouse enters an aqueduct, ten miles long, by which it is conveyed to Alnwick Hill, where it is filtered ready to be dispatched for consumption in the city. This essential operation of filtration is very efficiently carried out by means of four large filters, which are each half an acre in extent and consist of sand and gravel arranged in layers. The water is allowed to flow on to the surface of the filter and by passing through the layers of different materials is freed from almost all the suspended matter which it contains. I will refer to this, however, further on; in the meantime I wish to direct your attention for a moment to the quality of this much abused water. Much has been said and written against the character of our new water supply, but I think that with the exception of colour not much can be said against it as a potable water. It is not too hard nor yet is it objectionably soft. It has no unpleasant taste and I think, judging from the results of analyses which have been made, we may safely come to the conclusion that, excepting colour, it is well suited for all domestic purposes. On this diagram I show you the results of analyses of all these different waters, from which you see that in almost every particular (excepting, as I said before, that of colour), they are nearly just as they should be.

Analyses of Waters.

	Gladhouse.	Tweedale.	City.	Crawley.
Total Residue	4·88	4·00	5·84	11·28
Volatile Residue	1·28	1·04	1·84	...
Saline Residue	3·60	2·96	4·00	...
Lime	1·04	0·88	2·00	...
Magnesia	0·45	0·40	0·16	...
Chlorine	0·76	0·70	0·75	1·04
Saline Ammonia	0·0032	traces	0·0008	0·001
Albuminoid Ammonia	0·0128	0·0040	0·0056	...
Colour	24·85°	7·00°	10·00°	...

Hardness of Waters.

Lancaster	0·10°
Loch Katrine	0·30°
Thirlmere Lake	0·70°
Dee (Aberdeenshire)	1·50°
Ulleswater Lake	1·90°
Manchester	2·70°
Crawley Burn	6·08°
Swanston	6·22°
Colinton	9·17°
Coniston Water	10·36°
Thames	14·30°
Lea	18·20°
Trent	26·50°
Moorfoot	3·20°

The total solid residue, you observe, is by no means excessive, and, moreover, it consists in great part of saline matter, which in turn is composed principally of compounds of lime and magnesia. The item Colour, as it is a somewhat new expression in a report of an analysis of water, and one seldom or never made use of by any analyst save myself, is one which I feel requires a word of explanation. It has always been a difficulty with water analysts how properly to describe or put on record the results of their observations of the colour of water. It has long been felt that the usual mode of describing the colour of water was very faulty, such expressions as almost colourless, faintly yellow, a distinct brown, conveying no definite idea as to the amount of colour possessed by water and, therefore, being of no use for preserving or comparing the results of a water analysis.

Feeling this to be a great inconvenience in my own practice, I devised the extremely simple process which I now use in the examination of waters in which colour is an element of importance and which consists in adding to a given quantity of distilled water a coloured solution, until the distilled water is found to exhibit the same colour as the water under examination; the point at which this takes place being determined by comparing equal bulks of the two waters placed in 12 or 18 inch glass tubes. The only point attended with any difficulty is the manufacture of the coloured solution, and the difficulty here consists in making and keeping this always of fixed strength. This may be done very satisfactorily and accurately by mixing distilled water with a certain proportion of ammonium chloride and adding to the mixture thus produced a carefully measured amount of Nessler's solution, and taking the colour so produced as a standard by which the colour solution can be at any time prepared or verified. In another table I show you the results of the determination of colour by this method in the water supplied to most of our large towns.

Colour of Waters.

Perth (Wells)	4·00°
Paisley (Stanley)	4·55°
Dundee (Clatto)	5·00°
Loch Katrine	6·00°
Glasgow (Gorbals)	6·00°
Loch Ashie	6·50°
Dundee (Town)	7·00°
Perth (River)	10·00°
Paisley (Rowbank)	10·50°
Aberdeen	12·25°
River Ness	13·60°
Dumfries	16·00°
Greenock (Gryfe)	30·00°
Greenock (Loch Thorn)	35·00°

From this table you will perceive that the Gladhouse water as it leaves the reservoir does not hold a very high place in the scale, but when it is filtered, and especially after being mixed with other water ready to be sent into the city, the colour is by no means excessive. I have just to add one word in fairness to the Gladhouse water and that is that the reservoir is not as yet fully seasoned. There is still a quantity of decomposing vegetable matter in the reservoir; this, however, I should think is fast disappearing, so that in the course of a few months there will no doubt be much less colour derivable from this source. One of the main points to which I directed my attention in working out materials for this paper was the action which the different filters now before the public would have on the colouring matter of the Moorfoot water. To ascertain this I procured four filters:—

1. Carbon filter, carbon loose.
2. Carbon filter, carbon in block.
3. Miniature filter such as is used at Alnwick Hill.
4. Spongy iron filter.

The water upon which I made the experiments had a colour to start with equal to 20 degrees. This was then passed through each of these filters when the following results were obtained:—

Action of Filters on Moorfoot Water.

Filters Fresh.

	Slow.	Fast.
Filter No. 1	7·50°	7·50°
„ „ 2	15·00°	15·00°
„ „ 3	19·00°	19·00°
„ „ 4	Not improved.	

Also tried filtering power at slow rate.

These results, however, hardly yield results of much practical importance, inasmuch as they were obtained by using the filters when these were almost quite new. In order to test the lasting power of the filters, which is one of the greatest and most important points in connection with this subject, I allowed a large quantity of water to pass through the filters, so causing a certain amount of the purifying power to become exhausted, before filtering any water for the purpose of comparison.

From experiments made in this way I obtained the following results:—

Filters after Use.

	Slow.	Fast.
Filter No. 1	11·00°	11·00°
„ „ 2	16·00°	16·00°
„ „ 3	19·00°	19·00°
„ „ 4	Not improved.	

Filters after Standing in Contact with Water for One Day.

Filter No. 1	3·50°
„ „ 2	Not improved.
„ „ 3	11·00°
„ „ 4	Not improved.
Chemically Purified	1·50°
Natural Water	20·00°

From these results we are led to the following conclusions regarding the actions of these filters.

No. 1 and No. 2, that is the carbon filters, undoubtedly produce a certain amount of improvement. It will be noticed, however, that they get less powerful as they are more used, and I am fearful that after such filters have been in use for months they may become much less useful. This, however, I have not proved by direct experiment, and therefore I cannot speak decidedly on the point.

One word as to filtering apparatus at Alnwick Hill. The filters here, as I have said, are two acres in extent, there being four filters of half an acre each. The filters are made of sand and gravel, through which the water flows, with the result shown in the colour table. Removing all this colouring matter renders the filters by and by unfit for work, and they therefore require to be cleaned. This cleaning operation, which is carried out on one of the filters every month, is effected in a very neat and ingenious manner by means of a washing apparatus, which consists of a large wooden box (laid on the top of the empty filter), into which the sand, etc., is thrown, and through the bottom of which a powerful stream of pure water is forced. This mixing with the sand thoroughly washes it; the water then flows over the top of the box, carrying with it all the impurities, and leaving behind pure sand, etc. The water is allowed to flow off until it runs away clear. The operation is carried out in as economical a manner as possible, and yet you will not be surprised to learn that this simple operation costs a considerable amount of money, the sum expended in this way amounting to £40 per annum for 1,000,000 gallons per day. These few remarks I have thought to lay before you because, as they give information which is really authentic on a subject which is of vital interest to us all, they may be thought worthy of your attention. I exceedingly regret that the very many and pressing demands on my time have prevented me carrying out a further series of experiments, and so preparing a paper more worthy of your acceptance.

THE SOLUBILITY OF SOLIDS IN GASES.*

BY DR. A. SENIER, F.I.C., F.C.S.,

Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

The researches of De la Tour, and more recently those of Andrews, have shown that there is a certain point of temperature in the case of many gases, and probably in the case of all gases, below which they may be liquefied, and above which they cannot be liquefied, by pressure. Thus, carbon dioxide gas at 32° F. is liquefied by 38·5 atmospheres, at 55·6° F. by 49 atmospheres, and at 87·7° F. by about 76 atmospheres; but at temperatures above 87·7° F. no increase of pressure attainable by Andrews, 150 atmospheres and upwards, produced liquefaction. Again, carbon dioxide gas at, say 86° F., is reduced in volume by gradual application of pressure much more rapidly than air, until when the pressure reaches some 76 atmospheres liquefaction occurs. If then the pressure be constant and the temperature be increased to a point just above 87·7° F., the liquid changes to the state of gas without material alteration of volume and without sudden absorption of heat. Conversely, if the temperature be again reduced gradually to 86° F., the liquid state is again resumed, and without any material alteration in volume or sudden disengagement of heat. This point of temperature, above which the carbon dioxide is a gas even under very great pressure, and below which it may be liquefied by a comparatively slight pressure, was termed by Andrews its critical point.

The critical point of carbon dioxide gas is 87·7° F., according to Andrews; that of alcohol is 454·3° F., carbon disulphide, 523·3° F., and carbon tetrachloride, 532·1 F., according to Hannay and Hogarth. Water has a critical point above 773° F., as observed by De la Tour, and at that temperature, under great pressure, he found that the water gas exerted a solvent action upon the glass tubes so great as to almost preclude the possibility of such experiments. The critical points of oxygen, hydrogen, nitrogen, etc., are doubtless at very low temperatures, temperatures which, however, Cailletet and Pictet were able to command in their brilliant researches, so fresh in the memory of physicists and chemists.

Let me recall, parenthetically, the definitions proposed by Andrews for the terms gas and vapour. I do so because it appears to me that these valuable suggestions have been largely overlooked by our text-book writers. In place of the old unscientific notion of gas and vapour, Andrews proposed that a body above its critical point should be called a gas, and that the term vapour should be applied to bodies at temperatures below their critical points, but under such pressure that they are still aeriform. Thus vapours are aeriform bodies which can be liquefied by pressure alone, which is not the case with gases. Steam is a gas above about 773° F., and under any pressure which has been attained. Below 773° F. and above 212° F., it is a vapour under ordinary atmospheric pressure. Carbon dioxide is a gas above 87·7° F., and under any pressure which has been attained; but below that temperature it is a vapour under ordinary atmospheric pressure. Oxygen, hydrogen, nitrogen, etc., are gases under atmospheric conditions of temperature and pressure.

When it is considered that this critical point is a fixed one in the case of each gas under conditions of temperature and pressure both varying with the gas, and when we remember that the liquefying point (boiling point) is only a constant under identical conditions of pressure, it is evident, I think, that the former being constant amidst greater variety is the more important of the two; that is to say, more important in its bearings upon chemistry as a science. The exact determination of critical points

* A Report on Physical Chemistry, being the substance of a lecture delivered before the School of Pharmacy Students' Association, April 8, 1880.

then may be expected, as has been the case in respect to vapour densities, to enrich science with new general truths, *i.e.*, with new laws.

In his determination of the critical point of carbon dioxide, Andrews found the transition from liquid to gas, and from gas to liquid, to be very difficult to observe exactly. He was obliged to rely upon the surface line of the liquid, its refractive power, its entering into ebullition under reduced pressure, etc. Now it occurred to Hannay and Hogarth* that as solids were not usually supposed to be soluble in gases, if they were to convert a liquid in which was previously dissolved a solid, non-volatile at the temperature to be employed, into a gas in a sealed tube the solid might be precipitated at the critical point, and thus serve as a valuable experimental implement, an indicator by means of which the critical point might be accurately observed. If, however, precipitation did not occur, and other actions, possibly chemical, did not interfere, they appear to have foreseen that the new fact of the solubility of a solid in a gas would be established.

In order to test these hypotheses Hannay and Hogarth resorted to experiment. A solution of potassium iodide was made in alcohol and a strong tube about half filled with the solution was sealed in the blowpipe flame and subjected to gradually increasing temperature to about 716° F. At this temperature, some 280° F. above the critical point of alcohol, where of course the liquid state had long ceased to obtain, as well as throughout the experiment, no precipitation occurred. In other experiments it was shown that the critical point was only raised very slightly by the solution in the liquid of non-volatile solid matter; and hence there can be no question that in the experiment just described the alcohol was in a truly gaseous state. I have repeated this experiment† using a small heavy glass tube in which was sealed solution of potassium iodide. This was heated inside a glass cylinder in a current of hot air, the temperature of which was allowed to rise gradually to far above the range of a mercurial thermometer. The striæ which appear at the peculiar transition state, and which have been so exactly compared by Andrews‡ to the appearances produced when two fluids of different densities are allowed to mix, were well marked and the phenomenon of solution of the solid iodide in the gaseous alcohol was observed. My experiment, or I should say experiments, have been conducted, I believe, under conditions not identical with those which obtained in the experiments of Hannay and Hogarth, and thus while they give me no reason to doubt the substantial accuracy of the facts arrived at by those experimentalists, they have also given me what appear to be other facts previously unknown, which I propose to investigate more fully. Hannay and Hogarth were able, by means of a special apparatus, to introduce a crystal of potassium iodide into alcohol gas and observed that complete solution took place. Sudden variation of pressure, however, caused separation of some of the iodide in the solid and, what was most remarkable, the crystalline state. Substantially the same results were obtained in the case of other solvents and other solids. In some cases, however, chemical action occurred. An attempt was made to obtain sodium in solution in gaseous ammonia and in hydrogen, with results in the case of the latter solvent if not absolutely conclusive at least very encouraging.

Hannay and Hogarth then have established as truth one of their hypotheses, that a solid is dissolved by a gas. They have shown that this is not by any means an isolated fact and no doubt further experiments will show that it is a very general one.

Many facts not directly concerned with the hypotheses under examination were observed, and which may well prove the starting points for new fields of discovery. One of these has been alluded to already,—the fact that when under sudden variation of pressure and also under certain conditions of chemical action a solid is thrown out of gaseous solutions, the precipitate is crystalline. By an application of these facts Hannay claims to have crystallized carbon. The matter has been the subject of a "preliminary note" read before the Royal Society, and chemists are now awaiting full details of the experiment before an absolutely satisfactory conclusion can be arrived at.

QUINIC ACID, QUINONE, AND THEIR DERIVATIVES.*

BY O. HESSE.

Quinic Acid.—The quinic acid employed in this investigation was chemically pure, and was prepared from the calcium salt by decomposition with oxalic acid, according to the method which has been previously described by the author. By evaporation of an aqueous solution of quinic acid, the greater part of the acid quickly separates in a crystalline form, but the mother liquor still contains amorphous quinic acid, and the author states that the presence of a very small quantity of a foreign substance is sufficient to hinder the crystallization. The amorphous acid can easily be converted into the crystalline form by purifying its calcium salt with animal charcoal, then proceeding as before described. Quinic acid contains no water of crystallization, and the author draws attention to this fact because from a misconception of his earlier statement on the subject Graebe has assumed the formula of quinic acid to be $C_7H_{12}O_6+H_2O$.

Tetracetyl quinide $C_7H_6(C_2H_3O)_4O_5$ m. p. 124° (uncorr.), is obtained as an amorphous mass which becomes vitreous on cooling by the action of acetic anhydride on quinic acid in a sealed tube at 170°. It is purified by melting it repeatedly in hot water and finally washing it with cold water. On being dried in the air it is obtained as a white powder, which is insoluble in cold water and soluble with difficulty in hot water. It melts in boiling water and is gradually decomposed by longer heating its aqueous solution, which then becomes acid. Its aqueous or alcoholic solution becomes turbid on being cooled, and the anhydride separates in granular crystals. The formula as above assigned to this body was confirmed by it yielding the anhydride (quinide) $C_7H_{10}O_5$ when boiled with magnesia, and quinic acid when decomposed with lime, the author having previously shown that quinide is converted by the action of lime into quinic acid.

Action of Bromine on Quinic Acid.—By the action of bromine on an aqueous solution of quinic acid, an acid is obtained which the author had named carbohydroquinonic acid, on the supposition that it yielded hydroquinone when heated. But it was afterwards shown that the black precipitate which this decomposition product gave with ferric chloride was a pyrocatechin compound; hence the name of the acid was altered to carbopyrocatechuic acid. Strecker subsequently obtained the same acid by fusing piperinic acid with caustic potash, and named it pyrocatechuic acid, and to him is improperly ascribed the discovery of this acid.

The author has repeated his former experiments, and this time on a large quantity of pyrocatechuic acid, which had been prepared as before by the action of bromine on quinic acid, and he now finds that hydroquinine is not produced, as he had previously assumed. When operating with a large quantity of pyrocatechuic acid the decomposition does not proceed very smoothly; a carbonaceous mass is formed whilst phenol and pyrocatechin distil over.

In addition to pyrocatechuic acid another acid is produced by the action of bromine on quinic acid. It can be obtained by evaporating the product of the reaction to a syrup, agitating it with ether, then treating the ether residue with lukewarm water in which the new acid is insoluble, but which dissolves the pyrocatechuic acid. It can be purified by re-crystallization from boiling water. It crystallizes in colourless laminæ or in

* Abstract of a paper in *Liebig's Annalen*, 200, 232—255.

needles, which dissolve with some difficulty in boiling water and are almost insoluble in cold water, but easily dissolve in ether. It carbonizes when heated, giving pungent fumes and a brown coloured distillate which solidifies to a radiated crystalline mass and, like the original substance, gives no coloration with ferric chloride. Its hot saturated solution gives no precipitate with lead acetate but a considerable quantity of a yellowish white precipitate with basic lead acetate. The composition of this substance has not yet been ascertained, but it is said to be a bromine derivative.

Action of Concentrated Hydrochloric Acid on Quinic Acid.—Warm concentrated hydrochloric acid quickly dissolves quinic acid, but without decomposition; but when heated with it at 140—150° in a sealed tube it is converted into hydroquinone and paraoxybenzoic acid.

Graebe obtained pyrocatechuic acid by the action of potassium hydrate on quinic acid, and the author states that a similar result ensues by using sodium hydrate, and that neither oxysalicylic acid nor hydroquinone carbonic acid is produced.

Quinone.—As an addendum to his former remarks on this substance the author states that it is somewhat readily soluble in boiling petroleum ether, but very readily so in boiling ligroin (*sic*), and as the greater part of the quinone recrystallizes out on cooling in beautiful yellow prisms, these solvents serve as a ready means of purifying this substance.

The author is unable to confirm the statement of Sarauw, that diacetylhydroquinone is formed by the action of acetic anhydride on quinone. He is of opinion that quinone is to be regarded as the aldehyde of quinonic acid in this way :—

Hydroquinone.	Quinone.	Quinonic Acid.
$C_6H_6O_2$	$C_6H_4O_2$	$C_6H_4O_4$
Alcohol.	Aldehyde.	Acid.

Hydroquinone.—In consequence of a statement by Hlasiwetz and Habermann (*Liebig's Annalen*, 175, 62), with regard to the melting point of this body, the author has repeated his experiments and he now gives the melting point as 168—169° (uncorr.) instead of 172—173° (uncorr.). Hydroquinone is insoluble in boiling petroleum benzine, almost so in boiling chloroform, the chief part of it separating again from the latter on cooling. It forms no compound with phenol. Its concentrated aqueous solution gives a dark green or almost black precipitate of quinhydrone with ferric chloride or sulphate.

Quinhydrone is very easily soluble in slightly warm water, and this solution, unless disturbed, has a great tendency to remain saturated without crystallizing. Although in all cases the aqueous filtrate from the quinhydrone has a strong odour of quinone, yet it is impossible to obtain a complete conversion of hydroquinone to quinone by this method, nor even by heating the hydroquinone with ferric sulphate in a sealed tube at 80—100°. Quinone is, however, obtained in considerable quantity by the action of concentrated nitric acid on hydroquinone; by continuing the action of the nitric acid oxalic acid is produced.

Diacetylhydroquinone, m. p. 121° (uncorr.), is, contrary to the statements of other observers, an odourless and stable substance, even after long keeping.

Dinitrodiacetylhydroquinone, m. p. 94°, has been prepared and was of interest to the author, as he hoped that by the substitution of NH_2 for NO_2 in this compound a substance of the formula $C_{10}H_{12}N_2O_4$ would be obtained; in fact, a body which would stand in near relation to chitenin, $C_{19}H_{22}N_2O_4$, the dihydroxylquinine of Kerner. It was easily reduced by zinc and hydrochloric acid, yielding a base which, however, had no resemblance to chitenin or to any other alkaloid. In the free state this base was very unstable; its alcoholic solution gave a cherry red colour with ferric chloride.

Dipropionylichydroquinone, m. p. 113° (uncorr.), which crystallizes in colourless laminæ, and its mononitro-derivative, m. p. 86°, crystallizing in pale yellow leafy crystals, have been obtained, and are described in detail.

Quinhydrone.—As is well known, this substance dissolves very easily in warm water, but it is partly decomposed thereby into quinone and hydroquinone, the solution acquiring the characteristic smell of quinone. It dissolves in hot glacial acetic acid apparently unaltered, and crystallizes out on cooling in greenish black plates or prisms. It is insoluble in hot or cold petroleum ether and in ligroin. It is soluble with extreme difficulty in boiling chloroform, crystallizing out on cooling in small plates; but by this treatment the greater part of the quinhydrone is decomposed into quinone, which is carried away with the chloroform vapour, and into hydroquinone, which separates in colourless crystals. When heated it evolves bluish violet fumes and gives a bluish black sublimate.

The author does not agree with the structural formula assigned by Graebe or Wichelhaus to this body, but is of opinion that quinhydrone is to be regarded as a compound of one molecule of hydroquinone with one molecule of quinone, as by the action of acetic anhydride on it at 160—170° diacetylhydroquinone and quinone were obtained, the former approximating to the theoretical quantity. Phenoquinone, $C_{18}H_{16}O_4$, and methylquinhydrone, $C_{20}H_{20}O_6$, or $C_6H_4O_2.2C_6H_4$ $(OHOCH_3)$, have been examined and the above formulæ assigned them by the author, who disputes the accuracy of the formulæ $C_{18}H_{14}O_4$ and $C_{20}H_{18}O_6$, as given them by Wichelhaus.

THE PERCENTAGE OF EXTRACTIVE SUBSTANCES SOLUBLE IN ALCOHOL, AS A CRITERION OF THE PURITY OF SPICES.*

BY MAX BIECHELE.

The author employs the following method:—A flask of about 120 c.c. contents, is fitted with a cork, through one of the two holes in which passes the stem of a funnel of about 7 c.m. diameter; through the other, a tube leading to the top of an upright Liebig's condenser. Five grams of the spice to be tested, previously dried at 30° C., are placed on a filter, which should not quite fill the funnel, covered with a disk of filter paper, and absolute alcohol poured through until the flask is half full. The funnel is then covered with an inverted funnel, the stem of which has been broken off, leaving an aperture, through which is passed the lower end of the condenser. The alcohol in the flask is then heated to boiling, and maintained at that temperature, until the prolonged percolation of the condensed alcohol through the spice has removed all soluble matters, and the filtrate is colourless. The filter, with its contents, is then partially dried at 100° C., the contents removed to a weighed porcelain dish, thoroughly dried at 100° C., and again weighed. The volatile character of many of the extractive substances (essential oils, etc.) renders it impossible to estimate the residue from the evaporation of the alcohol. Proceeding by the foregoing method, the author has obtained the following percentages of extract from pure spices:—

Cloves	33·50
Cassia bark	26·60
Cinnamon (Ceylon)	23·90
Caraway seed	33·87
Fennel „	38·20
Black pepper	19·87
Long „	37·00
White „	16·87
Red „	18·13
Coriander seed	14·88
Star-anise „	25·68
Anise seed	36·24
Clove pepper	22·68
Mace	37·60
Nutmegs	32·70

INDUCED ELECTRICITY AND ITS APPLICATIONS.

A FEW weeks ago Dr. C. W. SIEMENS entertained the members of the Royal Institution with an account of the dynamo-electric machine, its history and some of its applications. The latter are of such a nature as to present a striking contrast between the significance of the knowledge possessed at the present day and that of some fifty years since, when FARADAY first observed that an induced current was set up in a coil surrounding the armature of a permanent magnet when the armature was forcibly severed from the magnet. So diverse and important are some of these applications that it would scarcely be possible to give a better illustration of the way in which the abstract scientific results and observations of to-day may be developed into furnishing the means by which daily necessities of ordinary life are to be provided for in the future.

FARADAY'S actual observation, made known to the members of the Royal Institution in 1831, was itself only the realization of a theory at which he had previously arrived by *à priori* reasoning as to the necessary production of the induced current under the conditions named, but that current was so slight and of such short duration that seven years elapsed before he could detect its existence with the instruments then at his command.

One of the peculiarities of the induced current, in which it differs from a galvanic current, consists in the very important circumstances that, though only feeble and instantaneous, it is the immediate outcome of the expenditure of mechanical force and that, by repeating the operation of severance by suitable mechanical arrangements, a rapid succession and an aggregation of currents can be produced and directed through a metallic conductor so as to produce in it all the phenomena of a continuous current of great magnitude. As Dr. SIEMENS described it, the single current of FARADAY'S original experiment might be compared to a single rain drop, itself of little power in falling, but which, when repeated often over the surface of an elevated plateau, becomes capable of giving rise at first to streams and then to a mighty river and source of power such as the Falls of Niagara.

Further study of the conditions under which the induced current is produced showed that the force expended to that end bore a definite relation to the force obtained and that mechanical force and electric current were mutually convertible, and then attempts were made to utilize the induced current, as for instance by WHEATSTONE in 1844, though without any practical success, until much time and thought had been devoted to the subject by those who followed in the wake of the great discoverer. One important step in this direction was made by Dr. WERNER SIEMENS in 1856 by the construction of an apparatus with which a succession of currents could be aggregated and a continuous current of considerable power produced. Further advance towards the production of powerful effects by the accumulation of magneto-currents was made by HOLMS and WILDE, when steam power was applied for the purpose, and by means of the machine constructed on the dynamo-electric principle attributable to WERNER SIEMENS and WHEATSTONE. The first machine of this kind brought before the Royal Society in 1867, by Dr. SIEMENS, differed from magneto-electric arrangements by substituting in the place of permanent magnets electro-magnets excited by the current produced by the rotation of the armature or helix of the machine itself.

The advantage of this electro-magnetic machine consisted in its accumulative action and the power of the current produced. Various improvements were then effected by PACINOTTI, GRAMME, and others, by adaptations of the principle upon which it was constructed, and ultimately one devised by Dr. SIEMENS admitted of a further increase in the strength and steadiness of the current being realized.

Among the applications of the dynamo-electric current, one of the first to be noticed is the transmission of power, and in Dr. SIEMENS' lecture this was illustrated by the working of a circular saw receiving its motion from a dynamo-electric machine placed in the basement of the Royal Institution, and receiving in its turn motive power from a gas engine. By this arrangement it was shown that 60 per cent. of the engine power expended could be turned to account at another place, and that in this way natural sources of power, such as waterfalls, might be made available for supplying motive power at distances of even twenty or thirty miles, or power might be transmitted to the depths of mines by the establishment of a stout leading wire connected with an electro-motor on the bank.

The propulsion of tramway cars upon railways is another application of the dynamo-electric current that has been effected by Dr. SIEMENS, and practically worked last year in Berlin. One of the carriages forming the train is fitted with an ordinary dynamo-machine and another machine is worked on the ground by engine power. The current is conveyed by a central rail or conducting rope and the return current is completed through the side rails of the tramway. In this way, thirty or forty persons can be conveyed at a speed of ten or twelve miles an hour, and the train can be started or stopped by moving a handle as required. A line of this kind is shortly to be constructed at the Crystal Palace.

The interest attaching to the electric light at the present time is entirely due to the comparatively cheap rate at which the electric current can be produced by the expenditure of mechanical power and by the combustion of coal for hat purpose, instead of the combustion of metallic zinc in the galvanic battery, and this is another of the applications of the induced current which has an important future. Incidentally, Dr. SIEMENS referred to the misconception prevailing as to the utilization of the electric light, and he pointed out that while glow lights could never equal the electric arc in economy of result, greater efficiency could be obtained from a powerful electric arc than from divided arcs, and therefore the development of electric lighting should be sought in the direction of creating powerful centres of light rather than by its subdivision.

Properly applied, the electric light is much cheaper than gaslight, but it is not likely to supplant gaslight for purposes where great subdivision is indispensable. By burning a thousand feet of gas in burners and consuming the same quantity in a gas engine giving motion to a dynamo-electric machine feeding an electric light, it has been shown by Dr. SIEMENS that about twenty times the luminous effect would be produced in the latter case if the working arrangements were sufficiently perfected. For lighting halls and large places, therefore, the electric light is, in Dr. SIEMENS' opinion, three or four times cheaper than gas.

The production of heat in the electric arc admits of the application of the dynamo-electric machine for the fusion of refractory metals. Assuming that a good steam engine converts nearly 15 per cent. of the heat energy of coal into mechanical effect and that 80 per cent. of that effect could be converted into electric energy to be expended without loss in an electric furnace, Dr. SIEMENS considers that 12 per cent. of the total energy of coal would be conveyed to the material to be melted—a result far exceeding in economy that of the best furnace yet constructed. In an experiment made to illustrate this application of the induced current two pounds of steel melted in the space of about twenty minutes.

The application of the electric arc to the ripening of fruit, etc., lately experimented upon by Dr. SIEMENS is one of the most recent and most surprising results arrived at yet, and though the cost of the light as produced by the aid of steam power would be too considerable for other than special cases, the cost would be very much less considerable in places where water power could be made available.

POISONOUS PIGMENTS.

THE attention of the public has again been directed to this subject within the last few months by the report of numerous cases in which it is alleged that injurious effects have been produced by arsenical wall paper and other articles in general household use. The subject is no less important than obscure, and it is therefore deserving of thorough investigation. With this object the Council of the Society of Arts has appointed a Committee to inquire into the practicability of preventing the use of arsenic in any processes by which it is allowed to remain in finished goods, and to obtain evidence as to the effect upon various trades of a total prohibition of the sale of articles containing arsenic. This inquiry will naturally raise the question whether the alleged influence of arsenical wall paper, etc., is sufficiently well founded. The Council of the Society of Arts, with a view of promoting the object in view, has issued to manufacturers of colours, dyers and others using colours in their manufacturing operations, a circular, asking for information on certain specific points. As connected with this subject, we may call to mind the recent statement of a foreign chemist, that glucose artificially prepared from amylaceous materials by means of sulphuric acid always contains arsenic, this ingredient being derived from the pyrities used in making sulphuric acid. Considering the vast extent to which artificial glucose is used in brewing, the presence of even a trace of arsenic in it may be of some importance.

BOTANICAL LECTURES AND DEMONSTRATIONS AT THE GARDENS OF THE ROYAL BOTANIC SOCIETY.

IT will be seen, by reference to the advertisement of the School of Pharmacy of the Pharmaceutical Society of Great Britain, that Professor BENTLEY will commence his lectures and demonstrations on Systematic and Practical Botany, at the Gardens of the Royal Botanic Society, in Regent's Park, on Saturday morning, May 8, at 8 o'clock. The lectures will be continued on the succeeding Friday and Saturday mornings, till the end of July.

ROYAL BOTANIC SOCIETY.

THE second spring exhibition of flowers was held in the Gardens of the Society at Regent's Park on Wednesday, the 21st inst., and the number of visitors amounted to upwards of sixteen hundred. Notwithstanding the chilling influence of the east wind and the low temperature, which compelled the band and the majority of the visitors to keep within the conservatory, the exhibition was a very successful one, and the display of choice flowers was at least equal to that of other occasions.

ROYAL SOCIETY.

AMONG the fifteen candidates for the Fellowship of this Society who have been selected by the Council, and recommended for election on the 3rd of June next, we notice the names of Professor ATTFIELD and Dr. W. A. TILDEN.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

ANNUAL MEETING.

The annual meeting of the North British Branch of the Society took place in the Society's Rooms, 119A, George Street, Edinburgh, on Tuesday, April 20, at 12 o'clock; Mr. J. B. Stephenson, President of the Branch, in the chair.

The President opened the meeting by asking the Honorary Secretary to read the—

ANNUAL REPORT, 1879–80.

The Council of the North British Branch of the Society beg again to submit their annual report.

Since the date of their last report the operations of the Society continue to be prosecuted steadily and satisfactorily without anything noteworthy occurring of a special character.

The Council have procured a renewal of the lease of the present premises for five years. Although the accommodation is somewhat scanty, as has been previously pointed out, still the advantages of the present premises, both as regards their character and locality, as well as the difficulty of bettering ourselves in any of these respects, coupled with the formidable objections to a removal, formed the ground of a strong recommendation, to which the Council in London at once gave effect in re-taking the premises.

The museum and library have been enriched by the addition of various specimens and books, and are still largly taken advantage of. During the past year there have been 1091 visitors during the day and 691 in the evening, for the purpose of study, making 10,151 from the opening of the rooms for that purpose.

Books have also been lent out from the library to the extent of 143 volumes; and the Council rejoice to believe that by these means they are in this department carrying out one of the primary purposes of the Society, viz., promoting the education of its members.

The Council also submit the result of the issue of special tickets to lectures on materia medica and chemistry. During the year 23 pupils took advantage of these tickets, and it is very gratifying to report that two of these have distinguished themselves, one having carried off the principal prize in Dr. Craig's materia medica class, and the other being second in Dr. S. Macadam's theoretical chemistry. Every information in connection with the summer courses will be obtained by applying to the Honorary Secretary at the Society's Rooms, 119A, George Street.

The Scottish Board of Examiners has met as usual since the date of last report, on fourteen days in all; and they have had before them 7 Major, 131 Minor, and 6 Modified candidates. Of the Minor 59 were rejected, constituting a percentage of 45. There were 63 candidates for the Preliminary examination in Edinburgh during the year. The number of candidates for both the Minor and the Preliminary examinations is considerably greater than last year.

As may have been observed in the Journal, a deputation is to visit Edinburgh during the April Examinations here, which take place in the last week of the month, and this Council have only to express their desire to accord them a hearty welcome, and their confidence, based on former experience, that the visit will be instrumental in promoting the very desirable end for which these deputations were appointed, viz., the effecting a thorough unity of action and sentiment on the part of the two Boards.

There have been seven evening meetings during the past winter, at which the attendance has been quite satisfactory; and the papers read have been uniformly interesting and instructive, and have been printed *in extenso* in the Journal. The Council have to thank their friends, both those belonging to the Society and outside of it, who have so kindly assisted them on these occasions.

Since the date of the last report the question of weights and measures has made considerable progress towards settlement. Owing to the action of the Council in London, the apothecaries' weights have all been legalized, and although there are still some points connected with the measures upon which there appears to be some difference of opinion as to the full bearing of the Act, this Council believe that, in future, measures will most probably be verified and marked by the makers, as they observe has already been done by some parties in London, so that the difficulty and loss to retail chemists will be restricted to any incorrect measures they may have at present in stock. It is true that, although the Act itself is compulsory, some local authorities may yet be very slow in obtaining standards and setting their inspectors to work, still it is the interest of all to have weights and measures so correct that in event of any visit being made officially no one need be annoyed. Of course when district officials receive their instructions it will enable druggists to send existing measures to be verified and if found correct they will be marked in the proper manner, and thus prevent, in many cases, the destruction of those measures in present use.

The Council regret that the decision in favour of the Society and against the London and Provincial Supply Association, Limited, upon which they had in their last report to congratulate the Society, has quite recently been reversed in a higher court. The case has, however, been very properly carried by the Council of the Society to the House of Lords, the ultimate court of appeal, and this Council fondly indulge the hope that, in this last resource, it may be decided in accordance with the whole scope and spirit of the Pharmacy Act of 1868, and that thus an evasion of its provisions on the ground of the party being a corporation, and not expressly specified in the Act, may be prevented.

The Council have to submit as usual the result of the voting, which has been tabulated on the sheet laid on the table.

It was with much regret that they received a declinature from Mr. H. C. Baildon upon his nomination for election. Mr. Baildon has been for so many years associated with all the operations of the Branch of the parent Society that the Council think it proper to take this opportunity of recording their sense of the value of all that Mr. Baildon has done for pharmacy, and especially in connection with the proceedings of this Branch of the Society; and they express a wish that he may yet be spared to assist them in their deliberations and to forward what was the original object of the association. Mr. Baildon was one of its earliest members, and has been unceasing in his efforts to further its best interests.

The report, on the motion of the Chairman, was unanimously adopted.

The President then submitted the result of the voting for the Council for 1880–1, when it was found that the following gentlemen had been elected:—

Mr. William Ainslie ....Edinburgh.
Mr. George Blanshard............ ,,
Mr. Thomas Davison ....Glasgow.
Mr. Daniel Frazer .... ,,
Mr. William Gilmour ....Edinburgh.
Mr. David Kemp ....Portobello.
Mr. W. R. Kermath ....St. Andrews.
Mr. A. Kinninmont...............Glasgow.
Mr. G. H. Laird ....Edinburgh.
Mr. G. D. Mackay .... ,,
Mr. Alexander Napier........... ,,
Mr. John Nesbit ....Portobello.
Mr. A. Seath.........................Dunfermline.
Mr. J. B. Stephenson ....Edinburgh.
Mr. J. R. Young .... ,,

In connection with the election the President stated that 212 voting papers had been sent out, and of these 83 had been given effect to. Two of the papers were informal. All the papers in connection with the nomination and election of the Council were submitted to the meeting.

Mr. Daniel Frazer (Glasgow) proposed the re-election of Mr. J. B. Stephenson as President, and the election of Mr. John Nesbit as Vice-President. Mr. J. R. Young, in seconding the motion, took occasion to refer to the great attention which the President had given to the business of the Branch during his tenure of the office. The motion was also supported by Mr. Kemp (Portobello) and cordially adopted.

Messrs. Stephenson, Napier and Young were re-appointed Auditors.

Mr. John Mackay was unanimously re-elected as Honarary Secretary.

BOTANICAL PRIZE FOR 1881.

A Silver Council Medal is offered for the best Herbarium, collected in any part of the United Kingdom, between the first day of May, 1880, and the first day of June, 1881; and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize, consisting of a Bronze Medal, and also Certificates of Merit, will be given at the discretion of the Council. In the event of none of the collections possessing sufficient merit to justify the Council in awarding medals or certificates, none will be given.

Competitors must be Associates or Apprentices or Students of the Society, and under twenty-one years of age.

The collection must consist of phanerogamous plants and ferns, arranged according to the natural system of De Candolle, or any other natural method in common use, and be accompanied by lists, arranged according to the same method, with the species numbered.

The collector must follow some work on British botany (such as that of Babington or Hooker), and state the work he adopts. The name of each plant, its habitat, and the date of collection, must be stated on the paper on which it is preserved.

Each collection must be accompanied by a note, containing a declaration signed by the collector, and certified by his employer, or a pharmaceutical chemist to whom the collector is known, to the following effect:—The plants which accompany this note were collected by myself, between the first day of May, 1880, and the first day of June, 1881, and were named and arranged without any other assistance than that derived from books.

In estimating the merits of the collections, not only will the number of specimens be taken into account, but also their rarity or otherwise, and the manner in which they are preserved, and should a specimen be wrongly named, this will be erased from the list.

The collection must be forwarded to the Secretary of the Society, 17, Bloomsbury Square, on or before the first day of July, 1881, indorsed "Herbarium for Competition for the Botanical Prize." After the Prize Distribution in October, collections will be retained one month, under the care of the Curator of the Museum, for the inspection of persons connected with the Society, and then returned to the collector, if required.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual business meeting was held on Monday, April 19, in the rooms of the North British Branch, Mr. D. Maclaren, President, in the chair.

The minutes of last meeting having been read and confirmed, the Chairman called upon Mr. Hutton to read the financial statement, which showed a membership of forty-five, giving an income of £5 15*s.* 6*d.*, with a balance from last session of £2 11*s.* 7*d.*, making in all £8 7*s.* 1*d.* The expenditure amounted to £4 2*s.* 9*d.*, leaving a balance in the hands of the Treasurer of £4 4*s.* 4*d.*

The Secretary then read the annual report, from which it appeared that the average attendance at the meetings showed a gratifying increase over the previous session. The papers read during the session had been all contributed by members, and the committee had been able to carry out the printed syllabus in its entirety. The membership showed a falling off of two as compared with last session. Taking all things into consideration the committee did not regard this as any reason for discouragement, but believed that if every member of the Association would make an effort, the membership might be very largely increased.

The President read a letter from Professor Maclagan intimating that the apprentices' prize had been won by Mr. Edwin Reynolds, who was then presented with a copy of Attfield's 'Chemistry.' It was resolved to send a letter of thanks to Professor Maclagan for his kindness in acting as adjudicator.

The following gentlemen were then appointed office bearers for next session:—Mr. J. D. Robertson, President; Mr. W. Aitken, Vice-President; Mr. W. Hutton, Treasurer, and Mr. J. R. Hill, Secretary.

It was resolved to vote the sum of £1 1*s.* to the Benevolent Fund of the Pharmaceutical Society, for the use of the rooms, and to send a letter of thanks to the Council of the North British Branch.

After the transaction of some further matters of detail, the meeting was closed with a vote of thanks to the office bearers and committee for the session just ended.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held at 17, Bloomsbury Square, on Thursday evening, April 8, Mr. R. H. Parker, Vice-President, in the chair.

The President stated that Mr. C. Thompson had kindly consented to defer the reading of his paper, announced for that meeting, to enable Dr. Senier to introduce a second subject into his report upon physical chemistry.

Dr. Senier then proceeded to give his report, which consisted of a lecture with experimental illustrations. The first part of the lecture was devoted to the recent discovery of the solubility of solids in gases, and the researches having a bearing thereon. The substance of this part of the lecture will be found on p. 876 of this Journal. The second part of the lecture consisted of an account of a recent application of phosphorescence, of which the following is a *résumé*:—

A Recent Application of Phosphorescence.

BY DR. A. SENIER, F.I.C., F.C.S.,

Demonstrator of Chemistry in the Laboratories of the Pharmaceutical Society.

It is well known that many bodies possess the property of phosphorescence, that is to say, have the power to a greater or lesser extent of vibrating luminous rays without any appreciable heat after the exciting cause has been removed. Thus many substances continue to emit light when placed in the dark after previous exposure to the sun's rays or to some other sources of light. This phosphorescence by insolation is manifested by bodies generally which are bad conductors of heat, and especially by sulphate, carbonate and fluoride of calcium, shells, petrifactions, the diamond and many organic substances. Bolognian phosphorus, first made in 1602 by calcining barium sulphate, emits a light after insolation, which is said to last more than a day. Similar results have been obtained in the case of Baudoin's phosphorus, made in 1675, by fusing calcium nitrate, and Canton's phosphorus, prepared first in 1761, by calcining oyster shells with sulphur. For most of our knowledge of the subject of phosphorescence we are indebted to Becquerel. He believed that phosphorescence was identical with fluorescence, except that there was a difference in degree respecting the time during which the light continues to be emitted. The phosphorogenic property is known to correspond pretty well with the actinic property of radiation in the position which it occupies in the spectrum. Thus if the dark rays immediately beyond the violet be allowed to fall upon a phosphorescent material, it at once changes their refrangibility so as to bring them within the limits of our visual powers. Thus far the action of the phosphorescent material is similar to that of quinine, but it does more, if placed in the dark it continues for some time to emit rays having colorific properties. Phosphorescence then involves fluorescence; but it is probably not fluorescence only.

It occurred to Mr. Balmain that a phosphorescent material, such as Canton's phosphorus, might be employed advantageously as a paint. Thus we have "Balmain's Patent Luminous Paint," a sample of which I hold in my hand. As a paint simply, it is by no means free from objection. The coarse white powder readily settles from the varnish in which it is suspended, and when the paint is being applied requires frequent stirring. Moreover, the paint is translucent, and several coats do not produce opacity. Through the kindness of Messrs. Ihlee and Horne, of Aldermanbury, the agents for the patentee, I am enabled to exhibit a number of articles coated with this paint. My friend, Mr. Lowe, F.I.C., F.C.S., will assist me in these experiments. It is to be noticed that the various objects emit a bluish luminosity very evident when the gas light is extinguished. It is sufficiently intense to illuminate distinctly near objects, and by the aid of the large framed sheets of glass having on their under surfaces three coats of the paint large print may be made out under favourable circumstances. The bluish tint lasts for an hour or so after illumination by sunlight, or conveniently by burning a fragment of magnesium ribbon, when it disappears leaving a distinct white luminosity for many hours. The life buoy which I exhibit is intended, of course, to float upon water, immersion in which, however, does not affect its luminosity. Diving apparatus has been coated with considerable success. For ornaments and experiments of an amusing nature the paint is well adapted. The framed sheets of glass already alluded to, and which are called Aladdin lamps, are already in use in several places where a faint light is sufficient and where heat is to be avoided—in the gunpowder magazines on board H.M.S. Northampton, etc., etc. By using a concave illuminated surface it is hoped to place an instrument safer even than the Davy lamp in the hands of colliers, to be used at least in times of danger. By its use domestic articles may be readily found in the dark—match boxes, etc. In surgery, for the illumination of instruments in certain cases, I think it may be found of unusual service. Very many other applications of this invention have already suggested themselves, and many more I am sure will yet be found.

After a discussion, to which Dr. Senier replied, a vote of thanks was passed, and the meeting adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting held April 21, Mr. O. Wallis in the chair, Mr. F. W. Branson read a paper on "Chalk, its Origin and Distribution."

The subject was introduced by the author giving a description of the principal rocks, the probable composition and origin of which were then described, as was also the position of the cretaceous rocks in the series. It was pointed out that the oldest primary rocks contained only the remains of the simplest types of life, and it was not until the comparatively recent upper secondary rocks were reached that fossil mammals and dicotyledonous plants were found associated. Chalk was then shown by means of slides to consist chiefly of the minute calcareous shells of foraminifers, the structure and affinities of living representatives being described; from the occurrence of like organisms in deep seas at the present time, it was concluded that chalk is the dried consolidated mud of an ancient deep sea, which covered the greater part of England and Europe. Data were then given proving the slow deposition of chalk, and lastly charts showing chalk areas were referred to.

After a discussion in which several members took part, the usual vote of thanks was passed.

The paper was illustrated by means of numerous diagrams, microscopic slides and fossils.

SOCIETY OF ARTS.

The Chemistry of Bread-Making.*

BY PROFESSOR GRAHAM, D.SC.

Lecture I.

(*Continued from page* 806).

Starch was known to the Greeks; they called it *amulon*, from α and μύλη, indicating that it was not the product of a mill; they did not obtain starch from grinding the corn, but by bruising wheat, and by the employment of water they obtained this fine flour; and, therefore, they called it flour made without a mill. This Greek word has given rise to the scientific word amylaceous, which is used to indicate bodies which contain starch. The method by which starch is obtained from wheat or potatoes is this:—Formerly, it was entirely by a process of fermentation; the corn was roughly ground or bruised, then steeped in water, and allowed to remain for several day until spontaneous fermentation was set up, and the product of this fermentation consisted, as usual, of carbonic acid gas, and its oxidized derivative, acetic acid. There was also lactic acid, formed by the breaking up of the sugar. This, therefore, was a wasteful process. After the glutinous matter of the wheat had been sufficiently disintegrated and broken down, the whole mass was worked in a bag with water, and in that way the fine starch passed through the minute holes in the bag, and ultimately was subjected to repeated washings, in order to get rid of any trace of albuminous matter or glutinous principles that were left, and then it was dried. The process, however, was not only offensive, from the putrefactive decay which went on, but it was also wasteful. In modern times, by much better mechanical rasping in the case of potatoes, grinding in the case of wheat and other materials employed, such as Indian corn, and rice, the principal amount of starch is obtained; but instead of allowing that to undergo fermentation, in order to decay or break up and get rid of the albuminous matter, caustic soda is employed to dissolve the albuminous matter. Caustic soda and caustic potash have the property of dissolving albuminous matters with great ease. You all know the soapy feel which the alkalies have when you rub them between your fingers, and you can very easily, by means of a solution of caustic alkali, dissolve out from an adulterated sample of wool the whole of the wool and leave only the cotton. It is in this way that the modern starch-maker gets rid of the small quantity of albuminous matter that may still remain in the starch after the grinding and washing process. This alkali dissolves

* Cantor Lectures: Delivered November and December, 1879. Reprinted from the *Journal of the Society of Arts*.

away the albuminous matter, but has no action on the starch itself.

Now, starch, however obtained, consists of minute cells, and these cells differ in size and also in form, according to their origin. The cells obtained from potato are about $\frac{1}{150}$th of an inch in diameter; those of sago are about $\frac{1}{300}$th, the cells obtained from wheat are about $\frac{1}{500}$th of an inch in diameter, and there are many smaller than those of wheat. The cell of potato starch, however, is larger than most; indeed, I think it is only exceeded in size by the cell of the maranta and tous-les-mois arrowroots. All the starches have characteristic appearances under the microscope, and it is on account of the difference of form and the difference in size that we are able to detect adulteration; thus, when ordinary potato starch is mixed with arrowroot, or when some cheaper starch is mixed with sago, we are readily able by means of the microscope, to detect and quantify the adulteration.

Starch is insoluble in cold water. Mr. Lewis—who has kindly volunteered his valuable services as demonstrator in this course—is now performing an experiment which everyone in the room has seen, but which I wish to repeat, having shown that starch will not dissolve in cold water. He is now acting on the starch in such a way, by means of heat, as to cause the little cells to be ruptured, and we shall then have the starch material, called granulose, pass out of the ruptured bag or cell, thus giving a solution or emulsion of the starch.

If to a solution of this boiled starch we add a little iodine, we obtain a blue precipitate, a combination of the iodine and starch, the so-called iodide of starch. With bromine we get, not a blue, but a yellowish reaction. This reaction of bromine on starch is so inferior, and of such very slight value in chemical investigations, that we rarely employ it; but the iodine reaction is remarkably sensitive, and by means of it we are able to detect very minute quantities of starch in various infusions in which these small quantities may exist. If we take some soluble starch, and add to it the liquid, called after its inventor, Fehling's solution, which consists of sulphate of copper, or blue stone, to which Rochelle salt, or the double tartrate of potash and soda is added, and then rendered distinctly alkaline by excess of soda, many organic substances, when added to such a solution as this of Fehling's, have no action, even upon being heated; but in the case of some we shall find there is a distinct action. Now, soluble starch does not produce any apparent action to you. I shall presently show you, when we come to consider one of the sugars derived from soluble starch, that we have a distinct attack upon the oxide of copper, which, in this liquid, is associated with sulphuric acid, as sulphate of protoxide of copper. The oxide of copper is deprived of one half its oxygen, which goes to oxidize the sugar, and a red sub-oxide of copper is formed, which you will presently see.

When soluble starch is examined by means of light that has been previously polarized, a remarkable action takes place. Polarized light is light which has been so acted upon that, instead of the ray of light vibrating in all planes at right angles to the axis of the direction of the ray of light—as when it has been acted upon either by a plate of glass inclined at an angle of 35° 25″ to the incident ray, or by means of tourmaline or a Nicol's prism, or in many other ways—it is compelled to vibrate in two directions only. The vibrations of light are not like those of a knot on a string. If I had a string fastened at the other end of the room, with a knot in it, and caused it to vibrate, the knot would only vibrate up and down in one plane, but with a ray of light the vibrations take place in every direction at right angles to the axis of the ray, so that a section of it would have the appearance of the spokes of a wheel. It is thus different from the vibration of a knot on a piece of string, or of a bladder, or of a boat floating on the ocean where there is a wave motion passing towards the shore. Now, an inclined plate of glass, a crystal of quartz, a Nicol's prism of calc-spar, have all of them, more or less, the power to convert these vibrations into two distinct sets. All these various wave motions are converted into one-half, which vibrates in one plane, and the other half vibrating in a plane at right angles to it. If a ray of light strikes an ordinary sheet of glass at an angle of 35° 25″, half of it will pass through the glass, and half will be reflected, and both halves will be polarized. They will be compelled—no longer to vibrate in an indefinite number of planes, all being at right angles to the axis of direction of the ray—but to vibrate in two planes, the whole of one set vibrating in one plane, and all the rest in the other, both sets of vibrations being in planes at right angles to each other, and also at right angles to the direction of the ray of light. Perhaps, as simple an illustration as any, is to take a wheel of a carriage together with the axle. Let the axle represent the direction of the ray of light, and let the numerous spokes of the wheel represent the numerous planes of the vibrations of ordinary light. These planes are variously inclined to each other, but all are at right angles to the axle, *i.e.*, the direction of the ray of light, in the same manner as the plane of vibration of the knot in the string is at right angles to the direction of the wave track. Now, imagine that the numerous spokes of the wheel are replaced by a $\oplus$ of two bars at right angles to each other, and manifestly also to the axle. In precisely the same manner the numerous planes of vibration of ordinary light are converted into vibrations in two planes at right angles to each other, and of course, also at right angles to the direction of the ray of light. Now, if I have previously polarized our light, and I have by certain means got rid of one-half of the light which is vibrating in one plane, and only use the other portion vibrating in the plane at right angles to it, I then find that if that light is passing through a tube to my eye, that some liquids, *e.g.*, water, would have no action at all, and I should find no difference; but, in the case of other liquids, I am obliged, in order to see the light required, to rotate the instrument either to the right or to the left in order to get the particular light which I had before. All these substances which so act on the plane of polarized light, and cause it to be rotated so that I must turn the instrument to the right in order to see the light, are called dextrorotary bodies. The other substances which rotate the plane of polarized light to the left, are called lævorotary. The amount of rotation brought about by a solution of starch is no less than 216°. In fact, I am obliged to rotate the tube nearly two-thirds round, in order to get the tint which I saw before putting the solution of starch into the tube.

Another interesting matter that I wish to draw your attention to, is the action of soluble albuminoids upon starch. I have here an analysis that represents the chief class of albuminous bodies, such as white of egg, and bodies analogous to it.

There are, no doubt, numerous bodies more or less resembling white of egg in general composition, some being soluble in water, others insoluble. There are considerable difficulties in arriving at the true molecular weight of such complex uncrystallizable substances as the albuminoids, and up to the present, we are unable to assign, with accuracy, any formula to these bodies. According to Lieberkühn, the albumen from white of egg has the following centesimal composition:—Carbon, 53·1; hydrogen, 7·1; nitrogen, 15·7; oxygen, 22·1; sulphur, 1·8, and from this he deduces the formula $C_{72}H_{112}N_{18}SO_{22}$. This, of course, is hypothetical, the probabilities are that the molecular constitution of many of the higher albuminoids is much more complex than is represented by Lieberkühn's hypothesis. Now, on comparing the centesimal composition of starch:—Carbon, 44·44; hydrogen, 6·17; oxygen, 49·39, = 100,—we see that in the albuminoids the carbon and hydrogen amount to 60 per cent. in the carbohydrates of the starch type these amount to 50 per cent. The characteristic difference, however, is in the substitution of nitrogen for a part of the oxygen.

If we take any substance containing an albuminoid, and it will be convenient for our purpose to take an infusion of ordinary malt, we shall find that on the unbroken, unboiled, cells of starch, the infusion of malt will have very little action. The infusion of malt itself contains some sugars, and, unfortunately, it is not easy to obtain, from a vegetable infusion, albuminoids without at the same time having sugar products formed; but at any rate you will be able to see a marked difference between the action which takes place when malt infusion is added to unboiled starch, and when it is added to a starch in which the cells have been previously burst and the granulose matter allowed to exude from the rupture. This is some starch to which malt infusion was added. You saw it was blue before adding Fehling's liquid, and it is blue now, after boiling. In other words, there is nothing that is reducing or taking away the oxygen from the oxide of copper. It still remains the ordinary protoxide. In this other tube, previous to the malt infusion being added, the solution of starch was boiled, that is to say, the starch cells were broken up by boiling, and here you see there is an action on the oxide of copper which must be perceptible at the other end of the room. That is a reaction by which some sugars decompose oxide of copper, robbing it of half its oxygen. This reaction only takes place near the boiling point, so that we are obliged to heat such solutions. You see now the production of a yellow colour, rapidly changing to red.

The reason I have shown you this experiment, is that I shall have occasion to refer hereafter to a very interesting process by which the baker long ago found out, before scientific men were able to tell him anything about it, the importance of using the material called in the trade, "fruit." This is simply potatoes. They do not take unboiled potatoes, but they boil the potatoes thoroughly, so as to entirely destroy the cell wall, and to allow the whole of the matter to exude from the cells; then they add this preparation, together with a small quantity of flour, to the yeast, in order to prepare what they called "ferment." The object in doing so, I shall hereafter explain to you, and it is a most ingenious and able application of empirical science to bread-making, by which as small an abstraction and degradation as possible of the albuminoid matters, and of the starch of the flour, is allowed to take place, and yet a sufficiently abundant disengagement of carbonic acid as is necessary to make a light porous bread is brought about.

Mr. Lewis will now take this infusion of starch and add to it a small quantity of dilute sulphuric acid—hydrochloric acid would do equally well—he will boil it for a short time, and you will find the starch is converted into sugar. You will remember I showed you that Fehling's liquid is not affected by the simple solution of starch, but if we take the solution of starch and boil it for a short time with dilute sulphuric acid, or hydrochloric acid, we shall convert the starch into sugar bodies. I shall have occasion hereafter to direct your attention for some time to the nature of the various sugar bodies—maltose, dextrin, and so on—that are formed in such cases, as they arrive. I shall be able to show that the same action has taken place by making use again of this valuable reagent of Fehling.

If starch be heated to the temperature of about 300° F., more especially if there be a slight quantity of moisture in the starch, it is converted into a substance which is called British gum. We call it dextrin because it differs from the ordinary gum arabic in its action upon the plane of polarized light. Dextrin is called so because it rotates the plane of vibration of polarized light 209° to the right. Here is a specimen of it. Dextrin may be prepared from starch in a variety of ways. The most convenient is to mix 2 parts of nitric acid, or aquafortis, with 300 of water and then apply that very weak acid liquid to 1000 parts of starch. They are thoroughly incorporated and left to dry in the air or by other convenient means. When dry, the substance is heated to the temperature of 220° F. A much lower temperature is sufficient when the acid has been previously employed than when merely dry starch is used. Another method of making dextrin from starch is to take starch, and boil it in a small quantity of water, then add to that, an infusion of malt. The malt converts the starch into a variety of products, but the first action is to convert the starch into maltose—which is a sugar I shall have to describe to you hereafter—and dextrin. So soon as the iodine liquid indicates that the starch has disappeared, or that the whole, or nearly the whole, of the starch has disappeared, it is then rapidly boiled, in order to prevent the ferment in the malt infusion carrying on the hydration of the starch any further, the object being to obtain the gum or dextrin, and not maltose sugar. I said that mere heat would convert starch into dextrin, but much more so if the heat be moist. The Vienna baker, and, imitating him, the Parisian baker, employs this ingenious reaction in the glazing of the beautiful rolls of Paris and Vienna. It is their practice, and it is adopted in London by a few of our bakers, to allow steam from a boiler to be injected into the oven just as the bread is about to be placed in it. This steam, coming in contact with the highly-heated walls of the oven becomes superheated; it is not wet steam, but perfectly dry steam. The bread is, however, wet on its surface, and placed in this atmosphere, and the action of the steam upon the surface of the roll is to cover it with a beautiful layer of British gum, just the same as you will find at the back of postage stamps, which is also made from starch.

Dextrin or British gum, when made by either of the processes I have described, possesses the following properties:—It is a gummy body, resembling in its viscosity the ordinary cherrytree-gum and gum arabic. It is employed largely in calico printing as a thickener, for the purpose of printing on the cloth the necessary mordants and colours. Dextrin is soluble in cold water, and starch, you will remember, is not. A solution of dextrin is precipitated by alcohol—more or less. You see the clear liquid is rendered turbid by the addition of alcohol. Iodine gives with dextrin little or no action.

There are two or three modifications of dextrin—erythro dextrin, which gives a brown tint on the addition of iodine; the others, achromatic dextrins, give no colour reaction, and are, according to Brown and Heron, the most numerous. Dextrin has no action on the Fehling's liquid, that is to say, pure dextrin, but if you repeat the experiment upon ordinary commercial dextrin, you will find there is a little action. This is owing to the mode of preparation. In acting upon starch by means of acid—which I have already shown you is one of the methods for making dextrin from starch—a small quantity of sugar must be formed. On the other hand, if you use the malt infusion, it cannot form dextrin without also forming maltose sugar, and hence, therefore, we have sugar formed as well as dextrin. The chemist has means at his command of separating from the ordinary dextrin the sugar, and also the starch, so as to obtain nothing else but dextrin, and a sample of dextrin so obtained has no action upon Fehling's liquid any more than a solution of starch has.

(To be continued.)

Parliamentary and Law Proceedings.

Result of an Action by an Assistant.

At the Woolwich County Court, on April 14, Before J. Pitt Taylor, Esq., Judge, the case of Holloway *v.* Carter, came on for hearing. This was a claim for a month's salary, £2 10*s*., and a quantity of patent medicines, pills, and other articles, held by defendant, and which were claimed by plaintiff as his property. Mr. Peake, solicitor, appeared for defendant.

Plaintiff said he had been an assistant to defendant, who keeps a chemist and druggist's shop, opposite the Arsenal Station, at Woolwich. He first went to defendant's on September 15, and left on November 13, two days less than the full month. He received one month's warning. Two days before the second month was up, defendant discharged him, and refused to pay him his wages or give up his property. The reason for so doing was that defendant accused witness of robbing him of medicines and pills, and also of selling goods on his own account. His time was his own after eight o'clock at night, and after that hour he used to sell pills and patent medicines on his own account. In his answer to Mr. Peake, he said he got the coated pills (produced) from a chemist named Kirby, in London, but he had no invoice with them. They were not sent to him in the boxes they were now in, but in a tin case, and he put them in the boxes himself. The reason why he put them in boxes was because they were some boxes given him by Mr. Twemlow, who was defendant's predecessor in the business; that he would swear to. They were given to him by that gentleman last August. Mr. Twemlow was not present, but he had seen him the previous day at his place of business in Castle Street, Holborn, London. Some envelopes marked "sudden death to fleas" were produced, which he said belonged to him, and were also given him by Mr. Twemlow when that gentleman left the business. He came into possession of the pills and patent medicines produced when he (witness) was in business in Bermondsey. He could not tell how Twemlow's name came on them, as he did not put it on. A railway blind and sling used for resting the arm in, was then produced, which he swore was in his room when he went into it first.

Plaintiff's brother, Eustace Holloway, swore the goods produced were his brother's; but he contradicted himself so much that the Judge told him to stand down.

At the request of Mr. Peake, plaintiff was recalled, and in answer to questions, said the reason why he only claimed 15 gross of pills and two dozen of patent medicines, when in his room was found 20 gross of the former and three dozen of the latter, was that he did not know exactly how many there were.

That being the plaintiff's case, Mr. Peake said the plaintiff had been selling pills and patent medicines on his own account to persons, and the inference was that he must have taken those goods from the shop of Mr. Carter, his employer, as he should endeavour to show. He then called the defendant.

Mr. John Carter, who said he took the business in September last of Mr. Twemlow, and engaged the plaintiff as an assistant, under a Mr. Rideal, who had charge of the business in his (witness's) absence, he being engaged in town, and not able to get to the shop till late at night. He paid plaintiff £30 per annum, and found his food and lodging, but as he had no room at his own house plaintiff and Mr. Rideal lodged at a Mr. Martin's, at No. 51, Sandy Hill, Plumstead. On the evening of the 10th of November Mr. Rideal told him something, and he gave him certain instructions, which resulted in the boxes of the plaintiff being searched, when in them were found the pills, patent medicines and other things produced. They were brought down to his shop, and the next morning when plaintiff came in, he told him that his services were no longer required and told him the reason why. Plaintiff said the things were his own, and he told him if he could prove it he should have them and his money too. Plaintiff said he bought the pills from a Mr. Kirby, of London, and witness immediately telegraphed to Mr. Kirby, whose answer satisfied him that plaintiff had not bought them of that gentleman. The whole of the medicines were such as the plaintiff could easily get rid of. Defendant further said that he considered it dishonest for a servant of his to sell goods of the same description as he did in his own time.

Charles Rideal, student of medicine, at one time chief assistant to Mr. Carter, related upon oath the finding of the medicines in the plaintiff's boxes, and said he could unhesitatingly swear that they were the property of Mr. Carter.

Defendant called two witnesses to prove that plaintiff had sold them pills of a night after eight o'clock, and that the parcels of medicine sent by the defendant's errand boys from defendant's shop to Sandy Hill, had, by the same boy, been afterwards taken to the house of a person in Burrage Road, who sold pills and other medicines to little shops.

At the conclusion of the case, his honour said he had no hesitation in saying that, in his opinion, plaintiff had been systematically robbing Mr. Carter, and that he had been very properly discharged by his employer. Judgment would be for defendant with costs of defendant, his solicitor, and three witnesses, two of them with subpœnas.—*Kentish Independent.*

Poisoning by Opium.

On Tuesday afternoon, Mr. Harris held an inquest, at Catford, on the body of George Heath, aged twenty-five. It appeared from the evidence that deceased, who had been a teetotaller for several months, was of a very excitable temperament. He resided with his father, and assisted him in his business. Something had occurred to excite the deceased on Saturday, and in the evening he was in the Black Horse, Rushey Green, Lewisham, and drank raw spirits and ale, his usual drink being lemonade. There he parted with a friend named Allbury, saying he should never see him again, and went to the shop of Mr. Reed, chemist, High Road, where he purchased two separate quarter ounces of opium, which he said he wanted for a restless mare. He had often been served with opium for vicious horses. He was seen at midnight to enter his father's stable, and nothing more was seen of him until his father's stableman went on Sunday morning to feed the horses, when he found the deceased lying in the hayloft in an insensible state. Mr. Steele, surgeon, was sent for, and the deceased was removed to his house, where he died at one o'clock the same day. A paper was found in the stable, which was labelled "Opium, Poison."

Mr. Steele said the symptoms were those of poisoning by opium. Four grains of opium would destroy life, but the paper had contained a much larger quantity.

The jury returned a verdict "That the deceased had committed suicide while labouring under temporary insanity."—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 20th January, 1880, Mr. Richard Lawton Smethurst, Chemist and Druggist, Salford, Manchester. Aged 59 years.

On the 22nd of January, 1880, Mr. Joseph Harrison, Chemist and Druggist, Stanningley, Leeds. Aged 62 years.

On the 1st of February, 1880, Mr. Matthew Tombs, Chemist and Druggist, High Street, Leominster. Aged 65 years.

On the 29th of March, 1880, Mr. William James Lankesheer, Chemist and Druggist, late of Bath. Aged 39 years.

On the 9th of April, 1880, Mr. Epaphroditus Dunn, Chemist and Druggist, Dudley. Aged 61 years.

On the 10th of April, 1880, Mr. Edward Fitt, Chemist and Druggist, Barking, Essex. Aged 69 years.

On the 18th of April, 1880, at Debenham, Mr. Charles Frederick Marchant, Pharmaceutical Chemist, late of the Butter Market, Ipswich. Aged 59 years. Mr. Marchant had been a member of the Pharmaceutical Society since 1846.

Erratum.—In the notice of the death of Mr. T. H. Pickup (before p. 846), it was erroneously stated that he carried on business in Preston. Mr. Pickup served his apprenticeship in Preston; afterwards he established a business in Blackburn, which he conducted for forty years.

Dispensing Memoranda.

Replies.

[399]. In answer to O. G., I should say the physician intended ext. tarax. liquid, which is sold under that name by wholesale houses.

R. A. C.

[399]. I do not wonder at the medical attendant's surprise at D. G's. mixture; and have never in any West-end establishments seen Battley's liquor used for the fluid extract, but a thick ext. tarax. liq. which is sent out by all the wholesale houses.

J. H.

[400]. It must have required a great stretch of imagination on "Junior's" part to think the prescriber meant the bottle to be covered with tinfoil, as his directions are perfectly plain. The lotion is first to be applied to the parts, and then covered with tinfoil. Had it been oiled-silk ordered instead of the foil he would surely never have thought of covering the bottle with that.

J. H.

[400]. The lotion not being affected by light, I should take it for granted that the prescriber meant the parts to be covered with tinfoil to prevent evaporation.

Y. T. R.

[401]. The following is contained in the Pharmacopœia, Aberdeen Hospital:—

Mist. Scillæ.

℞ Syrupi Scill. . . . . ℥ij
Aqua Menth. Pip. . . . . ℥j
Aqua . . . . ℥v
M. ft. mist.

BLOXAM.

A similar answer has been received from "Geo."

[401]. In answer to K., the following is a formula given in Beasley's 'Pocket Formulary' for mist. scillæ:—

℞ Oxymel of Squills . . . . . . ℥iv.
Hyssop Water . . . . ℥iij.
Peppermint Water . . . . . ℥j.
Spirit of Nitric Ether. . . . . ʒss.

J. S. NORMAN.

A similar reply has been received from G. Picknell and J. B. T.

[401]. If K. will refer to Squire's 'London Hospitals' he will find two formulæ for mist. scillæ, viz.—

Acetum Scillæ . . . . ♏ 40.
Aq. Pimentæ . . . . ad ℥j.
And
Acetum Scillæ . . . . ʒss.
Ac. Acet. Dil. . . . . ♏x.
Aq. . . . . ad ℥j..

I should think the latter of these is intended in the prescription.

R. A. C.

A similar answer has been received from R. J. Y.

[401]. K. will find two formulæ given in each of the following works:—Beasley's 'Pocket Formulary,' and Squire's 'Pharmacopœias of the London Hospitals,' for the preparation of "mistura scillæ." As the writer of the prescription did not notify his authority for this "mixture," it would be perfectly justifiable on the part of the dispenser to use either of the forms given in the works mentioned.

C. T. M.

[401]. The following is a formulæ for mist. scillæ, University College Hospital, as given in Beasley:—

℞ Oxym. Scillæ . . . . ℥j.
Syr. Poppies. . . . . ℥j.
Water . . . . ℥iv.
Mix.

G. PICKNELL.

[402]. In answer to "Jacque" I think the B.P. pulv. cretæ aromat. c. opio. should be used.

R. A. C.

[402]. When pulv. cretæ co. c. opio. is prescribed, the P.L. preparation should be used.

D. T. D.

[406]. If C. L. S. were to dissolve the pot. iod. and pot. citras. in half the quantity of aq. chlor., then separately, in a mortar, mix the quinæ sulph. and pulv. tragac. co., and to this add the vin. colch. and tr. card. co., and the remainder of the menstruum ordered (this should then be introduced into the bottle with the other ingredients already in solution and thoroughly agitated, so as to diffuse the quinine), the appearance of the mixture would be "pinkish."

It is evidently the intention of the medical practitioner to administer the quinine in a state of suspension.

C. T. M.

Queries.

[407].
℞ Hyd. Perchlor. . . . . gr. $\frac{1}{20}$.
Pot. Iodid. . . . . gr. $\frac{1}{2}$.
Ext. Aloes Barb. . . . . gr. j.
M. ft. pil. s. q. m. xij.
c. i. o. vel alt. noct.

Will some of your readers kindly inform me what s. q. is intended for?

R. A. CRIPPS.

[408]. I shall be glad to know what was intended by the following:—

℞ Zinci. Phosp. . . . . gr. iij.
Ext. Gent. . . . . q. s.
Ft. pil. mitte xxiv. Cap. j ter die.

If the phosphide is meant, is the dose excessive (9 grains daily), as it must contain a large amount of combined phosphorus; or can either the phosphite or phosphate be meant? I am not aware if these are used medicinally; if they are, I shall be pleased to know their doses. Writer of prescription unknown.

J. H.

Notes and Queries.

[652]. CHILI PASTE FOR RHEUMATISM.—
Olive Oil . . . . 2 lbs.
Powdered Chilies . . . . . $\frac{1}{2}$ lb.

Boil for seventy-two hours and add 6 oz. melted spermaceti. Scent with ol. lavand., q. s.

W. H. BROWN.

[655]. TRANSFER INK.—I have been asked for a recipe (or where such ink can be obtained) for the ink used to draw patterns on paper, which, when they are simply rubbed on silk transfer the patterns thereto for crewel work.

I should be much obliged if anyone will supply me with the information.

APPRENTICE.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

The Election of the New Council.

Sir,—For one, I fail to see why Mr. Gostling should take up the cudgels for Mr. Shepperley, and hold him up to our gaze as a suitable representative of our interests, or the trade in general.

We look rather to send representative men to the Board —men whom we can look up to, and whose tone and influence will have a tendency to elevate and benefit the body pharmaceutical. Now it seems to me that the qualification —if such it may be called—that this gentleman possesses, is, that he was the victim of the apothecaries' persecution, and I fail to see how, in any shape or form, this fits a man for a seat at the Council. On the contrary, the very *modus operandi* by which Mr. Shepperley carries on his business is one which would be repugnant to most educated pharmacists. Of course, this is purely a matter which concerns himself; but the making everything in the shape of medicine wherever possible into a patent medicine, with a view to assume functions which are the peculiar privilege of the medical profession, and taking refuge in so doing behind the patent medicine stamp (those who have seen the explanatory circular he issues, recommending some particular bottle or powder, from No. 1 to No. 60, for every ailment under the sun, will understand what I mean), would be, in the opinion of most gentlemen, a proceeding scarcely to be emulated, particularly if we are going to endeavour to cultivate a spirit of good will and fraternal feeling with the members of the medical profession with whom we come in contact.

I trust we shall be increasingly careful to select those representatives who will not only study our trade interests, but help to make us respected as pharmacists by other professions.

I think the trade will be more and more disposed to avoid the patent medicine trade and all that pertains to it, in the future, and, if we have any self-respect left, very rightly so too, when one is inundated with circulars from patent medicine proprietors offering "prizes"—forsooth!— to those who will buy a certain quantity, or will prove that they have bought the same in a given time, of their special nostrums. It is high time for the educated pharmacist to cut this class of thing and consign them and their goods and prizes to those who may be attracted by such baits, or to the grocer or draper. For these and other reasons too obvious to need detailing here, let us elect representatives who will really represent what we most value and care to cultivate and conserve.

Pharmacist.

Sir,—I see that my letter, suggesting Mr. Shepperley's retirement, has elicited a reply from an ardent supporter of that gentlemen's candidature. Probably it is his strong partisan feeling which enables him to detect insinuations in my letter, which I myself, and I venture to assert any impartial reader, would fail to find in it. The fact is, I know nothing of Mr. Shepperley personally. For aught I know to the contrary, in experience and knowledge he may be eminently fitted to be a member of Council. The single point which I wished to raise was this, whether it is not extremely undesirable for us to have on our Council the defendant in the most notorious and protracted of counter practice cases. Certainly our placing Mr. Shepperley on the Council would arouse the suspicion of the Society of Apothecaries, in the same way as our raising a memorial to the ex-Prince Imperial in Westminster Abbey is calculated to awaken the distrust of the French Republic. Mr. Shepperley's advocate thinks that our recognition of this fact betrays fear. I don't; but I believe in the maxim "discretion is the better part of valour." We are far more likely to be gainers by a policy of conciliation than by one of irritation and defiance.

In conclusion, I will state, in reply to your correspondent's query, that I am not and never have been a member of Council, nor am I nominated this year: it is only of the Society that I am

A Member.

Sir,—I was not only a subscriber to the special fund of the Trade Association for the defence of the Shepperley case, but obtained several donations for the same object, and of course the action of the Association had my hearty approval. To defend our rights was a very proper course to take, and I have no doubt it met with the approval of chemists generally. But I cannot think it is desirable to place the victor in a position where he may be called upon to ask favours of the very men he so lately successfully opposed. What we now want in the Council are men who will not only use their energies to protect our trade, but do what they can to carry out the intentions of the founders of the Pharmaceutical Society in obtaining for those who have fitted themselves for dispensers of medicines a greater share of that branch than they now enjoy, and I would rather make this a test for fitness of office than any other. R.

Sir,—Having read two letters from two members of the Society, concerning the condidature of Mr. Wills for the Council, I do not think they have shown the slighest reason why he should not be a condidate.

If he were on the Council and one of those who would select the Examiners, he could not possibly influence them in the conduct of the examinations. And he has stated that he does not wish the standard of the examinations to be altered. And from his position as teacher I think he is in every way competent to know the requirements of students. F. G. W.

Volumetric Estimation of Alkaloids.

Sir,—I am sorry to find it is necessary again to reply to Mr. Moss, as my last letter undoubtedly explains all that gentleman does not understand.

The calculations made by myself were exactly the same as those Mr. Moss has made, and the results, expressed to the nearest milligram, are also the same.

As I have frequently reiterated, these results are calculated from the known quantities in the formula—

$$3(BiI_3)2(\overline{Q}HI)x(HI).$$

It may be equally correct to say the results are calculated from the formula,—$3(BiI_3)2(\overline{Q}HI)$, but, inasmuch as the former I believe correctly represents the nature of precipitate, and the latter does not, I prefer my method of expression.

In the original MSS., "xHI" was added to all the formulæ, but I afterwards thought it advisable to add it only to those in which I knew "x" was not "O."

Buxton. John C. Thresh.

Fish in Foul Water.

Sir,—Referring to the article on River Water, March 27, by Dr. Tidy, a statement was made some time since in the *Hants Chronicle* that trout were found to affect sewage in the Ichen and to grow a large size in it. In that case, the presence of fresh water fish in a river would be no guarantee of the purity of the water. Rivis.

F. G. W. does not appear to have sent the whole of his letter.

H. C. H.—(1) *Nepeta Glechoma*; (2) *Rumex Acetosella*; (3) *Veronica Chamædrys*; (4) *Arenaria trinervis*; (5) *Stellaria Holostea*; (6) *Geranium molle*.

Dr. F. A. Castle is thanked for his communication.

W. Kennedy.—Hooker's 'Flora' would be best for a beginner, and Babington for a more advanced student.

"*Assistant.*"—The recipe for the preparation is a trade secret, and the right to the exclusive use of the name has been maintained in a court of law. See vol. viii., p. 578.

A. A. is thanked for his advice. With respect to his query he is recommended to consult a good modern dictionary.

T. R.—Apply to the Registrar under the Medical Act, 315, Oxford Street.

"*An Apprentice.*"—We know of no way of compelling a master to go beyond the terms of the indenture; but perhaps what you cannot claim as a right might be accorded as a favour if proper application were made by yourself or your friends.

A. W. Forster.—Several formulæ for pepsine wine were given in the last volume (vol. ix., pp. 521 and 543).

Communications, Letters, etc., have been received from Messrs. Becket, Norman, Hatch, Ross, Clark, Countryman, M.P.S.

THE BOTANICAL SOURCE OF TONGA.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

Mr. A. W. Gerrard recently placed in my hands a portion of tonga for examination, with the remark that the medicinal properties were in all probability contained in the fibrous portion.

I observed that the fibrous portion occupied the bottom of the little bags containing the tonga, the centre being filled with bark, amongst which a few morsels of broken leaves were scattered. The mode of arrangement seemed to confirm Mr. Gerrard's supposition that the fibrous portion was the most important ingredient.

The fibrous portion was therefore first examined. Under a lens it showed an endogenous structure, and when a small portion was placed under the microscope a few prismatic raphides and a large number of starch granules, some of them collected into small spheres, were observable. The starch granules somewhat resembled in shape those of the common arum, although they were larger in size, and the source of the drug was therefore sought for in the Araceæ.

On referring to Seemann's 'Flora Vitiensis,' the genus of that family most likely to produce a stem like the fragments found in tonga was considered to be *Rhaphidophora*. On comparing the structure of a small cylindrical portion given me by Mr. Gerrard with the specimens of the plants of that genus in the Herbarium in the British Museum, it appeared to correspond with the stem of *R. Vitiensis*, and having been permitted by the courtesy of the keeper of the Botanical Department to examine a fragment of the stem of that plant under the microscope, I found that the starch was of the same shape and size as that of tonga, and like it presented the curious character of agglomeration into little spheres. The prismatic raphides, also, were present as in tonga. In a carefully cut section of the tonga numerous sphæraphides are seen, and here and there a few scattered solitary crystals of a tabular shape. The sphæraphides are present also in the *Rhaphidophora*, but the section of the latter was too small to ascertain the presence of the tabular crystals. The cellular and vascular structure also corresponds with that of tonga. I have therefore no hesitation in referring the fibrous portion of tonga to a species of *Rhaphidophora*. In all probability the species yielding it is *R. Vitiensis*, which Engler, in his recent monograph,* makes a variety of *R. pertusa*, Schott.

Dr. Seemann makes no mention in his magnificent work of any medicinal use for this plant, but Dr. Masters, in the 'Treasury of Botany,' mentions that *R. pertusa* (*Scindapsus pertusus*, Schott) is used as a remedy for rheumatism and skin diseases. So many of the aroids contain an acrid, often volatile principle, that apparently but little attention has been paid to searching for other active principles, and Mr. Gerrard has done good service in showing that one member of this family, although retaining no acridity of taste, possesses an active alkaloid.

The bark which is mixed with the stem in tonga appears to resemble in its sweet and slightly astringent taste that of monesia bark and the "sweet bark" of Queensland; both of these barks are derived from trees belonging to the Sapotaceæ, and it may be presumed the tonga bark is derived from some member of the same family. The fragments of leaves are of exogenous structure, and are probably added as a blind, since they differ from those of the two families to which the other drugs belong, these leaves being present in minute quantity only and often absent altogether from the packets of the drug.

* Engler, 'Araceæ,' vol. ii., p. 244.

THAPSIA GARGANICA, OR BOU-NEFA OF THE ARABS.*

BY C. BLANCHET.

The *Thapsia garganica* is an umbelliferous plant which during recent years has attracted considerable attention in France, it yielding a rubefacient resin that has been made the basis of numerous preparations. Among the Arabs it is now known under the designation "bou-nêfa" (god of health), but in the time of Dioscorides it was called "dritz." In the present day the inhabitants of the Cyrenaican district call it "dérias," and the Kabyles use it under the name "deriés." A few years since it was alleged that the plant known to the inhabitants of the Cyrenaican district as "drias" was the real silphion plant of the ancients, and Dr. Laval, who collected the plant, described it as a new species, to which he gave the name *Silphium Cyrenaicum*. This claim, however, was refuted in an exhaustive treatise by M. Herincq, who demonstrated that the plant was identical with the *Thapsia garganica* of Southern Europe.† The author of the present paper, in the course of a lengthy section on the botany of the plant, expresses his agreement with the conclusions of M. Herincq.

The root bark of the *Thapsia garganica* is largely used as a medicine by the Arabs and Kabyles, internally against leanness, chronic diseases of the lungs and sterility; and externally as a remedy for rheumatic pains, gout, coughs, bruises, eruptions, etc. For internal use the bark, after drying, is reduced to a powder, and this is frequently made into a paste with roasted semolina, flavoured with honey and butter; the paste is called "taminat-bou-nêfa," and preserved for use when wanted. Semolina is also added to water in which fragments of the root have been macerated seven days. The water becomes albuminous, milky, and contracts a decided bitterness and disagreeable taste. Sometimes a tablespoonful of the powder is simply added to a glass of water and taken as a dose. Another plan is to cut the cleaned and dried root into slices which are boiled in a little rancid oil; the oil preserves the active principles and the slices are rejected. A preparation is made also by cooking "couscousso" in the vapour of water in which bou-nêfa has been boiled several hours.

A decoction of the root prepared in closed vessels is used for fumigations. As a purgative, the Arabs and Kabyles boil eggs in a decoction of the fresh or dried roots, one or more being eaten as a dose. Finally, as a remedy in long-standing pulmonary complaints, a drink in which the natives have great confidence is made by boiling fragments of the fresh or dried and cleaned bark in milk, about 150 grams to a litre. It is stated that the natives are not very particular as to the doses of these preparations, and the patients are consequently sometimes purged violently, chronic or acute diarrhœa and even abor-

* Abstract of a Thesis presented to the Montpellier School of Pharmacy. Communicated by the Author.

† *Pharm. Journ.* [3], vol. vii., p. 750.

tion being occasionally the result; no fatal cases, however, have been recorded.

For external use, the natives crush the roots and dry them under the ashes. The roots are afterwards cut into pieces with which the parts affected are rubbed In veterinary medicine the Arabs obtain good effects with an ointment prepared by digesting the fresh or dry root in tar.

The collection of thapsia in Algeria is made exclusively by the natives. It is commenced in December, about a month after the appearance of the first leaves, and is continued to the end of March; it is never extended beyond the appearance of the stem, which takes place about the middle of April. The plant contains the greatest quantity of active principle in January, but the natives in Constantine prefer for their own use the roots gathered in March, though why is not known. Only the roots are gathered, the leaves being cut away. When a sufficient quantity has been obtained, the roots are taken to the nearest stream and washed; an incision is then made longitudinally and the bark is removed from the central portion, an operation that is easily effected when the root is of a suitable age. The central part is rejected, as nearly the whole of the active principle of the plant is contained in the bark of the root. The bark is sometimes brought in by the collectors in the fresh state, and sometimes it is dried by spreading it out in layers, three or four inches thick. When collected in large quantities for a special market the fresh clean bark is worth 25 to 30 francs per 100 kilograms.

The collection is not pleasant work, nearly all those engaged in it returning with faces, arms and testicles puffed up and swollen. The Kabyles, who take less precaution than the Arabs, have frequently the whole body covered with pimples, which suppurate. Sometimes the collectors are seized with fever; but the worst cases are cured in a few days.

The root freshly cut is fleshy and heavy; by drying it loses about three-fourths of its weight.

The root bark of thapsia is not met with in European commerce. In the dry state it occurs in small unequal fragments, 4 to 10 millimetres thick, friable and brownish yellow on the external surface, which is sometimes smooth, and sometimes has more or less deep wrinkles that mark out small, prominent, convex, irregularly quadrilateral spaces. The internal surface is white, chalky-looking, often spotted with red, brownish, and finely striated longitudinally. The fresh surface of a section often exhibits a very clear golden yellow resin, which is found also in the internal crevices of the bark. The fracture is granular and compact. Examined with a glass it appears riddled with closely approximating, concentrically arranged, yellow-walled pores, amongst which is interposed the white chalky-looking tissue that forms the greater part of the mass. The bark retains for a long time the petiolar *débris*, represented by rosettes of fibres.

Together with the *Thapsia garganica* there grows another umbelliferous plant, called by the Arabs "cleka," and by the Europeans "false thapsia." This is referred by the author to *Ferula nodiflora*, Linn. (*F. communis*, Desf., *F. densa*, Delil.). The root of this plant is perennial, fleshy, greyish, nearly black on the exterior, and contains an abundance of an acrid milky juice, devoid of any vesicating action. Deprived of the ligneous portion and dried it presents a great resemblance to the bark of *Thapsia garganica*, and is now largely substituted by the Arabs for it. When the root is in a fresh state this fraud may be detected under the microscope. In the thapsia the primary interior layer of the liber is constituted by a series of broken concentric lines; in the cleka the layer is formed by a continuous line, and the resinous canals, which are regularly distributed, appear especially in the interior, whilst in the thapsia they are found especially in the exterior of the liber layer. When dry these characters can no longer be detected, and dependence must be placed on the colour of the external surface, which in the thapsia is brownish yellow and in the cleka greyish and nearly black. After the barks have been dried a long time, however, exfoliation takes place and the sophistication is difficult to determine.

The first recorded chemical examination of the root of *Thapsia garganica* was made by M. Stanislas Martin, who reported that he had found in it a rubefacient resin, tannin, starch, extractive, lime, ligneous matter and "thapsic acid." The author of the present memoir, however, gives his reasons for suspecting that the "thapsic acid" was really hydrochloric acid. Another analysis of *Thapsia garganica* root was made by M. Yvon in 1877, and was reported at the time in this Journal.* M. Blanchet also has made partial analyses of the dried and fresh bark, 90 per cent. alcohol being used to separate the resin, with the following result:—

	Dried Bark Collected in January 1879.		Fresh Bark.	
Water	0·00		80·70	80·70
Organic Matters	91·85		17·75	
Starch		20·52		4·41
Gum and Colouring Matters		7·32		1·47
Resins		5·55		2·15
Maters soluble in Alcohol and in Water		1·38		2·40
Elements not estimated		57·08		7·32
Inorganic Matters	8·15	8·15	1·55	1·55
	100·00	100·00	100·00	100·00

From these results it appears that the bark from fresh roots, which lose 80 per cent. of their weight in drying, yield 2 per cent. of resin, whilst bark that has been dried one year yields only 5·55 per cent. This M. Blanchet considers to be due to the oxidation of part of the resin, in which state it is no longer soluble in the alcohol. In the absence of a supply of newly dried bark no experiment could be made as to its resin value.

These results, however, do not quite agree with those reported by other authors. M. Beslier,† following the process of the Codex, obtained from the fresh roots about 2 per cent. of resin, from the same roots dried in a stove at a moderate temperature an average of 10 per cent., and from the bark, completely dried, about 15 per cent. On the other hand, M. Nielli, treating the fresh roots with 90° alcohol, obtained an average yield of about 4½ per cent., whilst the dried bark only yielded a little more than 5 per cent. According to this last result, as at least four parts of fresh bark are required to make one part of dry bark, there would be a great loss of active substance during drying. It appears, however, that as a matter of convenience,

* *Pharm. Journ.* [3], vol. viii., p. 162.

† Soubeiran's 'Traité de Pharmacie,' vol. ii., p. 192.

and to avoid loss of alcohol, M. Nielli uses the dried bark in manufacturing operations.

Some comparative experiments made to ascertain the relative value of 90 per cent. alcohol, ether, and carbon bisulphide as solvents of the resin showed that the alcohol was the best solvent, ether came next, and carbon bisulphide last.

When the brown thapsia resin is treated in a capsule with boiling water it softens and nearly liquefies. In this state it may easily be divided by stirring with a glass rod; it then takes a lustrous yellowish colour, which it retains on cooling and loses after a fresh treatment with alcohol. Upon heating it in a water-bath, also, it regains its brown colour, but more slowly. When the resin was maintained during six hours at a temperature of 100° C. M. Blanchet found that it became more compact and darker in colour; after cooling its adherence to the capsule was stronger, but the resin did not become brittle, as described by some authors. 25 grams, thus heated, lost 1·80 gram of its weight.

Pure thapsia resin is brown; it has an acid reaction, which it communicates to distilled water after a few minutes' contact at boiling temperature. The resin burns with a bright flame. When treated with sulphuric, nitric or hydrochloric acid in the cold it gives no marked reaction.

The directions in the Codex for the preparation of the thapsia resin are to wash the bark with hot water, dry and cut it, and then to treat it several times with boiling 90° alcohol until it is completely exhausted; the liquors are afterwards united and the alcohol distilled off by means of a water-bath. The residuary resin is purified by redissolving it in cold 90° alcohol, filtering the solution, and distilling until the residue has acquired the consistence of honey, in which state it is suitable for the preparation of the plaster and revulsive sparadrap.

M. Nielli, a pharmacien, of Philippeville, Algeria, who prepares this resin on a large scale, uses cold water instead of hot to wash the bark before drying, and after the first distillation submits the resin to repeated washings with boiling water until extractive and gummy matters are completely removed, and then treats it with 96° alcohol. M. Nielli operates upon the bark ground to a coarse powder in a special apparatus constructed of copper, as it has been found that the resin determines a rapid oxidizing action on vessels made of iron.

The advantage of this treatment of the crude resin with boiling water will be evident when it is mentioned that according to M. Martin the thapsia resin met with in commerce sometimes contains as much as two-fifths of its weight of matters soluble in water.

During the treatment of the resin an aromatic odour *sui generis* is disengaged, which is not disagreeable. This is due to a very volatile essential oil, which is soluble in alcohol, slightly soluble in water, and more soluble in ether, which separates it, on agitation, from water. The oil communicates to ether a magnificent blue colour.

The activity of the resin is so excessive that in spite of all precautions, during the treatment with alcohol, and especially during the evaporation of the alcohol, it is impossible entirely to prevent inconvenience to the operator. Even to remain a few minutes in the place where the operation is being carried on is sufficient sometimes to provoke a rather painful feeling of heat, which is localized generally in the neck, the eyelids and below the lobes of the ears.

The reducing of the bark to a coarse powder and the handling of the latter to put it into the apparatus, are the operations that require most care and are most dreaded by the Arab workmen.* It is very difficult to persuade the workmen to undertake the work a second time, as from the first hour it causes a very intense swelling, notwithstanding that they fasten cloths closely across their mouths and nostrils.

According to M. Blanchet thapsia plaster applied to the skin exercises a special action. The skin is irritated, heated and reddened, and becomes the seat of an extremely lively itching. This is followed by an eruption of very numerous and closely approximated miliary vesicles, full of purulent serous matter. When the application has been continued for only a short time, the vesicles continue to develop during some days, then they wither, assume a darker colour, dry and form small thin scales that soon exfoliate. When the action of the resin is continued for a longer time the vesicles become confluent, burst, and together form an ulcerating and suppurating surface, but without any true blister, in which the action of this resin is distinguished essentially from that of cantharides. The ulcerated vesicles dry up after a few hours and become covered with light squamæ that fall off without leaving any trace on the skin. The application of thapsia plaster is said to be beneficial, especially where it is desired to produce a revulsive effect in rheumatism, bronchitis, pleurodynia, pleurisy, etc., the length of the application being made dependent upon the amount of effect desired to be produced.

There is a formula given in the Codex for the preparation of the "sparadrap revulsif." Another formula, given by M. Desnoix, is as follows:—

Colophony	1500
Elemi	1250
Yellow Wax	1800
Turpentine	500
Thapsia Resin	550

Melt the colophony, elemi and yellow wax, add the turpentine and thapsia resin, strain through linen and spread.

A resin is also obtained by treating the "cleka," or "false thapsia," with 90° alcohol. It is yellowish-brown and, like thapsia resin, is soluble in alcohol, ether, and carbon bisulphide. This resin is, however, entirely without rubefacient effects. It gives no characteristic reactions with sulphuric, nitric or hydrochloric acid.

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.†

BY WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

Lecture I.

Digestion has been usually regarded as the special attribute of animals. They receive into their alimentary canal the food which they require for their sustenance in

* A form of apparatus used by M. Lallemand has already been described in the present series of the Journal, vol. ix., p. 144.

† The Lumleian Lectures, delivered before the Royal College of Physicians.

a crude form. It is there subjected to the action of certain ferments which transmute its elements, by a peculiar chemical process, into new forms which are fitted for absorption. Looked at in this restrictive sense, plants have no digestive function. They possess no alimentary canal, nor any vestige of a digestive apparatus. But when the matter is examined more profoundly, it is seen that plants digest as well as animals, and that the process in both kingdoms of nature is fundamentally the same.

In order to understand this generalization—which was first propounded by Claude Bernard, and constitutes one of the most important fruits of his splendid labours* —it is necessary to recognize digestion under two types or conditions, namely, a digestion which takes place exteriorly at the surface of the organism, and a digestion which takes place interstitially in the interior of the organs and tissues.

Exterior digestion is that common process with which we are familiar as taking place in the alimentary canal of animals, by which the crude food introduced from without is prepared for absorption.

Interstitial digestion, on the other hand, is that more recondite process by which the reserves of food lodged in the interior of plants and animals are modified and made available for the purposes of nutrition.

These two types of digestion are essentially alike, both as regards the agents and the processes by which they are carried out, and, although one type of digestion is more developed in the animal kingdom, and the other type more developed in the vegetable kingdom, both types are represented in the two kingdoms, and bear witness to the fundamental unity of the nutritive operations in plants and animals. I shall only be able to indicate in outline the facts and arguments on which Bernard sought to establish these propositions.

Exterior Digestion.—We all know that the alimentary canal is simply a prolongation of the external surface; that the skin is continued, at each extremity, without a break, into the alimentary mucous membrane. Accordingly, the processes which take place in the digestive tube are, strictly speaking, as much outside the body as if they took place on the surface of the skin. Upon this inner surface, if I may so call it, are poured out the digestive juices, charged with the ferments which are the special agents of the digestive processes. This is the common condition of exterior digestion as it occurs in animals; but it is not the only condition. Among some of the lowest members of the animal series, a permanent alimentary canal does not exist. In the amœba, any portion of the exterior is adapted for the reception of food. The morsel sinks into a depression formed on the surface at the point of impact; it is digested in this improvised stomach, and the indigestible portions are expelled through an improvised anus.

Among plants, exterior digestion is a much less prominent feature than among animals; but examples of its occurrence and evidence of its importance are not difficult to point out. In the lowest orders of plants—fungi and saprophytes, which are devoid of chlorophyll—exterior digestion is probably a function of prime necessity. In all likelihood, their carbon-containing food is only absorbed after undergoing a process of true digestion. The transformation of cane sugar by the yeast-plant is a striking example—though a distorted one—of exterior digestion. Cane sugar is a crude form of food both to plants and to animals, and requires to be transformed into invert sugar (a mixture of equal parts of dextrose or grape sugar and lævulose or fruit sugar) before it can be made available for nutrition. The yeast plant is no exception to this rule, and, when placed in a solution of cane sugar, it is under the necessity of transforming that compound into invert sugar before it can use it for its profit in fermentation. This transformation is effected by a soluble ferment attached to the yeast-cell, which can be dissolved from it by water. We shall see later on that a similar ferment exists, for a similar purpose, in the small intestine of animals, having the same property of changing cane sugar into invert sugar.

Even among the higher plants, exterior digestion is not quite unknown. The function may be said to be foreshadowed in the excretion of an acid fluid by the rootlets of some plants, which serves to dissolve and render absorbable the mineral matters in their vicinity. But genuine and most remarkable examples of this type of digestion occur among the so-called insectivorous plants, of which Mr. Darwin has given so interesting an account. In the sun-dews, the plant, by a peculiar mechanism provided on its foliage, seizes the insects which fortuitously alight on its leaves. A stomach is extemporized around the prey, into which is poured out a digestive fluid. The prey is digested, and the products absorbed, in essentially the same manner as in the gastric digestion of animals.

Interstitial Digestion.—Both animals and plants lay up reserves or stores of food in various parts of their tissues for contingent use, so that, if you suddenly withdraw from them their food-supplies, neither animal nor plant immediately dies—it lives for a certain time on its reserves. But, before these reserves can be made available for the operations of nutrition, they must first be converted from their inert and mostly insoluble state into a state of solution and adaptability to circulate in the nutritive fluid which constitutes the alimentary atmosphere of the protoplasmic elements. This conversion of inert store-food into available nutriment is brought about —certainly in some, presumably in all, cases—by the same agents and processes as the digestion which takes place in the alimentary canal of animals, and it is this identity in the agents and the processes which Bernard insisted on as the proof of the fundamental identity of the two kinds of digestion.

The storing up of food is carried on to a larger extent in the vegetable than in the animal kingdom, owing to the intermittent life of most plants. In their seeds, tubers, bulbs, and other receptacles, are laid up stores of albumen, starch, cane sugar, and oil—designed primarily for the growth and nutrition of the plant or its offspring —but which are largely seized on by animals and utilized for their food. Owing to their more continuous life, animals store up food less than plants. Nevertheless, they accumulate stores of fat in various parts of their body—of animal starch (glycogen) in their livers and elsewhere, and of albumen in their blood. Birds also store up large quantities of albumen and fat in their eggs.

The transformation of store-food has been followed out most completely in regard to starch, its congener glycogen, and cane sugar. Bernard worked out this subject with marvellous minuteness and success. It has long been known that the transformation of starch into sugar in germinating seeds was effected by diastase, and that a similar ferment, existing in saliva and pancreatic juice, performed the same office on the starchy food of animals. It has also been proved that the stores of starch laid up in the tuber of the potato and in various parts of other plants are changed at the periods of budding and growth in the same way, and by the same agent. Bernard showed that animal starch or glycogen is stored up largely, not only in the liver, but in a variety of other situations, and especially that it is widely distributed and invariably present in large quantities in embryonic conditions. In juxtaposition with the glycogen is found a diastatic ferment which transforms it into grape sugar, as it is required for the active operations of growth and nutrition.

The stores of cane-sugar which exist in the beet-root and in the sugar-cane are transformed or digested in like manner into invert-sugar when the plants enter on the

* Claude Bernard, 'Leçons sur les Phénomènes de la Vie,' tome ii.; edited after his death by Dastre. Paris: 1879.

second phase of their life—the phase of inflorescence and fructification. Here, again, it has been proved that the converting agent is a soluble ferment, the same ferment which, as already mentioned, is attached to the yeast-cell, and the same ferment which exists in the small intestine of animals for a similar purpose.

The transformation of store-proteids and fats has not been followed out with the same success as that of starch and cane sugar. But the evidence, as far as it goes, and analogy, point to the conclusion that the stores of albuminous and oily matters contained in the seeds, bulbs, and other receptacles of vegetables are subjected to a digestive process before they are made available for the nutritive operations of the plants, and that the changes thus effected are of the same nature and accomplished by the same agents as those which take place in the digestion of proteids and fats in the alimentary canals of animals.

I have, I think, said enough to show the scope of the evidence and the analogies from which Bernard deduced certain far-reaching generalizations, which I have ventured to summarize in my own language in the following propositions:—

1. Digestion, or the process by which crude food is changed into available nutriment, is a function of capital importance in every form of active life. 2. This function is exercised partly on food brought into proximity with the surface of the organism (exterior, chiefly intestinal digestion) and partly on reserves of food laid up in the interior of the organism (interstitial digestion). 3. The agents concerned in this function and their mode of action are essentially the same, whether the organism be a plant or an animal, and whether the action takes place in the interior of the tissues or on the general or intestinal surfaces.

General Characters and Properties of the Digestive Ferments.

The essential work of digestion is carried out by a remarkable group of agents, called soluble or unorganized ferments. These are found dissolved in the several digestive juices or secretions, which are thrown out on the path of the food as it travels along the alimentary canal. The physical and mechanical processes to which food is subjected in the mouth and stomach are all purely introductory or preparatory, and are solely intended to facilitate the essential work of digestion, which consists in the action of the digestive ferments on the alimentary principles.

The number of distinct ferments employed in the digestion of the miscellaneous food used by man is not accurately known; but there are at least seven or eight of them. The accompanying table presents in one view a scheme of the several digestive secretions or juices, and the ferments which they contain, together with an indication of the action of each ferment on the several alimentary principles.

Table of the Digestive Juices and their Ferments.

Digestive Juices.	Ferments contained in them.	Action on Food Materials.
Saliva	Salivary diastase or ptyalin.	Changes starch into sugar and dextrin.
Gastric juice . .	*a.* Pepsin.	Changes proteids into peptones in an acid medium.
	b. Curdling ferment.	Curdles the casein of milk.
Pancreatic juice	*a.* Trypsin.	Changes proteids into peptones in alkaline and neutral media.
	b. Curdling ferment.	Curdles the casein of milk.
Pancreatic juice (*continued*)	*c.* Pancreatic diastase.	Changes starch into sugar and dextrin.
	d. Emulsive ferment.	Emulsifies and partially saponifies fats.
Bile	(?)	Assists in emulsifying fats.
Intestinal juice .	*a.* Invertin.	Changes cane sugar into invert sugar.
	b. (?)Curdling ferment.	Curdles the casein of milk.

An examination of the table shows that a long and complicated series of ferment-actions is required to accomplish the digestion of our food. Starch is attacked at two points—in the mouth and in the duodenum—by two ferments, salivary and pancreatic diastase, which are substantially identical. Albuminous matters are also attacked at two points, in the stomach and in the small intestine; but here the two ferments—pepsin and trypsin—are certainly not identical. The ferment, of which the only known characteristic is to curdle milk, is found in the stomach and in the pancreas, and I think also in the small intestine. The bile is not known to possess any true ferment-action; but it assists, by its alkalescent reaction and by its physical properties, in emulsifying and promoting the absorption of fatty matters. The ferment which transforms cane sugar, strange to say, is not encountered until the food reaches the small intestine.

The known digestive ferments all belong to the class of soluble or unorganized ferments. They are sharply distinguished from the insoluble or organized ferments, of which the type is yeast, in not having the power of self-nutrition and self-multiplication. All living organisms possess this power either in a dormant (potential) or in an active (kinetic) state. Soluble ferments cannot therefore be said to be alive; but they are exclusively associated with living organisms, and take an essential part in their vital operations.

The digestive ferments are all the direct products of living cells, and may be regarded as detached repositories of cell-force. They are quite unknown in the domain of ordinary chemistry. Their mode of action bears no resemblance to that of ordinary chemical affinity, and has a distinctively physiological character. They do not derive their marvellous endowments from their material substance. They give nothing material to, and take nothing material from, the substance acted on. The albuminoid matter which constitutes their mass is evidently no more than the material substratum of a special kind of energy—just as the steel of a magnet is the material substratum of the magnetic energy—but is not itself that energy. This albuminoid matter of the ferment may be said to become charged, at the moment of elaboration by the gland-cells, with potential energy of a special kind, in the same way that a piece of steel becomes charged with magnetism by contact with a pre-existing magnet. The potential energy of the ferment is changed into the active form (*i.e.*, becomes kinetic) when it is brought into contact with the alimentary substance on which it is designed to act.

The chemical and physical characters of the digestive ferments appear to be tolerably uniform. In composition, they resemble proteid substances, and contain carbon, oxygen, hydrogen and nitrogen in the same or somewhat similar centesimal proportions as albumen. But, as not one of them has yet been obtained in a state of absolute isolation and purity, this is, strictly speaking, a matter of inference rather than an ascertained fact. They are all soluble in water; they are all diffusible, though with difficulty, through animal membranes and parchment paper. They are also capable (all those I have tried) of passing through porous earthenware by filtration under pressure; but some of them pass through readily, and others with the utmost difficulty, and only in the smallest proportions. They are precipitated from their watery solutions by absolute alcohol; but, unlike other proteids (peptones excepted), they are not truly coagulated by alcohol. When the alcohol is removed, the ferments are still found to be soluble in water, and to retain their activity unimpaired. They are coagulated and rendered permanently inert by the heat of boiling water, and, when in solution, they are coagulated and destroyed by a heat of about 160° F. (71° C.).

Each digestive ferment has its special correlative alimentary principle, or group of principles, on which alone it is capable of acting. Diastase acts exclusively on amylaceous substances. Pepsin and trypsin act only on the azotized principles; the emulsive ferment of the pancreas is only capable of acting on fatty bodies; the inversive ferment of the small intestine has no activity except on cane sugar.

The changes impressed on alimentary principles by the digestive ferments are not, chemically speaking, of a profound character, and they affect much more the physical state of these principles than their chemical composition. In the main, they are processes of deduplication and hydration, and the result is to render the substances operated on more soluble and more diffusible, to diminish their colloidal state, and to make them approach, or even to reach, the crystalloid state. This does not appear to be an invariable event, however. Cane sugar is a marked exception; it is converted in the small intestine into invert sugar (a mixture of equal parts of grape sugar or dextrose and fruit sugar or lævulose). But invert sugar, though more highly hydrated than cane sugar, is neither more diffusible nor more soluble.

It does not appear to be absolutely true that all food requires digestion before it can be absorbed. Fat is largely taken up by the lacteals in its unaltered state, except in so far that it is finely divided or emulsified. Grape sugar (dextrose) is not known to suffer any digestive operation, but to be absorbed unchanged. Perhaps it would be more correct to say that grape sugar is an article of food predigested for us by the agency of plants.

Although the mode of action of digestive ferments is special and peculiar, the results of that action are not peculiar, but can be obtained in other ways by ordinary chemical forces. By long continued boiling in water—and more rapidly by boiling with acidulated water—starch is converted into dextrine and sugar, and albumen is changed into a substance resembling peptone. The peculiarity of the action of ferments consists in this: that the ferments are able swiftly and without violence to produce changes which by ordinary chemical agencies can only be produced either by strong reagents or by long continued and very slow action of weaker reagents. It is interesting to remark that the changes produced in food by digestion are, in their ultimate results, very similar to, if not identical with, those produced by protracted cooking.

The Preparation of Artificial Digestive Juices.—The study of the digestive ferments has been immensely facilitated by a method first introduced by Eberle. Eberle discovered that an aqueous infusion or extract of the digestive glands possessed the same properties as the natural secretions or juices of those glands. The reason of this is, that the glands which secrete the digestive juices contain within them a reserve stock of their respective ferments. Accordingly, when the glands are infused in water, their reserve stock of ferments passes into solution. These infusions or extracts then constitute artificial digestive juices, which operate in a flask or beaker in the same way as the corresponding glandular secretions act in the alimentary canal. Solutions of organic matters are, however, extremely perishable; they pass quickly into putrefaction. In order to obviate this inconvenience, and to obtain an extract which is always handy for use, various preservative means have been employed. Bernard used carbolic acid; other have used glycerine or common salt. These preservatives, although perfect for the purpose intended, have a pronounced taste which it is impossible to get rid of. I have made a good number of experiments on this point. As the ultimate object I had in view was to obtain a solution which could be administered as a medicine by the mouth, or which could be employed in the preparation of artificially digested food, I sought for a preservative which had either little taste or smell, or one which was volatile and could be got rid of by vaporization. After a good many trials, I adopted the three following solutions as, on the whole, the best suited for the purpose:—

I. *Boracic Solution.*—This solution contains 3 or 4 per cent. of a mixture of 2 parts of boracic acid and 1 part of borax. An extract of the stomach or of the pancreas made with this solution keeps perfectly, and has little taste and no smell. For experimental purposes, this extract is, I believe, all that can be desired; it is neutral in reaction and is chemically inert. It answers well also for administration by the mouth when the dose does not exceed 1 or 2 tea-spoonfuls. But when larger quantities are required for the preparation of artificially digested food, and when food thus prepared has to be used day after day in quantity sufficient to sustain nutrition, larger quantities of boracic acid and borax are taken into the stomach than that organ can always comfortably tolerate.

II. *Dilute Spirit.*—The second solution is water mixed with 12 or 15 per cent. of rectified spirit. This solution makes a most excellent extracting medium, and the quantity of spirit in it is so small as rarely to be an objection to its use. In the preparation of artificially digested food, a final boiling is usually requisite, and in this final boiling the alcohol is dissipated. On the whole, this is, perhaps, the most generally useful of the three solutions.

III. *Chloroform Water.*—Chloroform dissolves in water in the proportion of about 1 in 200; these are the proportions employed in the preparation of the aqua chloroformi of the British Pharmacopœia. This forms a perfect solvent for the digestive ferments, and its keeping qualities are unrivalled. But, though the quantity of chloroform dissolved is so minute (about 2½ drops in a fluid ounce), it communicates a somewhat powerful smell and taste to the solution. This taste and smell are agreeable to most persons, but not to all. It is, however, quite easy to get rid of the chloroform. If the dose to be used be first poured into a wine-glass or saucer, and left exposed to the air for three or four hours, the chloroform passes off almost entirely in vapour, and leaves behind a simple aqueous solution of the ferments; or, if the solution be employed for the preparation of artificially digested food, the chloroform, being very volatile, disappears in the final boiling. It is, perhaps, well to mention that chloroform water has the property of reducing Fehling's solution, and that this property has to be taken into account in making experiments on digestion which involve testing for sugar.

Alimentary substances fall naturally into three well-marked groups; namely, carbohydrates, proteids, and fats. I propose to consider the digestion of the three groups in the order here indicated. I have, however, no intention of dealing systematically with these subjects, but rather to take up certain points and questions in regard to which I have myself made observations, or which have a bearing on the preparation of artificially digested food and its administration to patients. I shall treat the digestive transformation of starch in some detail, because this has been worked out almost to completeness, and because it probably furnishes a type which will hereafter be of service as a guide to the study of the more complex problem of the digestion of proteids.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, MAY 8, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ANNUAL REPORT.

THE course of events since the last anniversary of the Pharmaceutical Society has not been marked by any of those features of interest and agitation which result from the discussion of subjects concerning which there are differences of opinion among the members of the trade which the Society represents. For this reason pharmaceutical affairs have been characterized by a tranquillity approximating to dullness. Consequently, the Annual Report of the Council, which will be in the hands of members by the time this issue of the Journal reaches them, is brief and limited to the recapitulation of those proceedings which present the greatest degree of interest to the general trade as well as to members of the Society.

In legislative matters the only thing that has occurred to affect chemists and druggists has been the inauguration of the new system by which the weights and measures used by them are legalized and made subject to certification and inspection. Notwithstanding the delay in preparing standards requisite for the purpose, and in determining certain questions as to the mode in which apothecaries' weights should be stamped and graduated measures tested, it appears that these standards are now in the hands of many local inspectors and fit for use, so that chemists and druggists as well as manufacturers of weights and measures will have no difficulty in putting themselves in conformity with the law. At the same time it is to be noted that there is no ground for apprehending vexatious interference or any attempt to make the provisions of the Weights and Measures Act press harshly upon those who have been brought within their purview. On the contrary, the authorities of the Board of Trade have been most considerate and obliging in their response to the representations of the Council, and they have done everything in their power to prevent inconvenience.

The steps taken during the past year to enforce the provisions of the Pharmacy Act, 1868, have led to inquiry into a large number of complaints received by the Registrar, and while it is satisfactory to learn from the report of the Council that the result has been generally a discontinuance of the offences complained of, the fact that in twenty-one cases it was necessary to have recourse to legal proceedings is no less evidence of the utility of the Act. In regard to this point, however, the crucial question still remains open, and the report of the Council can only refer to the prosecution of the London and Provincial Supply Association as involving a question still unsettled. Mr. MACKNESS, the individual originally proceeded against by the Council for carrying on business in violation of the Pharmacy Act, having sought protection by merging his proprietorship in a limited liability company, has now come forward as the representative and champion of the co-operative stores, and disputes the illegality of the sale and dispensing of poisons by public companies, or corporations, as they are termed in legal phraseology. The decision given in his favour by the Lords Justices, some weeks ago, is perhaps the most important event of the past year in regard to chemists and druggists and their relation to the public. So much has this been felt by the Council that it has been determined to continue the proceedings by instituting the final appeal to the House of Lords, and among the reasons which have led to the adoption of this course reference is made in the report to the doubts expressed by the Lords Justices BRAMWELL, BAGGALLAY and THESIGER, as well as to the very forcible remarks embodied in the judgment of the Lord Chief Justice when he decided a former hearing of the case in favour of the Pharmaceutical Society by upholding the application of the Pharmacy Act against associations or companies no less than against individuals.

As regards the various pharmaceutical examinations, the conduct of which forms one of the most important duties of the Society, the experience of the past year has been most encouraging. From the increasing number of candidates for the Preliminary examination, the Council infers that the importance and desirability of passing this examination prior to apprenticeship is now being more generally recognized. During the year 1879 there were one hundred and thirty-four candidates for the Major examination as against eighty-one in the previous year. This circumstance tends to show that there is a growing appreciation of the higher grade of qualification, though its acquisition is still a voluntary matter, and that there is less reason than hitherto for regret that so many of those passing the Minor examination should be content with tha alone.

The desirability of maintaining the identity of the examinations in London and in Edinburgh has within the last few years led to a periodical interchange of visits by deputations of the respective Boards of Examiners to Edinburgh and to London, while the examinations are in progress, and only last month such a deputation from the London Board was present during the examinations held by the North British Branch. As yet no formal report of this visit has been presented; but we have reason to believe that when it appears it will not leave any doubt that the examinations are conducted with equal care in both places.

The financial position of the Society, as represented by the balance sheet issued, together with the Report of the Council, is decidedly satisfactory, inasmuch as it shows a continued increase in the revenue of the Society, but the contributions to the Benevolent Fund during 1879 were somewhat less than those of the previous year. This may be in part due to the depression in trade, and in part also to the special efforts made in 1878 to augment the Fund. At any rate it is satisfactory to learn that the Council has no reason to apprehend decrease of interest in the prosperity of the Fund, which has done and is doing so much to relieve the necessities of unfortunate members of the trade. At the same time it is pointed out that year by year the permanent engagements of the Fund are increased by the additions to the number of annuitants, and that it is not even yet possible to comprise in those additions all of the candidates that are approved. In order to show the extent of the good work done by the Fund, it may be stated that the amount required for payment of annuities this year is £1015, and taking the amount granted for casual relief as approximating to £700 a year, the total expenditure this year will be upwards of £1700.

The Society's Museum has, during the year, been enriched by many valuable additions, among which may be mentioned, in the first place, the materia medica and other specimens transferred from the India Museum collection, through the kindness of Sir Joseph Hooker, in compliance with the representation of the Council that if these valuable objects were placed in the Museum of the Pharmaceutical Society they would be specially accessible to persons interested in them, and thus become of great utility.

The Library of the Society has continued to augment by presentations and by the constant addition of books recommended in various ways and approved by the Committee that watches over it, until it is now reported to contain about seven thousand volumes. Among other acquisitions, that resulting from the application of the legacy left by Daniel Hanbury deserves especial mention, since it enriches the Library with a number of highly valuable works of reference. A new catalogue of the Library is now in course of preparation, and copies of it will shortly be sent to all Members of the Society and Associates in Business. Copies of it will also be supplied to Associates and Apprentices of the Society on application. An Index of the ten volumes of the Pharmaceutical Journal from July, 1868, to July, 1878, has been published during the past year, and each Member and Associate of the Society can obtain a copy, free of charge, on application to the Secretary.

Besides the matters above mentioned, the Report of the Council refers to the successful character of the evening meetings held in London and Edinburgh, and points out that these meetings have afforded useful opportunities for the consideration and discussion of various interesting subjects. It also states that the formal acceptance of the Hanbury Memorial Fund Trust has been completed, and a die prepared for a medal, to be offered for competition every other year "for high excellence in the "prosecution or promotion of original research in the "natural history and chemistry of drugs." We may suggest in reference to this offer that it ought to prove a powerful incentive to the production of really valuable papers at the evening meetings of the Society, since the award of the Hanbury medal by the Council is precisely the kind of recognition appropriate in such a case, and a reward that the recipient might justly be proud of.

The election of members of Council, which is one of the most important duties to be performed by members of the Society, will this year be marked by the introduction of a novel feature. We have now become somewhat used to candidates' addresses to the constituency, and from what we have noticed in some of these addresses it must be admitted they often have the merit of furnishing voters with a means of judging as to the manner of man who solicits their support. But this year the issue of addresses is accompanied by correspondence in which the merits of candidates are discussed, *pro* and *con.*, some writers protesting that certain candidates are disqualified for becoming members of Council, while others assert the opposite. Of course those who hold the one opinion or the other have a right to speak their mind, and we have no desire to take further part in the controversy than that of placing the circumstances clearly before our readers, since they involve questions of considerable importance.

The candidates for election as members of Council who have been commented upon as unsuitable for that position are Mr. Shepperley and Mr G. S. Wills. The former was objected to by "A Member" upon the ground of the notoriety he acquired some years ago in connection with the acrimonious disputes about "counter practice," and it was urged that since his candidature for election to the Council of the Pharmaceutical Society might excite the suspicion and antagonism of medical men and thus prejudice the interests of his brethren he ought to withdraw from the contest. Mr. Gostling, of Stowmarket—who is not, as we have been requested to state, the Mr. Gostling, of Diss, that is now a member of the Council—denounced this suggestion as conveying rude and ungentlemanlike insinuations, and he maintained that as Mr. Shepperley was successfully defended by the Chemists' Trade Association, he is therefore a suitable representative of the trade. To this "A Member" replied, disclaiming any insinuation prejudicial to Mr. Shepperley, and pointing out that he only desired to raise the question whether it was not extremely undesirable to have on the Council the defendant in the most notorious and protracted of counter practice cases. He also repudiated fear of the Society of Apothecaries, but thinking discretion the better part of valour looked to a policy of conciliation as more likely to be advantageous than one of irritation and defiance. A "Pharmacist" took exception to Mr. SHEPPERLEY, even if he could be regarded as the "victim of apothecaries," because he thought the "patent medicine" development of pharmacy adopted by Mr. SHEPPERLEY as his *modus operandi* was scarcely to be regarded as compatible with a representative man suited to make pharmacists respected.

Another correspondent on this subject said that though he had subscribed to the special fund of the Trade Association, and otherwise supported the defence of Mr. SHEPPERLEY, he could not think it desirable to make the victor in that litigation a member of the Council and a representative of the trade.

The objection raised by "A Member" and by an "Old Member" to the candidature of Mr. WILLS for election as a member of Council was chiefly based upon the circumstance that he is a professed teacher of candidates for the Society's examinations, and upon the opinion that he was thereby disqualified from taking a seat in the Council which has the control of examinations and the appointment of examiners. Another objection raised by Mr. REYNOLDS, in the letter which appears this week in our correspondence columns, is based upon the possible, if not probable, prejudice to the privileges of the Pharmaceutical Society that might result if such a "breach of propriety" were committed as electing the head of a pharmaceutical school to fill the position of a member of the Council. With this recapitulation of the points of the controversy respecting the eligibility of Mr. SHEPPERLEY and Mr. WILLS, we leave the question in the hands of the electors for decision.

TRANSPARENT SOAP.

WE have received several communications in reference to this subject which seem to show that there is a desire for information as to the reason why the transparent soap imported from abroad has been subjected to duty. The fact is simply that alcohol is used in the preparation of this soap and it contains in the finished state a considerable amount of alcohol. Consequently, it is liable to import duty on this account, and if it were not subjected to duty British manufacturers would be placed at a disadvantage, since they would have to use in the preparation of this soap duty paid spirit and could not compete with foreign makers. Methylated spirit, on account of its disagreeable odour, would probably be unsuited for the purpose in most cases and for the preparation of fancy soap especially.

We notice that, to prevent misunderstanding which might arise upon this subject, British manufacturers of transparent soap are issuing notices to their customers that for the present the price of the home-made soap will remain unchanged.

DEATH OF MR. CRACKNELL AND OF MR. CORTIS.

WE very much regret to have to record the death of Mr. CHARLES CRACKNELL, on Wednesday last, the 5th inst. The connection of Mr. CRACKNELL with the Pharmaceutical Society dates from a very early period in its history. He was one of the earliest pupils in the School of Pharmacy, and in March, 1844, received the first prizes for Chemistry and for Materia Medica, this being the first occasion on which prizes were given by the Society for those subjects. In 1845 Mr. CRACKNELL became a Member of the Pharmaceutical Society. In June, 1851, he was appointed an Examiner, and he performed the duties of this office during the long period of nearly twenty-four years, until the end of the year 1874. During the ensuing four years, from May, 1875, to May, 1879, Mr. CRACKNELL served the Pharmaceutical Society as a Member of the Council.

We also regret to have to report the death, at the age of seventy-six years, of Mr. CHARLES CORTIS, of Worthing. Mr. CORTIS joined the Pharmaceutical Society at its foundation, and for many years past has given his services to it as Local Secretary.

FIRE AT A WHOLESALE DRUGGIST'S.

OUR readers will be sorry to learn that a very serious fire, attended with loss of life, has taken place at the warehouse of Messrs. HODGKINSONS, STEAD and TREACHER, in Aldersgate Street, by which their premises and stock have been entirely destroyed and great damage done to the neighbouring houses. According to the evidence given at the inquest, the fire appears to have originated by the breaking of a bottle of oil of aniseed near a gas flame, but whether this was accidental or the consequence of an attempt to melt the oil by the gas flame was not clearly made out. There have now been so many destructive fires in wholesale druggists' warehouses that special attention is likely to be drawn to the matter, and we perceive that it was discussed, on the motion of Mr. INNES, at a meeting of the Metropolitan Commissioners of Sewers in Guildhall, with the result that it was resolved to refer the matter to the Sanitary Committee to report upon.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of this Association will be held on Thursday next, the 13th inst., at 8.30 p.m., when a paper will be read by Mr. W. ELBORNE on "The Preparation of Tinctures." A Report on Analytical Chemistry will be made by Mr. A. F. DIMMOCK on "VORTMANN'S Method for the Detection and Estimation of Chlorides in the Presence of Iodides and Bromides."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 5, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Richardson, Robbins, Squire, Symes and Williams.

The minutes of the previous meeting were read and confirmed.

The PRESIDENT stated that he had received letters from Mr. Schacht and Mr. Savage, apologizing for not being able to attend that day.

ELECTION OF COUNCIL.

Personal Explanation.

Mr. GOSTLING stated that a letter having appeared in the *Pharmaceutical Journal*, of April 24, signed by a gentleman having the same surname as himself, referring to the candidature of a certain gentleman for the Council, he thought it desirable to state most explicitly that he was not the writer of that letter, nor in any way responsible for it.

The PRESIDENT said he never thought Mr. Gostling was the writer of the letter.

Withdrawal of Mr. Butt.

The PRESIDENT said he had received a letter from Mr. Butt, who had been nominated to serve on the Council, expressing a desire to withdraw. He was sorry to receive such an intimation, because he thought Mr. Butt would have made a very useful member. The Council, however, could only act on that gentleman's wishes.

ROYAL BOTANIC GARDENS.

The Secretary reported that a letter had been received from Mr. Sowerby, Secretary to the Royal Botanic Society, stating that he would lay the application for the usual permission to Professor Bentley's students to visit the gardens before the Council.

HONORARY AND CORRESPONDING MEMBER.

The following gentleman was unanimously elected an Honorary and Corresponding Member of the Society:—
Surgeon-Major W. Dymock, Bombay.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Ashmead, John Stubbings.
Carruthers, Robert.
Cox, Frederick John.
Howell, Edmund.
Jones, William Harris.
Maben, Thomas.
MacEwan, Peter.
Powrie, Percival Chamberlain.
Shepherd, John William.
Thompson, John Tatham.
Williams, James Edward.
Williams, William.
Wimpenny, John McMillan.
Winfrey, Richard.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Carruthers, Robert ....Dumfries.
Cook, William Richard ....New Swindon.
Cox, Frederick John ....Nottingham.
Cox, Joseph ....Calcutta.
Fawcett, Christopher Airey ...Natal.
Jones, William Harris ....Friley Bridge.
Leach, Isaac ....London.
Maben, Thomas ....Hawick.
MacEwan, Peter ....Dundee.
Powrie, Percival Chamberlain...Mossel Bay.
Presslie, Robert Dowell ....Aberdeen.
Shepherd, John William ....Settle.
Shirley, Stephen Shillito ....London.
Tyrrell, John Walter ....London.
Warren, William ....London.
Williams, William ....St. Clears.

Chemists and Druggists.

The following registered Chemists and Druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Adams, Rowland ....Leyton.
Ellis, Frederick...................London.
Franklyn, Thomas ....Leyton.
Taylor, John ....London.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Bartlett, Geo. Fredk. Handel...London.
Beaven, Alfred George ....London.
Booth, Thomas ....Weaste, nr Manchester.
Bourne, Charles Matthew K....Boston.
Bowen, Ebenezer ....Pontardulais.
Bridge, George Edward ....Southsea.
Capern, Francis Thos. Mesmer...Weston-super-Mare.
Corden, Fredk. Wm. Walter ...West Cowes.
Cousens, John Stather............Eckington.
Cowap, Samuel Evan ....Midhurst.
Daniel, John ....Bristol.
Forster, Francis Alexander......London.
Fryer, John ....South Stockton.
Garside, Samuel Arthur ....Ormskirk.
Gregory, Walter ....Bristol.
Higgs, Alfred ....Kingston-on-Thames
Holdcroft, Francis Joseph ......Leek.
Hoult, Joseph Emanuel ....Cheadle.
Hughes, Evan ....London.
Hughes, Thomas Ignatius J. ...Liverpool.
Jesser, Alfred Henry ....London.
Jones, Thomas Pryce ....Llanidloes.
Lyle, William ....Berwick-on-Tweed.
McCormick, Frank Henry ......Manchester.
McNicol, John ....Hillhead.
Maudson, Beresford Frederic H.South Norwood.
Millar, James Hean...............Broughty Ferry.
Morley, John Thomas ....Ripley.
Murchie, William Gardiner......Lockerbie.
Nichols, Arthur Fitzroy ....Warboys.
Padley, William ....Hull.
Parris, Thomas Watkin ....Southsea.
Partington, John James ....Walsall.
Patterson, James ....London.
Phillips, John James ....Ashton-under-Lyne.
Redfern, John ....Bath.
Ridding, William ....London.
Ridley, Thomas....................Brampton.
Rundle, Charles ....London.
Smith, Frederick Adolphus......Darlaston.
Smith, John Thomas ....Wellingborough.
Sutcliffe, George Hargreaves ...Bacup.
Taylor, John ....Bolton.
Thompson, Mark Foggit.........Glasgow.
Truman, Henry Vernon ....Sunbury.
Wakefield, John ....Birmingham.
Williamson, Bamford, junr. ...South Shields.

Modified.

Allden, John.........................London.
Carter, John ....Woolwich.
Coates, Henry ....York.
Fewster, William Longwood ...Dewsbury.
Hey, Walter Thomas ....York.
Mickle, Edward ....Liverpool.

ASSOCIATES.

The following, having passed their respective examinations, and tendered (or paid, as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Bamforth, Joseph..................Manchester.
Bennett, Charles Joseph ....Widnes.
Bentley, John Thomas............Hull.
Blagg, Eli ....Hanley.
Bolton, Frederic William ......London.
Callander, William Wright......Exeter.
Cheal, Harry Alexander ....London.
Davidson, Peter ....Insch.
Elborne, William ....Grantham.
Goodchild, Alfred Clarke ......London.
Hardwick, Arthur ....Sheffield.
Hall, Alfred Lee ....Winchcombe.
Hebblethwaite, George Arthur.Hull.
Hogg, Robert William............Gateshead.
Horne, John ....Wednesbury.
Jacks, David Russell ....London.
Johnson, Edward ....Stockport.
Jones, Charles ....Ashton-under-Lyne.
Milne, Andrew ....London.
Morgan, William ....St. Clears.
Nethercott, Walter John.........Stroud.
Oliver, Henry Charles Hewitt...Maidstone.
Owles, Charles Edward ....Bungay.
Palmer, James Spencer ....Penzance.
Parkes, Harry Charles............Fareham.
Parsons, James Vincett ....Icklesham.
Playford, Frederick William ...Holt.
Ramsay, David Robertson ......Dundee.
Richards, Randolph Hutchings.London.
Seward, George Halifax ....London.
Simpson, Robert George ....Stowmarket.
Venables, Samuel Henry.........Wellington (Salop).
Welford, Richard ....Blackburn.
Wilding, George James ....Preston.
Wright, Eli ....Tipton.

Modified.

Orton, Edward Arthur............Marston Gabbett.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Adams, Henry George............Maidstone.
Armstrong, John ....Langholm.
Bellamy, Robert Arthur ....Bedale.
Bird, Frederick Chas. John ...Bath.
Campbell, Charles ....Manchester.
Chadwick, Charles Edward......King's Lynn.
Chaplin, John Henry ....Wakefield.
Crarer, Edward.....................Blairgowrie.
Cryer, Joseph ....Liverpool.
Davies, Daniel ....Newcastle Emlyn.
Dodsley, Charles Edward ......Mansfield.
Drew, Walter Clarke ....London.
Evans, Hugh Thomas ....Carnarvon.
Fooks, Henry ....London.
Forbes, James A. B................London.
Furmston, William Arthur......Wycombe.
Gilbert, Charles George ....Walthamstow.
Goodliff, George ....Huntingdon.
Hall, Charles Hurd ....London.
Heald, Alfred Francis............Burnham, Bucks.
Hinde, Albert Henry ....Lowestoft.
Holloway, Charles Terry.........London.
Horsey, Herbert Vaughan ......Southampton.
Jackson, Richard Herbert ......Hull.
James, Morgan William.........Llandovery.
John, Benjamin ....Narberth.
John, William ....Narberth.
Leech, John Frederick............Tideswell.
Lloyd, Edwin Henry ....Ashby-de-la-Zouch.
Mackereth, George Hemsworth.Thorparch Grange.
Metcalfe, James ....Bradford.
Milne, Alexander ....Montrose.
Morse, Frederick Bartho.........London.
Nicholson, Richard Thomas ...Maidstone.
Nowers, Lawrence Edward......Lydd.
Ogle, John Henry..................London.
Puckey, Courtenay ....Herne Hill.
Rickards, Henry W...............London.
Shapcott, William Henry P. ...London.
Smith, John Henry ....Cromford,
Smith, Sidney ....Bromsgrove.
Swain, Eliza ....London.
Taylor, Francis William.........Newport Pagnell.
Tregellas, Clifton Pari ....London.
Tucker, Thomas ....London.
Wing, John William ....Colsterworth.
Wingrave, Arthur ....Coventry.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

RESTORATIONS TO THE REGISTER.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

James Cartwright, 4, Belvedere Terrace, Hedon Road, Hull.

Michael Charles, 1, Albert Street, Cloudsley Road, Islington, London, N.

Thomas Franklyn, 3, Cuba Villas, Russell Road, Leyton, Essex.

THE VISIT OF THE DEPUTATION TO SCOTLAND.

It was resolved that the members of the London Board of Examiners who had attended the examination in Scotland last month be severally paid the usual examiner's fee for each day on which they attended the Board.

Mr. BOTTLE asked if the President had any report to make on the visit.

The PRESIDENT said he thought it was too early to make any remarks on this subject, as the members of the Board of Examiners who attended would no doubt present a report.

Mr. WILLIAMS though it was usual for the President to make a short statement.

The PRESIDENT said he had no objection to state generally that the visit had been very satisfactory. He would not for the reason just stated give any opinion on points of detail, but he believed there would be no adverse opinion in any way. He need hardly say that their friends in Edinburgh and Glasgow received the members of the deputation most cordially, and did everything possible, not simply for their comfort and enjoyment, but everything they could to give the deputation the best opportunity of seeing the conduct of the examinations from beginning to end and the general arrangements of the Society. He believed that at an early date a motion would come before the Council for authorizing some cleaning and painting to be done at the Society's rooms in Edinburgh.

THE ANNUAL REPORT.

The Council then went into committee to revise the draft Annual Report, which was considered and finally approved, and ordered to be issued with the Voting Papers.

REPORTS OF COMMITTEES.

LIBRARY, MUSEUM AND LABORATORY.

The Committee recommended that copies of the Index be sent to the provincial associations and to the medical and public libraries to which the Journal is now sent.

The Professors had attended and reported on their respective clases.

The Librarian's report had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
March	Day	292	19	8	12
	Evening	186	17	2	9

Circulation of books.	Town.	Country.	Total.
No. of entries	167	73	240
Carriage paid	£1 12s. 0½d.		

The following donations to the Library had been reported, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

American Pharmaceutical Association, Proceedings, 1878, vol. 26. From the Association.

Böhlendorff, H. v., Ein Beitrag zur Biologie einiger Schizomyceten, 1880.

Koroll, J., Quantitativ-chemische Untersuchungen über die Zusammensetzung der Kork-, Bast-, Sclerenchym- und Markgewebe, 1880.

Liborius, P., Untersuchungen über die Wurzelfasern von Rhinacanthus communis, 1880.

Pfeil, T., Chemische Beiträge zur Pomologie, 1880. From Professor Dragendorff.

Friedländer & Sohn, Bibliotheca historico-naturalis et mathematica, 1880. From the Compilers.

Pharmaceutical Society of Ireland, Calendar, 1880. From the Society.

Pharmaceutical Society of Victoria, Annual Report, 1880. From the Society.

Pharmacy Board of Victoria, First Report, 1880.
— Pharmaceutical Register for 1879. From the Board.

Radcliffe Library, Oxford, Catalogue of Books added during 1879. From the Radcliffe Trustees.

Sadler, J., Report on Temperatures during the Winter of 1878-9. From the Royal Botanic Garden, Edinburgh.

School of Pharmacy Students' Association, Papers read, Session 1878–9. From the Association.

The Committee recommended the purchase of the following works for the Library:—

Bibliotheca Chemica, 1840–58.
Bibliotheca Chemica et Pharmaceutica, 1859–70.
Carter, R. B., Eyesight, Good and Bad, 1880.
Huxley, T. H., The Crayfish, 1880.
Johnson, C. P., and J. E. Sowerby, Useful Plants of Great Britain.
MacMunn, C. A., The Spectroscope in Medicine, 1880.
Molimbrochius, A. V., Cochlearia Curiosa, or Curiosities of Scurvygrass, 1676.
Morton, W. J. T., Manual of [Veterinary] Pharmacy, 8th ed., 1880.
Oliver, D., Illustrations of the Principal Natural Orders of the Vegetable Kingdom, 1874.
Parkes, E. A., Manual of Practical Hygiene, 5th ed., 1878.

The Curator reported the average attendance in the Museum to have been, Morning 11: Evening 3.

The following donations to the Museum had been received:—

Japanese Belladonna Root. From Messrs. Hearon, Squire and Francis.

Pure Iodide of Potassium. From Messrs. Geo. Atkinson and Co.

Papaw Leaves, Yellow Bonduc Seeds, Japanese Belladonna Root, Sweet Bark from Australia (Achras species). From Messrs. T. Christy and Co.

Specimens of the bark of *Ptelea trifoliata*, *Abies balsamea*, *Rhamnus Purshiana*, *Æsculus glabra*, *Diospyros virginiana*.
Specimens of the Root of *Pterocaulon pycnostachyum* and *Polymnia Uvedalia*.
Specimens of the Herb of *Frankenia grandifolia*, *Penthorum sedoides*, *Lycopus virginicus*, *Gentiana quinqueflora*, *Erecthites hieracifolius*.
Specimens of the Seeds of *Uraria triloba*. From Messrs. Parke Davis and Co.

Bark of *Cinchona Officinalis*, var. *pubescens* (containing 6 per cent. of quinine and 5 per cent of cinchonidine), and "China Cuprea." From Mr. J. E. Howard, F.R.S.

Specimens of Morocco Drugs belonging to the late Dr. Leared. From Mrs. Leared.

Specimen of the Capsicum pods from which Natal Cayenne Pepper is prepared. From Mr. H. J. Savory, Griqualand.

Specimen of "Tonga" as imported. From Mr. A. W. Gerrard.

The following donation to the Herbarium had been received:—

Specimens of *Shorea hypochroa* and *Shorea Henryana*, with portions of the bark and resin. From Dr. Pierre, Director of the Botanical Gardens of Saigon, Cochin China.

At an adjourned meeting the Committee had considered the questions referred to it by the Council at its last sitting regarding the payment for papers read at the Evening Meetings of the Society in Edinburgh, and also before provincial associations, when published in the Journal, and had resolved unanimously to recommend the Council to discontinue the practice of paying for papers read at the meetings of the Pharmaceutical Society.

The Curator had reported the applications he had received from persons desirous of exhibiting apparatus, etc., at the Annual Meeting. Also, that an application had been received from the Leicester Chemists' Association for specimens of materia medica.

The Council went into committee to consider this report, and afterwards resumed.

Papers read at Evening Meetings.

Mr. MACKAY wished to make a remark on the portion of the report which referred to the payment of papers read at the Evening Meetings. It appeared that in future Edinburgh and London would be placed on the same footing, but he could not help feeling that the subject was one of great importance, and that the present position could not be too thoroughly understood. He wished to ask if it was to be understood that all papers read at the Evening Meetings be not only not paid for, but that the papers became the property of the Society, and being its property that the papers should be published *in extenso* in the Journal. If that were so, the other question which immediately arose was this, that if certain papers read at Evening Meetings were not published, then the Society was placed in a very invidious position. In other words, if the Society undertook not to pay, but received manuscripts suitable for reading at Evening Meetings, then it took possession without fee or reward of the labours of such men, and that being so, were the papers, after having appeared in the Journal, to be considered the property of the authors? If this were made a hard and fast line, a good many who might be working in an original groove would feel themselves rather unjustly used. Was the Editor to be put in the position of receiving a paper on the tacit understanding that it would be paid for, and then simply because it was to be paid for, that it was not to be read as a communication? These matters should be looked fairly in the face, because the Journal might be deprived of some very valuable papers. Its pages must be filled, and the Society trusted to filling them very much with papers read at the Evening Meetings. Supposing that some night there were not sufficient matter for the Evening Meeting, other than that which had been already accepted by the Editor as a contribution to be paid for. Was the mere fact of those papers being so accepted to prevent their being read? If it were not so, he should be glad to be set right, and it was really important to know whether that course should be adopted. If that were the decision, he should ask the Council to appoint some committee to act in Edinburgh, for the purpose of passing papers which, when read, should be printed *in extenso* in the Journal. In no other way would the invidious distinction in printing some papers and not printing others be got rid of.

Mr. Hampson said the Committee took all these points very fully into consideration. It was felt that it would be impossible for the Society to pay for papers read in Edinburgh, Bristol and elsewhere, unless it had some control over the selection or rejection of the papers. He must say that some papers had occupied the pages of the Journal, which had been read in Edinburgh, which he should take exception to, but this question was surrounded by many difficulties, and the only solution appeared to be to do as other societies did, and not pay for papers read at the meetings. The honour of reading a paper before the members of the Society and its publication, was something, and that was a sufficient reward for the majority of contributors. It was quite clear then that these papers should not be paid for; but it was also clear that if a gentleman chose to send a paper to the Journal and the Editor considered it of sufficient importance to print and pay for it, he got a reward of another kind. But the gentleman who read the paper at their meetings had the advantage of getting it fully discussed, and more interest manifested in it; and this was an important distinction between the two courses of procedure. There were certain advantages in each, but it would be clearly seen that the only proper arrangement was the one proposed.

Mr. Williams said this question was very well thrashed out in committee. He had always been of opinion that the Society ought not to pay for these papers. He had occasionally read a paper, but so strongly did he feel on the subject, that he always handed over the payment to the Benevolent Fund. He was quite aware that the Council was formerly induced to come to a resolution to pay for the papers, because there was rather a dearth of papers at the time, and it was thought many writers of good papers sent them to the Journal instead of reading them at the Evening Meetings, so that they might get payment. He did not think experience had really supported that supposition. He believed the Society would get quite as good papers and as many as were wanted, by simply relying on the *esprit de corps*. The papers paid for were naturally of another character, and were generally the work of gentlemen who made it more or less their business to write on scientific matters. With respect to the papers read before the North British Branch coming up to be necessarily published in the Journal, he thought it would be a dangerous thing to lay down a hard and fast rule, binding the Editor absolutely to publish every paper sent to him which had been read before the North British Branch. He did not consider that the Editor was absolutely bound to print every paper read in that house; and he knew that in the case of other learned societies papers were frequently read which the publication committee did not think proper to publish. It should be simply a question whether it was a benefit to the Journal to publish a paper, and the interests of the Journal should not be sacrificed to any fancied ideas as to a right at law. At the same time it was obvious that, as a rule, papers read before the Society either in London or Edinburgh would be published.

Mr. Symes, being one of those who moved the resolution which caused this inquiry, wished to say that in so doing he in no way advocated payment for papers read at the Evening Meetings or before provincial associations. He simply thought it was unfair to endow the papers read at the Society's meetings, and that local societies should have to use their efforts to get papers which could not be paid for. He should decidedly support the recommendation of the Committee that no papers be paid for at all which were read at the Evening Meetings of the Society. He was not going into the question of provincial societies, because the Committee did not seem to have reported on that. The recommendation, if carried out, would place everyone on terms of equality, and he did not think the Society would seriously suffer. He took it the North British Branch was quite competent to appoint any committee it pleased to look at the papers submitted to it. The Editor should have some discretion as to the publication of papers sent to him.

Mr. Frazer said he had always opposed the payment for scientific papers read before the Society. He never believed that the Society would not get papers of value without paying for them, and he had the same impression still. With reference to the point raised by Mr. Mackay he thought it might be understood that papers read at the Evening Meetings did not necessarily become the property of the Society. If that were settled, the Editor could then go to the writer of a paper, if he thought it valuable, and ask permission to insert it, and pay for it as a contribution. He did not think the papers read at the meetings should become the property of the Society, and the Editor might say, "I will take this one, and pay for it, but not that." Let the Editor fill the Journal from any source he pleased.

Mr. Squire thought the fact of a paper being read at an Evening Meeting and not published would not prevent it being handed to anyone else to publish, if he would pay for it.

Mr. Mackay said the discussion all proceeded from the understanding that a paper read at an Evening Meeting became the absolute property of the Society.

The President said such a paper was the property of the Society to this extent, that the Society acquired a right to publish the paper; but it did not retain the copyright. He constantly received papers published in other journals and read at meetings, from the writers of those papers, and he had known some of them collected and published as a book. He could not imagine that any Council would say the paper belonged to the Society and should not be republished by its author.

Mr. Greenish took it that everything published in the Journal was the property of the Society. He recollected instances where permission was asked and obtained to republish papers. He wished to point out the difficulty in which the Editor was placed. A paper might be sent him from a foreign correspondent who was accustomed to receive payment, which he, as a member of the Evening Meetings Committee, might think desirable to have read at the Evening Meeting, especially if, as might be the case, there were no other papers to be brought forward. It would be very hard in such a case to deprive the writer of his remuneration. That was just the point he wished to clear up.

Mr. Hampson said the Editor would accommodate himself to the new conditions.

Mr. Symes thought the Editor had no right to do what Mr. Greenish had suggested.

Mr. Greenish said Mr. Williams had spoken very strongly against receiving payment for a paper, but he could not accede to that view. A paper might be got up in an hour or two, or a man might spend two or three months' time upon it and more money than he would receive for it.

Mr. Atkins was very glad the Council was coming to a conclusion not to pay for papers read at Evening Meetings. He was sorry to find that it did not seem to see its way to any solution of the difficulty that a paper having been read at an Evening Meeting was disqualified for being paid for. He would rather have no Evening Meeting for six months than go on paying for papers for them, and was glad that Mr. Frazer had held that view so long. The point Mr. Greenish had raised was of importance, that if a paper were read at an Evening Meeting it could not be paid for anywhere, either in the Society's own Journal or elsewhere. That would certainly go a long way to deprive the meetings of papers. He thought it would be desirable to leave the management of the Journal entirely distinct from the conduct of the Evening Meetings. Let the Council keep to the idea that it would not pay for papers read, but let it be in the discretion of the Editor to pay for papers published in the Journal.

Mr. Robbins agreed with Mr. Greenish that it would be desirable to leave the question to the Editor whether a paper should be paid for or not.

Mr. Hampson thought the Council had better adhere to the resolution.

Exhibition of Apparatus, etc.

Mr. Symes wished to say a word about the Exhibition at the Annual Meeting. He was very pleased to learn that forty-three applications had been received for space to exhibit; and the arrangements seemed to be going on very well, except that he found the Curator in this dilemma, that he was without an assistant. It seemed that the young man who had been assisting the Curator had left, and, as he understood, the Committee did not think proper to allow him an assistant on the present occasion. A large amount of responsibility and work had been thrown on the shoulders of the Curator, which he was anxious to carry out well, and he (Mr. Symes) thought it a great pity the Committee did not deem it desirable to allow him an assistant. He would therefore recommend that the Committee be requested to reconsider the matter, or that a resolution be passed empowering the Curator to get such assistance as was desirable.

Mr. Williams said there was no such application before the Committee.

The President said the Curator reported that his assistant had left, and applied to the Committee for authority to engage another, but the Committee considered that the engagement of the assistant in the museum was only temporary, and could not recommend at present that another be appointed. So far as engaging an assistant for the purposes of this Exhibition, he did not think it was necessary at all, and he was very much surprised that the Curator should have put any such complaint into the hands of Mr. Symes. The Curator's application ought to come before the Library Committee, which met every month. The assistant was appointed twelve months ago for a special reason, which no longer existed, and, as he had left, the Committee thought it better to leave it to the new Council to appoint a successor, if it thought fit.

Mr. Symes said it was not a complaint by Mr. Holmes by any means; it was simply that he went to ask him how the Exhibition was going on, because he had written a great number of letters privately about it, and was much interested in its success. He asked the Curator what he was doing, and so on, and the Curator simply told him of the dilemma he was in, which he (Mr. Symes) thought was justifiable on his part. He should not have brought the subject before the Council if he had thought it would be accepted as a complaint, because it was nothing of the kind. The circumstance having come to his knowledge he brought it forward because he thought it was the duty of the Council to see that this matter was efficiently carried out.

Mr. Richardson said he was very glad that there appeared to be a prospect of success for this Exhibition, but he deprecated the remarks of Mr. Symes, as the subject should not have come forward in this way. As it had been mentioned, however, he thought some temporary assistance ought to be given to Mr. Holmes in order to make the Exhibition as successful as possible. All over the country these exhibitions were becoming common, and he looked forward with great anticipation to the re-introduction of an Exhibition in connection with the Society this year, and thought it would become of very great importance in future years to chemists at large. In his own town there had been an exhibition of gas apparatus, which he believed would cause a revolution in the town in the consumption of gas for domestic purposes.

Mr. Hampson said he should be sorry for Mr. Symes's remarks to be misunderstood, and he thought the explanation he had given was satisfactory. It was simply a fact elicited in conversation, and if the absence of an assistant was likely to be prejudicial to the success of the Exhibition, it was desirable that some temporary assistance should be given.

Mr. Gostling said it struck him that if the Curator really required such assistance he would ask for it, and that, in all probability, up to the present time he had got through his work satisfactorily. If he should require assistance, as no doubt he would, it would be quite within his province to apply for such temporary help at the next committee meeting, which would take place next Monday.

Mr. Greenish rather regretted to find this discussion raised. It so happened that this last month the Committee had had two meetings, at the first of which he was not present, but at the second there was certainly no application of the kind. At the meetings of the Library Committee the Professors and the Curator attended and entered freely and fully into conversation, and the proceedings were by no means formal or formidable. If any application for an assistant were to be made he should much prefer its coming before the Committee in the regular way.

Mr. Williams said what took place respecting the assistant which appeared in the report of the Committee had nothing whatever to do with the Exhibition. The assistant was appointed some time ago to assist in arranging the Hanbury Museum and some special work which was now done. The young man had left and it was simply a question whether it was desirable to appoint a permanent assistant. The Committee decided that there was no necessity for so doing. The question of temporary assistance in carrying out the Exhibition never came before the Committee at all, or no doubt it would have made a recommendation one way or the other.

The President said the Curator had only been five days without an assistant, and there were two porters who would do what he required.

Mr. Symes said he had not brought forward the matter as a grievance, but if he had been on the Committee he should have looked upon it in the same light as if it were a matter occurring in his own business, and he should have said to himself, was it wise to lose an assistant just when his work was being doubled? The Council knew the Curator always had his hands pretty full, and it did not seem wise to let his ordinary work accumulate while he was attending to this Exhibition.

The President said the Committee would meet next week, when Mr. Holmes, if he had anything to say, could bring it forward.

Mr. Atkins moved an amendment—

"That the reading of papers at Evening Meetings of this Society does not necessarily disqualify that paper for payment if published in the pages of the *Pharmaceutical Journal*."

The President said this was an abstract resolution which might leave the Council in a difficulty.

Mr. Mackay said it was opposed to the whole spirit of the recommendation of the Committee.

The amendment not being seconded, the resolution for the adoption of the report and recommendation of the Committee was agreed to.

Admission of Persons not connected with the Society to the Exhibition.

Mr. Symes then moved—

"That all registered chemists and druggists be admitted to the Museum and any other portion of the Society's building used for the purpose of the Exhibition on the day previous to and the day following the Annual Meeting."

He said the only reason for excluding the Wednesday was that it would be inconvenient to have strangers present when the Annual Meeting was being held.

Mr. HAMPSON seconded the motion, which was carried unanimously.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a registered chemist and druggist, in business up to the time of his death, in March last.

£10 to the widow of a former member, who has had two previous grants of like amount.

£10 to the widow of a member who died in 1870. She has had six previous grants.

£5 to the widow of a registered chemist and druggist who had been thirty years in business.

£15 to an associate, aged 29, suffering from ill health, and unable in consequence to earn his living.

£5 and a surgical instrument to a registered chemist and druggist, suffering from an accident and ill health.

Another case was ordered to stand over for further inquiries.

The report and recommendations were received and adopted.

HOUSE.

The report of this Committee only consisted of a recommendation for payment of certain accounts connected with repairs to the building.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor reporting the progress of certain cases which had been placed in his hands.

Several other cases of alleged infringement of the Pharmacy Act had been brought under the notice of the Committee and in some of them it was recommended that the Solicitor be instructed to take proceedings.

The Council went into committee to consider this report. On resuming—

The report and recommendations were received and adopted.

PORTRAIT OF MR. DANIEL BELL HANBURY.

The PRESIDENT read a letter from Mr. Thomas Hanbury, saying that he had employed an Italian artist to make a copy of a portrait of his father, Mr. Daniel Bell Hanbury, which he begged leave to present to the Society. The painting was brought into the Council room, and was considered to be a very faithful likeness.

On the motion of the PRESIDENT, seconded by the TREASURER, a cordial vote of thanks was passed to Mr. Thomas Hanbury for his kindness.

THE ADMINISTRATION OF POISONS TO HORSES.

Two memorials were presented to the Council, one from the Lincolnshire Association for Preventing the Administration of Poisonous Drugs to Horses, and the other from the Lincolnshire Chamber of Agriculture, praying that certain articles, viz., hellebore, butter of antimony, oil of vitriol, spirits of salts, nitric acid, and salts of copper, should be placed in the schedule of poisons, as they were frequently given to horses by farm servants and grooms, contrary to orders, and often with fatal effects.

On the motion of Mr. WILLIAMS, the memorials were referred to the General Purposes Committee.

An application from a member to have a duplicate copy of his diploma, which had been destroyed by fire, was also referred to the Library, Museum and Laboratory Committee.

REPORT OF EXAMINATIONS.

April, 1880.

ENGLAND AND WALES.

EXAMINATIONS IN EDINBURGH.

April 28 *and* 29, 1880.

Present—Mr. Sandford, President; Mr. Schacht, Vice-President; Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson, and Young.

Messrs. Benger, Brady, and Gale were present as a deputation from the Board in London.

Professor Maclagan was present on behalf of the Privy Council.

MAJOR EXAMINATION.

28*th.*—*Three* candidates were examined. *One* failed. The following *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Maben, Thomas ....Hawick.
MacEwan, Peter ....Lochee.

MINOR EXAMINATION.

28*th.*—*Eleven* candidates were examined. *Four* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Adams, John........................Glasgow.
Boyd, Samuel ....Dumfries.
Cairns Thomas Bourhill ....Edinburgh.
Currie, William Little............Glasgow.
Fowler, George.....................Tewkesbury.
Fraser, John ....Chester.
Gowans, John Bruce ....Perth.

29*th.*—*Eleven* candidates were examined. *Four* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Illingworth, George Skeen ......Aberdeen.
Macdougall, Rea Ireland ......Edinburgh.
Murchie, William Gardiner......Lockerbie.
Paterson, Alexander Clarkson...Edinburgh.
Peat, Joseph ....Accrington.
Priestley, Walter Herbert ......Barnstaple.
Wilson, William Wallace ......Glasgow.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The thirteenth general meeting was held at the Royal Institution, on Thursday evening, April 22, the President, Dr. Charles Symes, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations announced:—The current numbers of the *Pharmaceutical Journal*, from the Society; and the *Canadian Pharmaceutical Journal*, from the Editor.

A paper was read by Mr. Thomas Williams, F.C.S., on "The Metallurgy of Spiegeleisen and Ferro-Manganese, and their Employment in the Manufacture of Steel." The paper was discussed by Messrs. A. Abraham, Kehlstadt, Mason and Symes, at the close of which a cordial vote of thanks was passed to Mr. Williams.

The President then delivered his valedictory address as follows:—

Valedictory Address.

One of the penalties to be paid by those who aspire to the presidency of this Association is that they deliver a valedictory address, and it is not my intention on the present occasion to question the prudence of this arrangement; it was so ordered by our predecessors and, we will, if you please, just now accept matters as we find them. Happily, the custom which imposes this address also provides a programme, and it is my duty this evening briefly to review the work of the session, and to bring before you any other matter of importance, which might have escaped notice during our sittings.

At the commencement of the session, we considered our position, and I endeavoured to point out the individual and joint responsibilities of the members, and urged that if we were to maintain our position amongst kindred societies, and serve faithfully our day and generation in the special profession to which we belong, this responsibility must not be lost sight of. That such position has been fully realized, and that some efforts have been put forth, a *résumé* of the work of the session will show.

Mr. Johnson first gave us an interesting paper, on "Some Improved Forms of Apparatus," useful alike to the chemist and pharmacist, and which well illustrated how the application of mechanical ingenuity to daily laboratory work will facilitate operations which are otherwise tedious.

Mr. Conroy, on the same evening, gave us some interesting particulars concerning a sample of "Fictitious Scammony," which was being offered in the market, and described in detail the method he had used for its analysis and such precautions as were found necessary for obtaining accurate results.

Mr. Mason next gave us an exhaustive paper on "Menthol and Thymol," substances which have of comparatively recent date created some amount of notice, if not sensation, amongst members of the medical profession and pharmacists. The author regarded menthol as a liquid, having the composition $C_{10}H_{14}O$, and menthol camphor—the solid body, $C_{10}H_{20}O$. The discussion which followed showed that some difference of opinion existed on these points; but all agreed that the paper was an important one, and dealt most fully with a subject of considerable interest.

Mr. Conroy's second paper, "On Fucus Vesiculosus," was one specially suited to the time at which it was read. The advertisement columns of our newspapers everywhere bore evidence of American enterprise by the puffing of a nostrum called "Anti-fat," which was identified with this particular substance. The mere advertisement (however extensive) of a proprietary article would scarcely have justified an elaborate chemical investigation, but the medical profession took to prescribing different preparations of the fucus, and their journals descanted on its merits and demerits, so that it became the duty of the chemist to deal with its composition, which Mr. Conroy did in a very satisfactory manner, and although the sensation has so soon passed away his work stands for reference on future occasions. The paper concludes with a formula for a fluid extract, or liquor, which possesses whatever medicinal properties the plant may contain.

At our fifth meeting we joined the literary, scientific and art societies of Liverpool in an associated *soirée* at St. George's Hall. By contributions from its own museum and the help accorded by several manufacturing firms, the Chemists' Association was enabled to make an excellent display of chemicals, apparatus, etc.; these, with Mr. Mason's lecture, enabled us to provide our full quota of the entertainment which, as usual, passed off very satisfactorily. It seems to puzzle some of our metropolitan friends as to how such a gathering, amounting to over 3000 persons, can be brought together and entertained with the various subjects on the programme with perfect harmony and to the gratification of all. I can only assert that it was so, and feel assured that reminiscences of the very pleasant evening still linger in the minds of those who attended.

Mr. Davies, in a very interesting paper, dealt with "The Chemistry of Tanning," a technical subject of considerable commercial importance. After reviewing briefly the progressive stages (not very numerous) which led up to the present methods, he dealt more fully with "The Chemistry of the Tannins," which up to the present time is by no means fully worked out, chiefly on account of the difficulty of obtaining them in an absolutely pure state without decomposition. Indeed the excellent epitome of all that is known scientifically on the subject tended to show how much remains to be done.

The lecture was well illustrated with the various substances used in the art.

The seventh meeting was occupied by our own conversazione, held as formerly in this building, and at which Mr. Davies delivered a lecture on "Gases and Vapours." The subject was most *apropos* to the occasion, seeing that scientific men have recently been and still are specially engaged in investigating these forms of matter. Such a lecture in such able hands, and so fully illustrated with good experiments, was, I scarcely need say, a complete success, and contributed largely to make the whole proceedings so. The attendance was scarcely equal to former occasions, but this was accounted for chiefly by its having been held so near to the associated *soirée*, and at a time when festivities of the new year were attracting our friends to scenes of more excitement and gaiety. It has been thought worth our consideration whether we should not merge our own conversazione into the associated *soirée*, and concentrate the whole of the energy, which we now divide, into the one.

Mr. Kehlstadt at our next meeting gave us an excellent, though short paper, on his special branch of technology—"Coal Tar and its Distillation." This we well know is a subject of almost interminable interest, since the once waste body has become such a mine of wealth; the products now obtained from it are truly legion. It has been well said that in coal we have the sun's heat in bygone ages stored up for our present use, and we may add with equal truth his light also, resplendent with its gorgeous display of prismatic colours, when developed under the influence of chemical agencies.

Following this we had a paper in which I endeavoured to sketch, from my point of view, the relationship which existed (and still exists) between the "Pharmacist and the Pharmacopœia," with a view of showing the necessity for the former receiving official recognition in the revision the latter. It has been thought by some persons that in this we are asking more than is our due, and even an undoubted friend and well-wisher to pharmacy, desiring to judge the matter impartially, says:—"We have no more right to dictate as to the contents of the Pharmacopœia than has a cook as to how a dinner shall be prepared and served." Now this is an excellent simile; but anyone who will take the trouble to think it out will doubtless see that the conclusions are entirely in our favour.

Mr. Astrup Cariss, at very short notice, came forward with a paper on a subject with which he has identified himself for some years, viz., "The Relation of Chemistry to Sanitation." He pointed out the frequently occurring want of chemical knowledge on the part of those who had to direct sanitary matters, and the consequent injury to health, and waste of public funds. He gave some interesting examples in support of his statements, and put forth some well matured suggestions, which were calculated to remedy the evil. The paper gave rise to one of the best and most animated discussions we have had this session.

Mr. Haddock followed with a paper on "The Estimation of Copper," in which he reviewed the various processes that had from time to time been proposed for the purpose. He pointed out the defects which characterized most of them, and criticized them in a manner which at once showed his practical acquaintance with the subject. He spoke favourably of the process of Steinbeck, and also of the battery and platinum process of Luckow, considering this latter, with a modification introduced by Mr. Parnell, probably the best known. He regarded also the precipitation of copper by sodium or potassium hydrate as giving very satisfactory results when care was taken in working, and stated it to be the method he usually adopted. The paper was listened to with considerable attention, and was ably discussed.

The next meeting was occupied with three communications and the discussions thereon. One by Mr. Kehlstadt, "Resorcin and the Dyes prepared therefrom." Another by Mr. Conroy, on "Oil of Gentian," a rare product from a common drug, and the third, a description of a "Simple Form of Apparatus for Continuous Extraction."

To-night our late Honorary Secretary, Mr. Thomas Williams, has given us a paper on "Spiegeleisen and Ferro-Manganese, and their Employment in the Manufacture of Steel." The author has identified himself with metallurgy as a branch of chemical industry, and I am sure we have not been disappointed in our expectation of hearing the subject ably dealt with from competent hands.

These, together with some interesting communications of a miscellaneous nature, for which we are indebted to Mr. Conroy, Mr. Mason, Mr. Davies, Mr. Hallawell, and others, constitute the business of the session.

There is a subject which has not come before us in a formal manner to which I wish for a few minutes to direct your attention. It is an investigation which has arrived at a satisfactory stage of progress and has been made known to the world quite recently, viz., that of Messrs. Hogarth and Hannay, which has resulted in the artificial production of the diamond. The experiments of these gentlemen have been conducted on sound scientific principles, and great as is the discovery of the artificial production of the gem, it might be regarded as of secondary importance to the new line of investigation which has been struck out by these able experimentalists and thinkers.

We are all familiar with the solubility of solids in liquids, but an inquiry has now been opened up into the solubility of solids in gases under pressure, and after some amount of patience and perseverance they thus succeeded in getting crystallized carbon. Some idea of the enormous pressure used may be gathered from the fact that tubes constructed on the gun-barrel principle, having a bore of half an inch and an external diameter of four inches, were torn open in nine cases out of ten before sufficient pressure had been attained. A continuation of these investigations will probably throw more light on this new path before we meet again.

A few months since, some members of the Faraday Club, desirous of extending the operations of that body and of increasing its members, called a meeting in this institution to inaugurate the existence of a new society. At first some little anxiety was felt lest this effort at resuscitation on the part of others should affect prejudicially this Association. At present, however, there does not appear to be the least danger of its operations in any way clashing with us, and we have every reason to look forward to a continued prosperity.

Gentlemen, it now remains for me to thank you sincerely for the kind and willing help which you have given in bringing this session to a successful issue and to ask you to appoint my successor.

On the motion of Mr. R. Sumner, seconded by Mr. Edward Davies, F.C.S., a hearty vote of thanks was accorded to the President for the very able manner in which he had filled the chair during the session.

The election of President for next session was then proceeded with, by ballot, and resulted in the unanimous return of Dr. Symes.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The sixth meeting of the session was held at Britannia Chambers on Thursday, April 29. The chair was occupied by the President, Mr. R. FitzHugh, F.C.S., and there was a fairly good attendance of members and associates.

After some preliminary business the President, with a few appropriate remarks, presented the prizes given by Mr. Atherton, F.C.S., and Mr. W. Widdowson for the best essay on "The Art of Dispensing," the first being awarded to Mr. E. H. Judge and the second to Mr W. Gill.

The Chairman then called on Mr. Rayner to read his paper on "Health in the Drug Trade," which consisted of notes on recent correspondence in the *Pharmaceutical Journal* on the longevity of chemists. The writer criticized various letters that had appeared, and expressed his own decided opinion that chemists as a rule, lived as long as any other tradesmen, quoting several local instances where good old age had been attained.

Mr. Bolton, in a few remarks, endorsed Mr. Rayner's opinion, and expressed the hope that the young men, who now enjoyed much more frequent opportunities for recreation than formerly, would use those occasions well, and so tend to improve their health and lengthen their lives.

The President supported those views, and concluded by proposing a hearty vote of thanks to Mr. Rayner, which was seconded by Mr. Wilford, carried unanimously, and suitably responded to.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, April 22. Mr. H. Allen, Vice-President, in the chair.

Mr. C. Thompson read a paper on "Robert Boyle," of which the following is an abstract:—Robert Boyle, the fourteenth son of the Earl of Cork, was born January 25, 1627. He received his early education at Eton; after leaving he travelled on the continent for six years. He went to Oxford in 1664, where a great deal of his work was done. In 1668 he came to London, where he remained till his death. In 1663 the Royal Society was founded, Boyle being elected on the Council. In 1680 he was elected President, but refused the honour. He died December 30, 1691, and was buried in the churchyard of St. Martin's-in-the-Fields, London. His knowledge was very extensive: he knew seven languages and was well versed in all the sciences, but his research was principally confined to chemistry, which he rescued from the hands of the alchemist and gave a separate footing as an exact science. He published in all about thirty works, but eight or ten of these were not scientific, being devoted to theology. His most important work was entitled 'New Experiments, Physico-mechanical, etc.,' and contained an account of the air-pump which he had constructed and of the experiments made with it. In this work he enunciated the great general truth which he discovered, now known as "Boyle's Law," that "the temperature being constant the volume of the gas is inversely as the pressure." There has been much discussion as to whether this law holds good for all gases. In 1825 Despretz showed that CO_2, H_2S, NH_3 and CN are more compressible than air. Arago and Dulong examined air and found the law was applicable to it. Pouillet then corroborated Despretz's experiments. Regnault found that Boyle's law "was not applicable, as far as his experiments showed, to air, as it experiences a greater compressibility which increases with the pressure." Cailletet has lately repeated the experiments of Regnault, and finds that air after a pressure of eighty atmospheres begins to be less and less compressible, and would finally agree with Boyle's law.

After short discussion a vote of thanks was accorded to Mr. Thompson.

Mr. H. R. Arnold then gave his report on Pharmacy, which consisted in a report on—

Emulsifying Agents.

BY H. R. ARNOLD.

Since my last report upon pharmacy, the number of researches in that domain, as well as the introduction of any particular apparatus applicable to pharmacy, or the number of published papers throwing light upon any pharmaceutical subject, have been few. In February last, however, we were made acquainted with the fact that tinct. senegæ possessed emulsifying properties, while only a few months before we were introduced to a new emulsifying agent in tinct. quillaiæ saponariæ. I therefore thought it would be interesting to know how far either of these tinctures might be carried to any practical use, since the value of substances possessing good emulsifying properties cannot be over-estimated by the pharmacist. I have therefore paid more particular attention to these two tinctures, and in none of the samples have I used mucilage of acacia or tragacanth, as I presume most of us are familiar with the kind of emulsions those two substances form with bodies requiring to be thus treated.

The tinct. quillaiæ was made of the usual strength, viz., 4 ounces of the bark to 1 pint of rectified spirit. The tinct. senegæ was made strictly according to the B.P.

I have taken types of each of the following classes, viz., fixed oils, volatile oils, oleo-resins and resinous tinctures.

As an example of the first class I have taken ol. ricini; here is a mixture containing ½ oz. ol. ricini, emulsified with 20 minims tr. quillaiæ. The next sample contains the same quantity of ol. ricini, emulsified with 5 minims tinct. senegæ. Neither of these could be classed under the head of good emulsions, though the one containing tinct. quillaiæ is decidedly the better of the two. In this third sample is the same quantity of ol. ricini (viz., ℥ss), emulsified with ½ drachm of a solution of soap, made by dissolving 1 part sapo moll., P.L., in 2 parts glycerine and 6 parts water, the whole amount therefore containing rather more than 3 grs. of soap; this presents a very good appearance.

But as in each of these emulsifying agents we have bodies possessing in large quantities active medicinal properties, objection is sometimes made to them on that account, and thus another body must be sought, and one which is, comparatively speaking, inert in all proportions. Such a one is to be found in glyconin (*i.e.*, equal parts yolk of egg and glycerine). This sample has been emulsified by ʒiss glyconin, and is certainly to be preferred to any of the others for its consistency and miscibility, but yields to them in colour.

I have taken ol. tereb. as a type of the volatile oils. 20 minims of this require 20 minims tinct. quillaiæ, for its emulsification; it presents a tolerably good appearance. The same quantity of ol. tereb. may be emulsified with 5 minims tr. senegæ; both emulsions present a similar appearance. This oil may also be emulsified by the addition of a few grains of stearic acid, or ordinary commercial stearin; the emulsion will not, however, keep long without separating, but it is interesting, as showing how in the words of Schischkoff, "the emulsifying body performs its office when its smallest particles exert a sufficient attraction on any one constituent of the fat, even though absolutely indifferent to the remainder." As an example of the oleo-resins, I have taken bals. copaibæ, and I think you will agree with me that neither tinct. quillaiæ nor tinct. senegæ form an emulsion at all comparable with the older and commoner method, viz., with mucilage of acacia. Half a drachm of copaiba requires ½ a drachm of tinct. quillaiæ for its emulsification, and in the case of tinct. senegæ, though it has been stated that 5 minims is sufficient for ½ a drachm of copaiba, this was found not to be the case and was therefore doubled; and I would here just point out that in each case a better result was obtained if the body to be emulsified was added gradually to the emulsifying agent than *vice versâ*.

I now come to the last of the class of bodies I have experimented with, viz., resinous tinctures. Of these I have taken tinct. tolu and an alcoholic solution of Chian turpentine. In the case of the former, tinct. quillaiæ seems to answer very well; but not so with tinct. senegæ, for although so large a quantity as 20 minims of the latter was required for 20 minims tinct. tolu, yet this had not the effect of suspending the resin for any considerable time. With regard to the solution of Chian turpentine, neither tinct. quillaiæ nor tinct. senegæ answers well, the resin soon separating; hence while tinct. quillaiæ might be used for the emulsification of some resinous tinctures, on the other hand, tinct. senegæ seems quite inadmissible on account of its weak emulsifying properties.

Ext. filicis liq. may be made into a very good emulsion with either of these tinctures; yet the quantity of tinct. senegæ here required is rather large; but in such an active remedy that objection might be put on one side. I have now brought before your notice the chief merits of these two new emulsifying agents. Whether they will ever come into general use remains to be seen; but if not, it is interesting to know as much as possible of the capabilities of these two bodies, and the manner in which they act with different substances. So far as I have experimented with them, I fail to see that they possess any advantage over the old emulsifying agents.

The meeting then adjourned.

Dispensing Memoranda.

Replies.

[407]. I take it the letters s. q. should be transposed, the directions would read, translated, a sufficient quantity to make one pill.

W. R. Fowler.

---

[408]. As I. H. could not refer to the writer of the prescription, the "phosphate of zinc" would be the best preparation to use; dose of which is from 1 to 2 grains.

"Phosphide of zinc" is administered in much smaller doses, *vide* 'Year-Book of Pharmacy' for 1877, page 272.

Election of Council.

Sir,—I am sorry to find that a misapprehension has arisen as to my identity with the writer of the letter which appeared in the Journal of April 24, advocating the election of Mr. Shepperley as a member of Council. I beg to state that I am *not* the writer of that letter.

Thomas Preston Gostling,
Diss. *Member of Council.*

Sir,—The electors are invited to cast their votes for a candidate who is engaged in preparing students for the Society's examinations.

If the gentleman in question is blind to the impropriety of his request, I trust that my fellow-electors will not fail to detect the danger to their privileges involved.

Probably the most important act performed by the Council during its year of office is the selection of the Boards of Examiners.

The judicial fairness with which this has been done may have prevented our recognizing the fact, just as accurately adjusted machinery causes no friction or jarring noise. But it is by no means a matter of course that the Legislature should continue to permit the members of the Pharmaceutical Society to elect the whole of the Boards of Examiners for England and Scotland. It is a most honourable privilege, and if the proprietors of establishments for preparing candidates for examination had been members of the Council in 1868, it is safe to say that the privilege would not have been likely to be granted.

It is equally probable that it will be taken away when the Pharmacy Act is next amended if this breach of propriety is committed.

The candidate in question alludes specially to his "personal acquaintance" with pharmaceutical students. If any of the gentlemen alluded to have been intending to give him their votes for this reason, I would beg them to consider if some other mark of their friendship would not be more fitting. If the head of one pharmaceutical school exhibits anxiety for a seat upon the Council, it is doubtless supposed to carry advantages, and for the sake of these, or merely in self-defence, other teachers may make the same claim upon the friendship of their old pupils. It was a good maxim of the copy books—"Avoid the beginning of evil." Let us act upon that advice now.

Leeds. Richard Reynolds.

The following is the letter referred to as having been sent to the President by Mr. Butt, in explanation of his retirement as a candidate for a seat on the Council:—

"To the President and Council of the Pharmaceutical Society of Great Britain.

"Mr. President and Gentlemen,—At the time I accepted nomination as a candidate for election to the Council I hoped that, if elected, I might further certain objects which I believe to be desirable.

"It appears, however, probable that the representation at the Council table of the views I hold—in common I believe with the majority of the electors—would be imperilled by too great a division of votes at this election, and I have, therefore, determined with your permission to withdraw from the contest.

"I am anxious that my withdrawal should not be understood to imply that I do not still desire election to the Council, but I consider I can best serve the Society at the present moment by taking the step I now propose.

"13, *Curzon Street*, "Edward Northway Butt.
"*Mayfair, May* 3, 1880."

Sir,—Surely chemists are not blind to their future. The time for election of the new Council is near at hand. Let us unite and use our strength to send men who are worthy of such a position to represent us; men who will work and endeavour to suppress co-operative stores, which are becoming to many of us alarming. Support not those who are revengeful and daily damaging our trade by their $9\frac{1}{2}d.$ patent medicines and other ruinous charges on medicines dispensed, which at the present time does not allow barely an existence.

Hackney. W. M. Covell.

Sir,—The whole gist of the letters of a "Member" and "Pharmacist" is briefly stated thus: by the one "Mr. Shepperley has been the defendant in one of the most notorious and protracted counter practice cases, and is, therefore, not a suitable person to be a councillor," and by the other, "That the fact of Mr. Shepperley having been the victim of the Apothecaries' (?) persecution does not qualify him to represent us." With the first conclusion I entirely disagree, and as to the latter I suppose no one in his senses ever thought it did, but that his retirement from the contest by either is rendered necessary in consequence few, I think, will allow.

If I remember correctly, the Clerk to the Society of Apothecaries distinctly stated after the trial that had it been known that Mr. Jolly Death had been employed by the Nottingham Medical Defence Association to personate illness, with the view of getting a conviction against Mr. Shepperley, the Society's authority to prosecute would immediately have been refused. Now, in the face of an honourable statement as this, how can it be said that Mr. Shepperley's candidature will arouse the suspicion of this Society?

I repeat that because a man has unwillingly been mad the victim of local medical jealousy and persecution this ought not to be a sufficient reason for any member, however much he may love discretion, to ask Mr. Shepperley to reflect and retire from the contest.

I appeal to the sense of fairness of a "Member," who has doubtless in his time suggested something to a customer for the relief of a sore throat, in asking him, whether, had he unfortunately been placed in the same position, he would by such circumstance consider himself for ever afterwards ineligible to take any part in Pharmaceutical Government?

A "Member" has himself to thank for my having denounced his insinuations; if he did not intend his preamble about "conscience," "knowledge," "experience," "interests," "faithful performance," "onerous duties," etc., etc., to be read as parts of his attack, he should not have used such language. I am, however, extremely glad to see the *amende honorable* given in his last letter, more especially as he confesses to knowing nothing personally of Mr. Shepperley. In conclusion, in answer to "Pharmacist," who fails to see the reason why I should have taken up the cudgels in defence of Mr. Shepperley, I merely add, that I hope I have the courage of my opinions and having nominated, I defend him, and in writing a letter sign my name.

Geo. Jas. Gostling.

Alleged Presence of Arsenic in Glucose.

Sir,—In a paragraph in last week's Journal, headed "Poisonous Pigments," I find a statement of a foreign chemist, that glucose artificially prepared from amylaceous materials by means of sulphuric acid always contains arsenic derived from pyrites, etc.

During the last four years I have been engaged as analytical and consulting chemist to glucose manufacturers, and all chemicals, such as sulphuric acid, whiting, etc., were examined and arsenic has never been found to be present. There was a special agreement with the manufacturers of the acid that it should be made of sulphur only. In order to bleach the glucose I proposed the use of sulphuric acid gas, which was afterwards mostly removed by a special process, as its presence would have prohibited fermentation. Traces amounting to 0·015 per cent. could be recognized by the iodine test, starch being used as indicator.

As arsenious acid also discolours the iodine test, it may have been mistaken for sulphurous acid.

H. W. Langbeck.

Communications, Letters, etc., have been received from Messrs. Cox, Nichols, Haydon, Wood, Harrison, Horton, Tocher, Postans, Student, Apprentice, W. D., H. G.

CONTRIBUTION TO THE CHEMISTRY OF NIGELLA SATIVA.

BY HENRY G. GREENISH.

In the conclusion of a paper, published by Marquis, in the *Archiv für Experimentelle Pathologie*,* on the alkaloids of delphinium, attention is drawn by Professor Dragendorff to the suitability of the natural order Ranunculaceæ for the study of the relations existing between the chemical constituents of plants naturally closely allied to one another.

As a step towards extending our knowledge of the Ranunculaceæ, an analysis was made in 1878—79, by Dragendorff and Stahre, of the seeds of *Pæonia peregrina* (taken as a representative of Pæoniæ).†

The following examination of the seeds of *Nigella sativa* was undertaken with the object of ascertaining what relation, if any, the chemical constituents of the seeds bore to those of the other members of the subdivision Helleboræ on the one hand, and those of the Pæoniæ on the other.

The first examination of the seeds appears to have been that carried out in 1841, by Dr. Hugo Reinsch.‡ Among the substances found by this author, are, fatty oil (35·8 per cent.), ethereal oil (0·8 per cent.), two resins, bitter substance, nigellin, and a fluorescent body, together with albumen, gum, etc. The ill-defined characters of nigellin and the method of its preparation led to the conclusion that it could be no pure substance, and this opinion was confirmed by the examination of a sample in the museum of the Pharmaceutical Institute of this town. The latter, prepared exactly according to Reinsch's directions, formed a dark brown mass, of the consistence of a very soft extract, soluble in water, and did not, on the addition of an alkali (solution of potash), in any very perceptible degree show the fluorescence mentioned by Reinsch.

In 1871, Flückiger, in a communication published in this Journal,§ gives the history and botanical, pharmacognostic and microscopical characters of the seeds. As regards the constituents of the same, he confines his attention principally to the fixed and volatile oils. Of the former, he obtained 25·5 per cent., and is of opinion that in the solid fat deposited by standing myristic and palmitic acids are present. Of the volatile oil the yield was less than 0·8 per cent. It was levogyre, and possessed a strongly-marked blue fluorescence. The greater portion distilled at 256°, and its composition corresponded to the formula $C_{20}H_{34}O_2$ ($2\,C_{10}H_{16}+H_2O$).

The literature of the subject being so meagre, it was determined to make an independent analysis of the seeds. These were procured from a chemist in this town, and were obtained from plants cultivated in the neighbourhood of Moscow.

For the history, botanical, pharmacognostic and microscopical characters, I refer to the previously mentioned paper of Flückiger's. Be it permitted me here only to remark that the transverse section of the seed shows the volatile oil to be contained in cells in the outer seed coat, giving it a pitted appearance. The endosperm is loaded with oil globules, and after long keeping, groups of acicular crystals make their appearance, consisting probably of the crystalline solid fat contained in the fixed oil.

§ *Pharm. Journ. and Trans.*, 3rd series, ii., 161. (1871.)

I. Extraction of Fixed and Volatile Oils.—To extract the fixed and volatile oils, 1100 grams of freshly crushed seeds were macerated two days with sufficient petroleum ether to cover them to a depth of half an inch, the solution thus obtained filtered off, the seeds washed with petroleum ether, strongly pressed, dried and weighed. The loss in weight by this extraction with petroleum ether amounted to 300 grams or 27·2 per cent.

This does not, however, represent the total amount of oil present, since absolute alcohol extracts a further quantity, as will be subsequently seen. Petroleum ether possesses no power of penetration, and the reduction of the seeds to a very fine powder is neither easy nor advisable. The petroleum ether filtrate and washings were mixed, the petroleum ether recovered by distillation on the water-bath, its complete removal, together with the ethereal oil, being effected in a porcelain dish on the water-bath. A quantity of dark yellowish-brown oil was thus obtained, which, on standing, slowly deposited a crystalline solid fat. This was reserved for subsequent examination.

To obtain the volatile oil, 2000 grams of freshly crushed seeds were submitted to distillation with water. The yield of ethereal oil was about 12·5 grams=0·62 per cent. It was a yellowish, mobile liquid, possessing in a high degree the peculiar odour of nigella seeds. After standing several months in the museum of the Pharmaceutical Institute, it was found to have deepened in colour. Like the petroleum ether solution from the seeds, it did not possess in any perceptible degree the beautiful blue fluorescence which Reinsch and Flückiger ascribed to it. If a drop of this oil be boiled with water, the filtered aqueous solution gradually assumes a reddish coloration; on the addition of a drop of caustic potash solution the colour deepens rapidly to an intense, very permanent, violet-red, fading only slowly on exposure to light and air.

II. Aqueous Infusion.—After maceration with petroleum ether, the seeds were treated with cold distilled water for twenty-four hours, at the ordinary temperature. The infusion was filtered off, the seeds, washed with water, and the extraction and washing repeated, the residue of the seeds being finally pressed and dried at 40° C. The first infusion only was examined.

This brown-coloured, somewhat cloudy liquid was tested for legumin or casein by the addition of a dilute acid to a small portion. No precipitate being obtained, the absence of legumin and casein was inferred. The whole quantity was evaporated by distillation in a partial vacuum to about one-sixth of its original volume. During this operation, the separation was observed of dark coloured flocks, which proved to be albuminous matter, impure from the presence of colouring (and fatty) matter carried down out of the aqueous solution.

(*a*). *Precipitation of Mucilage.* — The filtrate from this albuminous matter was mixed with three volumes of alcohol (85·5 per cent.) A precipitate was produced in the form of voluminous light-coloured flocks which was filtered off, washed with alcohol, dissolved in water with the addition of hydrochloric acid (without this addition it was not completely soluble), and subjected to dialysis during six days, the water being frequently changed. At the end of that time hydrochloric acid ceased to make its appearance in the dialysate and a grey-coloured substance was deposited in the liquid in the dialyser. The contents of the latter were diluted with a moderate quantity of water and again precipitated with alcohol. The precipitated gummy matter was collected on a filter, washed, drained and finally dried over sulphuric acid. It formed a greyish mass not very easily soluble in hot water, the solution so prepared being slightly acid in reaction. It gave a cloudiness with solutions of acetate and of subacetate of lead, and traces with lime water. It burnt easily, leaving a small quantity of a white light ash.

(*b*). *Treatment of Residue with Absolute Alcohol.*—The filtrate, after precipitation of the mucilaginous matter by alcohol, was freed from the latter by distillation in a partial vacuum, the residue evaporated in a porcelain dish on the water-bath to a small bulk, and mixed with several volumes of absolute alcohol which caused the separation of a brownish, glutinous mass (β). The supernatant clear liquid was poured off, the residue washed with alcohol, the wash alcohol, being added to the clear alcoholic liquid, from which the alcohol was recovered by distillation. The aqueous residue so obtained yielded, on dilution with water, a brownish flocculent precipitate, which was collected on a filter, washed with water, and dried over sulphuric acid. It was found to be insoluble in water, soluble in alcohol, easily soluble in alkalies, being reprecipitated from the alkaline solution by the addition of an acid. These characters tend to refer the substance in question to the class of phlobaphens, it probably being a decomposition product of tannic matter. The aqueous filtrate from this phlobaphene (?) possessed an acid reaction, and was shaken successively with petroleum ether, benzin, chloroform and ether.

(i). The petroleum ether solution left on evaporation a scarcely visible residue.

(ii). Benzin removed from the aqueous liquid a yellowish-brown substance. The shaking was repeated several times till only small quantities of the substance were removed, and the united benzin solutions evaporated to dryness.

(iii and iv). Chloroform and ether removed further quantities of the same yellowish-brown substance.

The liquid was then rendered alkaline with solution of soda, and subjected to a repetition of the above treatment but without result.

By the treatment with the above liquids it is seen that the only substance removed is the yellowish-brown body dissolved out of the acid solution by benzin, chloroform and ether. The residues from all three solvents were united, and formed a clear, dark brown amorphous mass, from which crystals could not be obtained. It was easily soluble in alcohol, sparingly so in water, or in acidulated water; with readiness, however, in alkaline solutions. The aqueous solution reddened blue litmus paper. On boiling with dilute hydrochloric acid it evolved a somewhat penetrating odour, resembling the ericinol produced by the decomposition of glucoside ericolin of *Ledum palustre*. From this ericolin it may be distinguished by the fact that it cannot be regarded as a glucoside. The presence of sugar before or after boiling with dilute acids could not be recognized. The very small quantity of this substance at my disposal precluded the possibility of a closer investigation of its properties and relations.

The clear liquid after shaking with ether was reed from the latter by warming on the water-bath. It was then acidified with dilute sulphuric acid, and was found to give a precipitate with potassiomercuric iodide, and with the majority of the group reagents for alkaloids.

The substance giving these reactions was subsequently isolated from a fresh portion of seeds, the quantity present in this solution being too slight to admit of its separation.

(*c*). *Examination for Sugar.*—The glutinous mass (β), produced by the addition of absolute alcohol to the concentrated aqueous infusion, dissolved in water to a clear deep yellowish-brown solution, which reduced Fehling's solution, although to no very great extent. It was mixed with excess of solution of basic acetate of lead, the voluminous yellowish-grey precipitate filtered off, washed (by suspension in water), filtrate and washings freed from lead by sulphuretted hydrogen, filtrate and washings from the sulphide of lead evaporated to a small bulk on the water-bath, and finally dried over sulphuric acid. It formed a clear amorphous yellowish-brown mass, and deposited, after long standing, a small quantity of crystals. It reduced Fehling's solution as before, but only to a small extent. The examination of this substance was not carried further. It probably contained sugar, although the majority consisted of a substance not capable of reducing alkaline copper solution.

(*d*). *Examination for Acids.*—The lead precipitate which contained the lead salts of the acid present in the seeds, was suspended in water, and decomposed by a current of sulphuretted hydrogen, the sulphide of lead removed by filtration, and the aqueous solution of the acids evaporated on the water-bath to a small bulk, and dried over sulphuric acid. It formed a clear yellowish-brown amorphous mass, soluble in water, with strongly acid reaction. It was treated with absolute alcohol, which left a portion undissolved. The alcoholic solution, after removal of the alcohol and dilution with water, was treated with animal charcoal, by which means part of the colouring matter was removed. The acid liquid contained a relatively large quantity of phosphoric acid, traces of hydrochloric and sulphuric acid.

The substance which alcohol failed to dissolve was easily soluble in water, with a strong acid reaction, and such a solution gave precipitates with potassiomercuric and potassio-bismuthic iodides, with iodine and iodide of potassium, picric and tannic acids, and is the same substance as obtained in the attempt to isolate the alkaloid, the presence of which was anticipated from the above reaction. This, body, however, seems to belong to the class of albumens. With Millon's reagent, with sulphate of copper and solution of potash, it yields the appropriate reactions, and resembles the albumens in containing abundance of nitrogen; but differs somewhat from that class of substances in its strongly acid properties, it forming a compound with barium, which carbonic acid gas fails to decompose.

III. Extraction with Alcohol.—The residue of the seeds after extraction with water was treated with sufficient absolute alcohol to cover them to a depth of half an inch, and allowed to stand several days at a temperature of about 35° C. The tincture was then filtered off, the residue of the seeds strongly pressed, and the alcohol recovered from the tincture by distillation. The residue of the seeds was then subjected to a repetition of this treatment, the concentrated alcoholic tinctures so obtained being mixed and evaporated in the water-bath till all spirit was removed. Separation was then found to have taken place into an upper oily and a lower semi-solid tenacious resinous mass. The oily liquid, which proved to be fluid oil which had escaped extraction with petroleum ether, was poured off, the residue washed with petroleum ether, and dissolved in 50 c.c. warm absolute alcohol. This alcoholic solution on cooling deposited a very small quantity of a white substance, which collected, washed and dried, formed a white amorphous resin, burning with a luminous flame, and leaving no ash. The quantity (about a centigram) was so minute that further examination of this substance could not be made.

The alcoholic solution of the resin was subjected to a fractional precipitation with water. On reaching a dilution corresponding to an alcohol of 71 per cent., a quantity of a dark greenish coloured substance separated out, which was collected, washed with 70 per cent. alcohol, and partially dried by exposure to the air. It was then treated with petroleum ether and ether, the former of which solvents was coloured bright dark green, and removed a green fluid oil (oil with traces of chlorophyll). The ethereal solution left on evaporation a slight quantity of a whitish resinous (?) substance, not identical with the resin, insoluble in 40 per cent. alcohol. A small whitish residue was left undissolved, which proved to be identical with the following resinous substance.

The filtrate, on dilution to a strength corresponding to 40 per cent. alcohol, yielded a tolerably copious light coloured precipitate, which was collected, thoroughly washed, and dried by exposure to the air. The filtrate was evaporated to dryness on the water-bath, and proved to be almost entirely soluble in boiling water, and to contain traces of the resin insoluble in 40 per cent. alcohol. It was not further examined.

The precipitate insoluble in 40 per cent. alcohol was found to contain traces of the fluid oil, from which it was completely freed by treatment with ether. After this purification it formed a whitish amorphous powder, the dust from which caused an unpleasant prickling in the back of the throat, and a sensation of dryness in the nostrils, with a tendency to sneeze, which latter, however, was not very marked. No particular taste could be observed; but the alcoholic solution possessed a slight bitterness, which was quickly followed by a prickling and sensation of dryness in the throat.

In water, benzin, ether, petroleum ether and bisulphide of carbon it is almost insoluble; in chloroform slightly soluble; in alcohol, especially when warm, with ease, the solution being neutral to test-paper. If ether be added to the alcoholic solution no precipitation takes place, and if to the mixture water be added till the ether separates, the substance will be found to have been partially taken up by the ether which now is contaminated with alcohol. The residue left by the ethereal solution on evaporation is identical with the original substance and of the same greyish-white colour. The attempt was made by treating the dilute alcoholic solution with freshly ignited animal charcoal to decolorize it, but the resulting resin still possessed the same greyish tint.

By the slow evaporation of the alcoholic solution the substance was deposited in tufts of long thin greyish coloured microscopic prisms. Aqueous solutions of the alkalies dissolved it, but the addition of an acid to these solutions caused its separation.

A few drops of a weak alcoholic solution imparted to a relatively large quantity (several ounces) of water the property of frothing like soap solution, the froth remaining permanent for hours.

By destructive distillation no umbelliferone could be detected.

A dilute alcoholic solution gave with solutions of reagents in alcohol of about 50 per cent. the following reactions:—

Ferric chloride, a clear yellowish-green solution.

Acetate of lead, a cloudiness.

Basic acetate of lead a whitish precipitate, almost completely soluble in excess.

Mercuric chloride, opalescence.

Barium chloride, clear solution.

The hot aqueous solution failed to reduce alkaline copper solution even after several minutes' boiling.

With pure concentrated sulphuric acid it assumed a reddish then yellowish colour, the whole becoming in fifteen to twenty minutes beautiful rose-red, in the course of as many hours violet-red.

Commercial concentrated sulphuric acid (containing traces of nitric acid) produced a yellowish colour, the whole on warming speedily assuming a dark violet-red tint. Solution of stannous chloride caused almost complete decolorization of the solution with separation of violet coloured flocks. Pure sulphuric acid and sugar resulted in the slow production of a fine violet-blue colour disappearing in the course of a couple of days.

Sulphuric and nitric acids produced an orange-red, turning to yellow.

Boiled with concentrated acid it swelled, without going into solution. No separation of a crystalline substance could be observed.

On heating with a mixture of equal volumes pure sulphuric acid and water, the substance was carbonized.

On heating on platinum foil it first melted, and then burnt with a luminous flame, leaving but a trifling amount of ash. In a quantitative determination 0·2530 gram left 0·0005 gram ash, equivalent to 0·19 per cent.

The melting point was found to be about 205° C.

Dried over sulphuric acid the substance suffered but a very trifling further loss in weight at 110° C.

On burning with oxide of copper in a stream of oxygen, the following results were obtained:—

0·2232 dry substance yielded CO 0·5085, H_2O, 0·1805
0·1818 „ „ „ „ 0·4163, H_2O, 0·1495

equivalent to (calculated on substance free from ash)

	I.	II.	Mean.
C=	62·27	62·58	62·43
H=	9·00	9·15	9·07

This corresponds closely to the formula $C_{20}H_{33}O_7$ which requires—

C = 62·33
H = 8·57

On boiling with dilute hydrochloric acid the substance is decomposed into sugar and a greyish-white substance difficultly soluble in water. This decomposition-product was found to consist principally of microscopic acicular crystals.

Two hours' boiling with dilute hydrochloric acid (1 per cent.) was found sufficient to produce entire decomposition. Accordingly 0·913 gram of the dry substance was so treated with 50 c.c. 1 per cent. solution of hydrochloric acid in a flask provided with a long glass tube to admit of the condensation and return to the flask of the steam evolved so as to avoid concentration of the acid. After cooling the precipitate was filtered off, and washed with water till the washings and filtrate amounted to 100 c.c. As a mean of several estimations 12·05 c.c. of this solution were found necessary to reduce 10 c.c. Fehling's solution. This corresponds to a yield of sugar $=0·4149=45·4$ per cent.

The decomposition-product was dried and weighed. It weighed $0·5045=54·9$ per cent.

In a second experiment, in which 0·929 gram of the dry substance was boiled with alcohol containing 1 per cent. hydrochloric acid, the decomposition product, precipitated by the addition of water, after washing and drying, weighed 0·5323 or 56·3 per cent.

This substance yielded on burning with oxide of copper the following results:—

0·2670 dry substance yielded CO_2 0·739 gram; H_2O, 0·2492.

0·2152 dry substance yielded CO_2 0·5808 gram; H_2O, 0·2030.

equivalent to—

	I.	II.
	C=75·48	73·50
	H=10·31	10·47

In the second of these estimations a minute quantity of carbon escaped combustion, being deposited as such in the chloride of calcium tube, which, therefore rendered the percentage of hydrogen found somewhat too high, the carbon on the other hand decidedly too low. I have accordingly taken the first combustion only into consideration. This corresponds to the formula $C_{14}H_{23}O_2$, which requires—

Calculated.	Found.
C=75·33	75·48
H=10·31	10·38

Supported by these figures I have constructed the following equation for the decomposition which ensues when the substance in question is boiled with dilute hydrochloric acid:—

$$C_{20}H_{33}O_7+H_2O=C_{14}H_{23}O_2+C_6H_{12}O_6$$

According to this equation, 100 parts of the substance should yield 57·7 parts decomposition product and 46·6 parts sugar. I have found instead of 57·7, 54·9 and 56·3, and instead of 46·6, 45·4. These figures show a tolerably satisfactory agreement.

The decomposition product gave colour reactions similar to those of the mother-substance, but the tints were not so striking. It possessed also the peculiarity of imparting to water the property of frothing, and I do not think myself unjustified in assuming the same complex of atoms to occur in both substances.

The name I have adopted for this substance, which appears to be peculiar to nigella seeds, is that proposed by Professor Dragendorff, viz. melanthin; for the decomposition product melanthigenin. The word is derived from the Greek μέλας black, in reference to the colour of seeds which have themselves borne the name of melanthium (Guibourt).

The question now presents itself: With what substances already isolated and examined does melanthin show a similarity, and what are the chief points of distinction?

The property melanthin possesses of frothing in aqueous solution indicates a relationship with saponin and digitonin. From saponin it may be distinguished by its being very difficultly soluble in water, easily soluble in strong alcohol, and by its containing a larger percentage of carbon (saponin contains 54·26 per cent., melanthin 62·43 per cent.*). The digitonin of foxglove-leaves resembles saponin in its solubility in water, difficult solubility in strong alcohol and in the percentage of carbon it contains, and in addition to these characteristics the aqueous solution when heated with dilute acid assumes a red colour.

A greater similarity to melanthin is borne by the parillin of sarsaparilla, which Flückiger† has fully investigated and described. That body he succeeded in obtaining in pure white crystals, the composition of which on analysis proved to be—

C=60·4
H= 9·0

or very nearly identical with melanthin.

Heated during a whole day on the water-bath with dilute sulphuric acid, parillin was completely decomposed into parigenin and sugar.

Parigenin possessed the composition—

C=75·5
H=10·9

or very closely approaching that of melanthigenin.

As is seen, parillin and parigenin show somewhat close agreement with melanthin and melanthigenin. Among others, the following differences serve to distinguish them:—

(i). Melanthin is much more difficultly soluble in water.

(ii). The property of frothing, as also the reaction with sulphuric acid, is possessed by melanthigenin, but not by parigenin.

(iii). The decomposition of melanthin on boiling with dilute acid is rapid and complete.

(iv). On boiling with concentrated hydrochloric acid melanthin yields no scaly crystals.

The glucosides of hellebore, helleborein and helleborin, seem to be somewhat farther removed from melanthin, but still closely related to it.

Helleborein is distinguished from melanthin by its solubility in water, by the rapid appearance of a red coloration when dissolved in concentrated sulphuric acid, by its containing less carbon (52·3 per cent.), and by its marked property of exciting violent sneezing. Its decomposition product, helleboretin, dissolves in spirit with red colour, and assumes with concentrated sulphuric acid a brown-red tint.

Helleborin resembles melanthin in its slight solubility in water and ether, but may be distinguished by its solubility in chloroform and by the slowness and difficulty with which it is decomposed under the influence of dilute acid. It contains more carbon than melanthin. Its decomposition product, helleboresin, contains likewise more carbon than melanthigenin.

---

* With regard to the composition of saponin, it seems that the work accomplished in this direction by Herr Christophsohn ('Vergleichende Untersuchungen über das Saponin,' Dissert, Dorpat 1874) has been overlooked by Mr. Collier ("Saponin from the bark of *Quillaia saponaria*," *Pharmaceutical Journal*, [3], No. 482, p. 234). The former investigator obtained from the bark *Quillaia saponaria*, a saponin which, purified by repeated boiling with 95 per cent. alcohol, contained 2·61 per cent. ash. From Levant soapwort a saponin with only 0.87 per cent. ash. The composition of these saponins agreed closely with one another and with that of the saponines from *Rad. saponariæ rub.* and *Sem. A. grostemma githag.* The mean of eleven analyses was C=54·269 per cent., H=8·283 per cent., O=37·447 and differs widely from Mr. Collier's analysis, viz., C=44·53, H=9·09, O=46·38.

† *Archiv. d. Pharm.*, 3te R., x., 532.

Of the two glucosides, convallarin and convallamarin, contained in the lily of the valley (*Convallaria majalis*), the latter approaches saponin more closely than melanthin; it is easily soluble in water and contains about 53 per cent. carbon. Convallarin, on the other hand, is almost insoluble in water, easily in spirit, but may be distinguished from melanthin by the difficulty incurred in its decomposition with a dilute acid, by its giving a brown colour with sulphuric acid, and by its spirituous solution being precipitated on the addition of ether (melanthin being soluble in ether-alcohol). Its decomposition product, convallaretin, is easily soluble in ether and dissolves in concentrated sulphuric acid, turning slightly brown. Melanthigenin is difficultly soluble in ether and yields with concentrated sulphuric acid a red colour.

The arthanitin of Saladin (cyclamin) from *Cyclamen europæum*, also found in the roots of *Primula veris* (whence sometimes called primulin), is, like saponin, easily soluble in water, and contains only 55 per cent. carbon.

The yield of melanthin from Russian seeds was about 1 per cent. From German seeds which I subsequently worked up for this substance I obtained less than 0·1 per cent., and that impure.

The residue from the evaporation of the filtrate from melanthin formed a greenish mass, which still contained a small quantity of that principle associated with substances almost completely soluble in water (which had escaped extraction with that menstruum). It was not further examined.

(*To be continued.*)

NOTES ON CHIAN TURPENTINE.

BY R. MODLEN.

A recent paper in the *Lancet* (March 27th) having strongly recommended the use of Chian turpentine in cases of uterine cancer, I am induced to offer a few notes on the history of the drug. There is nothing original in them; they are merely extracts from works not generally accessible, but may prove of some interest.

Terebinthina chia (French, térébinthine de chio; Italian, trementina di cipro; German, cyprischen terpentin) is a liquid resinous exudation from *Pistacia Terebinthus*, nat. order, Terebinthaceæ, Juss., a handsome tree growing in most parts of the south of Europe, but especially in the Greek Archipelago. As *P. cabulica* it extends also to Beluchistan and Afghanistan, and as *P. Atlantica* it is found in North Africa. These different species are, however, considered by Hanbury and Flückiger as being merely slight variations of *P. Terebinthus*. In Languedoc and Provence it is a straggling bush, but in Palestine it is a handsome umbrageous tree.

Its Hebrew name is alah, variously rendered as oak, terebinth, tiel (linden), elm and even plane. The primary import of the word alah is strength, power, whence some hold that it signifies any mighty tree, especially the oak and terebinth. But as the oak has its proper name, allon, and is *not* a mighty tree in Palestine, one can have little hesitation in restricting the term alah to the terebinth. Dr. Robinson gives the best account of the tree as it is now found in Palestine. At the point where the roads from Gaza to Jerusalem and from Hebron to Ramleh cross each other, and about midway between the two last named towns, this traveller observed an immense terebinth tree, the largest he saw anywhere in Palestine. "This species is without doubt, the terebinth of the old Testament, and under the shade of such a tree Abraham may well have pitched his tent at Mamre. The terebinth (Arabic *but'm*) is not an evergreen, as is often represented; but its small feathered lancet-shaped leaves fall in the autumn. The flowers are small, and followed by small oval berries, hanging in clusters from 2 to 5 inches in length, resembling much the clusters of the vine when the grapes are just set. From incisions in the trunk there is said to flow a sort of transparent balsam, constituting a very fine and pure species of turpentine, with an agreeable odour, like citron or jessamine, and a mild taste, and hardening gradually into a transparent gum. In Palestine nothing seems to be now known of this product of the but'm."

In Palestine and the neighbouring countries the terebinth seems to be regarded with the same distinction as the oak is in our northern latitudes, and is very long lived. It attains the height of 30 to 35 feet.

The resinous juice is secreted in the bark, in special cells, precisely as mastic is formed in *P. Lentiscus*. To some extent it exudes spontaneously, but in greater abundance after incisions are made in the stem and branches. A large tree will yield from 6 to 11 ounces in a year. The harvest is from the end of July to October. In 1701, Tournefort visited Scio, when that island was said to produce scarcely 300 okes (oke = 2·82 lb. avoir.). A century later, Olivier stated that 200 okes was about the average yield. The trade is almost entirely in the hands of the Jews, who usually dispose of the gum in the Turkish Empire. In Greece it is sometimes used to flavour cordials, or mixed with wine in the same manner as mastic.

The gum as usually found in commerce, is a soft solid, becoming brittle by exposure to air. It is of a yellowish-green colour, and is composed of a resin and a volatile oil. All accounts agree in stating that it is extremely scarce in western commerce, coniferous turpentine being usually substituted for it. Dr. Pereira says it has an odour somewhat resembling fennel. By keeping, it acquires a somewhat less agreeable odour. It is soluble in rectified spirit, amylic alcohol, glacial acetic acid, benzol or acetone, and pure ether, B.P., the solution in each case being slightly fluorescent. An alcoholic solution reddens litmus and is neither bitter nor acrid.

Chian turpentine was well known to the ancients. It was the Τέρμινθος of Theophrastus.

Dioscorides, of Anazarba, in Cilicia, who wrote his great work on materia medica, A.D. 77 or 78, describes it as a finer sort of mastich. He says:—"There is also a resin in the lentisk (*Pistacia Lentiscus*), called lentiscine, by many, mastich. It is added to dentifrices, and to face liniments. The best resin and largest quantity comes from the island of Chio. The best is shining, like Tyrrhene wax in colour, large, easily crumbled, and fragrant. There is a green sort, but not so useful." Even in the time of Dioscorides there seems to have been need of an Adulteration Act, for he says, "It is mixed with frankincense and fir turpentines." (*δολοῦται δὲ λιβάνου κάι ῥητίνης υτροβιλίνης μιγνυμένων αἰτῃ.*)

In chapter 91 of book 1, he says, speaking of another substance which Sir R. Christison says is that known at present as Chian turpentine, "that the kernels of the fruit are edible, but disagreeable to the stomach. It acts as a diuretic, and is used in wine for diseases of the finger joints. The resin is imported from Arabia Petræa; it also grows in Judæa, Syria, Cyprus, Libya, and the Cyclades. This resin is by far the finest of any; then comes mastic, then pine and larch resins (turpentines). After these may be reckoned fir resins. It is very fit to give in cough and wasting away. It is given either given by itself or mixed with honey." He also gives a list of other diseases in which it was given at that time.

After being almost unknown in England, except as a botanical curiosity, the attention of the medical professsion has been drawn to the substance by Professor Clay, of the Queen's Hospital, Birmingham, as a cure for uterine cancer For most interesting particulars concerning the more purely medical part, I beg to refer to the *Lancet* of March 27.

The notes have been taken from Sir R. Christison's 'Dispensatory,' Edinburgh, 1842; Dr. Pereira's 'Materia Medica,' London, 1857; Dr. Kitto's 'Biblical Cyclopædia' (the botanical articles in which were written by Dr. Royle), London, 1856; C. G. Kühn's edition of Dioscorides, Leipsic, 1827; and Hanbury and Flückiger's 'Pharmacographia,' London, 1879.

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.*

BY WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

Lecture I.

(*Concluded from page 894.*)

Diastatic Ferments: Digestion of Starch.

The importance of starch as an article of human food has, perhaps, scarcely been duly recognized. If we regard the enormous proportion in which the seeds of cereals and leguminous plants, and the tuber of the potato, enter into our dietary, and the immense percentage of starch in these articles, it is probably not too much to say that fully two-thirds of the food of mankind consists of starch. In the raw state, starch is to man an almost indigestible substance; but, when previously subjected to the operation of cooking, it is digested with great facility.

Diastase has only a feeble action on the unbroken starch-granule, even at the temperature of the body. In the lower animals, and in germinating seeds, the starch-granule is probably attacked in the first instance by some other solvent, which penetrates its outer membrane, and thus enables the diastase to reach and act on the starchy matter contained within. By the aid of heat and moisture in the process of cooking, the starch-granule is much more effectively broken up. Its contents swell out enormously by imbibition of water, and the whole is converted, more or less completely, into a paste or jelly or mucilaginous gruel. It is in this gelatinous form exclusively, or almost exclusively, that starch is presented for digestion to man. The digestion of starch is accomplished by the saliva and pancreatic juice, both of which are rich in diastase. Diastase also exists abundantly in the liver, and in smaller quantities in the intestinal juice, in the blood, the urine, and apparently in all the interstitial juices. Diastase from all these diverse sources appears to act substantially in the same manner as starch, changing it by a progressive hydrolysis into sugar and dextrine.

If the action of a fluid containing diastase—say saliva or extract of pancreas—on starch paste be watched, the first effect observed is the liquefaction of the paste and the production of a diffluent solution. This change is effected with great celerity; in two or three minutes, the stiff paste becomes a watery liquid. This is evidently a distinct act, and antecedent to the saccharifying process which follows. By operating with small proportions of diastase and large proportions of pure starch paste, it is possible to hit on a moment when liquefaction is complete and saccharification is not yet begun. At this moment, the solution yields a pure starch reaction, and no reaction of dextrine nor of sugar. The process of saccharification follows immediately on the heels of liquefaction; and, in ordinary manipulations, the one process runs into the other.

The speed of the action depends primarily on the proportion of the diastase. By adjusting the proportions of diastase and starch in such degrees that saccharification will be completed in about a couple of hours, the successive steps of the process can be leisurely followed by applying from time to time the appropriate tests.

If you test as soon as liquefaction is complete, you get a pure blue with iodine and a slight reaction of sugar with Fehling's solution. In a few minutes, the sugar reaction becomes more decided; and, although you still get a pure blue with iodine in the ordinary way of testing, you will get, by greatly diluting the blue solution and then adding more iodine, a deep violet tint—showing the presence of erythro-dextrine mixed with starch. The next step is the total disappearance of the blue reaction with iodine, and the substitution for it of an intense reddish-brown coloration of erythro-dextrine. By-and-by, the reddish-brown colour is replaced by a yellowish-brown, indicating the preponderating presence of a different kind of erythro-dextrine. Meanwhile, the sugar reaction goes on increasing. The next step is the entire disappearance of any kind of coloration with iodine. But the action is still very far from complete; the proportion of sugar goes on increasing for a considerable time after iodine has ceased to tint the solution. At length, however, matters come to a standstill, and the proportion of sugar ceases to increase.

The explanation of this series of reactions is impossible on the old view of the constitution of starch. Until recently, it was supposed that the starch-molecule was represented by the comparatively simple formula $C_{12}H_{20}O_{10}$; and that, under the influence of diastase, this molecule was resolved by hydration into two molecules—one of dextrine and one of grape sugar.

The researches of Musculus and O'Sullivan* have shown that this is not a correct account of the transformation. In the first place, it was found that the sugar produced was not grape sugar (dextrose), but another kind of sugar called maltose. It was also found that the dextrines first produced, and which were coloured red or brown by iodine, were progessively changed, with simultaneous production of sugar, into a series of dextrines of a lower type, which did not yield any coloration with iodine. To these latter kinds of dextrine the term achroo-dextrines has been applied.

As maltose is now ascertained to be the kind of sugar which is mainly produced in the digestion of starch by diastase, this body assumes a new and considerable importance in physiological chemistry; and it will not be out of place here to give some description of its properties. Maltose is a fermentescible crystalline sugar of the saccharose (cane sugar) class, having very little sweetening power, and possessing one atom less water than grape sugar. Its formula is $C_{12}H_{22}O_{11}$. It possesses more rotatory power on polarized light than grape sugar, but considerably less power of reducing cupric oxide. The rotatory power of maltose is +150, that of grape sugar +58. The reducing power of maltose is 61, compared to that of grape sugar as 100. Maltose can be hydro-

* The Lumleian Lectures, delivered before the Royal College of Physicians.

* O'Sullivan's papers are published in the *Journal of the Chemical Society* from 1872 to 1876. A full account of these researches is given in a paper in the same journal for September 1879, by T. H. Brown and J. Heron.

lysed into grape sugar by prolonged boiling with dilute acids. Malt diastase does not possess this power; but we shall presently see that the diastatic ferments of the small intestine are able slowly to effect the same change.

The researches of Musculus and O'Sullivan have rendered it necessary to assume that the molecule of soluble or liquefied starch is a composite molecule, containing several members of the group $C_{12}H_{20}O_{10}$, which is to be regarded as the constituent radical of the composite starch-molecule. The starch molecule must in the future be represented by the formula $n\ (C_{12}H_{20}O_{10})$—the value of n not being yet definitely agreed upon.

Two able chemists of Burton-on-Trent, H. T. Brown and J. Heron, have extended these researches, and fully confirmed the main conclusions of Musculus and O'Sullivan. In a recent publication (*Journal of the Chemical Society*, September 1879), they have for the first time presented a fairly complete scheme of the succession of changes undergone by starch under the action of diastase. These chemists assume that the molecule of soluble starch consists of ten members of the group $C_{12}H_{20}O_{10}$, and that its formula should be written $10(C_{12}H_{20}O_{10})$. This view greatly facilitates the comprehension of the progressive hydrolysis of starch by diastase.

We have seen that starch in the condition of paste or jelly is distinguished sharply by its physical properties from liquefied or soluble starch. There must, therefore, in all probability, be some difference of molecular aggregation between starch in these two states; and it will not be a very bold assumption to suppose that starch in the gelatinous state consists of still more complex molecules than soluble starch, and that several molecules of soluble starch are grouped together to form the molecule of starch in the gelatinous state.

On the ground of these assumptions, we may represent the successive steps of the digestion of gelatinous starch by the following series of equations.

The molecule of gelatinous starch $= n(C_{12}H_{20}O_{10})$ is first resolved into n molecules of soluble starch. The molecule of soluble starch is then resolved by progressive deduplication and hydration into dextrine and maltose by the following succession of steps.

One molecule of soluble starch $= 10(C_{12}H_{20}O_{10}) + 8(H_2O) =$

1. Erythro-dextrine α $9(C_{12}H_{20}O_{10}) + (C_{12}H_{22}O_{11})$ maltose.
2. Erythro-dextrine β $8(C_{12}H_{20}O_{10}) + 2(C_{12}H_{22}O_{11})$ „
3. Achroo-dextrine α $7(C_{12}H_{20}O_{10}) + 3(C_{12}H_{22}O_{11})$ „
4. Achroo-dextrine β $6(C_{12}H_{20}O_{10}) + 4(C_{12}H_{22}O_{11})$ „
5. Achroo-dextrine γ $5(C_{12}H_{20}O_{10}) + 5(C_{12}H_{22}O_{11})$ „
6. Achroo-dextrine δ $4(C_{12}H_{20}O_{10}) + 6(C_{12}H_{22}O_{11})$ „
7. Achroo-dextrine ϵ $3(C_{12}H_{20}O_{10}) + 7(C_{12}H_{22}O_{11})$ „
8. Achroo-dextrine θ $2(C_{12}H_{20}O_{10}) + 8(C_{12}H_{22}O_{11})$ „

The final result of the transformation is represented by the equation

$$\underset{\text{Soluble Starch}}{10(C_{12}H_{20}O_{10})} + \underset{\text{Water}}{8H_2O} = \underset{\text{Maltose}}{8(C_{12}H_{22}O_{11})} + \underset{\text{Achroo-dextrine}}{2(C_{12}H_{22}O_{10})}$$

We must conceive that the energy of the ferment is exercised in gradually pulling asunder the component groups or radicals of the unstable molecule of soluble starch, detaching one after another from the parent molecule; each radical, as soon as detached, assuming an atom of water and becoming an atom of maltose. At each detachment, the parent molecule draws its remaining groups together to form a new kind of dextrine. As the process goes on, the dextrine molecule becomes smaller and smaller—that is, contains fewer and fewer component radicals; the higher dextrines giving a red or brown coloration with iodine, but the lower dextrines giving no reaction with iodine. It is to be noted that, after the transformation has reached its final term, there still remains a portion of achroo-dextrine unconverted into maltose. Upon this remnant, diastase has only a very slow action. The percentage result, when the reaction is completed, gives, in round numbers, eighty parts of maltose and twenty parts of achroo-dextrine. The eight varieties of dextrine indicated in the above table of equations have not all been obtained in the separate state; but there is strong evidence of the existence of at least several of them as distinct bodies.

The account just given of the transformation of starch has been deduced from a study of the action of diastase derived from malt. The question arises—physiologically an important question—whether the action of salivary and pancreatic diastase is identical with that of malt diastase. The researches of Musculus and von Mering* give an affirmative answer to this question. These observers found that saliva and pancreatic extract act on starch paste in the same way as malt diastase; the final products in all cases being achroo-dextrine and maltose, and not dextrose (grape sugar). At my suggestion, Mr. H. T. Brown was good enough to submit the question to a fresh examination in regard to pancreatic extact. His results fully confirm the conclusions of Musculus and von Meering. He found, however, that there was a slight difference in the results when the action of pancreatic extract and malt diastase on starch was continued a long time. The pancreatic ferment, in addition to the power, which it shares with malt diastase, of slowly converting the lowest achroo-dextrine into maltose, exhibited a power of slowly changing maltose into dextrose (grape sugar) which is not possessed in any degree by malt diastase. Mr. Brown also informs me that there is in the small intestine a ferment which possesses similar properties.

The respective Shares of Saliva and Pancreatic Juice in the Digestion of Starch.—The respective shares of saliva and of pancreatic juice in the digestion of our farinaceous food are probably variable, and perhaps not quite identical.

As all our farinaceous food is eaten after being cooked, the starch in it is more or less completely gelatinized; it is, therefore, probable that one of the chief uses of salivary diastase in man is to liquefy starch jelly. A very brief contact suffices for this; and it is manifest that the accomplishment of this change is an important advantage in the subsequent operations in the stomach. Our gruels, blancmanges, puddings, and similar farinaceous dishes, owe their thick pasty condition to starch in the gelatinous state; and nothing can be imagined more resistent to the rapid permeation of the meal by the gastric juice, and to the pulping of it into a uniform chyme, than the presence of coherent masses of starch-paste. If the saliva performed no other service than this, it would furnish an important aid to the digestion of a meal. There has been considerable dispute as to whether, and how far, the saccharification of starch goes on in the stomach. My observations lead to the conclusion that this depends on the degree of acidity of the contents of the stomach; and it is known that this varies within very wide limits. When a meal is swallowed, it takes some time for the gastric juice to permeate the mass, and the acidity of the gastric contents is for some time very feeble. As digestion proceeds, the contents of the stomach tend to become more and more acid. This is a point which each one can observe for himself. The stomach is by no means reticent of its doings. The posseting which we see in infants goes on in a less degree in the adult; and we are perforce made aware, sometimes inconveniently so, by our palates, of the ascending scale of acidity in the stomach. Saliva acts energetically in neutral and in slightly acid media; but its activity is checked and finally arrested when the acidity becomes pronounced. When digestion is proceeding comfortably and normally, a certain interval elapses before the acidity of the stomach becomes considerable; and during this interval the salivary diastase continues active, and has time to accomplish a good deal of work. But we must remember that our farinaceous food is, for the most part, not in the most favourable condition for rapid digestion. It is not generally in a state of mucilage but in the form of a solid paste, as in bread, puddings, and pastry. A good deal of it, too, is imperfectly cooked.

* Maly's *Jahresbericht für Thier-Chemie* for 1878, p. 40.

Consequently, the larger part of our starchy food reaches the duodenum still unchanged, or only partly changed; and this larger part of the work is consummated by the pancreatic juice in the alkaline medium of the small intestine. I shall have to return to this point in speaking of gastric digestion.

It has been noted as curious, that the saliva of man possesses more diastatic power than that of almost any other animal. Among the herbivora, which are large consumers of starch, the saliva has comparatively little diastatic power; and in some, as in the horse, it is almost or altogether wanting. I apprehend that this is due to the fact that man alone has learnt to cook his starchy food, and that the diastatic power of his saliva has become developed with the opportunity for its exercise. Diastatic power would be thrown away in the saliva of the horse, because he eats his food in the raw or uncooked state, and saliva is without action on raw starch.

When can Starch be said to be fully Digested?—Seeing that in the digestion of starch a number of intermediate products are evolved, the question arises, when can the digestion of starch be said to be accomplished? Is maltose the only product absorbed? are not the dextrines, especially the achroo-dextrines, also absorbed? The dextrines, even those coloured by iodine, are highly diffusible, and pass freely through parchment-paper in dialysis. In this respect, they contrast strongly with starch-jelly, and even with liquefied (or soluble) starch, both of which are undialysable. It seems not improbable that the lower dextrines are largely absorbed. Because, if we follow the history of starch after it has been transformed by digestion and absorbed, we are confronted with the remarkable fact that, after absorption, the products of starch digestion or at least a large portion of them, undergo a reconversion in the liver into a substance closely resembling undigested starch. Glycogen, in its essential features, is an exact counterpart of soluble starch. It forms an opalescent solution in water; it is undialysable; and it is transformed by diastase into dextrine and sugar.

It appears reasonable to suppose that it would be an advantage to the economy, if that portion of our starchy food which is destined to be stocked in the liver as glycogen should be absorbed at an early period of digestion, because, the less removed the digested product is from starch at the moment of absorption, the fewer steps it will have to retrace in recovering the amylaceous state after absorption.

It is not necessary to suppose that the ascending steps of the reconversion are identical with the descending steps of digestion; but it is probable that they are fundamentally alike, seeing the close similarity of the products at the two ends of the journey. At any rate, there is no warrant in the present state of knowledge for the opinion that sugar is the only absorbable product of starch digestion.

Absolute Energy of Diastase.—The notion that the energy of diastase is not consumed in action seems, on *à priori* grounds, to be quite untenable; such a notion contravenes a general principle in physics, that energy in performing work is expended and finally exhausted. It is easy to show experimentally that diastase is no exception to this rule. Payen and Persoz estimated that malt disatase was able to convert two thousand times its weight of starch into sugar. My own experiments with extract of pancreas indicate a much higher power than this. The following experiment illustrates at the same time the enormous diastatic power of pancreatic diastase, and the fact that this power is strictly limited.

A quantity of starch mucilage was prepared, containing one per cent. of pure potato starch; one hundred cubic centimetres of this mucilage contained exactly one gram of dry starch. The pancreatic extract employed was prepared in the following manner. Fresh pig's pancreas, freed from fat, was rubbed up with an equal weight of fine sand until it became a smooth uniform pulp. This pulp was spread out very thinly on sheets of glass, and allowed to dry in the open air for a fortnight. It was then scraped off with a knife, and formed a rough shreddy sort of powder. One hundred and twenty-five grams of this mixture of pancreas and sand were infused, at the temperature of the room, in one thousand cubic centimetres of saturated chloroform-water, with a little more chloroform added to insure against decomposition. The mixture was allowed to stand for four days with occasional agitation, and the product was then filtered clear through paper. The extract of pancreas thus prepared proved a very serviceable preparation, and most of my observations on pancreatic digestion were made with it.

This extract was found to be so extremely active, that it was necessary to dilute it largely in order to bring the quantities of starch operated on within due compass. Accordingly, a dilution was made of one cubic centimetre of the extract in one thousand cubic centimetres of water. Five numbered phials were then severally charged with one hundred cubic centimetres of the prepared starch mucilage, so that each phial contained exactly one gram of dry starch. One cubic centimetre of the diluted pancreatic extract was added to phial No. 1; two cubic centimetres to No. 2; four cubic centimetres to No. 3; six cubic centimetres to No. 4; and eight cubic centimetres of the same diluted extract to phial No. 5. The phials were then corked and placed in a warm chamber, where the temperature was steadily maintained by a Page's regulator at 100° F. (38° C.)

At the end of twenty hours, the contents of the phials were examined. All of them were perfectly transparent, and had entirely lost the opalescent appearance of the original starch mucilage, and not a vestige of sediment existed in any of them. The following reactions indicated the progress of the transformation.

No. 1 gave an intense blue coloration with iodine, and, when the blue solution was largely diluted and more iodine added, it developed a violet tint which showed the presence of erythro-dextrine; it also reduced the cupro-potassic solution freely.

No. 2 gave a strong blue reaction with iodine, and, by diluting and adding more iodine, the colour changed to a deep claret-red, indicative of abundance of erythro-dextrine. This and all the rest gave a strong sugar reaction with Fehling's solution.

No. 3 yielded no blue reaction with iodine, but an intense port-wine coloration of erythro-dextrine.

No. 4 gave no blue reaction with iodine, and only the faintest possible brown coloration with that reagent, showing only trace of erythro-dextrine.

No. 5 exhibited not a vestige of reaction with iodine. It contained neither starch nor erythro-dextrine, but it yielded a strong sugar reaction,

The transformation of No. 5 might be regarded as complete, but the rest still contained starch or erythro-dextrine, or both, Nos. 1, 2, 3 and 4 were restored to the warm chamber and re-examined at the expiration of seven hours. No. 4 no longer gave the slightest reaction with iodine; but Nos. 1, 2, and 3 showed only slight signs of further alteration, and were returned to the warm chamber.

At the end of forty-eight hours from the commencemeent of the experiment, Nos. 1, 2, and 3 were examined again.

No. 1 showed a strong blue coloration with iodine, and also a strong reaction of erythro-dextrine,

No. 2 no longer gave any blue tint with iodine, but it exhibited an intense erythro-dextrine reaction.

No. 3 only gave a yellowish-brown reaction with iodine of moderate intensity.

After a further sojourn of seventy hours in the warm chamber, the contents of the three phials were not found to be sensibly altered; they gave exactly the same reactions as before. It was evident that in these phials the diastatic action had run its course to an end within the period of forty-eight hours, and that the solutions had then come to a state of rest, the ferment had liberated all its energy, the limits of its power had been reached, and the task allotted to it was left unfinished. Nevertheless, it had accomplished an amount of work which, considering its infinitesimally minute mass, appears marvellous. We shall now endeavour to measure approximately the amount of this work as indicated by the above experiments.

The original pancreatic extract, when evaporated to dryness in a water-bath, was found to leave a residue of 1·5 per cent. of organic matter. This organic matter included, besides diastase, a quantity of proteolytic ferment (trypsin) and a certain quantity of the milk-curdling ferment. It also included a certain quantity of digested proteid matter; for, in making an extract of the pancreas, there is always accomplished some self-digestion of the glandular tissue. Taking into account these various admixtures, it would appear a very liberal allowance to estimate the diastatic ferment as amounting to one-fourth of the total organic matter. This would give us for the original extract a proportion of diastase, in round numbers, of 0·4 per cent., and for the diluted extract, of 0·0004 per cent.

The proportion of diastase added to phial No. 4 seems to have hit off with precision the limit of quantity required to transform one gram (15·5 grains) of starch in forty-eight hours at a temperature of 100° F. (38° C.). The amount of diluted extract added to this phial was six cubic centimetres; and, on the basis of the above estimate, this represents a quantity of net diastase amounting to 0·000024 gram. This yields us, by an easy calculation, the astounding result that pancreatic diastase is able to transform into sugar and dextrine no less than forty thousand times its own weight of starch.

The speed at which a given quantity of starch is transformed by diastase depends essentially on the proportion of ferment brought to act upon it. In the above experiments, the proportion of diastase was very minute in comparison with the amount of starch, and the action went on slowly for forty-eight hours. But if we reverse these proportions, and mix a small amount of starch with a large amount of diastase, the transformation is instantaneously accomplished.

If a test-tube be half filled with an active extract of pancreas, and a few drops of starch mucilage be quickly shaken therewith, you cannot detect the reaction of starch or dextrine in the mixture, however prompt you may be with the testing; the transformation has followed on the admixture as instaneously as the explosion of the charge follows the fall of the trigger. Between these extremes there are all gradations. This mode of action differs entirely from what is seen in the operation of ordinary chemical affinity. If you add a drop of acid to an excess of alkali, the acid is instantly neutralized and the action comes to an end; and conversely, if you add a drop of alkali to an excess of acid, the action is equally instantaneous; the affinity of the two bodies for each other is a mutual affinity. But this is not the case with the action of diastase on starch. The starch appears entirely passive in the process; all the energy is on the side of the diastase, and this energy can only be liberated gradually. There is something in this strikingly suggestive or reminiscent of the action of living organisms. To illustrate my meaning, let us compare the particles of the ferment to a band of living workmen, whose function is to scatter little heaps of stones. If the heaps be few and the workmen many, all the heaps will be scattered at once, and the energy of the workmen will still remain sensibly unimpaired. But if the heaps be millions and the workmen hundreds, and if the workmen be doomed to labour on until they fall exhausted at their task, the scattering of the heaps will go on for a comparatively long time, and the process of exhaustion will be a gradual one.

I may here mention that the diastatic ferment does not exist in the saliva and pancreatic juice of young suckling animals, except in minute proportions. Its quantity increases when the teeth are cut. In the human infant, diastase does not appear to exist in sufficient abundance to digest starchy matters effectively until about the sixth or seventh month. Until this period, it is, therefore, not advisable to administer farinaceous food to infants.

DIGESTION OF CANE SUGAR: INVERSIVE FERMENT.

Bernard* first called attention to the fact, already mentioned, that cane sugar (saccharose) required digestion both in animals and plants before it could be utilized in nutrition. The cane sugar stored up in beet-root and in the sugar cane is changed by ferment action into invert sugar before it is permitted to circulate in the sap, and take part in the nutritive operations of the plant. He also found that an analogous transformation was requisite before cane sugar could be assimilated by animals. He states that, when cane sugar is injected into the blood, it circulates therein as an inert body, and is in no degree used as nutriment by the tissues, but is eventually entirely removed unchanged with the urine. Cane sugar is, however, an important article of food, and is consumed by us in large quantities every day; and we know that, when thus consumed, it does not behave like an inert matter, circulating awhile in the blood, and then being eliminated by the kidneys as a waste product. It is evidently absorbed and assimilated, and must, therefore, somewhere or other, be transformed or digested in animals as it is in plants. Reasoning this way, Bernard sought for an inversive ferment for cane sugar in the alimentary tract; and after searching in the saliva, in the stomach, and in the pancreas in vain, he at length discovered it in the small intestine. In the small intestine, he found that cane sugar was transformed into invert sugar, and by a similar ferment with that destined for analogous purposes in yeast, in beet-root, and in the sugar cane.

The transformation of cane sugar into invert sugar is represented by a very simple equation:—

$$\underset{\text{Saccharose.}}{2C_{12}H_{22}O_{11}} + \underset{\text{Water.}}{2H_2O} = \underset{\text{Dextrose.}}{C_{12}H_{24}O_{12}} + \underset{\text{Lævulose.}}{C_{12}H_{24}O_{12}}$$

The inversive ferment was detected by Bernard in the small intestine of dogs, rabbits, birds and frogs. Balbiani found it in the intestine of the silkworm. It was recognized by myself in the small intestine of the pig, the fowl, and the hare. It does not exist in the large intestine.

But although my observations on this subject coincided in the main with those of Bernard, I noted two points which I think merit further attention. The first was that while a piece of small intestine infused in water yielded a mixture which was capable of inverting cane sugar, the same infusion when filtered through paper until it was perfectly clear had no such power. It seemed as if the inversive ferment did not pass freely, if at all, into true solution, but remained attached to some of the formed elements contained in the intestine. The second point which I noted was the extreme slowness of the action. When cane sugar was added to the unfiltered infusion of intestine, and the mixture maintained at blood-heat, it generally took a couple of hours before a reducing effect with the copper test could be obtained. Both these circumstances reminded one of the action of formed ferments, and I could not help thinking that there was here something which required clearing up at some future time.

THE PRODUCTION OF INDIGO IN BENGAL.†

Indigo is almost entirely obtained from leguminous plants of the genus *Indigofera*, that cultivated in India being the *Indigofera tinctoria*, and that in America the *Indigofera anil*. The plant is grown in India, China,

* Claude Bernard—'Leçons sur les Phénomènes de la Vie,' tome ii., p. 36. Paris: 1879.

† From the *Journal of the Society of Arts*, April 30, 1880.

Java, the Antilles, and Central America. It is planted either in the spring or the autumn, and generally in clayey soil. In India it has pinnate leaves and a slender ligneous stem, and, when successfully cultivated, rises to the height of 3, 5 and 6 feet. It is cut with pruning knives at the end of May, and as its growth is exceedingly rapid, two, and sometimes three crops are obtained, but the last crop, in its production of colouring matter, is not equal to the first. Mr. Kœchlin-Schwartz, in an article in the *Bulletin de la Société Industrielle de Mulhouse*, gives some interesting particulars of the preparation of indigo in Bengal.

In this province of India, the indigo factories—in addition to filters, presses, a boiler, drying grounds, and reservoirs—are provided with two rows, each consisting of 15 to 20 vats. These vats are constructed of brickwork, and covered over with a strong coating of stucco; they are generally from 18 to 20 feet square, and about 3 feet deep; the back row is nearly three feet higher than the front, and it is in the higher row of vats that the fermentation takes place. When the fermentation is completed, the liquid is turned off, and flows into the lower vats. The water of the Ganges, which is comparatively pure, and therefore well adapted for the purpose, is utilized in this process.

In the morning the plant is cut, taken to the factory, and loaded in the vats in the evening, one vat containing 100 packages or bundles, arranged in layers, on the top of which are placed transverse pieces of wood tightly wedged down, it being necessary that the plants should be well pressed, or the fermentation would not otherwise thoroughly take place. Water is then allowed to flow into the vats until the plants are submerged. The process of fermentation lasts from nine to fourteen hours, but depends entirely upon the temperature. To test the progress of the operation, a little of the liquid is drawn off into the lower range of vats; if it is of a pale straw colour, the quantity produced will not be so abundant, but it will be of a superior quality than when the colour is of a deeper yellow tinge. The colour of the liquid after fermentation, and when it is drawn off, is always more or less of a deep yellow. It is allowed to remain some little time, then the water, while still warm, is beaten by twelve naked men armed with long bamboos. While this is going on, the higher range of vats is being emptied and cleared for another supply of the plants, seventeen workmen being employed in cleaning one vat. The liquid is beaten for two or three hours, and gradually becomes a pale green colour, and the indigo forms into small flakes; it is allowed to remain half an hour, and the water is then turned off gently, corks placed at different levels in the vats being one by one withdrawn. The water returns to the river, and the deposit, which resembles a thin scum, is carried through a trough into a deep trench. By means of a hand-pump, it is then brought up and boiled for a short time in order to prevent a second fermentation—which would cause it to turn black and be spoiled. It is allowed to remain about twenty hours, and then the boiling process is again resorted to, which continues for three or four hours, when the boiling mass is poured off and strained through a filter. This filter is composed of a brick vat covered with stucco, 18 to 20 feet long, 6 feet wide, and about 3 feet deep; it is covered with bamboos, on which are spread rush mats, and over these a strong, well stretched linen cloth. On this cloth, after the liquid has been strained through, there remains a thick, deep blue paste, almost black.

The water which was in the vat, in flowing through the filter, leaves this deposit of indigo. The paste is then placed in small, solidly constructed wooden cases, perforated with small holes, and with a very strong linen cloth at the bottom; the cases are then covered with cloth, and a wooden lid perforated also with small holes; they are then pressed in a vice to extract every particle of moisture. When this operation is completed, the indigo is found in a large thick block, the cutting of which demands careful attention, and must be done very slowly. The blocks are then submitted to the action of the drying-ground, which consists of a large brick building of a good height, with windows furnished with closed lattices to exclude the rays of the sun, even thick bushy trees being planted all round the buildings to assist in keeping out the light. The cakes occupy from three to five days in drying, and are then sent to Calcutta. It is in this state that indigo is delivered into the market; its quality may be tested by its lightness or small specific gravity, and its bright colour when rubbed with the nail.

THE GLUCOSIDE FROM WHITE MUSTARD SEED.*

BY H. WILL AND A. LAUBENHEIMER.

Sinalbin, $C_{30}H_{44}N_2S_2O_{16}$, is prepared by extracting with warm alcohol white mustard seed (*Sinapis alba*) from which the oil has been removed by pressure and by treatment with carbon bisulphide. The crystals which are deposited are washed with carbon bisulphide and dissolved in a small quantity of hot water; the solution is then boiled with animal charcoal, filtered and mixed with strong alcohol, and the precipitate which is formed is recrystallized from alcohol, when pale yellow needle-shaped crystals of sinalbin are obtained. The mother liquor from the crude sinalbin contains sinapin thiocyanate. Sinalbin is insoluble in ether and carbon bisulphide, sparingly soluble in cold absolute alcohol, but freely soluble in water. The aqueous solution has a neutral reaction; when brought in contact with a trace of an alkali it acquires an intense yellow colour, which is turned red by nitric acid. Silver nitrate throws down a white precipitate which consists of the silver compounds of sinapin and of sinalbin thiocarbimide; the filtrate, which has a strongly acid reaction, contains sinapin (which may be precipitated by mercuric chloride) and grape sugar. When the precipitate is decomposed by sulphuretted hydrogen, sinapin sulphate, $C_{16}H_{24}NO_5HSO_4$, and the cyanide, $C_6H_4(OH)CH_2CN$, pass into solution; the latter can be extracted with ether. After recrystallization, from benzene, the cyanide forms colourless plates (m. p. 69°), soluble in ether, alcohol, warm benzene and warm water. On boiling with potash, ammonia is evolved and orthohydroxyphenylacetic acid,

$$C_6H_4(OH)CH_2.COOH,$$

is produced. The acid crystallizes in colourless prisms (m. p. 144·5°), soluble in alcohol, ether and hot water, and bears some resemblance to Salkowski's parahydroxyphenylacetic acid (*Ber.*, 12, 1438). The calcium salt, $(C_8H_7O_3)_2Ca + 4\,H_2O$, forms glistening prisms, sparingly soluble in cold water; the barium salt, $(C_8H_7O_3)_2Ba + H_2O$, triclinic prisms, slightly soluble in cold water. The silver salt, $C_8H_7O_3Ag$, is almost insoluble in water and is decomposed by heat.

On the addition of mercuric chloride to a warm aqueous solution of sinalbin, a precipitate is produced which contains, in addition to compounds of mercury with sinapin sulphate and the cyanide, C_7H_7OCN, a double chloride, viz., $C_{16}H_{23}NO_5HCl.HgCl_2$.

If ground white mustard seed is treated with water and filtered an acid liquid is obtained which contains myrosin, sugar, sinapin thiocyanate and sulphate. The myrosin may be precipitated from this solution by alcohol. An aqueous solution of sinalbin is decomposed by myrosin, thus—

$$\underset{\text{Sinalbin.}}{C_{30}H_{44}N_2S_2O_{16}} = \underset{\text{Sinalbin thiocarbimide.}}{C_7H_7O.NCS} + \underset{\text{Sinapin sulphate.}}{C_{16}H_{23}NO_5.H_2SO_4} + \underset{\text{Sugar.}}{C_6H_{12}O_6}.$$

The pungent principle in the mustard seed is contained in the albuminous precipitate, which separates out on the addition of the myrosin; by extraction with alcohol and ether it can be obtained in the impure state as a yellow oil insoluble in water.

THE EXHIBITION OF CHEMICAL AND PHARMACEUTICAL APPARATUS, ETC.

NEXT week is the time fixed for holding the usual "May Meetings" of Pharmacy, and before the issue of another Journal the Annual Meeting with its attendant Dinner and Conversazione will be things of the past. Full information as to where and when they are to be held will be found on the front page. Speculations as to their probable characteristics and how far they will vary from those of the meetings of former years would hardly be profitable on the present occasion and may be dispensed with in view of the full report of accomplished facts which we hope to present as usual in the course of a few days. But there is one thing in connection with the Annual Meeting this year concerning which a passing notice and some words of explanation will probably be useful, and that is the exhibition of objects more or less allied with pharmacy which is to be held in the Society's rooms, Bloomsbury Square, on the Tuesday, Wednesday and Thursday of the coming week.

It is satisfactory to find that notwithstanding some disquieting forebodings that were experienced at an early period after it had been decided to hold this exhibition, there is now every prospect that it will prove to be a decided success. A large number of manufacturers and others have responded to the invitation of the Council, and notwithstanding the exclusion—rendered necessary, by the limited space available—of many articles such as usually find their way into exhibitions, there will be ample food for thought and observation in those that will be shown.

The exhibits will be grouped as far as possible in six classes, each of which will occupy a separate room, and a catalogue which is being prepared will be a sufficient guide as to where the different objects are to be found. It may be stated here briefly that the first group, consisting of Gas-Heating Apparatus, including the apparatus used by MR. FLETCHER to illustrate his recent lecture before the Society of Arts, will be placed in the octagon room on the second floor, known as the Examiners' Laboratory. Pharmaceutical Apparatus will be arranged in the large front room on the first floor, which many visitors will recognize as one of the examination rooms. This group will include mixers, pill-coating, plaster and capsuling machines, tincture presses and other similar articles. In the examination room behind this there will be a display of Aerated Mineral Waters. In the Materia Medica Museum will be the Drugs, Chemicals and Pharmaceutical Preparations, a title that sufficiently discloses the nature of the exhibits included under it. The Chemical Museum, on the opposite side of the entrance hall, will be devoted to Scientific Apparatus, and here may be seen a capital collection of microscopes, spectroscopes, polarimeters, telephones, microphones, balances, thermometers, radiometers and various other apparatus. In the room behind will be shown, what will perhaps prove of most interest to many, shop fittings and bottles and different requisites for the shop and dispensing counter, besides a number of medical appliances such as frequently find their way into the chemist and druggist's stock.

It will be seen from the foregoing that the exhibits will be sufficient in importance and variety to well repay examination, and it is to be hoped that every chemist and druggist who possibly can will avail himself of the present opportunity of making himself acquainted with them. The present exhibition is an experiment, and it is evident that its repetition will be, to a great extent, dependent upon the amount of appreciation shown of this new effort of the Council to consult the convenience and promote the interests of the trade.

It only remains to add that the Exhibition will be open on Tuesday, Wednesday and Thursday, on the first two days from 9 a.m. till 5 p.m., and on the last day from 9 a.m. till 10 p.m. On Tuesday and Thursday the admission will be free to all registered Chemists and Druggists; but on Wednesday, the day on which the Annual Meeting is to be held, it will be limited to Members and Associates in Business of the Society.

THE SALE OF PATENT MEDICINES CONTAINING POISONS.

THE report on another page of a case of poisoning by chlorodyne affords a fresh illustration of the danger attending the pernicious habit, which has now been acquired by so large a number of persons, of taking or administering, without qualified medical advice, large doses of powerful and often poisonous preparations, concerning the nature of which they are almost entirely ignorant. An enormous development of this habit has been evident during recent years, and it has been doubtless due mainly to the freedom with which any toxic substance may be sold as a "patent medicine," the only restrictive condition being that a small tax shall be paid, whilst the possible—nay, probable—injury to the health of the community is ignored. By thousands of people pain and sleeplessness are looked upon less as symptoms of a disordered system than as inconveniences to be got rid of in the quickest possible way, and such persons are ready to grasp at anything that promises to assist them in attaining this end. In this mood some powerful anodyne or soporific, disguised under a fine sounding name and beslavered with testimonials as to its efficacy as a remedy against all the ills flesh is heir too, is brought under their notice. It may be had in unlimited quantities from any chemist, grocer, huckster or "stores," and when it is sold not a word of warning is given to the buyers as to the danger attending its use, for the simple reason that as a rule the sellers are themselves ignorant as to the nature of what is being sold. Temporary relief is perhaps attained by its use, but this is maintained after a time only by taking increasing doses, leading frequently to the contraction of a vicious habit and sometimes to an untimely death.

In the present case the cause of death was one of the preparations known as "chlorodyne," but it might just as well have been any of a thousand and one "patents" the names of which will occur to our readers. The deceased had for several years suffered from sleeplessness, for the relief of which he had been in the habit of taking chlorodyne. Being unwell he obtained, together with other medicine, half an ounce of his favourite soporific, the whole of which he took during one night in the hope of securing sleep. In the course of the next day he died, and in the opinion of the medical gentleman who made a *post mortem* examination his death was the result of poisoning by an overdose of chlorodyne.

It is not surprising to find that the case has been the subject of comment in the local press, or to find that some of the well-intentioned remarks assume a condition of things which does not exist. The *Leeds Mercury* considers that it is practically impossible to prevent the sale of these soothing drugs, for that if the law were to prohibit their sale in one disguise they would soon be offered in another. It admits, also, that no law would prevent a man from taking an excessive dose, if he were not deterred by his own judgment. As a remedy, it argues that all that can be done is to insist that the druggist, as far as possible, shall give his customer the means of guarding himself against danger. He is not to be left in doubt as to the risk he runs, and all those who use artificial aids to sleep are to be warned that at the best they are dangerous and at the worst are deadly poisons.

But this argument assumes that the sale of these "artificial aids to sleep" is entirely in the hands of chemists and druggists and that their composition is accurately and generally known. Neither of these assumptions is true. Unfortunately the sale is largely carried on by tradesmen who have no special qualification for advising as to the nature of such preparations, whilst, as was recently remarked in these columns, even the chemist and druggist would not under existing circumstances be justified in treating any such article or preparation as containing morphia or prussic acid, although he might have good reason for suspecting the presence of these or other poisons.

We are glad, however, to notice the increasing concurrence of opinion as to the necessity for legislation on this subject. Public opinion is undoubtedly ripening in favour of the abrogation of the exemption which relieves the sale of scheduled poisons under cover of the patent medicine stamp from the restrictions imposed upon the sale of the same poisons under their proper names. But there is still considerable haziness in the public mind as to the real state of the law, and we believe that the dispersion of this might be considerably promoted by the individual effort of chemists and druggists among their customers and acquaintances. When recently referring to this subject, in connection with the letter addressed to some of the London papers by Mr. Hubbard, we expressed an opinion that as a remedy for the various evils resulting from the sale of patent medicines containing poisons the only feasible course is to require the disclosure of the constituents that are of a poisonous nature, and to make the sale of preparations containing poisons subject to the limitations of the Pharmacy Act. To this opinion we adhere, and we believe that were the public mind made familar with the true state of affairs, legislation in this direction would not be refused.

THE ANNUAL DINNER.

It is hardly necessary to repeat here the announcement that the Annual Dinner of the Members of the Pharmaceutical Society and their friends will be held on Tuesday next at Willis's Rooms. But it may be useful to urge upon all who intend to be present that if they have not yet obtained their tickets they should do so at the earliest possible moment, in order to allow of those arrangements being made upon which the convenience and comfort of such companies so much depend. This year there are no stewards, and all applications for tickets should be made *at once* direct to the Honorary Secretary, Mr. Richard Bremridge, 17, Bloomsbury Square.

A CAUTION.

We are requested by a correspondent to caution the trade against the proceedings of a man, described as being about 5 ft. 5 in. in height, dark and slightly made. This person appears to pass himself off as the representative of a wholesale firm, for whom he solicits orders. Should he be successful, he pretends that he has come out without his pocket-book, and asks that the order may be written on a piece of paper for a memorandum. If, as is usually the case, this is done upon paper stamped with the chemist's name, his end is attained, and he uses the memorandum as an order to obtain the goods mentioned from the wholesale house, directing them to be charged to the chemist's account. This swindler's operations are said to be facilitated by the evident acquaintance with technical details which he possesses.

WOMEN PHARMACISTS.

It appears that attention has been recently directed in the New York press to the favourable field which pharmacy is supposed to offer for the employment of women. *New Remedies* remarks that "it is known "by those who are familiar with the subject that in "Great Britain the registration of women as pharmacists has only been accomplished through persistent efforts," whilst in the United States, on the contrary, no impediments have been offered. Of course this statement is a mistake. No difficulty has existed in this country as to the registration of women as chemists and druggists, by which they are qualified to carry on pharmacy to the fullest extent. The objection, which during the last year has been overcome, has been to their election as members of the Pharmaceutical Society.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 6, Professor Roscoe, President, in the chair. After the minutes of the previous meeting had been read and confirmed, the following certificates were read for the first time:—H. Brown, G. H. Hughes, H. Awbrey Lawrance, R. S. Marsden, E. A. Reilly, Brenton Symons, H. Kneebone Tompkins, A. Wingham.

The President then called on Dr. Hodgkinson to read a paper on—

The Action of Sodium on Phenylic Acetate. By W. H. Perkin, jun., and W. Hodgkinson.—One of the authors has already published some results as to the action of sodium on ethereal salts containing mixed fatty-aromatic groups. In the present paper they first give an account of the action of sodium on phenylic acetate prepared by heating dry phenol with acetylic chloride; the acetate boiled at 193° C. A most violent action took place with considerable rise of temperature. Hydrogen and much acetic ether were evolved, the silver salt from the latter being analysed. After the sodium had disappeared a solid body remained in the flask, which, when treated with water, formed a dark coloured solution and a small quantity of a thick oil. The aqueous solution yielded acetic acid, phenol and salicylic acid. The thick oil gave on distillation some undecomposed phenylic acetate and a crystalline mass, which was pressed between filter paper and crystallized from petroleum. Two forms of crystals were observed, and were separated by crystallization from alcohol. The substance most soluble in alcohol forms glistening white needles, melting at 48°, giving a red coloration with potash and having the composition

$$C_{15}H_{12}O_3.$$

The other substance crystallizes in yellow needles, melting at 138°, giving a yellow crystalline compound with alcoholic potash, and having the composition $C_{18}H_{14}O_4$. Experiments were now made by heating cresylic acetate with sodium. Acetic ether and salicylic acid were obtained, as in the previous reaction. Probably, therefore, these two substances are constant products of the action of sodium on acetyl phenols.

Dr. Hodgkinson then read a paper entitled—

Preliminary Notice on the Action of Sodium on some Ethereal Salts of Phenylacetic Acid.—In a contribution to *Liebig's Annalen*, by Max Conrad and the author of the present paper, it has been shown that the influence of the presence of a phenyl group in ethers of fatty acids results in the substitution of one or more of the hydrogen atoms in combination with the carbon immediately joined to the carbonyl group by the group containing the phenyl, giving a synthesis of so-called aromatic-fatty acids. From phenylic acetate the benzylic ether of β phenyl propionic acid was obtained as a primary product, and secondarily by the action of sodium on this substance dibenzyl acetic and β phenyl acrylic acids. Benzylic propionate, butyrate, etc., gave analogous results. The author of the present paper has experimented as to the effect of a phenyl group in the acid or negative portion of the ethereal salt. For this purpose α toluic acid seemed likely to give results, as from its ethyl ether might be formed ethylic phenyl acetoacetate.

$$\begin{array}{ll} C_6H_5 & CH_2 \\ & CO \\ & CH_2 \\ & COOC_2H_5. \end{array}$$

2·5 grams of sodium were warmed with 50 grams of the ether, a condenser was fitted to the retort, so that the liquid produced was removed, as fast as it was formed, from contact with the sodium. In one experiment 10 grams of a liquid distilled over which, after redistillation, boiled between 75° and 78°. On analysis it proved to be ethylic acetate. The residue in the retort, forming a thick mass, was treated with water and gave a solution in which sulphuric acid caused the formation of a white precipitate and an oily body. The latter was separated and distilled. On shaking the acidified aqueous solution with ether, phenylacetic acid was obtained, crystallizing from water in long needles melting at 76°. A small quantity of acetic acid was also obtained. The oily product on distillation separated into some unaltered ethylic phenacetate and an oil which, after purification, boiled at 250° at 60 mm., having the composition

$$C_{18}H_{20}O_2.$$

A residual oil gave on analysis numbers indicating

$$C_{18}H_{16}O.$$

The decomposition may thus be represented—

$$6(C_6H_5CH_2COOC_2H_5) + Na_2 = 2(C_6H_5CH_2COONa) + 2CH_3COOC_2H_5 + H_2 + 2(C_{18}H_{20}O_2).$$

The action of sodium on other ethers of similar constitution seems to be quite analogous, but more secondary products are formed. Experiments were carried out with propylic phenylacetate. Propylic acetate was formed. From the residue in the retort were obtained phenylacetic acid, a substance crystallizing from petroleum in white needles, having a composition indicated by the formula $C_{24}H_{20}O_3$, insoluble in acids and alkalies, and a yellow oil boiling at 335° at a pressure of 50 mm., giving on analysis $C_{22}H_{20}O_2$. The reaction has also been extended to primary isobutylic phenylacetate. It appears, therefore, that the first products of the action of sodium on the ethers of phenylacetic acid containing ethyl and its homologues are the corresponding ethylic, etc., ethers of acetic acid. The phenyl group of the phenylacetic acid being replaced by hydrogen it further reacts with sodium on another portion of the original ethereal salt, forming the above liquid and solid bodies, whose constitution is as yet undetermined, hydrogen being at the same time evolved. With benzylic phenylacetate the action of sodium appears to be analogous with that on the benzylic ethers of the normal fatty acids.

After a few remarks from Dr. Frankland, as to the importance of the results, the President proposed a vote of thanks to the authors, and expressed his gratification that a son of the Secretary had already commenced to contribute papers to the Society.

The next paper was on—

The Determination of Nitrogen in Carbon Compounds. By C. E. Groves.—The author described and exhibited an apparatus for facilitating the collection and measurement of nitrogen, evolved during the combustion of a substance according to Dumas's method. It consists of two vertical glass tubes, in size and shape somewhat resembling burettes. One, "a," is graduated, and is closed at its upper end by a glass stopcock; into its lower end is fixed a T tube, one leg of which is attached to the combustion tube (a bulb U tube containing a globule of mercury being interposed); to the other leg of the T tube is attached a long indiarubber tube, the other end of which is connected with the bottom of the second vertical glass tube "e." The combustion tube is charged in the ordinary way. The tube "a" is filled with potash solution, sp. gr. 1·25, and "e" is lowered until the opening of the T tube, which leads to the combustion tube, is free. Carbonic acid is then evolved and the air in the combustion tube swept out as usual. The graduated tube "a" is then filled with potash, and the stopcock closed as soon as the bubbles of gas are completely absorbed; the tube "e" is lowered until the level of the potash in it is a little below the T tube. The combustion is conducted in the ordinary manner. The advantages claimed for the apparatus are, its simplicity and the fact that as the combustion is carried out under diminished pressure, there is no tendency for the tube to blow out. The author also gives details of a method for using the same tube for six to twelve combustions. The mixture of CO and CO_2, obtained by the action of strong sulphuric acid on oxalic acid is recommended as preferable to hydrogen for reducing the oxidized copper gauze. The author also exhibited a simple arrangement for collecting or delivering small quanties of gas.

Mr. Perkin remarked that he had never yet been able to get all the air out of a tube by CO_2, he always had to use a Sprengel pump.

Mr. Kingzett had experienced the same difficulty as the previous speaker, and had obviated it in the same way.

Dr. Frankland strongly recommended the use of the Sprengel pump, and suggested the application of a water jacket round the measuring tube.

Mr. Groves, in reply, said that he had used a water jacket round the tube, and that by passing the CO_2 for the same time at the beginning as at the end of the combustion, the error due to the minute bubble of air could be almost completely corrected.

Mr. M. M. P. Muir then read a paper on—

Essential Oil of Sage.—The results of the author may be summarized as follows:—The composition of essential oil of sage varies with the age of the oil; when freshly distilled it contains comparatively small quantities of salviol, camphor, and cedrene; as the oil ages the quantities of these substances, especially of the first two, increase. The oil distilled from English sage contains much cedrene, boiling at 260°, with small quantities of $C_{10}H_{16}$, hydrocarbons and traces of oxidized compounds. The terpene of sage oil is identical with that from French turpentine, probably an isomeride of terpene boiling at 171° is also present. Salviol has the formula $C_{10}H_{18}O$, not $C_{10}H_{16}O$; when oxidized with chromic or dilute nitric acid it yields camphor melting at 174°, with oxalic and acetic acids. Salviol on distillation is slightly decomposed, water and a $C_{10}H_{16}$ compound being produced. Sunlight in the presence of air and in the course of time forms from the $C_{10}H_{16}$ compounds of sage oil salviol and small quantities of camphor. The latter substance is also formed by the action of sunlight on salviol. The action of phosphoric anhydride on salviol is very complex, there being formed polymerides of $C_{10}H_{16}$, one boiling at 171°, a hydrocarbon of the bezene series boiling below 130°, and a paraffin boiling between 170° and 180°; no cymene is found if the action be continued for some time. Phosphorus pentachloride acts upon salviol at high temperatures, producing a chlorinated derivative, which is decomposed on distillation, forming a $C_{10}H_{16}$ hydrocarbon boiling at 157° and probably the paraffin-like body mentioned above. Bromine acts energetically on salviol, hydrogen and carbon being liberated; a brominated oil may be separated and under certain conditions small quantities of camphor melting at 184°. Camphor separates chiefly from the portions of sage oil distilling between 205° and 208°; it is partially soluble in salviol, but separates out on cooling the solution to —15°. Sage camphor melts at 174°, boils at 205°; chemically it appears to be identical with laurel camphor; it is, however, optically inactive. The compounds present in sage oil are stable when pure, but when mixed with small quantities of other bodies they decompose. Processes of oxidation, deoxidation and polymerization probably occur simultaneously during the ageing and fractionation of sage oil. In discussing his results the author expresses an opinion that the camphor group may be regarded as a link between the "closed chain" and the $C_{10}H_{16}$ series, just as the $C_{10}H_{16}$ group forms a link between the fatty and the closed chain compounds.

Dr. Wright complimented the author on the completeness of his paper; though some of the reactions had been already worked out, additional and more complete evidence was always very valuable. He thought the author's views as to the relation between the closed chain compounds and the camphors were open to discussion.

Mr. Kingzett had been much interested in the paper, as it seemed that in many points the oxidation of sage oil was analogous to that of the terpenes. In one experiment he had obtained from turpentine colourless crystals closely resembling camphor; he should like to ask if Mr. Muir had observed during the oxidation of sage oil in the air any production of hydroxyl.

Mr. Muir had not specially looked for hydroxyl during the present investigation, but had noticed its formation in a previous research. He also replied to the criticisms of Dr Wright on the theoretical portion of the paper.

Mr. A. H. Allen then read a paper—

On the Presence of Nitrogen in Iron and Steel.—Numerous chemists have investigated this question, but as their results are not concordant, the question cannot be said to have received a definite solution. The principle upon which the author worked was to present to the nitrogen, if it existed in the iron, hydrogen in the nascent state, in a neutral atmosphere, which should rapidly remove the products from the sphere of action, and thus prevent any possible dissociation of ammonia at a high temperature. The reaction would probably be—

$$3Fe_4N_2 + 16H_2O = 4Fe_3O_4 + 6NH_3 + 7H_2.$$

A piece of hard glass tube was therefore connected at one end with a large retort containing water, and at the other with a Liebig's condenser. Fifty to two hundred grams of iron borings were placed, after heating to dull redness in a muffle, in the hard glass tube. The water was boiled until the condensed liquid was found by the Nessler test to be free from ammonia. The tube, with the iron borings (or steel filings), was then heated to redness in a Hofmann's combustion furnace; an evolution of ammonia at once commenced and continued for some hours. The presence of ammonia was proved by the alkalinity and odour of the distillate, the brown colour with the Nessler test, and the yellow precipitate with platinic chloride. (A tube was handed round containing 0·1185 gram of the double salt thus obtained.) Pure iron prepared by reducing pure hæmatite in a current of hydrogen, and then passing a current of steam as above, gave no trace of ammonia. That heated nitride of iron does evolve ammonia in a current of steam was proved by experiment. Ammonia is also formed by dissolving iron or steel in hydrochloric acid, either in the air or in a vacuum. In this way, by Nesslerizing the distillate, the author has succeeded in estimating with precision the nitrogen present in 1 gram of iron or steel. A series of determinations has thus been made of the nitrogen present in various brands of iron and steel; the quantity varied from 0·0041 per cent. in Spiegeleisen to 0·0172 per cent. in steel from Dannemora iron. No nitrogen was found in commercial aluminium or zinc, but traces were found in magnesium and sodium. No connection could be traced between the proportion of nitrogen and that of carbon or other foreign element present in iron or steel. Titanic plate iron contains only 0·0049 per cent. nitrogen. There is no positive evidence as to its condition; but the probability is in favour of the presence of nitride of iron.

The President said that the author had attacked successfully a difficult problem.

Dr. Wright thought the nitrogen might perhaps exist as a cyanide.

Mr. Allen, in reply, stated that he had no proof as to the condition of the nitrogen; he was only sure of its presence.

The following papers were taken as as read:—

On the Mode of Application of Pettenkofer's Process for the Determination of Carbonic Acid in Expired Air. By W. Marcet.—The author describes the apparatus which he has used in upwards of three hundred and fifty determinations, during a series of experiments on the influence of altitude on the phenomena of respiration ('Roy. Soc. Proc.,' 1878 and 1879). The air from the lungs is collected into a large indiarubber bag, whose capacity under a certain pressure is known, two bags are used, one holding 39·3, the other 68·4 litres. For the analysis of the air the following apparatus is used:—a thick glass tube or cylinder about two litres capacity is supported on a light tripod stand. Both ends are ground and are closed with thick ground glass discs, which, by means of grease and two screwed brass caps, close the cylinder airtight. In the upper glass disc three holes are made in which fit airtight, a thermometer, and two brass stopcocks. The lower disc has attached to its inner surface a thick vulcanite disc whose upper face is slightly funnel-shaped, so as to drain off completely any liquid from the cylinder. Perforations are made in the lower disc for attaching a tube from an air pump and for drawing off liquid. The cylinder is first dried and exhausted and the air from the large bag allowed to enter; the cylinder is again exhausted and filled a second time, the pressure being noted by a manometer and the temperature observed; a measured quantity of standard baryta solution is now introduced, the increase of volume is diverted into a small empty indiarubber bag connected with the cylinder so that the pipette can be emptied by closing its top and warming the bulb with the hand. All the stopcocks are now closed, the cylinder gently shaken, and the milky liquid is run into a bottle, which is corked and paraffined. Some of the clear liquor is decanted into a burette and titrated against a measured quantity of standard oxalic acid, turmeric being used as an indicator. The whole apparatus is portable and the results are perfectly reliable. The details of an experiment with the calculations are given.

Note on an Improved Form of Oven for Heating Sealed Tubes and Avoiding Risks of Explosions. By WATSON SMITH.—The author has constructed such an oven, having the following advantages:—A temperature of 420°–440° can be obtained in a few minutes with one moderately large Bunsen. It insures the safety (in case of explosion) of the experimenter and of the thermometer, has a simple construction and can be cooled down rapidly. It consists of a horse-shoe shaped inner tube of stout sheet iron, which contains thick iron tubes, surrounded by an outer D shaped cover of sheet iron. A figure accompanies the paper.

Note on a Convenient Form of Lead Bath for Victor Meyer's Apparatus for Determining the Vapour Densities of High Boiling Substances, together with a few slight modifications. By WATSON SMITH.—The author advises the cutting off the capillary delivery tube about half an inch from the main stem, and connecting the cut off delivery tube to the main stem with a piece of caoutchouc tubing only when everything is adjusted for a determination. Detailed drawings with measurements accompany the paper. A piece of iron gas tube 9 to 10″ long and 2″ internal diameter forms the lead-bath; two screens of sheet iron are used, one to steady the gas flame, the other to protect the upper part of the apparatus from draughts. The glass bulb is well smoked in a luminous gas flame and introduced into the lead very gradually.

After the thanks of the meeting had been given to the authors for their respective papers, the Society adjourned to May 20, when a paper will be read "On the Oxidation of Peaty Matter," by Miss Lucy Holcrow and Dr. E. Frankland, and the discussion on Dr. Tidy's paper (which will be printed this week) "On River Water" will take place.

SOCIETY OF ARTS.

THE CHEMISTRY OF BREAD-MAKING.*

BY PROFESSOR GRAHAM, D.SC.

Lecture I.

(*Continued from page 882.*)

Basic acetate of lead, added to a solution of dextrin, throws down a precipitate, and this is sometimes a convenient reagent to employ when you wish to remove dextrin from the infusions containing it. The action of yeast upon dextrin is very slow, but it does ultimately convert it into maltose sugar, and, of course, after that, into alcohol.

The next members of our carbo-hydrate series are cane sugar and maltose. Although probably of different molecular structure, they have the same centesimal composition. I have here a sample of the small crystals called Finzel's crystals, after the sugar manufacturer of Bristol, who unfortunately has been ruined by the export bounty system of the French Government, and who no longer now manufactures this product. On the whole, it is the purest sample of cane sugar that we can find in the market. Cane sugar is obtained not only from the cane plant, but also from the beet, the date, and the maple tree; it may also be obtained from many other plants, but these are the principal sources. The process of manufacture is not very intricate. It consists in the case of the cane of pressing the juice out, and then as rapidly as possible boiling it with a small quantity of lime, in order, first of all, to precipitate the albuminous matter, and so to neutralize the acid, because we shall see presently acids rapidly convert cane sugar, which is a crystallizable body, into the sugars which do not crystallize, which chemists call inverted sugars, or changed sugars, such as ordinary molasses consists of, and the solution of course is finally treated with animal charcoal in order to decolorize it. This latter part of the process is carried out in the refineries of England.

Cane sugar, when obtained in the pure state, you all know perfectly well, but there are some two or three reactions which I think may be of some interest to you. I said a little while ago that in these carbo-hydrates the hydrogen and oxygen are in the proportion to form water, and by the employment of a little oil of vitriol, which is a substance that has a great affinity for water, it actually breaks up the molecule of sugar, and in so doing unites the oxygens and hydrogen and forms water. That, of course, can only take place by the separation of charcoal. Mr. Lewis will add this material, which has such a power of absorbing water, to the solution of cane sugar, and you will soon see the separation of charcoal. It is already black. Presently it will intumesce, and, you now see, so rapid is the action, an abundant separation of charcoal, the hydrogen and oxygen having been converted into water and absorbed by the acid. This is the action of strong acid. If, instead of acting on the sugar by means of strong acid I had used strong potash, we should find very little change. Fehling's liquid, added to a solution of cane sugar, provided the solution has been recently made, has no action, or a very slight action. The action is only due to the effect of the alkali itself upon the cane sugar. While I am heating this, Mr. Lewis will take a solution of cane sugar, and add to it a very few drops of sulphuric acid. We are not now going to convert it into charcoal, but into other kinds of sugar. You will see that this cane sugar, which has not been treated by acid, has no action on Fehling's liquid. It does not reduce the protoxide of copper to the suboxide, yet boiling it with acid, even for a short time—and manifestly it would be much better to boil it for an hour—is quite sufficient to change the cane sugar to fruit sugar or inverted sugar. Having neutralized the acid by a little alkali and heated it again with Fehling's solution you see there is an abundant reduction from the protoxide of copper to the red suboxide.

This action is brought about not only by mineral acids, but by all kinds of albuminoid bodies. Mr. Lewis will take a solution of cane sugar and act upon it with a little malt infusion; this has the property of converting the cane sugar, to some extent, into the same products as result from the action of acids. That is the reason the West Indian planter is obliged, so soon as he has expressed the juice from the cane, to boil it as quickly as possible; were he not to do so, the acids of the juice and the albuminoid matters would rapidly convert the crystalline sugar into sugars that do not crystallize. These inverted sugars do not crystallize at all, and the origin of molasses in the manufacture of sugar is because in spite of all his care—formerly, indeed, in the West Indies, very

* Cantor Lectures: Delivered November and December, 1879. Reprinted from the *Journal of the Society of Arts.*

little care was taken—but in spite of even the care now taken there is always some crystallizable cane sugar converted into non-crystallizable sugars, and they come into the market in the form of molasses. Of course the larger portion of the molasses is converted into rum by fermentation and distillation. We are performing the same operation here, not by the use of the natural albuminoid bodies that exist in the plant, but by the aid of malt solution, and we have, even in so short a time, a partial conversion of the sugar solution.

The next matter to which I desire to draw your attention is that alcohol does not precipitate cane sugar; in other words, cane sugar is soluble in alcohol. Maltose sugar is precipitated by alcohol, which is able to dissolve a very small quantity of maltose, and one is obliged to take a very large quantity of alcohol in order to dissolve the crystalline substance called maltose.

The maltose sugar to which I now pass was first discovered by Dubrunfaut, but it was forgotten until O'Sullivan, of Burton-on-Trent, again studied the action of albuminoid ferments, such as we find in malt, upon starch. This table represents the action:—

Hydration Products of Starch. (*O'Sullivan.*)

$$\begin{array}{llll} & \text{Starch.} & \text{Maltose.} & \alpha\ \text{Dextrin.} \\ (1.) & C_{72}H_{120}O_{60} + H_2O = & C_{12}H_{22}O_{11} + & C_{60}H_{100}O_{50} \\ & & & \beta\ \text{Dextrin, i.} \\ (2.) & C_{72}H_{120}O_{60} + 2H_2O = & 2C_{12}H_{22}O_{11} + & C_{48}H_{80}O_{40} \\ & & & \beta\ \text{Dextrin, ii.} \\ (3.) & C_{72}H_{120}O_{60} + 3H_2O = & 3C_{12}H_{22}O_{11} + & C_{36}H_{60}O_{30} \\ & & & \beta\ \text{Dextrin, iii.} \\ (4.) & C_{72}H_{120}O_{60} + 4H_2O = & 4C_{12}H_{22}O_{11} + & C_{24}H_{40}O_{20} \end{array}$$

In other words, the first action is to add one molecule of water. That is brought about by the agency of albuminoid ferments. The same action is brought about also by the saliva of man, because that also contains an albuminoid ferment called *ptyaline*. In malt we have a similar albuminoid ferment, which has been called diastase. When one molecule of water is added it causes a lesion of the complex starch molecule into the distinct products, maltose sugar $C_{12}H_{22}O_{11}$ (the isomer of cane sugar and five molecules of dextrin $C_{12}H_{20}O_{10}$). The next stage is to add two molecules of water. Then a further lesion is brought about by the ferment. In the last stage we have four molecules added, and thus we obtain four molecules of maltose sugar and two of dextrin.

At our next meeting I shall point out that Brown and Heron, in some recent researches, and also Gruber and Musculus, give some other hydration products in addition to those that are represented by O'Sullivan. Maltose sugar differs from cane sugar in the following respects:—The formula is the same, that is, the composition of 100 parts is the same, and the molecular weight is, perhaps, the same, but the properties that distinguish maltose are the following. Cane sugar only rotates the plane of polarized light 73° to the right, whereas maltose rotates the ray 150° to the right. It is much more dextrorotary than cane sugar, although less so than starch. We saw that Fehling's liquid had no action on cane sugar, except, however, after a time, when the alkali began to break up the sugar. It has no immediate action, but we shall find on maltose sugar Fehling's liquid produces an abundant and immediate reaction on boiling, still the amount of reduction of the protoxide of copper to sub-oxide is not so great as in the case of the next sugars we shall have to speak of, namely, the dextrose and lævulose sugars. 100 parts of maltose sugar only produces as much action on Fehling's liquid as 61 parts of dextrose or lævulose sugars. Therefore, although maltose has the same formula as cane sugar there is a distinct difference, first in the action on polarized light, and secondly, in the action of Fehling's liquid. There is yet another difference; it is but slightly soluble in alcohol, therefore, the addition of alcohol to solutions of maltose will generally give a precipitate.

Maltose sugar is now being prepared somewhat largely in commerce, and here are some examples of it. One is the substance called O'Sullivan's dextrin maltose. It contains not merely maltose, but also dextrin. Here is another sample which is richer in maltose sugar and less rich in dextrin and has a lighter colour. The other important sugars, namely dextrose and lævulose, I propose to discuss at our next meeting, and will then call your attention to some later researches upon the hydration products of starch.

Lecture II.

To-night we pass on to the third sub-group, the glucoses, having the formula $C_{12}H_{24}O_{12}$. These are dextro-glucose and lævo-glucose. Sometimes they are called dextrose and lævulose. They occur in fruits, and probably are due to the action of acids, or soluble albuminoid ferments, or both together, on cane sugar which has been previously stored up in the vegetable organism.

Dextro-glucose, the first member on our list, has been very rarely found in fruits unassociated with lævo-glucose. A very well known example of this glucose is to be found in ordinary honey. Honey consists of dextro-glucose and lævo-glucose, and also cane sugar. Dubrunfaut, a good many years ago, pointed out that the ratio of the dextro-glucose and lævo-glucose in honey was not that which would have occurred had the product been formed only and solely from the inversion, or change, of cane sugar previously stored up. In other words, instead of being found there in equal quantities, as much of dextro-glucose as of lævo-glucose, he found there was always an excess of dextro-glucose, which would indicate that some of the dextrose was due to the action of some ferment, not upon cane sugar, but upon some such material as soluble starch.

As regards the preparation of dextro-glucose from honey, one of the simplest processes is to take granulated honey, and triturate it in a mortar with one-eighth of its own weight of alcohol. The alcohol will dissolve out the lævo-glucose because it is more soluble; and if this be repeated once or twice, that which is not dissolved in the alcohol will consist of the dextro-glucose and a small quantity of cane sugar, or sucrose.

Another simple plan is to take the crystalline honey, and submit it to severe pressure through a calico filter. If it be pressed with considerable force, the lævo-glucose is forced out in the liquid form, and you obtain the dextro-glucose, together with the cane sugar, in the solid condition.

A much cheaper way to obtain dextrose than from honey is to convert ordinary starch into dextrose. This is done by acting upon a solution of starch with dilute mineral acid. Dextrose was first prepared in this way by the celebrated chemist, Kirchhoff. He took a solution of starch, and acted upon it with acid to the extent of 2 per cent. of the water that he employed, and after keeping it at a temperature of from 80° to 90° C. for four or five hours, he obtained the formation of this dextrose. If this acid solution be neutralized with some powdered chalk, the sulphuric acid—for it is better to use sulphuric acid than hydrochloric—is converted into sulphate of lime, or gypsum, and on filtering you obtain a solution of the dextrose.

This dextrose is now made on a large scale. This bottle contains dextrose. This which you see here has also been made from starch, and is known commercially as glucose. I am indebted for these two specimens of dextro-glucose to the kindness of the managing director of the Manbré Saccharine Company. The way in which it is prepared generally—I do not know exactly how this sample was prepared—is to take Indian corn, which now is largely employed for that purpose by American manufacturers, or rice (which probably is the material that the Manbré Saccharine Company employ), or to take some other starch-yielding material. The rice or the Indian corn is first of all broken into a tolerably fine condition, and then is mashed with water, that is to say, it is digested or infused with water to which 1 per cent. of oil of vitriol has been added. This is heated up by means of steam, and, after some few hours, it is pumped into a boiler or digesting vessel, in which it is heated by means of steam coming direct from a boiler at 70 lbs. pressure. In a short time, the steam being injected from the boiler at that pressure into this other digesting vessel, the temperature rises, and ultimately the tension or pressure in the digester is the same as in the generating boiler, and a comparatively short time is sufficient to convert the starch into dextrose. Whereas, doing it as I am here, at the atmospheric pressure of 15 lbs. to the square inch, a much longer time is required for the purpose. So soon as the operation is complete, and the operators are able to tell that from an experiment I showed you at our last meeting—you remember that alcohol precipitates solutions containing dextrin; you also remember that alcohols precipitate solutions containing maltose sugar—then, at the particular moment when alcohol fails to precipitate either the dextrin or maltose sugar, they know that they have nothing left but dextrose, because in this process, which goes on with acids, as I shall presently show you, the bodies first formed are maltose and dextrin; but ultimately the maltose is hydrated to dextrin, and the whole of the dextrin is also hydrated to dextrose; so that, so soon as alcohol fails to give a precipitate, they know that the hydration process is complete. They then run it off into large tanks; powdered chalk is added to it, in order to neutralize the sulphuric acid; the whole is allowed to settle, and the clear liquid is drawn off, and passed two or three times through animal charcoal, in order to decolorize it. The amount of decolorization, to some extent, depends on the price that is to be charged for it, and the object for which it is to be employed. Ultimately, it is evaporated down in vacuum pans; that is to say, the evaporation takes place not at 15 lbs. pressure, but (by means of a steam-engine constantly pumping away the steam from the evaporating vessel), at a pressure of only some 2 or 3 lbs. It comes into the market in this solid form. The letter I received this morning from the manager of the Manbré Saccharine Company explained to me that it was quite easy for him to supply me with samples perfectly white. These are tinted. They have not been made at all for the purpose to which I propose to draw your attention in our next lecture. This sample was made to be used in the brewing of pale ale, but I wish to have some still whiter, because, as I shall have to point out, I propose that this dextrose shall be employed instead of potato, especially when inferior wheats are being used, in the manufacture of bread.

Now, as regards the properties of this dextrose. In the first place, as the name implies, it is dextro-rotary. It turns the plane of vibration of polarized light to the right hand 56°. It is less soluble in water, and also in alcohol, than cane sugar, and it is only half as sweet. If you try a portion from this bottle, you will find that it is not so sweet as cane sugar; indeed, it would take rather more than two parts of dextrose to produce the same sweetening effect as ordinary cane sugar. When oil of vitriol was added to a solution of cane sugar, you will remember that the cane sugar was broken up and charcoal was formed. You will find that the dextrose is more stable than the cane sugar, and that oil of vitriol does not break it up with the formation of charcoal. Mr. Lewis will kindly add some oil of vitriol to the solution of dextrose, and we shall find that there is no separation of charcoal.

While that is being done, I will pass on to the consideration of the other member of the series—lævo-glucose. This may be prepared from honey, either by the treatment of alcohol which I have explained, or else, and much more conveniently, by the simple method of pressure. It can be produced still more cheaply from what manufacturers call inverted or changed sugar, that is to say, ordinary cane sugar inverted or changed in its properties.

If you take 100 parts by weight of inverted sugar and rub it with 60 parts of hydrated lime—ordinary quick lime hydrated with water, so as to obtain a fine dry powder—and 1000 parts of water, at first you obtain a tolerably fluid mixture. Presently the lime reacts on the dextro-glucose and the lævo-glucose, which together constitute what is termed inverted sugar, and the whole mass solidifies. If, now, you take the solidified mass, and submit it to very great pressure, the dextrose combined with the lime—a dextro-glucosate of lime—is pressed out. It is fluid, whereas the lævo-glucosate of lime remains as a hard solid body. Now, if you take this lævo-glucosate of lime and digest it in water, and add oxalic acid to it, the oxalic acid throws down the lime, and you obtain the solution of the lævo-glucose. When prepared in this or any other way, it has the following properties. It is called lævo-glucose or lævulose, that is to say, it rotates the plane of polarized light to the left, 106°. When we want to indicate a right-handed rotation, we put a + before it, whereas — indicates a body which rotates the plane of polarized light to the left. This lævo-glucose is uncrystallizable; it is never solid; it will not solidify like the dextro-glucose, and it is as sweet as cane sugar. It is much more soluble, as I have already said, in alcohol, and also in water, than its congener, dextro-glucose.

So much for those two separately. I will now proceed to indicate the general chemical characteristics by which we can recognize glucose—not considering if it be dextro-glucose or lævo-glucose—but simply that it is a glucose.

In the first place, these glucoses reduce Fehling's solution. Mr. Lewis will take a small quantity of the dextro-glucose and add to it this Fehling's liquid, which, as I told you, consists of sulphate of copper mixed with the double tartrate of potash and soda, and rendered alkaline by caustic soda or caustic potash. When it is heated to a temperature of about 80° to 90° the protoxide of copper will be reduced, and you will see the red sub-oxide of copper. These glucoses, whether dextro- or lævo-glucose, have a peculiar action upon a solution of nitrate or chloride of cobalt. I ought to point out that cane sugar, when added to a solution of cobalt, has not the power of preventing the precipitation of the hydrated oxide upon the addition of an alkali, whereas, if we have a glucose present, then the oxide of cobalt is not precipitated from its solution by the addition of a little alkali.

On the left, we have a solution of cane sugar. The liquid you see is coloured by cobalt, and Mr. Lewis has added a little potash to it. On the right is glucose—I do not know whether he has given me dextro-glucose, but it is of no consequence. He has now added cobalt to this on my left hand, containing a solution of cane sugar, and next potash will be added to them, and you see there is a thick precipitate formed. If this solution of cobalt is added to the solution on the right, and then potash added, we shall not obtain any precipitate. That is one means of recognizing whether cane sugar contains some glucose, but as a reaction it is by no means so delicate as that resulting from the use of Fehling's solution.

The glucoses have a very marked and powerful reducing action, and by reducing action we mean that they are able to take away oxygen from other bodies; for instance, if you take an ordinary salt that you know very well, lunar caustic, or silver nitrate, if a glucose be added to that, together with a little ammonia—or, perhaps, a more convenient and better way of performing the experiment is to add a little ammonia to the glucose solution, so as to obtain an ammoniacal solution of glucose—then add silver nitrate to that, and gently warm it, the silver will be precipitated in the metallic state. When I say that, I do not mean that you will see the silver having the same appearance as in a shilling, for it will be a black powder. Occasionally it happens that it is precipitated on the sides of the glass, so as to give a mirror-like appearance to it. If that black powder were put under a powerful hammer, you could force the particles together, and then they would have all the appearance of ordinary metallic silver as known to you.

Glucose has the power of changing blue indigo into white indigo, and we call that a reducing action. It is not properly a reducing action, but the expression is due to the amount of knowledge we had many years ago, when we thought that white indigo contained less oxygen than blue. We now have another theory to explain it, but all I wish you to understand is, that this powerful reducing agent can change blue indigo into white indigo on being warmed with a little alkali. You see, on warming the tube, how rapid the action is.

If I take this reduced indigo—highly coloured at present, because potash acts on the glucose at a high temperature and converts it into various coloured products—and put it into water containing a little acid to neutralize the alkali, you see I obtain the blue indigo again. Glucose in an alkaline solution has the power of converting a liquid that is much employed by chemists for the detection of iron in solution. It is called the red prussiate of potash, and it converts this salt into red prussiate of potash. The red prussiate of potash is reduced to the yellow prussiate of potash, or the ferricyanide into the ferrocyanide. Ferricyanide was poured into this tube, together with ferric chloride, or tincture of steel, and there was no reaction. Now, upon the addition of glucose to the ferricyanide of potassium, it is converted into ferrocyanide. Now, ferrocyanide gives with tincture of steel a Prussian blue, whereas ferricyanide gives with tincture of steel no such Prussian blue. You see, from the foregoing experiments, then, that glucose is a powerful reducing agent.

Another experiment, which it is hardly necessary to show you, is that caustic potash or soda has no action, or very little, on cane sugar, whereas it rapidly converts the glucoses into coloured products. The yeast organism has a powerful action on solution of dextrose. It converts dextrose very rapidly into carbonic acid gas and alcohol. The same action takes place with lævo-glucose; but if you take a mixture of dextro-glucose and lævo-glucose, such as is made from inverted sugar, then you would find that the yeast organism uses much more dextro-glucose per unit of time than it does of the lævo-glucose. After some time you would, perhaps, find no dextro-glucose left, but there would still be some lævo-glucose left, which would give a certain fulness on the palate when you were drinking the ales for which it is employed.

This leads me to give you a short description of the method employed for the making of this inverted sugar. I have a sample of it here which has been made in that way. The cane sugar is dissolved in water and a small quantity of sulphuric acid is added to it, about 1 per cent. It is then heated, and in the course of an hour, or an hour and a half, the whole of the cane sugar has been converted into a mixture of equal parts of dextro- and lævo-glucose. This is evaporated down, and is employed very largely in the manufacture of beer—not exclusively, the proportion, perhaps, being one-fourth, or, more usually, one-sixth, along with malt—and the chief reason why the brewers employ this inverted cane sugar is that it contains no albuminous matters. Now, in certain samples of barley, especially in some seasons, such as the one which we have unfortunately passed through, there is a large quantity of soluble albuminous matters formed, on account of the bad maturation period, just when these soluble albuminoids should be converted into insoluble. Under these circumstances, either a material such as this dextro-glucose, or a material such as you see here, which is a mixture of dextro- and lævo-glucose, is employed in order to give a certain stability to beer which otherwise it might not have.

Now, the cane sugar has a dextro-rotary power of $+73\cdot8°$, lævo-glucose has a lævo-rotary power of $-106°$, and dextro-glucose a right-handed rotary power of $+56°$. If you then add those together, and divide by two, you will find that the mixture has a lævo-rotary power of $\frac{-106°+56°}{2}$ which is equal to $-25°$, the optical activity of inverted cane sugar.

(To be continued.)

Parliamentary and Law Proceedings.

Poisoning by Chloral.

At the Manchester City Police Court, John Walter Lee, was brought up on a charge of having attempted to commit suicide. It appeared from the evidence, that a little before twelve o'clock on the previous day it was discovered that the door of the room which the prisoner occupied at the Queen's Hotel was fast, the prisoner up to this time not having left his room. A joiner on the premises burst the door open, and the prisoner was found lying on his face on the floor in an unconscious state, having apparently fallen off the bed. A bottle labelled "poison," was found in the room, and from the appearance of the prisoner it was thought advisable to secure the services of a surgeon, who used the stomach pump and a battery, and ultimately brought him round with great difficulty.

Evidence was given showing that the poison was chloral, which had been obtained from Messrs. Thompson and Capper, homœopathic chemists, the label on the bottle indicating that six drops were sufficient for a dose.

The surgeon who attended the prisoner said there was very little doubt that death would have ensued had the prisoner not been discovered at the time he was.

Mr. Headlam remanded the prisoner for a week in order that his friends might be communicated with in the meantime.—*Manchester Paper.*

Death from an Overdose of Chlorodyne.

At the Leeds Town Hall on Wednesday, May 5, the Borough Coroner (Mr. Malcolm) held an inquest on the body of John Rivers, aged 42.

The Rev. H. F. Rivers, of Offham Rectory, near Maidstone, said the deceased was his brother. He had suffered from sleeplessness, and for several years he had been in the habit of taking chlorodyne. Witness had no suspicion that the case was one of suicide. The last letter received from the deceased by his sister stated that he was very happy and comfortable.

Mrs. Chaplin said the deceased came to live at her house seven weeks ago. He had been away for more than a fortnight, and returned in a cab on Saturday morning. He appeared to be very ill, and she assisted him upstairs. He continued ill during the day, and on Sunday he said he thought he was a little better. She wished to call a doctor, but he would not allow her to do so, and said he would go to a doctor himself. On Sunday night he vomited a good deal, and on Monday forenoon she asked Mr. Pickles, surgeon, to see him.

Mr. Pickles said he found the deceased very ill. He told witness that on Sunday he had gone to a chemist, and got medicine and a bottle of chlorodyne. During the night, when he found he could not sleep, he had taken all the chlorodyne. Witness asked if he had been in the habit of taking chlorodyne, and he said he had. He prescribed the usual remedies, which the deceased took. In the afternoon he called again, but the deceased was then dead. He had made a *post-mortem* examination of the body, and was of opinion that deceased had been poisoned by an overdose of chlorodyne. From 20 to 30 drops was a very large dose. He had seen the bottle, which was a ½-ounce one, and would contain 240 drops.

The jury gave a verdict in accordance with the medical evidence.—*Leeds Mercury.*

Poisoning by a Liniment.

The Leeds Borough Coroner held an inquiry at the Town Hall, on Wednesday May 5, with regard to the death of Septimus Oates, aged 28. The deceased had been in a depressed state for some months. Being left in the kitchen by himself for five minutes he got a bottle containing a mixture of opium and belladonna, which his sister used as an outward application for rheumatism, and went to the closet and drank a portion of the contents. His sister passed the door a few minutes afterwards, and he shouted out, "Good bye." She went to him, and found the bottle, which was marked "poison," on the floor. Dr. Jessop was sent for; and he ordered his removal to the Infirmary, but he died shortly after his arrival there. The jury returned a verdict to the effect that the deceased died from the effects of the opium and belladonna taken by him whilst suffering from temporary insanity.—*Leeds Mercury.*

Review.

Elements of Modern Chemistry. By Adolphe Wurtz, Member of the Institute, etc. Translated and edited, with the approbation of the Author, from the Fourth French Edition, by Wm. H. Greene, M.D., etc. London and Philadelphia: J. B. Lippincott and Co. 1879.

The author in his preface states that "the French editions succeed each other rapidly, showing that this little book responds to an educational need." This may be the case in France, yet when we consider the numerous excellent text-books on chemistry now existing in the English language, it is difficult indeed to believe that we require still another to introduce us to the general truths of the science.

It is needless to state that any work by such a distinguished author as M. Wurtz is entitled to receive the most profound respect, and we opened the book before us with the expectation of finding the subject treated in such a manner as to give this volume a pre-eminent position amidst the existing English manuals of chemistry. In this hope we are not entirely disappointed, for though we fail to see that this book responds to any educational need which is not already provided for by existing English works, it must be admitted that the translator in his preface is correct in stating that "this book is therefore a brief but accurate embodiment of modern chemical ideas, arranged in such a form that the most difficult principles are acquired gradually in the course of the descriptions."

First of all an introduction is devoted to the consideration of the peculiarities of chemical force or affinity, and some experiments are described by which the results of chemical action are shown to be widely different from those produced by mere admixture. It is, however, unfortunate that in this introduction a molecule of sulphide of iron is represented by a circle marked S, and another marked Fe connected by one line only. Though we quite recognize the fact that the author does not intend this single line to stand as a so-called bond representing the atomicity of iron and sulphur we rather think that a beginner would be led into the error of supposing that such is the case.

Following this introduction is a brief exposition of the principles of chemical philosophy, and we consider this the least commendable portion of the book. It is of course undesirable that a book intended for beginners should be heavily weighted at the beginning with an elaborate treatment of this portion of the subject; in fact we are inclined to believe that in the matter of chemical philosophy a learner is helped most by a somewhat dogmatic style of teaching, and more particularly by brief and clear explanations of the meaning, we might almost say definitions, of the terms used.

From this point of view we hardly think that the inquiring mind of an ordinary student would be quite satisfied by the explanation given here of the meaning of the term atomic weight. He would meet with it pretty frequently, and would naturally desire to know what this term really represents. If he referred to the index he would not find the term mentioned, but by careful search he would find the following:—"The equivalents represented merely the ponderable proportions, according to which bodies combine; the atomic weights represent the relative weights of the volumes of gases which combine. The equivalent of hydrogen—unity—expressed merely that hydrogen was the unit to which were referred the weights of other bodies with which it entered into combination. The atomic weight of hydrogen is the weight of one volume of hydrogen, taken as unity, and to this unit are referred the atomic weights of other bodies." If this were considered hardly a satisfactory explanation of the meaning of the term in connection with those elements which cannot be converted into vapour, such as carbon, the student in continuing his search would learn that the law discovered by Dulong and Petit—*the atoms of the solid elements possess sensibly the same specific heats*—permits the deduction of the atomic weights from the specific heats, and that "it is evident that if the product of the specific heats by the atomic weights be a constant that may be called the *atomic heat*, dividing this product by the specific heat should give the atomic weight." Exactly, but we venture to think the beginner would still consider his question unanswered, viz., what is really meant when the term atomic weight of carbon is employed?

The notion of equivalents is treated at some length, and the author concludes by saying that "in order to determine the equivalent of an element it is sufficient to find the quantity of that element which combines either with one of hydrogen or with a quantity of another element which is equivalent to one of hydrogen, for instance eight of oxygen." If this were all, the equivalents of all elements of varying atomicities would be indeterminate. The author omits to say that the equivalent is really the *smallest* quantity of an element which will combine with one of hydrogen or with an equivalent quantity of another element. Following the introductory chapters the author gives an account of the non-metallic elements, their methods of preparation, their properties, and their chief compounds. This portion is worthy of all praise. The main facts concerning each are given with admirable clearness and accuracy, any commercial processes concerned being described with a fair amount of detail, without the descriptions being rendered tedious. It is noticeable that arsenic and antimony are included in the non-metallic elements, while bismuth is placed among the metals. After the consideration of the non-metallic elements, the theory of atomicity is discussed in a separate chapter. The author then proceeds to give a very useful account of the general characters of the metals, their classification, their alloys, and of salts generally. The iron in ferric salts is not described as being tetratomic, but the two atoms are together called a hexatomic couple, for which the name ferricum is suggested for convenience.

In his detailed treatment of the metals and their compounds the author devotes a large amount of attention to the means practically adopted for the reduction of the metals. Thus the metallurgy of iron occupies no less than seven pages, while five only are given to the consideration of the salts of the metal. These descriptions of practical processes, as well as the illustrations accompanying them, are remarkably good; in fact the illustrations throughout are excellent, excepting here and there one of minor importance.

Turning to the portion of the book devoted to organic chemistry, we find that it commences with a rather meagre account of elementary analysis. The author states in his preface that "immediately on entering the immense domain of organic chemistry, we find the facts overwhelmingly numerous and complicated. Among all these facts a severe and careful choice has been made, the historical importance and the theoretical and practical interest of the compounds being borne in mind." The author has been most judicious in his choice, and there are indeed few bodies of first-rate importance and interest which are not considered with some degree of detail.

The author does not divide the bulk of organic compounds into two great groups—fatty and aromatic; but after some introductory matter, in which explanations of the terms saturated hydrocarbons, alcohols, ethers, aldehyds, acids, acetones, amines, organo-metallic compounds, etc., are given, the author proceeds to describe the series of substances usually included in the term fatty group, under the heads of monatomic and polyatomic compounds.

In connection with aromatic compounds, considerable attention is given to Kekulé's theory of the closed benzol chain, and a series of well selected graphic formulæ are given to illustrate how Kekulé's lateral chains may be grafted at different points of the benzol nucleus by substitution for the different hydrogen atoms, and so produce ortho-, meta- and para- derivatives.

On the whole the book before us is perhaps as good as any other of its class in the English language. The intention of the author apparently is not so much to induce students to accompany their reading by practical experiment as to cause them to acquire a knowledge of modern chemical facts and principles from description. This is shown by the fact that after the treatment of the non-metallic elements, no experiments such as would recommend themselves to the learner are described in detail.

The work would be very materially improved by a more copious index, and by the addition of a table of contents.

BOOKS, PAMPHLETS, ETC., RECEIVED.

The Pharmacopœia of the British Hospital for Diseases of the Skin. Second Edition. Edited by Balmanno Squire, M.B. Lond. London: J. and A. Churchill. From the Author.

Manual for the Physiological Laboratory. By Vincent Harris, M.D. Lond., and D'Arcy Power, B.A. Oxon. London: Bailliere, Tindall and Cox. 1880. From the Author.

Obituary.

Notice has been received of the death of the following:—

On the 6th of January, 1880, Mr. Edwin Brunt, Chemist and Druggist, Hyde. Aged 23 years. Mr. Brunt was an Associate of the Pharmaceutical Society.

On the 16th of April, 1880, Mr. Henry Taylor, Chemist and Druggist, Newbury, Bucks. Aged 63 years.

On the 20th of April, 1880, Mr. William Thomas Williams, Pharmaceutical Chemist, Cardiff. Aged 26 years.

On the 25th of April, 1880, Mr. Thomas Henry Brunt, Chemist and Druggist, Hyde. Aged 48 years. Mr. Brunt had been a Member of the Pharmaceutical Society since 1876.

On the 26th of April, 1880, Mr. David Smart, Chemist and Druggist, Port Glasgow. Aged 36 years.

On the 30th of April, 1880, Mr. William Bellerby, Chemist and Druggist, Newcastle-on-Tyne. Aged 61 years.

On the 2nd of May, 1880, Mr. William George Harding, Chemist and Druggist, late of Sudbury. Aged 48 years.

On the 4th of May, 1880, Mr. Charles John Hayward, Pharmaceutical Chemist, Lincoln. Aged 44 years. Mr. Hayward had been a Member of the Society since 1859.

Dispensing Memoranda.

[401]. The mist. scillæ referred to in Scotch ℞ is, doubtless, that given, under article "Scillæ," in 'Christison,' very much used in Scotland, viz.:—

℞ Syr. Scillæ,
Aq. Menth. Pip. . . . . āā ℥ij.
Tinct. Opii Ammon.,
Tinct. Lavand. Co. . . . . āā ℥ss.
Syr. Simp. . . . . ℥j.
M.

Vide 'Christison,' 1842, page 839.

Geo. Wilson.

[407]. The following I take to be the meaning of directions, as required by R. A. Cripps.

Misce, fiat pilula, sufficit quantum (s. q.) mitte duodecim (pilulas.).

Mix, and let a pill be made (mix), a sufficient quantity to send twelve.

H. W. Nichol.

[407]. In the prescription which R. A. Cripps inserts, there is no doubt but that "quantum sufficiat" was intended; for by taking into consideration the doses of the ingredients ordered, and the number to be taken, it cannot leave any doubt but that the mass was to be formed sufficiently large to enable each pill to contain hyd. perch., $\frac{1}{20}$ gr.; pot. iod., $\frac{1}{2}$ gr.; ext. aloes Bbd., 1 gr.

C. T. M.

[407]. In answer to R. A. Cripps, instead of "*q*" it ought to be "*a*," *secund. artem.* The writer evidently bringing the stroke of the "*a*" too far down.

Apprentice.

[408]. In answer to this query, I beg to state that according to the copy of the prescription zinci phosphas would be meant, the dose of which is from 1 to 3 grains.

It could not be meant for zinci phosphid., as the dose is from $\frac{1}{12}$ to $\frac{1}{8}$ of a grain.

323, *Park Road, Liverpool.* E. Whiston.

Correspondence.

H. Y.—(1) Probably *Bunium flexuosum*. (2) Probably *Arctium majus*. (3) *Alyssum saxatile*, not British. We cannot undertake to name plants when only leaves are sent.

A. Skirving.—The specimen is *Luzula sylvatica*.

J. W. D. Hume.—We will try to answer your question next week.

"*Nemo*" is thanked for his communication, which, however, does not meet the requirement of "*Apprentice*," who asked for a recipe for making the preparation.

R. L. G.—The preparation is a proprietary one, and we are not aware that the formula has been published.

J. Barrett.—The oleate of lead used by Dr. Sawyer in the treatment of eczema has been described by him as being prepared by "heating a mixture of oleic acid and oxide of lead." (*Practitioner*, Nov. 1879, p. 348.)

F. G. Foster.—There is no exception in the Pharmacy Act which renders legal the sale of scheduled poisons as homœopathic medicines by unregistered persons.

T. Horton.—The formula given by Mr. Squire (*Pharm. Journ.* [3], viii., 603), is—"Thymol, in crystals, ℈j; lard, ℥j. Melt together at the temperature of a water-bath and allow to cool."

J. Harrison.—The point has not been overlooked, the names of persons sending plants being all known.

Communications, Letters, etc., have been received from Messrs. Chipperfield, Mee, Howden, Haydon, Statham, Lyle, Postans, Covell, Gravill, Brown, MacEwan, Snif, Beta, D.D.

THE ANNUAL DINNER.

The Annual Dinner of the members and friends of the Pharmaceutical Society took place on Tuesday last, at Willis's Rooms, Mr. G. W. Sandford, President, in the chair.

Grace having been sung—

The President proposed "The Health of the Queen," which was received in the usual loyal manner, as was the next toast of "The Prince and Princess of Wales and the rest of the Royal Family." In proposing this toast the President alluded to the interest taken by the Prince of Wales in all that affected the welfare of the nation, and also to the youthful princes who were to be seen every day amongst them.

"The Army, Navy and Reserve Forces," was the next toast, proposed by the President. After referring in appropriate terms to the army and navy, he reminded his audience that this year was to be celebrated the majority, or coming of age, of the volunteer force, and it was therefore particularly the occasion for wishing them prosperity. With the toast he begged to couple the name of Captain Richardson, Leicester.

Captain Richardson, in responding to the toast, said it was an additional honour to speak to it at a time when our forces had so recently been distinguishing themselves in Afghanistan and South Africa, and he was especially proud to think of the important part played by medical men in the campaign in South Africa. He could not forget either the important part played by chemistry in modern warfare. Not long ago he had the pleasure of spending a day at Woolwich, where Professor Abel gave every scientific man present one of the greatest intellectual treats he could receive. Chemistry had done more for modern warfare than any other science, and though it might make it dreadful, he hoped it would also make the horrors of war more brief than in old times.

The Vice-President, Mr. G. F. Schacht, being called upon to propose the next toast, said he thought the Committee had done well in placing the toast of "Science" high up on the list, and perhaps it was not unbecoming that he, as Vice-President of the Pharmaceutical Council, had been requested to propose it, for the Society was based fundamentally on the assumption that pharmacy rested for all that was good in its past history, for all that was good in its present condition, and for all its hopes in the future, on a fair, worthy cultivation of science. It might be true that the Executive had not been able to pursue quite uninterruptedly the highest ends, but in that they had only shared the common lot; broadly speaking, it had pursued a steady course, and endeavoured to cultivate scientific pharmacy. As a member for some years' standing of the Pharmaceutical Conference, it had been his lot to visit several centres of activity throughout the British Isles, and wherever he had gone he had found pharmacists genuine devotees of science. Such persons had often been unknown out of their immediate local surroundings, but nevertheless they had been men doing good work in their own localities, and finding in that work not only their greatest usefulness, but their greatest delight. So often had this occurred that he hoped that the time was not far distant when this would be the rule in pharmacy, and not the exception. Connected with the toast he begged to name Professor Roscoe, not only because he was a distinguished chemist and physicist, and a man of science generally, but from his high official position. Not one present but had heard of Owens College, Manchester, and they must all admit how much of its success was due to the labours of Professor Roscoe. These had made it one of the most successful scientific experiments in modern times, and he felt especially pleased to have the opportunity of testifying his admiration for one who was not only a man of science, but one of the most successful organizers of scientific instruction.

Dr. Roscoe, in responding, begged to thank the Vice-President for the kind words he had spoken of himself. Good wine needs no bush and science needs neither apologist nor patron. Those who could look back for twenty-five years might well be satisfied with the progress English science had made; progress not only in quality and in the quantity of the scientific work which had been done, but progress especially in the amount of general recognition which scientific investigation and men of science had won for themselves throughout the country. At the present moment the man of science occupies a distinct position in the community. He does work which is generally recognized, and his position is a highly appreciated one in the body politic. Nor is this opinion confined to the educated few; it is pretty generally held among the educated many, and the recognition which science in England now receives is greatly due to the importance and to the character and ability of our scientific literature; partly also to the effect of the science lectures which have been given throughout the country, and thus it came about that this general recognition of and interest in science was something which had gone down almost to the lowest stratum of society. Looking at the matter from the purely educational view the older universities were found vieing with the modern higher educational establishments of the country to place science teaching in its highest departments on a proper footing. With reference to the institution with which he had the honour to be connected it might perhaps be interesting to state that they had now in the North of England a new university—the Victoria University, the charter of which was received the other day, so that a new English University had now become a positive fact. It had been born, and only required careful feeding and nourishment to bring it up to be a stalwart and useful member of society. The teaching of science was now percolating through all classes. In London the adoption of scientific instruction in Board Schools was an accomplished fact, in great measure owing to the efforts of Dr. Gladstone. A short time ago the idea of a ploughboy or a son of a mechanic receiving instruction in chemistry would have seemed quite a chimera, and not less so for a Cambridge man taking a degree in physiology alone, but both these things had now become established facts. When one considered the interest taken in scientific subjects by the mass of the people, and especially the interest taken in the theory of evolution by the world at large, and recollecting that this was the work of an Englishmen, they must all agree that at no other time had the work done by English men of science been more important than it was at the present day, and that the interest shown by the public in the support and acknowledgment of it was never greater than at the present moment. Again, what changes had not the Pharmaceutical Society undergone and what important results had not it accomplished during the last twenty-five years. As representing the Chemical Society, the Fellows of which confined themselves especially to chemistry as a science, he might congratulate the President on the progress which his Society had made and express the conviction which the Fellows of the Chemical Society entertained of the high importance of its labours, and the value of its results. He hoped their Society would long continue to flourish and become more and more completely the great educational establishment of the pharmaceutical profession..

The President next proposed the toast of the "Medical Profession," coupling with it the name of the President of the Medical Society of London. To the medical profession be said the Pharmaceutical Society owed the greatest respect. It was their duty to aid that profession in alleviating human suffering, and on the other hand the medical profession had done a great deal to advance pharmacy. He was lately reading a paper on modern surgery, which set forth in glowing terms the advances which had been made in recent years, having especial reference to the use of anæsthetics, showing how the surgeon was now able deliberately to perform operations, which formerly must be hurried whilst the patient was writhing under the knife; it then went on to speak of the antiseptic treatment, and he could not help feeling proud that chemistry and pharmacy had aided the surgeon in both these respects.

Dr. GANT responded very briefly, as he was suffering from a laryngeal affection. He begged, however, to thank the President for the kind terms in which the medical profession had been spoken of, and remarked that the Society he represented was the oldest of the kind in London, being now in its second century. The medical profession was very large, numbering some 18,000, including all branches, not the least important of which were the medical officers of health. He wished he could say that their relations with the public were altogether satisfactory, but it must be acknowledged that public opinion differed much as to what should constitute the profession, and there were those who seemed to be desirous of introducing an imperfectly educated order of practitioners. Only last year a learned serjeant-at-law declared in the House of Commons that he would have herbalists incorporated with legally qualified practitioners—men who as he confessed had never seen the inside of a medical college. Then again there was a small section which would not merely restrict, but altogether prohibit vivisection, from which alone scientific physiology could be learnt; and on the vaccination question, again, there was a great deal of ignorance abroad. Indeed, in one sentence the public needed to be protected not from the profession, but from themselves. One result, however, they could not disturb, and that was the cordial and highly satisfactory relation which existed between the Medical Profession and the Pharmaceutical Society.

Dr. B. W. RICHARDSON: The peculiar honour is entrusted to me of proposing what is emphatically the toast of the evening, "Success to your Society." I might propose this toast right heartily on the ground of old acquaintanceship, dating almost from the birth of the Society, certainly from its earliest days. It was my fortune, my good fortune, to know your founder, Mr. Jacob Bell; I had the pleasure of being a co-worker with him—and although once in the management of a public institution with which we were connected, I and my medical colleagues thought that he let his feelings over-ride his judgment, whereby a coldness ensued, that coldness was but as a passing April shower, followed by a long and genial summer of friendship, which has left on my mind, but one impression, the recollection of his untiring devotion to this the grand work of his life, and the pleasure of watching its growth from his time to its present magnitude, influence, and place in the public estimation. I might, again, propose this toast right heartily on personal grounds, in remembrance of the many services the members of the Society have rendered to physiological physicians, who, like myself, have striven to advance the therapeutical art by the experimental method. When the late Sir James Simpson was about to introduce chloroform his first care was to seek from two members of your fraternity, Messrs. Duncan and Flockhart, the chemical he wanted, in all its purity. When the late Dr. Snow was conducting his inquiries, inquiries which were the very basis of modern therapeutical investigation by experiment, he was wont to seek the same assistance from another member of your fraternity, the able translator and annotator of Fresenius, our friend, Mr. Lloyd Bullock. In like manner in the twenty-five years during which I have traversed the same path, whenever I have wished to introduce some new medicament into practical medicine,—peroxide of hydrogen, nitrite of amyl, the hydrides, the colloids, methylene bichloride, sodium ethylate, methylal, or other substance,—I have sought the same able assistance, and with equal success. To one member of your Council, one too, sir, who will, I hope, in due time fill the chair you now so worthily occupy,—Mr. Robbins,—my obligations in this respect are specially and singularly due; and to your honoured President of last year, Mr. Williams, a chemist in the truest sense of the word, they should also be expressed. But, sir, I would like to place this toast on far higher grounds than these. I wish success to your Society because of the great assistance it daily renders to the science of medicine in all her departments. In medicine now-a-days old things are passing away, and everything is becoming new. Galen, who for so many centuries ruled the curative medicinal art, is Galen no longer as our forefathers knew him. *In Deorum numerum receptus est.* He is received into the number of the gods, and remains only as a name. The Galenicals, once so potent for good or for evil, are almost forgotten. Galen, in his day, taught that the practitioner of medicine should prepare his own medical armament, keep his own dispensatory, send out his own remedies. In this day, whether for better or worse, the physician, the surgeon, or the obstetrician, finds it as much as he can do to visit, prescribe, direct and lead. To you, therefore, is virtually left the whole of the work of preparation and dispensation of remedies for the sick, so that to the body medical you are what the press is to the body political. You are not the physician, not the surgeon, not the obstetrician, but you are *the fourth estate* of scientific medicine. The further scientific medicine advances the more she requires you to be near her as her basis of supply: the more refined she becomes the more important it is for you to be able to meet her new and increasing demands. I for one, indeed, am liberal enough to wish that you were no longer of her, but with her. I could hope that by a friendly amalgamation of your body with the last of her great and useful organizations which co-ordinates most nearly with yours, you could, before very long, enter our pale altogether, become, like us, professional in the strictest sense of the word, and obtain, each one of you, the direct opportunity of rising to the highest attainable position in a united and common profession. Gentlemen, I would propose this toast on still higher grounds, even than those I have just named. I wish your Society success because of the public benefit it confers as a scientific, conscientious and trusted public body. At a time when the race for wealth at any price is the overwhelming maddening ambition, at a time when the ignoble and suicidal craving after luxury and false repose is the besetting sin, it is past all expression essential that duties such as you perform should be supervised and directed by and through a body of men who are raised above the ignorance that prompts, and the low cupidity that sustains that most criminal and cowardly of all crimes, the art of trafficking in the ills that flesh is heir to, and of taking advantage of suffering humanity in its most hopeless, helpless and defenceless states of physical and mental misery.

Mr. President and gentlemen, in the days when the old Greeks literally revelled in the radiance of intellectual light, there lived amongst them, to almost a century of life, a man called Isocrates the rich, an anomalous philosopher, who from timidity could never speak a speech, and who nevertheless wrote such splendid orations and such a noble work on rhetoric that he became accounted one of the grand orators of his country. This master taught his pupils that when any one of them was called to perform a public task he must "First think, then speak, and last of all fulfil." In obedience to this direction, I have thought, I have spoken, and last of all I fulfil by inviting you, in all brotherly affection, sympathy and sincerity, to join me in proposing continued prosperity for and continued usefulness to the Pharmaceutical Society of Great Britain, coupling with the toast the name of your worthy and distinguished President.

The PRESIDENT said he could only wish it had fallen to more able hands to acknowledge the kind manner in which Dr. Richardson had proposed success to the Pharmaceutical Society. It had been his privilege to be connected with that Society for the last thirty years, and he felt the greatest pleasure in hearing Dr. Richardson speak of what they had done in that time; they had established the Society on such a basis that it was respected by the profession and referred to with advantage in matters concerning the public health. They had done all they could for the advancement of pharmacy, though there were many difficulties to overcome, which never could have been overcome but for the efforts of the able man who led them on in the first instance and to whom Dr. Richardson had so kindly referred. It was now thirty-nine years since the Society was founded; in those days there were few such men as Mr. Bell, but there were a few both in London and the country. Those men were not selfish men, who tried to keep all the advantage accruing from their position to themselves, but endeavoured as far as possible to advance every member of the trade to their own position. Dr. Richardson had alluded to the time when all dispensing would be passed over from what was called the medical profession into the hands of pharmacists, and he also referred to advancing pharmacists into a branch of the medical profession. As to the first of these things, at any rate, he believed he was perfectly right in hoping that such a thing would come about, and that it would be really as much to the advantage of the medical profession as to chemists that it should be so. They were going on steadily with their examinations, and that the high standard attained would not be allowed to drop they were assured by the constant presence of Dr. Greenhow, who came at every examination to see that, on the one hand, they were faithfully and properly conducted, and on the other, that the examiners were not unduly hard upon the candidates. There were also material interests of the Society to which they were bound to look, and for which it was necessary that care should be taken in the selection of the men who met month by month to perform the duties of the Council and of others who were officially employed at Bloomsbury Square. In some of those duties they were much aided by his friend, Mr. Flux, the solicitor of the Society, whom he saw near him, and whom he was somewhat disappointed at not seeing in Parliament, as he had hoped he would have been. In conclusion, he might say that some of the happiest days of his life had been passed in association with the members of that Society.

The President lastly proposed the health of "The Visitors," coupled with the name of Dr. Buchanan.

Dr. Buchanan having responded in brief but appropriate terms, the meeting broke up.

During the evening a choice selection of music was sung by Miss Agnes Larkcom, Miss Julia Elton, Mr. Montem Smith and Mr. Winn.

Mr. Harradine officiated as toast-master.

THE EXHIBITION.

On Tuesday morning the Society's Rooms were opened to visitors for the examination of the chemical and pharmaceutical apparatus, preparations, and other objects of interest enumerated below. Up to Thursday evening, when the exhibition closed, the attendance was numerous and in all respects it may be said that this portion of the week's work was highly successful.

ROOM No. 1.
GAS APPARATUS.

Townson and Mercer, 89, *Bishopsgate Street Within, London, E.C.*

Fletcher's Gas Apparatus, as exhibited at the Society of Arts, on April 28, by M. T. Fletcher, F.C.S.
Crucible Furnace, with side chimney.
Muffle Furnace.
Perfected Ladle Furnace.
Fletcher's Solid Flame Burner.
Wallace's ditto.
Ditto, with horizontal tube.
New Evaporating Burner.
Fletcher's Hot-Air Bath, for pharmaceutical purposes.
Simple Furnace.
Foot Blowers.
New Soldering and Brazing Blowpipe with Taps.
Blowpipe, for use in Hand Brazing.
New Adjustable Stand for ditto.
Original Hot Blast Blowpipe.
Special Chemical Blowpipe.
Jeweller's Soldering Coals.
Melting Arrangements, for obtaining ingots of gold, silver, etc,, without the use of a furnace.
Simple Injector Gas Furnace, in which a safe arrangement is made for burning the vapour of light petroleum or benzoline.

ROOM No. 2.
PHARMACEUTICAL APPARATUS.

Baker, J., and Son, 14, *Tabernacle Walk, Finsbury, London, E.C.*
Mixing Machine for powders.
Morton's Mixing Machine for liquids.

Bourne and Taylor, 35, *Castle Street, Holborn, London, E.C.*
Cartner's Pill Coating Machine; Gas Furnace; Suppository Pan; Stopper Loosener; Patent Funnel; Funnel Measures; Pill Scoop.

Bracher, P. H., 77, *High Street, Wincanton, Somerset.*
Patent Desideratum Mixer, for mixing all kinds of powders.

Burroughs, S. M., 8, *Snow Hill, London, E.C.*
Corking Machine; Drug Presser.

Burton, Geo., 221, *St. John Street, Clerkenwell, E.C.*
Drug Mill.

Christy, T., and Co., 155, *Fenchurch Street, London, E.C.*
Tanning Testing Aparatus, for estimating value of barks, woods, fruits, etc.

Cocking, T. S., 72 *and* 74, *High Street, Sittingbourne.*
Pill Machine; Pill Piper, turns one pound of pil mass into perfect pipes in three minutes.
Pill Burnisher, with Reversible Strap; finishes off at one operation two gross of pills.

Erhardt and Co., 9, *Bond Court, Walbrook, London, E.C.*
Capsuling Machine.

Gall, F., *Carshalton, Surrey.*
Improved Label Damper.

Glew, J. C., 10, *Museum Street Holborn.*
Pharmaceutical Drying Closet, designed by Mr. T. E. Greenish.

Goodall, T. S., 5, *St. Peter's Street, Derby.*
Model of Grinding and Levigating Machine.

Hayward, Tyler and Co., 84, *Upper Whitecross Street, E.C.*
Hydraulic Tincture Press.

Hottinott, F. F., *Boundary House, Hadley, Barnet.*
New Pill Coating Machine.

Ladd, J. H., and Co., 116, *Queen Victoria Street, London, E.C.*
The Boomer and Boschert Tincture Press, with hoop and plates tinned; capacity, 6 gallons; pressure, 10 tons, worked by hand.
Small Patent Tincture Press, with Enamelled Cylinder; capacity, 2 quarts.

LYNCH AND CO., 171*a*, 171*b*, *Aldersgate Street, London, E.C.*
Pill Coating Machine, Pill Counter, Tincture Press.

MAW, SON AND THOMPSON, 7, 12, *Aldersgate Street, E.C.*
Faija's Patent "Perfect" Mixer, consisting of one or more mixers or stirrers revolving round a pan in one direction, and on their own axis in another.

NUTTER, N., 71, *Cornhill, London, E.C.*
Johnson's Hydraulic Filter, especially suited for precipitates, glucose, colours, anthracene, etc.

OBERDORFFER, E., *Grimm* 12, *Hamburgh.*
New Pharmaceutical Press.
Plaster Spreading Machine.

OLIVER, J. G., 9, *Western Road, Hove, Brighton.*
Model of Exhaustive Percolator and Air Pump.

POUND AND SON, 60, *Leather Lane, Holborn, London, E.C.*
Two Antiquated Pill Machines.

SHILLCOCK, J. B., *Bromley, Kent.*
Patent Leech Vase.

SYMES AND CO., 14, *Hardman Street, Liverpool.*
Enterprise Manufacturing Co's Screw Press.
Prentiss's Pharmaceutical Still.
Gas Heater for Dispensing Counter.
Apparatus for Continous Extraction.

VIAL, E., 1, *Rue Bourdaloue, Paris.*
Machine for Stamping Names, etc., on Pills.
Pill Finisher, with Movable Ring.

WYLEYS, WALKER AND CO., *Coventry and London.*

ROOM No. 3.

AERATED MINERAL WATERS.

GODFREY AND COOKE, 30, *Conduit Street, London, W.*
Eau Restaurative, an effervescing solution of hypophosphites.

IDRIS, TREVENA AND CO., *Pine Grove, Hornsey Road, N.*
Phosphade, an effervescing, agreeably flavoured solution of hypophosphites.
Peptade, ditto of pepsine.
Tasting Samples of Phosphade, Peptade, etc.
Fluid Magnesia, B.P. strength, in syphons for dispensing purposes, remaining in solution until the bottle is emptied.

PALK AND SMITH, 8, *The Strand, Torquay.*
Sparkling Rozelle, a non-alcoholic tonic fruit beverage.

PRNETICE BROTHERS, *Stowmarket.*
Florvita, a chemical manure for flowers, with specimens of plants, illustrating its effect upon growth and flowering.

RILEY, C. R., *Elm Tree Lodge, South Lambeth.*
Ginger Ale, guaranteed to remain clear.

ROOM No. 4.

DRUGS, CHEMICALS, PHARMACEUTICAL PREPARATIONS.

BURROUGH, J., *Gale St. Distillery, Chelsea, London, S.W.*
Specially Pure Spirits of Wine.

BURROUGHS, S. M., AND CO., 8, *Snow Hill, London, E.C.*
Effervescing Citrate of Caffeine.
Extract of Nux Vomica.
Distilled Extract of Hamamelis.
Compressed Chlorate of Potash Tablets.
Compressed Chloride of Ammonium Tablets.

CHRISTY, T., AND CO., 155, *Fenchurch Street, London, E.C.*
Alkaloids:—Duboisine Sulphate; Eserine Sulphate; Pilocarpine Hydrochlorate and Nitrate; Pelletierine Tannate.
Crude Drugs:—Alstonia Bark, Dita Bark, Sassy Bark, Sweet Bark from Australia, Australian Pepper Stem, Japanese Gentian, Japanese Belladonna Root, Moutan Peony Root, Kusam Root, Coptis Root, Caroba Leaves, Papaw Leaves, Paraguay Tea, Curari, Goa Powder.
Preparations:—Alcoholic Extract of Fresh Coca Leaves, Fluid Extract of Fresh Coca Leaves, Extract of Pomegranate Root, Australian Pemmican for making Beef Tea.

EVANS, LESCHER AND WEBB, 60, *Bartholomew Close, London, E.C.*
Fossiline.

FLETCHER AND FLETCHER, *Holloway Road, London, N.*
Iodine in large crystals.
Metallic Bismuth, refined by a new process, by which all traces of copper, silver, arsenicum, tellurium, selenium, sulphur and phosphorus are eliminated.
Chemically Pure Bismuth Salts.
Scaled Preparations.
Iodide of Bismuth and Quinine.
Permanent Solutions of Iodide of Iron, Bromide of Iron, and combinations of the Hypophosphites, Lactophosphates, etc., in a concentrated form, for the preparation of chemical syrups.

HAMILTON, LONG AND CO., *Dublin. London Agents—Young and Postans*, 35, *Baker Street, W.*
Solution of Pepsine and Pancreatine.

HEARON, SQUIRE AND FRANCIS, 5, *Coleman Street, E.C.*
Curari in Gourds.
Ditto, opened to show contents.
Chian Turpentine.
Fine Cusparia Bark.

JOBST, F., *Stuttgart. London Agents—Burgoyne, Burbidges, Cyriax and Farries*, 16, *Coleman Street, E.C.*
Pure Quinine crystallized, and the following Salts, Acetate, Anetholate, Arseniate, Carbolate, Citrate, Eugenate, Hydrochlorate, Sulphates (neutral and acid), and Tannate.
Sulphate of Cinchonine.
Santonate of Sodium.
German Opium, and the following active principles, Pseudomorphin, pure Laudanine, Meconin, and Thebaine.

LORIMER AND CO., *Junction Road, Upper Holloway, N.*
Pepsine Sauce.

MACKAY, MACKAY AND CO., 1 *and* 2, *Bouverie Street, E.C.*
Ammonio-Citrate of Cerium.
Salicylate of Quinine.
Chian Turpentine.
"Sanatizer," a combination of Carbolic, Cresylic, and Cymylic Acids, for disinfecting purposes.
"Oxychlorogene," a non-poisonous disinfectant generating Oxygen and Chlorine, when brought contact with organic matter.

MORSON AND SON, *Southampton Row, London, W.C.*
Ethidene Dichloride, Isobutyl Chloride, Conia Hydrobromate, Eserine Sulphate and Salicylate.
Sublimed Chrysophanic Acid.
Sublimed Menthol.
Jaborandi Leaves.
Cotoin and Paracotoin.

PARKE, DAVIS AND CO., *Detroit. London Agents—Burgoyne, Burbidges, Cyriax and Farries*, 16, *Coleman Street, E.C.*
Resinoids:—Apocynin, Chilonin, Eupurpurin, Hamamelin, Stillingin, Xanthoxylin.
Solid Extracts:—Black Cohosh, Culvers Root, Damiana, American Mandrake, Rhus Aromatica, Yerba Santa.
Fluid Extracts:—Berberis Aquifolium. Rhamnus Purshiana, Cereus Bonplandii, Eucalyptus Globulus, Jacaranda Procera, Grindelia Robusta, Piper Methysticum.
Empty Capsules for liquids, etc.

POUND AND SON, 60, *Leather Lane, London, E.C.*
Indestructible "Cheque" Ink.

SYMES AND CO, 14, *Hardman Street, Liverpool.*
Chrysarobine and Pure Chrysophanic Acid; Microscopical Sections of Araroba, showing its deposition in the tissue of the wood.

WHIFFEN, THOS., *Lombard Road, Battersea, S.W.*
Salicylate of Quinine.
Valerianate of Quinine.

YOUNG AND POSTANS, 35, *Baker Street, London, W.*
Effervescent Salicylate of Quinine.
Glycerole of Pepsine.
Preserved Ripe Indian Bael Fruit.

ROOM No. 5.
SCIENTIFIC APPARATUS.

BAKER, C., AND CO., 244, 245, *High Holborn, London, W.C.*
The "Model" Microscope.
Simple and Binocular Dissecting Microscopes.
Botanical Lenses on Adjusting Stands.
Cameras for Drawing and Measuring.
Cases of Dissecting Instruments and Apparatus.
Collection of Botanical and Chemical Microscopic Objects.
Microtomes Specially Adapted for Cutting Vegetable Sections.
New Microscopic Lamps.

CETTI, E., AND CO., 11 and 31, *Brooke Street, Holborn, W.C.*
Drs. Russel and West's Urea Apparatus.
Dr. Blackley's Urea Apparatus.
Professor Frankland's Water Analysis Apparatus.
Sprengel Pump.
Petroleum Testing Apparatus.
Dr. Mills's Colorimeter.

COLLINS, C., 157, *Great Portland Street, London, W.*
Histological and Pharmaceutical Microscopes.
Cheap Botanical Dissecting Microscope.
Microscopical Mounting Apparatus, in case.
Microscope Lamp.
Harley Binocular Microscope, full size.
Micro-specimens, Botanical, Chemical, etc., in cabinet.

DOLLOND, J. AND C., 1, *Ludgate Hill, London, E.C.*
Clinical Thermometers, with improved flat bore, presenting a broad line of mercury to the naked eye, hence more easily seen; the index is indestructible, and the price reduced one-half.
Chemical Thermometers, reading to 150° and 180° C., and 600° F., respectively.
Chemical Thermometer, self-registering to 200° F.
Chemical Thermometer, with flat stem to prevent rolling, reading to 300° F.
Beale's Urinary Test Cabinet.
Lownes's Patent new Short Length Barometer and Thermometer Combined.
Spirometer.
Student's Microscope, complete, in cabinet.

FIELD, R., AND CO., 99, *Suffolk Street, Birmingham.*
Polarimeter, with Polariser and Analyser of Zellett's and Nicol's prism respectively, and tube of 100—200 millimetres for holding essential oils, etc., when under examination.
Achromatic Microscopes, suitable for Pharmacists' use, with A and B eye pieces, ¼ in. objective, dividing to ½ in., and ¾ in. dividing to 1½ in., plane and concave mirror, wheel of diaphragms, stand condenser, draw tube, and triangular rack bar, with accessories, in cabinet.

HILGER, A., 192, *Tottenham Court Road, London, W.*
Chemical Spectroscope, dividing sodium lines easily, with arrangement for micrometer measurements, on universal stand.
Direct Vision Chemical Spectroscope, with comparing prism.
Chemical Pocket Spectroscope, with micrometer scale.
Chemical Pocket Spectroscopes, 4½, 3½, and 1½ in. long, in case. The 3½ in. size is Professor Smythe's Rainband Spectroscope, indicating twenty-four hours beforehand the coming state of the weather.

MURRAY AND HEATH, 69, *Jermyn Street, London, S.W.*
Steinheil's "Aplanatische Loupen," or new combined achromatic triplet magnifying glasses.

ORME, J., AND CO. (*late M. Jackson and Co.*), 65, *Barbican, London, E.C.*
Bayley's Cuprimeter, for the colorimetric estimation of copper, as described before the Chemical Society, April 1, 1880.
Bayley's Washing Bottle, for use in washing precipitate with sulphuretted hydrogen water, etc.
Electric Lamps (Hickley's Patent), as now in use at the Polytechnic, etc.
Orme's Carbonic Acid Apparatus, for estimation of carbonic acid in carbonates.
Crookes's Radiometers.
Hughes's Microphones.
Electro-Moteurs.
Vacuum Tubes in action with Ruhmkorff's coil and battery.
Electric Bells, in action.
Mann's Gravimeter, a new apparatus for ascertaining the sp. gr. of cement and other solids in a very easy manner.
Graduated Volumetric Apparatus, a set of.
Bunsen's Pumps, various forms of.
Ink, for writing on glass.
Finest Bohemian Beakers, Flasks, Basins, etc.
Self-Acting Spirit Blowpipes.
Balmain's Luminous Paint.
Petroleum Test Apparatus, as supplied to Trinity House, etc., according to Act of Parliament.
Letcher's Blowpipe Cabinets (Society of Arts).
Telephones (Hickley's Patent), fitted up in different parts of the building.

SCHMIDT, F., AND HAENSCH, *Berlin.*
Improved Microscope, with rachet movement for showing every portion of a slide.
Polarimeter, low priced.

SWIFT, J., 43, *University Street, London, W.*
New Petrological Microscope, for viewing biaxial crystals of extreme wide angle, the two systems of rings being brought into the field of the microscope by Swift's special optical arrangement.

"Challenge" Microscope.
Medical and Botanical Student's Microscope.
Microscopical Slides, including salicine, quinine, and other chemicals for examination under polarized light.

TOWNSON AND MERCER, 89, *Bishopsgate Street Within, London, E.C.*
Copper Water-Oven, with condensing worm attached.
Gas Apparatus, for heating tube.
Zenetti's Chlorine Water Apparatus.
Rheocord.
Wheatstone's Bridge.
Geissler's Burette and Stand; new form of clamps for burettes.
Steel and other Forceps.
Solution for Writing on Glass.
Erdmann's Floats, coloured.
Student's Chemical Balance.
Sets of Weights Assorted.
Nickel-Plated Spatulas.
Royle's Carbon Filter.
Flat Gas-burner; ditto for tubes.
Drechsel's Wash Bottle.
Volkard's Nitrogen Tubes.

WHEELER, E., 48, *Tollington Road, Holloway, London, N.*
Microscopical Slides, illustrating the minute structure of plants as described in botanical text-books.
Two Microscopes.

WYLEYS AND CO., *Coventry*; *and*
WYLEYS, WALKER AND CO., 223, *Upper Thames Street, London, E.C.*
Pharmacist's Microscope.
Microscopical Slides.
Cabinets of Materia Medica Specimens.
Chemical Apparatus and Reagents.
Chemical Balance.
Pharmaceutical Preparations.

ROOM No. 6.

MEDICAL APPLIANCES, SHOP FITTINGS, ETC.

ALLEN, J., AND SON, 64 *and* 65, *Marylebone Lane, London, W.*
Hot Air and Vapour Bath, for application to beds, and ditto for use under a chair.
Bronchitis Kettle, with Stand and Lamp, and ditto for the fire.
Inhaler.
Infant's and Invalid's Food Warmer.
Ventilating Croup Kettle.

ARNOLD AND SONS, 35 *and* 36, *West Smithfield, London, E.C.*
Patent Clinical Thermometer, with Coloured Scale to render the reading more easy, and constriction to prevent the index from descending into the bulb.
Patent Vaporizer or Bronchitis Kettle, Inhaler and Vapour Bath Combined, in which possibility of burning or getting out of order is prevented.
Patent Hypodermic Syringe, having a small oil reservoir to keep the plunger moist and always ready for use, with coloured gradations and screwed mounts.
Patent Eye Syringe, by the use of which access of air is prevented, and a delicate jet or spray thrown with or without force, as required.
New Patent Constant Current Battery, requiring recharging only once in two years, and with high electro-motive force.
Arnold's Invalid Alarm Bell.
Patent Simplex Enemas.
Registered Portable Enema, which can be carried about full of fluid and ready for use.
Registered Universal Enema, a combination that answers for rectum, vagina, eye, ear, nose, or for cleaning wounds.
Improved Throat Spray Producer, with metallic tube, which can be bent to any angle.
Lister's Carbolic Spray Producer, with three metallic flexible tubes, adapted to diffuse or concentrate the spray as required.
Lister's Carbolic Steam Spray Producer.
Dr. Benton's Improved Universal Douche, available for the eye, ear, nose, or for cleansing wounds.
Alexander's Urinary Test Case.

AYRTON AND SAUNDERS, 149, *Duke Street, Liverpool.*
Canty's Poultice Bags.

BOURNE AND TAYLOR, 35, *Castle Street, Holborn, E.C.*
Clinical Thermometer.
Dropping Tubes.
Spray Producers. Inhalers. Eye Douche.
Absorbent Cotton Wool.
Abyssinian Soda Tap.

COWAN, W., 24, *Avenue Street, Springburn, Glasgow.*
Vaccination Shields.

ERHARDT AND CO., 9, *Bond Court, Walbrook, London, E.C.*
Vegetable Parchment for dialysis, etc.
Extremely Thin and Polished Tinfoil, 5000 sheets to an inch in thickness.

GABRIEL AND TROKE, 82, *City Road, London, E.C.*
Registered Capsuled Horse Balls.

GLASGOW APOTHECARIES' CO., 32 *and* 34, *Virginia Street, Glasgow.*
Patent Shop Bottles, with glass labels fitted into a recess in the bottle, rendering the labels indestructible by acids, spirit, etc.

HOWLETT, S., 4, *Lindley Street, Mile End, London, E.*
Improved Counter Show Case, with mirror-lined drawers, instead of the ordinary trays.

HUNT, W. T., 60, *Avenue du Prado, Marseilles.*
Machine Folded Paper Caps for capping dispensing bottles, etc.

KIDSTON, FILMER, *Duke Street, Brushfield Street, Bishopsgate Street, London, E.C.*
Prize Dispensing Counter.

LYNCH AND CO., 171*a*, 171*b*, *Aldersgate Street, London, E.C.*
New Truss.
New Spray Diffuser.
New Dispensing Bottle.
Brighton Sea Salt.

POTHS, H., AND CO., 4, *Sugarloaf Court, Leadenhall Street, E.C.*
Glass Shop Bottles with burnt-in labels.
Porcelain Grease-proof Jars with ditto.
Wood Blocks for sending bottles by post.
German Flat Boxes with overlapping rim, preventing damage from pressure.
Dry Ink in packets for producing coloured inks by immediate solution in water.

TOOGOOD, W., 37, *Mount Street, Grosvenor Square, W.*
Beaker-shaped and Pipette-shaped Standards, used for testing apothecaries' measures.
Glass Apothecaries' Measures as required by the Weights and Measures Act.

TOOMEY, M. F., 54, *Rathbone Place, London, W.*
Dental Tray, for taking impression of the gums and teeth.

The Pharmaceutical Journal.

SATURDAY, MAY 22, 1880.

THE ANNIVERSARY MEETINGS.

THE reports of the proceedings of the past week occupy so much of our available space that we have not much opportunity to refer, in detail, to what took place at the several meetings, and must therefore be content to mention, only briefly, some of the more noteworthy features of the last few days.

The opening of the Exhibition, of which a description will be found at page 931, commenced the proceedings, and we shall, on a future occasion, refer to some of the objects exhibited.

Taking, as next in order of time, the Annual Dinner, it may fairly be said to have been in every respect as succesful as on any former occasion. The number present at it was one hundred and twenty-six, including several distinguished guests, and the complimentary mention of the services rendered by the Pharmaceutical Society by those of them who responded to the toasts will certainly be read with satisfaction by all who take an interest in the Society, as showing that the work it is doing is well appreciated and esteemed by cultivators of science no less than by the medical profession.

The Annual Meeting this year was, as might be expected, a reflection of the tranquil current of events recorded in the Report of the Council. There were no burning questions to discuss and consequently the proceedings did not involve any such great demand upon the time of the members present as has been the case on former occasions. In the PRESIDENT's Address a passing reference was made to the desirability of pharmacists possessing more exclusive rights as to the dispensing of medicines than it was possible to secure in 1868, and to the circumstance that our colleagues in Ireland have been more fortunate in that respect; but notwithstanding the suggestion of regret implied by this comparison, it was pointed out that the general esteem in which the Pharmaceutical Society is held as the representative of British pharmacists is such as to give no reason for dissatisfaction on their part with the position they hold.

In the discussion that followed the reading of the Council's Report attention was directed to the growing importance of the examinations conducted by the Society and to the increased expenditure in connection with this part of the operations. The propriety of endeavouring to maintain the efficiency of these examinations by liberal remuneration of the examiners was urged by Mr. UMNEY, who, as having had experience of what was required for the proper performance of their duties, could speak with authority as well as impartiality on this subject. Much of the time occupied by the meeting was, however, taken up with a discussion of the mode in which the votes for Members of Council are given and the conduct of the scrutiny of voting papers.

The Conversazione at the South Kensington Museum, on Wednesday evening, presented the usual attractions and was well attended.

Last, but not least in importance, the election of Members of Council for the ensuing year, as announced by the report of the Scrutineers on Friday morning, showed that there is less reason than formerly was the case to regret the prevalence of a want of interest in this duty, and the result is calculated to show that, at least among those who voted, there is a sound appreciation of the qualifications desirable in a representative of the general body. We do not suppose that any of those who took part in this election are unmindful of the benefits to be derived from sound instruction in those sciences which it is necessary for every member of the trade to be conversant with, or that they are any the less sensible of the services rendered by those who devote themselves to the business of imparting such knowledge. It has, however, been shown that the great majority of the electors recognize the incompatibility of the positions occupied by the professed teacher and the representative member of the executive body. In an almost equally marked manner it has been shown that, though the prosecution of a lucrative business extraneous to pure pharmacy is a thing any man may engage in if he desires, it does not constitute a qualification to occupy the position of a member of the Council.

PROSECUTIONS UNDER THE WEIGHTS AND MEASURES ACT.

ON various occasions remarks have been made conveying a disparaging suggestion that in calling the attention of our readers to the provisions of the Weights and Measures Act superfluous zeal has been manifested, and too much importance given to the matter; but some cases have during this week come before the Southwark Police Court which are calculated to lead to different conclusions. Five chemists and druggists, carrying on business in the south of London, have been summoned for having in their possession apothecaries' weights that were not correct and in conformity with the legal standards. The presiding magistrate, taking into account that the Act had only recently come into operation, and that these were the first cases of prosecution, imposed only a nominal fine of one shilling for each incorrect weight.

It appears, therefore, that the mention we have on various occasions made of the necessity for seeing that the weights and measures used by chemists and druggists were made to conform with the existing law has, contrary to the criticism above referred to, been insufficient. One of the defendants, in fact, pleaded that he did not know the Act was in operation, and that he had been unable to get any information on the subject; while another stated that some of the weights complained of were quite new, and had been supplied by a first-class firm. We think it desirable to mention these facts for the purpose of emphasizing the recommendations we have frequently offered as to the expediency of having apothecaries' weights and the measures used by chemists and druggists made to conform, as far as possible, with the requirements of the Act.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, May 19, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Richardson, Robbins, Savage, Symes and Williams.

The PRESIDENT read a letter he had received from Mr. Rimmington, saying he regretted he should not be able to attend the Annual Meeting, and expressing his sense of the courtesy and kindness he had always received from his colleagues at the Council board of whom he had to take leave, pressure of other business compelling him to withdraw.

Mr. ATKINS said they must all regret the retirement of Mr. Rimmington, and he thought it would be only right to send Mr. Rimmington some acknowledgment of his letter.

The PRESIDENT said the Secretary would no doubt see that this was done.

RESTORATIONS TO MEMBERSHIP.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

THE LATE MR. CRACKNELL.

The PRESIDENT moved the following resolution:—

"That the Council, having heard of the death of Mr. Cracknell, desire to express to the family of the deceased gentleman their most sincere sympathy at the loss which they have sustained, and at the same time to convey the assurance of the high esteem in which the late Mr. Cracknell was held by the Council for the valuable services which he rendered to pharmacy."

The PRESIDENT said that Mr. Cracknell had been so long connected with the Society, having been one of the earliest examiners, that everyone must have held him in the highest esteem.

The VICE-PRESIDENT seconded the motion, which was at once carried unanimously.

THE SALE OF POISONS.

The PRESIDENT read a letter received from the Privy Council, enclosing one from a medical practitioner calling attention to a case in which a dipsomaniac patient of his had been supplied with narcotic drugs more freely than he considered right, and stating that he had applied in vain to the Pharmaceutical Society.

The PRESIDENT submitted a draft reply, which he had drawn up for the approval of the Council, which, after some conversation, was agreed to.

The order of business at the Annual Meeting having been settled, the Council adjourned.

THIRTY-NINTH ANNUAL GENERAL MEETING.

The Thirty-ninth Annual General Meeting of Members and Associates in Business was held on Wednesday, May 19, at 12 o'clock, Mr. G. W. Sandford, President, in the chair.

The SECRETARY having read the notice convening the meeting,

The PRESIDENT addressed the meeting as follows:—

THE PRESIDENT'S ADDRESS.

It has been, as you know, frequently my privilege to welcome the Members of our Society in this room in days gone by. When last I had that pleasure I certainly thought I should not again be inflicted on you in this position. That I should still be among you and with you was, I need scarcely say, in those days, as indeed it is now, my earnest wish. But certain work in which I had laboured being accomplished, I naturally desired to retire from the more active duties, leaving them in other and more able hands.

It was not, however, the will of the Council elected last year to leave me in my retirement. They chose once more to place me in the proud position of President, therefore, once more I must ask your indulgence, and I may add help, in the proceedings of this the 39th Annual Meeting of the Pharmaceutical Society. That "39th" carries one back a long way, but to those who, like me, have been connected with the Society during all that time it seems but short. I look back and think of chemists as they were prior to 1840, and as they might now have been but for the efforts made by Jacob Bell and a few others to assert for them a better position in the body politic, and not only that, but to fit them to occupy it.

We need not be dissatisfied with our position. This Society stands as an acknowledged institution in Great Britain, and has been taken as a model for the guidance of our friends in other countries, in America and Australia, to say nothing of our more immediate neighbours and brethren in Ireland, who, profiting by our example, have even improved on our legislation, and obtained more exclusive rights as to the dispensing of medicines than we were able to secure in 1868. Whether we shall ever be able to extend our privileges in that direction I dare not venture to predict; that we might have so extended them fifteen years ago, had the whole trade been united, I verily believe. There are now, it is true, certain questions agitating the public mind, at least in so far as it is expressed in the public press, which seem to point in that direction. We see that the exemption given in our Act of 1868 to the makers and vendors of proprietary medicines is being called in question, and the tide of public opinion seems to set towards restriction in that matter. From time to time there come to your Council appeals from public associations calling for more stringent regulations, some of them so stringent as to render them altogether impossible; some also originally sent to high officers of State, and by them referred here for information. I do not mention these things to mislead you with vain hopes; but rather to show in what estimation our Society is held, and consequently how necessary it is for us all as individual members to maintain the position we have attained.

We all know how much has been written of late on the indiscriminate sale of intoxicating drugs. There is no doubt much unmerited blame has been thrown on us in that matter; we have been blamed for permitting sales which in many cases we had no power to prevent; but still our responsibility in such cases must not be lightly regarded.

I think chemists, who alone are permitted to sell certain drugs, can never be unmindful of the reason which induced the Legislature to restrict the sale, and should therefore second heartily the effort made by the Pharmacy Act to prevent the improper use, or rather the abuse, of such dangerous articles.

But when we are asked, as we have been of late, to place in the proscribed list a number of articles, the use of which may be objectionable, but is not really dangerous, I think we are bound to consider well whether we should not by doing so to a great extent destroy the value of the schedule, besides unnecessarily hampering both ourselves and our customers.

I may be permitted to mention, as the Annual Report of the Council has not done so, that in the middle of last year, one or two prosecutions were instituted against chemists for selling what was termed "adulterated cream of tartar." It is a difficult matter at all times for this Society to stand forth in defence of anything tending in the smallest degree to lower the quality of drugs. But all the interests of druggists are under its guardianship; their best interest lies in maintaining an unsullied reputation, and when that reputation is endangered by an unjust accusation I think we should not hesitate to disprove it. At the instigation of the Council, in 1875, due allowance was made in the "Sale of Food and Drugs Act" for the unavoidable admixture of extraneous matter with any food or drug consequent on the process of collection or preparation. Every analyst knows that such an admixture is constant in cream of tartar and will, if he choose to be officious, or as he would term it, diligent, yield him a triumph before a bench of magistrates.

It was in two such cases that the Council, being first satisfied that the cream of tartar was really up to a good standard, authorized its Solicitor to appear and assist in rebutting the charge of adulteration. In both cases the summonses were dismissed, and in one the magistrates granted costs to the defendant.

The result shows the value of watching "Bills" in their progress through Parliament, and the necessity of maintaining for this Society such a character as will enable it to assert itself before the Legislature when occasion may require.

It has lately been my privilege to visit Edinburgh. I cannot forbear mentioning here, in our annual gathering, as I have already done in Council, how heartily our North British friends received me and my colleagues in that deputation, as the representatives of the parent stock of the Pharmaceutical Society.

I desire not to detain you longer, but I cannot sit down without expressing the great delight I felt in our meeting at Willis's Rooms last evening. I could not help feeling that it would have been utterly impossible before the establishment of this Society to have brought chemists together in so hearty a gathering.

At the conclusion of the Address, upon the President asking the Secretary to read the Annual Report,

Mr. Gostling (Diss) said as the report had been for some time in the hands of the members, he would move that it be taken as read.

Mr. Robbins (London) seconded the motion, and it was unanimously agreed to.

The following is the text of the Report:—

The Annual Report.

Shortly after the last Annual Meeting, the Council deemed it advisable to settle the vexed question of the admission of women to the Pharmaceutical Society. On the two occasions when this question was submitted to the General Meeting, the expression of opinion was so evenly balanced that it appeared likely to continue a source of contention. The election of Members undoubtedly rests with the Council, but in former years the opinion of the Council, like that of the Society, was so evenly divided that an appeal to the general body was deemed desirable. This change does not threaten any important result in the constitution of the Society; up to this time only four ladies have been admitted.

It is gratifying to observe in the Financial Report presented herewith that the increase in the revenue of the Society has continued. The increased revenue has been largely due to the greater number of candidates both for the Preliminary and Major examinations. An unusually large balance (£3405 15*s.* 5*d.*) was brought forward at the end of 1878, the Council were thus enabled in 1879 to purchase £3500 New 3 per Cent. Stock. In the last Report a regret was expressed that so many candidates for examination were satisfied to remain in the second grade of the Society. During the year 1879, *one hundred and thirty-four* candidates presented themselves for the Major examination, whereas in the previous year there were but *eighty-one.* In the Preliminary examination there was an increase of *three hundred and forty-four* candidates, of whom the great majority were not more than eighteen years of age. The Council infer from this that the importance of passing the Preliminary examination prior to connection with the trade, *the desirability of which has been so constantly urged*, is now more generally recognized.

With a view of ensuring the identity of the examinations in London and Edinburgh, the importance of which cannot be too strongly urged, the President and Vice-President, with three members of the Board of Examiners for England and Wales, were deputed to be present at the examinations held last month at the North British Branch, and will in due course report the impression made on them. Their report not having yet been formally presented, it is beyond the power of your Council to enter more fully on the subject in this summary of the proceedings of the past year. There is, however, no doubt that the two examinations are conducted with equal care.

The Library, now containing about seven thousand volumes, has constantly engaged the attention of the Council. From month to month, on the presentation of the Librarian's report, books which have been recommended by Members and others entitled to use the Library have, on the approval of the Committee, been purchased. A selection is also made from books submitted by publishers, and many others have been presented. A new Catalogue of the Library, including also that of the North British Branch, is in the press, and will be sent to all "Members" and "Associates in Business" of the Society. "Associates" and "Apprentices" of the Society will be supplied with copies on application.

An Index of the ten volumes of the *Pharmaceutical Journal*, from July, 1868, to June, 1878, has been compiled and printed; each "Member" and "Associate" of the Society is entitled to receive a copy thereof, free of charge, on application to the Secretary.

It will be remembered that the late Daniel Hanbury bequeathed a legacy to enrich the Library of the Pharmaceutical Society. The Council decided that this bequest should be applied to the purchase of *standard works of reference*, not to be circulated, but to remain permanently in the Library. The amount of the legacy has now been expended, and the following is the list of books purchased:—

Pfeiffer, Nomenclator Botanicus.
Pfeiffer, Synonymia Botanica.
Loureiro, Flora Cochinchinensis.

The formal acceptance by the Council of the Hanbury Memorial Fund Trust has been completed; the amount invested is £400 Consols, and a die has been prepared for a medal which is to be offered for competition every two years "for high excellence in "the prosecution or promotion of original research "in the natural history and chemistry of drugs."

During the year many valuable additions have been made to the Museum. When it was determined by Government to break up the India Museum, this Council, feeling that many specimens of Materia Medica and matters allied thereto contained in that collection would be not only extremely valuable, but specially accessible to persons interested in them if placed in the Museum of this Society, so represented the matter to the Secretary of State for India, hoping that he would, if possible, secure the transfer of such articles to Bloomsbury Square. Ultimately it was decided that the whole vegetable collection should be sent to Kew to be under the sole control of the Director of the Museum there, and the applications which had been made to the India Office were transferred to the same authority for consideration. Through the kindness of Sir Joseph Hooker, the Director of the Royal Gardens, Kew, this Society has already received many interesting specimens, and there is reason to believe that more will follow.

The Evening Meetings, both in London and Edinburgh, in the papers read and the discussions which followed, have afforded opportunities for the consideration of various interesting matters. The Meeting held in London in December was specially devoted to discussion on the new regulations regarding apothecaries' weights and measures set forth in the Weights and Measures Act, 1878.

When the new Act was passed, the use of apothecaries' weights and measures in the sale of drugs was legalized, but no definition or schedule of them was appended to the Act. Under these circumstances, in January, 1879, the Board of Trade applied to this Society for general information as to apothecaries' weights and measures. A full description of them was thereupon forwarded to the Board of Trade by the President, and an "Order in Council" founded thereon has since been issued. Considerable delay has arisen in preparing the standards. They are, however, now ready and in the hands of many local inspectors. Every consideration has been shown by the authorities to chemists and druggists in this matter, and there is certainly no disposition to bring the provisions of the Act into operation hurriedly or harshly. Nevertheless it is of course desirable that chemists should put themselves in conformity with the law, and the difficulty of so doing has ceased, the makers of apothecaries' weights and graduated measures being now able to supply both with the Government mark of verification.

A large number of complaints of alleged infringements of the Pharmacy Act, 1868, were received by the Registrar in 1879. In all cases inquiries were made and communication with the offenders opened. The result generally was a discontinuance of the offence, but in twenty-one cases it was found necessary to have recourse to legal proceedings to enforce obedience to the law.

The question of the legality of the sale and dispensing of poisons by public companies (called in legal language "corporations") involved in the prosecution of the "London and Provincial Supply Association," which was in abeyance at the time of the last Annual Meeting, is still unsettled. The Bloomsbury County Court having decided that such a practice was legal, so long as a qualified man was employed to superintend the business, the Pharmaceutical Society appealed against that judgment to the Court of Queen's Bench, where the decision of the lower Court was reversed by no less authority than the Lord Chief Justice of England and Mr. Justice Mellor. On the appeal of the defendant, however, the case was carried to a higher Court, in which, as all must have observed from the reports in the Journal, a decision has been given adverse to this Society. The case is so important that the Council have felt it their duty to continue proceedings, and have instituted a final appeal to the House of Lords. The Council have been fortified in their resolution to take this course, not only by certain forcible remarks embodied in the report of the judgment of the Lord Chief Justice, who decided in favour of this Society, but also by doubts expressed in the separate judgments delivered by the Lords Justices Bramwell, Baggallay, and Thesiger in giving an adverse decision.

In 1879 the subscriptions and donations to the Benevolent Fund fell short of those received in the previous year by about £40. The Council are inclined to attribute this to the general depression of the year rather than to a decrease of interest in the prosperity of a Fund which is doing so much to relieve the necessities of unfortunate members of the trade. Year by year the permanent engagements of the Fund increase by the addition to the number of annuitants. In determining the number to be elected on the last occasion, it was painful to the Council to be obliged, from want of funds, to restrict it to three, there being several other approved candidates on the list. The amount granted in casual relief in 1879 was £698 10s. It may be added that in the present year the amount required for annuities is £1015, and presuming that the occasional grants will not be less than formerly, the expenditure will be upwards of £1700.

Mr. J. B. Mackey (London): I have much pleasure in moving

> "That the Report of the Council as now read be received, adopted and printed in the Society's Journal and Transactions."

It is not necessary for me to make any comments on this report, as everything is progressing so favourably. Many years have elapsed since I joined the Society, and having fulfilled the duties of Auditor for some years, I can bear testimony to the accuracy of financial matters, and the steady satisfactory progress of the Society.

Mr. Stacey (London): I beg to second the motion. It is hardly necessary to detain you long when things seem to flourish, as they evidently have done, to a great extent, under the guidance of the Council. I would refrain also from going into matters of a controversial character, because I take it that we ought to rely upon our Council, and when we look round upon the men that constitute the Council we must feel sure that they give their full attention to all the subjects interesting and affecting this Society. There are two subjects of the greatest importance which I am glad to see that the Council have dealt with, and dealt with with a firm hand; the first one being that alluded to at the commencement of the report; and although many might have a different view and may not feel well pleased personally at the action the Council have thought proper to take in that matter, still I believe as a body we ought to rest content and accept it as their best judgment. There is one remark in the report which does not convey to my mind any meaning—"This change does not threaten any important result in the constitution of the Society." I do not understand the meaning of those words exactly, but they perhaps are intended as a little *placebo* and we must receive them as such. If the Council do not anticipate any important result in the constitution of the Society arising from this change I would, as it were, throw out a word of warning, that a very important principle has been shifted and upset, and in years to come they may refer back and find that perhaps one principle would have worked better than another. I think it is a subject of great congratulation that the Society goes on progressing in the amount of funds that it receives and also that the funds of the Society are very carefully expended, and that our Council evidently has first in view the improvement of the education of all its members, and endeavours to interest them by improving the library as it has done to so great an extent, by improving the museum and in all other ways furthering the cause of education in connection with the Society. I think no one can read the report without feeling satisfied that it is the first duty of the Council to further the interests of this Society in that as well as in other directions. I am very glad indeed to see that they are ready at all times to take action to maintain the Pharmacy Act of 1868; that is most important. In connection with that, I am also glad to see that they are ready to take action in this matter of the dispute which is referred to in the last clause but one of the report, and I am willing to suppose that they have given that matter the most careful consideration, for it appears to me one of the most important matters that has ever come forward affecting the interests of the Society. I should call it almost a crisis in this Society. We must not be carried away by impulse in considering this matter. It is, I see, decided that the matter should go to the House of Lords, there to be decided. That is the first and natural impulse, to take it to the House of Lords; but there is a much larger consideration connected with that matter, though I hope, and I am willing to accept the decision of the Council that this is the wiser course, particularly seeing the knowledge that our President has upon all such matters. But when we remember the difference of opinion of the judges, and find that three of the first judges in the land in the Court of Appeal stated that the Act was a muddle—for those were almost their terms; they said certainly it was very imperfect—it becomes evident that there is one thing that this Society has to aim at, namely, the amendment of the Act of Parliament, so that, as our President has most clearly stated, we should maintain our position and that there should be no dispute as to the readings of that Act of Parliament which protects us and protects the public. I hope that it is the wiser course. But there is one consideration which I think is worth a good deal of thought: the more we stir in this matter in bringing it before the public the more difficulty shall we have in a certain sense. That is to say, as long as we are dealing with lawyers, with Parliament, and Acts of Parliament, we shall be all right. But the public at large have very little appreciation and never think whether they are going to be poisoned or not; they would not give it a thought hardly, or thank you for protecting them from being poisoned. I do not want to see this brought forward as a public matter throughout the country; if it is, I am quite convinced that it will become much more difficult for our Council to deal with, for although things are much tending to this, that some day we shall have to meet public opinion, yet public opinion outside understands nothing whatever of our business or trade, or of the use or danger of drugs and poisons. I have no doubt that we shall find that the Council in the coming year will use the greatest discretion, but I thought I might give expression to these few sentences, that we might not as a body be carried away with impulse and have the idea, if the House of Lords gives a judgment in our favour, that everything is done. I believe everything will not be done. We may close the co-operative stores or we may not, but I have yet to learn that even the decision of the House of Lords will make the Act of Parliament strong enough to enable us to close the co-operative stores. I think these are matters which we should all consider and be ready to meet when they do occur. Then with regard to the last clause I will just say a word. I hope that the reading of that clause will be sufficient to stimulate the members of the Society to supply the want that is shown to exist in the funds of the Benevolent Fund. I think little need be said on that point, because I think we, as a trade, are of a generous disposition and have good hearts, and that a perusal of the clause will be sufficient to bring forward the necessary funds. I have great pleasure in seconding the motion.

Mr. Urwick said he could not quite endorse all that had been said, although he might congratulate the Council upon some parts of the report. He congratulated the associates who had come forward for the Major examination; to him that appeared to be one of the most gratifying things in the report, and he hoped young men would press forward and not be content simply with the lower qualification of the trade or profession. He was sorry to see that the expenses were rather on the increase and that sufficient was not laid by, believing that there should be a greater margin between the income and expenses. It was true they were accumulating, but he noticed that the whole of the sum carried forward from last year had not been funded, only £3388 out of £3405 having been invested, the remainder being unaccounted for. He found that there was not so much at the end of the working this year as there was last, but this might be accounted for by the examiners having a larger allowance. He was told last year not to judge of it in a commercial way, but it appeared to him the examiners in past days had not had justice done to them, or else the present examiners had more than justice done to them. It seemed to him they were landed in that position, because the increase was so much greater. Last year attention was called to the large item of "postage, £443," and he was glad to see this had been reduced to £206. The report stated that a large number of complaints of alleged infringements of the Pharmacy Act were received by the Registrar, and he took it that the stereotyped letter was forwarded in each case by the Secretary, informing the persons they were doing wrong. That might be wise in a general way, but he did not think it was always to the interest of the Society that the Council should adopt that course; when good evidence was brought before them it would be to the advantage of the Society if a different course were taken, He had in his possession evidence of a case which had occurred quite recently, which he would bring before the attention of the Council. The Legislature and the public had called for education amongst chemists; they had insisted upon their being qualified, and he thought taking a stand upon that point, the Council should do a little more for the members when their interests were encroached upon. Catalogues had been sent to the Society calling attention to the fact that grocers were prepared to dispense medicine and to sell all kinds of drugs. This was the time, as he took it, for the Council to inform them they were doing wrong and that if they persisted in it they would be prosecuted; but the Council had been rather slow to act in the matter. The chemists in the neighbourhood of one of these grocers had taken upon themselves to test what was dispensed, and for this purpose drew up a prescription containing poison, which was duly made up and delivered at the expiration of twenty-four hours. Mr. Urwick having given the particulars of the case, as well as the name and address of the grocer and chemist concerned, said he hoped the case would be taken up by the Council. The report did not refer to one subject which he should like to have seen introduced, and pursued, viz., that of getting pharmaceutical chemists more embodied with medical men in the preparation of a new Pharmacopœia, because he thought if this were done it would result in a better work being produced.

Mr. Howard Hall, referring to the case just mentioned by Mr. Urwick, said it might turn out that the grocer was simply agent for the chemist. With regard to the first paragraph of the report, relating to the admission of women, he thought the mistake, if there was any mistake, in admitting women to the privileges of the Society, had been in allowing them to come as students, or to attend the Professors' classes. The Society, having been ready to take their money for instruction, ought not to debar them from the privileges of membership, and if women were willing to undergo the test of examination they ought to be allowed to become members. He was glad Mr. Stacey had alluded to the ungracious remark "This change does not threaten any important result in the constitution of the Society." If it did not why was anything said about it? It seemed to him very much like a wasp, the sting of the paragraph was in its tail, "up to this time only four ladies have been admitted." He should like to ask the members whether they had considered the case of a chemist being left with a family of daughters. He might have a good business, but yet by a sort of *esprit de corps* they might be debarred from the privilege of membership. It was absurd. Mr. Urwick had referred to the fees paid to the examiners, and having compared the accounts of 1879 with those of 1878, he found that the excess in fees to examiners last year amounted to £580 18*s*., though the Council might no doubt be able to explain that. One item of expenditure had not been included in the accounts, viz., the expenses of the deputation to Scotland, but he supposed this would appear in the next account. The report was not altogether *couleur de rose*, because the actual increase of income in 1879 over 1878 was only £870, and the increase of expenditure in the item of Examiners alone was £580. The increase of members was not so great as the report led one to imagine; for as he worked the figures out there were actually 18 less members as pharmaceutical chemists, 13 less chemists and druggists, 67 more associates in business, 20 more associates not in business, 31 more apprentices, and 7 less entrance fees than in 1878. When the accounts came to be analysed they did not look so favourable as at first sight, because an enormous balance had been brought forward from the previous year. He was glad to see that the item of postage, to which Mr. Urwick had referred, had been reduced from £443 to £206, and that there had also been a reduction in the expenses of the Library, House and Secretary's Department. As a great deal of correspondence had taken place lately in the Journal with regard to the members of Council, he might mention that, being one of the scrutineers appointed to examine the votes on the last occasion, he found that most of the Liverpool members had plumped for one candidate, and, as he pointed out in a letter to the Editor, the business of the Society could not be performed by country members only, there ought to be more London men on the Council. At the present moment there were only a few London men on the Council, though there were plenty of gentlemen in London quite able to conduct the business of the Society, and he hoped therefore that the general body of members would recollect that the great part of the Society's business must be done by London members.

Mr. Mackenzie (Edinburgh) hoped that the financial statement would be drawn up in a manner more uniform with the views of the members rather than that the members should run in conformity with the rules adopted. In the receipts and expenditure, allusion was made last year to several points, such as the Journal, and in the present report he noticed that nothing was put to the good of the Journal, although there was a considerable sum expended upon it. Surely there must be some income derived from the Journal, and if so, it ought to be shown. Allusion was also made to the North British Branch, and he should like to have the percentages of candidates examined at that Branch as compared with the London Branch. The examiners' fees were all under one head, but if they had the amount paid for examiners' fees in Scotland, and those in England, and the number of candidates passing in England as contrasted with Scotland, they would have some idea how things were done, and would see whether one compared favourably or unfavourably with the other. There was one thing which pained him very much, and therefore he would refer to it, and it was not in this case the amount of expenditure, but the smallness of expenditure in the shape of grants towards provincial education. Last year nothing was done in that direction, but this year the Council had made a small effort and had expended £35. In his opinion the provinces demanded more than that. He could look back to the time when the Society was beating up the country for members, and one of the things put forward to induce persons to become members was that something would be done for the education of young men in the trade. So far as his memory carried him there was no such clause as that those in office would make it their constant care to increase their store and keep the money all at home. They had a great deal of money locked up in the Three per Cents., which, if laid out upon education, might yield 100 instead of 3 per cent. If spared another year he should insist upon full particulars being given of the item under the head of "Clerks and Servants, £770." That was a large item to spend, and the members ought to be told something more about it, there having been an increase of something like £50. Other items had also increased, and he hoped that next year there would be no necessity for putting any questions upon the subject. As to the report, there were several matters for which the Council deserved credit, though he did not think that the increase of revenue was a thing to be boasted of. He noticed some reference to a deputation having visited Scotland, but unfortunately he overlooked the date of their coming, or otherwise he would have attended. Last year the report stated they were also in Scotland, and great things were expected from the visit; but he supposed that such an expenditure would not be required in future, as the report stated that both examinations were conducted with equal care. At page 5 of the report he noticed that a large number of complaints of alleged infringements of the Pharmacy Act had been received by the Registrar during the past year. He was one of those who believed that the Society had not yet thoroughly realized its position through its officials; they had not become, as they ought to, a terror to evil doers. For thirty-nine years the Society had been gaining prestige which other persons sought to get the benefit of, and when infringements occurred the usual letter was sent out by the Secretary; but he thought the time had now come when that printed letter should be put in the waste paper basket. As they paid about £200 or £300 a year for law expenses, they ought to get a little more for it, and he believed that if a letter were written by the Solicitor it would carry more weight than one from the Secretary. In the next report he hoped to see a clause to this effect, that the Council had proceeded vigilantly against every case of infringement and investigated them to the utmost. Certain persons had advocated a wider system of reporting the proceedings of the Council, which had been done, and he congratulated the Council upon it, but he was surprised to see no mention of it in the report. He hoped next year to see a statement in the report that the Council had thought fit to give candidates, who came up for examination and passed two-thirds of the requisite subjects successfully, information upon the remaining third. This was done by the College of Surgeons and Physicians, and he hoped it would be done by the Pharmaceutical Society. With regard to the first part of the report, which dealt with the question of the admission of women to the Society, the subject having been brought up at the annual meeting on two successive occasions, and lost, it was certainly a bold thing for certain members of the Council to again take up the question. He did not wish to go into the merits of the case, but he thought a majority ought to be respected, when it had been legitimately obtained, and he certainly never dreamt that the matter would be again taken up after the decision of the meeting. He thought the Council should either have abided by that decision or obtain a *plebiscite* from the whole of the members. He could not help expressing his surprise at the action of some from whom he expected better things, and who, after advocating things remaining as they were, had suddenly turned right-about-face, without showing any necessity for so doing. He admired the consistency of the President in adhering to his views; but he did not like the expression in the report about the election of members resting with the Council. It was also as well to remember that the election of the Council rested with the members.

Mr. Umney (London) desired to say one or two words on the subject of the examiners' fees. Having had the honour of a seat on the Board of Examiners for five years, though he had not now that privilege, he felt he had some right to speak on the matter. He imagined that the Council had simply acted in common justice. As far as he knew the history of the Society, for about fifteen or twenty years the Board of Examiners consisted of gentlemen (Hanbury, Deane, Cracknell, etc.) who came forward voluntarily to conduct the examinations when the Society at that time was not in a position to pay for their services. Then there was another stage, which lasted probably about ten years, when the Society remunerated the examiners to the extent of about two guineas a day. They had now come to the third stage, with a Society in a flourishing condition, and he felt they had not meted out more than justice, and indeed he questioned whether the fees were as high as they should be. The examiners did not simply come down at eleven o'clock, go through the routine and leave at four, but they had to give a deal of attention and thought to the subjects they had to examine upon, for if not the examinations would soon become a mere farce. There were at least half a dozen establishments in London which in three months would perfectly gauge each and every one of the examiners and know every question they would ask, unless they really took a great deal of pains with the matter. Speaking for himself, he could say that when he was an examiner he had frequently to give very special thought to certain subjects and to avoid asking over and over again the same questions. Examiners were not infallible and were liable to slip into grooves. He hoped, rather than see the fees decrease, that if the funds of the Society allowed they might be further increased.

Mr. Andrews (London) asked if members present were entitled to place in the ballot box the voting papers of country members.

The President said that according to the rules they could only receive the voting papers of those present.

Mr. Andrews did not think that was clearly expressed on the paper.

Mr. Postans (London) said a gentleman came to him the other day, who had signed his name outside the envelope, and, leaving it open, told him he could mark it as he pleased and deliver it. Of course he told him that such a proceeding would be entirely irregular; but that only showed what vague notions some people had about the matter. While on his legs he wished he could say a word to induce a large number of gentlemen to join the Society, for it was much to be regretted that a larger percentage who passed the examinations did not become members. It was very important that they should be a large and united body, for they had much to accomplish, and whether they could accomplish the ends they desired would depend very much on the way in which they went about it. One or two things in connection with the Birmingham Association, though no doubt done with the best possible motives, he thought might be left to the Pharmaceutical Society, and he referred more particularly to the preparation of the Pharmacopœia, on which he noticed a discussion had taken place in that body.

Mr. Hampson (London) said that the Council felt that the Board of Examiners were underpaid, and it was necessary in the interests of the Society that they should get the best men obtainable. In reply to Mr. Mackenzie's observations with regard to the admission of women to the membership of the Society, he might say that the matter was not brought forward by any member of the Council, but those ladies applied, as they had a right to apply, for admission in the ordinary course; in fact the good sense of the Council was manifested on that occasion.

Mr. Whittle (London) wished to say a word or two on this question. He had always felt that it was a serious one, and the Council appeared to have thought so too, as they had taken the opinion of the meeting on two occasions, on each of which it was decidedly against the ladies. There was no specific reason for saying it was expedient to go out of their way to elect those ladies, and he considered it a most revolutionary proceeding. They could not stop there, but they would have to admit them to the Council, and if so, why not to the Board of Examiners? He maintained that from its foundation, the Pharmaceutical Society was intended to be a society of men, and that it ought to remain so. He agreed with a previous speaker that to work the Society efficiently there should be a larger number of members of Council resident in London, because matters might crop up which required immediate attention, and it was also a considerable burden on the funds to have a large number of gentlemen who had to travel long distances. Some short time ago they were told they wanted new blood, and last year they had some new blood, and he was quite satisfied with what they had at present, and hoped that the retiring members this year would be re-elected. It was also a pity they did not know more of the persons who were put forward. He did not know anything at all about half of the names which were published, and they might be good men, or they might be bad. There ought to be some guarantee that they transacted their own business well before they were put on the Council to transact the business of the Society. He begged to thank the President for his consistency, for ever since he had known him the President has always stuck to what he thought, and did not mind what other people said.

Mr. Barclay (Birmingham) said as Mr. Postans had alluded to the association to which he had the honour to belong, it was only fair that he should put him right publicly, as he had done privately, and to state that that association never contemplated taking any direct part in any way with regard to the Pharmacopœia; it was a purely trade organization, but it was quite within its limits to urge on the Pharmaceutical Society that it should take part in the compilation of a new Pharmacopœia. He was glad to find by the report that the Pharmaceutical Society had been moving in the direction of protecting trade interests, and in the steps they had taken during the past year they deserved the hearty support of the whole trade. The Society, he thought, had done the right thing in going to the House of Lords, and he had no doubt if unsuccessful there it would be on the whole the best thing that could happen, because it would bring about the amendment of the Pharmacy Act. He was not afraid of public opinion, which he believed would support pharmacists and those who were at the head of affairs in protecting the public against unregistered men. He was glad the meeting had so heartily supported the report, notwithstanding the criticisms passed upon it, which were very wholesome, and he only wished that in another quarter there was more of the same sort of thing. There was nothing like a little discussion to let daylight into affairs, and when conducted good naturedly, as it always was there, it might be the means of conveying information to the Council which might guide them in coming years.

Mr. Romans (Wrotham) said he had not received a voting paper, and on application to the office could not get one.

The Secretary said the whole of the voting papers were carefully checked over by two persons as usual. He could not say why Mr. Romans had not received his.

The President said the rule was that a second voting paper could not be issued.

Mr. Mackenzie said if that were the case they ought to be registered.

Mr. Whittle said that the proof of postage was always considered sufficient.

Mr. Brown (Greenwich) asked if it had come to the knowledge of the Council that some of the judges who gave the decision in the late co-operative case were members or shareholders of the co-operative stores.

The President said he thought it would not be wise, and it was certainly no part of the business of the Society, to impeach the position of English judges.

Mr. Smith also thought it would be very unwise to do anything of the kind.

The President, in reply to the observations which had been made, said Mr. Umney had very well explained why the fees to the examiners had been increased. Reduction in postage had been occasioned to a certain extent by an alteration in the registration, which led to a diminution in the cost of certain formal letters which were sent by the Secretary. He then gave particulars of the case alluded to by Mr. Urwick, stating that action had been taken by the Council in the matter, and he read a letter that had been received from the grocer, in which that person said that he had no desire to break the law, but acted simply as an agent for a chemist and druggist, which he had been informed he could do. Mr. Mackenzie asked why they did not give the income of the Journal, but the fact was that they showed the balance after having given away, as they did, about 6000 copies weekly; after doing that, and providing for the postage of those copies, the whole expense did not exceed £700. With regard to the proportion of candidates in England and Scotland, the President read the statistics on the subject given in the Registrar's report, and commented on in this Journal (before pp. 623 and 628). With regard to the law expenses, he should say that the Society had really more work going on than many members imagined; the Council always considered questions of that kind privately, and did not publish all the prosecutions which were instituted, though in many cases they did so, and the report referred to this matter. He could also inform Mr. Mackenzie that it was often his unpleasant duty, being President of the Board of Examiners, when a young man failed in a particular subject, say chemistry or botany, to inform him of the fact. He was not told at the end of the examination what points he had been good in, and what not; but if he failed signally in one particular thing it was announced to him. As to the delivering of voting papers, an envelope had been enclosed to each member, on which was stated that it must be returned to the Secretary on or before May 17, or be delivered personally at the time of election, so that he thought there could be no question in the mind of any reasonable man.

The motion was then put and carried unanimously.

Mr. Mackenzie said he was pleased to hear what the President said about the examinations, but he thought it would be well if the Council instructed the Secretary to be a little more courteous in the replies he gave to country members seeking information. He had received one letter from him which seemed a sort of formal thing, and gave him no information one way or the other, and if he had only stated half what the President had done it would have given him more satisfaction.

The Secretary said it had always been his endeavour to carry out the business of the Society in as courteous a manner as possible, and it was very gratifying to him to know that although he had held the office for nearly twenty-five years this was the first time that it had been alleged that he had failed in this respect.

The President said the next business was to appoint scrutineers. Twenty gentlemen had signified their willingness to undertake the duty, and he would move that they be appointed accordingly.

The names having been read, the motion was agreed to unanimously.

Mr. Bottle said it had been remarked that certain plumper votes had been given by members residing in Liverpool, and he should like that explained, because he could not think it should be generally divulged or even known as to where plumpers came from. There either did exist, or ought to exist, an arrangement that when the envelopes were opened the voting papers were all mixed up together before they were recorded.

The President said he was present the other day when a great number of the voting papers were received, and could bear witness that as they came in they were locked carefully away in a drawer by the Secretary. Whether he afterwards opened the drawer and opened the envelopes and looked into them, he could not tell, but he did not think that it was probable.

Mr. Bottle said that hardly met the point he referred to.

The Secretary said all the voting papers received would be brought before the scrutineers on the following day in bulk; they were never examined separately.

Mr. Richardson thought the method of voting papers was not quite satisfactory, and he hoped that in an amended Pharmacy Act a different mode would be adopted. They could not be too jealous about this matter, and he would suggest that every voting paper should be sent by post, and none delivered personally.

Mr. Barclay was glad this question had been opened. For the sake of all persons concerned it was of the utmost importance that there should not be a shadow of suspicion outside that there was anything like partiality, and he would advise that they should have official auditors, that all the votes should be sent in, not to the office, but to some official accountants in time to be examined, and the result made known at the meeting. In that way there could not be any chance of dissatisfaction.

The Solicitor said this was not a matter of statute at all, but was provided for by the bye-laws, and if desired it was competent to a meeting properly called to modify the bye-law. But concerning the suggestion just made he must confess he had never heard a word of suspicion thrown on the conduct of these elections, and that the present mode by which it was conducted answered some ends, which in all elections were regarded as essential. For instance, the election took place at that meeting, and it was adjourned for the purpose of receiving the report of the scrutineers, when the report was brought up and dealt with as a part of the meeting. If the idea were carried out of having the results of the scrutiny known before the meeting it would be impossible that any suggestions then made concerning the fitness of any of the gentlemen proposed could be taken into consideration, or that those suggestions should have any influence on the members who performed their duty by attending personally. By the existing mechanism a means was provided by which those who did not attend personally could, through the medium of the post, cause their votes to be recorded. This practice, as far as he could ascertain, had been in existence from the commencement, and the box being placed on the table every vote recorded was recorded in the face of the meeting, and it would be hardly practicable for the gentlemen who voted early to vote often, as possibly otherwise might be the case.

Mr. Mackay (Edinburgh) said it might be interesting to know how Mr. Hall came to the conclusion that there were certain plumper voting papers received from Liverpool. If he understood anything at all about present machinery, the voting papers being returned were put into safe custody, and when the scrutineers met were scattered over a certain number of tables, and it occurred to him that no scrutineer could possibly know how any particular members voted unless he took the trouble to put the envelope and voting paper apart for the purpose of comparison. If that had been done by the scrutineers he thought the sooner they appointed some one else to scrutinize the conduct of the scrutineers the better.

Mr. Hall said the matter was perfectly simple. There were say four thousand of these papers issued, of which the Secretary received about two thousand by post. Last year he happened to be at the table where all the Liverpool voting papers were placed and every one of them contained simply one name. Seeing that they were asked to return fourteen members it seemed a waste of power to concentrate all their votes on one candidate in that manner.

The President: Mr. Hall has shown that being appointed a scrutineer he obtained possession of certain information, and he had now been violating the confidence which was placed in him by making it public. He was very sorry he had brought the matter forward. To alter the bye-laws and to appoint official auditors would, in his opinion, be a very bad thing. If there were any suspicion of foul play public auditors would be as liable to that as others. But there was another point to be considered. In the early days of the Society it was only those who lived beyond a certain distance from Bloomsbury Square who were allowed to send their voting papers through the post, because it was considered necessary to keep personal voting in force in order to secure a good attendance at the annual meeting. If everyone chose to send by post there might be no meeting at all. They need not come with their voting papers filled up, but might hear what was said with regard to the fitness of this candidate or that, and fill the paper up accordingly. As far as personal delivery was concerned he imagined that every man who wrote his name in the book at the entrance was considered to be present at the meeting, and his voting paper might be put in the box, but if his friend gave him his paper yesterday to be put in the box to-day he should not feel justified in doing so.

The Secretary explained how it happened that the Liverpool voting papers all came together last year. For the convenience of sending to country members with regard to the appointment of local secretaries, the names were arranged in lists of towns, and the voting papers had been arranged in the same way, but he had now discontinued that, so that if Mr. Hall were present on the following day he would find the papers all mixed up, and it would be impossible to know where they came from.

Mr. Urwick thought they ought to be obliged to Mr. Hall for the information he had given them, and that the President's remarks were rather stronger than necessary.

Mr. Symes said it was not his intention to have spoken on the present occasion, but he was somewhat called upon to defend his friends in Liverpool. It struck him, notwithstanding what Mr. Urwick had said, that a scrutineer should not possess the information which Mr. Hall appeared to have, and although he did not in general approve of anonymous letters, he thought under the circumstances it would have been better if he had called attention to the matter in a different way. He must also be allowed to say that he did not come there as the representative of Liverpool. He found that he had received 1270 votes, of which at the outside not more than 100 could have come from Liverpool. He was elected by the whole country, and came there to do his duty to the utmost, as all other members of the Council had done. He had had much pleasure since he had been there in seeing the efforts of his colleagues, and he was quite sure that if some gentlemen who had passed their criticisms to-day were members of the Council and behind the scenes, they would see a great deal to modify their views. He hoped the result would be to prevent in future anyone, scrutineer or otherwise, obtaining information which he should not possess.

Mr. Brown (Greenwich) asked what check there was on putting the voting papers into the box, and suggested that some one should be appointed to take the name of every gentleman who voted, and see that he was a member.

The Secretary said no one was admitted into the room unless he was entitled to vote.

Mr. Long thought the suggestion of sending all the papers by post was a very good one. He should like to know how many more annual meetings they were to have. There seemed to be a general impression that Othello's occupation had gone and it would be a question what they should do with the funds of the Society if co-operative stores succeeded in their present contention. It would be useless to go on with the business of a chemist and druggist when all the valuable part of it was taken away from them, and the only business they could do would be after the stores were shut up, on bank holidays and Sundays. The judgment of the justices who tried the case he must term nonsense. He thought the appeal must be right, both from the misdirection of the judge, and because the verdict was against the evidence. It was quite incorrect to say that a corporation could not be examined. The Pharmaceutical Society was a corporation and all the members were examined. The real secret of the case was their bondage, and the hard work and the unpleasantness in the drug trade which caused men to get out of it if they could. If they raised their position and made themselves and their assistants more happy and comfortable, there would be no traitors in the camp, and if the stores had no qualified assistants they would not be able to do business.

Mr. Mee then moved—

"That the cordial thanks of the meeting are due and are hereby tendered to the Council for the valuable service they had rendered the Society and to chemists and druggists generally during the past year."

Mr. Smith had great pleasure in seconding the motion and congratulating the Council and President on the ordeal they had just passed through. Most of the objections raised had been answered fairly, and for himself, as an old member of the Society, he had the greatest confidence in the Council and hoped that a large number, if not the whole of them, should be retained in their seats for the present year.

Mr. Barclay felt great pleasure in supporting the motion. He had been much pleased with the action of the Council in this important crisis, and he thought when the members were satisfied they ought to express themselves as readily as they would when they had to find fault. He knew from his own experience in a more humble capacity the responsibility which rested on the Executive in prosecuting such a case as the Council had in hand, when a false step might lead to very serious results, and, therefore, the hands of the Council ought to be strengthened by the whole of the members when they were taking the right course. He took it that the motion would also include a vote of thanks to Mr. Sandford for presiding on that day. Birmingham, for some reason or other, was credited with knowing something about electioneering, and he must say they were rather proud of their knowledge and of the results. With regard to the question which had been raised of the voting, he hoped the Council would look a little more carefully into it. They were now in quiet times, when an alteration might be made without any kind of feeling. But if anything went wrong or strong feeling were aroused it would be more difficult to make any change. It was too late for members to make up their minds as to the candidates when they came to that meeting, and he therefore begged to repeat the suggestion he made before. He also desired to thank the Council for the exhibition they had instituted, and he thought that if they kept abreast of the times in that manner there would be no fear of not obtaining a good attendance at the annual meetings.

Mr. Andrews also supported the motion, and agreed that official scrutineers would be more satisfactory.

The motion was carried unanimously.

The President, on behalf of the Council as well as himself, begged to thank the meeting very cordially for the kind way in which they were always received, although they were sometimes called over the coals for their shortcomings. They had a good many difficult duties to perform, and it was not always easy to avoid an apparent negligence of the interests of their fellow members; but he could assure them that the interests of the whole trade were always present to the members of the Council. They were obliged to use their powers with discretion, and he hoped they should always continue to do so, but at the same time to uphold the interests of the druggists. He was glad attention had been called to the question of voting, and it might be as well in future to have someone with a list to check the names of those who voted; but he should be sorry to see anything like an official scrutiny introduced. He thought they might trust the Council in the ensuing year to make any improvement in the arrangements which might be desirable.

The following Registers were placed before the meeting by the Registrar in compliance with the provisions of the Pharmacy Acts, 1852 and 1868:—

Registrar of Members, Associates, and Apprentices of the Society.

Register of Pharmaceutical Chemists.

Register of Assistants.

Register of Apprentices and Students under the Pharmacy Act of 1852.

Register of Chemists and Druggists under the Pharmacy Act of 1868. Six volumes.

The portrait of Mr. Daniel Bell Hanbury, recently presented by Mr. Thomas Hanbury, was hung behind the President's chair during the meeting.

The meeting was then adjourned to Friday, at eleven o'clock, to receive the report of the scrutineers.

ADJOURNED MEETING.

Friday, May 21, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT, IN THE CHAIR.

Mr. W. K. Hopkin, the Chairman of the Scrutineers, said that before reading the report he thought it advisable to make a few remarks respecting the manner in which the present scrutiny had been conducted. Up to last year it had been the practice to sort the voting papers received through the post, so as to bring those together that came from the same district, in order to facilitate the scrutiny of the voting for Local Secretaries. It thus became possible, as mentioned at the meeting on Wednesday, for a Scrutineer to identify the voting from a particular locality. On the present occasion a different plan had been adopted. The voting papers, which had been in the custody of the Secretary since they had been received, were handed over to the Scrutineers without being previously sorted. The Scrutineers were divided into groups of five at a table. In the first place, one Scrutineer of each group examined the envelopes containing the votes received through the post to see that they were duly signed, opened the envelopes and took out the voting papers. Another examined the folded papers to see that not more than fourteen names were left on each. The recording of the votes was then proceeded with in the following manner:—One Scrutineer called out the names of the candidates voted for; a second checked the names as they were being called, and the other three recorded them. At every fifth vote a tally was called to see that the three were all in accord. He might say also that all the voting papers that had been handed in by the Secretary as having been received through the post too late had been examined to see whether the post-mark agreed with this statement. In his opinion the work could not have been done in a more satisfactory manner had it been entrusted to professional hands.

The President said that he regretted the manner in which the subject had been brought forward on Wednesday. With respect to plumping, each voter had a perfect right to use his own judgment as to the way he voted.

A conversation then ensued as to the way in which the personal voting at the annual meeting should be conducted, and the Secretary suggested that the scrutineers should in future be appointed at the commencement of the meeting and that two should be at once told off to see that all the votes are delivered in accordance with the bye-law.

The President said he had no doubt that the subject would receive attention from the Council and that a satisfactory plan would be devised before the next annual meeting.

The Scrutineers then brought up their report:—

Scrutineers' Report.

We, the undersigned Scrutineers, appointed at the Thirty-ninth Annual General Meeting of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following:—

Voting papers reported by the Secretary to have been issued		3650	
Voting papers received		1907	
Voting papers issued but not returned			1743
Voting papers received			1907
Voting papers disallowed:—			
Informal having more than fourteen names	4		
Received by post too late	77		
Envelopes unsigned by voters	16		
			97
Voting papers registered			1810

Result of the Poll.

Schacht	1614	Frazer	1389
Symes	1588	Squire	1358
Hampson	1570	Andrews	1048
Savage	1564	Radley	1043
Greenish	1551		
Mackay	1541		
Hills	1535	Spink	995
Gostling	1492	Postans	847
Sandford	1461	Shepperley	681
Atkins	1422	Wills	579

W. K. Hopkin, *Chairmv*

Charles B. Allen.	William Warren.
J. H. Baldock.	W. H. Symons.
G. F. Gutheridge.	W. I. Gulliver.
J. Horncastle.	Isaiah Bourdas, junior.
W. H. Ferguson.	W. Ralph Atkins.
W. Pickard.	Charles A. Blake.
Charles R. Riley.	T. Edward Greenish.
Alfred E. Tanner.	Charles J. Mead.
Thomas Henry Powell.	R. Fisher Young.
Richard A. Robinson.	

The New Council.

The Chairman then declared that the following gentlemen would constitute the Council for the ensuing twelve months:—

Andrews, Frederick, 34, Leinster Terrace, W.
Atkins, Samuel Ralph, Market Place, Salisbury.
Bottle, Alexander, 37, Townwall Street, Dover.
Churchill, Walter John, 46, New Street, Birmingham.
Frazer, Daniel, 113, Buchanan Street, Glasgow.
Gostling, Thomas Preston, Market Hill, Diss.
Greenish, Thomas, 20, New Street, Dorset Square, N.W.
Hampson, Robert, 205, St. John Street Road, E.C.
Hills, Thomas Hyde, 338, Oxford Street, W.
Mackay, John, 119, George Street, Edinburgh.
Radley, William Valentine, 7, Hampton Road, Southport.
Richardson, J. G. F., Houghton House, Stoneygate, Leicester.
Robbins, John, 372, Oxford Street, W.
Sandford, George Webb, 47, Piccadilly, W.
Savage, William Dawson, 4, Park Road East, Brighton.
Schacht, George Frederick, 7, Regent Street, Clifton, Bristol.
Shaw, John, 24, Great George Place, Liverpool.
Squire, Peter Wyatt, 277, Oxford Street, W.
Symes, Charles, 14, Hardman Street, Liverpool.
Williams, John, 16, Cross Street, Hatton Garden, E.C.
Woolley, George Stephen, 69, Market Street, Manchester.

Auditors.

There being only the requisite number of candidates (five) for the office of Auditors, the Chairman declared the following duly elected for the ensuing twelve months:—

Hodgkinson, William, 127, Aldersgate Street, E.C.
Lescher, Frank Harwood, 60, Bartholomew Close, E.C.
Stacey, Samuel Lloyd, 300, High Holborn, W.C.
Thompson, Henry Ayscough, 22, Worship Street, E.C.
Watts, William Manning, 32, Lower Whitecross Street, E.C.

On the motion of the President, seconded by Mr. Spink, a vote of thanks was given to the Scrutineers.

Mr. Hopkin proposed, and Mr. Horncastle seconded, a vote of thanks to the Chairman, which was unanimously agreed to.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, April 7, 1880.

Present—Professor Tichborne, President; Dr. Aquilla Smith, Vice-President; Sir George Owens, M.D., Dr. Collins, Messrs. Bennett (Kingstown), Brunker, Doran (Bray), Goodwin, Hayes, Holmes, Oldham. Simpson.

The minutes of the meetings held on March 3 and 8 were read and signed.

Read a letter from Sir James Gell, Attorney-General for the Isle of Man, thanking the Council for the information they had given him as to the working of the Irish Pharmacy Act.

Read letters, dated February 12 and March 31, from Mr. M. R. Nugent, of Limerick, requesting permission to be examined for the licence under the provisions of a regution passed by this Council on November 5, 1879.

The Registrar stated that there were several other applications of the same nature, which he had been obliged to postpone, pending the decision of the Privy Council. The new regulations had been collected by him, and forwarded to the said Council for confirmation on December 30, 1879, but that up to the present time he had not received any reply, except an acknowledgment of their receipt.

Proposed by Mr. Holmes, seconded by Mr. Brunker, and resolved:—

"That the Registrar be directed to write to the Clerk of the Privy Council reminding him of certain resolutions which were forwarded for confirmation in December last, and stating that some inconvenience has arisen from the fact of their not yet being brought into operation."

The following candidates for the membership, who were duly proposed and seconded (as follows) at the meeting on March 3, were now elected members:—

By the President and Mr. Hayes:—
John Blair, Patrick Street, Cork.
John Patrick Harold, Ormond Quay, Dublin.
John Charles Thomas Day, George Street, Limerick.

By Mr. Holmes and Mr. Doran:—
Andrew M'Connell, Castlepollard.
James Robinson, Lincoln Avenue, Belfast.

By Mr. Bennett and Mr. Hayes:—
Arthur Trevor Owen, Appian Way, Dublin.
Frederick Meyers, Upper George's Street, Kingstown.

By Mr. Holmes and Mr. Hodgson:—
David Baxter, Ballymoney.

The Registrar laid on the table the following books, presented to the Society by the British Pharmaceutical Conference.

Bell and Hills Library Fund.

Medicinal Plants, by Robert Bentley, F.L.S., and Henry Trimen, M.B., F.L.S., 4 vols. Lond. 1880.
Miller's Elements of Chemistry, vols. 1 and 2. Lond. 1877—78.

From Thomas Hanbury, in memory of his brother Daniel Hanbury, F.R.S. and F.L.S.:

Fluckiger and Hanbury: Pharmacographia. Lond. 1874.
Hanbury (Daniel), Science Papers, chiefly Pharmacological and Botanical. Lond. 1876.

Proposed by Mr. Bennett, seconded by Mr. R. Simpson, and resolved:—

"That the marked thanks of this Council be presented to the members of the British Pharmaceutical Conference for their very handsome and valuable donation of books to the Library of this Society."

MEETING OF THE COUNCIL.

Wednesday, May 5, 1880.

Present—Professor Tichborne, President; Sir George Owens, M.D., Dr. Collins, Messrs. Brunker, Doran (Bray), Goodwin, Hayes, Hodgson, Holmes, Oldham, Pring (Belfast), Simpson.

The minutes of the meeting held on Wednesday, April 7, were read and signed.

Read a letter from William S. B. Kaye, Esq., LL.D., Clerk to the Privy Council, relative to the resolution on a course of practical chemistry, which had been sent in for confirmation.

The draft of a reply was read and amended, and the Registrar was instructed to forward a copy to the Privy Council.

Read a letter from Mr. John Watters, M.P.S.I., of Kilkenny, relative to alleged arbitrary action of the Prisons' Board, Ireland.

The Registrar to inform Mr. Watters that the Council regret the circumstances of which he complains, but cannot advise him; they think his best course will be to consult a lawyer.

Read a letter from John Campbell, M.B., Secretary to the Medical Faculty of the Catholic University, requesting that the Laboratory of the School of Medicine, Cecilia Street, be placed on the list of those recognized by the Council for laboratory practice, and inviting an inspection by the Council.

Proposed by Mr. Pring, seconded by Mr. E. M. Hodgson, and resolved—

"That Dr. Collins, with Messrs. Brunker and Hayes, be appointed as a committee to inspect all such schools of medicine in Dublin, as may apply for recognition of their practical courses of chemistry by this Council, and that they be requested to visit the Cecilia Street school during this month, and to report as to its efficiency to next meeting of Council."

Read report from the Law Committee on some cases of compounding by unqualified persons, which had been reported to them, recommending that legal proceedings be taken against the offenders.

Proposed by Mr. Doran, seconded by Mr. Goodwin, and resolved—

"That the report of the Law Committee be adopted, and that the cases be placed in the hands of our Solicitor."

The Examiners' reports of the examinations held in April were laid on the table. At the Preliminary examination, held on Monday, April 5, *ten* candidates presented themselves, all of whom, excepting one, passed.

At the Pharmaceutical examination, held on Wednesday, April 7, *six* candidates presented themselves, of whom the following *four* passed.

John Isaac Bernard, Merrion, Co. Dublin.
Samuel Cheyne Nicholl, 33, High Street, Belfast.
William Livingston Ross, Enniskillen.
George Robert Young, Antrim Ville, Belfast.

Proposed by Mr. Oldham, seconded by Mr. Hodgson, and resolved:—

"That the report of the Examiners for the Preliminary and Pharmaceutical examinations be adopted."

The four candidates who passed the Final examination were now registered as Pharmaceutical Chemists.

Mr. Thomas Sheppard Hance, Limerick, who was proposed and seconded in April as a candidate for the membership, by the President and Mr. Hayes, was now elected a member.

Some bills, together with rent and salaries, were ordered for payment, and the Council then rose.

Chemists & Druggists' Trade Association.

MEETING OF THE EXECUTIVE COMMITTEE.

The meeting of the General Committee, preparatory to the annual general meeting of members, was held at the Inns of Court Hotel, on Tuesday, May 18, at 11 a.m. The chair was taken by the President, Mr. Thomas Barclay.

The Secretary having read the notice convening the meeting,

The President said the first business was to fill up the committee, on which there were four vacancies.

Messrs. Carr (Berwick-on-Tweed), Pasmore (Exeter), Mason (Liverpool), and Joseph Ball (Birkenhead), were accordingly added to the committee.

Mr. Harrison (Sunderland) then moved that the report and accounts be received and adopted, and recommended to the annual meeting. He thought the report could not be considered at all unsatisfactory, seeing that they had a balance in hand of £830, and last year it was only £896, and the past year might be looked upon as one of exceptional expenditure. The only point in the report with which he was not quite satisfied was the part relating to the service of chemists and druggists on juries. Early in the year he had communicated with the secretary telling him that in his opinion and that of many in his neighbourhood, the time was very suitable for taking up this question. Circumstances had now considerably altered, but still he hoped they would not wait until they had a new Pharmacy Act or a Jury Bill, but would endeavour to get the exemption now enjoyed by members of the Pharmaceutical Society at once extended to all on the Register. He believed it would be a long time before a new Jury Bill was passed, even with the present liberal House of Commons, because there were so many conservative notions and ancient prejudices bound up with the ideas of a British jury.

Mr. Phillips (Wigan) seconded the motion, and said he sympathized with the remarks of Mr. Harrison on the jury question.

Mr. Greaves (Chesterfield) took some exception to the part embodying the resolution on the subject of confining the sale of patent medicines containing poisons to registered chemists and druggists. He thought most gentlemen on the Executive Committee resided in large towns, and were hardly aware of the circumstances of rural districts. In his own neighbourhood there was an area of some 500 or 600 square miles with only fourteen registered chemists, and nine of those were in four places; and there were only two examined men in the whole number. Mr. Greaves went on at some length to point out the difficulties which occurred where there was no registered chemist within several miles, until the President inquired if he was arguing in favour of a repeal of the Pharmacy Act. Mr. Greaves replied in the negative, and said that he had done his best to assist in carrying out the Act, but the requirements of the public must also be kept in view, for if they obtained any legislation which was beyond public opinion it would become a dead letter.

Mr. Jervis (Sheffield) thought the greater part of the district referred to by Mr. Greaves was moorland.

The President, in putting the motion, said he must say, in reply to Mr. Harrison, that they were advised by the solicitor (who, he regretted, was unable to attend today) that no steps could be taken in the matter of the jury exemption before an amended Pharmacy Act or a new Jury Bill were brought in. He could not agree that the financial position of the Association was very satisfactory, since their balance had somewhat decreased, and they could not consider the expenditure during the year had been at all exceptional. In reply to Mr. Greaves, he must remind him that their action in connection with the sale of poisons had been quite in accordance with public opinion. The press were almost unanimous in requiring that those who sold poisons, whether in the shape of patent medicines or otherwise, should be registered chemists and druggists. They were not, therefore, simply acting in their own interest in this matter, but in the interests of the public, in moving in this matter. No one would attempt to do anything opposed to public opinion, because if they did they would not only fail, but bring disgrace upon themselves. In country districts he understood it was the habit for people to keep themselves supplied with what they were likely to require from the nearest market town. Mr. Greaves's argument, if carried to its legitimate extent, would upset the Pharmacy Act altogether, and there would be free trade in poisons. He must also remind Mr. Greaves that the Executive Committee represented country districts as well as large towns.

After a few further words from Mr. Greaves in explanation, the resolution was put and carried unanimously.

The President said the next business was to prepare the list of names to be recommended to the annual meeting for the election of the Executive Committee.

Messrs. Throstle, Mackenzie and Davidson were appointed scrutineers. Whilst the scrutineers were examining the papers,

The President referred to the subject of one of the members being summoned (as will appear below), and he also moved a resolution of sympathy with Mr. Jones, the late President, in his illness.

This was seconded by Mr. Hampson, supported by Mr. Cross (Shrewsbury) and carried unanimously.

The President then said Mr. Andrews had drawn his attention to the large amount of outstanding subscriptions which were unpaid. It was a very important matter, as they were rather short of funds.

Mr. Andrews said if a list of defaulters in his own neighbourhood were given him he would look them up.

Mr. Maltby (Lincoln) also volunteered to do the same in his district, saying, that at the time of the Shepperley case he had collected as much as £20 in Lincolnshire. He thought it would be a good plan for the Secretary to send a list of subscribers to some gentlemen in each neighbourhood who would undertake to collect them.

Mr. Symes said he, and he believed several others, had always had such a list forwarded to them, and in going round he often made new members.

Mr. Walker suggested the desirability of appointing local secretaries in the different districts similar to those of the Pharmaceutical Society. There were many persons who were reluctant to pay their five shillings, or did not do so, but if they happened to receive a summons for some breach of the law they sent it up with great alacrity and called upon the Association to defend them.

The President said every member of the General Committee was *ex officio* a local secretary.

Mr. Maltby also suggested that in collecting subscriptions efforts should be made to obtain additional donations so that they might have an invested fund to fall back upon in case of need.

The following list was reported by the Scrutineers to be chosen for recommendation to the annual meeting as the—

Executive Committee for 1880–81.

Andrews, Frederick, London.	Jervis, W., Sheffield.
Arblaster, C. J., Birmingham.	Johnson, T. S., Malvern.
Barclay, Thomas, Birmingham.	Kerr, Charles, Dundee.
Bell, C. B., Hull.	Mackenzie, James, Edinburgh.
Churchill, W. J., Birmingham.	Maltby, Joseph, Lincoln.
Cole, F. A., Colchester.	Owen, John, London.
Cross, W. G., Jun., Shrewsbury.	Phillips, J., Wigan.
Davison, Thomas, Glasgow.	Southall, William, Birmingham.
Delves, George, Exeter.	Stead, T. B., Leeds.
Hampson, Robert, London.	Symes, Charles, Liverpool.
Harrison, John, Sunderland.	Walker, George, Coventry.
Holdsworth, T. W., Birmingham.	Williams, F. P., Manchester.

The Annual Meeting.

The annual general meeting of members was held at 12.30. Mr. Barclay, President, in the chair.

The President said that they must all regret the absence of Mr. Jones, the late President, which was quite unexpected, through his being out of health. He had always taken the liveliest interest in this Association from its earliest inception, and he was sure nothing but necessity would have prevented him being present.

The report, which was taken as read, referred with satisfaction to the abandonment of the appeal in Mr. Shepperley's case, and congratulated the members on the success thus obtained. The second division of the report referred to cases of infringement of the Pharmacy Act, in ten of which convictions had been obtained, whilst eight had been reported during the year by the Secretary to the Registrar of the Pharmaceutical Society, though in one only of these had proceedings been taken in a court of law, when a penalty of five pounds was inflicted. A hope was expressed that in future the Pharmaceutical Society would more frequently utilize the evidence placed at its disposal by the Association. With regard to service on juries, the sub-committee reported that it would be useless to attempt taking any steps for exempting chemists and druggists from service until an amended Pharmacy Act or Jury Bill was before Parliament. The report next referred to several cases in which the Association had successfully defended persons prosecuted under the Sale of Food and Drugs Act; one case, however, the Committee had declined to defend, thinking the accused had not used sufficient care. The sale of poisons under cover of the patent medicine stamp had also engaged the attention of the Committee, and a memorial had been forwarded to the Pharmaceutical Society on the subject. The desirability of the Pharmaceutical Council taking an official part in preparing any revised edition of the Pharmacopœia had also formed the subject of a resolution, and reference was also made to the action of the Association in defending a member prosecuted under the Weights and Measures Act.

The list of members showed a total of 4527 annual subscriptions for the year, being an increase of 181.

Mr. Green (Woolwich) moved that the report and balance sheet be received and adopted. He hoped that what had taken place in the General Committee early in the morning would lead to a further amount of subscriptions.

Mr. Mason (Liverpool) seconded the motion.

Mr. Spink (Westminster) said the report dealt with a variety of matters respecting the general interest of the trade, and there was no doubt that the Association had done good service, but there was one evil not mentioned in the report at all. He did not rise to move a resolution unless it were absolutely necessary, but to make a suggestion, viz., that the Committee should take into consideration the trading proclivities of the Civil Service and select delegates from its body to give evidence before the Parliamentary Committee which no doubt would be going on with its labours when Parliament met, for unless the chemists and traders generally made a firm and determined stand now any effort in future would be absolutely futile. As that Association had been for some years watching the best interests of the trade and the means by which they might be allowed to live, he thought it would be as well to send delegates to the Committee to give evidence. He had attended before the Committee himself, and one of the first questions asked him by the chairman was whether he represented any society; and he felt strongly convinced that if he had appeared in a representative capacity more weight would have attached to his evidence. Considering the way in which they were hampered on all hands by Weights and Measures Acts and other things, and the examination they had to undergo, it was grossly unfair that these people should come and set up in trade and sell things at less than cost price. The stores interfered more with their business than any other; of course their turn-over was very small and consequently according to the ordinary tariff the profits were proportionately high, but these stores had a large business in other matters and were able to put forward their goods in some cases absolutely below cost price. He had the honour to be a candidate for a position in another place, and if he should attain that position he should advocate there what he was now doing, that delegates be selected to attend and give evidence before the Parliamentary Committee.

Mr. Long had much pleasure in supporting the resolution that the report and accounts be adopted, and he also thought it very important that they should do all they could to put down co-operative trading in poisons.

The President thought the question raised by Mr. Spink was of such importance that it had better be dealt with specifically by a separate motion later on.

The motion for the adoption of the report was then put, and carried unanimously.

The President said the next business was to elect the Executive Committee and officers for the ensuing year. He would call upon the Secretary to read the names selected by the General Committee.

This having been done,

Mr. Spink moved that the names selected by the General Committee form the Executive Committee for the ensuing year.

Mr. Brown (Greenwich) seconded the resolution, and it was at once carried unanimously.

The President said it had been usual to elect the officers by ballot, and Messrs. Spink and Urwick were appointed scrutineers to examine the voting papers.

Whilst these gentlemen were examining the papers,

The President said it might be interesting to the members to know that one of their members had been summoned to appear before the magistrates to-morrow morning under the new Weights and Measures Act. He had been summoned not for having ordinary weights used by ordinary traders, but for grain and drachm apothecaries' weights. They had been tested by the inspector, and reported to be not correct. Last night, the Executive Committee determined the Solicitor should be telegraphed for, and he would no doubt arrive that evening and take charge of the case. They did not know to what extent these weights were wrong, and of course were somewhat in the dark at present, but inasmuch as it was the first time that apothecaries' weights had been called in question, they thought it their duty to take it up, especially as the gentleman who had been summoned informed them that he had been always very particular, and had had his weights and scales certified every two or three months, but he had never had his grain and drachm weights tested. It would depend very much on the kind of balance which was used in testing these small weights, because no doubt if one were used with such a fine beam that it would turn with $\frac{1}{100}$th of a grain, hardly any of the weights in the country would be correct. One of the seventeen weights which had been objected to was a 3-grain weight.

Mr. Long thought this question of the weights was a great bogie. For 1*s.* 6*d.* they could save all trouble. He had both his sets of dispensing scales and sets of weights adjusted for 1*s.* 6*d.* each; but still they did not all weigh alike, for after having the Government stamp on them, if you put the 2 grain and the 3 grain together they would not balance the 5 grain. However, that did not signify so long as they were stamped.

Mr. Hampson desired to ask Mr. Long if they were stamped how long they would remain correct. It was very important to bear in mind that under this Act the trader was quite unprotected. If such a thing occurred as that an inspector had a grudge against a man, he might easily file a little off one of the weights, and there was no protection to the tradesman whatever; they were absolutely at the mercy of the inspector. Under the Sale of Food and Drugs Act there was some protection, because the sample purchased was divided into three portions, but it was not so here. Of course, he did not mean to say the inspector would tamper with the weights, but they were absolutely at his mercy.

Mr. Phillips (Wigan) said he believed it would also be now illegal to use scales with anything attached to them to adjust them. It often happened in cleaning scales they got a little bit incorrect, so that they were obliged to put a little bit of lead at the bottom to balance; but he believed that would now be illegal.

Mr. Churchill said he believed that according to the Act it was no use for a country chemist to buy weights stamped with the London stamp, they must bear the stamp of the local authority in his own district. As soon as he got home he should communicate with their own inspector to see if he was ready to stamp the weights.

Mr. Symes thought this view was not correct, . at that weights stamped in London were good in any part of Great Britain.

Mr. Robinson (Norwich) thought inspectors were not very anxious to carry out the law. He had recently inquired of the inspector in his own town, and he told him he had not yet received the standards and did not suppose he ever should.

Mr. Andrews thought there were very few inspectors who could properly test a 3-grain weight.

The President said he might take this opportunity of mentioning the next election of the General Committee. It was a very costly proceeding in the matter of postage and printing and involved a deal of trouble to the members, and, therefore, two years ago they decided that the election of the General Committee should take place in alternate years, and unless there was some good reason for altering it they should do the same again. He would therefore move, "That this meeting directs that the next election of the General Committee take place in 1882."

Mr. Shepperley seconded the motion, which was carried unanimously.

The President said another resolution which would commend itself to the meeting was with reference to the late Chairman. As he had said earlier in the meeting, they all felt the loss of Mr. Jones, and he was sure if he had been in anything like health he would have been amongst them that day. His sympathies were so much with the Association and he had done such good work for it in the past, that he was sure it would be the wish of the meeting that some expression of sympathy should be sent to him and his family. He would therefore move, "That this meeting of the Chemists and Druggists' Trade Association hears with regret of the illness of Mr. S. U. Jones, its late President, which prevents him again sitting on the Executive Committee, and expresses the hope that he may be speedily restored to health." Mr. Jones was elected President at the inception of the Association, when it was looked upon somewhat coldly by some gentlemen in high quarters, and Mr. Jones, in his position as President, was very useful in giving confidence to the members. He did a great deal to consolidate and help it forward, and he deeply regretted his absence from the Executive Committee. He was always at his post, and by the thoughtful and considerate judgment he gave to every question which came before him he rendered the Committee great service. He had, therefore, much pleasure in moving the resolution.

Mr. Hampson, as Vice-President, seconded the motion.

Mr. Innes (Liverpool) supported the motion.

The motion was then put and carried unanimously.

The Scrutineers having now returned,

Mr. Spink begged to inform the meeting that there was no change whatever in the Executive for the coming year, and he thought they might accept gladly this unanimity of feeling amongst those present. He only wished the same unanimity existed among all the members of the trade as apparently existed there, for although there were two or three differences of opinion the vote might be taken as practically unanimous. It was very much to be regretted that a larger number did not come to the meeting.

Mr. Urwick said with the exception of one or two votes the decision was unanimous, and he was very pleased it was so, because it showed that the members were perfectly satisfied with the way in which the business had been conducted, and he trusted the officers would go on and work as thoroughly in the future as they had hitherto done.

The President, in thanking the meeting on his own behalf and that of his colleagues for this renewed mark of confidence, said he could speak, at any rate, for his colleagues, that during the year they had given their best attention to the interests of the Association; their hearts had been thoroughly in the work, and he felt sure the meeting had done well in re-electing them. For his own part he felt great interest in the Association, and had done from the first, and during the past year he had done his utmost to further its interests, and those of the entire trade. The resolution adopted with regard to the report was one for which he would also thank them. That report shadowed forth the work of the Executive during the year, but it by no means showed the amount of work which the Committee had had to go through. The amount of care and anxiety with regard to the various matters which came before the Law Committee especially could not well be stated in words. They were glad to know that they had had a slight increase numbers during the year, but there were still over three thousand remaining outside, and it only needed a little enthusiasm and effort on behalf of the members of the General Committee to largly increase the numbers during the coming year. The work which had been done must commend itself to the trade generally, and he trusted that a strong effort would be made to increase the number of members so that at the next annual meeting they might congratulate themselves on a still further increase. The receipts during the year had been £1256 and the expenditure £1395, which was going in the wrong direction, showing a deficiency of £139, and that was accounted for in this way, that at the last annual meeting they had a balance of £896, whilst this time there was only a balance of £830. When there was a balance in hand there was always a general feeling that it was not the time to increase subscriptions or give donations, and he was therefore glad that at the general meeting that morning Mr. Maltby, of Lincoln, made a very practical suggestion, that they should endeavour to increase the donations in order to have a sort of guarantee fund, which might be drawn upon in the event of any exceptional necessity, so that they need not consider so carefully whether they dare go forward or not in the defence of cases put before them so long as they knew they were cases which ought to be defended. When Mr. Shepperley's case was before them their friends stepped forward very liberally, and he had no doubt they would always have a similar response if necessary; but still it would be better, and make them more free in the Executive Committee if they had some invested funds. It was not unfrequently the case that they had to inquire of the Treasurer how their funds stood when a case came before them, and that somewhat tended to cramp their action. During the past year the donations had been rather small, only £143. The first year they had £1028, and in the second year £375, and in the third year £1645. They had, however, during the last year a special donation, which required perhaps a little attention, and that was £165 from the Apothecaries' Company, which was very welcome. They were well pleased with it for many reasons. A very serious matter in connection with the state of the funds was that over one thousand subscriptions were still unpaid, and that called for the attention of every member of the Association. He believed that there were a large number who had not sent up their subscription because it was so small, and no one had asked them for it, but that morning in the General Committee, several gentlemen had volunteered to go round in their own districts and collect the subscriptions and he trusted the Secretary would have further volunteers in that way before the meeting closed. With regard to the amount received from the Apothecaries' Company they were very glad to receive it, because it showed the case was finished, and it saved them an immense amount of anxiety, and not only themselves, but the whole trade, and the Apothecaries' Company as well, for if it had gone on with that sort of thing it could not have failed to bring disgrace and ignominy upon itself. None of them who mixed much with medical men, but knew that there was no sympathy on the part of the better class of members of that profession with that prosecution, and they might be quite certain now that no chemist would be interfered with in the future who followed his calling in the ordinary way and did not do anything beyond what chemists had undertaken to do since the business had first grown up. During the year there had been some Medical Bills introduced which had been watched very carefully, but they were glad to find that their friends had not in any of those Bills attempted to interfere with the rights of chemists and throughout had abstained from including the penal clause in the Apothecaries' Act. During the year the Association had undertaken to prosecute offenders for infringement of the Pharmacy Act, though they were limited in their action in this matter, and could only prosecute under the 17th section, so that vendors who called themselves chemists though they were not so, and who labelled their poisons as chemists, they had no control over. If, however, they did not comply with the 17th section they could take action, and in ten such cases they had obtained convictions. It was also satisfactory to know that in no case in which a conviction had been obtained had any chemist been called upon to give evidence. This proved the necessity and usefulness of the Association most incontestably. Eight cases had been sent to the Pharmaceutical Society, and in one of those the Secretary had used the evidence forwarded to him, and had obtained a conviction. It was a subject for congratulation that they had thus for the first time obtained concerted action between the two Societies; they were not working in any way in antagonism to the Pharmaceutical Society and so long as that Society would do its utmost to protect the interests of the trade, so long would it have the hearty sympathy of the Association, and anything the Executive could do would be readily done to assist it. They must not forget that the Pharmaceutical Society occupied an entirely different position to themselves, as it not only represented the trade, but the Government and the public; they, on the other hand, were a purely trade organization, and could undertake cases in the police court with regard to adulteration, and many other things which the Pharmaceutical Society could not so well do, and, therefore, he felt there was work, both for the Society and the Association, and they might work harmoniously, although not on the same lines. He mentioned this because the Society was sometimes blamed for not doing what it could not properly do, and he hoped also to secure the co-operation of those members of the Society who had not yet joined. During the past year the Pharmaceutical Society had had an important matter before it, and they heartily endorsed its action with regard to the London and Provincial Supply Association. The Council might feel assured that the Executive watched with great interest and anxiety its action in that matter, and were very glad to find they had had the courage to go to the House of Lords where it wished them every success. It had a good case, and if beaten in the House of Lords it would necessitate the united action of all parties connected with the trade to get an amended Pharmacy Act to prevent such a state of affairs continuing. If the law were weak the sooner it were made strong the better, because it was an outrageous thing that any corporate body, say half a dozen grocers, could employ a qualified chemist, and set up a large trade. There was a law against a chemist taking a partner who was not a qualified man, or even the widow of a chemist carrying on the business with a qualified assistant, and yet according to the latest decision, half a dozen grocers might meet together and employ some nondescript chemist to carry on a large business. If this were found to be the real state of the law they must get the law amended as soon as possible. With regard to the Jury Bill some little feeling had been expressed that the Association might have done something during the year, but their solicitor advised them that it would be unwise to take any action until an amended Pharmacy Act or a Jury Bill came before the House. He was glad to find, however, that their friend Mr. Harrison, who had always been enthusiastic on this subject, was now a member of the Executive, and, therefore, there was no doubt it would receive due attention. With regard to the Adulteration Act several cases had come before them during the year, one of which they could not defend, because it appeared that the individual prosecuted had not used sufficient care, and they felt they could not defend anything in the shape of adulteration. Three cases, however, they had defended successfully. After alluding in some detail to these cases, the President said that magistrates and analysts alike were most of them ignorant of the technicalities of the trade, and they found it was necessary there should be some amendment of the Act. At present they were obliged to pay the costs of the analyst attending to give evidence, although the decision might be in their favour, and they intended the first opportunity to move for an amendment of the Act so that the costs should follow the event. They also wanted a central board established to which the evidence should be sent before any prosecution was authorized, and not leave it in the hands of the local analyst. He believed the Association generally were agreed that it was the right course to take, to go forward and endeavour to obtain such an alteration of the law as would prevent patent medicines containing poisons being sold by unqualified persons. This was one of the objects set forth when the Association was first started, and it was satisfactory to find that that and other objects had been kept steadily in view, and that on the whole the Association had been fairly successful.

Mr. Urwick inquired if the Association would take up cases of sending out poisons by unqualified persons, which the Pharmaceutical Society would not take up.

The President said those were cases which the Executive were always glad to hear of, and though they could not pledge themselves without looking into the case, he was prepared to say that if the Solicitor thought it was a case which they might successfully prosecute, they would take it in hand at once.

Mr. Hampson, as Vice-President, also desired to thank the meeting for his re-election, and said he should endeavour to work for it, if possible, more zealously than he had hitherto done. It was difficult to pick out any special questions on which to speak, as he was interested in most of them, but he should like to say a word on the question of co-operative trading. He had given this subject a great deal of attention, and had argued it at the Pharmaceutical Council. He was very much pleased that a case had been taken into court, and that it was being carried to the highest tribunal. There was one aspect of it he should wish to refer to, namely, its effect on medical practice. They were said to be a branch of the medical profession, and he should like to ask what would be the effect of dispensing being practised in large stores for the bulk of the population, instead of under the conditions which prevailed at present. His impression was that it would react very much against the medical profession if this continued, for they certainly would not have men of intelligence coming into the trade. It was hard enough to get a living now, but if these things went on it would be simply impossible. He heartily sympathized with Mr. Spink with reference to the smallness of the gathering, notwithstanding its representative character. This was the metropolis of Great Britain, and everybody was grumbling about the state of trade, and yet they could not get the room full. That showed how apathetic they were with regard to their own interests. Another matter of importance was the question of the Pharmacopœia. He thought it only just that it should be partly framed by the chemists of the country, and he hoped that matter would continue to have the support of the Executive. The real point they had to consider was what could they do to make pharmacy worth practising. As they all knew, he heartily advocated the case of Mr. Shepperley; but they would have in future to concentrate their efforts in one point—the obtaining of the dispensing of the country. At present, they had not got it; they had simply the fragments from the rich man's table; they were not pharmacists—they were little better than pettifogging hucksters, many of them. The time might arrive when they could appeal to the Legislature on this question, for he contended that it was as much their function to dispense prescriptions as it was for doctors to prescribe. He hoped they would keep that idea before them, and at the fitting time concentrate all their energies upon it.

Mr. Shepperley congratulated the President on the very able manner in which he had explained the report of the past year. He must express his own pleasure on the repose to which the Apothecaries' Act, which had caused him so much trouble and anxiety, was now relegated.

Mr. Spink then moved:—"That this meeting recommends the Executive to appoint delegates to appear before any Parliamentary Committee which may be appointed to receive evidence on the question of co-operative trading."

Mr. Urwick seconded the motion. He thought the Committee did not pay so much attention to any man who volunteered to give evidence on his own account as they would to anyone regularly appointed, and he hoped the Pharmaceutical Society also would adopt the same course.

Mr. Long said it was a most absurd thing that persons should evade the law by two or three combining together. Betting was illegal, but Kerr and Benson were not allowed to escape with impunity because they combined to carry on an illegal business. The great thing was for chemists to be more united. They were the makers of genuine patent medicines, and they might very well put all the other rubbish into the dust hole. Why did they not supply themselves, and not allow other people to take the trade out of their hands?

Mr. Churchill thought that Mr. Long had hit the right nail on the head. Many chemists were the proprietors of patent medicines, and some few that made these articles confined the sale of them to qualified men. He trusted that wherever chemists found that was being done they would heartily support those proprietors.

The motion was then put and carried.

Mr. Alldin drew attention to the fact that the name of one of the judges before whom the case now pending was last tried appeared as a member of one of the co-operative stores.

Mr. Spink said he thought it was always understood that if any judge were interested in the trial of a case which came before him he should leave the bench, and if a judge held a shares in a co-operative society, he did not think it was consistent that he should adjudicate on a question in which it was interested.

Mr. Andrews also thought this was a point of importance which might be dwelt upon by counsel in the House of Lords.

The resolution was then put and carried unanimously.

Mr. Throstle (Cambridge) then moved:—"That this meeting affirms the necessity of early closing and pledges itself by each of its members to favour a system of moderate hours."

Mr. Long seconded the motion.

Mr. Mackenzie said this was a matter which each one could carry out for itself. If everyone would look to his own door, and shut it at the proper time, all would be well, but everybody waited to see his neighbour closed first, and this led to late hours.

Mr. Hampson thought this was a matter which depended a good deal on the action of localities.

Mr. Urwick said every man had the option to close when he liked. He himself, when he commenced, closed every Sunday, and at nine o'clock every evening, although his neighbours did not; but now they had all come to it.

The President thought this was rather a difficult question, and one to be left to the local traders. He would suggest that the resolution should be framed in this manner:—"That this meeting agrees upon the desirability of its members adopting a system of earlier closing, and recommends its adoption as far as practicable."

Mr. Throstle said he would adopt this resolution, and after some observations from Mr. Burton, it was agreed to unanimously.

The meeting concluded with a vote of thanks to the President, moved by Mr. Urwick, and seconded by Mr. Harrison.

Communications, Letters, etc., have been received from Messrs. Saunders, Moss, Greenish, Williams, Burrough, Macaulay, Hind, Levy, Inquirer, Antidote, Fraxinus W.B.O., Q.S., A.D.B.

"THE MONTH."

The law of compensation, which seems to run throughout nature, has this year been manifested in a remarkable manner. The enormous quantity of rain which fell last spring has been succeeded by an equally remarkable drought during the present one, and although the south-west wind seems just at the point of striving for the mastery, there appears but little probability that the old adage that "a dripping June puts all in tune" will come true this summer.

In the London gardens the fragrant lilac and the lovely pink hawthorn present but a very meagre display of blossom, and scarcely perfume the air, while the golden clusters of the laburnum lack both their wonted richness of colour and wealth of blossom. Nevertheless, flowers are fully a fortnight in advance of last year.

May is the month when the study of flowers in a practical manner usually commences in the various schools of medicine and pharmacy, and pleasure and profit may be well combined by a ramble in the green lanes and leafy woods at this season of the year. In the woods the lovely green of the foliage is relieved here and there by the snowy whiteness of the blossoms of wild cherry, or the rowan tree, and the pale blue carpet of the wild hyacinth; the meadows are decked with the still more delicate hue of the cuckoo flower, with its graceful sprays, and the broom, with its profusion of golden blossoms, gladdens the eye and enables one with all the more vigour and earnestness to investigate the truths which lie hid in so much beauty. The curious axillary bulbils of *Dentana bulbifera*, the sensitive stamens of *Berberis vulgaris*, the curious flowers and root of the moschatel and the still more remarkable ones of the fumitory and polygala, the apetalous flowers of the violet, the curious leaves and flowers of *Pinguicula vulgaris*, are all worthy of examination at this time of the year. Nor should the green flowers of the common wood spurge, nor those of the *Arum maculatum*, *Orchis Morio* and *O. maculata*, and the various fir, willow, and other catkin-bearing trees, be neglected by the student of botany. From each and all some useful lesson may be learnt.

Among the especially medicinal plants which may be met with in the country this month are the broom, juniper, bistort and bogbean. In botanical gardens several others may be found.

At Kew the caraway and podophyllum, medicinal rhubarb, and at Regent's Park the angelica and the aconite and *Dicentra formosa* are coming into blossom in the open ground. In the Economic House at Kew *Cissampelos Pareira*, *Pelargonium capitatum*, and *Anacardium occidentale*, or cashew nut, are now in blossom.

The *Anacardium occidentale* will afford an opportunity to visitors to observe the growth of the fleshy peduncle, which ultimately becomes so much larger than the ovary, and forms the "fruit" or edible portion. According to a writer in the *Gardeners' Chronicle*, May 22, p. 660, the fruit, which ripens in Jamaica at the end of June, varies much in flavour in different individuals, some being very astringent, and others deliciously refreshing when eaten fresh. In the candied state he considers them to be scarcely distinguishable from Eleme figs. The juice of the fruit produces an indelible dark brown spot on linen wherever it falls, and is also used as a remedy in attacks of dysentery. The mode of obtaining the kernels for

food is a curious one. The kidney-shaped nut contains an extremely caustic viscid oil (cardol) in the pericarp, which has been known to produce in sensitive subjects all the symptoms of erysipelas when the nut has been bitten and the oil has come into contact with the lips. The nuts are heated in a shallow iron pan until the oil contained in the integument catches fire and they are then stirred briskly till it is consumed. When this has been done they are removed from the fire, and the roasted kernels placed in hermetically sealed bottles until required for use.

In the Regent's Park Gardens the ipecacuanha and the pretty fragrant flowers of *Kæmpferia rotunda* have been in blossom. Apart from the curious structure of the flower of the latter,—common to the Zingiberaceæ, in which two of the three stamens of the inner whorl are abortive and the outer three converted into petals, one of which is larger than the others and forms a labellum,—the manner in which the plant produces its flowers is very curious; the blossoms proceeding directly from the root, only one flower opening at a time and lasting only a single day. The fragrance of the flower also adds considerably to its beauty. This little plant is interesting on account of it having been stated to be the source of round zedoary; it is, however, well known now that both the long and round zedoary are the produce of one and the same plant, the long zedoary being the lateral and the round zedoary the central tubers.

Those who are studying the British flora will find several rare species in flower in the Herbaceous Ground at Kew, of which may be mentioned *Maianthemum bifolium*, *Leucojum æstivum*, *Geranium phæum*, *G. sylvaticum* and *G. sanguineum*, *Doronicum pardalianches*, *Stellaria nemorum*, *Lychnis alpina* and *L. viscaria*, *Linum perenne*, *Alchemilla alpina*, *Potentilla rupestris*, *Linum perenne*, *Meum athamanticum*, *Vicia Orobus* and *Euphorbia cyparissias*, *E. palustris* and *E. dulcis*, *Cypripedium Calceolus* and *Crambe maritima*. One of the most prominent flowers of this month is the iris, of which the two species yielding orris root, *I. Florentina* and *I. Germanica*, are by no means uncommon in gardens, the delicate, exceedingly pale bluish tint of the former making it appear almost white against the dark violet blue flowers of the latter. Another species used in medicine in America, *Iris versicolor*, and the one from which iridin is obtained, is not to be seen so generally in this country, and the rhizomes of other species are not unfrequently sold for it. Those who are desirous of making a practical acquaintance with the meaning of the term viviparous will find an excellent illustration of it in a curious variety of a fern, *Polystichum angulare*, at the Regent's Park Gardens; in this plant a number of young ones are produced along the upper surface of the rachis. In the Palm House at Kew a still more remarkable instance may be seen. The flowering stems of *Cypella gracilis*, after flowering, appear to have produced no fruit, and the vigour of the plant seems to have been diverted to produce young plants from the axil of the spathaceous bract whence the flower arose. In several instances a young plant with a well developed aerial rhizome is thus produced, which appears to originate from the long pendent leaf; careful observation, however, reveals the abortive ovary still remaining in the axil whence the young plant springs, and shows that the young plant really arises from the inflorescence.

In the May number of the *Journal de Pharmacie*, Professor Planchon describes the "Ramou" or *Strychnos Castelnœana*, Weddell, from which the curari of the Upper Amazon is produced.

A fatal case of poisoning by hemlock water dropwort has been recorded from Chelmsford. Several boys, while at play, are stated to have picked parts of the plant, and eaten them. Three were taken ill, and one died after a short illness of an hour or two. The root is the part of this plant generally eaten, from its resemblance to parsnips, and it cannot be too widely known that it is a most powerful poison, death having in some cases on record been produced in three quarters of an hour, while no antidote is as yet known.

Within the last few days a piece of root has been received from a correspondent which is stated to have been sold and used as *Actæa racemosa*. The root is that of *Potentilla Tormentilla*. As the same substitution may possibly occur again, it may be well to point out the characters by which the two roots are distinguished. *Actæa racemosa* is of a blackish colour externally, sparingly furnished with lateral branches and has numerous transverse lines or scars, often ¼ to ½ inch distant from each other, where the leaves have fallen off. Internally it is of a greenish colour in the centre and circumference, with distinct, yellowish, woody rays radiating from near the centre, which is rather darker than the rest of the rhizome and more horny. The large, wiry rootlets have a meditullium resembling a Maltese cross in shape. The taste is faintly bitter and herby. Potentilla root is, on the other hand, rarely branched, is of a red-brown colour externally and marked with numerous small pits on the surface, internally reddish and porous, but hard, and has a powerfully astringent taste.

A specimen of the *stem* of ipecacuanha has during the present week been received for identification. It differs so much in appearance from the *root* that it is not surprising that it is often mistaken for an adulteration. The stem of ipecacuanha often has small portions of the root attached, and may be known by the extreme thinness of its bark from *Richardsonia scabra* and other roots, which are sometimes substituted for ipecacuanha, but hardly ever mixed with it. When, as is sometimes the case, large quantities of ipecacuanha stem are mixed with the root, the sample should either be rejected or picked over, since it is obvious that a wine made with a sample containing so small a portion of bark to its bulk would fall much below the B.P. strength. Indeed, it may be hoped that in the next edition of the Pharmacopœia a given quantity of the bark, separated from the woody meditullium, will be ordered to be used instead of a given quantity of the root as met with in commerce. Such directions would lead to a much greater uniformity in the strength of preparations of this valuable drug than is likely to obtain under present conditions.

At the recent sales of Java bark at Rotterdam, a large quantity of bark was offered for sale in something like the following proportions:—*Calisaya Schukkraft hybrid* 40; *C. succirubra* 25; *C. Hasskarliana* 9; *C. javanica* 8; *C. Ledgeriana* 7; *C. anglica* 6; *C. officinalis* 3; *C. Pahudiana* 0·1. According to the published analyses the root bark in almost every case was equal in the amount of quinine it contained to the richest stem bark of the same species, thus verifying Mr. Howard's previous statement. The best samples of *C. anglica*, *Hasskarliana*, *javanica* and the *Schukkraft*, gave an average of 1—1½ per cent. of quinine, while the *Ledgeriana* furnished 7 per cent. of pure quinine with very little of any other alkaloid.

In the London market a large quantity of the singular bark known as *China cuprea* has lately been offered for sale. This bark is readily distinguished from all other cinchona barks by its remarkably smooth inner surface, which is very fine grained. It yields about 1·75 of quinine and has a short fracture like hard Carthagena bark, but contains a quantity of red colouring matter, which is not easily separated from the alkaloids. Cinchona bark, stated to come from Borneo, has also been offered for sale.

At the recent bark sales in London this month cinchona bark from Jamaica appeared for the first time, and was sold at a good price, the red fetching 4*s*., and the crown bark 6*s*. per lb., the latter price being not quite so high in proportion as the bark deserved. From the *Gardeners' Chronicle* it appears that the sale of cinchona bark from the Government plantations in that island will reach £5000, so that the cultivation of cinchona in Jamaica may be considered to be commercially a success. The credit of introducing the cinchona into that island and Ceylon is claimed entirely for the Kew Gardens by Mr. W. T. Thiselton Dyer, in his recent address before the Colonial Institute.

In the same journal it is also stated that the botanical source of Socotrine aloes, according to specimens brought home by Dr. I. Bayley Balfour, must certainly be *Aloe Perryi*, Baker, instead of *Aloe Socotrina*, as heretofore.

A correspondent writing from the Cape of Good Hope gives it as his experience that Cape aloes is never to be obtained perfectly pure at Port Elizabeth, unless specially obtained as a curiosity, it being always mixed in ignorance with the juice of *Agave*.

Those persons who have ever accidentally tasted the stem of a pansy flower, by putting it in the mouth, will have become acquainted with the fact that the juice of the plant has a pleasant flavour. It is rather interesting to find from a chemical analysis made by M. Mandelin, and communicated to *New Remedies* by Professor Dragendorff, that the plant contains salicylic acid. Some years ago a writer in the *British Medical Journal* called attention to the heartsease as a valuable remedy for the cutaneous disease called *crusta lactea* in children, the decoction of the leaves in milk being taken, and poultices of the leaves applied. Its beneficial action may therefore be now accounted for by the presence of salicylic acid—if that does, as M. Mandelin supposes, exist in a separate state in the plant. As the leaves yield on distillation an acrid oil, possessing the flavour of the plant, it yet remains to be proved if the salicylic acid be not a product rather than an original constituent of the plant.

Salicylate of quinine seems to be increasing in favour with the medical profession. Dr. A. Hewan states that while toxic effects more or less serious result from the administration of salicylic acid and salicylate of soda in doses thought necessary to reduce the temperature, no injurious consequences whatever have hitherto followed the free use of salicylate of quinine given even in its full dose of 3 grains, while greater benefit has been derived from it than from salicylate of soda or salicylic acid. Mr. Dearden, of Church, near Accrington, has published in the *Lancet*, May 1, p. 697, a formula for an extemporaneous preparation of salicylate of quinine, which is as follows:—Salicylic acid, 1 drachm, disulphate of quinine, 10 grains, simple syrup, 1 ounce, strong liquor ammoniæ, 1 drachm, water to 12 ounces. The acid and quinine are put into the bottle with about 8 or 9 ounces of water, the liquid briskly agitated for a few seconds. The bottle is allowed to stand a little while uncorked, the liquor ammoniæ then added, and finally the syrup and the remainder of the water. A few drops more of the ammonia may be required to get a perfectly clear solution. It is necessary to remember that only the natural salicylic acid should be used, or at all events, salicylic acid freed from the other acid which Mr. J. Williams showed some time since to be present in the salicylic acid obtained from carbolic acid. It is impossible to say until more is known of that second acid, how far the cases of poisoning by salicylic acid and salicylates may be due to its presence in commercial salicylic acid.

Whooping cough has lately been very prevalent around London, and, consequently, various remedies have been advocated. According to a recent letter in the *Lancet*, May 8, p. 749, Dr. Mott, of New York, recommends quinine as a remedy for whooping cough, on account of the influence of this drug in preventing the growth and development of the fungus which he, as well as Dr. Letyerich, has found in the sputa, and which is believed to be the cause of the disease. He recommends the quinine to be given in the form of powder mixed up in syrup. Dr. J. Lowe, of King's Lynn, states that he has found the internal administration of benzol a successful remedy in this troublesome disease, when the acute stage is past and the lungs free from congestion. His formula is as follows:—Benzol 2 to 10 minims every four hours in combination with tincture of henbane, compound tincture of chloroform, mucilage of acacia and water. The benzol must, however, be quite pure, in which state it has an aromatic or ethereal odour, and not the strong gas-like odour generally present in ordinary commercial samples. Cases of poisoning by benzol he attributes to impurities contained in it.

Chian turpentine still continues to attract considerable attention in medical circles. In the *Lancet* for May 15, p. 783, Professor Clay gives the tests by which he judges of the purity or genuineness of this substance, which may be briefly summarized thus: If it has a bitter taste it is not pure; if it contain Canada balsam, on heating it the characteristic odour of that substance will be evolved; if it gives off an odour of turpentine when heated and is entirely soluble in alcohol it is not pure; the odour is between that of fennel and elemi, and the taste slightly resembles that of mastic; the powder on the surface shows no trace of crystalline structure when examined under the microscope. Dr. Battye suggests that Strassburg turpentine is the best substitute for Chian turpentine on account of its containing more silica, to which he supposes the efficacy of Chian turpentine to be due, forgetting, apparently, that Dr. Clay expressly states that in his hands Venice and Strassburg turpentines "have not produced the same beneficial effects on cancerous growths as Chian turpentine has done," while he finds Canada balsam to be "positively injurious" in cancer. As there is in circulation in trade some "Chian turpentine" which is nothing more than dried Canada balsam, pharmacists will do well to make themselves well acquainted with the odour of that drug. This so-called Chian turpentine is of a pale yellow colour, perfectly clear and transparent, with a powdery surface, but when chewed or heated is readily recognized by its odour and taste, which are totally different from the fennel-like odour and mastic-like taste of the genuine drug.

The *British Medical Journal*, May 15, page 744, quotes from the *Recueil de Médecine Vétérinaire* a statement by M. Bouley to the effect that garlic has been known to subdue the symptoms of hydrophobia. "A young man who had been bitten by a mad dog speedily presented the symptoms of hydrophobia. His family, in a state of great alarm, scarcely knowing what to do with the sufferer, shut him up in a loft where some garlic had been left to dry. In his delirium the poor fellow seized the bundles of garlic, ate greedily of them, and soon became exhausted and fell into a deep sleep. When he awoke he was cured and the symptoms of rabies had disappeared." Possibly the medicinal properties of garlic have been too much neglected. During the prevalence of cholera the Jews are said to have used with success the application of garlic to the pit of the stomach and the soles of the feet, and it is generally believed by sailors that onions have the property of absorbing diseases, and that those who partake of onions which have been lying in the room in which there is a person ill of an infectious disease will assuredly take the disease. There is often some germ of truth in generally accepted facts.

It is possible that some who in glancing over a recent number of this Journal came across the uninviting words "homatropine" and "oxytoluyltropeine," turned over the page with a half-formed wish that it were occupied with subjects more akin to pharmacy. But this was not the case with all, for by the prompt action of an English pharmacist the chemical curiosity became, within a few days of the first appearance of its description in this country (see before, p. 751), the subject of a physiological research, with the result that the substance with the unfamiliar names promises to take a place in the pharmacy as an addition to our mydriatics. The hydrobromate salt of homatropine or oxytoluyltropeine, the base which is obtained by the treatment of amygdalate of tropine with dilute hydrochloric acid, has been used in a series of physiological experiments by Mr. John Tweedy, who reports (*Lancet*, May 22) that it appears to possess many of the properties of atropine, but in a weaker degree. Dr. Sydney Ringer also adopts this statement as describing its action on the eye, but says that though relatively weaker than atropine it is not merely weaker in the sense that it only does what a weak solution of atropine would do, since its action on the iris and ciliary muscle is very powerful while it lasts. A solution of hydrobromate of homatropine, four grains to the ounce, widely and fixedly dilates the pupil in from fifteen to twenty minutes, and affects the accommodation in an equally rapid manner. Its chief peculiarity and advantage seem to be that its effects disappear much more rapidly than those of atropine, and it is moreover said to be singularly unirritating to the eye. It is important that homatropine should not be confounded with the amygdalate of tropine from which it is prepared, for the amygdalate has been found to be quite inert, in the sense that it does not possess any of the properties of atropine.

In the *Berliner Klin. Wochenscrift*, 1880, No. 12 and 13, Dr. O. Pinner calls attention to the use of a solution of acetate of alumina as an antiseptic in surgical operations. For this purpose a $2\frac{1}{2}$ per cent. solution is used at first, and reduced afterwards to 0·05 per cent., which is found to be strong enough to disinfect and deodorize perfectly. Dr. Pinner finds that a solution of the strength of 1·5 to 2 per cent. will stop all movement in bacteria, and prevent their multiplication in a liquid containing them. A full account of the mode of using it, etc., may be found in the *Medical Times and Gazette*, May 8, p. 507.

Sulphate of soda has been found (*Zeits. d. Oester. Apot. Ver.*, xviii., 43) by Herr Sonneberg to be useful in the treatment of poisonous effects produced sometimes by the prolonged use of dressings with a 5 per cent. solution of carbolic acid. The dose is 5 to 8 grams of sulphate for adults, and 2 to 5 grams for children, in 200 grams of water. The urine, which in such a case has become deep green tinged with brown, quickly reassumes its normal colour and the dressings can then be continued without danger.

A very curious instance of the toleration of opium by an infant is published in the *British Medical Journal* of May 15. In this case to an infant of four months old its mother administered from 6 to 8 drachms of laudanum in twenty-four hours to relieve abdominal pain. As a rule, infants are much more sensitive to the influence of opium than adults, hence this instance of idiosyncrasy is all the more remarkable. It would have been interesting to know whether either of the parents were accustomed to take laudanum.

The sale of the various forms of sea salt is likely to be diminished in London, for it is announced that the Great Eastern Railway Company will undertake to supply sea water to any part of London within their ordinary delivery at the rate of 6*d.* for 3 gallons. The water is to be brought from Lowestoft and delivered at any address in air tight cans for the price named, the cans being left if required until the following day, when the Company's vans will call for them without any extra charge. Not only will Londoners be able to have a "real sea bath in their own room," but can now keep marine aquaria in their own houses.

According to M. Judicis (*Répertoire*, May, p. 198), the methods of adding alcohol, heating and fermentation for the preservation of lemon juice are all unnecessary, since the unfermented juice simply allowed to deposit and filtered through paper may be preserved in well closed bottles perfectly well. The disadvantage in this method is the slowness with which the juice filters.

Killing the slain is a proverbially useless occupation, and ostrich pepsine has so recently received its quietus in this Journal that almost an apology is due for referring to it here again. Exception, however, is craved in favour of a note on a communication from a correspondent at the Cape, who has had peculiar facilities for observing the bird both in the healthy and diseased state. This gentleman states that he is perfectly certain that the digestive powers of the ostrich are very small and only effective on certain kinds of food, and that the tenpenny nails and iron bolts upon which its digestive reputation is based are not digested at all, but simply bent and crushed by a powerful gizzard that is so thick and tough as to be with difficulty cut by a knife. The writer vouches that he has himself seen buttons and coins that have been worn to the thickness of wafers by the grinding action of this organ, and that the hardest stones assume a fine polish under its action. It would be a pity to spoil, by a paraphrase, the *naiveté* of what follows: "When a bird is in poor condition, and fed on maize, by carefully dividing the breast feathers you can hear this gizzard, or living grinding mill, at work." Presuming upon the possession of such an apparatus ostriches eat so enormously that stoppages, which unless relieved will kill a bird in twenty-four hours, not unfrequently result; powerful drastics are then given, of which they are said to require a larger dose than a horse. What this bird's long-enduring stomach can bear is, however, illustrated by the following list of articles which, according to *Nature* (May 20), were found in the stomach of an ostrich that recently suffocated itself at Rome by thrusting its neck through the bars of its cage—four large stones, eleven smaller ones, seven nails, a necktie pin, an envelope, thirteen copper coins, fourteen beads, one French franc, two small keys, a piece of a handkerchief, a silver medal of the Pope, and the cross of an Italian order.

The researches of Messrs. Hannay and Hogarth, by which they claimed to have shown that solids might be dissolved in gases, have attained additional interest since their association with the artificial production of the diamond. The subject is continued in a paper by Dr. Ramsay, read before the Royal Society on April 22, which describes some experiments and gives deductions from them which are not in accord with those of Messrs. Hannay and Hogarth, and if correct, are important in their bearing on views as to the nature of the different forms of matter. It may be stated at once with respect to one of Messrs. Hannay's experiments which has been referred to in these columns, that Dr. Ramsay holds it to be certain that potassium iodide is absolutely insoluble in alcohol vapour. In one of the experiments sufficient methyl formate was introduced into a tube drawn out in the centre to a capillary passage to fill to about two-thirds one of the two chambers; heat was then applied so as to fill the remainder of the tube with vapour and the tube sealed. Upon heating the sealed tube, the liquid, as usual, expanded, and at the moment when the meniscus disappeared it nearly filled one half of the tube. On cooling the liquid always condensed entirely in the portion in which it was originally placed, and this occurred whether that portion was kept higher or lower than the other during the experiment. It was noticed that the half of the tube in which the liquid was placed appeared full after the meniscus had vanished, while the other seemed empty, but Dr. Ramsay has reasons for believing that the specific gravity of the matter in both portions is the same at the temperature at which the meniscus vanishes. When an alcoholic solution of potassium iodide was used it condensed similarly in the portion of the tube in which it was originally placed and no trace of the salt could be found in the gas when the other portion was broken off and examined. Dr. Ramsay's theory appears to find utterance in his definition of the "critical point" as "that point at which the liquid, owing to expansion, and the gas, owing to compression, acquire the same specific gravity and consequently *mix with one another.*"

Among the lectures of the month may be mentioned one delivered before the Society of Arts, by Dr. B. W. Richardson, on the ingenious diving apparatus invented by Mr. Fleuss, in which by the gradual release of compressed oxygen an accessible atmosphere can be maintained in a condition compatible with life. The oxygen is stored up in the helmet in a chamber of the capacity of one-quarter of a cubic foot and capable of bearing a pressure of sixteen atmospheres, into which sufficient oxygen can be introduced under pressure to last for breathing purposes during five hours. A cuirass that is worn contains two metal chambers which are fitted with small particles of porous indiarubber, saturated with solution of caustic soda. The breathing is effected through a leather ori-nasal mask, fitting closely to the face. In the inspiration the air is drawn through two valves, opening inwards, one on each side of this mask, and in expiration it passes downwards through a kind of artificial wind-pipe to the first chamber in the cuirass and then to the second. Here the carbonic acid is taken up by the soda, the moisture condenses and runs into a receptacle, and the nitrogen and the residual unused oxygen pass upward and escape through an opening near the shoulder into the helmet, where it is renovated by oxygen from the store chamber, the supply of which can be controlled by means of a tap in the helmet, so as exactly to compensate for the quantity consumed. Using this apparatus it is claimed that a person may remain under water as long as he can go without food. What is quite as important, perhaps, is that it renders it possible also for a person to remain for a long time without injury in a noxious atmosphere, as has been demonstrated in some experiments conducted under the superintendence of Dr. Richardson, in which Mr. Fleuss remained twenty minutes in the diving bell at the Polytechnic Institution, when filled with carbonic acid, and afterwards for a similar time in an atmosphere of amyl hydride.

The vacancy at the School of Mines caused by the regretted resignation of Dr. Percy, has been filled by the appointment Mr. W. Chandler Roberts, who, since the year 1870, has held the post of chemist to the Mint. It is a curious coincidence that the annual report of the Deputy Master of the Mint for 1879, which has just been issued, contains an interesting summary of the work done in the chemist's department during the past ten years, put forward apparently as a justification of the institution of the office, and as evidence that a mint cannot be properly conducted without constant attention to the progress of metallurgical science. Amongst the points specially mentioned are the adoption of the chlorine process for toughening brittle gold, by which a fertile source of dispute between the Mint and the Bank, as to the right to return bars unfit for coinage, has been removed; the spectroscopic investigation of the alloys of gold and copper, carried on in conjunction with Mr. Norman Lockyer, which have demonstrated the possibility of distinguishing between alloys differing in proportions by only one-thousandth part; and experiments made with Professor Hughes's induction balance, the action of which depends upon the fact that equal and similar volumes of various metals or alloys exercise widely different effects on an electric current flowing round a coil of wire. Professor Hughes's original instrument has been modified and improved, and is now capable of detecting minute differences in the composition of alloys within certain limits, but unfortunately these do not include the gold-copper alloys used for coinage.

The number of pieces struck at the Mint during 1879 was 30,050,344, as against 24,491,230 in 1878, and their value, real or nominal, was £662,664 3*s.* Of these the British coins numbered 27,800,344, having a value of £648,289 3*s.* 0½*d.* The remainder consisted of coinage for the Hong Kong Settlement and Cyprus. Notwithstanding that since the introduction of the bronze coinage in 1860, bronze coins to the value of £1,446,000, or nearly three times the entire value of the old copper coinage, have been issued, the demand for it in this country shows little tendency to decrease, the nominal value of the issue last year having been £38,970. The annual profit or loss on the operations of the Mint usually depends mainly on the amount of silver bullion purchased, and the quantity of worn silver coin withdrawn from circulation, the bullion being converted into coin at a profit to the State, whilst the worn coin, purchased at its full nominal value, is recoined at a loss. The average of the past eight years shows an annual profit of £21,117, but last year there was an excess of loss amounting to £29,499. On the other hand, the profit on the entire bronze coinage struck last year was £35,396. One source of loss is the dirt on the surface of the old gold coins, for which it is estimated that the department pays nearly £300 on every £1,000,000 withdrawn for recoinage.

The value of a medium of inquiry, such as is offered by the columns of this Journal devoted to dispensing queries, cannot be better illustrated than in the many replies, having a direct bearing on some one or other of the subjects, received from different parts of the country. In one of the April numbers of the Journal an inquiry was made for a formula for mist. scillæ, the writer stating that it occurred in a Scotch prescription that had been dispensed in Aberdeen. Mr. G. Wilson, in the Journal of May 15, p. 928, supplies the formula, and says that it is very much used in Scotland. The prescription being a Scotch one, the formula for its preparation from Christison would be used in preference to one from some other sources.

In prescription No. 407, it appears probable that signa quæ was intended by the writer; but whether that, sec. art., or quant. suff. was intended, one or the other, is quite superfluous, the prescription would have been intelligible enough in the absence of either of them. The Latin language often suffers damage at the hands of those writers who deal in elaborate directions.

The question whether zinci phosph. should be read as phosphide or phosphate, in prescription No. 408, is a very proper question for a dispenser to ask himself, when it may be either of the two preparations of zinc differing materially in their relative activity. When a difficulty of this kind occurs the dispenser must be guided mainly by the dose. Phosphide of zinc is given in doses of one-twelfth to one-fifteenth of a grain. The dose, therefore, of the zinci phosph. in the prescription is incompatible with phosphide of zinc, but corresponds with the average dose of the phosphate of zinc. In this case phosphate of zinc should be used by the dispenser in that prescription.

The position of a dispenser requires an amount of intelligence, which is not sufficiently appreciated either by the public on whose behalf it is so often exercised, or by some members of the profession who now and then fail to write their prescriptions with that exactness which could be desired. If brains determine the difference between the exercise of a profession and that of a trade, surely the pharmacist may claim a position on a rung of the ladder a little higher than is sometimes allotted to him.

The prescription No. 409 should be dispensed by dissolving the phosphate of soda in the greater part of the water, adding the tinct. colch., and lastly the quinine dissolved in the dilute phosphoric acid. The mixture should be quite as clear and colourless as water, having the faintest possible opacity due to the tinct. colch., but no colour or precipitate of any kind, or any separation; should either of these occur, distilled water being used, the cause may be looked for in the sodæ phosph. On standing twelve hours, however, there will be a copious deposition of needle crystals, most probably phosphate of quinine. It would materially add to the interest and value of the questions if the writers would state clearly the order of mixing adopted and also the result, together with their reason for requiring further information.

"Salicine" asks a question in No. 410, to which, the remarks just made equally apply. Where is the difficulty and what order of combining produced it? It is presumed that it is something which has resulted from the combination of potass. iodid. with quin. disulph. The quinine should be rubbed to a fine powder and suspended by the mucilage of tragacanth, and the potass. iodid., previously dissolved in the aq. camph. with the vin. aloes, should be added. A decomposition resulting in the formation of hydriodate of quinine will gradually take place, but it will be much retarded by the mucilage of tragacanth. Care must be taken to avoid bringing the potass. iodid. and quinine together without the greatest possible dilution, interposing at the same time the mucilage as a further preventive of decomposition. Two ounces of mucil. tragac. would be a fair proportion for that mixture.

The quinine in No. 411 should not be dissolved, but rubbed to a fine powder and diffused through the liquid, unless the writer's intentions to the contrary are known by the dispenser. It is quite possible that the writer may have intended the quinine to be dissolved, this being the most usual condition in which it is prescribed with ferri sulph. and magnes. sulph., and some dispenerss would assume such to be the case in this instance; but a pharmacist, without any further knowledge than is conveyed in this prescription, would be perfectly justified in sending out the mixture with the quinine in suspension, and with a "shake" label on the bottle. The difficulty in this instance seems to be in the solution or otherwise of the quinine, and the appearance of the mixture would depend on which view is taken by the person dispensing it. A dispenser may expose himself to censure for adding an acid which does not form a part of the prescription; but he could justify his sending out the quinine in suspension, on the principle of a strict adherence to the letter of the prescription without necessarily a lack of intelligence.

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.*

BY WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

Lecture II.

Pepsin and Trypsin—Digestion of Proteids.

Various kinds of albuminous or proteid substances are used by mankind as food. The most important of these are muscular flesh, the casein of milk and egg-albumen from the animal kingdom, and gluten, albumen and legumin from the vegetable kingdom.

Proteids are attacked by the digestive ferments at two points in the alimentary canal, by pepsin in the stomach and by trypsin in the small intestine. Between these two acts of digestion there is a complete break in the duodenum, owing to the abrupt change of reaction from acid to alkaline which occurs at that point.

Gastric digestion is, in all creatures, an essentially acid digestion; but the most varied opinions have been entertained as to the nature of the acid. It has been supposed in turn to be hydrochloric acid, lactic acid, acid phosphate of lime, butyric acid and even acetic acid. Much of this confusion has arisen from not distinguishing between the acid of pure gastric juice as secreted into an empty stomach and the acid of the gastric contents during the digestion of a meal. A good deal of light has been thrown on this subject by the recent researches of C. Richet.† This observer found himself in exceptionally advantageous circumstances for the study of the gastric juice. He had under observation a young man on whom Verneuil had successfully performed the operation of gastrostomy for the relief of impermeable stricture of the œsophagus, the result of swallowing inadvertently a quantity of caustic potash. The complete occlusion of the œsophagus enabled Richet to obtain and examine the gastric juice in a pure state, uncontaminated with saliva. All food had to be administered through the fistulous opening left after recovery, and the observer could at any moment—as in the famous case of Alexis St. Martin—withdraw portions of the gastric contents for examination. Richet also took advantage of the new method of separating the various organic and mineral acids from one another, made public by Berthelot in 1872.‡

Berthelot had found, on shaking up an aqueous solution of any acid with ether and then allowed the two fluids to separate, that a part of the acid passed into the ether, and that the remainder clung to the water, and that the ratio between these two parts was a constant quantity. He called this ratio the *coefficient of partage*, and found that its value was a fixed characteristic for each particular acid. Solutions of the mineral acids were found to yield nothing, or almost nothing, to ether when agitated with it; but organic acids were found to pass into the ether in considerable, though very variable, quantities, the proportion varying in a constant ratio according to the nature of the acid.

Testing pure gastric juice, uncontaminated with food or saliva, by this method, Richet found that almost all the acid was retained by the water, and that only a small proportion—about one in twenty-two—passed into the ether. This showed that the acid of pure gastric juice was almost entirely a mineral acid, with only a minute admixture of organic acid. The organic acid (tested by the same method) exhibited a coefficient of partage closely corresponding with that of sarcolactic acid. The nature of the mineral acid was determined by a method similar to that employed by C. Schmidt, and yielded the same result, namely, undoubted evidence that the mineral acid of pure gastric juice was hydrochloric acid. But

* The Lumleian Lectures, delivered before the Royal College of Physicians.

† 'Du Suc Gastrique,' by Ch. Richet. Paris: 1878.

‡ *Ann. de Chimie et de Physique*, 4e serie, tome xxvi., p. 396.

Richet found that this mineral acid did not behave in the presence of salts of the organic acids quite in the same way as free hydrochloric acid does. The observations of Berthelot had shown that when free hydrochloric acid is added to a solution of acetate of soda, or other similar organic salt, the mineral acid attaches the base entirely to itself and throws the whole of the organic acid free into solution, so that the mixture, when tested by the method of coefficient of partage, behaves exactly like an unmixed solution of the organic acid. When pure gastric juice was put to this test it was found that, although it liberated the organic acid largely, it did not do so to the same extent, by a good deal, as if the mineral acid contained in it had been entirely free. It behaved, rather, as hydrochloric acid does when united with a feeble organic base, such as leucin or peptone; and, on the ground of what appear to be very careful experiments, Richet came to the conclusion that this feeble base was probably leucin, derived from the gastric mucus, and that the acid of pure uncontaminated gastric juice was hydrochloric acid in loose combination with leucin.

Richet next proceeded to examine the free acid actually existing in the stomach during the digestion of a meal in his patient with gastric fistula. He found, as might have been expected, that this differed from the acid of pure unmixed gastric juice in this respect, namely, that it contained a very much larger proportion of organic acids, in comparison to the mineral acid, than pure gastric juice. It was evident that the mineral acid had to a large extent seized upon the bases of the acetates, malates, lactates, butyrates and other organic salts always present in the food and had set free their organic acids. The real work of digestion, then, so far as the acid constituent is concerned therein, is largely performed by various organic acids thus set free from the articles of food which are undergoing digestion.

Richet found that the acidity of the contents of the stomach during digestion, although it varied through considerable limits, had a marked tendency to maintain the normal average. If acid or alkali were added to the digesting mass the mean was presently restored automatically, the stomach in the former case ceasing to secrete acid and in the latter case secreting an increased quantity of acid.

The Effect of Gastric Juice on the Salivary and Pancreatic Ferments.—The observations of Berthelot on the power of a mineral acid to set free the acids of organic salts and to take their place with the bases, and the further observations of Richet, showing that the acids actually free in the gastric contents during digestion were organic acids, have led to the re-examination of a point of some importance, namely, as to whether the salivary, and more especially the pancreatic ferments, were or were not destroyed by the acid contents of the stomach. The matter has a practical interest in this way. If the gastric acid destroys these ferments, it is evidently useless to administer pancreatic preparations by the mouth during digestion, because they would be rendered inert by the acid contents of the stomach. On the other hand, if they are not destroyed in passing through the stomach, but merely lie dormant and recover their activity in the alkaline medium of the small intestine, then we can administer pancreatic preparations during digestion with every prospect of their passing uninjured through the pylorus and proving useful in assisting digestion in the small intestine.

A series of experiments bearing on this question were submitted by T. Defresne to the Académie de Médecine and the Académie des Sciences towards the close of last year, and have attracted some attention. On the ground of these experiments, Defresne arrived at the following conclusions, namely: that saliva continued its action on starch in the stomach without interruption; that the pancreatic ferments in like manner preserved their activity in the presence of the gastric acid; that the acids of the chyme, being organic acids, did not really destroy these ferments, but merely reduced them to a state of temporary inertness, so that when the acidity of the chyme was neutralized in the duodenum they recovered their powers and exhibited undiminished activity both on starch and on proteids.

As the question had a direct bearing on the medicinal administration of pancreatic preparations, and indirectly on the administration of malt diastase and malt extract, I thought it desirable to repeat some of Defresne's experiments and to put the question raised by these experiments to the test in other ways.

One of Defresne's (apparently) most convincing experiments was the following, which I give nearly in the words of the abstract of the paper published in the *Proceedings of the Académie de Médecine* for November 4, 1879. When 20 grams of dilute hydrochloric acid, having twice the acidity of the normal chyme, are mixed with 20 grams of egg albumen, what follows? The acidity of the medium is no longer due to free hydrochloric acid, but to the lactic and phosphoric acids of the white of egg which have been set free. In presence of these acids pancreatine may be digested for two hours in the warm chamber with impunity. And if at the end of this period the acidity of the mixture be neutralized, digestion is accelerated and the pancreatine peptonizes thirty-eight times its weight of albumen.

I repeated this experiment in the following manner:—Forty grams of chopped boiled white of egg were mixed with 40 cubic centimetres of dilute hydrochloric acid of the strength of 4 per 1000. This mixture was subjected to a preliminary digestion of two hours in the warm chamber at 40° C. (104° F.). The object of this preliminary digestion was to allow the hydrochloric acid a sufficient time to seize on the bases, and to set free the organic acids of the white of egg. At the end of this time, 5 cubic centimetres of an active extract of pancreas were added to the mixture. A second experiment was arranged in exactly the same way, except that filtered saliva was substituted for extract of pancreas. The mixtures were kept in the warm chamber for a further period of one hour, and were then filtered and carefully neutralized. On testing the neutralized filtrates, I obtained approximately the same results as Defresne. The diastatic and proteolytic ferments of the pancreatic extract were found active, but not so active by a good deal as if the extract had been diluted to the same extent with simple water. In the second experiment with the filtered saliva, the ptyalin had preserved its activity quite unimpaired.

These experiments, however, involve a fallacy which vitiates the deductions intended to be drawn from them. White of egg has a highly alkaline reaction, and although the acid used in the experiment possessed double the strength of the normal gastric juice, it was found that the mixtures, at the end of the two hours' preliminary digestion, had only a comparatively feeble acidity—in fact, only one-seventh of the normal acidity of the gastric contents. It has long been known that the salivary and pancreatic elements are able to resist a feeble acidity, but the question really at issue is: Can these ferments resist the average acidity of the contents of the stomach, when, moreover, this acidity is rendered still more destructive to them by the presence of pepsin?

I tested the question in this way. A distinction is drawn, and rightly, between acidity due to free hydrochloric acid, and a similar degree of acidity due to an organic acid. Now, lactic acid is a typical organic acid, and it is also an acid which is often, if not always, present in the contents of the stomach during digestion. I prepared a solution of lactic acid corresponding in saturating powers to the normal gastric acid (2 per 1000 HCl). To 50 cubic centimetres of this dilute lactic acid, I added 5 cubic centimetres of a solution of pepsin, and 5 cubic centimetres of an active extract of pancreas. I prepared a second similar experiment, but substituted filtered saliva for pancreatic extract. The mixtures were then placed in the warm chamber for one hour. At the end of this period the solutions were exactly neutralized and tested. They were both found to be absolutely inert. Not a vestige of amylolytic nor of proteolytic power had escaped destruction.

I had an opportunity of trying the same question in a still more satisfactory way. While I was examining the throat of a patient suffering from an ailment which did not affect his general health, a portion of the contents of the stomach was ejected, and fortunately caught in a clean vessel. This was immediately filtered, and about 10 cubic centimetres of clear acid solution were obtained. The period of digestion was three hours after breakfast. One half of this was devoted to testing its saturating power. It was found to possess an acidity very nearly corresponding with that of normal chyme. To the remaining portion five drops of extract of pancreas and five drops of filtered saliva were added, and the mixture was placed in the warm chamber for one hour. At the end of this time it was exactly neutralized, and divided into two equal portions. One portion was tested with a drop of starch mucilage, and found to be absolutely devoid of amylolytic power. The other portion was added to an equal volume of milk rendered slightly alkaline with bicarbonate of soda, and was then placed in the warm chamber. Not the slightest digestive action was produced on the milk in twelve hours.

I may mention that in the above experiments I used milk as the test of proteolytic activity. I had become thoroughly familiar with the behaviour of milk with pancreatic preparations during a long course of observations, and was therefore able to detect the slightest signs of pancreatic action.

With this evidence before me I am unable to accept the conclusions of Defresne and others in Paris, who allege that saliva and pancreatic preparations can resist the normal acidity of the stomach in full digestion, and who recommend the administration by the mouth of pancreatic preparations during the period of chymification. I will in my next lecture point out the time and the method in which these preparations may, I believe, be administered by the mouth with sure prospect of success.

Digestive Proteolysis.—The changes undergone by albuminoid substances in digestion are still very imperfectly understood. It is, however, known that the chief end-product of the transformation is peptone. It is also known that between any native proteid—egg albumen, muscle-fibrine, casein, or legumin—and the end-product, peptone, there are intermediate grades and by-products, which have hitherto proved difficult to define and isolate. The constitution of the proteid molecule is still unknown to chemists. That it is a highly complex aggregation is certain; and it can scarcely be doubted that the way to a better knowledge of its constitution lies in a persevering study of the action on it of the digestive ferments. It has been already seen that in the case of starch the action of diastase furnished the key to the constitution of the starch molecule; and, similarly, it is not unreasonable to expect that the mystery of the proteid molecule will be finally solved by a study of the action on it of pepsin and trypsin. Attention has hitherto been too exclusively directed to peptic digestion, which is complicated by the interaction of an acid. Pancreatic digestion is, in this respect, a simpler process—inasmuch as it requires the interference neither of an acid nor an alkali, but is a reaction, pure and simple, between the ferment and the proteid. This, however, is a question of the future.

Characters of Peptones.—The end-product, peptone, has been fairly isolated and its characteristics defined. If the filtered product of a pancreatic digestion of egg albumen be evaporated to dryness in a watch-glass at a temperature of 104° F. (40° C.), there remains a glassy straw-coloured residue resembling dried gum. With the point of a penknife this can be chipped off in shining scales, which may be easily reduced to a fine whitish powder—this is nearly pure peptone. This substance is extremely soluble in water; and its solutions, even when highly concentrated by evaporation, betray no jellying and no viscosity, but continue diffluent almost to the moment of desiccation; only just before drying up do they assume a slightly syrupy consistence. When the latter point is approached, the solution deposits beautiful white crystalline sheaves of tyrosin and spheres of leucin. From the constancy with which these crystalline bodies make their appearance in pancreatic digestion, it may be inferred that they constitute an essential portion of the final products of the transformation.

The reactions of peptone are mostly of a negative character. Its solutions give no precipitation with nitric acid, nor with boiling, nor with ferrocyanide of potassium and acetic acid. The behaviour of peptone with alcohol is peculiar. When a strong peptone solution is dropped into absolute alcohol, the peptone is precipitated as a white sediment, but it is not truly coagulated into an insoluble modification, as all the other proteids are; for when the alcohol is removed, the deposit is found to have preserved its solubility in water—even after prolonged contact with the alcohol. Solutions of peptone are precipitated by those metallic salts which throw down other proteids, also by tannin when the solutions are neutral. When the solutions are rendered alkaline, the cupro-potassic test (Fehling's solution), added in very small quantity, produces a rose-red coloration, whereas other proteids produce a violet tint. Physiologically, by far the most important reactions of peptone are its extreme solubility in water and its diffusibility through organic membranes. With regard to the latter point, contradictory statements have been made by different investigators. Otto Funke rated the diffusibility of peptone through the membrane of the small intestine higher than that of common salt. On the other hand Von Wittich concluded that peptones did not pass through parchment-paper more rapidly than unaltered albumen. My own observations support the view that peptone is incomparably more diffusible through parchment-paper than the native proteids. In the case of milk, the effect of digestion is very marked in regard to its behaviour in the dialyser. When milk was dialysed for forty-eight hours into twice its volume of water, not a trace of proteid matter could be detected in the diffusate; but when milk had been previously digested for a couple of hours with pancreatic extract, an abundant reaction with tannin and Fehling's solution was obtained after dialysing it for eight hours.

My results with egg albumen were equally striking. I prepared a solution by agitating white of egg with nine times its bulk of water, and straining the product through muslin. When this solution was dialysed into twice its volume of water for thirty-two hours it yielded absolutely no reaction with tannin nor with the cupro-potassic test. But when the same solution was previously digested, either with pepsin and acid or with pancreatic extract, and then dialysed, it gave in five hours a slight but distinct reaction, both with tannin and with Fehling's solution, and in sixteen hours a most abundant reaction.

The theoretical views held by physiologists in regard to the intimate nature of the transformation undergone by proteids in the presence of pepsin and trypsin are still unsettled, but recent opinions converge towards the idea that the process is, in the main, one of progressive deduplication with hydration, similar in type to the transformation of starch by diastase. This view receives a positive support from the recent analyses of Henninger. By operating on highly purified albumen, fibrin and casein, Henninger* succeeded in obtaining peptones in a state of great purity. An analysis of peptones so obtained indicated that they contained less carbon and nitrogen, and proportionally more hydrogen, than their

* A. Henninger, 'De la Nature et du Role Physiologique des Peptones.' Paris: 1878.

original proteids. The differences were, it is true, small, but they pointed distinctly in the direction of the conclusion that there was a fixation of the elements of water by the proteid, in the course of its transformation into peptone.

Henninger also believes that he has succeeded in reversing the process and in reproducing an albuminous substance from peptone by operating on it with dehydrating agencies. He found that when fibrin-peptone was heated with anhydrous acetic acid at 80° C. (176° F.), or was maintained for an hour at the temperature of 160° to 180° C. (320° to 356° F.), it yielded a body which agreed closely in its reactions with syntonin.

The intermediate products which are generated in the course of proteid digestion, and stand between the original proteid and the end-product peptone, are very imperfectly understood. The laborious reseaches of Meissner and Kühne have shown that several such intermediate bodies are produced, but these have not yet been adequately isolated and defined.

SULPHUR DEPOSITS IN ICELAND.*

BY C. G. W. LOCK.

The principal localaties where sulphur is found are the Hlítharnámar, the Kraflanámar, the Fremri-námar, at Theistareykir, and at Krísuvík, besides minor quantities at Hengill, and other spots. I have spent more or less time at all these places, but my chief experience has been with the four first-named. Vapours are emitted in abundant clouds from vents and fissures in the earth's crust; and around these openings are found deposits of "flowers of sulphur," or sulphur in a very finely divided state.

I am aware that it is the fashion to describe the sulphur mines of Sicily and the sulphur diggings of Iceland on parallel lines. For all practical considerations, however, they are as distinct as a coal-seam and a forest. The Sicilian mines consist of deposits formed in past geological ages, now lying at great depths, and utterly devoid of reproductive power; the Icelandic beds, on the other hand, are the work of to-day, lie on the very surface of the ground, and live and grow with unabated energy, replacing the deposit as fast as it is removed. It is not surprising, therefore, that the minerals themselves show no analogy, beyond the fact that sulphur is present in both. The Sicilian is a hard mass of sulphur-impregnated rock; the Icelandic is a sulphur powder, more or less contaminated with foreign materials. The area comprised in the Icelandic sulphur districts collectively amounts to, perhaps, a dozen square miles; but it must not be supposed that the whole of this is equally productive. The photographs on the table will give an ideal impression of the sulphur grounds; the green spots indicate the live vents. In a very recent consular report, it is stated that an Edinburgh firm now has the whole of the brimstone trade of the islands in its hands. This is emphatically incorrect, and a good opening still exists for anyone who will learn wisdom from experience. In searching the history of the working of these beds, it will be found that the chief causes of failure, when it has occurred, have been constitutional defects in the associations formed for the purpose, and ignorance of the requirements of the case. The sulphur itself has, in no instance, been wanting; indeed, it is being constantly renewed. It forms a layer of varying thickness, covered by an earthy crust, and underlaid by clays, containing sulphur mixed with various acids and salts. The sulphur layer is invariably very wet, in consequence of the steam condensed among it. The sulphur crystals are almost absolutely pure, but the simultaneous formation of other minerals, such as gypsum, and various accidents of broken surface, wind, wash, etc., help to create a mechanical admixture of impurities; so that the bodily removal of the whole sulphur layer would yield a product containing about two-thirds sulphur to one third impurities. Ingenious plans have been devised for separating these impurities. Two or three centuries ago, when the wars of Scandinavia were kept alive with gunpowder made from Icelandic sulphur, the method in vogue was to melt the crude mineral with train oil; the latter, taking up the earthy matters, was easily skimmed off the surface. The site of the refinery at Húsavík may still be pointed out, and deserves a visit; but let us hope that visitors, finding stray remnants of the mineral, will not, like the Edinburgh Reviewer, straightway enlarge upon the "sulphur mines of Húsavík."

The company which worked the northern diggings decided against refining of any kind, a notion being current that, with sufficient care, the sulphur might be gathered in a clean state, apart from mineral impurities. Practice demonstrated, however, that the operation, which appeared so easy in collecting pocket specimens, was exceedingly tedious and costly when the quantity had to be reckoned by tons, while more sulphur had to be left than was extracted. Moreover, the dampness and fineness of the material, coupled with the viscissitudes of climate and transport, rendered the gathered mass a dirty, wet powder. A cargo sent home resembled that contained in the bottle. Its pulverulent condition unfitted it for sulphuric acid manufacture, and its impurity was a bar to its use for gunpowder. It was forced upon the market when stocks were heavy and prices exceedingly low, and it barely found a buyer at a figure that covered its cost. Instructions were then sent to smelt the crude sulphur in *calcaroni*, as is done in Sicily to this day; one moment's thought would have shown the absurdity of attempting to smelt a heap of wet powder in a country where there is no fuel.

It remains to suggest some improvement upon former plans. In the first place, I would advise the removal, from each pit, of all the sulphur earth, to be treated with bisulphide of carbon, in order to dissolve out the sulphur. Before subjection to the bisulphide of carbon, the sulphur earth would require drying; but this might be economically managed by utilizing the abundant natural heat of the steam emitted all around, in some such way as the well-known arrangement for concentrating the boracic acid solutions in the Maremma of Tuscany. Sulphur extracted by the bisulphide process is said to be preferred by gunpowder-makers and others, and has a much higher market value than the best Sicilian produce. The refuse earth may be returned lightly to the pits, so as to serve again as a filter and condenser for the escaping gases; but I would suggest a trial of the plan long ago pointed out by Dr. Foster, that of building, over the vapour-vents, suitably ventilated chambers, constructed of the ever-abundant basaltic blocks, in order to collect the future deposit as "flowers of sulphur," the most valuable form of the mineral.

The summer months should be devoted to shipping the produce, which may be collected and prepared at all seasons. The transport of the refined sulphur to the port, so far from being the great undertaking which some people prophesied, may actually be made a source of profit—at least, in the case of the northern diggings, which are the farthest inland. A tramway is to be condemned absolutely; it would be exceedingly expensive to build; it would cost a fortune to keep in repair; and it would be useless and unused eight months out of the twelve. The island possesses its own transport system, to which the natives are accustomed; it can accommodate itself to the ways, even when they are such as indicated in this sketch; it can be increased or diminished according to need; and it will cost nothing for repair. The basis of all transport in Iceland must be the Icelandic ponies.

* Extract from a lecture delivered before the Society of Arts.

BROMIDE OF ETHYL (HYDROBROMIC ETHER).*

BY JOSEPH P. REMINGTON.

This anæsthetic, which has attracted considerable attention lately, was the subject of a paper by the writer in 1877, which was read before the American Pharmaceutical Association at its meeting at Toronto, Canada. At that time the process which was recommended was a modification of that of Personne, and served well on the small scale to make the preparation experimentally; it was not expected that the demand would at any time be so great as to require a process adapted to a manufacturing scale; but the calls became so frequent that it was found necessary to devise a more practicable method than the one then recommended.

De Vrij's process,† which depends upon the decomposition of potassium bromide by sulphuric acid in the presence of alcohol, was again looked to as a basis for a working formula, and the process recommended by Dr. E. R. Squibb‡ for preparing hydrobromic acid by distilling from a mixture of potassium bromide, sulphuric acid and water, suggested a plan by which the contamination of ordinary ether could be avoided, and this process was subsequently recommended by Dr. Greene.§

In a series of experiments intended to ascertain practically the process which could be adopted if it be deemed advisable to introduce the new agent into the U. S. Pharmacopœia, the following is selected as the best:—

Potassium bromide (not powdered) .	58 parts.
Sulphuric acid, sp. gr., 1·838 . . .	44 ,,
Alcohol (clean), 95 per cent. . . .	44 ,,
Water	28 ,,

Pour the water into a flask having double the capacity of the liquid ingredients above, and gradually add the acid; when the liquid has become cool add the potassium bromide, and having placed the flask in a sand-bath, adjust a thermometer, and with a bent glass tube connect the flask with a well cooled condenser, insert a narrow glass tube in the cork of the flask, and by means of a short rubber tube connect it with a narrow glass tube which is terminated by a syphon; the shorter limb of this syphon is inserted in the bottle containing the alcohol, which is elevated three feet or more above the flask. Heat the contents of the flask to 116° C., and having attached a screw pinch cock to the short rubber tube of the syphon, allow the alcohol to drop or flow in a small stream into the flask, carefully regulating the rate of flow so that the temperature should not fall below 100° C., nor rise above 116° C. When all the alcohol has passed into the flask continue the distillation until the temperature rises to 116° C., and then disconnect the receiving flask. Agitate the distillate with an equal bulk of distilled water, to which has been added five parts of solution of soda (or sufficient to render the liquid slightly alkaline), and when the mixture has clearly separated into two layers, pour off the uppermost layer, and having introduced the heavier liquid into a clean flask, containing a few fragments of chloride of calcium, redistil it.

Bromide of ethyl is a colourless, very volatile liquid, not inflammable, having an agreeable odour, and a hot saccharine taste. Its specific gravity is 1·420. It boils at 40° C. (104° F.). It is very sparingly soluble in water, freely soluble in strong alcohol and ether. When a small portion is evaporated from a porcelain plate by causing it to flow to and fro over the surface, little or no foreign odour is yielded as the last portions pass off, and the plate is covered with a slight deposit of moisture.

ARIZONA SHELLAC.*

At a recent meeting of the California Academy of Sciences Professor Stillman read a paper on the gum and colouring matter found on the *Acacia Greggii* and the *Larrea Mexicana* or creasote plant. The gum which exudes from these plants is very abundant, and is the product known to commerce as shellac. The same plants produce lac dye. Professor Stillman suggested that California might compete with British India in supplying this valuable product. Mr. B. B. Redding said that these lac-yielding plants were as plentiful as sage-brush from Southern Utah to New Mexico, and from the Colorado Desert to Western Texas.

The lac is most abundant around stations on the Mojava and Colorado deserts, and exudes as the result of an insect's sting. Calcutta exports a million pounds sterling in value annually of shellac, selling at 25 to 35 cents a pound, and almost as much more of lac dye, selling at 30 to 40 cents a pound. In 1876 the United States imported 700,000 pounds of shellac alone. To collect this is simple work for boys, and will prove an important industry. It will require little or no capital. The twigs are boiled in hot water, and the gum rises to the top, is skimmed off, strained and dried on smooth stones, and hand-pressed into flakes, ready to make sealing wax or varnish. The residue, when allowed to settle, makes lac dye. The plants live on a rainfall of three inches a year.

In vol. vi. (Botany) of the Reports of the U. S. Geographical Surveys west of the 100th meridian we find the following information relative to these two plants, which would seem to be worthy the attention of commercial men and manufacturers:—

P. 108—"ACACIA GREGGII, Gray.—A small tree, 10 to 20 feet high, pubescent or glabrous, unarmed or with scattered stout recurved prickles; pinnæ 2 or 3 pairs, on a slender petiole; leaflets 4 to 5 pairs, oblong or oblong-ovate, 2 or 3 lines long, rounded or truncate above, narrower at base, rather thick, and with 2 or 3 straight nerves; flowers in cylindrical spikes an inch or two long, the peduncles equaling or exceeding the leaves; pods thin, coriaceous, flat, 3 or 4 inches long by 5 to 7 lines broad, shortly stipulate, acute, curved, glabrous, and reticulated, more or less constricted between the seeds; seeds half an inch long.—From Western Texas to Southern California; collected in Western Arizona, 1872."

P. 41—"LARREA MEXICANA, Moricand, *Creosote bush.*—Common from Western Texas to Kern County, California, and southward to Mexico. Dr. Loew's examination proves that the reddish-brown exudate on the branches, caused by an insect, will yield a red colouring matter showing all the reactions of cochineal. 'The alcoholic extract of the leaves, on evaporation, yields a greenish-brown residue of a specific and somewhat disagreeable odour, more strongly perceptible on boiling the extract with water. This residue is only to a small extent soluble in water, and the solution has an acid reaction. It yields a light yellow precipitate with acetate of lead. The part of the alcoholic extract that is insoluble in water is easily soluble in alkalies. It also dissolves in nitric acid at a moderate heat, whereby oxidation takes place. On addition of water a yellow brittle mass is precipitated.' The Mexicans are said to use an infusion of the leaves for bathing in with good effect in rheumatic affections." (Also vol. iii., Wheeler's Reports).

P. 80—"LARREA MEXICANA, Moric (*L. glutinosa* Engelmann), Valley of the Gila, Arizona.—This shrub is especially common on the hills bordering the Gila, also on the sandy wastes adjacent to Tucson and Camp Lowell, in Arizona, even imparting its strong odour to the air."

In the third volume of these reports this plant is also called stinkweed and etiontio.

WHAT IS A POTABLE WATER?

THE questions raised of late in reference to the water supply of towns have naturally brought into special prominence the subject of water analysis as a means of ascertaining the quality of water and its fitness for drinking purposes; but notwithstanding the importance of the data sought to be ascertained, such difference of opinion exists as to the significance of the results obtained by different systems of analysis, that in some cases the conclusions arrived at respecting a particular water supply are absolutely contradictory, while in many other cases they are at least discordant.

This discrepancy of opinion as to the wholesomeness of water has reference chiefly to the organic substance present to some extent in all natural water, and it has been rendered very apparent at recent meetings of the Chemical Society by Dr. TIDY's paper on River Water, of which an abstract was published in the Journal last March, and by the proceedings at the last meeting, which are reported in the present number. Dr. TIDY, as the advocate of rivers as a source of water supply, contends that the organic substance in river water undergoes such rapid alteration by atmospheric oxidation that, however dangerous the nature of the impurity and however objectionable the source of the pollution, a moderate flow along the course of a river is sufficient to ensure the total conversion of hurtful impurity into innocuous products and to render the water wholesome and fit for drinking. This is the doctrine put forward by the late Dr. LETHEBY and by Mr. HAWKSLEY, the engineer. It is one that finds favour with the proprietors of water works drawing their supply from rivers and with the local authorities of many towns, as well as manufacturers, both of which regard this doctrine as furnishing a reason for limiting to the utmost the restrictions to be placed upon their action as pollutors of river water by the discharge of town drainage and factory refuse.

This doctrine of spontaneous purification is, however, disputed by Professor FRANKLAND, and as the general result of experiments upon the subject he comes to the conclusion that there is not in the United Kingdom a single river long enough to provide for the oxidation of organic substances introduced into the water by sewage. Filtration of water for a considerable depth through well aerated soil is considered by Professor FRANKLAND to be a much more effectual means of purification, and he holds that while a long flow of water along a river is insufficient for removing all noxious material, downward filtration of polluted water may sometimes afford considerable guarantee that all hurtful impurity has been removed or rendered harmless by the conversion of its elements into other forms of combination. But even in regard to this possible purification of polluted water, Dr. FRANKLAND, as one of the Rivers Commissioners, reports that it is to be distinctly understood that although the purification of water polluted by human excrements may reasonably be considered on theoretical grounds to be some safeguard against the propagation of epidemic diseases, still there is not in the form of actual experience a tittle of trustworthy evidence to support such a view, but, on the contrary, there are cases which show that even very efficient filtration does not prevent the propagation of such disease by water.

Having regard to the importance of the wholesome character of water used for drinking, it becomes a matter of very general concern to consider first what constitutes potable water, and secondly, how to form a judgment on the suitableness of water for drinking purposes. This is especially the case at the present time, now that the Public Health Act has conferred powers on sanitary authorities to institute proceedings with a view to closing impure wells and other sources of supply, and has left the decision of such questions in the hands of local magistrates. Dealing with the matter from this point of view Mr. EKIN, of Bath, has just published a small *brochure* in which he propounds the questions above stated, and considers how far the results of different systems of analysis furnish valuable and trustworthy indications concerning the quality of water.

Leaving out of consideration the mineral constituents that are present to some extent in almost all natural water, as not coming properly within the scope of the term impurity, attention is directed to those materials derived from vegetables or animals, which are commonly spoken of as organic substances, and it is shown that the most dangerous impurity of water is that originating from its having been contaminated with surface drainage containing animal refuse. Examination of water for organic substance is therefore the first and most important thing to undertake in analysing a sample of water, and it may reasonably be taken for granted that the wholesomeness of any sample of water would be in some way proportionate to the amount of organic impurity. But what is the precise relation between the determined amount of organic substance and the quality of water? That is the essential thing to ascertain, and in endeavouring to do so a serious difficulty is encountered. Whatever means may have been adopted to determine the amount of organic substance in water, there will still be a want of means by which animal may be distinguished from vegetable organic substances, and hence it happens that the conclusions drawn from the results of analysis must always be, to some extent, conjectural, and the decision as to the quality of a particular sample of water very much a matter of judgment rather than one of experimental determination.

It is to this point that Mr. EKIN directs especial attention as the one of chief importance. He denounces the custom of laying chief stress on the mere amount of organic substance as one that is misleading and fallacious, and for this reason he contends that the standards of organic purity set up by the Rivers Pollution Commissioners and by other analysts have not in regard to the question of wholesomeness any foundation in fact. For the same reason, in speaking of the several methods of determining the amount of organic impurity in water, Mr. EKIN speaks of them all as being absolutely worthless, so far as distinguishing between organic substance that is dangerous and organic substance that is innocuous. As the result of a fair trial of all methods, he thinks they may probably be relied upon equally as giving a rough approximate indication as to whether organic substance is present in excess or not, and in so far a preference may be due to the method that is least troublesome and most convenient. But he holds that the nature and origin of the organic impurity in water are the points of paramount importance to be considered in deciding upon the wholesomeness of water.

It is only by the aid of collateral evidence that any knowledge of these important points can be arrived at. Sewage and animal excreta convey to water large quantities of putrescible organic material and ammonia, which by fermentation and oxidation give rise to the production of nitrites and nitrates, and by these changes noxious impurities are destroyed, and water gradually becomes purified. As regards the presence of oxidized nitrogen compounds in water, and its bearing upon the sanitary question as to the quality of water, Mr. EKIN holds opinions that are somewhat different from those commonly entertained, and he is decidedly disposed to look with at least suspicion upon water containing a large amount of nitrites and nitrates, inasmuch as they certainly indicate that the water has been contaminated with animal excreta, while at the same time it is not certain that the whole of the noxious impurity derived from that source has been destroyed. This may be the case even with water containing with nitrates only a very small amount of organic substance. In support of this opinion, Mr. EKIN refers to the case of spring water from the magnesian limestone, mentioned in the report of the Rivers Pollution Commissioners as containing on the average as much as 1·686 parts of nitrogen in the state of nitrites and nitrates, and but a minute proportion of organic substance, although at the same time the same water is described as having been previously polluted to such an extent as to mask its true character. In such a case as this Mr. EKIN would dissent from the representation of the water being "unpolluted spring water," as adopted by the Commissioners, and would prefer to class it among those of a suspicious nature at least.

Mr. EKIN considers, moreover, that it is not enough to prove that the organic substance in water is in a minimum amount and that ammonia and nitrites are absent, for waters presenting these apparently favourable characters have been found to give rise to illness, but that it is necessary to prove that the organic substance is harmless, that there are no specific germs or fever poisons present and that the organic substance will not vary with the rainfall. When these points are proved, but not till then, can the water be considered safe. This is certainly a high estimate of what is required in deciding on the quality of water, and though we thoroughly agree with Mr. EKIN as to the desirability of attaining such knowledge as he indicates, we cannot dispel the fear that we are still far from being able to command it. In regard to this point we would refer our readers to the remarks of Professor HUXLEY upon the possible consequences of the presence of bacteria in water, and if we may rely upon his statement, there seems some reason for giving up chemical analysis of water altogether. Whether by such a course the "biological turbidity" surrounding the subject of water supply would be removed or not we do not pretend to say, but so far as the chemistry of the matter is concerned, we are strongly disposed to think that we ought not to reject the aid that analytical results are capable of furnishing when used with caution, and without overweening assertion of the value appertaining to those obtained by particular methods. Above all things we believe that, as Mr. EKIN contends, it is not so much by the actual results obtained by any system of analysis that the quality of water is to be decided, but by making the inferences from those results subject to consideration of various collateral circumstances connected with the history of the water.

To those who are interested in the subject of water supply, we heartily recommend Mr. EKIN's *brochure* as being calculated to help them in forming sound opinions and also in carrying out any inquiry as to the quality of water that they may be called upon to make.

EXEMPTION OF NEW YORK PHARMACISTS FROM JURY SERVICE.

A COMMITTEE appointed by the New York pharmacists has just obtained the extension of the exemption from jury service to every licensed pharmaceutist or pharmacist carrying on his profession as a means of livelihood. It appears that the word "licensed" will limit the exemption to persons holding a licence from the Board of Pharmacy for the city and county of New York.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The annual general meeting was held in Anderson's College, 204, George Street, Glasgow, on Wednesday, May 12, for the purpose of electing the President and office bearers for the session 1880–81. The retiring President, Mr. Kinninmont, F.C.S., occupied the chair.

The Secretary was called upon to read the minutes of the previous meeting, which were confirmed by the members.

The President then asked the Secretary, Mr. John C. Hunter, to give his report of the Council work done during the closing session, of which the following is a summary:—

During the session 1879–80 the Association held six meetings at which papers were read on various subjects, abstracts of which have appeared in this Journal. The Council held three meetings for trade purposes. One of these was a general meeting of the trade to discuss what steps were necessary concerning the sale of patent medicines and proprietary articles by persons outside of the business at prices below their normal value. The result of its deliberations was to appoint a committee to draw out a list of those articles that might be reduced to meet the competition of outside traders, and the Committee was empowered to give its results to the Price List Committee, so that it might print the alteration in price of some articles already in the price list. This having been done, circulars were sent to the trade in and around Glasgow, recommending the adoption of the reduced prices for the articles mentioned therein.

The Council tried to get up a chemistry class under the charge of Dr. Milne, but as the number of students did not come forward it could not be gone on with, much to the disappointment of Dr. Milne, who had given himself a good deal of trouble in arranging the probable hours that might suit those who would present themselves. This was the only educational business of the Council during the session.

The number of members on the roll is just about the same as last session, and the attendance at the meetings during the session has been satisfactory.

The Secretary of the Assistants' Section, Mr. Adam, reports that five meetings have been held during the session, when papers were read on various subjects by Messrs. Lee, Simpson, Paris, Adam and Gilmour, and on the whole the attendance has been fair.

The President called upon the Treasurer, Mr. Maltman, to read his financial statement, which showed a balance of £7 16*s*. 6*d*. over expenditure for the session 1879–80, now closed.

Mr. John Currie, Sauchiehall Street, then said that it was extremely satisfactory to know that the finances of the Association were in a healthy state. He would move the adoption of the reports.

This was seconded by Mr. Brodie and carried by the members.

The election of President and office bearers for the ensuing session was then proceeded with, and the following gentlemen were elected for session 1880–81:—

President, Mr. Robert McAdam (Glasgow Apothecaries' Company); Vice-President, Mr. Robert Brodie; Hon. Secretary, Mr. John C. Hunter; Treasurer, Mr. Maltman; Librarian, Mr. Joseph A. Clarke. Members of Council: Messrs. Daniel Frazer, Alexander Kinninmont, Thomas Davison, John Currie (Sauchiehall Street), John McMillan, John W. Pettigrew, R. C. Rait, William Simpson, William Weir, John C. Steel, William White and John Fenwick. Auditors: Messrs. John Walker and Archibald Paterson.

Votes of thanks were unanimously voted to the retiring President, Mr. Kinninmont; the Treasurer, Mr. J. A. Clarke; and to the Secretary, Mr. J. C. Hunter.

EDINBURGH CHEMISTS' ASSISTANTS' ANNUAL SUPPER.

The Edinburgh Chemists' Assistants' Association held its third annual supper on the evening of Tuesday, May 18, in the Waterloo Hotel. There were about fifty gentlemen present. In the unavoidable absence of Mr. D. Maclaren, Ex-President, the chair was occupied by Mr. J. D. Robertson, President, Mr. Boa acting as croupier. After supper the chairman gave the usual loyal and patriotic toasts, which were warmly responded to, that of the Army, Navy, and Reserve Forces being acknowledged by Mr. C. P. Henry.

In proposing "Success to the Edinburgh Chemists' Assistants' Association," the Chairman said:—The toast which I have now the honour to propose is one in which most of you take a warm interest. It is now nearly three years since the idea of forming such an association was originated. An association existed previous to that date, but in the course of time it died a natural death. After the usual preliminaries the present Association became an established fact. On the occasion of the last annual supper, held at the end of the first session, the chairman paid a high compliment to the members on account of the fact that all the papers read during the session had been contributed by members of the Association, and I am proud to-night to be able to pay you the same compliment, and to say of the session just ended, that all the papers read at our meetings were of a highly interesting nature. In point of numbers our average attendance last session has been better than during the previous session. Though our membership is smaller than it might be, it will, I think, compare favourably with that of kindred associations in other places. Take London as an example, with a population about fifteen times that of Edinburgh and Leith, with, I suppose, a proportionate number of chemists, and I find the London association numbers seventy-five, and ours forty-five. It does not follow from this, however, that we should not do our utmost endeavour to increase our numbers; by all means let every member do his best to accomplish this object. Our present position is very satisfactory; to the future we look, not with fear and trembling, but confident that, with increasing numbers and more opportunities of meeting one another, we shall be able effectually to break down that apparently insurmountable barrier which exists between the assistants in this city. Our aim should be mutual improvement and progress; with these ever in our minds we can, individually, add much to the success of our Association and our annual supper. Gentlemen, I ask you to join me in wishing continued prosperity to the Edinburgh Chemists' Assistants and Apprentices' Association.

The toast having been enthusiastically responded to, a brief address was given by Dr. Andrew Wilson, who said he was honoured and gratified by being invited to be present at the annual supper of the Edinburgh Chemists' Assistants' Association. He had the duty before him of complimenting the assistants on the success of their endeavours to mutually improve themselves and their profession, and he did so with all cordiality. It was a pity that, as Thackeray had said, all the fine things one "thought of in the cab" should flit out of one's head before speechmaking time. Not to say that his "cab thoughts" were ever brilliant; but he found himself there that evening with but one thought, namely, that of saying that the status of pharmacy as a profession was being rapidly advanced. Now, they had the Major and Minor examinations guarding the entrance to pharmacy, and for these examination mercies he supposed they must be devoutly thankful. Examinations were simply a necessity in a profession like theirs, but, as a university examiner himself, he would remind all concerned that examinations were not, as they were too frequently made, an end. They were only a means to an end, and that was the higher culture of the profession, not merely as chemists and druggists, but as intellectual men. Let them not lose sight of that fact. Sometimes the details of examinations were hard and grievous to bear; but whether too stringent or not, their system of examinations would bear fruit in time to come, and would, he contended, raise the professional status. It had been his fortune to meet not a few earnest lads, who, whilst serving behind the counter, had manfully fought their way through a medical curriculum, and were now in the ranks of the medical profession. That spirit of industry and work, he thought, prompting a man to better things, would be fostered by wise examination rules. Last of all, he would say, work for culture. Find in studies (such as botany or some other branch of natural science, or in literature) a source of intellectual recreation, when business cares and worldly worries are laid aside for the nonce. Elevate the intellectual side as individuals, and the advance of the profession was an assured thing. He again congratulated the assistants on their good work of the past session, which seemed to him to augur hopefully for the future.

Mr. Hutton, in proposing "The University and Royal Colleges of Physicians and Surgeons," referred to the many illustrious men who had been trained within their walls. He thought that a friendly relation ought to be maintained between chemists and medical men, as the former had frequently to consult the latter with regard to their prescriptions, and he suggested that much good might result if medical men occasionally consulted chemists with regard to the same subject.

The toast was acknowledged by Dr. Caird, who cordially reciprocated the sentiments expressed by Mr. Hutton, and referred to the many instances in which chemists could be of assistance to medical practitioners.

Mr. Fisher, in proposing "The North British Branch of the Pharmaceutical Society," referred to the deep interest which they all took in the prosperity of the Society at large. They rejoiced to see a friendly relation kept up between the Branch and the parent stem in London, by means of deputations to the various examinations. It was very gratifying to find that the importance of the North British Branch was yearly becoming more apparent by the ever increasing number of candidates who present themselves for examination, many of them hailing from across the border. The advantages which Scotch assistants derived from having a branch of the Society established in their midst could not easily be overestimated, and it must always be with gratitude that they recalled how zealously its leading members fought for its maintenance at a time when its existence was seriously threatened.

The toast was briefly acknowledged by Mr. Robert Stenhouse.

The other toasts were, "The Medical Gentlemen present," proposed by the Chairman, and acknowledged by Dr. Andrew Wilson; "The Office-bearers of the Association," by Dr. Black; "The Ladies," by Mr. Hill; "The Croupier," by Mr. Wallace, and "The Chairman," by Mr. Welsh.

The evening's proceedings were enlivened by a number of excellent songs and recitations, by members of the Association and others.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, May 20, Professor H. E. Roscoe, President, in the chair.

The following certificates were read for the first time:— P. S. Brown, E. Moritz and F. E. Matthews. It was announced that the Longstaff Medal had been awarded to Dr. T. E. Thorpe, of Leeds; the presentation will probably take place in October.

The President then called on Dr. Frankland to read a paper on—

The Action of Air upon Peaty Water. By Miss Lucy Halcrow and E. Frankland.—Dr. Tidy in his paper on "River Water" (*Chem. Soc. Jour.*, 1880, 295) contends that the peaty matter in running water is rapidly oxidized. He instances the water of the Shannon, which he alleges loses thus more than 38 per cent. of its organic matter during a flow of one mile, and the water supply of a town in the north of England, which similarly loses 50 per cent. of its organic carbon during a flow of less than four miles through an open brickwork conduit. If peaty matter in solution in water possesses this extraordinary affinity for oxygen at ordinary temperatures, it cannot be necessary to appeal for proofs of it to large bodies of water which are always more or less liable to alterations from other causes. The authors have, therefore, studied upon an experimental scale the action of exceptionally strong peaty water upon atmospheric air, so as to ascertain how far air loses oxygen by contact with such water, and have submitted to eudiometrical analysis, limited volumes of atmospheric air which had been exposed for various periods to the action of large volumes of peaty water from unpolluted mountain sources. A sample of peaty water, freely exposed in a stratum of 5 inches deep to the action of sunlight and air without shaking in a glass bottle for seven days, lost only 6 per cent. of its organic elements, at the same time depositing a slight brownish sediment. Four experiments are given as to the composition of the air which had for some time been in contact, without shaking, with peaty water; the following will serve as an example:—Original water contained 0·0399 parts of organic carbon and 0·074 N per 100000; after a year it contained 0·0354 C and 0·069 N; the air which had been in contact with the water contained CO_2 0·10, O 20·76, N 79·14. The results prove that the extent to which the peaty matter of the upland water was oxidized in periods of more than a year was very small indeed, as the carbon alone would have been sufficient to have taken up the whole of the oxygen from 100 c.c. of air. Experiments are next quoted in which the peaty water was violently agitated with air in accurately stoppered bottles of about 500 c.c. capacity, half filled with the sample under examination. The water before use contained in 100 volumes 2·01 vols. of air having the composition 1·99 per cent. CO_2, 31·96 per cent. O, 66·05 per cent. N, and was, therefore, well aerated. Four experiments are then given in which the water was well shaken with the inclosed air, in one case on the connecting rod of a steam engine making one hundred strokes per minute for ten and a half hours at temperatures from 18° to 30°. In no sample was the colour materially altered and the composition of the enclosed air remained almost unaffected. Thus the air in the bottle which had been attached to the steam engine contained 0·12 per cent. CO_2 20·75 per cent. O, 79·13 per cent. N. Analyses were also made of air which had been shaken up with the Kent Company's water, the Colne Valley Company's water, and pure distilled water respectively. An analysis of the atmospheric air used gave CO_2 0·12, O 20·94 per cent., N 78·94 per cent. The volume of air contained in each bottle was 234·5 c.c., and from this the organic carbon alone in the water (0·00728 grm.) would remove during complete oxidation 0·0194 grm or 13·5 c.c. of oxygen, leaving the residual air with only 15·1 per cent. of oxygen. If we compare the percentage amounts of oxygen found in the different samples of air which had been in contact with peaty water with those found in the air which had been similarly shaken up in the Kent and Colne Valley Companies' waters and in the organically pure distilled water, and lastly with the percentage of oxygen in the air of the room in which the experiments were made, it is evident that minute quantities of oxygen have been absorbed by nearly all the peaty waters, but even in an extreme case in which the water travelled more than twenty miles on the connecting rod of a steam engine, the amount of oxygen absorbed by 250 c.c. of extremely peaty water was only 0·345 c.c., which is scarcely one thirty-ninth of that required for the complete oxidation of the organic carbon alone, or in other words only $2\frac{1}{2}$ per cent. of the organic matter was oxidized. Assuming that all the oxygen taken up was employed in the oxidation of organic matter, and deducting from this percentage the amount of oxygen absorbed by the Kent and Colne Valley Companies' waters, we have only 1·6 per cent. of total organic matter in the peaty water oxidized in the steam engine experiment. The authors, therefore, conclude that if peaty matter dissolved in river water is spontaneously oxidized (of which there is as yet no sufficient proof) the process takes place with extreme slowness, and cannot be accomplished to any considerable extent in the flow of a river. During the experiments a considerable precipitation of brown peaty matter was observed when the strong bog drainage was mixed with a small bulk of distilled water. The cause of this precipitation the authors intend to investigate.

The President, in proposing a vote of thanks to Dr. Frankland and Miss Lucy Halcrow (who was present at the meeting), said it would perhaps be advisable not to take the discussion on this paper until Dr. Frankland had read a further communication.

Dr. Frankland, in ackowledging the vote of thanks, said that the work in the paper was almost entirely carried out by Miss Halcrow.

The President then said that the discussion on Professor Tidy's paper would now take place. He suggested that it would be well to limit the discussion to the point of the oxidation of organic matter in rivers. He then briefly mentioned the chief statements in Professor Tidy's paper, on which he based his assertion that organic matter is rapidly oxidized in running water, and called on Dr. Frankland to open the discussion.

Dr. Frankland said he must apologize to Professor Tidy for confining himself on that evening to the question of oxidation. There were many portions of the paper in which he cordially agreed with Professor Tidy, and his researches on the water of the River Nile and on Filtration were of the highest value. He should, however, consider only the question of oxidation. Can running water be at all times safely used for dietetic purposes a few hours or days after it has been mixed with sewage? This is a question of vital importance to many millions of people in this country. Twelve years ago there was a general impression amongst chemists and others that polluted water quickly regained its original purity by spontaneous oxidation. This opinion had no foundation in quantitative observations; indeed there was not a single experimental fact to support it, for the previous condition of water analysis did not permit of the quantitative investigation of organic matter dissolved in water. Two classes of persons strongly interested in its acceptance were chiefly instrumental in the organization and diffusion of this opinion. These were the pollutors of river water and water companies drawing their supplies below the sewer outfalls of towns. Both these influential classes have always contended that even the most abominable of organic rubbish is destroyed by oxidation, in fact utterly burnt up during the flow of a few miles. This was a comfortable doctrine and therefore a popular one; nevertheless it did not pass entirely unchallenged; indeed it is difficult to imagine how any chemist, accustomed to the habits of organic compounds, could accept such an opinion without proofs. In 1865 Professor Brodie entered his protest against the popular doctrine. The first Rivers Pollution Commissioners, R. Rawlinson, J. T. Harrison and Professor Way, concluded "that as a water supply, the Thames polluted with the sewage of the inhabitants of the river basin is open in kind, if not in degree, to the same objections as well water infiltrated by liquid from an adjoining cesspool. Well water so tainted may appear to sight, taste and smell to be harmless, and has been known to be drunk for a length of time without apparent mischief, but beyond all doubt that same water is liable under particular conditions to become poisonous." The prevailing opinion was, however, in favour of the rapid oxidation of organic matter in running water when the Second Rivers Pollution Commissioners, of 1868, undertook the quantitative investigation of the subject. During six years they determined the rate of oxidation during the flow of intensely and moderately polluted rivers, and secondly in artificial mixtures of sewage and water by prolonged agitation with air, and thirdly by observing the diminution of dissolved oxygen in a mixture of sewage and water excluded from the air. For the determination of the rate of oxidation in strongly polluted water, the rivers Mersey, Irwell and Darwen were selected as streams offering favourable conditions for quantitative experiments, because after being intensely polluted each of them flows for several miles without encountering any further material pollution, and their waters are well mixed by weirs, etc. The speaker then detailed the analyses, which unmistakably disclose the fact that a flow of between 11 and 13 miles at a temperature of 18° C. produces but little effect upon the organic matter dissolved in the water, and that at or below 13° C. oxidation is practically arrested, although in the case of the Irwell the water was most effectively aerated by falling over six weirs. The results may be summarized thus—

						Percentage reduction of organic elements.
Irwell after a flow of	11	miles at	6·5° C. .	.		1·7
„	„	„	„	„	12·7° C. . .	0·0
„	„	„	„	„	17·8° C. . .	26·5
Mersey „	„	13	„		4·5° C. . .	20·5*
Darwen „	„	„	„		8·7° C. . .	0·0

Next, as to the rate of oxidation in a river less polluted in which animal and vegetable life still flourished. For this purpose the Thames between Reading and Shiplake Paper Mill was chosen. Every care was taken to ensure fair and strictly comparable samples. Some difficulty was experienced in effecting this owing to the great distance necessary to ensure a complete mixture between the waters of a main stream and those of a tributary. Thus, the Kennet, after joining the Thames, flows nearly two miles before its individual character ceases to be apparent, and it is only after the passage of the weir and rapids at Sonning Bridge that a thorough mixture takes place. The samples were taken on a bright sunny day at the end of May, and therefore under circumstances very favourable to oxidation; but the reduction in the proportion of organic matter was exceedingly small, only 5·7 per cent. at 16·7° C., so that allowing for the retardation of the process by night, etc., it would be incorrect to assume that the river would clear itself of organic matter by a flow of seventy miles. These results were checked by experiments with artificial mixtures of sewage and water. The mixture was violently agitated every day, and was daily syphoned off, and allowed to fall slowly about 3 feet at a temperature of about 20° C. In ninety-six hours the organic carbon was thus reduced 6·4 per cent., and the organic nitrogen by 28·4 per cent. After one hundred and ninety-two hours the reduction was 25·1 per cent. carbon and 33·3 per cent. nitrogen. This shaking, etc., was supposed to be equivalent to a flow of ninety-six and one hundred and ninety-two miles respectively, at a rate of one mile an hour. Similar experiments with a mixture of urine and water gave similar results. By studying the rate at which atmospheric oxygen disappears when dissolved in polluted water, it was again proved that oxidation takes place very slowly, the results being that in the first period of twenty-four hours, 6·8 per cent. of the sewage was destroyed; in the second period of twenty-four hours, 8·9 per cent.; in the third period of forty-eight hours, 14·3 per cent.; in the fourth period of twenty-four hours, 5·4 per cent.; in the fifth, 5·8 per cent.; in the sixth, 2·1,

* No correction for unpolluted affluents.

making all together 43·3 per cent. That even this oxygen was not all used up in oxidizing the carbon was proved by the fact that the quantity of carbonic acid present remained constant. The Rivers Commission, therefore, concluded from the experiments made upon rivers and artificial mixtures of sewage and pure water that the oxidation of the organic matter in sewage proceeds with extreme slowness, and that no river in the United Kingdom is long enough to effect the destruction of sewage by oxidation. For six years these results have never been called in question. Dr. Tidy, however, whilst conceding the accuracy of the experiments, objects to the conclusions, and from his own experiments concludes that peaty matter is rapidly, and sewage matter still more rapidly, oxidized in running water, and states that in his opinion the oxidation of organic matter in sewage proceeds with extreme rapidity, and that after a run of a few miles, if the dilution be sufficient, the removal of the whole of the organic impurity will be effected. This conclusion is founded upon the results of analyses of samples of water taken from the Severn, the Shannon, and from certain conduits in the north of England, and also upon experiments made with sewage matter flowing through glass-lined troughs. A careful examination, however, of the conditions under which the samples were taken and the experiments made proves that they are in most cases consistent with the results arrived at by the author of the present paper, while none affords any trustworthy basis for the conclusions arrived at by Professor Tidy. As regards the Severn, the analyses, if they prove anything, prove too much. Thus comparing sample No. 2 with sample No. 3, it appears that a flow of 30 yards has reduced the organic elements by 32 per cent.; the river should therefore be quite pure after flowing 100 yards. The next mile only produced a diminution of 12 per cent. more. This discrepancy is doubtless due to a want of care in taking the samples, and is caused by the varying admixture of the pure water from the affluent, the Teme, with the polluted water of the Severn. This is indeed proved by the chlorine determinations, which show for the first 30 yards flow a diminution of 41 per cent.; whilst during the next mile only another 11·4 per cent., and proceeding therefore, *pari passu* with the diminution of organic matter. Professor Tidy suggests that the rapid decrease of the chlorine in 30 yards is caused by its absorption by vegetation, but produces no proof of such a powerful, and at the same time irregular, absorption. The river Wear is next considered. It is stated that between Bishop Auckland and Durham, a flow of 13 miles, the whole of the sewage of the former town is oxidized, and indeed the river is purer than it was above Bishop Auckland. Even the nitrates themselves appear to be oxidized, so that the Rivers Commissioners testify that the Wear at Durham is a "good water." The fact has apparently been completely overlooked by Professor Tidy that during this 13 miles flow a considerable tributary of highly ferruginous water enters the Wear; the potency of iron in removing various organic matters from water being well known, and referred to by the Rivers Commissioners. It is therefore probably to this ferruginous tributary and to the influx of a larger affluent, the Brownie, that this diminution of organic matter is due. At all events no one can allege that the cleansing is due solely to oxidation. As regards the alleged statement of the Rivers Commissioners, they really said that the water was good *considering its source*, having previously described the impurity of the latter. As to the evidence drawn from the composition of Thames water at Lechlade and Hampton, the only evidence on the subject is furnished by two samples taken at Lechlade, on April 18, 1868, and at Hampton, on May 4, 1868, the former containing ·133 and 0·033 of organic carbon and nitrogen, the latter 0·260 and ·024. At Lechlade the river was running 100,000,000 gallons daily, at Hampton, 554,000,000. A flood had also occurred on April 21–24. But granting that the Thames at Hampton contains no more organic matter than at Lechlade, it by no means follows that the sewage of a million people has been got rid of. For:—1st. Its volume has been augmented more than fivefold, to some extent by pure spring water. 2nd. A considerable proportion of the sewage drains into cesspools, etc., and only enters the Thames after a flood. 3rd. When the Wey mixes with the Thames about 6 miles above Hampton the mixture becomes turbid, and a precipitation of organic matter takes place. 4th. For several miles above Hampton the Thames runs through a vast deposit of flint, gravel and sand, which sops up its water like a sponge, restoring it again at a lower level, and thus vast volumes are exhaustively filtered through gravel and sand, and the organic matter is consequently oxidized in a porous medium, a most potent agency in nature for the removal of organic matter. As regards the Shannon, Professor Tidy's observations were limited to a portion of 37 miles, 23 in Loch Derg, and 14 in the river. It was found that in flowing through Loch Derg the organic elements diminished from 1·02 to 0·84 per cent., *i.e.*, about 18 per cent. The next sample, taken a mile lower down, shows a diminution of more than 38 per cent. The next sample, 4 miles lower down, shows an increase of 75 per cent. Four miles lower, at the foot of the Castle Connell falls, a further sample was taken, it showed a diminution of 28 per cent. The last sample was taken above the junction of the river Mulkear, and here the organic elements had again increased 53 per cent. Thus from the analyses a run of a mile, having a surface of less than one-tenth of a square mile, reduces by oxidation the organic elements 38 per cent., whilst the passage through Loch Derg of 23 miles, exposing a surface of over 50 square miles *plus* 2 miles of river, diminishes them by only 18 per cent. After leaving this oxidizing section, the river flows 4 miles and arrives at O'Brien's Bridge, and has gained 75 per cent. of peaty matter. To account for this increase by an influx, even of black peaty water, requires an augmentation of the river by one-third of its total volume. This increase is quite incredible, and the author concludes that somehow or other the samples taken did not fairly represent the main body of the river, and that the conclusions drawn by Professor Tidy are therefore quite unwarranted. The analyses of the peaty water flowing through an open and a closed conduit quoted by Professor Tidy are probably in a similar way rendered fallacious, owing to the probable introduction *en route* of spring water into the open conduit. The mysterious influence which so favours the oxidation of polluted water running in rivers with numerous unpolluted affluents appears to be always absent when the water is put under conditions admitting of the application of accurate experimental tests. Professor Tidy therefore constructed a series of V shaped troughs, lined with glass, altogether 200 feet long; by means of this apparatus he finally demonstrated the oxidation of sewage in water. To these experiments the author objects, 1. That the water was exposed to an enormously greater solid surface than in any river. 2. It is not stated that the sewage was filtered, and loss might occur by deposition on the troughs. 3 and chiefly. After a short time the urea in sewage would be transformed into ammonic carbonate. Thus there is no evidence whatever of the destruction by oxidation of the dead organic matter by a flow of 12 miles, still less is there any ground for assuming that the organized and living matter of sewage is destroyed under like circumstances. Bacteria develop, multiply and flourish for weeks in attenuated liquids. Here the author read a letter from Professor Tyndall, in which, after apologizing for his compulsory absence, he designates Professor Tidy's views on germs as very plausible, but utterly chimerical, and continues, "Well, what about the germs of bacteria, do they commit suicide by endosmic action? So far is this from being the case that Dr. Tidy cannot take a single drop of water from his tap that does not contain living germs, capable when placed in a proper nutritive fluid of developing themselves into countless multitudes of bacteria. Pray ask Dr. Tidy what reason has he to suppose that other germs must behave differently from those of *Bacterium termo*." The author then criticizes the assumption that the epithelial scales from scarlet fever patients, etc., are daily oxidized and disappear, and challenges Professor Tidy to prove by a delicate balance any marked diminution of weight in such a mass of organic *débris* from oxidation. The author then upholds and justifies his statement as to the immunity which would be conferred on the metropolis from epidemics of cholera if it had a supply of pure water, by reference to statistics from Bethlem Hospital, Millbank Prison, etc. In conclusion, the author agrees with Professor Tidy when he says of water supplied to a community, "Art may be fairly asked to improve a good water, but it is simple madness to ask her to deal with bad water;" and again, "that impure water has been one of the most active causes of disease is a fact which, to my mind, has been proved beyond doubt. The researches of Dr. Ballard on typhoid, etc., supply evidence that should make us very jealous indeed of allowing to be used for drinking a water over which hangs the merest shadow of a suspicion. No one can be too strictly a water purist." The question therefore, Can running water be at all times safely used for dietetic purposes a few hours or days after it has been mixed with sewage? is answered by the author in the negative.

The President said that all must compliment Dr. Frankland on the complete, clear, and withal good-natured criticism to which they had listened with so much interest. He would ask Professor Huxley to say something on the subject of bacteria.

Professor Huxley did not wish to take part in the chemical controversy, but it had struck him on reading over Dr. Tidy's paper that there was a good deal of what he might venture to call "biological turbidity" in it. To this turbidity he would, as far as was in his power, act as a filter. He would state briefly only what were demonstrable facts. Diseases caused by what people, not wisely, call germs, *e.g.*, splenic fever, pig typhoid, etc., are caused invariably by bodies of the nature of bacteria; these could be cultivated through twenty to thirty generations, and then when given to the ox or the pig would invariably give rise to the characteristic disease. There was no reason even to imagine that any body capable of causing disease by such means could be anything but a body having the nature of a bacterium. Now, bacteria are just as much plants as mushrooms or cabbages, or the *Wellingtonia gigantea*, so that we know under what conditions bacteria can live and what they can do. Bacteria can be sown in Pasteur's solution just as mustard and cress can be sown in the soil; they thrive, and the liquid becomes milky; and he would ask the President whether there was any known method by which if one drop of this Pasteur's solution were placed in a gallon of water its constituents could be estimated?

The President having answered that he thought that it was doubtful,

The speaker continued, every cubic inch of such water would contain 50 to 100,000 bacteria, and one drop of it would be capable of exciting a putrefactive fermentation in any substance capable of undergoing that fermentation. For purposes of public health the human body may be considered as such a substance, and we may conceive of a water containing such organisms, which may be as pure as can be as regards chemical analysis, and yet as regards the human body as deadly as prussic acid. He was aware that chemists might consider this as a terrible conclusion, but it was true, and if the public were guided by percentages alone, they might often be led astray. The real value of a determination of the quantity of organic impurity in a water is, that by it a very shrewd notion can be obtained as to what has had access to that water. If it be proved that sewage has been mixed with it there is a very great chance that the excreta of some diseased person may be there also. On the other hand, water may be chemically gross and yet do no harm to anyone, the whole source of damage being, in the belief of the speaker, in the diseased germs. As to the bursting of the envelopes by endosmosis, it was a question whether they had any envelopes; bacteria would be large if $\frac{1}{20000}$ of an inch in diameter, and moreover, ordinary water was full of them, and in it they could be shaken for an indefinite period without harm. As long as bacteria had nutrition there was no reason to suppose that oxidation or endosmosis would affect them. If, however, they were deprived of nourishment and exposed to sunlight, the case might be very different.

The Secretary then read a few remarks which had been sent by Dr. Mills. Dr. Mills has calculated the ratio of $\frac{\text{oxygen consumed}}{\text{sum of organic } C+N}$ and finds that it is not constant, but varies in different streams. He does not think it possible to determine the peat in a water by its tint depth, owing to the difference of colour. River water commonly contains a slimy or pectinous material which tends to separate out on any substance which acts as a nucleus. This has, in the author's opinion, a most potent influence on the purification of river water. The oxygen theory of the natural purification of waters seems utterly untenable. The criticisms of the author coincide in several respects with those already advanced above by Dr. Frankland. In conclusion the author expresses his admiration of the patience with which Dr. Tidy has collected his facts, and of the meritorious accuracy of his analytical results.

Professor Bischof called attention to the omission of the cholera years in the statistics given by Professor Tidy.

Professor Tidy in his reply relied mainly on the powerful testimony given in his behalf by the statistics of the last ten years. Notwithstanding the possible contamination of a large bulk of river water by a minute drop of a fluid containing germs, yet there were as many cases of fever in towns supplied solely by well water as in those supplied by river water; this holds good for towns all over England as well as in different districts of the same town. He took exception to the laboratory experiments of Dr. Frankland on oxidation; they were doubtless most interesting and satisfactory experiments as regards shaking fluid up in bottles, but they did not represent the flow of a river. There was no vegetation, no animal life. As regards the diminution of sodium chloride in the Severn, he contended that plants did cause a decrease in the quantity of sodium chloride in running water. As to the Shannon, he knew every inch of it, and perfect streams of black drainage entered into Loch Derg and elsewhere, quite sufficient to account for the discrepancies noted by Dr. Frankland. He collected the samples of water himself, and did his utmost to collect them fairly. He had no interest whatever in commending any water. In conclusion, Professor Tidy said that although his paper might be considered in some respects an attack on Dr. Frankland, he wished to thank him for the freedom and the kind way in which he had met him at every turn, and expressed a hope that Dr. Frankland would join him in fighting the prevailing heresies on this question which tended so to upset the public mind.

Dr. Frankland having declined, owing to the late hour, the right of reply, the meeting, which had been crowded all the evening, separated shortly after eleven, and the Society adjourned to June 3.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, May 13. Mr. R. H. Parker, Vice-President, in the chair. Mr. W. Elborne read a paper on "The Recovery of Residual Tinctures from Marcs by Upward Diplacement with Water." The paper will be published in an early number.

After a discursion, in which the Chairman, Messrs.

James, Allen and Wright took part., the thanks of the meeting were awarded to Mr. Elborne.

Mr. A. F. Dimmock made a report on analytical chemistry on "Vortmann's Method for the Detection of Chlorides in the Presence of Iodides and Bromides." This method is based upon the action of chlorides, bromides, and iodides when heated with peroxide of lead in acetic acid solution. The bromine is completely dissipated as free bromine; the iodine is partially liberated as free iodine, the remainder forming iodate of lead. With chloride all the chlorine remains as chloride of lead. To the solution containing the three salts acetic acid is added, then peroxide of lead, and the solution boiled for half an hour, after which it is filtered and the filtrate tested for chlorides in the usual manner.

A discussion ensued, in which the Chairman, Secretary, Messrs. Allen and Branson took part. Mr. Dimmock announced his intention of working at the method quantitatively, as Vortmann had given no results in his original paper read before the Berlin Chemical Society.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual general meeting of the above was held at the rooms of the Association, 32A, George Street, Hanover Square, on May 12.

On the motion of Mr. O. Wallis, Mr. F. W. Branson took the chair.

The minutes of the previous meeting having been read and confirmed, the Honorary Secretary, Mr. F. W. Maggs, read the following report:—

"The Council present the report of the third session, with full confidence that it will be received with satisfaction by all the members. The number of members during the year has been increased by twenty-one. Fourteen scientific and eight social meetings have been held, with an average attendance on paper nights of twenty members and four visitors. A programme of meetings, issued in September, has with three exceptions been carried out. The Council has met for the transaction of business on eleven occasions, and numerous committee meetings have also been held. A very successful conversazione, held at St. James's Hall on October 22, was largely attended. The annual dinner was held at the Holborn Restaurant on January 28, at which ninety-one members and friends were present. A testimonial consisting of a complete series of Dickens's works was presented to Mr. E. Cardwell, in October, in recognition of his services as Honorary Secretary, and as a mark of the esteem in which he was held by the members. The retiring Council tender their thanks to all who have assisted their efforts, and trust that their successors will receive such support as will enable them to promote the continued success of the Association, and render the institution a permanent one."

The adoption of the report was moved by Mr. Wrenn, seconded by Mr. Hardwick and carried *nem. con.*

The Treasurer, Mr. O. Wallis, then read the financial report:—The income for the past year had been £68 11*s.* 5*d.*; made up of balances of previous year, £18 11*s.*; seventy-five members' subscriptions, £18 15*s.*; three honorary members' subscriptions, £3 13*s.* 6*d.*; nineteen donations from wholesale firms and friends, 19 guineas; six donations from members, 6 guineas; balance from dinner account, £1 6*s.* 11*d.* The chief items of expenditure had been rent, £30; conversazione, £16 0*s.* 6*d.*; miscellaneous, £12 5*s.* 11*d.*, leaving a balance in hand of £10 5*s.*

On the motion of Mr. Piper, seconded by Mr. Lapthorne, the report was adopted.

In the discussion which followed, various methods were proposed for still further increasing the scope and usefulness of the Association, amongst them, one for the establishment of a branch, to suit the convenience of members residing in other parts of the metropolis, but after due consideration the scheme was postponed for the present. Some slight alterations in the rules relating to honorary members were proposed by Mr. Hardwick, which, after discussion, were carried.

The following are the Officers and Council for the ensuing session:—

President, Mr. F. W. Branson; Vice-Presidents, Mr. F. W. Collinson and Mr. G. F. Snow; Hon. Treasurer, Mr. C. Parkinson; Council, Mr. A. Davidson, Mr. S. Hardwick, Mr. F. W. Maggs, Mr. C. B. Miller, Mr. A. J. Phillips, Mr. W. P. Robinson, Mr. F. J. C. Squire, Mr. O. Wallis and Mr. W. A. Wrenn; Hon. Secretaries, Mr. J. H. Hartridge and Mr. C. A. Tharle.

Parliamentary and Law Proceedings.

Prosecutions for Defective Apothecaries' Weights.

At the Southwark Police Court, on Wednesday, the 19th inst., the first prosecutions for contravention of the Board of Trade new denominations and standards of apothecaries' weights and measures, made by Order in Council last August, took place.

The first case was against William Wilkinson, chemist and druggist, 114, Lambeth Walk.

James Strougnell, inspector of weights and measures, testified to seizing seventeen weights upon defendant's premises on the 20th ult. Eight of the weights were too heavy and nine too light, and were as follows:—One 2 drachm weight one grain heavy; one 2 drachm weight five-tenths of a grain heavy; one 2 drachm weight one and a half grain heavy; two 2 drachm weights one and a half grain light; one 2 drachm weight one grain light; one 1 drachm weight two-tenths of a grain light; two 2 scruple weights three-tenths of a grain light; one 2 scruple weight two grains light; one 4 grain weight one-half grain heavy; four 4 grains weights three-tenths of a grain heavy; one 3 grain weight one-half grain light; one 3 grain weight three-tenths of a grain light.

In reply to Mr. Glaisyer, Solicitor to the Chemists and Druggists' Association, who defended, the witness said he examined the avoirdupois weights upon defendant's premises and found them all correct. The standard for apothecaries' weights was issued last August, and not at the time the Act was passed. He believed all or most of the weights seized were in use. They were in a small drawer under the scales. He thought some of them were new and believed defendant handed them to him. He did not remember whether defendant told him how recently he had had his weights examined. Witness had not published any notice of the standard set up for apothecaries' weights. He believed defendant or his assistant asked to be recommended a place to buy fresh weights, but as a rule witness did not recommend anyone as it would be unfair to the different makers. Witness advised defendant to get fresh weights, and he promised to do so.

Mr. Glaisyer: Is this the first case of a chemist being brought before the court with respect to apothecaries' weights?

Witness: Yes, I believe it is.

Mr. Glaisyer: Here or eleswhere?

Witness: Yes, I believe so.

Mr. Glaisyer said he was not prepared to dispute the statement of the inspector, and he accepted the fact that some of the weights were heavy and others light. He would urge, however, in mitigation of the penalty, that defendant, as far as he had been able to do so, had had his weights examined periodically. There was no charge with regard to the avoirdupois weights, which the inspector found perfectly correct. With regard to the apothecaries' weights the standard had been set up more recently than the Act of Parliament, and the defendant, in common with his brother chemists, was unaware that the standard had been started. Moreover, the person who had examined the defendant's weights had not correct apothecaries' weights to examine them by. This was the first case of the kind, and might act as a warning to chemists throughout the country to have their weights according to the standard. Four of the weights, he was told, were perfectly new and had never been used, and were supplied by a first class firm. Until recently there was no standard by which dispensing weights could be properly tested, and immediately defendant knew what was required he purchased new weights stamped and marked.

Mr. Mews (Chairman on the Bench) said: As this is the first case which has been brought, we shall simply order the defendant to pay a nominal fine. It is quite necessary that chemists, as well as persons in other businesses, should have correct weights. The fine is 1*s.* on each weight, altogether 17*s.*

Horatio Pass, chemist and druggist, 245, Wandsworth Road, Lambeth, was also fined 1*s.* in each case for having twelve incorrect apothecaries' weights, viz.:—One 2 drachms three-tenths heavy; two 1 drachm three-tenths heavy; one 2 scruples four-tenths heavy; one 2 scruples three grams light; one ½ scruple three-tenths heavy; one 1 scruple three-tenths heavy; one 1 scruple half a grain light; one 6 grains three-tenths heavy; one 5 grains three-tenths heavy; one 3 grains three-tenths heavy; one 2 grains two-tenths heavy.

In this case defendant pleaded that he did not know the Act was in operation; that he had been unable to get any information on the subject. He added that there appeared to be a difficulty as to whether weights stamped in one district would be right in another.

Magistrates' Clerk: The Act is in operation all over the country.

Defendant: But you cannot get the weights stamped in the different districts.

Messrs. Poingdestre and Truman, chemists and druggists, 187, Newington Butts, Edward Wood, chemist and druggist, Northcross Road, Crystal Palace Road, and Robert John Smith, chemist and druggist, 38, Thornton Street, Surrey, were also ordered to pay small fines for having incorrect apothecaries' weights.

These offences were proved by Mr. James Webb, Inspector, and George Carr, his assistant.

Defendants all pleaded ignorance of acting illegally. Mr. Smith said some of the weights seized upon his premises had not been in use for thirty years, and that until the seizure he was unacquainted with the new Act. Mr. Wood stated that the weights seized upon his premises had been used merely for compounding and not for retail.

In each case the weights seized were forfeited.

Poisoning by Chloral Hydrate.

On Wednesday, May 19, Mr. George Collier held an inquest at the Prince of Wales Tavern, Bishop's Road, Victoria Park, on William Tickell, age 62, an inmate of Bethnal Green Workhouse, who, it was alleged, died from an overdose of chloral.

Mary Ann Styles, a paid nurse at the workhouse, stated she had had charge of deceased in the infirmary for three years. He was suffering from palsy and heart disease. At 11 o'clock on the night of Thursday, the 13th inst., he received his usual draught of chloral, which was given by direction of the doctor. He had the same dose as was nightly given him—two tablespoonfuls. Witness did not know what quantity of chloral was in the draught. After she had given it him he complained of pain in his throat. The witness then sent for the night superintendent, Mrs. Wagstaff. Tickell died about 12 o'clock. Witness, in reply to questions, said it was not her duty to send for the doctor, but to communicate with the night superintendent. Witness went on duty at 6 p.m., and would continue until the same hour next morning.

Emily Wagstaff, the night superintendent, said she was called to see the deceased about 10 minutes to 12 o'clock. He died just as she entered the ward. It was the witness's duty to administer the draught through the nurse, who took it from her and handed it to the patient. The witness gave the quantity ordered by the doctor, namely, 20 grains.

Dr. Boyd, assistant medical officer, stated that when the death occurred he had been only two days on duty. His business was also to dispense medicine, and instead of filling the bottle intended for the ward in which the deceased was lying with drachms of concentrated solution of chloral, he mistook the prescription for ounces, the symbols with the exception of an additional line or mark being identical. In consequence of the witness mistaking the drachms for ounces, the deceased and four other patients received 160 grains instead of 20, being eight times the proper quantity. He could only account for the death of the deceased through his having a diseased heart. The other patients slept soundly and were drowsy during the day, and directly the witness discovered what had occurred he took means to repair it. Chloral was very uncertain in its action. He gave the overdose in ignorance.

Dr. T. R. King, resident medical officer, stated that deceased suffered from heart and lung disease. Two of the patients under his care were taking half as much again as the dose administered in the present case, and they felt no effect but drowsiness. Chloral was largely used as a substitute for opium.

After some discussion twelve jurymen out of sixteen returned a verdict in accordance with the medical evidence—viz., that the deceased died from heart disease, but they considered his death was accelerated by an overdose of chloral administered inadvertently by the assistant medical officer.—*Hackney and Kingsland Gazette.*

BOOKS, PAMPHLETS, ETC., RECEIVED.

The Spirit of Nature. Being a Series of Interpretative Essays on the History of Matter from the Atom to the Flower. By Henry Bellyse Baildon, B.A. London: J. and A. Churchill.

Proceedings of the American Pharmaceutical Association at the Twenty-Seventh Annual Meeting, held in Indianapolis, 1879. Philadelphia: 1880. From the Secretary.

Obituary.

Notice has been received of the death of the following:

On the 7th of May, at Troon, Mr. William Rankin, Pharmaceutical Chemist, late of the firm of W. Rankin and Co., Kilmarnock. Aged 78 years. Mr. Rankin, became a Member of the Pharmaceutical Society in 1848.

On the 11th of May, 1880, Mr. Joseph Hill Appleton Chemist and Druggist, Attercliffe. Aged 69 years.

On the 19th of May, Mr. Hiram Ogden, Chemist and Druggist, Broughton, Manchester. Aged 46 years.

Dispensing Memoranda.

Reply.

[407]. The prescription cited by Mr. R. A. Cripps, with its *s. q.* of doubtful signification, occurs in an examination paper for the 1878 Bell Scholarships, and may be found on page 226 of the 'Pharm. Calendar' for 1879. Possibly *signa quæ* was the "full Latin" required by the examiner.

Q. S.

Queries.

[409]. How should the following be dispensed and what should its appearance be ?—

WEIGHTS AND MEASURES ACT.

Sir,—One of your editorial articles of Saturday last refers to the recent prosecutions under the above Act, and to "the disparaging suggestions" which have been made on account of the Journal having contained a considerable amount of matter referring to the various provisions, etc.

No one will doubt but in keeping the subject constantly before us your intentions were good, but it is proverbial that we may have too much even of a good thing, and we have all heard of the evil which resulted from calling "Wolf!" when no wolf was near.

Now, sir, at the time your warnings appeared the inspectors were quite unprepared with standards for verification of weight and measures, therefore application to them was useless and constant agitation would simply have the effect of annoying them and causing them to visit the applicants in an unpleasant way when it was within their power to do so.

You say "One of the defendants, in fact, pleaded that he did not know the Act was in operation, and that he had been unable to get any information on the subject." As regards "not knowing the Act was in operation" it is quite clear he has not been a reader of the *Pharmaceutical Journal*, and as to information, I presume he meant official information from the inspector, and it is undoubtedly true that most of these persons are not in a position to give it.

The Weights and Measures Act is still, I believe, a very imperfect piece of legislation; but had it provided that on receipt of the standards for apothecaries' weights and measures the inspectors should give notice to the chemists and druggists that they were prepared to examine and verify, then it would have operated more justly than it does at present, it would have been less inquisitorial in its bearing and would have saved the inspectors from appearing in the character of official informers.

CHARLES SYMES.

TINCT. SENEGÆ AS AN EMULSIFYING AGENT.

Sir,—In reference to an article of Mr. Collier's, recommending tincture of senega as an emulsifying agent for fixed and volatile oils, I would beg leave to disagree with that gentleman regarding the statement he makes that senega would not be objectionable in small doses, and that emulsions made with it would be equally as fine preparations as those made with acacia. I have lately experimented with senega on different oils according to formulæ given by Mr. Collier, and find that in most cases the oil separates in the course of twenty-four hours, and I cannot understand why the latter process should be adopted when we fulfil all the requirements of an elegant and satisfactory emulsion by the use of acacia, and at the same time without altering the medicinal properties of the oil administered. In some cases senega would I think be most objectionable to many practitioners, not only on account of its exciting violent attacks of sneezing in some cases, but also on account of the taste which is so disagreeable to many, and so repulsive to the stomach, since I am aware of numerous cases in which the minute dose of senega could not be retained.

I would also beg leave to differ with Mr. Collier in the assertion he makes that liquor potassæ is used when not required, merely as an emulsifying agent, as in the whole course of my seventeen years' varied dispensing I have never noticed one single instance in which it was used unless its presence was indicated.

In conclusion I would state that pharmacists, medical practitioners, and the public generally are satisfied with the elegant emulsions so simply made with acacia, and until we discover some better substitute, why discard one of the most useful preparations of the Pharmacopœia in favour of one that is by no means its equal ?

JOSEPH LEVY,
Dispensing Chemist for Western Railways, Cape Town.

CLAY'S CHIAN TURPENTINE EMULSION.

In a recent communication to the Journal, Mr. Martindale says of this formula "Mix it as you will the sulphur will separate from such a mixture and aggregate the resin in masses, first to the top and then at the bottom of the bottle." That this is not exactly correct anyone may demonstrate for himself who will commence by throwing the ethereal solution on the powdered tragacanth in a mortar, gradually adding the water, and finally the sulphur first rubbed down with the syrup. I have now before me a bottle of the emulsion mixed in this manner a week ago, from which no such separation as Mr. Martindale describes has taken place; on the contrary a very slight shaking is sufficient to restore it to its original condition.

Plough Court. CHARLES EVE.

Querist.—Apply to the Registrar under the Dental Act, 315, Oxford Street.

W. J. Smith.—The specimen consists principally of stem, which is often mixed with the root. See p. 954.

H.—(1) *Saxifraga granulata.* (2) *Plantago lanceolata.* (3) *Carex*: send specimens later on in fruit. (4) *Medicago lupulina.* (5) Probably *Ranunculus bulbosus*: the stem and root should be sent.

"*Dens.*"—Your proper course would have been to have registered as having practised dentistry on your own account. With respect to your present position you are recommended to consult a solicitor, as a decision must depend upon the result of an investigation of facts.

Student and *W. R.*—See the remarks on the dispensing of pills containing carbolic acid in "The Month," before, pp. 326 and 425, Nos. 360 and 371.

B. and *W.*—The restrictions of the Pharmacy Act apply to the keeping open shop for the retailing, dispensing or compounding of poisons.

S. L.—The name belongs to an isomeric modification of turpentine oil, which is described in Watts's 'Dictionary,' vol. v., p. 924.

THE RECOVERY OF RESIDUAL TINCTURES FROM MARCS BY UPWARD DISPLACEMENT WITH WATER.*

BY WILLIAM ELBORNE,

Bell Scholar in the School of Pharmacy of the Pharmaceutical Society.

The preparation of tinctures occupies a prominent position in the routine of all engaged in practical pharmacy. Accordingly, it is a subject which has been closely investigated and with which all pharmacists are more or less familiar; nevertheless, the results of my experiments will, I hope, be interesting. It will be proper first to review the four different processes of the Pharmacopœia, namely, simple solution, maceration, percolation, and maceration with percolation combined. As the majority of tinctures (38) are made by the last process, namely, maceration and subsequent percolation, it was some of this class that were first prepared and to which I will first allude. The directions in this process are to macerate in three-fourths of the spirit, percolate, continue percolation with remainder of spirit, press, mix, filter and make up to the required volume with spirit. I presume the object of continuing percolation with the remainder of the spirit is chiefly to displace the concentrated tincture produced by maceration, so that by the subsequent pressure of the marc there may be the least quantity of the active constituents retained by the exhausted drug, which retention varying with different drugs will more or less inevitably occur in spite of their marcs being submitted to hydraulic pressure. It follows, therefore, that the preparation of tinctures is attended by certain losses of the weak tincture formed by continuing percolation with remainder of spirit, which implies not only some loss of strength to the tincture, but, what is commercially of great importance, loss of spirit. The use of the tincture press which is involved in the B. P. process has to many persons objections which are tolerated for want of a more easy and economical process. Attempts have been made to dispense with it altogether, but have resulted in failure or only partial success. Amongst them is that of pouring water upon the marc with a view to displacement of retained tincture, but I am aware of the objections raised against this process and especially pointed out by Professor Redwood (*vide* 'Practical Pharmacy,' p. 92).

It will be convenient to allude to these objections, as the result will show that they tend favourably in support of the process which I am about to bring before you:—First, the specific gravity of water being higher than that of rectified or proof spirit, it naturally permeates down into the spirit which at the same time has a tendency to rise into the water, thus materially assisting the diffusion or mixing of the two liquids; secondly, vegetable tissues possessing a greater affinity for water than for spirit, the latter is readily liberated from them and rendered free to rise into the water. Having mentioned the disadvantages of this process, I arrive at that which forms the leading feature of this paper, namely, upward displacement or the removal of the residual tincture retained in a marc by means of water (the heavier liquid) rising from below.

Working on this principle, the objections above mentioned are inapplicable and the results are fairly satisfactory. One impediment, however, is the slight diffusion which takes place at the line of contact, but this may be partially remedied by using a modification of the menstruum. Of the group prepared by maceration and percolation, the following proof spirit tinctures were made, viz.:—Træ. aurantii, calumbæ, cinchonæ, cinnamomi, lupuli, rhei, and with rectified spirit, træ. aconiti and zingiberis fort. The quantity prepared of each was one pint, and in those made with proof spirit, specific gravity ·920, I used a spirit having specific gravity ·915, made by diluting the requisite quantity of rectified spirit with distilled water to 19 ounces instead of 20, and adding $2\frac{1}{2}$ drachms extra of rectified spirit, thus allowing for the contraction of volume, and for use of the mixture immediately. My mode of procedure is to powder the ingredients and macerate them with the whole of the spirit specific gravity ·915 for the

specified time with occasional agitation; the supernatant liquid is then drawn off, the dregs stirred up and transferred to a cylindrical percolator and allowed to drop until the liquid passes clear and

* Read at a meeting of the School of Pharmacy Students' Association, May 13, 1880.

bright; the receiver is then attached and both the turbid and supernatant liquids returned to the percolator. Instead of tying a piece of muslin over the bottom of the percolator, as is usually done, a cork is inserted with a hole bored through the centre capable of admitting a piece of ordinary glass tube, above which is put an inch layer of coarsely pounded glass to prevent the orifice becoming choked. Percolation being complete, another half-inch layer of glass is placed on the top of the marc to prevent the floating of solid particles. Having removed the receiver and supported the percolator on a retort stand, the open end of a piece of glass tube two inches long is inserted in the cork, the other end of the tube being previously drawn out in the flame so as to leave only a capillary opening. To this end is attached about a yard of indiarubber tubing communicating with a vessel placed above containing distilled water, the pressure of a column of water being thus obtained. The indiarubber tube being filled with water and adjusted to the percolator, the wire clamp attached to the lower portion of the tube is removed, when a slow and steady flow of water commences; after the lapse of an hour and a half sufficient displacement will have been effected, the water having risen considerably above the marc and with it will have been removed the retained tincture, which forms a dense stratum upon its surface. On dipping a glass rod into this upper stratum and applying it to a flame, the displaced tincture burns nearly as readily as the percolated portion, indicating its comparative strength of spirit. Nevertheless, diffusion will have taken place to a slight extent and is perceptible by the gradual shading off of the highly-coloured tincture into the water beneath it. To finish off the tincture, its measure was brought up to 19½ ounces by the addition of the requisite quantity of surface liquid from the percolator, the product filtered and made up to a pint with proof spirit. Thus having measured the product of percolation, I know exactly how much surface liquid to draw off to bring the measure up to 19½ ounces, which is done by means of a glass siphon, and having mixed the two products, filtered by the automatic method through a thin 3 inch paper, and made up to a pint with proof spirit, I have produced a tincture prepared at a comparatively small loss. On reference to the table below the results arrived at will be seen. The first column indicates the percentage loss of tincture prepared by the B. P. process, and represents notes taken by Mr. Umney when these tinctures were prepared on the large scale with the use of the hydraulic press.* The second column, showing the loss by upward displacement, was obtained by taking the specific gravity of 2½ ounces of liquid distilled from 8 ounces of surface water left in the percolator after completion of the tincture, referring to tables specially compiled for estimating the percentage of alcohol in its aqueous mixtures, and to that result adding the centesimal loss by filtration. With the proof spirit tinctures, in each instance the specific gravity of distillate was very constant, indicating an average final loss of 5 drams to the pint. The third shows the specific gravity of completed tincture taken in a Regnault's bottle, and the fourth, the amount of solid constituents contained in a fluid ounce, obtained by evaporating to dryness over a steam-bath.

* *Pharmaceutical Journal*, October 22, 1870.

	Loss per cent. (by vol.) by B.P. process.	Loss per cent. by upward displacement.	Specific gravity of tincture.	Amount of dry extractive matter per fl. oz. (in grains).
Tinct. aconiti . . .	7·9	2·5	·858	8·68
Tinct. aurantii . .	6·3	3·85	·948	13·7
Tinct. cinchonæ . .	15·0	5·0	·944	13·4
Tinct. cinnam. . .	10·0	3·03	·942	7·99
Tinct. calumbæ . .	7·1	3·0	·940	7·39
Tinct. lupuli . . .	10·0	2·89	·948	9·32
Tinct. rhei	5·0	2·7	·950	15·9
Tinct. zingib. fort. .	37·0	7·5	·848	7·9
Tinct. cinchonæ (by upward displacement and distillation), sp. gr. . .	—	—	·945	—

As regards the practical working of upward displacement, I have found it answer successfully with the above tinctures. In each prepared with proof spirit, the water did its work with comparative uniformity and absence of clogging, with the exception of tinct. zingib. fort. The time occupied in the various displacements was generally from an hour and a half to two hours, and in the case of tr. rhei, three hours. Also, when the percolator was quite empty the water required fifty minutes to rise to the same level at which all the displacements were brought; this is mentioned to draw attention to the capillary tube which regulates the supply of water. The percolator was 2 inches in diameter and was cylindrical, which form is preferable to any other for this process as it exposes the liquids to a uniform surface. In allusion to the preparation of tr. rhei, having drawn off the requisite supernatant tincture in a glass measure, it was stirred up and set aside for one hour previous to mixing it with the product of percolation; at the expiration of that time about a ¼-inch layer of what probably was coagulated albuminous matter had risen to the surface, which before mixing was strained off through a double fold of fine muslin. Upon examining the tincture twenty-four hours afterwards, a further deposition had taken place and filtration was necessary, thus rendering useless my previous precaution; a similar occurrence accompanied the preparation of tr. aurantii. Bearing upon this point—several B.P. tinctures are prepared from drugs which, resembling rhubarb and orange peel, contain a large quantity of mucilaginous and albuminous matter; accordingly with these similar depositions might be expected, resulting from the matter taken up by the extra half ounce of liquid drawn from the percolator in excess of the original quantity of menstruum used in bringing the measure up to 19½ ounces. These matters are precipitated by the alcohol which the respective tinctures contain and may be eliminated by filtration. Tr. aurantii and rhei were therefore set aside for twelve hours previous to being filtered and have since then kept their brightness. In tr. cinchonæ the liquid drawn off was slightly turbid, but this was not filtered, for on mixing with the percolated portion its alcoholic strength was sufficient to render the product quite bright. This tincture is liable to deposit, and with the view of preventing such deposition, in drawing off the displaced portion the approximate ½ ounce of liquid containing diffused tincture was rejected and the measure brought up to only 19 ounces (the original quantity) making up to a pint with proof spirit. Tr. aurantii was prepared by maceration and percolation instead of maceration only. In the preparation of tr. zingib. fort. for the verification of the first result it was prepared again. For the displacement of the first tincture, the column of water being doubled, it required thirty-six hours with a loss of 20 per cent. For the second lot, half a pound of sand was mixed with the powdered ginger, and percolation being complete, a piece of wire gauze was placed upon the marc and kept firmly in its position by suitable means to prevent the marc being forced upwards; the displacement was then effected by putting the percolator in connection with an ordinary water tap; with such a pressure the fittings require a little extra adjustment in the way of corks and tubes being tied, else sooner or later they will be blown out of their places. Nevertheless, this modification answered very well indeed and required three hours for its performance; so much as $8\frac{1}{2}$ ounces of bright tincture containing no trace of admixed water were taken from the surface of the percolator, the loss in this case being 7·5 per cent.

It will be admitted that the great objection attending the preparation of tr. aurantii, tr. rhei and the like, is the mucilaginous matter taken up by the lower part of the displaced portion; therefore I have prepared a pint of tr. cinchonæ in another way. Having drawn off what is seen to be strong tincture, the approximate 8 ounces of liquid from the percolator is transferred to a retort and distilled until sufficient liquid has come over to bring the tincture up to a pint. By this method the albuminous matter is avoided and the loss reduced to a minimum or to no loss at all except that of a little time; nevertheless, I think that if the distillation were roughly done with a flask and long glass tube, good results might be obtained.

In conclusion, I am not aware that upward displacement by hydrostatic pressure has been practised in pharmacy up to the present time, although the principle is extensively resorted to for filtering purposes in the arts.

The above experiments were conducted in the laboratories of the Pharmaceutical Society.

THE EXHIBITION OF PHARMACEUTICAL APPARATUS, ETC.

The desire on the part of the Council to afford to the members of the Society attending the annual meeting an opportunity of seeing recent improvements in pharmaceutical apparatus and other objects of interest was evidently thoroughly appreciated. The doors had hardly been opened five minutes on Tuesday morning, May 18, before the visitors began to flock in, and from that time until ten o'clock on Thursday night, during the hours that the Exhibition was open, the rooms were never at any time entirely empty, even during meal times, and on Wednesday after the meeting the room containing the apparatus was crowded to excess.

So anxious were some to see what was to be seen, that many came late on Thursday night. During the three days that the exhibits were open for inspection, it is estimated that at least one thousand persons visited the Society's rooms.

That the Exhibition has led to useful results both to the visitors, and in many cases to the exhibitors, appears certain from the expressions of opinion which have been heard

It will of course be impossible to mention in detail and more fully than we have done already all the objects exhibited, but for the benefit of those persons who were unable to visit the Exhibition a short account of the articles which are believed to have been the most interesting will be given in these columns, and the apparatus illustrated as far as possible, where it has not already been figured in this Journal. For the sake of convenience the chemical portion of the Exhibition will be treated of first, afterwards the scientific and pharmaceutical apparatus, and finally the aerated waters and articles used for invalids, shop-fittings, etc.

The show of drugs and chemicals was rather small, although many of the articles exhibited attracted considerable attention from the visitors. Messrs. Burgoyne, Burbidges, Cyriax and Farries, exhibited a series of rare quinine salts, prepared by Messrs. Jobst, of Stuttgart, including the anetholate, eugenate, carbolate, etc.; also, in fine crystals, santonate of sodium, a salt which is undeservedly neglected in this country. A specimen of German opium, with the rare alkaloids, laudanine and pseudomorphine, were also shown. All the above specimens have been liberally presented to the Museum of the Society since the close of the Exhibition. The same firm also exhibited a large series of specimens of new American drugs, and the solid and fluid extracts of them prepared by Messrs. Parke, Davis and Co. Among those hardly known in this country were noticeable damiana, *Rhus aromatica*, yerba santa, *Cereus Bonplandii*, *Rhamnus Purshiana*, and *Berberis aquifolium*. One or two others, such as *Eucalyptus globulus*, kava-kava, caroba, and *Grindelia robusta*, are, however, not altogether new to English pharmacists.

Several resinoid principles, such as are used by the Eclectics, were also exhibited by this firm, including apocynin, chilonin, eupurpurin, hamamelin, stillingin, and xanthoxylin. These active agents have also been presented to the Museum of the Society. Some empty gelatine capsules for enclosing nauseous drugs, manufactured by Parke, Davis and Co., seemed generally approved of. These consisted of two halves, about one-quarter of an inch in diameter, and one half overlapping the other, so that by moistening the edge of the one half of the capsule, after filling the other, the two fitting together perfectly, they adhere and are then easily swallowed. These capsules were exhibited in different sizes. What may be termed "elegant pharmacy" was also represented by another American firm—Messrs. S. M. Burroughs and Co. A large bottle of distilled extract of hamamelis, or witch hazel bark, presented a beautiful blue fluorescence, and except for a slightly opaline character might almost have been supposed to be a solution of quinine. Effervescent citrate of caffeine and compressed tablets of mixed pepsine and pancreatine were among other novelties. The latter, from their slightly mucilaginous character, are easily swallowed, and not unpalatable. The chlorate of potash tablets, prepared by Messrs. Wyeth Bros., were also present. These are said to be prepared by drying and then powerfully compressing the dried salt, and it is claimed for them that they thus furnish a more concentrated solution of the salt when dissolved in the mouth, and that they are less disagreeable to the taste than the lozenges.

One of the most attractive objects in this room was a fine mass of crystals of pure iodine contained in the hemispherical vessel in which they were sublimed, exhibited by Messrs. Fletcher and Fletcher. This firm also exhibited concentrated liquors for the preparation of various chemical syrups. A bottle of one of these liquors, that of iodide of iron, was left open to the air during the whole of the Exhibition, and remained apparently unaltered in colour, and showed no trace of oxidation at the margin or surface of the fluid. A new salt, iodide of bismuth and quinine, and a fine specimen of metallic bismuth, stated to be purified by a new process from arsenic, tellurium, selenium, copper, etc., and pure bismuth salts, were also exhibited, the nitrate being particularly fine. Chian turpentine, evidently genuine, was exhibited by Messrs. Hearon, Squire and Francis; and Messrs. Mackey, Mackey and Co. The former firm also exhibited a magnificent specimen of cusparia bark in quills, 1½ inch in diameter, and more than 2 feet long; also some gourds of curari. A new salt of cerium, the ammonio-citrate, was also exhibited by Messrs. Mackey, Mackey and Co. Messrs. Morson and Son exhibited some beautiful sublimed crystals of menthol, sublimed chrysophanic acid, and the new anæsthetics, ethidene dichloride and isobutyl chloride. The former has been the subject of frequent experiments of late; but the latter, probably owing to the difficulty of obtaining always the same liquid and not one of its isomers, does not appear to have been so favourably received by the medical profession. Salicylate and sulphate of eserine, the former nearly white, and in small acicular crystals, are also recent introductions. These specimens seemed to be free from the tendency to redden, so characteristic of physostigmine or eserine in a state of purity and in presence of traces of ammonia or other alkali. Some fine crystals of hydrobromate of conia, a powerful but little known salt, cotoin, and paracotoin, were also exhibited by the same firm. A specimen of jaborandi was remarkable for its fine green colour and powerful odour.

Messrs. T. Christy and Co. also exhibited a number of rare and little known drugs and alkaloids, etc. Coca has been tried in this country, and pronounced by many to be a failure. It has not, however, been fairly tried, since those who use it in Bolivia, etc., are careful always to use "coca fresca," and the coca which arrives in this country has generally lost a good deal of its aroma. It has not yet been proved how far the properties of the leaves may be due, as is the case in some degree with coffee berries, to a volatile oil. The alcoholic extract made from the fresh plant in Bolivia is therefore claimed to be the best representative of the active properties of the leaves that can be obtained in this country. The sample of Goa powder exhibited was remarkable for the brightness of its colour. A specimen of Paraguay tea was accompanied by a gourd in which the tea is brewed, and a "bombilla," or tube strainer, through which it is sucked. Curari, papaw leaves, Japanese belladonna root, said to contain 1·35 of pure atropine per 1000, sassy bark, some very large quills of *Alstonia constricta*, and some fine pieces of white quebracho bark, and other rare drugs, formed a curious and almost unique collection. In addition to these were tannate of pelletierine, the new alkaloidal salt of pomegranate root bark, sulphate of duboisine and salts of pilocarpine and eserine, prepared by M. Petit, of Paris.

Messrs. Gerrard and Tanner also exhibited a large specimen of sulphate of duboisine, salts of pilocarpine and other rare alkaloids. Spirit of wine can scarcely claim the merit of novelty, but the specimen exhibited by Mr. J. Burroughs, of Chelsea, was stated by the exhibitor to be pure, and more fit for perfumery, etc., than the ordinary article.

Remarkably fine specimens of valerianate and salicylate of quinine were exhibited by Mr. T. Whiffen; other specimens of the latter salt were also to be found in the exhibit of Messrs. Mackey, Mackey and Co., and in the form of an effervescing preparation in that of Messrs. Young and Postans. Some time since Dr. Fayrer recommended fresh Indian bael fruit in preference to the extract made from the dried fruit, for diarrhœa, and this want appears to have been met as far as it is possible to do so by the importation of the fresh fruit preserved by means of sugar, a specimen of which was exhibited by the last named firm. The natural history of araroba may be said to have been illustrated to a certain exent by Messrs. Symes and Co., who exhibited not only microscopical slides showing the deposit of araroba in the wood, but also specimens of chrysarobin and chrysophanic acid, which, it will be remembered, was shown by Liebermann and Seidler to be formed from chrysarobin and not to exist naturally in araroba.

Around the walls of the room which contained the chemical exhibits were hung a series of the diagrams from Dr. Dodel-Port's beautiful 'Botanical Atlas,' which is now being prepared by Messrs. W. A. and K. Johnston for publication in this country. The large diagrams of the prothallium of ferns, the insect fertilization of flowers, and of the schizomycetes and other cryptogams will, it is believed, prove a most valuable acquisition to lecturers on botany. The same publishers also exhibited their well-known 'Balfour's Botanical Diagrams.'

Scientific and chemical apparatus was well represented, this portion of the exhibits being located in the Chemical Museum. Messrs. J. Orme and Co.'s table attracted a large share of attention, Hickley's patent telephone having been fitted up so as to communicate with the room at the top of the house in which the gas-heating apparatus was exhibited, and many of the visitors being desirous of trying its powers of communication with friends upstairs. The electric bells, electromotors, and especially the Geissler's tubes, which were frequently lighted up, formed a constant source of attraction; Balmain's luminous paint, and the Society of Arts (Fletcher's) blow-pipe cabinets, and Crookes's radiometer were also evidently objects of interest to some of the visitors.

Bayley's cuprimeter, for the colorimetric estimation of copper, recently described before the Chemical Society (April 1), Mann's gravimeter, a new apparatus for ascertaining the specific gravity of cement and other solids in a very easy manner, and Orme's carbonic acid apparatus for estimation of that acid in carbonates, were among other useful articles exhibited.

Messrs. Townson and Mercer also showed a number of interesting objects. Among these a copper water oven for drying substances below 212°, with a condensing worm attached, Zenetti's chlorine with apparatus, a Rheocord and Wheatstone's bridge, and a student's chemical balance, the only one exhibited, were more especially worthy of notice; but the most attractive articles exhibited by this firm were Fletcher's gas apparatus, the whole collection of which was placed in another room, and will be described later on.

Messrs. Dollond and Co. exhibited, among other articles of interest, a spirometer, which received a large share of attention from the younger visitors, who were evidently desirous of becoming acquainted with the capacity of their lungs, and Beale's compact urinary test cabinet. There was also a series of chemical and clinical thermometers, one of the latter with an improved flat bore, presenting a broad line of mercury to the eye, and hence more easily seen, with an indestructible index, which seemed to be especially approved of; the price of this instrument is stated to be reduced one-half.

The only regrettable incident at the Exhibition occurred in connection with this exhibit. A small case of clinical thermometers, valued at two guineas, was not to be found on Friday morning, when the articles were removed by the owners. The Exhibition could hardly have been visited by a kleptomaniac, or his propensity would have been further indulged, and it can only be supposed that the case may have been packed by accident among the goods of some other firm, in which case it is hoped this notice may be sufficient to direct it to its rightful owners.

Messrs. Dollond and Co. also exhibited Lowne's Patent Short Length Mercurial Barometer and Combined Thermometer, which is claimed to possess the advantage of a column of mercury 4 to 8 inches in length instead of 30 inches, and hence smaller size, greater portability and cheapness; it also has a fixed scale combined with great accuracy. In this instrument the closed end of the mercury tube consists of a globe containing carefully dried gas, and to prevent a difference of pressure arising from alteration in the temperature of the external air the mercury in the U-tube joins that contained in the stem of the thermometer, so that the height of the mercury in the barometer is not altered by heat, but only by atmospheric pressure.

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.*

BY WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

Lecture II.

Pepsin and Trypsin—Digestion of Proteids.

(*Continued from p.* 961.)

Comparison of the Action of Pepsin and Trypsin.—The action of pepsin and trypsin, although similar in the main results, is certainly not identical. There is a markedly larger production of leucin and tyrosin in tryptic than in peptic digestion. Moreover, the action of the two ferments on different proteids appears to vary both in character and in energy. Milk is much more readily digested by pancreatic extract than by artificial gastric juice; but in the case of egg-albumen the advantage lies decidedly with the gastric juice. The study of the digestion of egg-albumen by the two methods yielded some interesting results. I employed for this purpose a dilution of egg-albumen with water, in the proportion of one in ten. This remains uncoagulated after being boiled in the water-bath, and furnishes a favourable medium for studying the digestion of albumen, much more favourable than the chopped boiled white of egg usually employed. It permits the ferment to be at once brought into uniform and intimate contact with the particles of the albumen, thus obviating the irregularity and want of constancy which necessarily attend the operation of a solvent acting on solid pieces of variable size, which can only be attacked progressively from their surfaces. In the raw state, this solution is digested with extreme slowness by artificial gastric juice; and pancreatic extract is nearly inert on it; but after being boiled it is attacked with energy by both the gastric and the pancreatic ferments.* When the boiled solution was treated, in the warm chamber, with pepsin and hydrochloric acid the transformation of the albumen went on rapidly and without interruption to its close. In the earlier periods of the action, the mixture gave a dense precipitate with nitric acid and with ferrocyanide of potassium, but this precipitation became progressively less and less pronounced, until, at the end of two or three hours, these reagents only produced a slight haze. The albumen was now completely digested, or at least as nearly so as could be reached, for this remnant of a reaction persisted even after a further digestion of twenty-four hours.

When the same solution was treated with pancreatic extract, the progress of events was different. For an hour or two (the time varying with the quantity of extract added) there was no apparent change; but at the end of this time the mixture lost its diffluent condition, and became converted into a gelatinous mass, exactly resembling a thin starch jelly. By-and-by the gelatinous matter broke up into little masses, which floated in a transparent liquid. At this point, the action seemed to be arrested. The floating masses of jelly remained almost undiminished in quantity after twenty-four and even forty-eight hours. When the mixture was filtered, the liquid portions came through perfectly transparent, and the jelly-like matter was left in the filter. The filtrate was found to be a rich and very pure solution of peptone, uncontaminated with any undigested or half-digested albumen. The jelly-like matter was found to be insoluble in water, hot or cold, but it dissolved readily in acids, and was rapidly digested by pepsin and hydrochloric acid. If a large amount of pancreatic extract were used, a considerable proportion of the jelly-like matter was slowly dissolved; but the main result was always the same, the pancreatic ferment was only able to convert a part of the albumen into peptone, whereas the gastric ferment converted the entire quantity, with the exception of an insignificant residuum.†

In the case of milk the relation of the two ferments is reversed. Tryptic digestion of milk is rapid, and leaves only a very slight residue, whereas peptic digestion is slow and leaves a large residue. I have some further observations to make on the digestion of milk by pancreatic extract, but it will be more convenient to take up the subject when I come to speak of the use of this ferment for the preparation of artificially digested food.

Peptogens.—I may here advert to a singular view advanced by Schiff in regard to the production and secretion of pepsin and trypsin. Schiff found that when an insoluble aliment, such as white of egg (or fibrin, or meat which had been deprived of its soluble portions), was introduced into the stomach of a fasting animal no pepsin was secreted, and the albumen remained undigested; but

* The Lumleian Lectures, delivered before the Royal College of Physicians.

* In cooking this solution it is advisable to use the water-bath, for otherwise some of the albumen coagulates and cakes on the bottom of the vessel, and the liquid froths up in an inconvenient manner.

† Most observers have noticed the occurrence of this indigestible residuum (named "dyspeptone" by Meissner) in the artificial gastric digestion of proteids. I have noticed the same in the digestion of milk by pancreatic extract.

if with the albumen certain soluble aliments were introduced into the stomach, then pepsin was produced, and digestion immediately began. To these substances, which had the power of provoking the formation and secretion of pepsin, Schiff gave the name of "peptogens." Among the most effective peptogens were found to be solutions of dextrine, extract of meat (or soup), infusion of green peas, bread (which contains dextrine), gelatin, and peptones. On the other hand, solutions of grape sugar, soluble starch, fat-emulsion, or gum, had no peptogenic effect; and milk and coffee had not much. Schiff further found that peptogenic substances were just as effective when they were injected into the blood, or into the cellular tissue, or introduced as enemata into the rectum, as when they were introduced directly into the stomach. On the other hand, when peptogens were injected into the small intestine their influence was not observed; their effect seemed to be annulled by some action of the mesenteric glands, or by some change induced in them in their passage along the thoracic duct. On the ground of these experiments—and they were numerous and oft-repeated and gave constant and decisive results—he concluded that the absorption into the blood of these soluble aliments was a necessary preliminary of proteid digestion and that no pepsin or trypsin was secreted unless these substances existed beforehand in the blood. The first act, according to Schiff, of gastric digestion was the absorption from the constituents of a meal of these soluble peptogens by the veins of the stomach. On this followed immediately the secretion of pepsin, and the commencement of digestion proper.*

These views and experiments of Schiff have not been allowed to pass without challenge, but they have not yet been overturned. If they should be substantiated, they will give, curiously enough, a scientific sanction to the prevailing custom of commencing dinner with soup.

The Milk-curdling Ferment.

You all know that one of the most striking properties of gastric juice is to curdle milk. This property is utilized on a large scale in the industrial art of making cheese. Rennet, which has been used for that purpose from remote antiquity, is simply an infusion of the fourth stomach of the calf in brine. The curdling of casein by rennet does not depend upon the acid of the gastric juice, for it takes place when the milk is neutral or even faintly alkaline. It has until lately been believed that this property was an inherent attribute of pepsin, but this opinion is no longer tenable. Brücke succeeded, by a process which I need not particularize, in producing pepsin which had an energetic action on proteids, but which did not possess, except in the feeblest degree, the power of curdling milk. Mr. Benger also found that an extract of pig's stomach in saturated brine, while it possessed energetic action as a milk-curdler, had comparatively only feeble proteolytic powers. We must therefore regard the agent in gastric juice which curdles milk as a distinct substance from pepsin.

In the course of my experiments on pancreatic extract, I made the unexpected observation that the pancreas also contained an agent capable of curdling milk. I found this property in the pancreas of the pig, the sheep, the calf, the ox, and the fowl. In whatever way the extract of the gland was made, whatever solvent was used, this property of curdling milk was present in it; but the brine extract exceeded all others in curdling capacity. If a few drops of extract of pancreas be added to some warm milk in a test-tube, the milk becomes a solid coagulum in a few minutes. Some minutes later, the whey begins to separate from the curd. In short, the action resembles exactly that of calf's rennet; and, so far as I know, you could make cheese with pancreatic rennet as perfectly as you can with gastric rennet. There is, however, not an absolute identity of the two agents. I said just now that gastric rennet produced curdling in neutral and even in faintly alkaline milk; but if the alkali exceed a very small proportion, ordinary rennet does not curdle milk. I found that an alkalescence exceeding that produced by one grain of bicarbonate of soda to an ounce of milk altogether prevented the milk from being curdled by gastric rennet. But this is not so with pancreatic rennet. You may add 2, 3, or 4 grains of bicarbonate of soda to each ounce of milk, and still the pancreatic rennet will induce curdling with undiminished energy. Milk is likewise curdled by pancreatic extract, when quite neutral, and even when very faintly acid. Indeed, it appeared to me that a very faintly acid milk curdled more actively with pancreatic extract than neutral milk, but not so actively as alkaline milk.

That the curdling agent of the stomach and pancreas is a true ferment, and not some inorganic chemical agent, seems to be proved by the fact that boiling, or even heating to 160° F. (70° C.) instantly destroys its power. I found, moreover, that like other soluble ferments, it is precipitated, but not truly coagulated, by alcohol; for it recovers its solubility and activity when the alcohol is removed, even after a contact of several weeks.

The curdling ferment of the pancreas is a distinct body from trypsin, as the following experiments show. 1. Some brine-extract of pancreas (which was known to possess proteolytic energy) was acidulated with hydrochloric acid in the proportion of 1 per 1000, and then placed in the warm chamber at a temperature of 104° F. (40° C.) for a period of three hours. It was then carefully neutralized with bicarbonate of soda. When thus treated, the extract was found to have lost its proteolytic power, but its curdling action on milk was almost as energetic as ever. 2. A portion of the same brine-extract of pancreas was filtered under vacuum pressure through porous earthenware. The filtered product was found to possess an undiminished faculty of curdling milk, but it had almost no power of dissolving the curds. The curdling ferment had evidently traversed the earthenware freely, but only traces of trypsin had passed through.

What is the real function of the curdling ferment? Seeing its striking reaction with milk, one's first idea is that it must have something to do with the digestion of casein. But a little consideration shows that this idea is altogether improbable. Although all mammalia start life on a milk-diet, milk does not form a part of the normal diet of any adult creature except man. Nor can its universal presence in the mammalian digestive organs be regarded as a vestigial phenomenon—a "memory" of the suckling phase of their existence—for the same curdling property is found in the stomach and pancreas of the fowl, which never at any period of its life fed on milk. Moreover, it may be doubted whether the ferment in question is the actual agent which curdles milk on its passage into the stomach; for the acid of the gastric juice, which also curdles milk, would probably be beforehand with it, inasmuch as its action is a good deal more prompt than that of the ferment. In the pancreatic digestion of milk, the occurrence of curdling has appeared to me to be a distinct hindrance to the process. Has this ferment any true digestive functions? I think this is quite open to doubt. Its action on milk is apparently akin to that of the fibrin ferment on the blood, and it may likewise have some kindred purpose, but what that purpose may be I am unable to conjecture.

Emulsive Ferment: Digestion of Fats.

The digestive change undergone by fatty matters in the small intestine consists mainly in their reduction into a state of emulsion, or division into infinitely minute particles. In addition to this purely physical change, a small portion undergoes a chemical change whereby the glycerine and fatty acids are dissociated. The fatty acids thus liberated then combine with the alkaline bases of the bile and pancreatic juice, and form soaps. The main or principal change is undoubtedly an emulsifying process, and nearly all the fat taken up by the lacteals is simply in

* See Schiff's 'Leçons sur la Physiologie de la Digestion,' vol. ii., p. 200 *et seq.* Paris: 1867.

a state of emulsion, and not of saponification. It is, however, quite certain that both these processes do take place in the small intestine, though in very unequal degrees. The only question in connection with the digestion of fat which I propose to examine is: Whether these changes are produced by the operation of soluble ferment, or by some other and different agencies? In his latest utterances on this subject, Bernard* insisted that the digestion of fat, like the digestion of starch and proteids, consisted in the action of a soluble ferment, which he named *Ferment Emulsif.* This ferment, he alleged, first emulsified and then saponified fats. In the intestine, the change scarcely went beyond emulsion—in this condition fat was found in the contents of the lacteals. Saponification took place almost exclusively further on, and later in the blood. It is certainly established that the pancreatic juice exercises a marked influence on the digestion of fats; and it is in the pancreas, according to Bernard, that the emulsive ferment is to be found. Bernard demonstrated that healthy pancreatic juice has quite a special faculty of emulsifying fats. Pancreatic tissue has also the same property. If a portion of fresh pancreas be rubbed up with fatty matter and water, you get an emulsion which is fairly persistent. I have not had an opportunity of examining the behaviour of pancreatic juice with fatty matter, and cannot therefore speak of its properties; but it is singular if, as alleged, the effect of pancreatic juice and pancreatic tissue on fat be due to the presence of a soluble ferment, that the extracts of pancreas possess none of the same power. I have made extracts of pancreas in various ways—with simple water, with chloroform-water, with dilute spirit, with solutions of boracic acid, of borax, and of both combined, with glycerine and water, with brine, and with solution of salicylic acid and of salicylate of soda; and yet I could not satisfy myself that any of these extracts possessed any special power of emulsifying fats, nor of liberating the fatty acids and inducing saponification. Paschutin† states that the emulsive ferment of the pancreas can be extracted by a solution of bicarbonate of soda. An extract of pancreas, made by myself with 2 per cent. solution of bicarbonate of soda, was indeed found to have a very marked emulsifying power; but it had the same power, even in an enhanced degree, after being boiled, which showed that its emulsifying properties could not depend on the presence of a soluble ferment.

I was equally unsuccessful in my attempts to verify the alleged power of extracts of pancreas, and of crushed pancreatic tissue, to liberate the fatty acids. When fresh pancreas, finely triturated with sand, was digested with milk in the warm chamber, I could not obtain satisfactory evidence of the development of free acid from the decomposition of the fat of the milk by a soluble ferment. The pancreas itself yields a slightly acid solution when infused in water, and a mixture of milk and pancreatic tissue always showed a slight acid reaction; but when this primary acidity was neutralized, no further production of acid took place until such a time had elapsed as was sufficient to permit the development of organized ferments and the origination of the lactic fermentation. If the development of organized ferments were prevented by the addition of antiseptics—such as chloroform or a combination of boracic acid and borax—a mixture of milk and crushed pancreas remained neutral for several days. The same results followed when I operated on emulsions made with crushed pancreas and lard or olive oil. In my numerous observations on the digestion of milk with various pancreatic extracts, I never could detect the production of an acid reaction, unless organized ferments were permitted to intervene.

I obtained similar negative results with almond emulsion. Bernard attributed the formation of an emulsion when almonds (or other oily seeds) were rubbed up with water, to the presence in the seeds of a soluble ferment. But I found, to my surprise, that almonds which had been boiled for seven hours still produced a perfect emulsion. As all known soluble ferments are destroyed by boiling, this result seems irreconcilable with Bernard's view. I also found that almond emulsion, kept in the warm chamber for six or eight hours at a temperature of 100° F. (38° C.), showed not the slightest evidence of an increase of its original faintly acid reaction. It appeared to be more probable that the fatty matter in the almond existed in the seed in the condition of a solid emulsion; and that the formation of a fluid emulsion by trituration with water was due simply to the liberation of the minutely divided oil-particles, rather than to the intervention of a soluble ferment.

It is with considerable hesitation that I venture to place myself in even apparent contradiction with so great an observer as was Claude Bernard; and I by no means pretend that these observations traverse the main conclusions for which he contended as to the digestive transformation of fat in plants and animals. The views which Bernard developed on the digestive process are based on inductions so wide, and observations so multiplied, that I feel satisfied that their substantial accuracy will be ultimately established in regard to fat, as they have already been established in regard to starch and cane sugar.

Some observations made by Brücke promise to throw a fresh light on the digestion of fat. Brücke found that oils and fats which contained an admixture of free fatty acids—in other words, which were more or less rancid—were emulsified by a slight agitation with a weak solution of carbonate of soda. J. Gad extended these observations, and showed that even simple contact of a rancid oil with the alkaline solution was sufficient to effect a mechanical division of the oily matter. I have repeated these observations, and the results are very remarkable. The different behaviour of two specimens of the same oil, one perfectly neutral and the other containing a little free fatty acid, is exceedingly striking. I have here before me two specimens of cod-liver oil—one of them is a fine and pure pale oil, such as is usually dispensed by the better class of chemists; the other is the brown oil sent out under the name of De Jongh. I put a few drops of each of these into these two beakers, and pour on them some of this solution, which contains 2 per cent. of bicarbonate of soda. The pale oil, you see, is not in the least emulsified; it rises to the top of the water in large clear globules; the brown oil, on the contrary, yields at once a milky emulsion. The pale oil is a neutral oil, and yields no acid to water when agitated with it—in other words, it is quite free from rancidity; but the brown oil, when treated in the same way, causes the water in which it is shaken to redden litmus paper. I was surprised to find that olive oil (salad oil), which appeared quite sweet and had not the slightest taste or smell of rancidity, gave a milky emulsion with the soda solution. This oil did not yield any acid reaction to water when agitated therewith. Nevertheless, it evidently contained a little free fatty acid (probably oleic acid, which is insoluble in water, and therefore does not acidify water shaken up with it); for, when a portion of this oil was washed with a strong solution of carbonate of soda, and then allowed to separate, the oil thus freed from acid no longer gave an emulsion with the weak soda solution. It would appear that an admixture of only a very small proportion of free fatty acid is sufficient to induce emulsification—a quantity so small as not to cause any appreciable rancidity to the senses of smell or taste. This specimen of almond oil is to all appearance perfectly sweet; but it communicates a rather sharp acid reaction to water shaken up with it, and it gives, as you see, an instantaneous and perfect emulsion with the soda solution.

The bearing of these observations on the digestion of fat is plain. When the contents of the stomach pass the pylorus, they encounter the bile and pancreatic juice,

* Claude Bernard, 'Leçons sur les Phénomènes de la Vie,' tome ii., page 346. Paris: 1879.

† Hoppe-Seyler, *Physiologische Chemie*, p. 257. Berlin: 878.

which are alkaline, from the presence in them of carbonate of soda. Thus the fatty ingredients of the chyme, if they only contain a small admixture of free fatty acids, are at once placed in favourable circumstances for the production of an emulsion without the help of any soluble ferment, the mere agitation of the contents of the bowel by the peristaltic action being sufficient to effect the purpose.

This view of the matter renders it necessary that fresh inquiries should be made into the effect of gastric digestion on fats. It has hitherto been supposed that fatty and oily substances undergo no change in the stomach; but it is quite possible that something may have been overlooked. It was noticed by Richet, in the patient with a gastric fistula, that the fatty matters were detained a long time in the stomach, and that they only passed through the pylorus with the last portions of the meal. It is also a familiar experience to most dyspeptics, that rancid eructations are a frequent occurrence in the later stages of gastric digestion. If it should turn out that, among the complex operations taking place in the stomach, there occurred some slight decomposition of the neutral fats, and a liberation of a small quantity of free fatty acid, such a result would supply the necessary condition for the emulsification of the neutral fats in the duodenum. In speculating on this subject, it is difficult to shut one's eye to the possibility of the intervention of formed or organized ferments in the digestive process. It is well known that fatty acids are liberated in the decomposition of neutral fats by bacterioid ferments (zymophytes); and the presence of ferments of this class in the living stomach has been so repeatedly observed that it may well give rise to the suspicion that they are a normal ingredient of the gastric mucus, and have a normal function to perform in the digestion of some portions of our food. It is not, however, desirable to push speculations of this kind in advance of observed facts; and I only mention them as hints for further inquiry in regard to the digestion of fat.

(*To be continued.*)

A VISIT TO THE NATIVE CINCHONA FORESTS OF SOUTH AMERICA.*

BY HENRY S. WELLCOME.

During the past year, while in South America, I visited some of the principal cinchona districts, and the following notes are based upon my personal observations and information obtained from native bark dealers and gatherers.

The cinchona forests of Ecuador—of which I shall speak in particular—were for many years the only source from whence the world was supplied with barks; they still yield large quantities, and are being actively worked.

The bark-producing territory of Ecuador is divided into two general districts, known as Bosque de (forest of) Guaranda and Bosque de Loja.

The vast tract of wilderness extending from the boundary line of New Granada, about 1° north latitude, south to 2° south latitude, covers with its rich verdant mantle the western slope of the gigantic Chimborazo and the outlying ranges of the Cordilleras, from the waters of the Pacific up to an altitude of over ten thousand feet, encompassing within its higher limits the picturesque city of Guaranda.† This district is now the source of the larger portions of barks exported from Guayaquil;‡ many miles of its entangled forests have never yet been explored.*

The older cinchona district, known as Bosque de Loja, was the source of the first barks taken to Europe, or of which we have any authentic history. This district extends from 2° south latitude south to the boundary line of Peru, about 5° south latitude, and, like the Bosque de Guaranda, covers the western slope of the Cordilleras below the timber line. The cinchona bark, with which the Countess of Chinchon,† wife of the Viceroy of Peru, was cured of fever, in about the year 1640, was collected near the town of Loja. Howard considers it well established that this bark was none other than the Royal Crown Loja quill.‡ It is of interest, too, that the cure of the princess was probably due less to the alkaloid quinia than to the lower alkaloid cinchonidia, which predominates in that bark.§ The Loja forests still continue to furnish barks to the Guayaquil market; but there has been a gradual falling off in quantity during the past few years, which is not surprising, considering that they have been worked constantly for over two hundred years, and been more thoroughly explored than any other forests of South America.

To reach the southern portion of the Bosque de Guaranda a small steam launch plies between the city of Guayaquil and Pueblo Nuevo, a small town about seventy-five miles distant, on one of the eastern branches of the Guayaquil River. The trip is an exceedingly interesting one; hundreds of Indian canoes and balsa rafts|| are met, laden with fish, vegetables and fruit for the Guayaquil market.

We passed innumerable little floating islands, covered with exuberant growths of aquatic plants. Loathsome alligators crawl up the river-banks and bask in the warm sun; great numbers of white herons flock along the shore. Here and there little hamlets of bamboo nestle in shady nooks, surrounded by groves of oranges, mangoes and bananas.

Occasionally we are startled by the thundering boom of the ever active volcano, Saugay.¶ To the north, towering far above the clouds, we saw the lofty summit of Chimborazo, "grand monarch of the Andes," in all its resplendent glory; a dazzling pinnacle of everlasting snow, emblematical of a spotless purity, that presents a mocking contrast with the people who dwell upon its slopes, and call it their father. According to a legend cherished by the Chimbo Indians,** "many years ago

---

* From the 'Proceedings of the American Pharmaceutical Association,' 1879.

† The first cinchona trees discovered within the Guaranda district were found near this city, hence the name of the forest.

‡ Guayaquil, the main shipping port of Ecuador, is a city of 30,000 inhabitants, situated on the Guayaquil River, sixty miles from its mouth. The river is navigable to this point by large ocean steamers.

* The limits of these districts are not clearly defined, and can be stated as approximations only.

The northern portion of the Guaranda forest is also known as "Bosque de Esmeraldas," from the name of an adjacent seaport on the coast of Ecuador, from whence some barks from that portion of the district are exported.

† It is not known whether Linnæus corrupted purposely or by error when he gave the name "cinchona" to the new genus (which he established for it) to commemorate the name of the Countess of Chinchon, through whose beneficent efforts the great remedy first became generally known in Europe.

‡ From *Cinchona condaminea*; grows to the height of eight to twenty feet, and at an altitude of 6000 to 9000 feet.

§ At that time the Royal Crown barks were considered the finest quality, but have long since ceased to hold that regard; under the advanced knowledge of quinology analysis shows it to rank low in the yield of the alkaloid quinia. By cultivation, in the East Indies, it has been made to increase its percentage of the valuable alkaloids.

|| Balsa rafts are made by lashing together with bejucos the trunks of a tree called balsa palma; they are as light as cork and exceedingly buoyant. Rigged with masts and sails these craft cruise along the coast, and sometimes venture well out to sea.

¶ The volcano Saugay was active at the time of the Spanish conquest, and has been in constant eruption ever since. It discharges every thirty or forty minutes; the explosions are often heard in Guayaquil, over one hundred miles distant, and her ashes fall in the streets.

** The descendants of the Chimbos now live in the Valley of Chimbo, on the western slope of Mount Chimborazo.

their nation was founded by the great Chimbo razo (Chimbo father); they prospered under his wise guidance and became a powerful people, but finally the great father died and changed to the mountain of snow (Chimborazo), that he might furnish his children with water to drink. But on the very day that the mighty Inca nation* conquered them, Chimborazo was so stricken with grief that his head fell off." An irregular spur, jutting out from the north side of the mountain, just above the snow-line, is pointed out as being his head.

Arriving at Pueblo Nuevo peons† and beasts are engaged and equipped for the journey, on muleback, or, as sometimes facetiously termed, "on the hurricane deck of a mule." All travel and transportation must be done on the backs of beasts or Indians, as wheeled vehicles are useless for want of roads. In the higher altitudes llamas serve as beasts of burden, and in the valleys of Quito and Riobamba I have seen sheep, goats and cattle used for the same purpose.

From Pueblo Nuevo extends a few miles of the narrow gauge railroad‡ constructed under the administration of the late President Garcia Moreno. It was his greatest ambition to open to the outside world the glories of the higher Andes. But shortly after the road was begun an assassin's knife checked his energetic and enterprising career.

The trail through the forest is simply a rough bridle-path, worn by years of travel, though not improved by use, sometimes leading us through low marshy places of nearly bottomless mire, where the beasts floundered about, sinking deeper and deeper, until they and ourselves were nearly submerged. Proceeding to the interior the forest growths show greater exuberance; the trees are so netted with vines, creepers and trailing lianas, and the foliage so closely woven together, as to present almost impenetrable walls on either side of the way, draped with rich verdure, while leaves of bright and varying tints light up and relieve the sombre shades.

The many beautiful flowers attract and please, but do not so deeply impress and charm one as does the gorgeous foliage in which nature has so lavishly grouped the choicest gems and wrought such perfect harmony in her infinite variety of elaborate designs and rich colourings.

Before reaching the highlands we passed through forests of the ivory-nut palms, with their long, graceful, feather-like branches; and a few scattering trees of *Cinchona magnifolia* (a valueless variety) are met with.

Occasionally we found clearings, with extensive haciendas of cacao, coffee, sugar-cane and annatto, and halted for the night at one of these estates. The huts are constructed of bamboo, and erected on stilts, to prevent the entrance of animals and reptiles, as also for safety in times of floods, which frequently occur during the wet season.§ The house-furnishing is very simple; neither chairs, tables, beds or stoves are found in these huts; fire is used for cooking only, and is prepared on a flat rock or on the ground. The fare is quite as meagre; our bill consisted of calde, locro and roasted plantain. Calde is their most substantial dish; it is prepared by boiling together—in something like the style of an Irish stew—the tough, rank meat of a gaunt black pig of the country, with potatoes,‖ onions, garlic and Chili peppers. Locro is a peculiar mushy soup, made by boiling potatoes and eggs together with various condiments. Plantains are roasted by burying them in hot coals and ashes before removing the peel.

Food is served in a rough carved bowl of wood, or calabash; the liquid portion taken with a wooden spoon and the solids fished out with the fingers.

The natives in these forests do not burden themselves with extensive wardrobes. The young, under fifteen years of age, often appear in the innocence of perfect nakedness.

There is something peculiarly fascinating about the careless simplicity of these people, their procrastinating manner of life and romantic surroundings.

In the place of beds we found repose upon the floor; but the nights at the equator are too delightful for sleep; the skies are so clear and transparent that one can seem to peer into the remotest depths of space, and, verily, to view the realms of Deity. Nothing can surpass the enchanting splendours of the tropical skies; the stars shine out in the great azure dome with a brilliancy unknown in our northern climes, while myriads of more distant luminaries cluster like clouds in the background.

We miss the Dipper of the constellation of the Great Bear, but are amply repaid by a view of the Southern Cross in its stead.

The bright moon and starlight penetrating the mingled foliage of the lofty forest trees produce mystic shadows, delineating divers grotesque, unearthly forms, and adding to the weirdness of our surroundings; the lightning-beetle* flashes out a vivid gleam of greenish-yellow light, that, to the brilliancy of a diamond, is like contrasting the electric light to a tallow dip.

Balmy, zephyr-like breezes gently fanned us into such a dreamy, fanciful mood that we could easily have imagined ourselves transported to a fairy-land, were it not for the ravenous onslaughts of cannibalistic fleas and mosquitoes, forcibly reminding us that we were yet beings of flesh and blood.

At midnight the temperature fell to about 50° F., and a damp, clammy chill came over us, making us wrap more closely in our blankets.

After continuing our journey for some distance into the foot-hills, we left the regular trail and struck into a newly cleared way to the north, keeping our peons ahead, with machetes† in hand, to cut away the bejucos‡ which hang in loops that threaten to catch beneath the chin and jerk one from his beast. Very strong clothing is required in travelling through these forests, for the many hooked branches play havoc with one's habit and often cut ugly flesh-wounds.

In crossing the rivers a tree felled across, from bank to bank, served as a foot-bridge, over which we passed, while our mules were made to swim; it is not without considerable danger that these crossings are made, and frequently serious accidents occur.

In some of the more travelled Andean trails, where the banks are very high and abrupt, the rivers are crossed by hammock or swinging bridges, made of bejucos. The small mountain streams are usually forded; frequently we follow up their banks, recrossing sometimes half a dozen times within a mile.

The cheery, musical ripple and murmur of those crystal clear waters, breaking over the numerous rocky declivities, which form an almost continuous array of rapids, with now and then furious cascades, produce a

* The ancient Peruvians found in possession of the country at the time of the conquest by Pizarro.

† Peon, an Indian servant, labourer, or slave.

‡ A German engineer has recently contracted with the Ecuadorian Government to extend the road to Quito, but considering the present financial condition of the country, the realization of such a stupendous feat of engineering in our day is extremely doubtful.

§ The wet season, called "invierno," lasts from December until May; during those months frequent heavy rains occur, and, together with the melting of snow on the high mountain-peaks, produce furious floods.

‖ Potatoes were first introduced into Europe from Ecuador.

* *Pynophorus noctilucis.* In the evening these beetles are worn as jewellery by the native women, and with very charming effect. The insect is attached to the clothing by means of a sort of harness of thread. The light proceeds from two small lobes on the thorax; they continually dim and again intensify the glow of these little lanterns, producing a peculiar wavering brilliancy that is quite dazzling.

† The machete is a large heavy knife carried by the natives; it has a blade fifteen to twenty-five inches in length.

‡ Bejucos, a name applied to all woody climbing vines.

most grand and striking contrast with the sombre silence of those majestic forests.

I was greatly disappointed on entering for the first time a tropical forest at midday, by the almost oppressive silence that prevailed and apparent want of animal life. Occasionally we heard the zip of a humming-bird and traced, like a flash, the glitter of its brilliant plumage in the sunlight as, for a moment, it darted from one flower to another, then, fairylike, disappearing in an instant.

Great numbers of beautiful butterflies floated silently past, waving their banner-like wings, so resplendent with lustrous hues.

Now and then a reptile glided across our pathway, and a gang of monkeys, taking fright at our approach, would scramble away into the tops of the higher trees.

Little else of animal life was seen during the day, but at twilight and in early morning the whole forest seemed to be alive: above all, in the hubbub of unearthly noises, could be distinguished the shrill screeches of the macaws, toucans and parrots, and the yelling or howling of monkeys.

Little music could be found in all these discordant sounds. It is remarkable that among the many tropical birds of gay plumage there are very few sweet songsters; their notes are nearly always harsh and shrill.

Getting fairly into the mountains the difficulties and dangers increase; zigzagging up almost vertical cliffs, only to find steep descents, and descending to climb again. In these mountains it is necessary to trust entirely to the mules.* Often having to go through narrow passageways, between huge boulders, dodging projecting rocks, then winding our way around the mountain-sides in narrow grooves, barely wide enough for the beasts to gain a footing, sometimes along the verge of frightful precipices of several hundred to a thousand or more feet. In some of the older trails there can be seen in the far depths of the chasms below whitened skeletons of human beings and mules, and now and then ghastly human skulls are found placed in niches cut into the bank along the passage, invariably with a cross above them, being tenderly suggestive of lurking dangers. Words are inadequate to picture the terribly broken and precipitous character of these Andean ranges; on every side traces of eruptive violence are distinctly visible; every rock shows the marks of a tremendous crushing force; the irregular masses of rock and earth heaped together form tortuous ridges and bold craggy spurs, with numerous intersecting fissures, ravines and vast chasms; every physical feature is modelled on a scale of magnificence and grandeur. Towering proudly above the Guaranda and Loja cinchona districts, and grouped within a radius of one hundred miles, are the lofty trachyte and porphyritic peaks of more than twenty volcanoes,† four of which are now active. Ecuador is a very hot-bed of eruptive elements; she is frequently convulsed by earthquakes, and at irregular intervals her volcanoes break forth with terrific fury, belching their fires high into the heavens, ejecting volumes of molten lava, and devastating the surrounding country with showers of stones, ashes and mud.

It must have caused our planet to quake to its very centre when nature's mighty convulsive forces burst their subterranean bonds, upheaving, rending and fragmenting the earth's surface, forming midst that awful chaotic tumult these vast cordilleras, with summits so near to heaven that they will never be defiled by the footprints of mankind.

In many places, while penetrating the forests, we were obliged to dismount and climb, while our mules were lifted almost bodily up the jagged steeps by the peons; but finally we reached a point beyond which it was impossible to take the animals. Leaving them in charge of a peon, we proceeded on foot, picking our way through the blind mazes of dense jungle, clambering over the decaying trunks of fallen trees, continually ascending and descending steep places until we gained a point on one of the great spurs, where we saw spread out before us a boundless undulating sea of wilderness, as far as the eye could reach, a gorgeous expanse of matted verdure, illumined by showy blossoms of glowing colours; here and there tall, slender columns of the palms pierced the forest roof and gracefully waved aloft their drooping, feathery branches.

The surpassing grandeur of this view was enrapturing beyond expression. On every hand the manifold and varied beauties unfolded themselves with almost bewildering rapidity; but suddenly a huge bank of clouds drifted upon us like a Newfoundland fog, curtaining the scene for a few moments and then quickly passing off.

Our cascarillero* soon descried some cinchonas in the distance, by the glistening leaves, which reflected brightly the vertical rays of the sun.

This characteristic reflex of the foliage, together with the bright roseate tints of the flowers, afford the means of discovering the cinchonas among this mass of forest giants. In prospecting by the appearance of the leaves alone a novice is easily misled by the india rubber tree, which has a glossy leaf very like the magnolias of our Southern States, and when seen at a distance reflecting the bright sunlight is easily mistaken for the cinchona.

Our cascarillero led us down a steep, slippery bank, formed of a reddish-yellow micaceous clay, which yielded like grease beneath our feet; we were obliged to cling to vines and limbs for support, as every few steps rocks would detach and fly crashing through the thickets below.

Finally reaching the bottom of the ravine, we followed the sinuous course of a small stream until suddenly our guide shouted "Cascarilla!"† and we were gladdened by the sight of several fair-sized trees of *Cinchona succirubra* on a slope near by.

(*To be continued.*)

* The sagacity of a mule is truly wonderful. They are the only safe animals for travelling in these mountains. They are far preferable to donkeys.

† Many of these volcanoes are continually mantled with snow.

* The bark collectors are called cascarilleros.

† Cascarilla is the Spanish word for bark.

THE STIGMATA OF MAIZE.‡

Professor Castan has recently called attention to the stigmata of maize as a remedy which he has found to be of great use in gravel and nephritic colic. In the latter disease there ensued after the administration of the drug a marked decrease in the painful symptoms, and he therefore supposed that the stigmata acted less as a diuretic than as a local anæsthetic.

The different results which the use of the stigmata of maize has given at the hands of different observers, appears to be due in large measure to the fact that the strength of the extract varies, according to the nature of the soil, to the climate, to the time, to the mode of picking, and to the manner of drying the stigmata. The formula for the preparation of the syrup is not yet fixed, since the quantity of the active principle varies in different samples of the stigmata. The *Pharmaceutical Union* adopts formulæ which contain in one case six, and in another twelve grams of extract to the kilogram of syrup. The latter receipt is based on the assumption of a strength of 12 per cent. This quantity appears, however, to be too small, since the best samples of stigmata yield 25 to 30 per cent. of extract, or on an average, 27·5 per cent. The kilogram of syrup will therefore contain 27·5 grams with this strength (27·5 pro mille). The daily dose of the syrup will be two to four spoonfuls, representing about one to two grams of the extract. In all cases the syrup should be used in preference to an infusion of the stigmata of maize.

The Pharmaceutical Journal.

SATURDAY, JUNE 5, 1880.

THE PHARMACEUTICAL EDUCATION OF THE FUTURE.

The report of the proceedings of Council last Wednesday will have an especial interest from the fact that one of the subjects to which most time was devoted is of very considerable importance, both in regard to the interests of pharmacy and those of the public. Thanks to the work of the Pharmaceutical Society of Great Britain it is now essential in carrying on the business of pharmacy that the pharmacist, though assuming no higher position than that of a tradesman, should differ from other tradesmen by having, not only a thorough training in the practical branch of his business, but also a sound acquaintance with certain branches of science bearing upon his practice, and that he should give proof of possessing such qualification before being entitled to carry on business. This distinction involves the possibility of attaining somewhat more of a professional status than has generally been enjoyed by chemists and druggists in this country, and thus becoming, as in other countries, more closely related to medical practitioners as forming a branch of the medical profession.

The promotion of education has always been the leading idea of the efforts made by the Pharmaceutical Society for the furtherance of these objects, and naturally the condition of the educational system will always be a subject to fix the attention of its Council. We do not wonder, therefore, to find an early pupil of the Society's School of Pharmacy, now holding the honourable position of Vice-President of the Council, bringing forward a motion for a special inquiry into the mutual relations of pharmaceutical education and pharmaceutical examination, with a view to reporting thereon to the Council. It is not, we think, a strained interpretation of the proposal to infer there is something wanting somewhere, and that the Committee will have to make known the nature of the want, and suggest fitting remedies.

At the very outset the Vice-President emphatically declares the standard and purpose of the examination to be perfect, or as nearly so as he could judge after giving very particular attention to the way it was conducted. He also speaks with no less decision as to the able and kindly way in which the individual examiners perform their duties. Consequently we cannot from this point of view suppose that there is any defect in the present method of examination which has induced Mr. Schacht to urge upon his colleagues this inquiry. It is true that he goes on to say that there is a certain class of candidates for examination with which the examiners experience great difficulty, and the picture he presents of the circumstances causing this difficulty is a sorry one; but notwithstanding this, and notwithstanding the suggestion that the hands of the examiners might possibly be strengthened for dealing with such cases, he does not say a word to indicate that he has observed any incapability of testing thoroughly the actual merits of candidates. On the contrary, he distinctly says that in the ordinary course a very few minutes suffice to show an examiner whether a candidate is well grounded or perfectly incapable of passing. And when we learn from Mr. Schacht that these two classes constitute the minority of the candidates, there cannot be much reason for hesitating as to the seat of the defect for which he seeks to provide a remedy.

It is, then, the education,—technically speaking, the pharmaceutical education,—of the majority of the candidates for examination that must be defective and in regard to which it may be necessary to take measures to ensure improvement. We will not here speak of those devices, superadded to ignorance, by which attempts are made to deceive the examiners, but will be content to accept the statement that candidates sometimes present themselves totally ignorant of the subjects they ought to know. Mr. Schacht speaks of this circumstance as calculated to excite astonishment at their audacity, but perhaps a somewhat more liberal estimate of their ignorance will more charitably account for it.

How, then, are we to hope pharmaceutical education may be improved? This is a question of vast importance to the entire body and especially to the younger members of it. We fear there is not much to expect from an extension of that system which is perhaps in the abstract the most perfect one, under which the young initiate learns all he requires to know during the period of his apprenticeship. It is but rarely that the pharmacy can be regarded as a school of pharmacy, and in various ways the tendencies of the age do not favour its being so. Some of our best pharmacists will not undertake the trouble and responsibility of teaching apprentices. Then, also, the manufacture of pharmaceutical preparations has become so much a special trade that there is less opportunity now than in the past for learning, even in the best establishments.

We may therefore look upon it that the idea of the pharmacy being the school of pharmacy is rather a reminiscence of the past than a dream of the future. And this brings us face to face with the question, What is to be the nature of the school of pharmacy of the future. How and where are the youths who determine to engage in this occupation as the business of their lives to acquire such sound and thorough knowledge of the subjects which are essential for carrying on that business as will enable them, not only to face the Board of Examiners without a misgiving or a fear, but also to prosecute their business with all the advantages to themselves arising from perfect mastery of their art and with that guarantee of security to the public which will justify their claim to a semi-professional position?

This, we take it, is the question which it is intended by the motion of Mr. SCHACHT to consider; it is truly a grave one, and there are many reasons for giving it every attention.

DEATH OF MR. W. W. STODDART.

MANY of our readers will see with regret the announcement on another page of the death on Tuesday last, from heart disease, of Mr. WILLIAM WALTER STODDART of Bristol. As a former member of the Council of the Pharmaceutical Society, as President of the British Pharmaceutical Conference, and in connection with the classes of the local Association, Mr. STODDART for many years took an active part among the leaders of pharmacy, and we hope to be enabled on a future occasion to refer more fully to his valuable services.

DEATH OF DR. ALFRED SWAINE TAYLOR.

THE Pharmaceutical Society has also just lost one of its Honorary Members in ALFRED SWAINE TAYLOR, M.D., F.R.S., the distinguished toxicologist, who died from heart disease, on the 27th ult. Dr. TAYLOR was born in 1806. He studied medicine and surgery under Sir ASTLEY COOPER and Mr. J. H. GREEN, and became M.R.C.S. Eng. in 1830, M.D. St. And. in 1852, and a Fellow of the Royal College of Physicians in 1853, having meanwhile been elected a Fellow of the Royal Society in 1845. Dr. TAYLOR was the first occupant of the chair of Medical Jurisprudence in Guy's Hospital, and as an authority upon medico-legal questions he had a great reputation.

THE ROYAL SOCIETY.

THE following is a list of the gentlemen who were elected Fellows at the meeting of the Royal Society on Thursday last:—THOMAS CLIFFORD ALLBUTT, M.A., M.D., F.L.S.; Professor JOHN ATTFIELD, Ph.D., F.C.S.; HENRY FRANCIS BLANFORD, F.G.S.; The Rev. WILLIAM HENRY DALLINGER; WILLIAM TURNER THISELTON DYER, M.A., F.L.S.; Lieut.-Col. HENRY HAVERSHAM GODWIN-AUSTEN; The Right Rev. CHARLES GRAVES, D.D., Bishop of Limerick; Professor DAVID EDWARD HUGHES; HENRY M. JEFFERY, M.A.; Professor FREDERICK M'COY, F.G.S.; J. FLETCHER MOULTON, M.A.; Professor CHARLES NIVEN, M.A., F.R.A.S.; JOHN RAE, LL.D.; Professor J. EMERSON REYNOLDS, M.D.; WILLIAM A. TILDEN, D.Sc.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of the above Association will be held on Thursday next, the 10th inst., when the following communications will be read:—"Chian Turpentine," by Mr. R. H. PARKER; "Note on Cinchonas forwarded to India," by Mr. R. W. HOUGHTON. A Report on Botany will be made by Mr. D. HOOPER on "The Medicinal Flora of Afghanistan."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, June 2, 1880.

Present—Messrs. Andrews, Atkins, Bottle, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Sandford, Savage, Schacht, Shaw, Squire, Symes, Williams and Woolley.

Mr. SANDFORD having taken the chair, the minutes of the Council meetings of May 5 and 19 were read and confirmed.

Mr. ATKINS suggested that it would be very desirable in future to shorten the reading of the minutes by omitting to read *in extenso* letters which had been received and entered.

Mr. RICHARDSON supported the same view. With the increasing pressure of business he feared that ere long the reading of the minutes at full length would very seriously encroach on the time of the Council.

MODE OF ELECTING MEMBERS OF COUNCIL.

Mr. BOTTLE desired to call attention to the mode of conducting the annual election of members of Council, which did not seem in all respects satisfactory, and gave notice of a motion to refer the matter to the Library, Museum and Laboratory Committee.

Mr. RICHARDSON said he would second the motion.

DEATH OF MR. STODDART.

Mr. SANDFORD said that under ordinary circumstances he should have at once called on the Council to elect his successor in the Presidential chair, but before doing so he had a very painful duty to perform, inasmuch as Mr. Schacht had just informed him of the decease on the previous day of their old friend Mr. Stoddart. At the previous meeting the Council had to regret the death of an old friend and good man, Mr. Cracknell, and now in Mr. Stoddart the Pharmaceutical Society had lost one of its brightest ornaments. Having been associated with him for about eight years on the Council, he felt very much grieved and depressed at the loss the Society had sustained, for although other occupations had of late kept Mr. Stoddart away from its meetings, yet he had always advanced the honour of pharmacy and the Pharmaceutical Society. He was quite certain that all the members would join in sending a message of condolence and sympathy to Mrs. Stoddart and the family. He would therefore move—

"That the Council, having heard of the death of Mr. Stoddart, desire to express to Mrs. Stoddart and the family of the deceased gentleman their most sincere sympathy at the loss which they have sustained, and at the same time to convey the assurance of the high esteem in which the late Mr. Stoddart was held by the Council."

Mr. SCHACHT said there could be but one feeling in all their minds, and he should perhaps best consult that feeling by simply seconding the motion in silence.

The motion was carried unanimously.

ELECTION OF PRESIDENT.

Previous to ballot being taken,

Mr. ATKINS inquired of Mr. Sandford if he had quite determined not to accept office again.

Mr. SANDFORD having stated that he could not accept the Presidency again,

A ballot was taken in the usual way, and—

MR. THOMAS GREENISH

was unanimously elected President.

Mr. GREENISH, on taking the chair, begged to thank his colleagues for the compliment they had paid him. It must be a source of pain to every member of the Council that one who was so thoroughly conversant with the business and so courteous in his manner as Mr. Sandford, should be unable, from considerations of health, to retain his position as President. He felt it a disadvantage to follow him, but he felt sure that Mr. Sandford would be as happy to afford him any advice and assistance he might require, as he should be to take advantage of it. He could only bow to the decision of the Council, and endeavour to the best of his ability to perform the duties, relying on its cordial co-operation and support.

Election of Vice-President.

On a ballot being taken—

MR. GEORGE FREDERICK SCHACHT

was re-elected Vice-President. He said he was much obliged for this renewal of the confidence of his colleagues, and he would take that opportunity of thanking them for conferring this honour upon him a year ago; he had gained a great deal from his experience in that responsible position, and he had only to assure them he would do his best to make that experience available to the advantage of the Society.

Election of Treasurer.

On a ballot being taken—

MR. JOHN ROBBINS

was elected Treasurer. He thanked the Council for the honour conferred upon him, and could only say he would would do his best to fulfil the duties of the office, and he hoped that at the end of the year he should leave a good balance for the incoming treasurer.

Vote of Thanks to the late President.

Mr. Bottle moved that a record should be placed on the minutes of the appreciation by the Council of the services rendered by the late President, Mr. Sandford. It had been his privilege to sit at the Council table for many years in connection with Mr. Sandford; he feared to say how many years Mr. Sandford had been a member, but he thought nearly thirty, and for nearly twenty years he had had the privilege of sitting there in his company. He had always experienced the greatest kindness from him, and had found him courteous to every member of the Society. Mr. Sandford had rendered immense services to the Society, and the members of the Council must have all regretted that in the early part of the year he had been compelled to tender his resignation, as he felt the pressure of the duties rather too heavy for him.

Mr. Savage, as another old member, had much pleasure in endorsing everything which had been said by Mr. Bottle. He might even go further and say that a more efficient President never occupied the chair. Though some members must occasionally differ from him they all felt the most entire confidence in him.

The Vice-President, as one who had during the past year been most intimately associated with the late President in his official duties, desired to add his testimony to what had been so well expressed by Mr. Bottle. Although he had at times felt constrained to differ from him on points of policy, he had never been treated with any the less cordiality on that account. He had much pleasure in supporting that motion.

Mr. Frazer, as a Scotch member, also bore his testimony to the good qualities of Mr. Sandford and to the kindness with which he had received him on his first election to the Council.

Mr. Symes, as a younger member than those who had yet spoken, desired also to express his sense of the kindness, courtesy and ability with which Mr. Sandford had always conducted himself in the trying position of President.

The President said the only objection he had to this motion was that some gentlemen seemed to suppose that they were going to lose Mr. Sandford's services, whereas he expected to have a great deal of work out of him yet. He had always told Mr. Sandford that he considered him a very obstinate man, but Mr. Sandford was always very courteous, and he felt that the Council could ill afford to spare him from that chair. He was sure, however, that it would still have his assistance. He would, therefore, put the motion—

> "That the best thanks of this Council be given to Mr. Sandford for the able and courteous manner in which he has filled the office of President."

The motion was carried unanimously.

Mr. Sandford said it would not be becoming in him to take up much time in returning thanks, but he must say a word or two in gratitude for the kindness which had been expressed that morning, and which he had experienced ever since he had the honour of sitting at the Council. He had, as Mr. Bottle had said, been there about thirty years, and for many years he had occupied the Presidential chair. Last year he took that position contrary to his own judgment, but in accordance with the wishes of the Council, and he had endeavoured as far as possible to carry out the duties to the best of his ability. As the President had said, he was somewhat obstinate, but he was delighted to hear his friends say that with all his obstinacy he had always been found courteous. As for differing in opinion, it must be expected that when twenty-one men got together there would be, and there should be, differences of opinion. Things would not go on well if all were of the same opinion. They should respect each others' opinions, and he always endeavoured to do so. He was very glad to see Mr. Greenish in the chair. As for rendering him any assistance, he did not think it would be wanted; but Mr. Greenish might depend on him at any moment for any aid he could give him. He must say, before sitting down, that he was not in failing health, but he was in advancing years, and he felt the time had come when he ought to have a little more leisure. But it would be always a pleasure to him to do all he could to forward the work of the Pharmaceutical Society.

Vote of Thanks to the Vice-President.

Mr. Hills moved a vote of thanks to the Vice-President for his services during the past year, which was seconded by Mr. Sandford, and carried unanimously.

The Vice-President briefly acknowledged the compliment.

Secretary and Registrar.

Mr. Elias Bremridge was unanimously appointed Secretary and Registrar.

Assistant-Secretary and Deputy-Registrar.

Mr. Richard Bremridge was also unanimously appointed Assistant-Secretary and Deputy-Registrar.

Standing Orders.

It was unanimously resolved that the Standing Orders of the Council be adopted for the ensuing year.

Elections.

Members.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Bucher, William Henry ....Crediton.
Hugill, Arthur Major ....Chislehurst.
Lord, William Henry ....Birmingham.
Williams, James Edward ......London.
Winfrey, Richard..................Long Sutton.

Chemists and Druggists.

The following registered chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Evans, Frederick William ......Treherbert.
Milne, William......................Torquay.
Parsons, George Henry ....London.

ASSOCIATES IN BUSINESS.

The following, having passed their respective examinations, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Bowling, John Henry ....Pembroke Dock.
Hornby, Charles Haycock ......Stockport.
Parkes, George James Robert...Wolverhampton.
Pugh, George ....London.
Robertson, John ....Arbroath.
Sanders, Thomas Scholes.........Salford.
Scoley, Thomas Edward ....London.
Wilson, William Wallace ......Glasgow.
Yeats, Thomas Flasby ....Liverpool.

Modified.

Greaves, John ....Cardiff.
Llewelyn, Ynyr ....East Molesey.

ASSOCIATES.

The following, having passed their respective examinations, and tendered (or paid, as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Fraser, John ....Chester.
Gelsthorpe, James ....London.
Glanville, George Grantley......London.
Illingworth, George Skeen ....Aberdeen.
Powell, John Alfred ....Reading.
Priestley, Walter Herbert ......Barnstaple.
Webster, Geo. Samuel Gothard...Alfreton.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society :—

Dobie, Robert Douglas ....Glasgow.
Duplock, Walter ....Petersfield.
Fox, Frederick William ....Lincoln.
Hucklebridge, Philip ....London.
Jolley, Sam Herbert ....Heaton Norris.
Metcalfe, Percival William ...Bradford.
Morrell, Frederick ....London.
Orry, John George ....East Kirkby.
Rae, Robert S. ....Annan.
Routly, John..........................Brighton.
Wheeley, John Thos. Martin ...London.
Wood, George Alfred ....Bridgnorth.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

ADDITION TO THE REGISTER.

The Registrar reported that—

Thomas Manning, Harleston, Norfolk,

having made the statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and this declaration having been supported by a duly qualified medical practitioner, his name had been placed on the Register.

APPEAL FROM THE REGISTRAR'S DECISION.

The Council then went into Committee to consider the correspondence, etc., relating to an appeal by Mr. Joseph Robinson Lund, of Bradford, from the decision of the Registrar not to put him on the Register.

On resuming, it was resolved that Mr. Lund's name be placed on the Register.

APPOINTMENT OF COMMITTEES.

The Council then proceeded to appoint the Committees for the ensuing year, the following being the result of the discussion:—

General Purposes.—The whole of the Council; four to form a quorum. To meet at six o'clock on the evening before the Council meeting, and at such other times as may be required.

Finance.—Messrs. Andrews, Gostling, Richardson, Savage, Squire and Symes. To meet at half-past four on the day previous to the Council meeting.

Library, Museum and Laboratory.—Messrs. Andrews, Bottle, Hampson, Hills, Richardson, Robbins, Sandford, Squire and Williams. To meet at twelve o'clock on the second Wednesday in each month, except August and September.

House.—The same as above. To meet at eleven o'clock on the same days.

Benevolent Fund.—Messrs. Bottle, Churchill, Hampson, Hills, Mackay, Radley, Robbins, Sandford, Shaw, Williams and Woolley. To meet at half-past three on the day preceding the Council meetings.

Evening Meetings.—The three Professors, the Editor, and the Curator of the Museum. The Committee to meet at twelve o'clock on the Wednesday preceding the Evening Meetings, and at such other times as may be found desirable.

Mr. WILLIAMS proposed the appointment of a Committee such as was appointed some time ago, consisting of the London members, to confer with the President whenever occasion might arise.

After some discussion, however, Mr. Williams withdrew the motion, it being the general opinion that the President should take the responsibility of action in any emergency which might arise, taking such advice as he might deem desirable.

Pharmacy Act Amendment.—Messrs. Andrews, Bottle, Hampson, Mackay, Sandford, Squire, Symes, Williams and Woolley. To meet as occasion may require.

Special Committee to Consider the Condition of the Society's School.—Messrs. Andrews, Bottle, Gostling, Hampson, Robbins, Sandford, Savage, Squire, and Williams.

Previous to the appointment of this Committee being agreed to, some discussion took place as to the desirability of postponing it for a time, and the Council ultimately went into Committee to consider certain matters referred to. On resuming the Committee as above constituted was agreed to.

The President and Vice-President are *ex officio* members of all Committees.

APPOINTMENT OF EDITOR AND SUB-EDITOR OF THE JOURNAL.

Dr. Paul was re-appointed Editor of the Society's Journal for the ensuing year, and Mr. F. Passmore the Sub-Editor.

LOCAL SECRETARIES.

The appointment of Local Secretaries was deferred for a month in order that the Library, Museum and Laboratory Committee might recommend a list of names.

The SECRETARY said that last year there were 323 towns eligible to have local secretaries; the number now eligible was 306, and the number of towns from which votes had been received was 210. There were no additions to the list this year, but 16 towns had been removed from it.

REPORTS OF COMMITTEES.

FINANCE.

Messrs. Hampson, Robbins, Schacht and Squire, having acted as a Finance Committee and examined the accounts presented during the month, recommended them for payment.

The report and recommendation were received and adopted.

LIBRARY, MUSEUM AND LABORATORY.

The Librarian's report had been received, and included the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
April.	Day	339	18	9	13
	Evening	206	15	5	9

Circulation of books.	Town.	Country.	Total.
No. of entries	174	69	243

Carriage paid . . . . £1 6*s*. 11*d*.

The following donations to the Library had been reported, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Grevillea, Record of Cryptogamic Botany and its Literature, 1872–80, Nos. 1-47.
From Mr. Caleb Weeks.

Medical Students' Register, List of Students Registered during 1879.
From the General Medical Council.

Mitchell Library, Glasgow, Report on the Library, 1874–9. From the Library.

Institute of Chemistry, Register of Fellows, etc., 1880. From the Institute.

Chemists and Druggists' Trade Association, Fourth Annual Report, 1879–80. From the Association.

University of London, Calendar, 1880.
From H. M. Government.

Scheibe, E., Darstellung und Beschreibung der Borcitronensäure und ihrer Salze, 1880.

Schwartz, V., Beiträge zum forensisch-chemischen Nachweise von Blut aus Flüssigkeiten, Harn, Zeug und Erden [1880].
From Professor Dragendorff.

The report was received and adopted.

HOUSE.

The report of this Committee was received and adopted.

THE PRESENCE OF REPORTERS.

The Council then went into Committee to consider the regulations with regard to the presence of reporters.

On resuming, the following resolution, moved by Mr. RICHARDSON, seconded by Mr. SYMES, was carried unanimously—

"That the Society's reporter be subject to the same regulations as regards being present or absent during the discussions of the Council in Committee as other reporters."

PHARMACEUTICAL EDUCATION AND PHARMACEUTICAL EXAMINATIONS.

The VICE-PRESIDENT then moved the following resolution of which he had given notice:—

"That a Special Committee be appointed to inquire into and consider the relation to each other of pharmaceutical education and the pharmaceutical examinations; and that they be empowered to invite the co-operation of any members of the two Boards of Examiners, of the professional staff, or other individuals whose opinions and advice they may deem it desirable to obtain; and that they be requested to frame a report to the Council on the subject at their earliest convenience."

In moving this resolution he said he had no hidden convictions in his own mind of what the appointment of the committee would lead to; he was not proposing it with any desire to carry any views of his own; indeed, he had none formulated. The fact of his introducing it arose from the circumstance that in his capacity as Vice-President during the last year, and through the courtesy and kindness of the President, they had been able to divide the duties which fell upon them in the examination rooms, and that gave him many chances of seeing what took place there. It was almost unnecessary to say he came to the conclusion that the standard and purpose of the examination was, as nearly as he could judge, perfect. The mark which the Examiners set as the gauge of efficiency of those who came up seemed to him to be correct, and he was very glad to have confirmed by further experience, by actually sitting by the side of each examiner in turn, his previously formed opinion that the individual examiners did their work in a wonderfully able manner, not only as regards their ability, but the kindliness of spirit which they manifested to those under their so-called "torture." But there was one part of the matter which he could not say gave him equal satisfaction and that was the condition of preparedness of the candidates. In many respects he was sorry to say they presented themselves hopelessly and surprisingly ignorant, sometimes in all the subjects, sometimes in a few of them. He could speak of some cases in which he was astonished at the audacity of the men coming up for examination with so much ignorance. A very few minutes sufficed to show an Examiner that such men were perfectly incapable of passing. Then there was another section of men who soon proved that they were well grounded students, and in that class again there was very little difficulty in coming to a positive conclusion. But there was a third and perhaps a larger proportion still to be spoken of. They were men who gave the examiners all great difficulty in deciding whether they did or did not know the subjects in which they were to be examined sufficiently well to justify them in being passed. These men presented two or three phenomena. Some of them were really poorly enough educated, but still fairly up to a certain point; others presented themselves with a poor amount of information but an amazing power of deception, showing a degree of artfulness and skill which they used to the very last degree to baffle the Examiner, and to make it appear they were more capable than they really were. He was sorry to say that section was rather large, men who must know they did not know enough to pass, but who resolved to try and persuade the examiners they knew a great deal more than they did. Contrivances such as would astonish many an adult were adopted by these youths as though they were trained deceivers. Such cases presented great difficulty to the examiners, every one of whom he believed to be a conscientious man, anxious to do his duty, and it had occurred to him, as well as to others, that it was possible their hands might be strengthened by processes which a committee might possibly think right to propose. It seemed to him that of all things the Council should aim to cultivate reality of knowledge and positiveness of study, that there should be nothing slurred in education, that students should be even guarded against themselves where they were apt to fall into the dilemma of making the superficial take the place of the real. If it were possible, by any regulations a committee could suggest, that these young men should really be led in youth to a better comprehension of their duties in adolescence, such regulations would not cause anything like injustice to them, or place them under unfair difficulties; but would really be doing them the greatest kindness. It was in this spirit he proposed a Committee of Inquiry, not with any preconceived ideas to be worked out, but that those facts which he had endeavoured feebly to sketch out should, if they were true, be brought more or less home to the minds of the Committee in the hope that some steps might be taken to remedy them, and, on the contrary, if he had misread the phenomena it was time it should be made clear that he was not a very careful observer. He only wished that the whole thing should be looked into carefully, that the conditions and opportunities for culture which these candidates possessed should be made clear, and that the result of those opportunities should be tolerably well brought to the test. If these were found to be faulty in any direction, then the Committee might investigate the probable processes by which a better state of things might be attained. He would only, in conclusion, repeat that he had no foregone conclusions in the matter.

Mr. SYMES, in seconding the motion, said the experience of Mr. Schacht, who had given great attention to the matter, had no doubt enabled him to arrive at the conclusion that the present method of examination, however well conducted, was not capable of testing thoroughly the actual merits of the candidates. He took that to be the idea which had prompted an inquiry into this subject. No doubt the great question of pharmaceutical education could be led by examination; arrangements could be so framed by the Council in conjunction with the examiners such as would more or less indicate the direction in which education should take place, that is education for examination, and he took it that the majority of men who came and passed fearlessly and satisfactorily were those who did not study for examination at all, but for the sake of the benefit they were to derive, first, from the knowledge itself, and, secondly, from the use they knew that knowledge would be to them in the later business of life. In looking round it was easy to point to these men and see that their knowledge had been of great advantage to them and added more or less to the advancement of pharmacy. If men would look at the thing in a proper light, that of itself would be sufficient to induce them to study thoroughly and honestly; but as they would not do so, and as the Council was told a large majority either came up hopelessly ignorant or devoted the time and attention which should be given to study to acquiring tricks and means by which to overcome what they regarded as the difficulties of the examination, it was most desirable that these subjects should be placed on a proper footing and an endeavour made to ascertain if there were any other means by which the examination could be rendered such as would test the merits of the candidates in a more perfect manner, or whether it was desirable to take action in some other direction. He thought it desirable to leave the question a broad one and not suggest any direction in which the Committee should work. Professor Attfield had issued a pamphlet which contained certain proposals on this subject, but he did not know that it was the business of the Council to discuss them at present. Still, he took it the Committee would have to consider that pamphlet. It was evident, however, certain schemes having been put forward, that at least something more was wanted, and it was on that broad basis he would support the motion.

Mr. Hampson regretted that this motion had been brought forward, that day especially, as the Council had received a communication on similar lines from Professor Attfield, recommending, it seemed to him, an active propaganda of certain notions. As far as he could see, the only object of this resolution was the bringing about of something like an enforced curriculum. That might not be the avowed aim of Mr. Schacht, but it was the only solution, because it was the only method adopted in connection with other examinations, so that this Committee, if formed, would have to consider whether affairs had arrived at such a condition that it was desirable to establish an enforced curriculum. That really was the issue. He would not express any opinion at this time whether the time for that was come or not, but he would remind the Council that it had had no complaints from the examiners; they had not told the Council that they found themselves incapable of testing the candidates, or that it was impossible to carry on their work satisfactorily. If they had found, as Mr. Schacht would lead the Council to suppose, that it was impossible for them to distinguish the capable from the incapable, they would no doubt have complained of such a want of power. But this proposition really was the result of a certain obtrusive pamphlet issued by one of the professors. He, with others, had had a copy of it, and had passed a general opinion on the subject; but he thought it was unfortunate that at this moment, when another Committee had just been appointed, which had to take into consideration the existence of the school,—not simply its method of teaching, but its very existence,—that this motion was even brought before the Council.

Mr. Gostling thought it would have been wiser to have allowed the motion to wait until after the report of the Committee just appointed had been given in to the Council. The whole business was a most difficult one, and one which would tax the energies and judgment of the members of the Committee to the utmost. All agreed, no doubt, as to the statement which had been made by Mr. Schacht with reference to the condition of the candidates for examination; there were, no doubt, in every examination men who were thoroughly qualified to pass, and another class of men who would avail themselves of the best opportunity they had of summarizing facts, and of collecting data so that they might be able to go into the examination room and appear to know that which they did not know; but there was no doubt that the examiners themselves in most of these cases could judge pretty well between the true and the false. It might be there were men who were able to answer certain questions very properly, but whose general manner and style of answering were such as to induce suspicion as to whether they really knew the subjects they professed. But still from the knowledge he had of some of the examiners he was inclined to think they could form a pretty correct opinion as to these young men. He felt there was a great responsibility resting upon the Council in the matter, and he should be obliged to vote against the appointment of this Committee until the report of the Special Committee for the purpose of taking into consideration the general condition of the school was given..

Mr. Atkins desired to recognize the clearness and impartiality with which the Vice-President had placed his twelve months' observation and experience before the Council, but he was inclined to agree with Mr. Gostling that it was desirable this matter should be deferred until the whole question had been dealt with and brought up to the Council. As he understood, the examiners did their work thoroughly well; in fact, as far as they were concerned, in the examination room there was nothing to be desired. Then was it any technical point affecting, not the examiners but the examinees in the examination room which could be improved? He took it it was not, but that what the Vice-President had in his mind was what Mr. Hampson referred to, namely, the education which preceded the examination altogether. He had read very carefully the pamphlet which had been referred to, and he did feel that if the Council was going in for an enforced curriculum it had a great deal to do besides talking of education. He valued education highly and was prepared to support any just and right scheme for its promotion; but there was another interest, and a pressing interest too, which was unavoidably connected with this question of education, and that was the value of the trade itself. If the Council was going to deal with the question of a costly compulsory training preliminary to the examination, it must consider whether the conditions of the trade really warranted it. He knew very well that with some select and profitable businesses, which really were but the minority, this question might not be a pressing one; but there were some thousands of businesses throughout the country which were a long way below the right standard of remuneration, and the Council must consider very carefully the course to be pursued as to enforcing a compulsory and costly curriculum of education.

Mr. Williams looked on this subject as one of very great importance. It had come under his notice when in the examination room that many men presented themselves in a very unfit state for passing, and it was more than possible that some did succeed in getting through who were really anything but qualified, but he still felt that there was a great difficulty in meeting the views of those who advocated a departure from the present system, and the requiring of a curriculum. He quite agreed that it would be a far better system to institute that every man who came up should not be permitted to undergo examination until he had proved that he had undergone proper education, but it was obvious that to some extent that was a question of expense. It was met to a certain extent at present by apprenticeship, but apprenticeship was frequently an inefficient mode of education. He did not exactly understand whether it was now suggested that apprenticeship should be done away with or simply that this system of a curriculum of education in a college should be supplementary to the original apprenticeship. He might remind the Council that the condition of things in North Britain varied considerably from the condition in the south, and the Council should be very cautious in any steps it took in this direction, for what might be suitable in London or in the south might probably be very much against the pecuniary interests of many in the north. He was sorry that Mr. Frazer had left, and that Mr. Mackay was not present, because their opinion on the subject would have been valuable. He must also remind the Council that to carry out anything like what was suggested by the motion, it would require an amended Act of Parliament, which many were hoping for, but the present Act did not give power to insist on a curriculum. The Act declared plainly that the Examiners were to examine all persons who should present themselves for examination. The Act was purposely framed in that way. He was not prepared to say it would not be a great improvement, as far as the education of the rising generation of pharmacists was concerned, to insist that the Act should be altered, and that the Examiners should be empowered to ask for certificates of the candidates having attended courses of lectures or some proper curriculum of education, but the question was, had the Society the power by a bye-law or any resolution of the Council to make such a regulation. It appeared to him it had not until it had a new Act of Parliament, and then the members of Council must ask themselves, as men of common sense, whether such a clause in the Act would be popular with the trade and with the public. It would, he believed, make the entering into the business more costly than at present, which would be objectionable to many. In a pamphlet he had seen it was suggested that it might be of benefit to the few who were prepared to take advantage of it; but he was not prepared to take that position. He thought it would be a great pity to restrict the entry into the business to those only who had good means, and that the poor man should be excluded. However desirable it was to improve the condition of education of those who presented themselves for examination, the Council must not take a rash step, and for the present he thought it would be wiser not to adopt this motion until at any rate it had the report of the Committee which had been appointed to consider the question of the Society's own school, because it would be some guide as to what should be recommended for a general system.

Mr. ANDREWS said this question had engaged his attention for many years, and he felt sure that sooner or later it must come up before the Council, to be dealt with. But he saw this objection to the appointment of the proposed Committee, that it would be working upon subjects, if not exactly the same, yet so nearly allied to those of the other Committee just appointed that it appeared to him that it would be a great waste of time. When the existing Committee had given in its report probably some of the very subjects here referred to would be dealt with. He would not go into the question of compulsory education, because he thought that was really discussing the question which should be first considered by the Committee.

Mr. SAVAGE said the subject was surrounded with difficulties. At the first blush there appeared no difficulty in approving the suggestion of the Vice-President, but at the same time he thought it would be well to wait the result of the Committee already appointed, because the two seemed to work very much on the same lines. Do what one would there would always be difficulty in this matter, for if one went to the College of Physicians or Surgeons, where a curriculum of education was insisted upon, there were found there two classes of individuals, workers and non-workers. Some men would apply themselves to their studies and others would not. It was originally necessary to have a seven years' apprenticeship before entering the Apothecaries' Company, but that was subsequently abolished, and it was decided that any one who presented himself with a sufficient amount of ability and possessed the requisite amount of information, no matter from what source obtained, should receive a diploma, and he believed there were many men in the profession now who had rendered very good service to the community who had not gone through the curriculum. Therefore, whilst the proposition seemed a reasonable one, he thought it would be well to postpone it until after the report from the other Committee.

Mr. SANDFORD said members of Council were all aware that it would be a very great advantage if all students could go through a regular course of study before coming up for examination. He was perfectly satisfied of that, although he did not agree exactly with the terms made use of in the pamphlet which had been referred to. That pamphlet spoke about subordinating examination to education, but that, he submitted, never could be done. You might educate up to an examination, but all examinations must be as to a man's fitness to perform a certain duty, not as to what he might have been taught in a certain school, although he quite admitted that the knowledge of his having been in a good school for a certain number of years would be a great satisfaction to the Examiners, and would be in the end good for the candidate himself. He feared, however, that the time had not yet arrived for such a course as seemed to be there shadowed forth. They knew when the Pharmacy Act of 1852 was passed, and again in 1868, an enforced curriculum was really in disfavour. Members of Council must have observed from a great deal of correspondence in the *Times* and other papers lately as to the insufficiency of examination to test a man's qualification that a different feeling was growing up in the minds of the public as to enforced curricula. There seemed to be a growing feeling that examination itself was not quite sufficient. It was a serious question, and he feared it would go beyond the power of the men generally brought into the business. He noticed in the pamphlet referred to, the point to which Mr. Williams had alluded, about a certain number of men being kept out of the trade; but it must not be looked at in that light. The Council wished to see only qualified men in the trade, but it was perfectly well known that the trade was one into which good men might come without very much capital, and he thought the time had not yet at any rate arrived to institute any bar of this kind against those men. He therefore thought it would be better if this resolution were postponed, at least until after the conclusion of the inquiry about the condition of the school.

Mr. BOTTLE said he did not himself see the particular relation between the Committee already appointed and the Committee which was now asked for; one seemed very little, if at all, to trench on the other. In the discussion which had taken place all the speakers had rather begged the question as to the intention of the Committee, and it seemed to be taken for granted that an enforced curriculum was what this proposed Committee would aim at, and that there were objections to such a course. There could be no doubt there were objections, and a curriculum could not be enforced without obtaining an alteration of the Act of Parliament; but it had been in the minds of some for a long time that it would be necessary to go to Parliament to get a new Bill, and surely it would be well before entering on that expensive amusement to consider whether the time had not arrived when the attention might be directed to the question of an enforced curriculum. His own observations in the examination room were perfectly in accord with those of the Vice-President. He had noticed that the Examiners had been at times extremely puzzled to find whether a man had been really honestly and fairly before them or whether he had been trying to shuffle through without the knowledge he should have possessed. If anything of this kind were to be done reasonable notice must be given, because a curriculum could hardly be enforced without three years' notice, after the Act of Parliament passed, and probably it might not be possible to get an Act for two years, so it would be five years before the regulation would really come into operation. The question then arose, was it too soon to contemplate such a progress in their profession? He did not think it was. Something had been said about the expensiveness of it, but it was known it had been done in the medical profession and even in veterinary practice, and the class of men entering the latter was not superior to those who came into the chemist and druggist's business. He for one was inclined to think the Council should begin to consider when a curriculum should be insisted upon.

Mr. SYMES wished to say, before the Vice-President replied, that in seconding the motion he did not intend to commit himself to any particular process of inquiry. The discussion had led rather into the work of the Committee. He was very much inclined to think with Mr. Bottle that the Council should go into the broad question and go into it early. If the other Committee would discuss the merits of the school or the very existence of it, surely this Committee might be appointed now, because the Council would be in a better position to inquire into the whole question than it would be hereafter if it had no school. If, as he hoped, an amended Pharmacy Act were obtained, even although it were a year or two hence, it would be far more satisfactory that this inquiry should be made now and that the report of the Committee should be in the possession of those who had to do with the framing of the Act rather than to leave that work until the time when the Act was ready. If, as had been stated, the Society did not possess the power of making such a regulation, it was only right that it should consider in good time whether it were desirable to seek for such power. He trusted the whole matter would be handed over to the Committee entirely unfettered.

Mr. RADLEY felt convinced that the general opinion of members in the country was that the examinations were already sufficiently strict and that any alteration in the education suggested would be scarcely received with favour. At the same time, it was a very important question, and one which might and ought to be discussed and brought forward before the trade generally.

The VICE-PRESIDENT said he had no reason to find fault with the direction the discussion had taken so long as it was clearly understood, as expressed by Mr. Symes, that the question was not one of enforcing the curriculum at all, but that that question with anything else was to be taken into consideration by the Committee. As it had been suggested that this motion was the natural outcome of a certain pamphlet, he must give it the most unqualified denial. That the pamphlet had come out simultaneously with the views which had been developing in the minds of other gentlemen might be the fact, but it was not true that this motion was the outcome of the pamphlet. He should also say that the two Boards of Examiners had expressed themselves very definitely and distinctly upon this matter, deprecating the existing order of things and suggesting inquiry.

Mr. HAMPSON: Not officially.

The VICE-PRESIDENT said he considered it was official, inasmuch as the Scotch Board had certainly passed a resolution to that effect, which he believed in due course would come before the Council. He was not pinning his faith any more than anyone else to the fact of an enforced curriculum, but he wanted the whole matter to be considered, and he was sorry it was thought desirable to postpone the matter. He could not see the reason for so doing. The report of the Committee on the condition of the Society's own school would not cover the ground to be covered by the Committee he proposed, which would have to consider the existing processes of pharmaceutical education and the existing order of pharmaceutical examinations. The latter matter possibly included the subject of the work of this school, but it certainly did not lie inside it. He was sorry there should be an opinion that this subject might wait. He thought it better the Committee should be constituted early, in order that it might go through the process of collecting information quietly, patiently and in the spirit which should actuate a legislative body. It could not get together the information it required under a long time and a great many sittings, and he certainly hoped that gentlemen would see that in agreeing to this motion they were committed only to a process of inquiry.

The motion was then put with the following result:—

For,—Messrs. Bottle, Churchill, Radley, Robbins, Schacht, Symes and Woolley.

Against,—Messrs. Andrews, Gostling, Hampson, Hills, Sandford and Williams.

The motion was therefore carried.

Mr. Savage was present and did not vote.

It was then agreed that the following gentlemen should constitute the Committee:—Messrs. Atkins, Hampson, Mackay, Sandford and Symes.

It was also agreed that a letter bearing upon the subject, from Professor Attfield, should be referred to this Committee.

BENEVOLENT FUND.

The SECRETARY reminded the Council of the vote of thirty guineas, made last November, for the purpose of obtaining the election of an orphan into an asylum, which money was not expended, as he found there was no chance of the child being elected. Another election would take place in the course of this month, and he presumed it would be his duty to attend and apply the money if he thought it desirable.

Mr. WILLIAMS said the vote had been already made, and he took it as a matter of course that the Secretary would act on it on the first opportunity.

THE SALE OF PATENT MEDICINES.

A letter was read from the Wigan Chemists and Druggists' Association, enclosing a resolution requesting the Council to take such steps as might be necessary to repeal that portion of the Act of 1868, which excludes patent medicines from its operation.

Parliamentary and Law Proceedings.

POISONING BY VERMIN KILLER.

An inquest has been held at Brixton by Mr. William Carter, Coroner for East Surrey, as to the death of Carl Meyer.

Selina Sennitt, servant at the house, stated that she took hot water to her master's room, and failing to gain a response to her knocks went to her mistress's bedroom to arouse her. They proceeded together to deceased's bedroom and found him lifeless and cold. Dr. Power at once attended and pronounced life extinct.

Mr. Paul Bock deposed that in consequence of certain information he searched a chest of drawers. He found a common glass tumbler containing about a teaspoonful of greyish-white fluid, which he handed to the officer of the court. The letter produced had been handed to witness by the wife of deceased. It was a letter to Mr. Frick, deceased's chief clerk, and commencing with the words, "When these lines reach you I shall be no more," went on to detail his business struggle, and asked the addressee to help in liquidating the estate. The letter was written in a desponding tone, and contained no further reference to death. Witness knew nothing of deceased's financial position. For some time past deceased had been greatly depressed, but no suspicion was entertained that he would make an attempt on his life.

William Smith, officer of the court, deposed that he received from Mr. Bock a glass which was soiled, and contained 10 or 12 drops of bluish-grey fluid. He did not taste it. He took possession and gave it to Dr. Lees for analysis, as also a jar sealed by Dr. Power.

Joseph Lees, M.D., said that he received a tumbler and jar (sealed) from last witness, and had carefully analysed their contents. He found the tumbler to contain Prussian blue, starch, and strychnia. In the contents of the stomach he found Prussian blue, but no starchy matter or strychnia. The latter was a vegetable poison, rapid in its action on the human body, and rapidly decomposing in the stomach. He had formed the opinion that deceased had taken the contents of the tumbler.

Robert Hardy, dispensing chemist, 42, Fenchurch Street, deposed that he knew deceased, and last saw him alive on the afternoon of Tuesday, 4th ult. He did not on that occasion supply anything, but on the previous had sold deceased a packet of Battle's Vermin Killer, the latter remarking that he wanted to destroy some mice. Witness would not have let him have it if he had been unknown, knowing that it was a dangerous article. It was a 6*d.* packet.

The Coroner having addressed the jury, the court was cleared, while the jury deliberated. On the readmission of the public, it was announced that a verdict had been returned of "Suicide by taking poison while in a temporary state of mental derangement."

Notes and Queries.

[656]. STARCH GLAZE.—I should be much obliged if through the medium of the Journal, anyone will furnish me a good formula for starch glaze, combining stiffness and gloss, so essential in laundry work.

PORTIA.

[657]. LIQ. AMMON. ACET. CONC.—Will some brother druggist kindly give formula for making liq. ammon. acet. conc., 1 to 7? COUNTRYMAN.

[658]. COMPOUND TINCTURE OF MYRRH.—Will some one kindly give a form for compound tincture of myrrh? I cannot find one in any of the usual books.

F. W. WOOD.

[659]. FREEZING CRYSTAL.—W. B. O. would thank anyone for a cheap form of freezing crystal.

[660]. PRESERVATION OF INFUSION OF MALT.—Can any of your readers inform me how a cold infusion of malt may be preserved for a week or two, without risk of destroying its diastase? A. D. B.

[661]. "ASBESTOS PAPER."—Required for wrapping deeds in. The writer has heard that such an article has been made; would feel obliged for information as to the maker and where it is to be obtained.

INQUIRER.

THE VOTING AT THE ELECTION OF COUNCIL.

Sir,—I feel I am under the necessity of addressing you in order to remove some misapprehension on the part of our much respected President (Mr. G. W. Sandford), on the occasion of his acting as Chairman at our Annual Meeting on May 19, and the adjourned meeting on May 21.

I think from his position as chairman he scarcely acted with that impartiality which constitutes the nature of his office and is the usual characteristic of his own noble nature; the strictures he passed upon me for my action and subsequent conduct as a scrutineer and a private member, might have become him very well as an individual member entitled to his opinion, but they lost all grace and failed to carry conviction, when they issued from his lips as the summing up of a chairman. I am sorry to find Mr. Sandford repeated, in my absence on May 21, his regret at "the manner in which the subject had been brought forward on Wednesday." I can only say I acted conscientiously, and am quite satisfied to leave the subject in the hands of my fellow members. Those who may wish to know why I brought the subject forward, will please refer to my letter, addressed to you, Mr. Editor, and appearing in the number of the Journal for June 7, 1879, third series, No. 467.

Dr. Symes, as the person hinted at,—for let me say *en passant*, Mr. Shaw, also of Liverpool, whose admirers were not guilty of the same presumption, shall I call it, as Dr. Symes's, knew full well there was no necessity to resort to the, to me, perfectly unnecessary method of plumping, for our candidates have no need of the artifices and methods customary at Parliamentary elections, in order to secure their seats,—Dr. Symes had the manliness to stand up and defend himself and his fellow electors from any design of trying to gain an advantage over the general body of the electors, who voted for him in the innocence of their hearts and the belief they were acting wisely in giving him one of their fourteen votes.

Dr. Symes lays claim to be the representative "of the whole country." I was glad to hear him say it; let his acts prove his profession, and let us hear no more of Liverpool, or, indeed, other towns plumping for their pet local nominee.

During this discussion we have had it reiterated that the Council must be truly national and representative. How can it be so, if the electors are bent upon excluding metropolitan members from the Council?

	Council 1879. Country Members.	Council 1879. Town Members.	Council 1880. Country Members.	Council 1880. Town Members.
Elected . .	10	4	8	6
Non-elected	3	4	5	2
Total . .	13	8	13	8
Candidates rejected.	0	6	1	3

	Attendances. County.	Attendances. Town.	Total of meetings.
Council . . .	10·0	9·125*	12
Committees .	30 692	51·125*	67

The above table clearly shows that the heavy burden of the Society's work falls chiefly upon the town members. Can we not increase their numbers and at the same time endeavour to lighten their work?

As regards the last election, although the constitution of the Council remains as last year (country members, 13; town members, 8), I think I may congratulate the electoral body when we find we have secured the *bonâ fide* election of six town members.

Thus in 1879, 11,397 votes secured the election of 10 country members of Council, while 3946 votes secured the election of 4 town members of Council. A total of 8115 votes having been recorded among eleven (11) town candidates, leaving a balance of 2972 votes unused, and as I observed in my letter of last year, Liverpool and district, may be held accountable for certainly more than half this number, by making use of the system of plumping.

The figures this year are much more encouraging: 11,653 secured the election of 8 country members, while 8523 votes were bestowed on the 6 successful town members, besides 2421 votes given to the 3 unsuccessful town candidates, making a gross total of 10,944 votes given to town candi-

* Mr. Slipper, as a town member of the Council, has adversely affected these figures, his attendance at only one meeting out of a total of thirty-four he was appointed to attend, considerably lowers the average of his town colleagues.

dates. There remain 2062 votes unprofitably wasted, which again is matter for congratulation as compared with last year's 2972 votes.

I am very glad to notice this improvement, as it proves the remonstrances in my former letter have not been without beneficial effect. Permit me to say as I write, I have no wish to restrict voters in the legitimate exercise of their right of private judgment as to the fitness of individual candidates; but I most strongly condemn the dog-in-the-manger principle of plumping for merely local candidates. If our elections are to be conducted on this principle, the sooner we adopt the system of equal electoral districts for the return of representatives on the Council the better we shall assimilate our representation to the requirements of particular districts. I must point out how really very satisfactory the votes on the last election come out. In a grand total of 1810 voters possessing 25,340 votes, against 1606 voters with 22,484 votes, we have an increase of 796 voters with an increase of 11,144 votes, a number of votes nearly equal to the total which secured the election of the 10 country members of Council in the 1879 election. Out of the large number of 25,340 votes, I find only 2062 votes were unused or wastefully lost. This is a very decided improvement upon last year, where I find 22,484 votes were available, while 2972 were unused or lost by the system of plumping, or the equally objectionable system of restricted or partial voting.

In conclusion, let me address those voters who act on the principle of desiring none but country members on the Council, and who invariably vote on the system of excluding all London candidates. I most unhesitatingly condemn the system as an impracticable, impolitic and unwise use of voting power. What we should desire and aim to have is a true and correct representation of the whole national electorate. How can this be, if voters act on the policy of town *v.* country. I was grieved to see Mr. Butt's name withdrawn from the list of town candidates. I consider Mr. Butt an admirable candidate for a seat on the Council. To my idea he is the embodiment of what we want in a candidate, a long country experience, mellowed and ripened into a keen judgment of town necessities and requirements. Some other names occur to me as equally desirable, but who I daresay, are not willing to see their names figure at the lower extremity of the poll, owing to a want of appreciation of their abilities and qualifications on the part of the greater bulk of country voters. I say we have men able and willing to serve us loyally and well, who combine all we require, as regards experience of mixed country business, who are settled in London, and are fully aware of all the burning questions which trouble the repose or agitate the bosoms of town and country practitioners of the art of pharmacy.

88, *Silchester Road, Notting Hill, W.* T. HOWARD HALL.

P.S.—Note the increase of travelling expenses; in 1879 they are £343 13*s.* 3*d.*, as against £242 14*s.* 3*d.* in 1878.

THE WEIGHTS AND MEASURES ACT.

Sir,—The Weights and Measures Act seems to be exercising the minds of many of our brethren anxious to be within the pale of the law, but in some doubt as to what it exactly requires of them.

It seems to me that the Pharmaceutical Society has not had its proper influence in the modifying of this measure as it affects our peculiar interests. Impelled as we are by our own convenience and reputation to use the means best adapted for the end, and in which there can be no question of defrauding the public, it appears as though we were specially selected for the endurance of official worrying.

I am told by a firm which is taking a leading interest in supplying Government stamped weights and measures, that the grain weights in use are no longer to be recognized; but instead of the indentations denoting the number of grains, they must now be represented by figures. Gentlemen who have used both will readily understand how much more distinct and easy of recognition the old dotted weight is; the one you can pick up from the scale box with confidence and without stooping, the other requires a close scrutiny. Again, many pharmacists use delicately adjusted beam-balance scales for small quantities of potent drugs, and most of us have sets of metrical weights. Surely in such matters as these, if our leaders led, something of freedom might be left us in the professional branch of our calling.

We all want to obey the law, and should be glad of any explicit information we can get through the medium of the Journal, and should appreciate any influence that the Council might exert to guard our privileges.

W. WARREN.

24, *Russell Street, Covent Garden, W.C.*

Sir,—Wishing to be legally safe with my dispensing weights, I purchased of one of the first scale makers a set of ½ grain to 2 drachm weights, each of which bears the official stamp of verification. As I possess a tolerably sensitive balance, it occurred to me to test their correctness so far as might be done by comparing them amongst themselves, and to my great disappointment I find they are all abroad. Assuming the ʒij weight to be correct, its numerical equivalent in smaller weights shows an excess of nearly ½ grain. The 2 and 4 grain weights compared with the 6 grain are fully one-third of a grain light, and so on. Under such conditions, is any pharmaceutical chemist safe?

Penton Street, N. J. BLAND.

CLAY'S CHIAN TURPENTINE MIXTURE.

Sir,—Experimentally trying Mr. C. Eve's mode of making the above (p. 972), I find, as the anæsthetic ether is so volatile and the turpentine so tenacious, that with all dexterity possible, much of the former is evaporated and about half the latter adheres to the mortar and pestle and never becomes emulsified; the sulphur, therefore, has no chance of aggregating this part of "the resin in masses." Nor will the patient get the full dose of it, as it is never put into the bottle. I consider Mr. Eve's process of rubbing an ethereal solution in an open mortar a very unskilful one.

His principle in making the mixture is that I suggested for making mucil. tragacanth. (*Pharm. Journ.*, 1870, p. 520). I had previously tried it for dispensing the Chian turpentine emulsion by pouring the ethereal solution upon the tragacanth powder placed in a bottle, adding the water gradually, and lastly the sulphur and syrup rubbed together, without good results. I leave the subject to your readers for corroboration.

I may add that Mr. Eve's mixture (not containing the full quantity of resin even) is not nearly so good an emulsion as one made with acacia.

WM. MARTINDALE.

THE SEASON.

Sir,—I noticed a point in your article of "The Month" with surprise, viz., that the vegetable kingdom was a fortnight in advance of last year. My experience is very different; on the 2nd inst. I could not find a specimen of *Convallaria majalis* in flower, though several acres were abundantly covered.

THOMAS ROMANS.

"*Sior.*"—Probably charlock; send a better specimen.

"*Vance*" *and* "*Dentist.*"—The presence of your names on the Register would have been sufficient evidence of that part of your claim. In the absence of such proof each case will, we presume, have to be decided according to the evidence that can be produced.

"*Assistant.*"—Try salicylic acid. See vol. vii., p. 595, of the present series.

"*Country Major.*"—At present it is impossible to say.

"*Inquirer.*"—Rubini's essence of camphor is a solution of camphor in an equal weight of rectified spirit.

J. H. W.—We should think not, as coming under the exemption in favour of artificial mineral waters, but the question had better be addressed to the Inland Revenue authorities.

"*Inquirer.*"—The commencement of a report describing more fully some of the articles shown at the recent exhibition will be found on p. 975.

COMMUNICATIONS, LETTERS, etc., have been received from Dr. Vogl, Professor Dyer, Messrs. Parkinson, Roberts, Calvert, Cocking, Dodd, A. P. S., J. W. H., R. F., Associate.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 831.)

EULOPHIA, several species, ORCHIDACEÆ. SALEP. *Vernacular*: SAALAB-MISRI (Hind.); SHÁLÁ-MISHIRI (Tam.): SÁLAM-MISRI (Bomb.); CHÁLÉ-MICHHRI (Beng.).

History, Uses, etc.—*Eulophia campestris*, Lindl., and *Eulophia herbacea*, Lindl., are generally named as species which produce at any rate a portion of oriental salep, but we have no complete information upon the subject. *E. herbacea* and several other species of *Eulophia* are natives of the Bombay Presidency, but although some of their tubers are sold by the herbalists as salam-misri, they do not yield any of the saleps of Bombay commerce; these are all imported from Persia, Cabul and northern India. Salep does not appear to be mentioned in the older Sanskrit works on medicine. Mahometan writers usually describe it under the Arabic name of Khusyu-uth-thaalab (foxes' testicles); they identify it with the sáturiyun and turphullon of the Greeks and mention several kinds. The odour of the fresh root is said to resemble that of *semen hominis* and to have an aphrodisiac effect if clasped in the hand. The dry tuber has a great reputation in the East as a nervine restorative and fattener. It is also much prescribed in paralytic affections. The palmate tubers are most esteemed. The nature of oriental salep appears to have been unknown in Europe until Geoffroy in 1740 discovered its source and showed how it might be prepared from the tubers of orchids indigenous to France.

Description.—Three kinds of salep are generally to be met with in the Bombay market, viz., palmate, large ovoid and small ovoid (threaded). All of them are more or less translucid and gum-like, and have been decorticated before being dried. Salep has hardly any odour or taste, with water it forms a bulky jelly having a faint peculiar flavour. In the East it is mixed with milk and flavoured with spices and sugar.

Microscopic Structure.—The bulk of the tuber consists of a parenchyme, the cells of which contain either mucilage or starch altered by heat. It is traversed by small fibro-vascular bundles.

Commerce.—The following kinds of salep are met with in the Bombay Market:—

Abushaheri or Lasaniya, Rs. 15—35 per maund of 41 pounds.

Punjahi-salep, Rs. 10 per pound (palmate tubers).

Punjabi, Rs. 2½—7 per pound.

Besides these imitation salep is largely prepared; it is said to be made of pounded potatoes and gum.

VANDA ROXBURGHII, *R. Br.*, ORCHIDACEÆ. *The roots. Vernacular*: RASNA (Hind., Beng., Bomb.).

History, Uses, etc.—Dutt informs us that the roots of *Vanda Roxburghii* and *Acampe papillosa* are indiscriminately used as rásna by native physicians in Bengal. The drug is mentioned by Sanskrit writers under the names of rásná and gandhanákuli, and is said to be bitter and aromatic and useful in rheumatism; it is given internally and applied externally. The following form for internal administration is found in most Sanskrit works on medicine:—"Rásnápanchaka. Take of rásná, *Tinospora cordifolia*, wood of *Pinus longifolia*, ginger, root of *Ricinus communis*, of each equal parts, and prepare a decoction in the usual manner" (Confer. Dutt's 'Hindu Materia Medica,' p. 259). In the Concans the roots of *Saccolabium papillosum*, Lindl., are used; this I suppose to be the same plant as the *Acampe papillosa* mentioned by Dutt.

Description.—*Vanda Roxburghii* has a creeping stem, sending forth long, thick, round, ramous, fleshy, whitish roots, which fasten firmly to the trunk or branches of the tree they grow on. The plants are seldom more than two or three feet in length; leaves sheathing, bifarious, approximate, recurved, linear, keeled, præmorse, five or six inches long; scape generally axillary, solitary, naked, supporting from six to twelve large beautiful flowers; petals five, nearly equal, expanding, oblong; margins waved and here and there a little inflected; upper surface checkered with yellow and dusky ferruginous purple, underneath white; lip shorter than the petals; horn conical, protruding towards the germ, between the two lower petals; lamina oblong, turgid; apex two-lobed; sides reflex, so as to be convex above and deeply concave underneath; colour bluish-purple or violet towards the apex; the upper lip, or portion which forms the attachment of the lip and horn to the base of the column of the fructification, has two lateral lobes, obliquely broad lanceolate, with their acute points incurved towards the apex of the column. Column of the fructification thick, short and obtuse, open in the interior margin near the apex. This mouth or opening tapers down through the column into a point which ends in the belly of the germ; operculum suborbicular, with two pits for the two round polliniferous balls. When the lid is removed gently the two anthers rise with a jerk in their broad cordate filaments; the lid is inserted on the interior parts of the top of the column by a large infundibuliform base. If removed with less care and before the anthers are ripe they remain in their cells and the funnel-shaped base of the filament rises erect. Stigma, or channel for conveying the subtile male essence to the germ, a clammy opening in the fore part of the column near its top. Pericarpium clavate, with six sharp ridges running the whole length. (Roxburgh.)

Saccolabium papillosum.—Leaves strap-shaped, unequally two lobed at the apex; peduncles much shorter than the leaves; sepals and leaves subspathulate; sepals equal, larger than the petals; lip three lobed; lateral lobes short obtuse, middle one suborbicular, saccate at the base; flowers yellow, transversely streaked with purple; lip white, transversely streaked with rose colour; flowers very stiff and fleshy ('Bombay Flora').

Commerce.—The bazar rásna comes from Kattiawar. Value Rs 2 per maund of 41 lbs. A small kind of rásna is also sold at a very high price, viz., R. ¼ per tola (180 grs.); it does not appear to be the root of an orchidaceous plant.

IRIS GERMANICA, *Linn.*, IRIDACEÆ. *The rhizome. Vernacular*: BIKH-I-BANAFSHAH (Pers.), IRSA.

History, Uses, etc.—Orris root is not mentioned by the older Hindu physicians. It is known in India by its vulgar Persian name bikh-i-banafshah (violet root). Mahometan writers mention several kinds of iris under the names irsa and súsan; but their descriptions are not sufficiently accurate to enable us to identify them with any certainty. From Meer Muhammad Husain's account (Confer. 'Makhzan,' article Súsán) I conclude that both the *Iris* *fœtidissima*, L., and *Iris pseudo-acorus*, L., are used medicinally in Persia. The correct Persian for *I. Germanica* appears to be súsan-i-ásmánjuni. The word súsan is said to be derived from the Syrian. Susáni-irsa is evidently a corruption of the Greek iris. Iris root is considered by Mahometan hakeems to be deobstruent, aperient and diuretic, especially useful in removing bilious obstructions. It is also used externally as an application to small sores and pimples. From the large number of diseases in which this drug is recommended it would appear to be regarded as a panacea for most diseases (Confer. 'Makhzan,' article Arsa). According to Hooker, *Iris Germanica* is cultivated in Kashmir.

Description.—Indian orris root differs from the European drug inasmuch as the bark of the rhizome has not been removed.

Microscopic Structure.—The rhizomes of different species of iris hardly differ in structure. They consist of a brown epidermis, composed of compressed and nearly empty cells, covering a white cortical cellular tissue, containing starch; this is separated by a layer of brownish compressed empty cells from the central woody yellowish tissue of the rhizome. The latter is built up of large, thick-walled, spherical, porous cells, loaded with starch; here and there between the cells may be seen a prism of oxalate of lime. The vascular bundles are numerous, in each irregular rings of spiral vessels surround a central bundle of jointed vessels.

Commerce.—Bombay is supplied with orris root from Persia and Kashmir. Value As. 2 per lb.

Iris Sp.?

Lakri-pashanbed or pakhanbed is a rhizome found in all the bazars; the prefix "lakri" being added to distinguish it from the mineral known as pakhánbed.

The drug occurs in pieces one to two inches long and about half an inch in diameter. The external surface is scaly with numerous circular constrictions, of a reddish-brown colour, marked with small scars to a few of which rootlets remain attached; substance hard, compact, of a dull red colour. When soaked in glycerine it stains it of a rich reddish-brown. The taste is acid and astringent; the odour musky and aromatic. The minute structure of the rhizome has a general resemblance to that of orris root; but numerous stellate raphides are present. The drug is chiefly used as a diuretic. It is said to come from Marwar. Value Rs $3\frac{1}{2}$ per maund of 41 lbs.

(*To be continued.*)

THE EXHIBITION OF PHARMACEUTICAL APPARATUS, ETC.

(*Continued from page* 977.)

Not the least interesting to the visitors to the Exhibition was the collection of gas-heating apparatus, which had been previously exhibited in the rooms of the Society of Arts, by Mr. T. Fletcher, of Warrington, and described in the Journal of that Society for April 30. Owing to the danger from fire likely to arise from having them in operation in an ordinary room, this portion of the Exhibition was placed in the Octagon Room at the top of the Society's house, in which the benches being entirely of slate, the apparatus could be put in action with perfect safety.

Most things worth seeing or having necessitate a certain amount of trouble, but the labour of ascending to the top of the Society's house to see this apparatus was grudged by few who examined the contents of this room.

One of the most useful pieces of apparatus here shown was the "Solid Flame Burner" (fig. 1), by which an explosive mixture of gas and air is burnt perfectly so as to produce a solid flame that is consequently

Fig. 1.—Fletcher's Solid Flame Burner.

perfectly free from smell. Over one of these burners not more than 5 inches in height, an egg may be boiled in a tin saucepan, or $\frac{1}{2}$ cwt. of lead melted in an iron pot.

Another, which was stated by some of the visitors who had tried it to answer perfectly, was the "Hot-Air Bath" (fig. 2) for pharmaceutical purposes. The

Fig. 2.—Fletcher's Hot-Air Bath.

chief feature in this is the use of an "Evaporating Burner" (fig. 3), which differs from other burners in

Fig. 3.—Fletcher's New Evaporating Burner.

consisting of a number of small flames raised by means of little conical projections above the surface of the copper disc from which they issue. This burner is enclosed in a perforated cylinder with a wire netting at the top. The currents of cold air, so fatal to glass and porcelain vessels, which are liable to occur when an ordinary coil burner is used, are rendered impossible by the use of this apparatus. The flame also is blue and smokeless.

But perhaps the most remarkable, and at the same time, the least pretentious-looking of the whole apparatus, was the "Perfected Injector Gas Furnace" (fig. 4), by means of which, with $\frac{1}{2}$-inch gas pipe and the smallest foot blower, a crucible full of cast iron scrap can be melted in ten minutes and steel in fifteen minutes, starting with all cold. This furnace consists of a hollow cylinder of porous fire clay, with a hole in one side of it, a solid base and a movable cover, furnished with a stopper (D) to permit of viewing the contents of the crucible. In the hole at the side is placed the nozzle of the gas burner. The burner consists of a tube, through which a jet of air under pressure is driven by a foot blower. Into this tube gas enters at the side, the tube being open behind the place where the gas enters, so that the fine stream of air under high pressure entering the

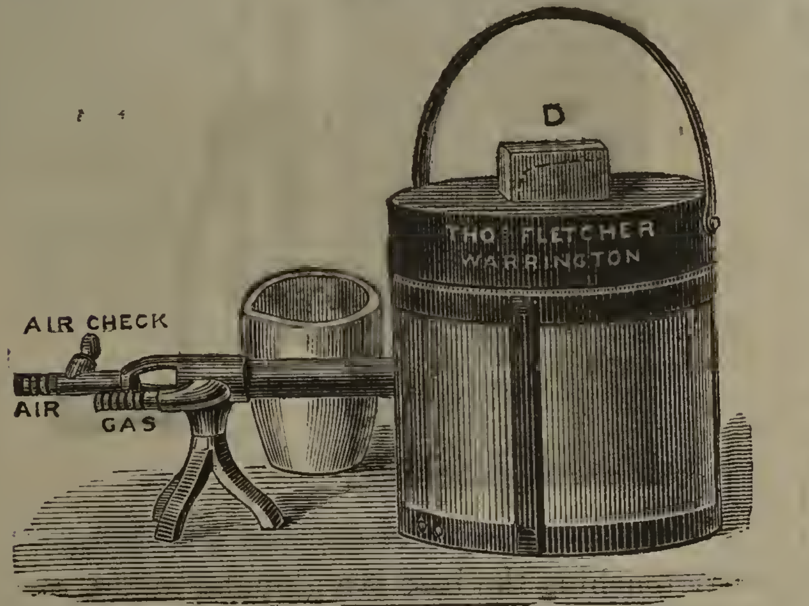

Fig. 4.—Fletcher's Perfected Injector Gas Furnace.

portion of the tube close to the furnace acts as an injector and by suction draws in the larger quantity of air required for complete combustion of the gas. By this exceedingly simple and ingenious plan, an amount of pressure and a quantity of air is obtained which could otherwise only be got by large and costly blowing apparatus. A perfectly explosive mixture is thus made rapidly in very small quantities and burnt in a close non-conducting chamber, so perfectly and so instantaneously that not a trace of flame is visible in the furnace. By this simple arrangement it is claimed that cast iron may be rendered almost as fluid as water, and a dazzling blue heat obtained in ten minutes or a quarter of an hour. The gas consumed in order to melt 2 lbs. of iron is said to be only 7 cubic feet. No crucibles known will stand a greater heat than this furnace gives with ease, and no furnace could be better adapted for melting small quantities of the rarer metals, manganese and nickel being easily melted in it. For enamels, etc.,

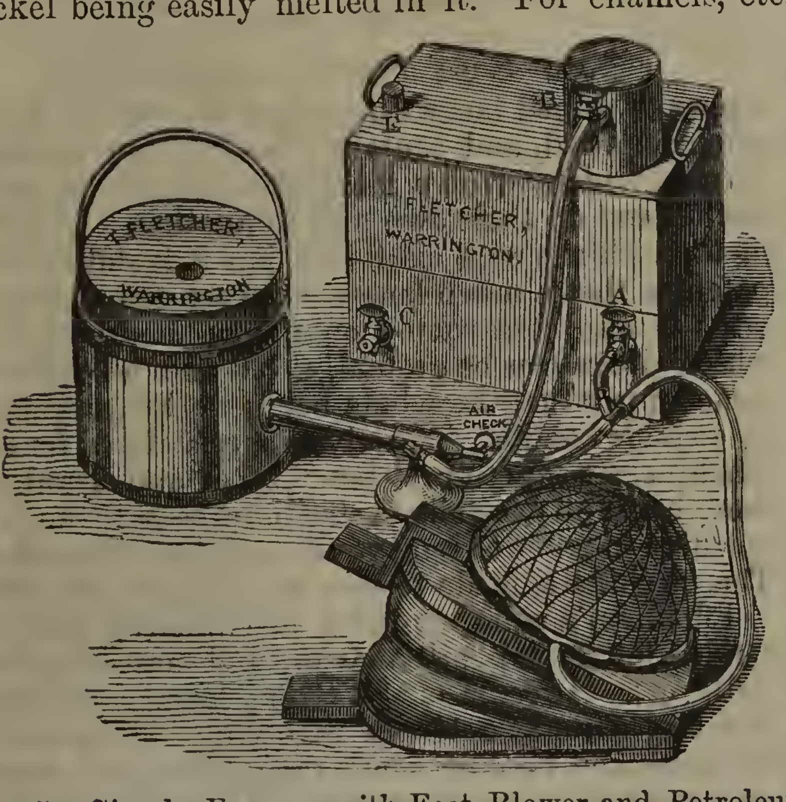

Fig. 5.—Simple Furnace with Foot Blower and Petroleum Apparatus.

to which the presence of the sulphur in coal gas would be injurious, the air gas made from benzoline by a special apparatus devised by Mr. Fletcher can be used (fig. 5). Half a pound of iron was melted during the time of the Exhibition in this furnace, and became so fluid that it ran like water through a small unnoticed hole in a sand mould prepared for it.

Another interesting piece of apparatus was a blowpipe with an air jet coiled round the gas pipe and with a Bunsen burner underneath (fig. 6), so that both the air and gas could be heated at the same

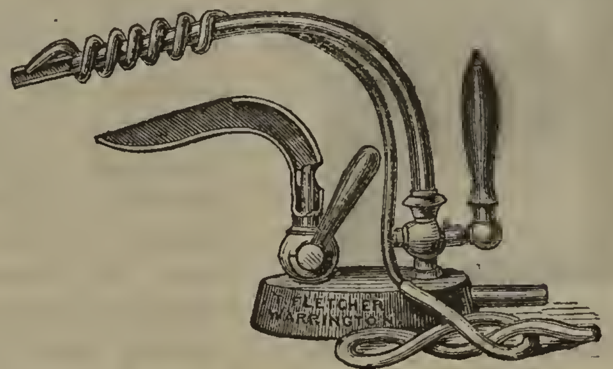

Fig. 6.—Fletcher's Patent Hot Blast Blowpipe.

time; by this blowpipe a heat is obtained far above that required to melt platinum.

A crucible furnace capable of being used as a reverberatory furnace, a muffle furnace, a ladle furnace and several other pieces of apparatus in this exhibit also attracted considerable attention. The peculiar porous clay of which the furnaces are constructed conduces in great measure to their success. This is made by mixing one part of refractory fire-clay with three parts by bulk of sawdust and adding rice-flour paste until slightly cohesive; the mixture is then moulded and burnt in an open kiln until the sawdust is burnt away. A porous material is thus obtained which conducts the heat so slowly that a furnace where the walls are only one inch thick and in which a crucible full of cast iron has just been melted can be taken and carried about with the bare hands. This process has been patented.

The whole of Mr. Fletcher's apparatus exhibited at the Society of Arts was purchased by Messrs. Townson and Mercer, and was exhibited by that firm.

The drying closet devised by Mr. T. E. Greenish, and figured and described before in this Journal, vol. ix., p. 81, was also exhibited in action in this room. In this room also was a small gas burner for shop use, exhibited by Mr. Symes, by means of which a decoction, etc., could be boiled and then kept hot at a lower temperature by turning off four jets of flame and leaving only one burning. A powerful electromotor machine was also exhibited in this room by Mr. Melhado. This machine is sufficiently powerful to drive a sewing machine, but is capable of application to pharmaceutical purposes.

The pharmaceutical apparatus was arranged almost entirely in the larger Examination Room, a few tincture presses, on account of their great weight, being placed in the Entrance Hall, and in the Materia Medica Museum on the ground floor. Mixing machines, tincture presses, and pill-coating machines formed the principal objects in this collection.

Bracher's patent "Desideratum" mixer (fig. 7) consists of a block-tin vessel, in two parts, the upper of which is a sieve, through which the powders are driven by revolving blades, turned by a handle at the top; the lower part also contains revolving blades, which mix the powders after they are sifted by constantly bringing the lowest layers to the surface, and *vice versâ*. In the larger machines the contents are discharged by withdrawing a slide. These machines are stated to be capable of mixing from 50 to over 500 lbs. of powder per hour. The whole apparatus can be easily cleaned.

Fig. 7.—Bracher's Patent "Desideratum" Mixer.

Messrs. J. Baker and Son's mixing machines, although not received until the second day, attracted considerable attention. These machines, or rather two forms of them, were exhibited last year at an evening meeting of the Society. The size stated to be most convenient for retail chemists (fig. 8), which is capable of mixing from a few ounces to 5 lbs. consists of two block-

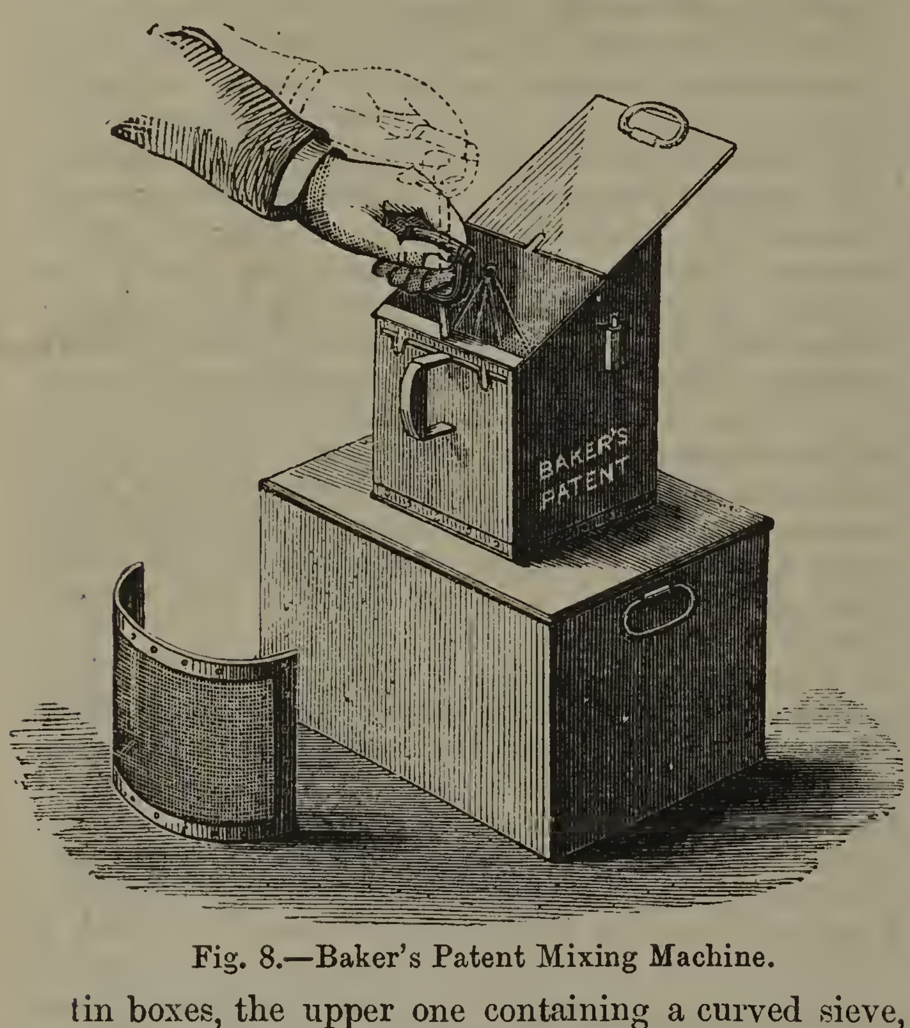

Fig. 8.—Baker's Patent Mixing Machine.

tin boxes, the upper one containing a curved sieve, with a mixer, worked backwards and forwards over its surface by means of a handle.

A much larger machine, of which only a model was exhibited, has a more complex structure, and is adapted for use by either hand or steam power, and is intended for wholesale dealers. This consists of a hopper, in which two mixers revolve horizontally in opposite directions, and thoroughly mix the powder before it passes through into the curved sieve contained in the box below it, the passage of the powder being regulated by a movable slide. Over the sieve two mixers work in opposite directions by an ingenious arrangement connected with the axle, worked by the handle; the powder passes through the sieve into the drawer, and the gritty matter remaining in the sieve can be thrown into another drawer by merely tilting the machine. The sieves can be removed, and finer or coarser ones substituted at will.

Morton's patent liquid mixer (fig 9), intended for emulsions, cold cream, pomades, etc., consists of a cylinder, with a concave base, resting in a water-bath;

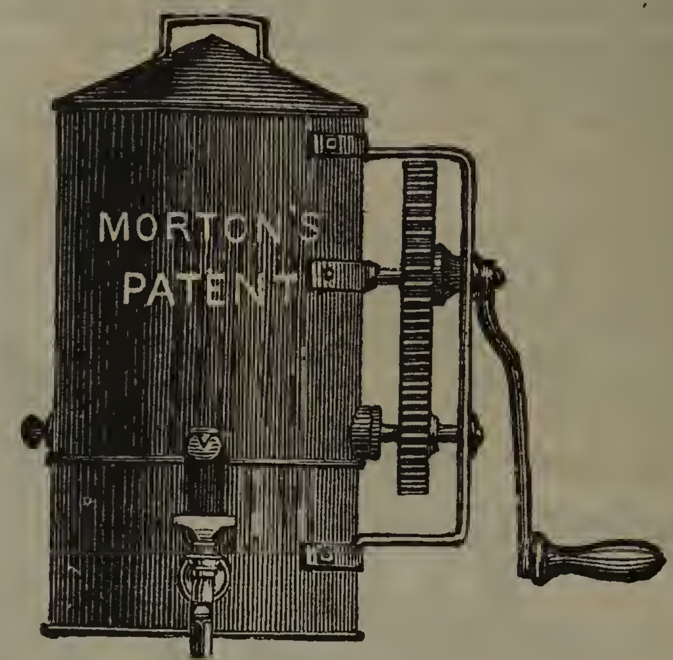

Fig. 9.—Morton's Patent Mixing Machine.

nearly touching the base is a globular mixer, consisting of three row of wires, the inner row of which remains stationary, while the other two work around it, so that the whole of the fluid at the bottom of the vessel is continually kept in motion, instead of merely the central portion, as is generally the case when a fluid is stirred vertically. Both these machines can be taken to pieces and thoroughly cleaned when required.

Faija's patent "Perfect" mixer (fig 10) consists of a

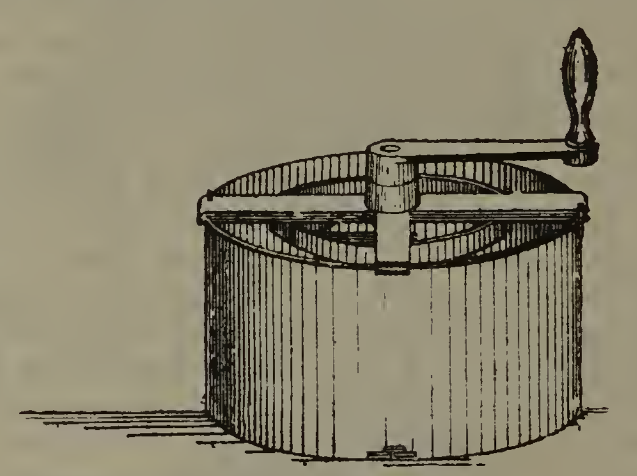

Fig. 10.—Faijas' Patent "Perfect" Mixer.

copper or tinned box with a heavy wooden lid, for use when required, and contains one or more mixers or stirrers, which revolve round the interior in one direction and on their own axis in another. Only two small machines were exhibited, but it is stated by the patentee that a much larger and more complete apparatus is also constructed on the same principle, by which drugs can be ground, sifted and mixed in the same apparatus, the whole being worked effectually by a single handle. The advantages claimed for these machines are superior efficiency, speed and cleanliness, there being no necessity to stop the process in the larger machine in order to remove the powders after mixing. The machine is made to mix up to 2 cwt. at a time.

Pfleiderer's patent mixing machine (fig 11) is intended for mixing pill masses, and masses for horse balls, etc. It consists of a strong metal box, open at the top, with two blades revolving in opposite directions, and bearing some resemblance in shape to the screw of a steam vessel. These blades are revolved by means of two cogwheels turned by a

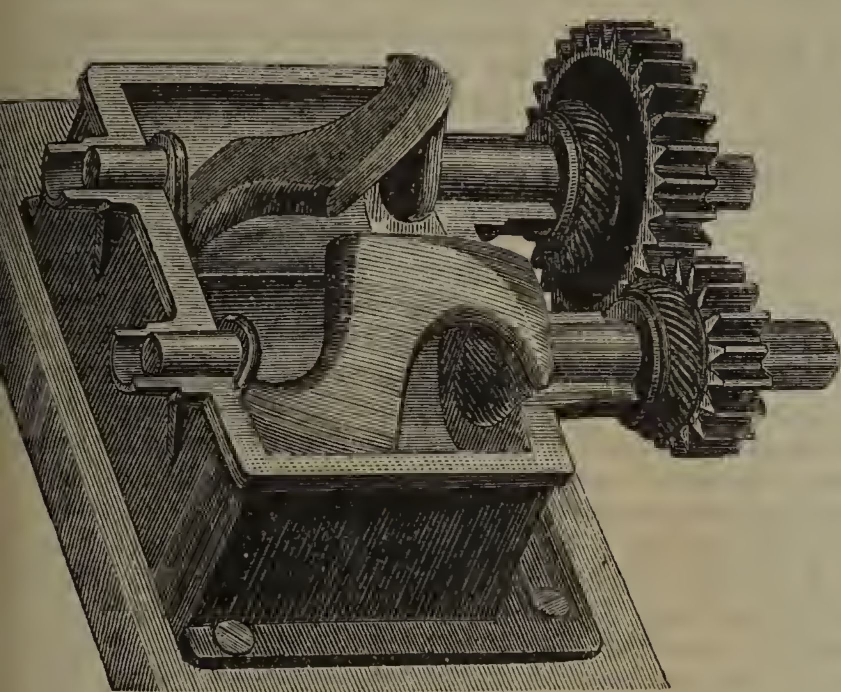

Fig. 11.—Pfleiderer's Patent Mixing Machine.

handle at the side. The whole apparatus can be easily taken to pieces and cleaned.

Messrs. J. Ladd and Co. also exhibited a small tincture press, differing from the ordinary kind in having a shallow inverted conical base (which allows the fluid to drain more readily from the pressed cake), in being enamelled inside, and in having an extra pressing plate for use when the cylindrical strainer is not required. In another one exhibited by the same firm the central screw was driven by turning a handle at the side and the upper part of the press could be pushed on one side so that the cylinder could be emptied without removing it.

Messrs. Lynch and Co.'s tincture press is already well known. In this machine after direct pressure has ceased, extra pressure is put on by a cogwheel turned by a handle at the side. In the Entrance Hall Oberdorffer's and Hayward Tyler and Co.'s tincture presses occupied a prominent position. The latter has already been described and figured in the *Pharmaceutical Journal*, 3rd series, vol. ii., p. 286. The former is constructed on the elbow lever principle, the pressure being applied by straightening two compound or elbow levers, and extra pressure afterwards applied by a vertical lever. This press has an arrangement for heating by steam the plate on which the cake is pressed, a simple lever for tilting the apparatus to admit of draining off the expressed fluid, and a shelf for the receiver to stand upon.

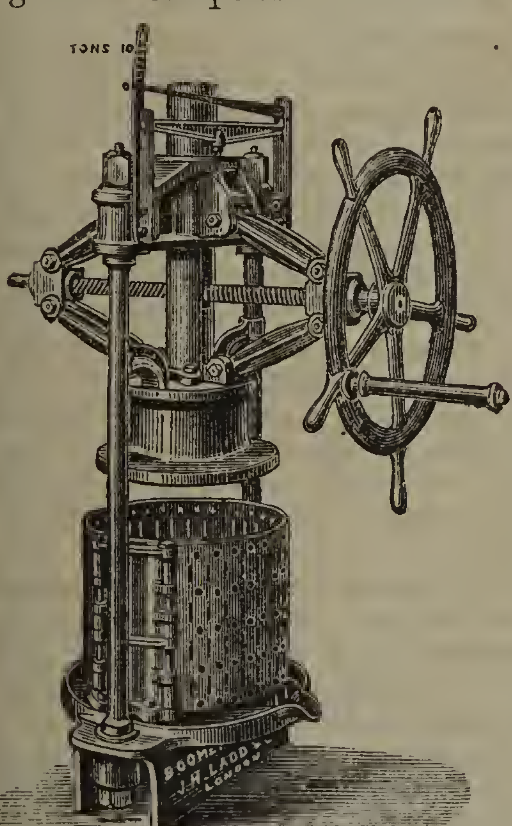

Fig. 12.—The "Boomer and Boschert" Tincture Press.

The "Boomer" press (fig. 12), exhibited by Messrs. J. Ladd and Co., differs from that of Oberdorffer in the fact that the pressure when the elbow lever is straightened is transmitted direct from the base to the apex, while in the other a great deal of the pressure falls upon the pins in the angle of the lever, on account of the connecting block not being, as in the Boomer press, equal in width to the arms of the lever. The pressure exerted by straightening the lever causes a slight deflection in the solid cross bar at the top of the press, a fact which is ingeniously turned to account in the Boomer press to gauge the amount of pressure exerted. A press of 6 gallons capacity is said to exert a pressure of 10 tons when worked by hand.

The small tincture press made by the Enterprise Manufacturing Co., of Philadelphia, and exhibited by Messrs. J. Ladd and Co., attracted considerable attention. In external appearance it somewhat resembles a sausage-making machine. Its structure can be seen from fig. 13. The advantages claimed

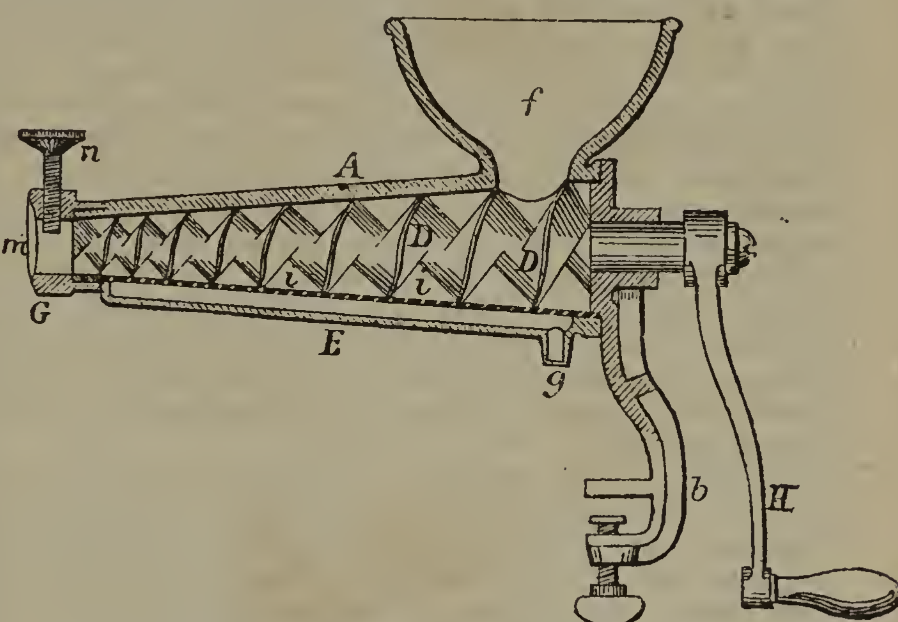

Fig. 13.—The Enterprise Manufacturing Co.'s Screw Tincture Press.

for this press are its adaptability to small quantities of material, the fact that the use of press cloths can be dispensed with, and that the residual cake is delivered uniformly dry, instead of being dry on the surface and moist in the centre. It is said by Professor Remington to be particularly useful for such bulky drugs as arnica flowers, hops, etc., but not so suitable for drugs in fine powder or of a sticky or tenacious character. The spiral screw (D) can easily be taken out and cleaned. The material is prevented from passing through with the liquid by a finely perforated plate (i), lying in a groove at the bottom of the cylinder, and this plate is kept clean by the action of the screw over its surface.

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.*

BY WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

(*Continued from p.* 980.)

Lecture III.

The suggestion to administer to invalids artificially digested food appears at first sight a somewhat startling proposal. So great an interference with the order of nature would seem to go beyond the legitimate province of art. But when we reflect how largely art already interferes in the preparation of our food, the taking of this further step will appear less surprising. The practice of cooking is in reality as complete a departure from the ways of untutored nature as artificial digestion would be.

* The Lumleian Lectures, delivered before the Royal College of Physicians.

Among the almost countless species of animals, not one of them, except man alone, cooks his food; insomuch that man has, not inaptly, been defined as the cooking animal.

Effects of Cooking.—The process of cooking fulfils far more important ends than that of improving the savour of food—far more important even than the mechanical disintegration which generally attends the process. It produces certain chemical changes in several of the most important alimentary principles, which render them incomparably more susceptible to the action of the digestive ferments than in the uncooked state. The discovery of the use of fire-heat in the preparation of his food must, indeed, have constituted one of the earliest and most important steps in the process by which man has emerged from the ranks of the dumb creation. The stores of proteid and farinaceous nutriment contained in the seeds of cereals and leguminous plants, and in the bulbs, tubers, roots, and succulent stems of certain vegetables are, in the raw state, nearly altogether beyond his powers of digestion. By the discovery of the art of cooking, these immeasurable stores were at one stroke laid open to him. It is, moreover, chiefly by the same art that he has been enabled to take his food at intervals, in separate meals; and has thereby been for ever relieved of the necessity which is imposed on all animals in the wild state of having to spend almost the entire of their waking hours either in seeking after their food, like the carnivora, or in consuming their food like the vegetable feeders. This immunity secured to him the untold advantage of possessing the leisure requisite for the cultivation of his higher faculties.

The practice of cooking is not equally necessary in regard to all articles of food. There are important differences in this respect, and it is interesting to note how correctly the experience of mankind has guided them in this matter. The articles of food which we still use in the uncooked state are comparatively few; and it is not difficult in each case to indicate the reason of the exemption. Fruits, which we consume largely in the raw state, owe their dietetic value chiefly to the sugar which they contain; but sugar is not altered by cooking. Salads may be regarded more as a relish for other food, and as having a *quasi* medicinal purpose, rather than as a substantial source of nutriment. Milk is consumed by us both cooked and uncooked, indifferently, and experiment justifies this indifference; for I found on trial that the digestion of milk by pancreatic extract was not appreciably hastened by previously boiling the milk.

Our practice in regard to the oyster is quite exceptional and furnishes a striking example of the general correctness of the popular judgment on dietetic questions. The oyster is almost the only animal substance which we eat habitually, and by preference, in the raw or uncooked state; and it is interesting to know that there is a sound physiological reason at the bottom of this preference. The fawn-coloured mass which constitutes the dainty of the oyster is its liver, and this is little else than a heap of glycogen. Associated with the glycogen, but withheld from actual contact with it during life, is its appropriate digestive ferment—the hepatic diastase. The mere crushing of the dainty between the teeth brings these two bodies together, and the glycogen is at once digested without other help by its own diastase. The oyster in the uncooked state, or merely warmed, is, in fact, self-digestive. But the advantage of this provision is wholly lost by cooking; for the heat employed immediately destroys the associated ferment, and a cooked oyster has to be digested, like any other food, by the eater's own digestive powers.

With regard, however, to the staple articles of our food, the practice of cooking it beforehand is universal. In the case of farinaceous articles, cooking is actually indispensable. When men, under the stress of circumstances, have been compelled to subsist on the uncooked grain of the cereals, they have soon fallen into a state of inanition and disease. By the process of cooking, starch is not merely liberated from its protecting envelopes, but it suffers a chemical change, by which it is transformed into the gelatinous condition, and this enormously facilitates the attack of the diastatic ferments. A change of equal importance seems to be induced in the proteid matter of the grain. I found that the gluten of wheat was incomparably more digestible, by both artificial gastric juice and by pancreatic extract, in the cooked than in the uncooked state. In regard to flesh meat, the advantage of cooking consists chiefly in its effects on the connective tissue and the tendinous and aponeurotic structures associated with muscular fibre. These are not merely softened and disintegrated by cooking, but are chemically converted into the soluble and easily digested form of gelatine. I made some instructive observations on the effects of cooking on the contents of the egg. The change induced by cooking on egg-albumen is very striking. For the purpose of testing this point, I employed the solution of egg-albumen before spoken of, made by mixing white of egg with nine times its volume of water. This solution, when boiled in the water-bath, does not coagulate nor sensibly change its appearance; but its behaviour with the digestive ferments is completely altered. In the raw state, this solution is attacked very slowly by pepsin and acid, and pancreatic extract has almost no effect on it; but, after being cooked in the water-bath, the albumen is rapidly and entirely digested by artificial gastric juice, and a moiety of it is rapidly digested by pancreatic extract.

My object in making these remarks is to show that the changes impressed on food by cooking form an integral part of the work of digestion—a part which we of the human race get done for us by the agency of fire-heat, but a part which the lower animals are compelled to perform by the labour of their own digestive organs. It must also be borne in mind that the digestive process carried on in the alimentary canal is, strictly speaking, executed on a doubling of the exterior surface, and not in the true interior of the body. If we take all these considerations into account, it will appear, I think, not unnatural that we should try to help our invalids by administering their food in an already digested, or partially digested condition. We should thereby only be adding one more to the numberless artificial contrivances with which our civilized life is surrounded.

Preparation of Artificially Digested Food.

Dr. Pavy* was, I believe, the first to carry into actual practice the idea of preparing an artificially digested food. At his suggestion, Messrs. Darby and Gosden introduced a preparation which consisted of meat reduced to a fluid state by artificial digestion. The formula for this preparation has not, so far as I know, been made public. It is still in the market, and is sent out and advertised by Savory and Moore under the title of "Darby's Peptonized Fluid Meat." A specimen of this preparation is on the table before me. It has the appearance of a light brown very thick treacle. It has a strong salt taste and an agreeable meaty flavour, without any bitterness. It is mostly soluble in water. The solution does not precipitate on boiling, nor with nitric acid, and it gives a strong reaction of peptone, with Fehling's solution, and with tannin.

I have also before me a specimen of artificially digested meat prepared by Mr. Benger. It is a greyish-looking extract, with a pleasant meaty flavour, and is quite devoid of bitterness. It dissolves mostly in water, and the solution gives the usual reactions of peptone in great intensity. Mr. Benger informs me that it is made by operating, at a temperature of about 140° F., on finely triturated raw beef with pancreatic extract and a little carbonate of soda. The solution thus obtained is neutralized with hydrochloric acid, and then evaporated at

* 'A Treatise on Food and Dietetics.' Second edition, p. 559.

212° F. to the consistency of a solid extract. Both of these preparations appear to me to be much superior in value to any of the meat extracts hitherto introduced.

But, however useful preparations of this class may prove to be, in a limited range of circumstances, it is pretty evident that, if artificially digested food is to be employed on the large scale, and among all classes, means must be found to bring the preparation of it within the range of culinary operations and the apparatus of the kitchen and sick-room.

The difficulty hitherto encountered in the production of an artificially digested or peptonized* food, suitable for invalids, is mainly owing to the use of the gastric method in its preparation. If you subject any native article of food—say milk, bread, egg or meat—to artificial digestion with pepsin and hydrochloric acid, you destroy more or less completely the grateful odour and taste, and the inviting appearance, which made it desirable as food, and convert it into an unsavoury mess, from which the human palate turns away with disgust. The unsavouriness of artificially digested food is, however, not due to any ill taste or smell inherent in the products of digestion—which, when purified, are both odourless and free from any unpleasant flavour—but to a number of by-products of various kinds, which accumulate as digestion proceeds. One of these by-products is a substance with a pure bitter flavour, which seems to be a constant accompaniment of gastric digestion. It is also developed in some cases in the later stages of pancreatic digestion. I have not observed this bitter substance, except in the digestion of proteids. It is evidently a normal educt of the process, and its presence probably accounts, in most cases, for the bitter flavour of the eructations, of which dyspeptics complain, and which is generally attributed to the regurgitation of bile. If would be interesting to know more about this substance.

My own efforts to produce a palatable peptonized food have been chiefly directed to the pancreatic method. The pancreas excels the stomach as a digestive organ, in that it has power to digest the two great alimentary principles, starch and proteids; and an extract of the gland is possessed of similar endowments. This double power is a manifest advantage in dealing with vegetable aliments, which contain both starch and proteids.

Any extract of pancreas may be used for the preparation of artificially digested food; but the most suitable are those prepared with dilute spirit or chloroform-water. The extract sent out by Mr. Benger, under the name of "Liquor Pancreaticus," is an almost faultless pharmaceutical preparation. It is made by extracting perfectly fresh and finely chopped pancreas, with four times its weight of dilute spirit. By some ingenious devices, Mr. Benger has succeeded in overcoming the mechanical difficulties of the manufacture, and has produced an extract which possesses the diastatic and proteolytic properties of the pancreas in a highly concentrated degree. It is a nearly colourless solution, with very little taste or smell beyond that of the spirit used to preserve it. It is of this preparation that I must be understood to speak in what I have now to say on the production of artificially digested food by pancreatic extracts.

My attention was first turned to the artificial digestion of milk; and I soon found that it was possible, by means of pancreatic extract, to digest this important article of food with comparatively little disturbance of its taste and appearance. Milk contains all the elements of a perfect food, adjusted in their due proportion for the nutrition of the body. Two out of its three organic constituents—namely, the sugar and the fat—exist already in the most favourable condition for absorption, and require little, if any, further assistance from the digestive ferments. It is, therefore, obvious that, if we could change the casein of milk into peptone without materially altering the flavour and appearance of the milk, such a result would go far towards solving the problem of supplying an artificially digested food for the use of the sick.

* I may be permitted to use the word "peptonized" as a convenient abbreviation for the phrase "artificially digested."

Pancreatic Digestion of Milk.

When milk is subjected to the action of pancreatic extract at a temperature of 100° F. (38° C.), in an open glass vessel, a series of changes takes place in it, which are highly interesting to watch. The first thing that arrests the observer's notice is that the tough wrinkled skin, which quickly forms on the surface of warm milk when exposed to the air, is either not produced not all, or is only produced in a very imperfect degree. In its stead, there forms a slight brittle and perfectly smooth pellicle of quite a different appearance. The next thing noticed is that the milk becomes more or less softly curdled. By and by, the curds begin to redissolve, and the milk gradually reassumes its originally diffluent condition. A portion of the curd is, however, very resistent, and remains undissolved for many hours. If the milk be diluted beforehand with one-third or one-fourth of its bulk of water this curdling phase is altogether omitted, or is only observed as a slight and transient thickening. Next follows a very curious change of aspect. The milk loses its glossy white appearance, and gradually assumes a dull yellowish-grey shade which is characteristic, and the degree of which enables the practised eye to judge with considerable precision how far the peptonizing process has advanced. This change of aspect is, however, by no means conspicuous, and would scarcely be remarked in a cursory observation, except by comparison with unaltered milk. While these changes are proceeding, the milk gradually loses its proper flavour, and at length develops a pure bitter taste, which is to many palates not disagreeable. No really unpleasant flavour is produced, unless the process is allowed to go on to incipient decomposition.

The progressive transformation of the casein into peptone, of which these outward signs are the indications and accompaniments, may be followed by testing the milk from time to time with acetic acid. At first, the addition of the acid causes an abundant precipitation of curdy matter, but this reaction progressively diminishes in intensity until at length it ceases altogether. When this point is reached, the transformation may be regarded as complete. All the casein has been changed into peptone—even nitric acid no longer causes a precipitate. The time occupied in the transformation (supposing the temperature and the activity of the preparation to be constant) depends on the quantity of pancreatic extract added, and may be made to vary from a few minutes to several hours. In the ordinary operation of preparing peptonized milk for invalids, two or three teaspoonfuls of the liquor pancreaticus are added to one pint of milk, diluted with a fourth of its bulk of water. With these proportions, the process is usually completed in from two and a half to three hours.

Modified Casein or Metacasein.—The conversion of casein into peptone does not take place by a direct transformation of the one body into the other. You all know that milk does not curdle or coagulate in the least degree on being boiled, but when milk is subjected to the action of pancreatic extract (provided no alkali is added), it speedily loses this negative property and curdles abundantly on boiling. This coagulation on boiling is most intense a few minutes after the addition of the extract, and it very gradually diminishes in intensity as the action goes on, and ceases altogether at the same time that acetic acid ceases to cause a precipitate. It was, moreover, found that if the milk were boiled at the period of the greatest intensity of this reaction and thrown on a filter the whole of the albuminoid matter of the milk was caught on the filter in the form of curds, and the filtrate showed not the slightest reaction of casein. These reactions revealed the interesting fact that in the transformation of casein into peptone by pancreatic extract the first step in the process is the conversion of casein into an intermediate body, and that it is this intermediate body which is subsequently gradually changed into peptone. This body may provisionally be called *metacasein*, signifying thereby that it is still casein, but in a modified condition. Metacasein is characterized by two reactions, which, taken together, serve to distinguish it from other proteid bodies; it is coagulated by boiling in neutral media and it is precipitated in the cold by acetic acid. The conversion of casein into metacasein in pancreatic digestion takes place almost suddenly, as is shown by the following experiment:—5 cubic centimetres of pancreatic extract were added to 100 cubic centimetres of milk, diluted with one-fourth of its bulk of water and maintained at blood heat. The first slight, almost doubtful, evidence of coagulation on boiling was perceived in three minutes; in five minutes coagulation on boiling was pronounced; and in nine minutes it had reached its maximum. From this point coagulation on boiling and precipitation on the addition of acetic acid diminished in intensity *pari passu* very gradually for a period of two hours, when both reactions finally ceased.

Taking these observations and reactions together, it is evident that the conversion of casein into metacasein constitutes a first and distinct step in the transformation of casein by trypsin and that this step is antecedent to the further and slower changes by which metacasein is transmuted into peptone. It is impossible not to see in this a striking analogy with the sudden transformation of gelatinous starch into soluble starch under the action of diastase, as described in a previous lecture.

When milk is rendered slightly alkaline by the previous addition of a little bicarbonate of soda no precipitation on boiling occurs during its digestion by pancreatic extract. But the metacasein is nevertheless produced, and its presence may be detected by carefully saturating the alkali and then boiling. For although metacasein is precipitated on boiling when the solution is neutral it is not precipitated when the solution is even slightly alkaline. This is the reason why in preparing peptonized milk for the sick it is desirable to add to it a small quantity of bicarbonate of soda.

The foregoing account of the behaviour of milk with pancreatic extract will greatly facilitate the comprehension of the practical rules which must be followed in preparing peptonized dishes for invalids. I confine myself at present to articles of which the basis is milk, or farinaceous gruel, or both together.

Peptonized Milk.—A pint of milk is diluted with a quarter of a pint of water and heated to a temperature of about 140° F. (60° C.) Two or three teaspoonfuls of liquor pancreaticus, together with 10 or 20 grains of bicarbonate of soda, are then mixed therewith. The mixture is then poured into a covered jug and the jug is placed in a warm situation under a "cosey" in order to keep up the heat. At the end of an hour or an hour and a half the product is boiled for two or three minutes. It can then be used like ordinary milk. The object of diluting the milk is to prevent the curdling which would otherwise occur and greatly delay the peptonizing process. The addition of bicarbonate of soda prevents coagulation during the final boiling and also hastens the process. The purpose of the final boiling is to put a stop to the ferment action when this has reached the desired degree and thereby to prevent certain ulterior changes which would render the product less palatable. The degree to which the peptonizing change has advanced is best judged of by the development of the bitter flavour. The point aimed at is to carry the change so far that the bitter taste is distinctly perceived, but is not unpleasantly pronounced. As it is impossible to obtain pancreatic extract of absolutely constant strength, the directions as to the quantity to be added must be understood with a certain latitude. The extent of the peptonizing action can be regulated either by increasing or diminishing the dose of the liquor pancreaticus or by increasing or diminishing the time during which it is allowed to operate. By skimming the milk beforehand and restoring the cream after the final boiling the product is rendered more palatable and more milk-like in appearance.

(*To be continued.*)

A VISIT TO THE NATIVE CINCHONA FORESTS OF SOUTH AMERICA.*

BY HENRY S. WELLCOME.

(*Continued from page* 982.)

The older cinchona trees, as found in their virgin forests, are really very grand and handsome.

The cinchonas appear to seek the most secluded and inaccessible depths of the forests for their habitation. They are rarely grouped in large numbers or close together, but are distributed in more or less irregular, scattering patches; sometimes single trees are found widely separated from any others of its family; variety and diversity are notable features of tropical forests.†

The *Cinchona succirubra* ranges from forty to eighty feet in height, trunk straight and branches regular; leaves opposite, evergreen, broadly oval, six to ten inches in length, of a rich dark green colour, sometimes tinged with crimson,‡ the upper surface of an almost waxy lustre, pubescent beneath, finely veined, midrib decided and strong.

The flowers§ have a five-toothed, superior calyx and tubular corolla, are arranged in terminal panicles of bright rose tint and diffuse a pleasing fragrance.

The capsules are ovoid and contain thirty to forty flattened seeds, winged all around by a broad membrane, irregularly toothed and lacerated at the margin.

The bark of the large trees is usually completely covered and fringed with mosses of the most delicate, lace-like texture, interspersed with lustrous variegated lichens and prettily marked diminutive trailing ferns.

Air plants and vines in profusion entwine themselves among the branches and hang in graceful festoons, forming hammocks, in which cluster an abundance of parasitic growths, particularly of the orchid family; these plants cling to every limb and vine, flourishing in their fullest splendour, exhibiting many remarkable phenomena in their curious mimicry of insect and animal forms.|| Vegetable growths develop with wonderful luxuriance beneath the almost dismal shades of the closely interlacing branches, which permit but the faintest rays of sunlight to ever filter through their rich, leafy drapery; everything saturated and dripping with moisture, the very air we breathed seemed a clammy vapour. In these forests the atmospheric changes are continuous and very abrupt; drifting banks of gloomy clouds are followed by glaring sunshine and then tempestuous showers, all in rapid succession.

The temperature is more even, averaging about 65° F., seldom exceeds 80° F., and very rarely falls below 45° F.¶ As stated above, the reflection of the shining leaves and the bright, showy colour of the flowers afford the means of discovering the cinchona trees. When the cascarilleros

* From the 'Proceedings of the American Pharmaceutical Association,' 1879.

† Agassiz once in Brazil counted over one hundred different varieties of trees within an area of half a mile.

‡ The leaves of *Cinchona succirubra* show more red than any other variety. It is due to the larger amount of cinchotannic acid present.

§ At the time of my visit (month of June) none of the cinchonas were yet in blossom.

|| The Indians hold some varieties of the orchids in superstitious regard, on account of the peculiar forms they assume, notably among which is the flower of the Holy Spirit, which appears the very prototype of a dove.

¶ Altitude about 6000 feet.

enter the forests to prospect* for cinchona patches they ascend to such high spurs as command a good view of the surrounding valleys and mountain slopes. Skilled cascarilleros can determine very accurately a paying forest at a great distance, and are usually able to distinguish the varieties by the colour of the flowers and general appearance of the tree. After discovering a forest that indicates sufficient value to render it profitable to work, a certain limit† of forest land is condemned and a claim made to the Government; upon the payment of a certain fee a title‡ is granted. These claims are christened usually with some sacred name, such as Bosque de San Miguel, or Bosque de Sacramento.§ As a rule the bark gatherers are of that happy-go-lucky sort,—very much like our Western miners,||—inveterate gamblers, and while they have money dispense it freely, consequently are "dead-broke" every year long before the bark harvest begins.

After discovering a new forest and securing it with a Government title, the cascarillero applies to a bark dealer for funds with which to work his claim; if he can present satisfactory evidence that his forest is a profitable one, sufficient money is usually advanced to work it, the title being held by the merchant as security and with it an agreement that the bark shall be delivered and sold to him exclusively.¶ Sometimes the dealers purchase claims outright and employ men to work them.

The season for bark gathering begins about the 1st of August and lasts until October or November;** during these months the bark cleaves most readily and the forests are more easily accessible.†† A master cascarillero with his gang of peons‡‡ enters the forest and first establishes a main camp, with bamboo huts for habitation and for sheltering the bark. These camps are located near a spring or river and on an elevated point where there is an opening in the forest, so as to allow the bark as much exposure as possible. Sufficient supply of provisions is taken into the forest to last during the season.§§

The peons are formed into squads, each division being placed in charge of a jefe,|||| who is held responsible for his subordinates. These squads scatter through the forest and establish small camps; when they get fairly settled the bark-gathering begins; one or two from each division seek out the trees, while others cut down¶¶ and peel them. The trees are first decorticated from the ground up as far as can be reached, and then, after felling and removing the clinging vines and mosses, the rough outer bark is beaten off with a club or mallet. The bark is then cut around the trunk in sections of two to three feet and longitudinally in strips of six to eight inches in width, then removed with the blade of a machete. The root-bark is obtained by digging away the earth and cleaving with a machete (the pieces are very rough and irregular).

When first taken from the tree the inner surface of cinchona bark shows a handsome cream tint (with juice of the same colour), but on exposure to the atmosphere rapidly darkens to a dirty red. The blade of a new sheath knife with which I cleaved some bark of *Cinchona succirubra* was stained a beautiful purple colour wherever it was touched by the juice.*

The barks are usually taken to the main camp for drying and storage.

The thick bark of the trunk requires great care in drying because of the excessive dampness of the atmosphere, which sometimes necessitates the use of artificial heat to prevent moulding; it is piled up in tiers with sticks between the layers to allow free circulation of air and weights are placed on top to flatten it.† The thin bark from the young trees and small limbs dries more readily and rolls itself up into quills.‡

One of the greatest difficulties connected with the gathering of cinchona bark is that of transporting it to the coast at the end of the season. It is roughly sorted, according to the part of the tree from which it is obtained, and packed in bales of about one hundred and fifty pounds each; the Indians carry these bales on their backs a distance of sometimes several hundred miles to a transfer warehouse, from whence it can be transported by mules to the nearest seaport.§

The Indians bear the main weight of the burden upon their heads, by placing over the forehead a strip of raw hide to which are attached cords of the same material lashed to the bale. They stoop forward to maintain their equilibrium and use long Alpine staffs to steady and aid them in ascending the dangerous cliffs. The skeletons of hundreds of wretched peons now lie bleaching beneath the tropical sun, their earthly toils having been ended by a mis-step on the verge of a precipice, or by falling victims to the deadly fevers while bearing upon their backs the very specific intended for the relief of the sick in distant lands.

An old Indian, while relating to me the dangers encountered in collecting cinchona bark, said that at the time of the Spanish conquest his people were robbed of their possessions, had since then served as slaves, and are now made human sacrifices to furnish health to the white foreigners.

The malaria in some of the forest valleys is simply fearful, and owing to great exposure and want of nutritious food the Indians yield very quickly to its influence.

I was told by a bark merchant that during a severe malarial season, several years since, as many as 25 per cent. of the Indians employed in one district died from fevers before the harvest was completed.

Malarial fevers are regarded with great terror by the Indians, and it is only by extreme poverty, or obligation as peons, that they are induced to enter the bark forests to encounter the dangers for the meagre pittance of ten to twenty-five cents per day.

* The term prospect is used in the same sense as in the search for mines.

† The boundary is usually indicated by certain mountains, valleys or streams.

‡ These titles are granted on very much the same plan as those upon mining claims in the United States.

§ These claims are each called bosques (forests).

|| Only they lack the energy of our miners.

¶ For many years the bark trade of Bolivia was monopolized by the Government; the cascarilleros were obliged to sell their bark to a bank established for that purpose, and receive for it whatever price the officials chose to pay. This system was conducted with such flagrant injustice and dishonesty that it was finally broken up. Now each of the republics levies a duty on all barks exported.

** In some forests the season begins as early as June.

†† Because of less rainfall during the summer; it is almost impossible to enter the forests during the wet season.

‡‡ Sometimes as many as three or four hundred.

§§ In the older forests potatoes and plantains are grown near the main camp.

|||| Jefe,—pronounced *hefa*,—meaning chief, and sometimes called major-domo. Each squad is allowed to elect its own jefe; the qualifications required for gaining such distinction among their fellows are bravery and superior muscular power.

¶¶ The axes used for cutting down the trees are something of the broad-axe pattern, and are of American manufacture. American edged tools of all kinds receive preference in those countries.

* Caused by the action of cinchotannic acid upon the steel.

† This forms what is known as flat barks—called by the natives *tabla* (which signifies flat).

‡ Called by the natives *canulon*, which means a tube or pipe.

§ The worn appearance of most cinchona barks seen in the market is produced by the rough handling it gets during transportation to the coast.

The final sorting and classifying of barks is done at the main bodegas* at the coast,† where it is packed in ceroons of cowhide‡ or bales of heavy sacking; there it is that most of the adulteration and sophistication is done. The admixture of inferior barks with higher grades is not so much the result of ignorance as has been supposed by many, for the bark dealers are very expert in determining the different varieties and estimating the values of barks; but, strange to say, very few bark merchants ever become wealthy.

(*To be continued.*)

PERSIAN OPIUM.

The following memorandum on the opium of Persia is taken from a report on the trade of the Persian Gulf, by Consul-General Ross:—

For the last two years the Persians have shown unprecedentedly great activity in extending and improving the cultivation and growth of opium in the country. The heavy losses which they suffered on more than one occasion from their badly prepared and adulterated stuff, and the tempting profits which they found were obtainable from better produce, have apparently impelled them to the course now taken. While a few years ago a case of Persian opium weighing 18 tabreez mans (or 140 lbs.) would not fetch in China more than 280 to 350 dollars, it has recently realized from 500 to 615 dollars. This change cannot, of course, be attributed altogether to the improvement in the quality of the Persian drug, as prices are regulated mainly by the state of the Indian produce and by the demand in the China markets. The Bengal and Malwa crops failed in the last two years owing to drought and other circumstances, and the limited out-turn, coupled with heavy speculation, tended towards the increase of prices. The prospect of the crops of the current year is said to be favourable, but the trade in opium is not expected to be very remunerative.

To return to the Persian opium. From the time the attention of the native merchants was attracted to the trade in this article, about twenty-five years ago, there has been, with two or three exceptions, a gradual annual increase in the production of the drug. But this increase has never before been so very considerable as to become prominently noticeable.

It was reported in 1859 that about 3000 "shah mans." or 300 cases of opium, were produced in Persia; and in 1861 that about 10,000 "shah mans," or 1000 cases, were expected to yield from the crops of the year, a quantity which was then noticed to be double the out-turn of the previous year.

In the trade report of this Residency for the year 1874–75 the fluctuations of the annual estimated produce of opium in Persia from the year 1868–69 to 1874–75 were shown in a tabular statement attached to a special report on the subject. The largest produce for any one year did not exceed 2600 cases (a quantity inappreciably small in regard to the demands in China), and in 1874-75 it had fallen to some 2000 cases. In the following year there was a further decline, the exports amounting to about 1890 cases. Since 1876-77, however, a reaction appears to have taken place, as in that year 2570 cases were exported from Bushire and Bunder Abbass alone.

In the early part of 1877-78 the probable yield of the crops was estimated at 3500, but the actual number exported from Bushire and Bunder Abbass amounted to 4730 cases.

* Storehouse.

† In Bolivia the sorting and packing is usually done before transporting to the coast.

‡ The ceroon consists of a closely packed bale sewed up in cowhide (hair side out). The hide having first been rendered soft and elastic by soaking in water, on drying it shrinks and forms a very strong and firm package.

Last year (1878–79) the out-turn was stated to have been 6700 cases, while 5900 were exported from these ports.

The probable yield of the crops of the current year, 1879–80, is at present estimated to be as follows:—

	Shah Mans.	Cases.
In Khonsar, about	14,000	950
Kerman	4,500	300
Yezd	15,000	1,000
Ispahan	37,000	2,400
Nereez	6,000	400
Shiraz	20,000	1,300
Kazran	1,500	100
Shuster	1,500	100
Total	99,500	6,550

In addition to the above 6550 cases of opium, about 3000 "shah mans," or say 550 cases, are expected to come to Yezd from Herat, making the whole stock about 7100 cases. The Shuster opium is sent through Mohammerah direct, and sometimes *viâ* Bushire to Mussat, for transmission to Zanzibar; but a part of it is supposed to be smuggled into the Indian frontier provinces, *viâ* Mekran and Beloochistan. Thus 7000 cases are expected to be available during the current year for export through Bushire and Bunder Abbass to China and England.

Small quantities of opium are said to be grown in Tehran, Tabreez and Kermanshah, but these mostly find their way to Europe *viâ* Turkey, Smyrna being, it is alleged, the port where it is mainly taken to and where it is mixed with the local drug and forwarded to the continental markets.

Opium is made up into cakes, varying in weight from $\frac{3}{4}$ lb. to $1\frac{1}{2}$ lb., and in number from 96 to 192 or more; and these are packed in fig or vine leaves, and sometimes in poppy seeds or stalks, into cases containing each from $10\frac{1}{2}$ to 11 "shah mans"—a "shah man" being equal to about $13\frac{1}{4}$ lbs. English.

The object in so packing in cases as regards the weight is that the contents, after the deficiency caused by drying up in course of transit, which is calculated at from 5 to 10 per cent., may realize at destination (China) one "picul," which is about 135 lbs. Another reason is that the weight is arranged for convenience of carriage by pack animals (generally mules) employed in these regions.

About five-sixths of the produce of opium in Persia is intended for China. The drug suitable for that market being required to be fine, and prepared with oil, and not rich in morphia, permits its being swelled up with foreign substance, and thus being, as far as practicable, adulterated to the extent to preclude discovery by the mode of testing or "touching" used in China.

It is said that pure and superior opium, though not so finely manipulated, has been rejected in China, while the fine opium containing admixtures has found favour and fair market.

The preparations made for the China marts—being, say, of a quality of 80 "touch" (containing 80 per cent. pure juice and 20 per cent. foreign substance)—yield from 9 per cent. to 10 per cent. morphia.

The preparations for England, which have recently been specially made pure and which have come into favour in Europe and America, have, it is said, yielded morphia averaging about 12 per cent.

The average price for fair quality of opium suited for the China market has been for the last two years about 950 rupees per chest, and for the special preparations for England about 100 rupees more.

To these are added the charges of transit and other contingent expenses from the place of product to the port of shipment, amounting to about 30 rupees, and, further, a custom and octroi or other duty of about 20 rupees, payable by a Persian, or 5 per cent. *ad valorem* by a British or other foreign merchant.

The Pharmaceutical Journal.

SATURDAY, JUNE 12, 1880.

THE LAW AS TO THE MANUFACTURE AND SALE OF METHYLATED SPIRIT.

AMONGST the Parliamentary papers issued during the present week is a "Bill to consolidate and Amend the Law Relating to the Manufacture and Sale of Spirits," prepared and brought in on behalf of the Government by Lord FREDERICK CAVENDISH, Mr. Attorney-General and Mr. Solicitor-General. As indicated by its title, the principal object of this Bill appears to be to gather together into one enactment the legislation on the manufacture and sale of spirit, which is now scattered through upwards of twenty different Acts of Parliament, and incidentally many points of considerable interest to chemists and druggists are dealt with.

The Bill is divided into three parts. Part I. is devoted to spirit other than methylated, and specifies the conditions and restrictions under which the businesses of distilling, rectifying and brewing can be carried on, and also the regulations for warehousing. It further re-enacts the existing provisions as to dealers and retailers of spirits and the permits and certificates and stock books necessary for the dealing in and removal of spirit from one place to another.

Part II. relates to methylated spirit, and as this is a subject concerning which inquiries are frequently made it may be useful to describe the scope of this part of the Bill in greater detail.

Methylated spirit, subject to the provisions of the Act, is still to be exempt from duty. The only persons allowed to methylate spirit, however, are such distillers and rectifiers as are specially authorized by the Commissioners of Inland Revenue, persons licensed to methylate, and persons called "authorized methylators." The only persons permitted to supply methylated spirit are "authorized methylators" and licensed "retailers of methylated spirit." An "authorized methylator" must not supply methylated spirit except in vessels containing not less than five gallons, distinctly labelled with the words "methylated spirits," and accompanied by a permit, and the sale, delivery and removal of the spirit have to be carried out in accordance with forms prescribed by the Excise authorities. Neither may he supply methylated spirit to any persons other than "retailers," those who are themselves authorized to methylate, and persons specially authorized by the Commissioners, upon application and giving security, to receive methylated spirit for use in some art or manufacture carried on by them. On the other hand, "a retailer" of methylated spirit must not sell to or for the use of any one person more than one gallon of methylated spirit at a time. Neither must he receive or have in his possession at one time a greater quantity than fifty gallons. He may receive this quantity from an "authorized methylator," but from another "retailer" he must not receive it in quantities exceeding a gallon at a time. "Authorized methylators" have to carry on the methylation and store the spirit in rooms approved by the Commissioners, and "retailers" have to keep the Commissioners informed as to the places where they keep and sell the spirit, and both have to keep a strict account of stock and sales. Any person, not being an "authorized methylator," having in his possession any methylated spirit not obtained from a person authorized to supply it, will be liable to a fine of £100. The removal of methylated spirit in contravention of the Act, and the supply of it by "authorized methylators" to improper persons are offences also liable to heavy penalties. Indeed, it need hardly be said that all the provisions are similarly guarded.

The only forms in which spirit may be used for methylating are as plain spirit of strength not less than 50 per cent. above proof, and rum of strength not less than 20 per cent. above proof, and the quantity of spirit used for methylation at one time is in the case of British spirit to be not less than 450 gallons, and of foreign spirit in an excise warehouse the contents of the cask in which it is imported. The substance mixed with spirit for the purpose of methylation must be wood naphtha, or methylic alcohol in the proportion of not less than one-ninth of the bulk of the spirit, or some other substance approved for the purpose by the Commissioners of Inland Revenue. But, before methylating, the substance intended to be used must be examined and approved by an officer appointed for the purpose, and the whole of the operation is carried on under stringent regulations.

The precautions against the improper use of methylated spirit are contained in the latter clauses of Part II. It is provided that any person who prepares or attempts to prepare methylated spirit for use as a beverage, or as a mixture with a beverage; or who sells any methylated spirit, whether so prepared or not, as or for or mixed with a beverage; or uses any methylated spirit or any derivative thereof in the preparation of any article capable of being used wholly or partially as a beverage, or internally as a medicine; "or sells or has in his possession any article in "the preparation of which methylated spirit or any "derivative thereof has been used," will be liable to a penalty of £100 and forfeiture. But nothing in this section is to apply to the use of methylated spirit or a derivative in the preparation of sulphuric ether or chloroform, for use as a medicine or in any art or manufacture, or prevent the sale or possession of sulphuric ether or chloroform for such use.

When gum resin has been mixed with methylated spirit it will be penal to separate it or to alter the article in any way except by the addition of more resin or a simple colouring matter. Any liquid containing methylic alcohol so purified, by filtration or otherwise, as to be free wholly or partially from any flavour or odour that would otherwise pertain to it, is to be deemed low wine prepared for the purpose of distilling spirit from it, and to be chargeable with duty accordingly. This provision may, however, be modified or dispensed with at the discretion of the Commissioners.

Part III. is supplemental, and contains nothing calling for remark here except that SYKES's hydrometer is still to be used for deciding the spirit strength of liquors according to a table forming one of the Schedules of the Bill.

THE POSITION OF CHEMISTS AND DRUGGISTS IN REGARD TO THE WEIGHTS AND MEASURES ACT.

WE have much pleasure in directing attention to Mr. HAYDON's letter on this subject, in which he joins his efforts with our own in seeking to impress upon chemists and druggists the desirability of bringing themselves into conformity with the provisions of the new Weights and Measures Act.

There is, however, one point in which we think somewhat differently from Mr. HAYDON as to the proper course to be taken, and that has reference to communications with the local inspectors in various districts. As a rule, we should be rather disposed to recommend avoidance of any communication with those officials, not out of any disrespect for them in their proper capacity, but because in many cases they have no authority to deal with apothecaries' weights and the measures used by chemists and druggists, and, as has been found in most cases, they are only able to say they have no instructions, or that they expect in a short time to receive them. By applying to the inspectors on this subject they are really put in a false position, and in regard to the object in view it appears to be the very last thing that should be done.

To put into words the object which we think desirable for chemists and druggists to secure in regard to the Weights and Measures Act, it is that they should be in a position to receive the visits of the local inspector without fear of being subjected to inconvenience by reason of having in their possession apothecaries' weights and glass graduated measures that are not correct or are not stamped as the Act requires.

One way of securing this object is to purchase new sets of weights and measures that have been verified and stamped for the sellers. This has we know been done in many cases, and it is a very effectual plan so far as inspection is concerned, for the Act provides that a weight or a measure stamped in accordance with the requirements of the Act is to be regarded as a legal weight or measure throughout the United Kingdom.

Still some persons may be disinclined to go to the expense of discarding all their apothecaries' weights and graduated measures, and replacing them by new ones already verified and stamped. We can imagine such objections being made with good reason; but we do not think that under such circumstances there need be any fear of becoming liable under the Act, and to obviate such a contingency we would suggest that the chemists and druggists of any one of the towns or districts specified in the Weights and Measures Act should address themselves collectively or individually to the corresponding local authority, stating that they are desirous of placing themselves in conformity with the law and require to have their weights and measures verified and stamped.

Whatever might be the result of such an application we believe that it would have the effect of protecting those who made it from vexatious prosecution. At any rate it would be evidence that an attempt had been made to comply with the requirements of the Weights and Measures Act. As the local authorities are for each town or district the only persons who have power to take the initiative in putting the Act into operation, and to provide the means as well as lay down the regulations by which that is to be done, it is with them that the responsibility lies of seeing that chemists and druggists are furnished with due opportunities for satisfying its requirements.

We think it is a great mistake to trust, as so many seem disposed to trust, to the inaction of the local authorities, because there is no knowing how long that may last, and after being lulled into a false security in that way chemists and druggists might suddenly find themselves in a position of much difficulty. Even supposing their apothecaries' weights and graduated measures to be correct they would still be liable to a penalty if those weights and measures were not duly stamped, and they have reason for complaint against the local authority of their town or district so long as they are unprovided with the means of obtaining verification of their weights and measures.

We believe that it is equally a mistake to suppose that because the Weights and Measures Act does not contain any provision for penalties in the event of any local authority failing to carry it out, the Act may be looked upon as one of a merely permissive character, so that, if the local authorities be inclined to remain inactive, the Act may be disregarded altogether as not deserving any attention. Those who will take the trouble to read the Act will perceive from its language that it is not by any means permissive, but that the duties assigned to the local authorities who are empowered to carry it out are assigned to them as obligations which they shall perform. There is no evidence of the Act being intended to remain a dead letter, and we have no doubt that if the absence of provision for penalties in case of non-performance of duties appertaining to local authorities were to have the effect of making it so to any extent, this defect would speedily be remedied by further legislation.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The annual meeting of this Association was held at the Flying Horse Hotel, Nottingham, on Tuesday, June 1, Mr. R. Fitzhugh, F.C.S., the President, in the chair. The gathering was a very good one, a fair number of members being present, together with a few visitors.

The minutes of the last meeting having been read and confirmed, and Mr. C. Fletcher having been unanimously elected a member,

The Honorary Secretary proceeded to read the annual report, which was as follows:—

Annual Report.

In presenting their annual report the Council have pleasure in congratulating the members on the continued prosperity of the Association, and on the better attendance at the general meetings during the session. There are now fifty-five members and twenty-five associates against fifty-nine members and twenty-six associates last year, and the Treasurer has a balance in hand of £51 17*s.* 9*d.* The Council have to regret the loss of two old members of its body by death during the past year.

Six meetings have been held during the session, four general ones and two social ones for members only.

At the inaugural meeting the President presented the prizes to the successful associates in last session's classes on materia medica, the recipients being Messrs. Talbot, Gill, Hare and Granger, and then delivered his address, in which he spoke principally of the advantages of education to the chemist, and the relationship between masters and apprentices.

The second meeting was for members only, and the subject discussed was "The Present Aspect of the Drug Trade," ably introduced by Mr. Bolton. At the third meeting, Mr. H. Major, B.A., delivered a most interesting and instructive lecture on "Earthquakes and Volcanoes." Mr. F. H. Spenser was the lecturer at the fourth meeting, when the subject was "Sound," illustrated by numerous experiments, which was treated in a most interesting manner by the lecturer. The next meeting was a social one, and the subjects discussed were "The Present Rates Charged for Carriage of Goods;" "The Thursday Afternoon Closing Movement," and a letter from the Manchester Chemists' Association relative to the sale of patent medicines containing poisons by unregistered chemists. A sub-committee was appointed to make inquiries about the high rates charged for carriage of drugs with a view to their reduction, and a resolution was passed asking the Council of the Pharmaceutical Society to use their influence to amend that portion of the Pharmacy Act of 1868 which excludes proprietary medicines from its operations. The meeting was very divided in opinion about the Thursday afternoon closing movement, and although a vote was taken on the subject it was understood to be merely an expression of opinion, and no decision was come to.

At the sixth meeting Mr. Rayner read a paper on "The Health of the Drug Trade," being some observations on a recent correspondence in the *Pharmaceutical Journal*, on the longevity of chemists, in which he expressed a very strong opinion that chemists as a body are as long lived as any other trade.

Prizes were offered by Mr. Atherton, F.C.S., and Mr. W. Widdowson, for the best essay by the associates. The subject chosen for competition was "The Art of Dispensing." Nine students entered, and the winners of the prizes were Mr. Judge and Mr. Gill.

The Council arranged with Mr. Reuben Widdowson to give a course of lectures on "Inorganic Materia Medica and its Chemistry" to the associates. Only a very small number entered for the course, but the Council are pleased to notice that the attendance was extremely regular and the attention and general conduct very good.

An examination has recently been held and the prizes offered by the Council will be presented to the successful associates at the inaugural meeting next session.

In accordance with the wish expressed at the last annual meeting, the Council made application for a room at the new University Buildings, and for the use of the laboratory. Some correspondence has taken place on the subject with the Town Clerk, but the University Buildings Committee have not yet come to any decision. In view of the likelihood of having a room, where the library and museum may be permanently located, the Council have not deemed it expedient to expend any of the funds in increasing either, but would recommend their successors, in the event of the application being successful, which they have every reason to hope will be the case, to make such increase as may serve to uphold the position of the Association and be of benefit to the members and associates.

The library has been fairly used during the session, and with one or two exceptions the books are in a satisfactory state.

The annual supper was held at the Flying Horse Hotel in January, and it is almost unnecessary to say was a thoroughly enjoyable evening.

Mr. Wilford, on behalf of the Auditors, then presented the Treasurer's report, and upon the motion of Mr. Lewis, seconded by Mr. Clarke, both reports were received and adopted.

The meeting then proceeded to appoint the officers for the ensuing session, with the following result:—Mr. R. Fitzhugh, F.C.S., was re-elected President; Mr. W. H. Parker, Vice-President; Mr. J. Rayner was re-elected Treasurer, and Mr. C. W. Warriner, Honorary Secretary, in the place of Mr. Robert Jackson, who has been compelled to resign on account of his leaving the profession. Messrs. F. White and J. Lewis were appointed Auditors.

Fifteen gentlemen were nominated for the Council; the ballot was taken with the following result:—Messrs. Beverley, Bolton, T. B. Fletcher, Humphreys, Jackson, Oldershaw, W. Widdowson and Wilford.

A hearty vote of thanks was accorded to the retiring officers for their services during the past session, for which the President briefly thanked the members present on behalf of himself and his colleagues.

Mr. Fletcher suggested that non-members should be admitted to the social meetings, and after a short discussion, the President thought that would be met by Byelaw 10, which says that each member may introduce two friends.

Mr. W. H. Parker then introduced the subject of the Thursday half-holiday closing movement, mentioning that the chemists at the West-end had already commenced to close from one o'clock until six in the evening. This was supported by Mr. C. Fletcher, who remarked that no decrease in business had taken place on that day in consequence. After a lengthy discussion in which Messrs. Warriner, Humphreys, Bolton, Clarke and Jackson took place,

Mr. Rayner proposed, and Mr. Warriner seconded:—"That a special meeting of the trade be called to discuss the question of the half-holiday closing movement," which was carried.

The President then rose and stated that he had a most pleasant duty to fulfil. In consequence of the retirement of their late energetic Honorary Secretary, Mr. Robert Jackson, the Council thought that in recognition of his valuable services for the past five years to the Association and the trade generally, some suitable mark of respect and esteem should be made to him, and he was happy to say such feeling was endorsed by the whole Association with the exception of two or three members, and the result was the handsome testimonial before them. The President in a graceful and appropriate speech, then in the name of the Association presented Mr. Robert Jackson with a handsome timepiece and liqueur cruet, the former having upon it a plate bearing the following inscription:—"Presented to Mr. Robert Jackson by the Nottingham and Notts Chemists' Association, as a recognition of his useful and energetic services as Honorary Secretary to their Society for a period of five years. Nottingham, June 2, 1880." He said that in losing Mr. Jackson the Association was losing a member who had thoroughly had its interest at heart, and who for five years had been untiring in the discharge of his duties as Honorary Secretary, and for the past eleven years had been an active member of the Association.

Mr. Jackson then responded and heartily thanked the members of the Association for their kind testimonial and high appreciation of his efforts, feeling personally that he had not merited it, but assuring the members that so long as he should live and especially while he remained in Nottingham, the welfare and success of the Association and of the private members of the trade generally would always be dear to him, as amongst them he had spent some of the happiest hours of his life.

A hearty vote of thanks to the President concluded the meeting.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, June 3, Professor H. E. Roscoe, President, in the chair.

The President announced that a ballot would take place at the next meeting of the Society, on June 17. The following certificates were read for the first time:—J. K. Crow, A. G. Chamberlain, H. A. Mott.

The President then called upon Mr. W. H. PERKIN to read a paper—

On Some Products of the Oxidation of Paratoluidine.—In a previous paper on mauvein, *Journ. Chem. Soc.*, 1879, 728, the author briefly referred to some experiments on the oxidation of paratoluidin by chromic acid. The present paper continues the study of this reaction. A solution of the sulphate of paratoluidin was mixed with a solution of potassic dichromate. After twenty-four hours a large quantity of a brown precipitate formed; this was collected, washed, dried and extracted with benzene. The benzene was coloured a rich orange-red, and on evaporation furnished a red crystalline product. After a great deal of trouble and many recrystallizations this was separated into two new bases, one less soluble than the other. The least soluble gave on analysis numbers indicating the formula C_7H_7N. Its crystalline form has been described and figured by Mr. L. Fletcher. The substance melts at 216° to 220°; it crystallizes in beautiful rhombohedral, garnet-red crystals from benzol and ether. It readily dissolves in alcohol acidified with hydrochloric acid, forming a brownish-red solution, changing to a red-purple. With concentrated sulphuric acid this substance assumes a magnificent blue colour. A platinum salt was formed, indicating as the formula for this substance $C_{21}H_{21}N_3$. It is designated by the author triparatolylenetriamine. The more soluble base was also obtained pure after much trouble. Analyses indicated the formula $C_{28}H_{27}N_3$. It may be derived from the preceding substance by replacing one atom of hydrogen by tolyl, and is therefore designated tolyltriparatolylenetriamine. It melts about 175° C. and dissolves in alcohol acidified with acetic acid with a purple colour. It separates from its ethereal solution in small, flat, prismatic crystals. It is an organic base, forming easily decomposable salts. In concentrated sulphuric acid it dissolves with a dull violet colour, quickly changing to a pale yellowish-green. A platinum salt was prepared and analysed. No special advantage was obtained by substituting acetic for sulphuric acid in the oxidation process. By using a solution of paratoluidin in glacial acetic acid and a solution of chromic acid in the same solvent a different reaction was obtained. Golden yellow needles were deposited which when purified proved to be parazotoluene, and fused at 143°.

Dr. DUPRÉ then read a paper—

On the Detection of Foreign Colouring Matters in Wine.—In January, 1876, the author proved that the true colouring matter of wine dialysed very slowly (*Analyst*, ii. 26 and xi. 186), while the various colouring matters said to be used in adulterating wine dialysed freely. Also that small cubes of jelly, ⅝" in the side, cut from a plate of jelly with a wet knife could be used with great advantage in the analysis, as follows:—Such a cube immersed for a definite period in the wine is taken out, washed with a little water and a central slice cut out; if the wine is pure it will be found that in twenty-four to forty-eight hours the colour has penetrated but a very little way in the cube, whereas many colouring matters will have reached the centre. Since then the author has extended his researches and the present paper gives an account of experiments made with many colouring matters as above described. The results confirm those already obtained. The colouring matter of pure wine dialyses very slowly. The only artificial colouring matter tried which does not dialyse quickly is that of alkanet root. Althæa, beet, bilberry, Brazil wood, carnation, cherry (red and black), clematis (purple), cochineal, cranberry, currant (red and black), elderberry, indigo, litmus, logwood, mallow, raspberry, red cabbage, red poppy, rhatany root, rosanilin, saffron and strawberry all dialyse and penetrate rapidly into the jelly. Alkanet can be readily distinguished from the colouring matter of wine by giving an absorption spectrum of three bands in acid solution. Ammonia changes wine colouring matter to greenish-brown, which gives one indistinct absorption band in the yellow. Alkanet is turned blue and gives two absorption bands. The nature of the colouring matter can often be detected by the colour of the gelatin cube, *e.g.*, indigo, logwood, etc.; if not, it is best to dialyse the wine through parchment paper and then apply the tests suggested by Gauthier and others to the dialysate. The cubes of jelly are cut from a jelly containing 10 per cent. of dry gelatin, to which it is preferable to add 10 per cent. of glycerin.

The President asked if Dr. Dupré could account for the non-diffusibility of the colouring matter—whether it was of an albuminous nature?

Dr. Frankland suggested that the colouring matter might be in suspension; that it did not subside was no evidence against this view, as gold had been obtained by Faraday in a state of suspension so fine that it did not settle after many years' standing.

Professor Emerson Reynold asked if the age of the wine did not alter the dialysing power of the colouring matter.

Mr. Page suggested as a substitute for the sheets of paper stretched on hoops usually employed in dialysis, tubes made of parchment paper, which could be obtained of almost any length, and were very convenient, as no joint had to be made. They could be obtained from K. Brandegger, Elwangen, Würthemburg, at 4s. to 5s. the 100 metres.

Dr. Dupré, in reply, did not think that the colouring matter was albuminous, but that it resembled somewhat a tannin. In his opinion the colouring matter was not in suspension, in proof of which it did not colour the must until sufficient alcohol had formed to bring it into solution. He had examined 1834 port and two year old port without detecting any difference in the dialysing power of the colouring matter.

On the Action of Organozinc Compounds upon Nitrites and their Analogues. I. Action of Zinc Ethyl on Azobenzene. By E. FRANKLAND and D. A. LOUIS.—When azobenzene is added to an ethereal solution of zinc ethyl, and the mixture warmed to the boiling point of the ether, a reaction commences, accompanied with the evolution of much gas; as soon as it ceases it can be continued by adding a fresh quantity of azobenzene, and so on until the reaction becomes sluggish, care being taken to employ an excess of zinc ethyl. An amber coloured jelly was thus obtained. It was decomposed by water, much gas being evolved; a reddish-brown oil separated out with the zincic hydrate. By treatment with caustic soda the zincic hydrate was removed. The oil thus obtained was purified, and proved by analysis, etc., to consist mainly of anilin. The gas evolved during the reaction consisted of three volumes of ethylene and one volume of ethylic hydride. From 80 grams of azobenzene 70 grams of anilin were obtained. Besides the anilin a small quantity of a high boiling point viscid oil was obtained, the investigation of which is not yet complete.

II. On the Action of Zinc Ethyl upon Benzonitrile. By E. Frankland and J. Castell Evans.—Equal volumes of zinc ethyl and benzonitrile were heated in a sealed tube to 150°. On cooling the contents solidified to a brownish mass. After treatment with alcohol and hydrochloric acid white needles remained, sparingly soluble in alcohol, but dissolving readily in carbon disulphide, fusing at 229°. By analysis, etc., this substance was proved to be cyaphenine, $C_{21}H_{15}N_3$. The above reaction also takes place under ordinary pressure. On heating cyaphenine with concentrated hydrochloric acid in a sealed tube to 250° it can be converted entirely into benzoic acid and ammonia. The liquid obtained by treating the product of the zincethyl reaction (after decomposition by alcohol) with hydrochloric acid deposited on standing faintly greenish six sided plates. These, after purification, gave numbers indicating the formula $C_{17}H_{21}N_2Cl$. A further investigation of this hydrochlorate, which fuses at 257°, is promised. The gas evolved during the action of zinc ethyl on benzonitrile consisted of equal volumes of C_2H_4 and C_2H_6.

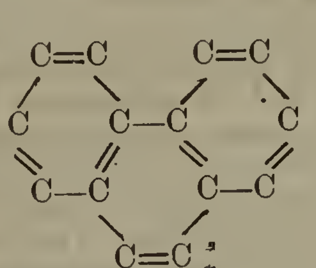
Dr. Armstrong suggested that it would be better to get rid of such terms as ethylic hydride. The researches of Dale and Schorlemmer had proved that there was no difference between ethane and ethylic hydride, moreover, the latter name suggested a distinction between one atom of hydrogen and the other atoms of that element, which did not exist.

Dr. Frankland quite agreed with Dr. Armstrong as to the desirability of abolishing the term if the identity of the two substances was fully proved, but in his opinion it was necessary to be very careful in abolishing an idea because it did not conform to the theories of the day. He quite admitted that Schorlemmer had proved the identity of a fraction of the products of the action of Cl on the two gases, but nothing had been done with the remainder of the products. He had waited for several years for any further investigation of the subject and at last had determined to take up the question himself.

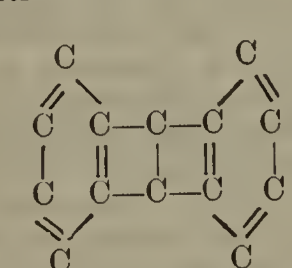
Dr. Japp contended for the convenience of the term methylic hydride, irrespective of the question of isomerism, as in Butlerow's reaction.

Professor Hartley then read a communication—

On the Relation between the Molecular Structure of Carbon Compounds and their Absorption Spectra.—In a previous paper in which the author was associated with Professor A. K. Huntington, it has been shown (1) that every increment of CH_2 in a homologous series of alcohols or of acids effects an absorption of the more refrangible of the ultra-violet rays, so that the greater the number of carbon atoms in the molecule, the shorter is the transmitted spectrum. (2) That the terpenes always transmit continuous spectra, but polymerization largely increases their absorptive power. (3) That benzene and its derivatives invariably show, in addition to abnormally great absorptive power, the peculiarity of absorption bands. After taking into consideration the numerous substances examined, the conclusion seemed inevitable that banded absorption spectra were caused by the double linking of three pairs of carbon atoms in a compactly closed chain, and in the present paper the author has studied the effects of various atomic groupings on the absorption of ultra-violet rays. The first question was whether substances with two doubly-linked adjacent carbon atoms exhibit any peculiarities in their absorption spectra. To decide this point ethylene, amylene, and allyl alcohol were selected for examination, but in neither case were any absorption bands seen. To ascertain the effect of the treble linking of two carbon atoms the spectra of acetylene and valerylene were examined, but no absorption bands were noticed. In all cases, therefore, where the carbon atoms are arranged in an open chain no absorption bands are seen. In no carbon compound has any arrangement of the hydrogen or oxygen atoms been identified with the presence of absorption bands. With hydrocarbons containing at least six atoms of carbon and their derivatives there are three possible arrangements which admit of the carbon atoms forming a closed chain. (1) Three pairs of carbon atoms may be doubly linked as is assumed to be the case in benzene. (2) Two pairs may be doubly linked. (3) The six atoms may be singly linked. There are reasons for believing that oil of turpentine and terpene have two pairs of carbon atoms doubly linked, and that a closed chain including these two pairs of atoms forms the nucleus of such substances. These bodies exhibit no absorption bands, so the author concludes that a closed chain of carbon atoms in which only two pairs are doubly linked exhibits no absorption bands. Now, the constitutional formula of camphor is probably founded on a closed chain of carbon atoms; it is found to be very diactinic, more diactinic than the terpenes, so that probably its atoms are not so compactly united; this is consistent with a singly linked closed chain of carbon atoms. Camphoric acid similarly shows no absorption bands. The author, therefore, concludes that no molecular arrangement of carbon atoms causes selective absorption, unless three pairs are doubly linked together in a closed chain. The author next considers the absorption spectra of condensed benzene nuclei; it was expected from the generally accepted views as to the constitution of naphthalene and anthracene, that these substances would give a larger number of absorption bands than benzene, and that the bands would be of greater intensity, *i.e.*, they would be capable of withstanding a great degree of dilution before they disappeared. The results obtained are rather remarkable. Thus a solution of naphthalene containing 1 in 60,000 shows four strongly marked bands. Phenanthene contains the carbons of three benzene rings, disposed as follows:—

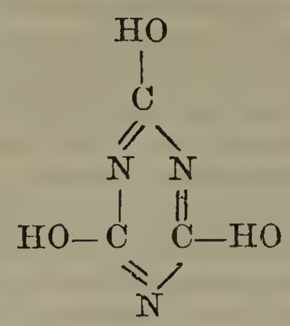


And it shows three strong absorption bands in a solution containing 1 in 4000. Anthracene, which may be considered to have a structure—



was also examined, it was dissolved in glacial acetic acid, it has a considerable absorption when the dilution is carried as far as 1 in 50 millions. Pyrridin gives an absorption spectrum. Hydrocyanic acid is very diactinic.

Cyanuric acid is not, and the author concludes that it has the formula—



Many of the photographs of the spectra were exhibited.

The President congratulated Professor Hartley on his interesting results. Such work was of the greatest importance. The question as to the connection between structure and physical properties would probably form one of the most interesting chapters in the chemistry of the coming time.

Mr. Groves asked if Professor Hartley had investigated the effect of substitution in the side chains.

Professor Emerson Reynold asked if the absorption spectra were sufficiently definite to identify the various substances. The work seemed to him to be most important; it gave some air of reality to the three links and two links of which chemists now speak so frequently.

Dr. Japp suggested the investigation of the class of trimolecular nitriles, so as to have compounds with a closed chain, like the benzene ring.

Professor Hartley, in reply, said that if the substances were pure, it was perfectly easy to identify them, and the quantity of some substances, even in mixtures, could be roughly estimated.

On a Simple Method of Determining Vapour Densities in the Barometer Vacuum By C. A. Bell and F. L. Teed.—Notwithstanding the simplicity of the apparatus recently proposed by Meyer, many cases remain, *e.g.*, those of easily decomposable substances of high boiling point, etc., in which the older method of Hofmann would be preferable. Moreover, most liquids volatilize in a vacuum at 100°, and this temperature can easily be maintained for any length of time. The authors have introduced two new devices: (1) By varying the external pressure or otherwise, the vapour is made to occupy a known volume; and (2), its pressure is directly determined by a single observation, which is independent of the atmospheric pressure. Thus the calculations are enormously simplified, and errors of observation are avoided. The simplest form of the apparatus consists of a glass cylinder, 34 centimetres long and 3·3 centimetres internal diameter, closed at its upper end; to its lower end is fused a stout glass tube, 8 millimetres internal diameter and 83 centimetres long; 5 centimetres below the junction with the cylinder a glass tube is fused in so as to form a T, which is bent up so as to lie parallel with the cylinder, and is sealed off a little below the upper end of the cylinder. The lower end of the long glass tube is closed by an indiarubber cork, through which passes a glass stopcock. The whole of the upper part of the apparatus is surrounded by a steam jacket. A fine line is etched on the glass tube about 1 centimetre below its junction with the cylinder, and from a point on exactly the same level, the side tube, which serves as a barometer, is graduated upwards in millimetres. The apparatus is filled with mercury, and after various precautions, the liquid introduced in a thin glass bulb, converted into vapour, and the pressure in the barometer tube observed at which the vapour depresses the mercury to the mark etched on the tube. The volume of the cylinder being known, the calculation is extremely simple.

Mr. Kingzett communicated verbally some results on—

The Oxidation of Phosphorus in Moist Air.—He had proved that under these circumstances both ozone and peroxide of hydrogen were formed. Details are promised in a future paper.

The Society then adjourned to June 17, when a ballot for the election of Fellows will be held, and the following papers read:—1. "On Penthathionic Acid," by T. Takamatsu and Watson Smith; 2. "On a Crystal of Diamond," by Harry Baker; 3. "Some Orcinol Derivatives," by J. Stenhouse and C. E. Groves; 4. "On the Determination of Carbon in Soils," by R. Warington and W. A. Peake; 5. "Note on Camphydrene," by H. E. Armstrong; 6. "On the Action of Nitric Acid on Diparatolylguanidine," by A. G. Perkin.

Parliamentary and Law Proceedings.

Prosecution under the Pharmacy Act.—Pharmaceutical Society of Great Britain *v.* Hartley.

This action, which was brought for the recovery of a penalty of £5, incurred by the defendant "in selling or keeping open shop for the retailing, dispensing or compounding poisons or a poison, contrary to the provisions of the Pharmacy Act, 1868," was tried on June 3, at the Sheffield County Court, before T. Ellison, Esq., the judge.

Mr. Granger appeared for the Society; the defendant, who resides at Neepsend Lane, Sheffield, did not appear.

Proof having been given that the summons had come to defendant's knowledge,

Mrs. Jane Brown proved that on April 28 last she purchased at defendant's shop a pennyworth of "red precipitate," and,

Mr. Ward having proved that he had tested the purchase made of defendant, and found it to be red precipitate,

The Judge gave a verdict for the plaintiffs for the amount of the penalty and costs.

Death from an Overdose of Laudanum.

On Wednesday June 3, an inquest was held at the Fleece Hotel, Thirsk, concerning the death of Harriet Clarkson, a domestic servant, sixteen years of age, who had been found dead in her bed that morning at the house of Mr. R. Jaques, postmaster, at Thirsk. The girl had been subject to toothache, and on Tuesday night had obtained at a chemist's shop in Thirsk a 3-ounce bottle of laudanum.

The Coroner (J. S. Walton) strongly condemned the law as it now stands as regards the supplying indiscriminately laudanum in any quantity, and to those who choose to buy it, and he thought that at least the parties to whom it was sold ought to be personally acquainted with those to whom they were supplying it, for in this case the young man who supplied it to the deceased did not know her.

The jury returned a verdict of "Found dead, and that deceased had died from an excessive dose of laudanum."

Poisoning by Laudanum.

An inquest has been held at Hoyland Nether, touching the death of Jane Evans, aged 2½ years, the daughter of a miner residing at High Royd, near Hoyland, who died from having laudanum instead of paregoric administered to it by mistake. The child was suffering from a cold, and the mother purchased twopennyworth of paregoric at the shop of Mr. Willey, at Hoyland. She administered three doses to the child, which became affected by it, and died on Tuesday. Dr. Ritchie found that laudanum, instead of paregoric, had been administered. The jury, after hearing the evidence, returned the following verdict:—"Inadvertently poisoned by laudanum, sold by Joshua Willey, druggist, for paregoric."

THE SALE OF PAREGORIC DEVOID OF OPIUM.

At Sheffield, on Tuesday, before T. W. Rodgers, Esq. (in the chair), and S. Roberts, Esq., John Skelton, a herbalist, carrying on business at 144, Gleadless Road, Heeley, was charged, on a summons, with selling 4 ounces of paregoric not of the nature, substance and quality of the drug demanded by the purchaser, Mr. P. O'Connell, one of the inspectors of nuisances for the borough.

The Town Clerk (Mr. Yeomans) appeared in support of the summons, and Mr. H. Auty represented the defendant.

The purchase of the article was admitted, and therefore only Mr. S. H. Allen (the borough analyst) was called. He produced his certificate of the analysis, which stated that the article submitted to him was deficient of alcohol and was coloured with cochineal and wholly destitute of opium, which is the most important ingredient of paregoric. The object of selling it without opium, added Mr. Allen, was, without doubt, to avoid the Pharmacy Act. Paregoric was, in the common acceptation of the term, a drug, and was composed of the oil of anise, benzoic acid, camphor, spirit and opium.

Mr. Auty, for the defence, said the article sold to Mr. O'Connell was what was known as balsam of aniseed and was given to him in mistake.

The Bench, in giving judgment, said that in their opinion this was a very bad case. The defendant did not profess to sell drugs and he was not authorized to sell drugs, but when a person applied to him for paregoric he gave him what was not paregoric, but a compound entirely destitute of the principal ingredient of that drug, and so contrived as to deceive the purchaser. The sale was a wilful violation of the law, for something which was not a drug was sold for a drug. The sentence of the court was that the defendant should pay a fine of £5 and costs, the alternative being a month's hard labour. The defendant was allowed a fortnight in which to pay the money.—*Sheffield Daily Telegraph.*

Dispensing Memoranda.

Replies.

[409]. I think in this prescription the quantity of phosphoric acid ordered is insufficient to dissolve the quinine. I should dispense this by rubbing the quinine to a fine powder, putting it into an 8-oz. bottle with the phosphoric acid, phosphate of soda, and tincture of colchicum; and then filling with aqua, labelling "The mixture to be shaken." Its appearance then made is a colourless mixture, with a white powder which is readily diffusible on being shaken.

GRIFFITH ROBERTS.

[411]. This mixture should have a diffusible precipitate of finely powdered quinine sulphate. It would, in my opinion, be very wrong to add acid.

GRIFFITH ROBERTS.

[657]. LIQ. AMMON. ACET. CONC. 1 to 7:—
℞ Ammon. Carb. . . . . ʒiv.
Acid. Acetic. Fort. . . . . ʒxx.
Solve.

This solution should be neutral. Test in the usual way, and if too acid, add a little more ammon. carb.; if too alkaline, a little more acid.

PAGE D. WOODCOCK.

[657]. The formula for liq. ammon. acet. conc., 1 to 7, is prepared thus:—

Saturate acid. acet. sp. gr. 1·038, ½ gallon, with pulv. ammon. carb. 2½ lbs. or q. s., carefully avoiding excess.

ʒj added to ʒvii of water form liq. ammon. acet. (P. L.)

Patrington, Yorks. TWADDELL.

[658]. COMPOUND TINCTURE OF MYRRH.—I think there is no formula for the above, under tr. myrrh, in any text-book, but it is a thing frequently asked for and much used in veterinary practice. Tinctura myrrhæ et aloes is intended, sometimes called "Black Tincture," the formula for which is—

Aloes	3
Myrrh	$1\frac{1}{2}$
Spirit	40
Water	20

Methylated sp. is commonly used by "vets" themselves.

T. S. MINETT.

[658]. In answer to F. W. Wood concerning compound tincture of myrrh, I infer he means that used in veterinary practice. I send formula from 'Morton's Veterinary Pharmacy':—

Take of—

Spiked Aloes in Coarse Powder	1 pound.
Gum Myrrh in Coarse Powder	$\frac{1}{2}$ pound.
Rectified Spirit	1 gallon.
Water	$\frac{1}{2}$ gallon.

Digest for fourteen days, frequently shaking, then filter.

Patrington, Yorks. TWADDELL.

[658].

℞ Myrrh.,	
Aloes BB.	āā ℥j.
S. V. R.	℥xv.
Aq.	℥x.

Powder myrrh and aloes coarsely, and put to the spirit for three or four days, frequently shaking, then add aq., shake as before for three or four days longer and filter.

PAGE D. WOODCOCK.

[658]. In reply to F. W. Wood, I beg to append a formula for tinct. myrrh. co.:—

℞ Gum Myrrh	℥j.
Aloes Barb.	℥ij., ʒvj.
Cake Saffron	ʒvj.
Proof Spirit	$\frac{1}{2}$ gallon.

This may be made by macerating the saffron in boiling water q. s. for twelve hours, and then prepare by percolation or by macerating the whole for seven days. The first is the plan by which I have always made it.

W. S.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

PHARMACEUTICAL EDUCATION AND PHARMACEUTICAL EXAMINATION.

Sir,—At the meeting of Council last week, I stated, during the discussion on the motion for "an inquiry into the relation to each other of pharmaceutical education and the pharmaceutical examinations," that the Scotch Board of Examiners had recently passed a resolution to the effect that "they were not altogether satisfied with the existing condition of things, and that they were inclined to favour certain possible changes if found practicable."

I have just received a communication from the Chairman of that Board telling me that I have been misinformed as to the terms of that resolution.

I beg therefore to withdraw the statement, and to express my regret for having uttered what was not strictly correct.

When, however, the words of the resolution which really was passed come to be published, your readers will be able to judge of the extent to which I inadvertently misrepresented its meaning.

Clifton. G. F. SCHACHT.

MR. HOWARD HALL AND THE ELECTION OF COUNCIL.

Sir,—Mr. Howard Hall has once more buckled on his armour in defence of his London colleagues and in defiance of those country members "who invariably vote on the system of excluding all London candidates."

Mr. Hall, however, is on a false scent, and refuses to see anything pharmaceutical beyond the sound of Bow bells. What all the provincial members of the Pharmaceutical Society desire is "a true and correct representation of the whole national electorate," and not a Council comprised almost exclusively of town members, who have no sympathy with or practical knowledge of the wants of provincial chemists and druggists.

The Council of 1880 consisting of thirteen country and eight town members, is, in my opinion, a fairly representative body. For many years the rulers of the craft were chosen from the ranks of London pharmacists, the result being a reign of sleepy conservatism and neglect of provincial pharmacy, which was yearly leading to most serious consequences to the trade generally. Thanks, however, to the exertions of the Chemists and Druggists' Trade Association, the slumberers in the snug rooms of 17, Bloomsbury Square were rudely awakened to a sense of their neglect. Country members became alive to the importance of a change in the constitution of the Council, and Mr. Hall and his coadjutors should not complain if for some time to come Messrs. Symes, Churchill and Co. keep the question of trade interests more prominently before the Council than did the aristocratic West Enders of the old *régime.* Mr. Symes and the other "pet local nominees" are proving themselves faithful representatives of "the whole country" and deserve our warmest thanks.

Leominster. M. J. ELLWOOD.

Sir,—If Mr. Howard Hall is correctly reported in the Journal of May 22, p. 945, I must be included in the all there stated by him. I have waited in the hope and expectation that a younger and more vigorous pen than mine would have vindicated the Liverpool voters, for from what I know of the Liverpool members, I believe them to have a will of their own and a way of their own, which could not be bound by any single cord however strong.

Mr. Hall's sweeping charge could not have occurred except by concerted action, of which, I think, I should have known something; but the first notice I have of plumping is from the report of your Council proceedings of the above date.

I do not think it needful to go into the manipulation of votes and members as given by the same gentleman in the Journal of June 5, nor do I think even the Liverpool voters need the assistance of such an electioneering agent as Mr. Hall appears to be to convince them that there is necessarily such an amount of detail work, for which we are indebted to the London members of Council in the past, present, and to come, as to induce the country members to record their vote largely for metropolitan men, and then the best selection from the country to which our judgment may lead us. Such has been my object in the past and such I expect it to be so long as I vote. I thank Mr. Mackay for his remarks as to scrutinizing the scrutineers, and hope the Council, if they cannot protect us from such a more than unpleasant position as the present, they will allow us to record our name at foot of voting paper and make it open voting.

Liverpool. R. SUMNER.

WEIGHTS AND MEASURES ACT, 1878.

Sir,—I shall be greatly obliged if you will allow me space to again impress on members of the trade through the medium of your pages the advice you have on so many seasonable opportunities given them as to the desirability of their obtaining, as far as possible, weights and measures conforming to the requirements of this Act of Parliament.

Stamped apothecaries' weights and measures legalized for use throughout the United Kingdom may now be procured through the usual channels for the supply of weights and measures used by chemists, and I cannot too strongly urge all members of the trade to at once provide themselves with these stamped weights and measures, as by so doing they adopt a cheap, and at the same time the most complete, safeguard against annoyance and expense to which they otherwise would be liable in the event of a prosecution being brought against them, for the possession of an unstamped weight or measure renders the owner liable to a penalty of £5, although the weight or measure may be otherwise accurate.

An erroneous impression appears to be gaining ground that weights and measures stamped in one district will not be acknowledged by the authorities residing in other districts. The provisions of the statute are very clear on this point, the 45th section being as follows:—"A weight or measure duly stamped by an inspector under this Act shall be a legal weight or measure throughout the United Kingdom, unless found to be false or unjust, and shall not be liable to be re-stamped because used in any place other than that in which it was originally stamped."

The Board of Trade was empowered by the Act to adopt standards for apothecaries' weights and measures, such standards to be approved by Her Majesty in Council. The standards for these weights and measures were issued to certain metropolitan districts on August 14, 1879. On May 19 last several London chemists were summoned to appear at the Southwark Police Court for having in their possession inaccurate apothecaries' weights, and nominal fines were in each case inflicted. The inspector who prosecuted acknowledged in course of cross-examination that no notice had been given to chemists residing in his district that he had been supplied with standards for apothecaries' weights.

Inspectors appointed under this statute, residing in country districts, will, if not already supplied with these standards, in all probability receive them from the Board of Trade at an early date, when wholesale prosecutions may result if some steps are not taken by chemists themselves, either to obtain new weights and measures duly stamped, or to ascertain when the inspector for their district obtains standards, and forthwith take their old weights and measures to him for verification.

It cannot be too widely known that the Board of Trade has no power to issue instructions to local authorities as to the carrying out of this Act; the appointment of inspectors, and the duty of testing and stamping weights and measures resting with justices and town councils. It would be only courteous treatment to members of the trade for inspectors to give them notice when they receive their standards, and to allow some little time in which apothecaries' weights and measures may be verified before enforcing the penal clauses of the statute.

The chief inspector for the Birmingham district has promised, in response to a representation from the President of this Association, to give such notice to all chemists residing in the district, and to allow two or three months in which their weights and measures may be verified. It is very desirable, and such a course would probably obviate a considerable amount of vexation and expense to the trade, that one or two leading chemists in each district should call upon the inspector appointed for the district, and request him to give a similar undertaking, and failing a satisfactory reply to then proceed to the local authorities, who would doubtless take care that no injustice should be done by precipitate action on the part of the inspector.

W. F. HAYDON,
Secretary to the Chemists and Druggists' Trade Association of Great Britain.

Office of the Association, 23, Burlington Chambers, New Street, Birmingham, June 9, 1880.

"ARTISTS' COLOURS."

Sir,—I attended the meeting held at the Grosvenor Gallery on Tuesday last, when the subject of artists' colours was taken into consideration, and it occurred to me that beyond the great interest necessarily attaching to a subject so important as the relationship of science to art, the matter was worthy of attention by pharmacists, as suggesting a source of legitimate profit in a new field of labour.

I will not attempt to give a detailed account of the meeting, but the complaint of Mr. Holman Hunt and other artists amounted to this:—"That for the last twenty years their colours had been deteriorating in quality; that they did not know the nature or composition of some of the pigments they were using, as they were often sold under deceptive titles, and that even when correctly named, they were frequently so adulterated as to be a source of the greatest inconvenience and injury." In short, the subject generally was considered of so much importance that one speaker proposed that the whole question should be submitted to a committee of chemists for their advice. Whether this will be done or not, I, of course, cannot say, but I hope I shall not be considered intrusive if I suggest to some of our younger members that a new occupation seems here to present itself, which will not only be especially interesting, but lucrative also.

The principal requirements are, not so much new inventions, though undoubtedly there is scope in that direction, but that, firstly, known pigments should be prepared in the utmost possible purity, and secondly, that their composition and the substances with which they are incompatible should be distinctly stated.

34, *Leinster Terrace.* FREDERICK ANDREWS.

CLAY'S CHIAN TURPENTINE EMULSION.

Sir,—Professor Clay having stated that his formula was in successful use at Birmingham, an unqualified statement that it was an impossible one appeared with an air of improbability. That it was not impossible it was the object of my note to point out. Difference of material must, I suppose, account for difference of result; Mr. Martindale's skill is known to be above the reach of criticism.

There was no desire to defend Mr. Clay's formula; it is obviously not of the best, and I certainly never said that the mixture made with tragacanth was superior or equal to that made with gum arabic.

The use of a mortar is justifiable in this case, because the ether forms no part of the remedy; as Professor Clay's paper shows, it was adopted as a means of transforming the pills originally used into a mixture.

I may add that the "principle" of the emulsion referred to was in use here thirty years ago, long before the date of Mr. Martindale's paper.

Lombard Street. CHARLES EVE.

Sir,—I have had considerable experience in respect to the Chian turpentine emulsion, and I can fully corroborate the statement of Mr. Martindale that made according to the published form a satisfactory emulsion cannot be obtained. I have also proved the fallacy, as Mr. Martindale points out, of attempting to make it by adding the ethereal solution of Chian turpentine to the powdered tragacanth. After numberless experiments the following I have found the most successful, though far from perfect.

Into a clean dry 16 ounce bottle put first the pulv. tragac. and moisture with S. V. R. about ʒj; then add the whole of the water necessary for mucil. tragac., B.P.; to the mucilage thus formed add the solution of Chian tereb., and agitate briskly until thoroughly mixed. Next place the sulphur in a mortar and rub to a paste with a little water before adding the syrup, taking care that every lump of sulphur is broken; this is now to be poured into the bottle containing the tereb. Chian and mucilage, and the whole well shaken.

A much better emulsion can, however, be made by dissolving the tereb. Chian in ol. amygd. instead of ether, and rubbing the "oleo-resin" thus artificially made with mucil. tragac. or acaciæ (the latter is better) in a mortar.

I conclude by saying that everyone who appreciates good dispensing will do well to profit by the very valuable and practical suggestions thrown out by Mr. Martindale from time to time through the medium of the Journal.

9, *Bruton Street, Berkeley Square.* J. S. PALMER.

TINCTURE OF SENEGA AS AN EMULSIFYING AGENT.

Sir,—I have shown that mercury shaken with tinct. senegæ is reduced to such an extreme state of subdivision that it has the appearance of a powder resembling hyd. c. creta, and this powdery condition is maintained so long as the senega is present. Now if some chloroform or any fixed or volatile oil be treated in a similar manner it is formed into a cream-like fluid, the particles are entirely separated, and if a sufficient quantity of senega has been used they permanently retain this condition of subdivision. This cream of oil and senega, when mixed with water, upon agitation is at once diffused and after a time the cream separates, forming a layer at the top of the water, easily miscible again by shaking. In the paper which I read at an evening meeting of the Pharmaceutical Society, I gave a number of formulæ for the preparation of various emulsions in which 5 minims of tinct. senegæ were used to render miscible an ordinary dose of oil. Mr. Levy, of Cape Town, who has experimented with these formulæ, finds that it takes twenty-four hours for the separation of the oil. He has obtained very excellent results with his tinct. senegæ; all the emulsions I have prepared separate in a considerably shorter time than this. It is one of the objections which may be urged against tinct. senegæ as an emulsifying agent,—and the same objection applies also to the use of alkalies—that the separation is more rapid than with acacia or tragacanth. All emulsions separate upon standing, the time required for separation depending upon the thickness of the fluid. The milk of animals may be taken as the type of this class of preparations. In this case the fat or butter is diffused through an aqueous liquor, and held in suspension by the presence of caseine, sugar, and alkaline salts. After a time the fatty matter separates as a layer of cream. This is precisely what occurs with emulsions of oil and tinct. senegæ. If sufficient tincture has been used the oil separates as a cream, not as free oil; if an insufficient quantity, as for instance, ℥ss ol. morrhuæ and 5 minims of the tincture, the separation occurs as a layer of cream and oil. This, however, mixes upon agitation very readily.

Mr. Levy makes some remarkable statements regarding the taste and effects of small doses of senega. At Guy's Hospital both the infusion and tincture are largely used. There is a mixture in the Hospital Pharmacopœia containing ʒss of the tincture with ℥ss of the infusion for a dose. Tinct. senegæ is used daily as an emulsifying agent for copaiba, ol. terebinth, and especially ol. morrhuæ; hundreds of prescriptions containing it have been dispensed. I frequently see the prescribers, but I have never heard one word saying that any unpleasant results have followed the use of this tincture; on the contrary, I have frequently been told that it is an excellent thing to make cod liver oil mixtures for children.

It is very remarkable also that Mr. Levy in his seventeen years' experience of pharmacy has not heard of the use of liq. potassæ simply as an emulsifying agent. It was used for this purpose long before he entered into pharmacy. In Mohr and Redwood's 'Practical Pharmacy,' bearing the date 1849, page 342, occurs the following:—"Emulsions are sometimes made with an expressed oil and an alkali. One of the most common emulsions used as a simple remedy for cough is formed by agitating some oil of almonds with solution of potash or spirit of ammonia." "Six drachms of oil of almonds, 1 drachm of solution of potash, and 5 ounces of distilled water, form a good emulsion if mixed in the proper way." Liq. potassæ is used in the preparation of mistura olei, Guy's Hospital Pharmacopœia, as an emulsifying agent. It would be possible for me to give more instances of the use of liq. potassæ for this purpose, but I have no doubt that the above will be sufficient to show that this agent is employed for the preparation of emulsions.

I desire by no means that acacia should be discarded, as Mr. Levy appears to think, for senega. Acacia is one of the most valuable emulsifying agents we have; it is not, however, perfect. Mucilage of acacia is apt to become sour and lose its emulsive property to a great degree. Emulsions made with it are generally thick, and in this condition they are very repulsive to some patients.

Guy's Hospital. HENRY COLLIER.

THE SEASON.

Sir,—My experience does not at all coincide with that of your correspondent, Mr. T. Romans, whose letter appeared in your last week's issue. On referring to my diary I find that I gathered a specimen of *Convallaria majalis* in full bloom on May 18. So far as the immediate neighbourhood of this town (Blandford) is concerned, I can thoroughly endorse the statement made in your excellent article, 'The Month,' "that flowers are *fully* a fortnight in advance of last year,"—and not only are they earlier, but they are far more abundant. Last year, the whole energy of the plant seemed to be devoted to the production of leaves; flowers were few, and perfected fruits and seeds were fewer still. In my short walks in this locality in the course of last month I noticed, amongst others, the following plants in full bloom much earlier than last year:—

Cruciferæ:—*Lepidium campestre*; Cistaceæ:—*Helianthemum vulgare*; Polygalaceæ:—*Polygala vulgaris*; Caryophyllaceæ:—*Lychnis vespertina, Silene inflata, Stellaria graminea*; Celastraceæ:—*Euonymus Europœus*; Leguminosæ:—*Lotus corniculatus, Onobrychis sativa, Vicia sativa, Lathyrus pratensis, Trifolium incarnatum, Trifolium minus*; Rosaceæ:—*Geum urbanum, Potentilla anserina, Tormentilla officinalis, Rubus fruticosus, Rosa canina*; Cucurbitaceæ:—*Bryonia dioica*; Saxifragaceæ:—*Saxifraga umbrosa*; Umbelliferæ:—*Sanicula Europœa*; Caprifoliaceæ:—*Lonicera caprifolium, Viburnum opulus, Sambucus nigra*; Rubiaceæ:—*Galium Aparine, Asperula odorata*; Compositæ:—*Chrysanthemum leucanthemum, Carduus nutans, Leontodon hispidum, Picris hieracioides, Tragopogon minor*; Aquifoliaceæ:—*Ilex aquifolium*; Convolvulaceæ:—*Convolvulus arvensis*; Scrophulariaceæ:—*Rhinanthus Crista-galli*; Labiatæ:—*Stachys sylvatica*; Boraginaceæ:—*Myosotis palustris, Borago officinalis*; Dioscoreaceæ:—*Tamus communis*; Orchidaceæ:—*Listera ovata, Habenaria bifolia, Cephalanthera grandiflora, Orchis maculata.*

Blandford. M. MITCHELL BIRD.

Sir,—A correspondent in your last issue bases his surprise at your opinion as to the comparatively earlier advent of spring flowers this year upon one case which he cites, that of *Convallaria majalis*, without, however, giving the date on which he found it last year. The proverb about the one swallow which does not make a summer may apply. One stumbles occasionally upon an unusually early specimen, and mere accident may cause us to overlook others which will seem late. It is safer to take a larger number of perhaps more ordinary specimens for forming a general conclusion, and these I feel sure will fully substantiate your opinion. I append a few chosen at random from my calendar for May only, to which month your notes referred.

CONTRIBUTION TO THE CHEMISTRY OF NIGELLA SATIVA.

BY HENRY G. GREENISH.

(*Concluded from page* 913.)

IV. Extraction with Solution of Soda.—The residue of the seeds, after treatment with alcohol, was macerated with a 1 per cent. solution of soda for twenty-four hours. The liquid at the end of that time being only very slightly alkaline, it was made distinctly so with solution of soda, and the maceration continued for a few hours. The filtered liquid was then acidulated with sulphuric acid, which caused the precipitation of very dark grey flocks. These flocks collected, washed, dried and powdered, formed a dull black powder, which on burning with soda-lime yielded ammonia corresponding to 15·08 per cent. nitrogen (calculated on dry substance free from ash). This substance may therefore be regarded as impure albuminous matter.

The acid filtrate, on being tested with alkaloid reagents, was found to give a precipitate with most of them. To isolate the alkaloid, the presence of which was thus indicated, an attempt was made to remove it from solution by shaking it with petroleum ether, benzine, ether, chloroform, bisulphide of carbon and acetic ether, but neither from acid nor alkaline solution could more than traces be removed. Recourse was then had to precipitation with potassio-mercuric iodide, and for this experiment 800 grams of the seeds, freed from oil by petroleum ether, were macerated with water acidulated with sulphuric acid. After removal of mucilaginous substances by alcohol and recovery of the alcohol by distillation, the filtrate, evaporated to a small bulk, was precipitated with potassio-mercuric iodide, the precipitate filtered off, washed, suspended in water, decomposed with sulphuretted hydrogen, and the filtrate from the sulphide of mercury, after removal of excess of sulphuretted hydrogen by warming, freed from iodine by precipitation with sulphate of silver. Excess of silver having been removed from the filtrate as sulphide, hydrate of barium was added to remove sulphuric acid and liberate the base. The filtrate from the sulphate of barium freed from excess of barium hydrate by CO_2 was evaporated to dryness. Boiled with absolute alcohol this residue gave up to that solvent but a small quantity, which still contained traces of barium, and the aqueous solution of which possessed an alkaline reaction. The insoluble residue was dissolved in water, freed from barium, which it still contained, by sulphuric acid, and the filtrate precipitated with alcohol. The substance so precipitated was identical with the albuminous substance previously isolated (*II.* (*d*)). It contained nitrogen, dissolved easily in water with a strong acid reaction, and precipitated by addition of alcohol, the so purified substance yielding reactions similar to those of the albumens. So far is it from being an alkaloid that it forms with barium an easily soluble compound from which CO_2 fails to precipitate that base.

The amount of melanthin which I had had at my disposal having been only a few grams, it was considered desirable to obtain, if possible, a further quantity. Accordingly 2 kilograms of crushed seeds (which in this case were obtained from plants cultivated in Germany) were percolated to exhaustion with petroleum ether. The petroleum ether solution showed a magnificent blue fluorescence, which in the petroleum ether extract from Russian seeds could not be distinctly observed. After the recovery of the petroleum ether the residue was heated on the water-bath to expel the last traces of that menstruum, as well as the volatile oil. The fixed oil thus obtained still retained the blue fluorescence, which became much more evident on dilution with petroleum ether. The fluorescent substance is therefore not, or at least not wholly, volatile on the water-bath. It differs from the pœoniofluorescin isolated by Dragendorff and Stahre from peony seeds in its solubility in petroleum ether. Unfortunately a further quantity of these German seeds could not be obtained, so that the preparation of the volatile oil and its comparison with that prepared and examined by Flückiger was necessarily postponed. Worthy of note is the fact that the formula which I have found for melanthigenin, $C_{14}H_{20}O_2$, calculated to C_{20}, gives almost exactly $C_{20}H_{34}O_3$, differing in only two atoms of oxygen from $C_{20}H_{34}O$, found by Flückiger to constitute the greater portion of the volatile oil. Possibly by the ripening of the seeds melanthin decomposes into sugar and melanthigenin, which latter by reduction yields part, at least, of the volatile oil.

Examination of the Solid Fat.

The three several portions of fixed oil obtained deposited, on standing, solid fat. This was filtered (the three portions being united), allowed to drain, and saponified with solution of soda. The soap, after salting out, was decomposed with hydrochloric acid, the fat acids washed repeatedly with warm water and finally dissolved in warm absolute alcohol. From this alcoholic solution there separated, on cooling, white crystalline mammilar masses. The filtrate from these crystals was subjected to a fractional precipitation with alcoholic solution of acetate of magnesia in the presence of ammonia. The precipitates were washed with alcohol, and dried by pressing between filter paper. They were then decomposed by hydrochloric acid, and the fat acids so liberated washed repeatedly with warm water.

The fat acids from the first precipitate contained a large quantity of a fluid fat acid, probably oleic acid, and were not further examined.

The acids from the second precipitate were dissolved in warm 95 per cent. alcohol. The solution, on standing, deposited crystals which, filtered off, washed and dried, melted at 47°–50°.

The filtrate on standing deposited a second crop melting at 53·5°. The filtrate from this crop deposited at 0° a third crop melting at 54·5°–55°. The filtrate from this third deposit at $-10°$ a fourth crop melting at 57°.

The acids from the third precipitate were recrystallized repeatedly from 95 per cent. alcohol. The following were the melting points of each crystallization:—

i.	The crude fat acids	52·5°—53°
ii.	First crystallization	54·5°—55°
iii.	Second crystallization . . .	55·5°
iv.	Crystals from the mother liquor.	55·5°
v.	Third crystallization	55°—55·5°

On crystallizing for the second time a small quantity of a fluid oil, difficultly soluble in alcohol, was separated, probably causing the slight rise in the melting point.

From the last crystallization sufficient fat acid was obtained to allow of a combustion being made which gave the following results:—

0·2462 gram fat acid free from ash yielded 0·2857 gram H_2O and 0·666 gram CO_2

$C=73·77$
$H=12·88$

There can be no doubt that the fat acid examined was myristic acid, which possesses the composition

$C=73·69$
$H=12·28$

and which, according to Heintz, melts at 53·8°. It crystallized from alcohol in pure white mammilar masses consisting of tufts of feathery crystals. The presence of this acid in nigella seeds has already been conjectured by Professor Flückiger. The small quantity of fat acid melting at 57°, isolated from the second precipitate, I take to be a mixture of myristic with probably palmitic or stearic acid.

The succeeding precipitates yielded similar results, but in each case, especially in the fifth and sixth, the solid fat acid was mixed with a relatively large quantity of the fluid oil mentioned in the description of the third precipitate. The melting points of the crude fat acids in 4 and 5 were respectively 47° and 48° C.

The white solid substance which had crystallized from the alcoholic solutions of the fat acids was filtered off, washed, and proved on examination to be partly easily soluble in boiling 95 per cent. alcohol, partly difficultly soluble. The part easily soluble in alcohol was undecomposed soda soap, and yielded, after decomposition with hydrochloric and repeated recrystallization of the fat acids, a small quantity of an acid melting at 71° C., which may be regarded as stearic acid, although I had not sufficient at my disposal to render a combustion possible.

The part difficultly soluble in alcohol proved to be a calcium soap produced by the decomposition of the soda soap with calcium chloride present in the common salt used in the separation of the soda soap. This insoluble lime compound yielded a tolerably large quantity of a pure white fat acid, melting at 55°–55·5° C.

The mean of three analyses showed the composition of the recrystallized acid dried at 100° C., to be

$C=70·7$
$H=12·4$

The formula $2(C_{14}H_{28}O_2)H_2O$, requires

$C=70·88$
$H=12·23$

There can be no doubt then that this is a further quantity of myristic acid. That it still contains water may be explained by the fact that it was only once recrystallized from alcohol. In an attempt to estimate the amount of moisture present in the acid it was found to undergo volatilization and partial decomposition at a temperature of 110° C.

The fatty acid in the solid fat of nigella seeds consists therefore of myristic, with traces of stearic and (?) palmitic acids.

Quantitative Analysis.—The seeds employed were the Russian seeds previously examined, carefully freed from impurities by picking.

I. Determination of Moisture and Ash.—0·6472 gram of the powdered seeds lost by drying at 110° C. 0·0590 per cent. moisture and essential oil, = 9·11 per cent. The residue incinerated yielded 0·0265 gram ash = 4·08 per cent.; 0·5740 gram yielded moisture and essential oil 9·04 per cent., ash 4·21 per cent. Mean of the two estimations:—

Moisture and Volatile Oil = 9·07 per cent.
Ash . . . . = 4·14 „

The ash, treated with water, did not impart to that solvent an alkaline reaction (absence of more than traces of alkali metals). It dissolved almost entirely in dilute nitric acid without effervescence (absence of carbonates), and the solution proved to contain traces of sulphates and chlorides with much phosphate of calcium. The ash consisted, therefore, principally of phosphate of calcium.

II. Volatile and Fixed Oils.—The method adopted for the determination of the volatile oil was that described by Osse.* Although this method carefully performed may be taken as the best at our disposal, it must be admitted that, considering the difficulties which stand in the way of an absolutely correct determination of volatile oils, the results here given must be received as approximate rather than exact. The determination was made as follows:—

5 grams of the seeds, reduced to as fine a powder as possible in an agate mortar with 10 grams of powdered glass, were transferred to a glass stoppered cylinder and 42·5 c.c. petroleum ether added; the whole occupying a bulk of 50 c.c. The petroleum ether used was obtained from the ordinary petroleum ether by distillation in a water-bath, the first portion only being used. The seeds were macerated seven days with frequent shaking.

A watch glass capable of containing about 5 c.c. was enclosed between two large closely-fitting clamp glasses, and the whole tared. The clear petroleum ether solution was measured into the watch glass with a pipette, and allowed to evaporate at the ordinary temperature in a current of dry air. Before the whole of the petroleum ether had been removed, the watch glass was enclosed between the clamp glasses and weighed; it was then exposed to the current of air for periods of thirty seconds, being weighed immediately after the expiration of each such period. As soon as two successive weighings showed the same loss, the watch glass with the oil was heated for half an hour to 100° C., cooled and weighed. The loss in weight, *plus* the difference between the two previous weighings, gives the amount of essential oil. A further exposure of half an hour to a heat of 100° failed to produce increase or decrease in weight:—

		P.C.	Per cent.
1 c.c. yielded volatile oil	0·0018	= 1·53	Mean 1·64.
2 c.c. „ „ „	0·0040	= 1·70	
5 c.c. „ „ „	0·0107	= 1·81	

The remainder of the petroleum ether solution was filtered off, the residue of the seeds washed, dried, again powdered and extracted with petroleum ether to ensure, as far as possible, the removal of the fatty oil. The petroleum ether filtrates were evaporated to dryness and weighed. To this was added the weights of residues in the three foregoing estimations. The whole amounted to 0·8223 gram = 36·44 per cent.

The residue of the seeds dried at 40° C., was macerated with absolute ether. This solvent removed 0·0281 gram = 0·56 per cent., apparently the last traces of fatty oil. Total quantity of fixed oil 37·00 per cent.

The residue after treatment with ether, was dried at 40° C. and macerated with benzin, which, however, removed only 0·0120 gram = 0·24 per cent.

III. Treatment with Ether, Alcohol and Water.—1 gram of the powdered seeds was macerated with

* *Archiv der Pharmacie*, 3te R., vii., 104.

pure ether (50 c.c.) seven days, filtered and washed. The ethereal solution, evaporated to dryness, left a residue consisting of a thick, yellowish-brown oil, weighing 0·3810 = 38 10 per cent.

The dried residue of the seeds was treated similarly with absolute alcohol. The alcoholic solution evaporated to dryness left a residue weighing 0·0545 gram = 5·45 per cent. This residue, treated successively with ether (to remove traces of oil) and water, was found to be almost entirely soluble in those liquids.

The dried residue of the seeds was macerated for two days with 100 c.c distilled water and filtered. 25 c.c. of the filtrate, evaporated to dryness, left a residue weighing 0·0283 = 11·32 per cent.

IV. Treatment with Alcohol and Ether.—2 grams of the powdered seeds were macerated for seven days with 100 c.c. absolute alcohol, filtered, washed, and the alcoholic solution evaporated to dryness. The residue weighed 0·8678 = 43·39 per cent. The residue was only partially redissolved by alcohol, having apparently undergone some change during the evaporation and drying. This was accomplished first at 100° C., towards the end at 110° C., and required considerable time for its completion.

The dried residue of the seeds was treated with ether. The ethereal solution, evaporated to dryness, left a residue weighing 0·0027 = 0·13 per cent.—traces of fatty oil. The total amount extracted by alcohol and ether (43·52 per cent.) shows a satisfactory agreement with the amount extracted by ether and alcohol in experiment III., viz., 43·55 per cent.

V. (a). Treatment with Water.—To facilitate the action of the water, 5 grams of the powdered seeds were exhausted of oil by petroleum ether. The residue collected on a tared filter, washed, dried and weighed, was found to have lost 2·324 grams = 46·48 per cent., fixed and volatile oils and mixture.

The residue was macerated with 95 c.c. distilled water at the ordinary temperature for forty-eight hours, and filtered. Of the filtrate 5 c.c. evaporated to dryness at 110° C., left a residue weighing 0·0390 gram, and containing ash 0·0047. Combustible substances soluble in water 13·03 per cent.

15 c.c. were acidulated with acetic acid, a small quantity of chloride of sodium added, and the whole boiled for five minutes. The coagulated albuminous matters were filtered off, washed with dilute spirit, filtrate and washings concentrated to a small bulk, and three volumes absolute alcohol added. The precipitate which had formed after the lapse of twelve hours was collected on a tared filter, washed with alcohol, dried and weighed. It weighed 0·0195 and contained ash 0·0045. Mucilaginous substances free from ash 0·0150 = 1·90 per cent.

The filtrate and washings were collected and evaporated to a small bulk (to remove alcohol), carefully neutralized with a weak solution of soda and acetate of copper solution added in slight excess; the resulting precipitate, which was small in quantity and of a whitish colour (absence of tannin), was collected on a tared filter, quickly washed with a small quantity of water, dried and weighed. It weighed 0·0045, and on incineration left ash (oxide of copper) 0·0015. Organic acids precipitated by acetate of copper = 0·0030 = 0 38 per cent.

To the filtrate from the copper precipitate, neutral acetate of lead solution was added in slight excess, and the precipitate, after standing three hours, was collected, washed, dried and weighed; it weighed 0·0070, and contained oxide of lead 0·0023. Organic acids precipitated by acetate of lead = 0·0047 = 0·59 per cent.

The filtrate from the lead precipitate was freed from lead and copper by a stream of sulphuretted hydrogen; the filtrate from the deposited sulphides was concentrated on the water-bath, and boiled with an excess of Fehling's solution. The resulting suboxide of copper was rapidly collected, washed with boiling water, dried, incinerated, the ash moistened with nitric acid and again incinerated and weighed; it weighed 0·0480, equivalent to 0·02175 gram grape sugar = 2·79 per cent.

10 cubic centimetres of the aqueous filtrate were mixed with 30 c.c. absolute alcohol, and the precipitate of albuminous and mucilaginous substances, which had formed after twenty-four hours' standing, was collected, washed and dried; it weighed 0·0255 and contained ash = 0·0045. Mucilaginous and albuminous substances (insoluble in 75 per cent. alcohol) = 0·0214 = 4·06 per cent.

Deducting from this the mucilaginous substances previously estimated, 1·90 per cent., there remains for albuminous matter 2·16 per cent.

The filtrate and washings from this precipitate were evaporated to dryness in a tared glass dish. The residue weighed 0·0513 gram = 9·74 per cent. This residue was then treated with absolute alcohol; the insoluble matter was collected, washed and dried; it weighed 0·0202, and contained ash 0·0033. Substances not precipitated by 75 per cent. alcohol, but insoluble in absolute alcohol = 0·0169 = 3·21 per cent. Part at least of this precipitate consists of the acid albuminous substance mentioned in the first part of this paper, part probably is the substance known as arabic acid.

The filtrate and wash alcohol were evaporated to dryness in a platinum dish, and the residue weighed. It weighed 0·0312 and contained ash = 0·0022. Substances soluble in alcohol = 0·0290 = 5·51 per cent. Of this sugar forms 2·75 per cent., the organic acids precipitated by acetate of copper and lead 0·97 per cent., together 3·72 per cent., leaving 1·79 per cent. substances soluble in water and in alcohol not further identified.

The estimation of nitrogen in the aqueous extract showed the presence of 0·08857 per cent. corresponding to 5·58 per cent albuminoid matter. Of this 2·16 per cent. have been already accounted for, the remaining 3·42 per cent. may be sought for partly in the substances not precipitated by 75 per cent. spirit, but insoluble in absolute alcohol (3·42 per cent.), partly, probably, also in the unidentified substances (1·79 per cent.).

The residue of the seeds after extraction with water was washed with water containing 0·2 per cent. salicylic acid. This addition was found necessary to retard the development of bacteria, which otherwise quickly make their appearance and thrive rapidly, though the washing be conducted in the ice-cellar. The residue was dried and weighed. The loss in weight was 1·0115 gram = 20·23 per cent., or 5·41 per cent. in excess of the substances dissolved by water. This 5·41 per cent. must be reckoned an albuminous matter, the presence of which in the filtrate was proved. The slowness with which the liquid filtered, and the final blocking of the filter rendered the complete removal of these albuminous substances by water impossible. They were subsequently dissolved accompanied by other matters, by treatment with dilute solution of soda.

VI. Treatment with Alcohol.—The residue of the seeds was now macerated with 100 c.c. absolute alcohol for six days, then filtered off, washed, washings and filtrate evaporated to dryness. The residue weighed 0·0971 = 1·94 per cent. and consisted of a resinous substance (melanthin) and traces of fixed oil. Freed from the latter by treatment with petroleum ether the residual melanthin weighed 0·0705 = 1·41 per cent.

VII. Treatment with Solution of Soda.—The residue of the seeds, after treatment with alcohol, was dried, macerated twenty-four hours with 100 c.c., 0·5 per cent. solution of soda and filtered. 50 c.c. were acidulated with acetic acid, the precipitate collected, washed and dried, weighed 0·0550, and contained ash 0·0014. Albuminous substances dissolved by soda reprecipitated on the addition of an acid 0·0536 = 2·14 per cent.

25 c.c. of the filtrate from albumen precipitate were mixed with 75 c.c. 95 per cent. alcohol and the precipitate, after twenty-four hours, collected, washed, dried and weighed. It weighed 0·0205 and contained ash 0·0034. Metarabic acid = 0·0171 = 1·36 per cent.

The residue of the seeds was collected, washed with water, dried, and weighed. The loss in weight incurred by treatment with soda was found to be 0·4249 = 8·88 per cent. Deducting albuminous substances 2·14 per cent. and metarabic acid 1·36 per cent., there remains as substances not further identified 5·38 per cent.

The nitrogen present in the residue of the seeds after extraction with solution of soda amounted to 5·62 per cent. = albuminoids 35·40; or calculated on the original seeds 12·19 per cent., showing a total loss of 15·21 per cent. (see *XI.*,) of which 5·58 per cent. were present in the aqueous extract, and 5·41 per cent. in the wash water, leaving a residue of 4·22 per cent. dissolved by soda. Of these 4·22 per cent. 2·16 per cent. have been accounted for; the remaining 2·06 per cent. are probably to be referred to albuminous substances soluble in water, not removed by treatment with solvent and accounted for here under the 5·38 per cent. unidentified substances.

VIII. Treatment with Sulphuric Acid.—The residue of the seeds (after washing and drying) was macerated with sulphuric acid (1 vol. diluted with 4 vols. water) for forty-eight hours. The filtrate, which was almost colourless, contained no oxalate of calcium, and on dilution with alcohol gave but a very trifling precipitate. No further notice was taken of this solution.

IX. Treatment with Chlorine Water.—After removal of the sulphuric acid by washing with water the residue was treated with 500 c.c. chlorine water (containing 0·538 per cent. chlorine), and after forty-eight hours standing, collected, washed first with water, then with very dilute (0·3 per cent.) solution of potash, finally with alcohol, dried and weighed. The loss in weight by treatment with sulphuric acid and chlorine water amounted to 0·1925 = 3·85 per cent.

The substances already removed from the seeds amount in all to 82·05 per cent., leaving a deficit of 17·95 per cent. not yet accounted for.

X. Estimation of Cellulose.—1·5595 gram of the powdered seeds were freed from oil by treatment with ether, and then mixed with 50 c.c. nitric acid (1·16 sp. gr.) and 1 gram chlorate of potash; the mixture was gently warmed to set up the action and then allowed to stand two days. After dilution with water the resulting cellulose was collected on a tared filter, washed first with water, then with weak ammonia, finally with alcohol. It weighed when dry 0 1330, and contained ash 0·0032. Cellulose = 0·1298 = 8·32 per cent.

Deducting the cellulose, 8·32 per cent., from the substances not yet accounted for, there remain 9·63 per cent. substances removed by the digestion with nitric acid and chlorate of potash, or deducting ash 2·11 per cent., 7·52 per cent.

XI. The analysis of the residue insoluble in solution of soda shows that these substances must be very rich in nitrogen. Possibly they represent an insoluble form of albuminous matter. The estimation of the total nitrogen present in the seeds amounted to 4·35 per cent. (mean of two estimations), equivalent to albuminous matter, 27·64 per cent. These albuminous substances are distributed as follows:—

Dissolved by Water . . .	10·99 per cent.
" " Soda Solution .	4·22 "
" " treatment with Chlorine Water, and with Chlorate of Potash and Nitric Acid	12·43 "

Conclusions.

The close analogy which the melanthin of *Nigella sativa* bears to the helleborin of the botanically nearly related *Helleborus* carries out the anticipation of Dragendorff, that plants naturally closely allied frequently contain similar important constituents. At the same time, the well-defined alkaloids which characterize *Delphinium* and *Aconitum* appear in *Nigella* to be entirely unrepresented. Possibly a connecting link could be found in the fat acids of the stavesacre seeds, which have not as yet been subjected to a thorough investigation, just as the presence of myristic acid in the *Nigella* seeds points to the *Myristicaceæ* as not standing far removed.

The pæoniofluorescin of Dragendorff and Stahre differs from the fluorescent substance of *Nigella* in its insolublility in petroleum ether. The presence, however, of a substance resembling the phlobaphens has been shown, and although no tannin could be found, it may be regarded as resulting from the decomposition of a body belonging to that class.

Noteworthy in the seeds is the presence of volatile oil, which in Ranunculaceæ is generally absent. Connecting this with the fact that nigella is one of the few Ranunculaceous annuals, and dependent therefore on its seeds for its propagation, it does not appear improbable that the antiseptic ethereal oil should act, in the universal "struggle for existence," as an additional protection to the seed. As has already been pointed out, melanthigenin stands in a simple relation to that portion of the volatile oil found by Flückiger to possess the formula $C_{20}H_{34}O$, the production of which from melanthigenin would only be another of those cases of reduction, which in the life of the plant play so important a part. The difference in the amount of melanthin obtained from Russian and German seeds may be due to the different circumstances under which the seeds were grown. The latter were a trifle smaller, but it is possible that the severer Russian climate exerts an influence on the ripening of the seed. From unripe seeds I should expect a larger percentage of melanthin than from the Russian or German seeds now analysed.

As to the object of melanthin in the seeds, be it observed that, like saponin, this body possesses considerable emulsifying properties, and is probably of service in the secretion of the fixed oil.

Finally, the nitrogenous body isolated seems deserving of closer investigation. Agreeing with the albumens in the qualitative reactions, it differs from them in important characters, viz., easy solubility in water, and in forming with barium a compound from which carbonic acid fails to precipitate the base.

Dorpat, Russia.

THE EXHIBITION OF PHARMACEUTICAL APPARATUS, ETC.

(*Concluded from page* 997).

The only pill machines exhibited were those patented by Mr. Cocking. The smaller one (fig. 14), Cocking's cylindrical piper, consists of two grooved

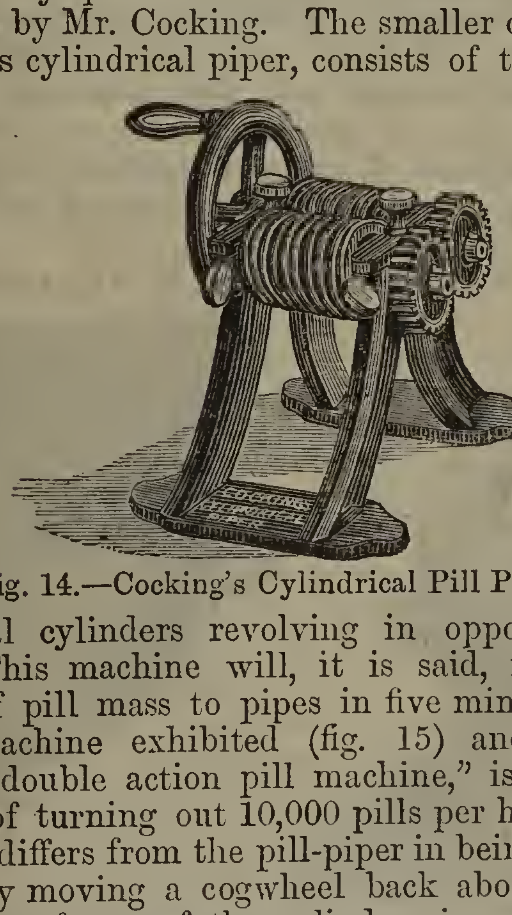

Fig. 14.—Cocking's Cylindrical Pill Piper.

horizontal cylinders revolving in opposite directions. This machine will, it is said, reduce one pound of pill mass to pipes in five minutes. The larger machine exhibited (fig. 15) and called a "patent double action pill machine," is said to be capable of turning out 10,000 pills per hour. This machine differs from the pill-piper in being arranged so that by moving a cogwheel back about an inch the action of one of the cylinders is reversed, the one then revolving in a downward and the other in an upward direction, so that the pipes if laid across the space between the cylinders are immediately

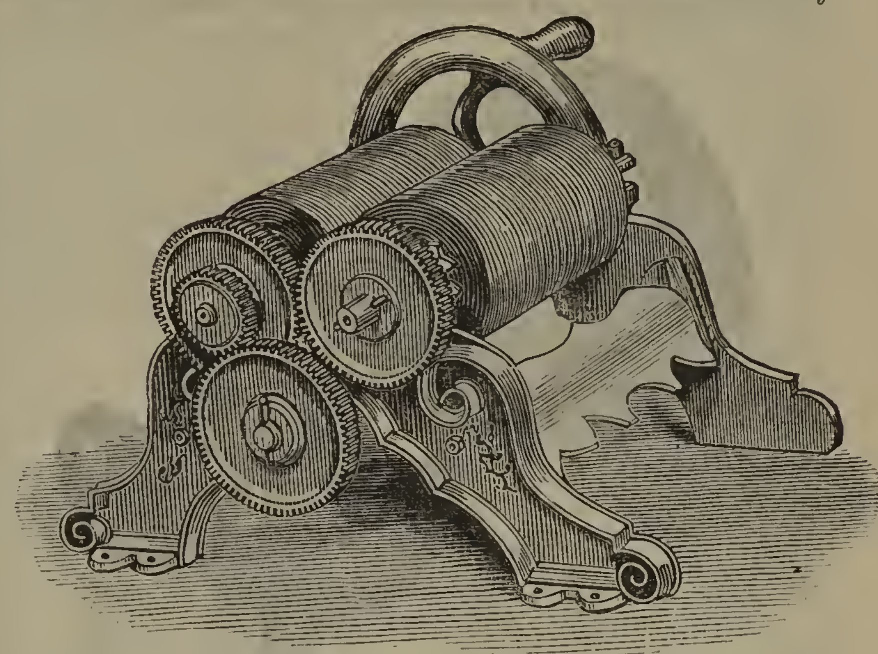

Fig. 15.—Cocking's Patent Double-Action Pill Machine.

cut and rolled into pills as fast as they can be made to succeed to one another.

One of the most ingenious pieces of apparatus in the Exhibition was a machine for printing the names on each pill, exhibited by M. Vial, of Paris. This instrument consists of a hopper in which the pills are placed and from which the pills pass down a tube one by one and are dropped into a hole in a revolving cylinder, from whence one turn brings them under a wheel, furnished with type that takes the ink from another wheel with which it comes in contact at each revolution. The pill is ingeniously kept in place, while it is being printed, by a pin which rises at the right moment; the next turn of the handle depresses this pin and causes another to rise which pushes the printed pill out of the machine. According to the inventor, from 25,000 to 30,000 pills can be printed in ten hours at the rate of fifty turns a minute. The whole apparatus does not occupy 18 inches in length by about 6 in width and is worked with the greatest ease. Another simple but ingenious contrivance, by the same inventor, is a pill finisher, which consists of a movable ring in which a flat disk of wood works freely. Pills of any size can therefore be finished by the same instrument, instead of having, as with the ordinary pill finisher, to use a separate one for pills of different sizes.

A pill-counting machine was also exhibited by Messrs. Lynch and Co. This consisted of a trough or open box, having at one end twenty-four small holes of a sufficient size to easily admit of one pill passing through each. The trough is suspended on two pivots, fixed in lateral supports; underneath the trough is a spring flap, which when pressed admits one pill through each hole, and when the pressure is released and the machine tilted delivers the twenty-four pills through a tube into a pill box placed beneath the instrument. The number of holes can be reduced by covering them with stops, which may be fixed securely by a screw pressure at the side, and thus the trough being filled with pills, six, twelve, or twenty-four pills can be delivered as rapidly as the machine is tilted and the flap pressed or the boxes placed beneath the delivery tube.

Of pill coaters there were three forms exhibited. One by Messrs. Bourne and Taylor, called Cartner's patent pill coater (fig. 16), consists of a spherical copper vessel, open at one end and made to revolve in a semi-vertical position by turning a handle connected with cogwheels. No. 1 size is said to coat a pound of pills in fifteen minutes. In using it the globe is set in motion and revolved about twenty times a

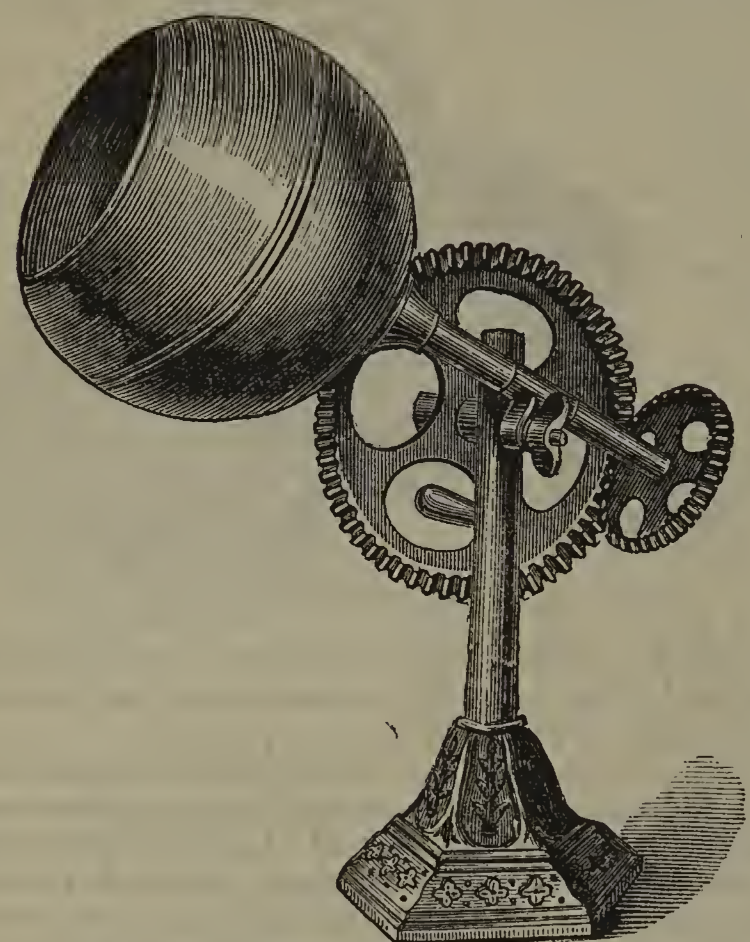

Fig. 16.—Cartner's Patent Pill Coater.

minute, a thin solution of syrup and mucilage (½ drachm of each to 1 oz. water) being sprinkled over them during their revolution, and in about two minutes afterwards a little finely powdered French chalk, repeating the operation as often as requisite.

The pill coater exhibited by Messrs. Lynch and Co. consists of a closed cylinder in a horizontal position, supported on two posts, the pin on which it revolves being attached to the cylinder so as to give it an oblique position when at rest, and an eccentric motion when the handle attached to it is turned round.

Mr. Hoddinott's pill coater essentially consists of a cylinder revolving horizontally and possessing a few small holes to let off the superfluous chalk. The advantages claimed are: (1) the horizontal revolution of the cylinder gives an increased "throw" to the pills, so that each is thoroughly and equally covered; (2) the perforations dispose of superfluous powder, the presence of which prevents the pills from polishing.

Messrs. Symes and Co. exhibited a form of percolator for continuous extraction. The receiver is placed in a tin can containing water and heated by a gas burner, and as the fluid percolates into it, a portion of the spirit continually ascends in the form of vapour through a tube in the centre of the percolated mass, and coming into contact with a vessel containing cold water or ice, which fits on the top of the percolator, is condensed and falls back as pure spirit on the mass to be percolated.

Messrs. Erhardt's capsuling machine (fig. 17) for

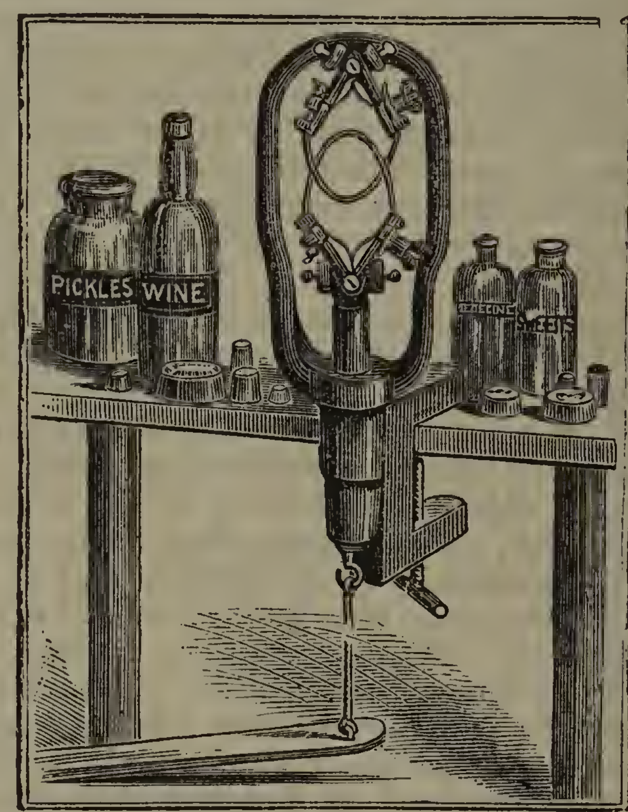

Fig 17.—Erhardt's Capsuling Machine.

quickly covering bottles with metallic caps, is a small instrument which can be attached to the counter by a clamp. The capsule having been placed on the top of the bottle is pushed between the two cords, and the cords tightened so as to be pressed close to the neck of the bottle, the pressure being applied by means of a treadle, and afterwards removed and the bottle then disengaged quickly by a spring in the lower part of the machine.

Messrs. Wyleys, of Coventry, exhibited a cheap and effective student's microscope, materia medica cabinets for medical and pharmaceutical students, and a number of microscopical slides illustrating botany, objects of materia medica, and various chemicals; also a student's chemical balance and volumetric apparatus, etc.

Johnson's hydraulic filter (fig. 18), exhibited by

FIG. I.

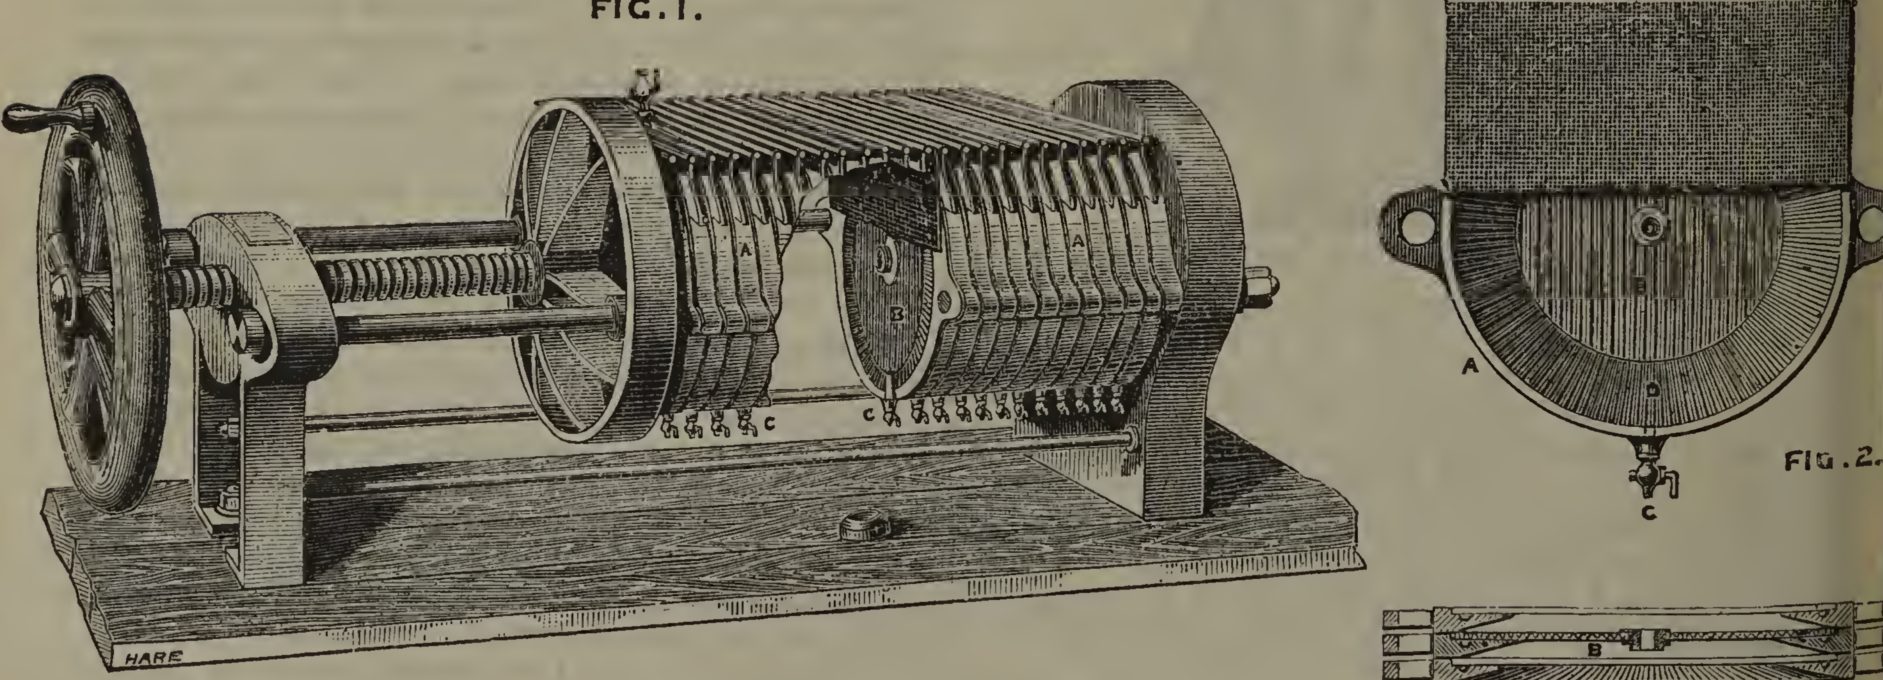

Fig. 18.—Johnson's Hydraulic Filter.

Mr. N. Nutter, attracted much notice from chemical manufacturers. In this machine, the substance to be pressed is placed between cloths and put between the vertical plates of the press and the fluid runs out at the bottom perfectly clear. It is said to be especially suitable for precipitates, from which it is desirable to remove as much as possible of the mother liquor and the salt contained in it, such as peroxide of iron or alkaloids, the pressed cake being thin. This result is obtained in less time and with greater certainty than if the pressed cake be thick, as in an ordinary press. The machine is easily cleaned and is said to be very lasting.

Mr. P. Burton exhibited Kenrick's American drug mill in action (fig. 19). This mill was shown at an

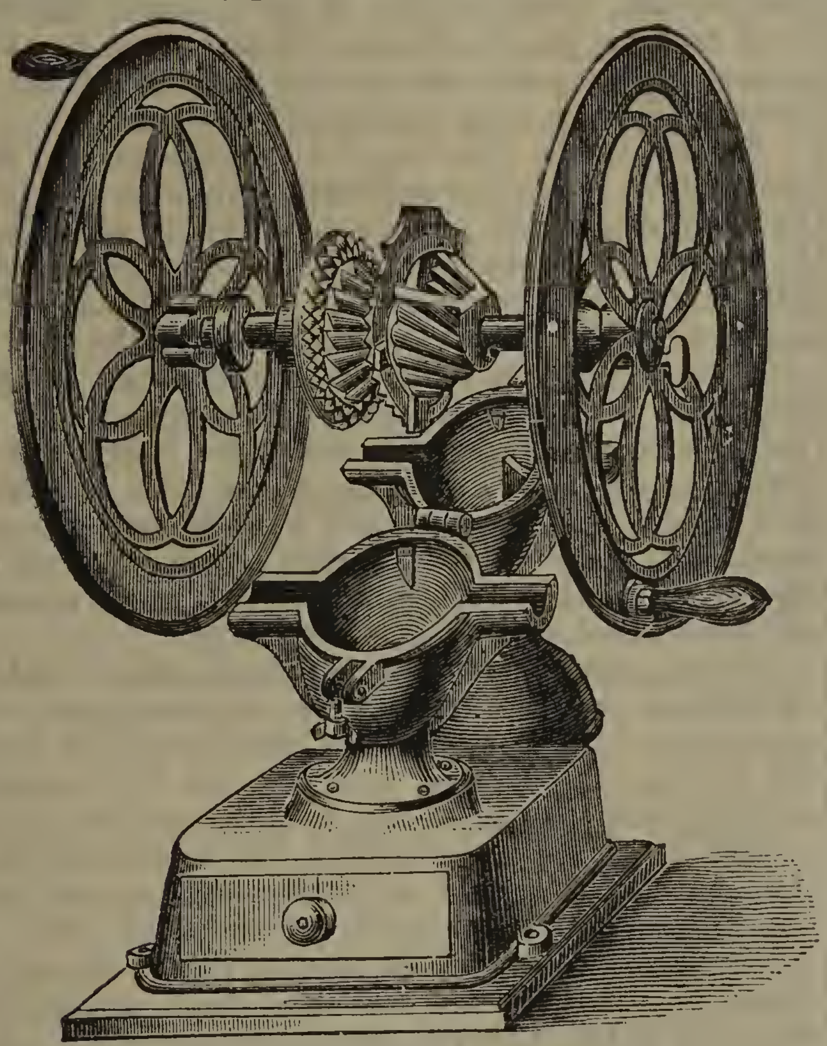

Fig. 19.—Kenrick's American Drug Mill.

evening meeting of the Society in 1877. It is stated to grind powders sufficiently fine for percolation, provided that they do not contain much resin or fixed oil. The above figure shows the mill opened for cleaning.

Of plaster spreading machines only one was exhibited, by Mr. E. Oberdorffer, of Hamburg. In this apparatus the calico, or other material, is fastened to a roller, from which it can be unwound at any rate required by means of a handle and clamp; it is then passed under a funnel-shaped trough, containing the melted plaster, and heated by a row of small gas jets; finally it passes over another roller, over which it is pulled by the operator, arrangements in the machine permitting of any desired width and thickness being spread.

A very pretty model of an exhaustive percolator and air pump, designed and exhibited by Mr. J. G. Oliver, of Brighton, attracted considerable attention. It consists of a stand, in the centre of which is supported a double metallic cylinder, with a piston working in the central one. The outer cylinder is moved over the inner, to which it fits closely, by a handle and cogwheel at the side. In the central cylinder the substance to be percolated is packed between metallic gauze strainers and the liquid is poured on the top of it. When the outer cylinder is drawn down by means of the handle, a vacuum is gradually produced, and the liquid is, so to speak, drawn through the mass to be percolated. The outer cylinder has two taps at its base, and to make the apparatus into an air-pump one of the taps is closed, and the other connected with the vessel to be exhausted by means of an indiarubber tube.

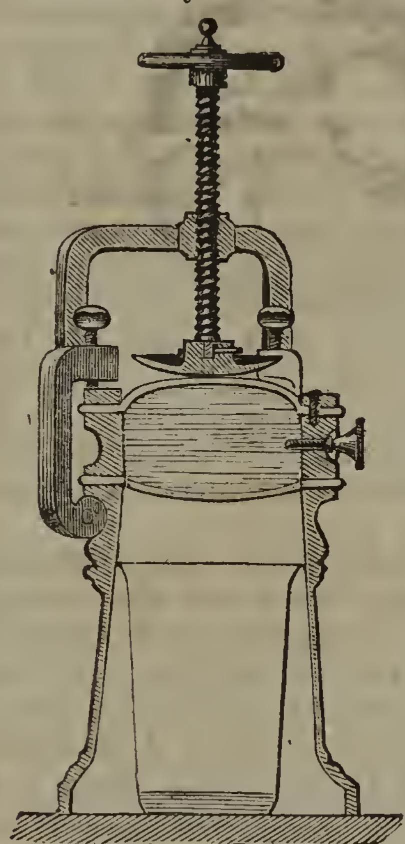

Fig. 20.—Christy's Tannin Testing Apparatus.

Messrs. T. Christy and Co. exhibited a small apparatus for testing the amount of tannin available for tanning purposes in barks, leaves, pods, etc. (fig. 20). In this apparatus a decoction of the substance to be tested is deprived of its tanning material by being made to percolate through a piece of hide of given size, and the liquid tested before and after the operation.

The improved label damper exhibited by Mr. Gall, of Carshalton, differs from the ordinary form in having a second roller covered with vulcanized indiarubber above, but coming into contact with the first.

Other objects exhibited in this room were Messrs. Bourne and Taylor's collodion filters, which have glass covers, fitting air-tight, and a tube in the funnel to allow the air to pass from the receiver back into the funnel as it is displaced by the liquid.

The Silicated Carbon Filter Company also exhibited various filters, including some for use in hot climates, for travellers, for shop and home use, etc.

In the room devoted to mineral waters, there was an abundance of material, the taste of some of which the visitors evidently enjoyed.

Among the aerated waters Messrs. Corbyn and Stacey exhibited Zoedone; while Messrs. Idris, Trevena and Co. exhibited Phosphade, an effervescing solution of various hypophosphites; Peptade, a similar solution of pepsine; lemonade, potash and other waters. The last-named firm also exhibited an effervescing solution of carbonate of magnesia in syphons for dispensing use, which is said to have the advantage of not depositing any magnesia in crystals, the solution remaining clear until the bottle is emptied.

Messrs. Godfrey and Cooke exhibited a solution of hypophosphites, under the name of Eau Restaurative; whilst, on the other hand, Messrs. Palk and Smith showed a liquid, under the name of Sparkling Rozelle, which is stated to be a non-alcoholic tonic fruit beverage, and unlike some of its rivals boasts of being free from phosphorus in any form. Mr. Riley exhibited ginger ale which was claimed to have the advantage of never becoming "mothery." Some of these liquids were evidently much approved of, judging by the celerity with which the bottles were emptied, zoedone, phosphade and lemonade being especially appreciated by the visitors.

Messrs. Prentice Brothers, of Stowmarket, exhibited their "chemical manure" for stimulating the growth and blossoming of flowers, and made an attractive show with specimens of flowers which had been treated by it. Messrs. Palk and Smith, of Torquay, also exhibited a similar compound.

In the room containing scientific apparatus, to which reference has been previously made (p. 977), Messrs. Cetti and Co., also, exhibited several useful pieces of apparatus, amongst which more especially worthy of notice were a petroleum test apparatus as supplied to Trinity House and required by Act of Parliament; Dr. Mills's colorimeter, in which a movable white disk shows by its position in the tube containing coloured fluid the difference in tint as compared with a similiar disk in a standard solution, the colorific value being read off in figures on the side of the testing tube; the distance of the disk from the surface of the fluid indicating the depth of colour. Another useful piece of apparatus was Dr. Russell's and Dr. West's apparatus for estimating urea in urine, in which the amount of urea is estimated by the quantity of nitrogen given off when urine is warmed with a standard solution of hydrobromite of sodium.

An excellent series of microscopes was exhibited by several makers. Messrs. Baker and Co. showed also the most recent forms of microtomes for cutting sections, and various forms of camera lucida; also botanical lenses on adjusting stands, which form a very cheap dissecting microscope for students. A binocular dissecting microscope with the tube bent almost at a right angle was evidently new to many of the visitors, and appeared to be an excellent instrument.

Mr. C. Collins exhibited a full-size Harley binocular microscope, cheap botanical dissecting microscopes, histological and pharmaceutical microscopes and microscopic slides. The largest collection of microscopical slides was, however, that of Mr. E. Wheeler, which seemed to be drawn from all the kingdoms of nature, animal, vegetable, and mineral; some of them were of extreme beauty, and others of much interest to pharmacists. The slide of tonga, the new remedy for neuralgia, was a remarkably pretty object.

Messrs. Field and Co., of Birmingham, had a cheap and very compact instrument for the use of pharmacists; also a useful polarimeter of a low price, having a polarizer and analyser of Jellett's and Nicol's prism respectively, and tube of 100—200 millimetres for holding essential oils, etc., when under examination. A similar cheap polarimeter was also exhibited by Messrs. Schmidt and Haensch, of Berlin. These instruments are now coming into somewhat general use, not merely for essential oils, but for testing alkaloidal and other solutions. The last-named firm also exhibited a cheap microscope with a curious rachet movement connected with the stage, so that by moving a small lever with the fingers the glass slide is made to travel backwards and forwards, at the same time being pushed upwards in such a manner that no portion of the object on the slide can possibly escape observation.

Messrs. Murray and Heath exhibited their "Steinheil's Applanatische Loupen," a new combined achromatic triplet magnifying glass, resembling a Coddington lens in power, but allowing more light to fall on the object, the focal distance being greater, and forming a very useful lens at a moderate price for examining minute objects. It is stated that the demand for these little lenses is in excess of the supply.

Mr. J. Swift exhibited several valuable microscopes with all the recent improvements of construction; one of these was a new petrological microscope for viewing biaxial crystals of extreme wide angle, the two systems of rings being brought into the field of the microscope by a special optical arrangement of the inventor.

The room containing the medical appliances and shop fittings seemed to be the one most interesting to visitors, next to that containing the pharmaceutical and gas-heating apparatus.

In this room Filmer Kidston's handsome prize dispensing counter formed a prominent and ornamental feature in the centre. It was furnished with many of the recent improvments; the pill machine, cork presser, etc., being capable of being drawn out and used without placing them on the counter, and the sponge case so arranged that the sand would not be scattered on removing a sponge.

A very useful show case was exhibited by Mr. Howlett, in which the ordinary trays were replaced by movable drawers; this was shown to advantage by being placed in the chemical department and filled with numerous bottles of chemicals while others were placed on the shelves outside the case.

Messrs. Allen and Co. exhibited their useful apparatus for invalids, including various forms of kettle for use in bronchitis, the water being heated either by a lamp or over a fire, as desired. Inhalers, a ventilating croup kettle, and a useful food warmer for infants and invalids were also shown. Several of these are probably already well known to the readers of this Journal, or if not, deserve to be.

Messrs. Arnold and Sons exhibited a large number of enemas, with all the latest improvements and combinations, so that some of them could be used for rectum, vagina, eye, ear, nose or for cleaning wounds, an arrangement which, however economical, strikes one as not altogether an agreeable one. Among other improved apparatus exhibited by this firm were a patent clinical thermometer, with a coloured scale to render the reading more easy, and a constriction to prevent the index from descending into the bulb; Lister's carbolic steam spray producer for surgical operations; and a new patent constant current battery, with high electromotive force, requiring to be recharged only once in two years, if used with ordinary care.

Messrs. Lynch and Co. exhibited a very pretty and powerful perfume spray diffuser, the jet being produced by a piston, and continued for some seconds after pressure is removed; a new form of adjustable truss; and glass measures graduated and stamped according to the requirements of the Weights and Measures Act.

Mr. W. Toogood also exhibited a number of glass measures, having the stamp of the Marylebone and Westminster inspectors respectively marked upon them, and also specimens of the standards used by inspectors for testing apothecaries' measures.

The Glasgow Apothecaries' Co. exhibited a number of their patent shop bottles, in which the label is let into a recess in the front of the bottle, the label itself consisting of a curved strip of glass with the label at its back, so that when cemented into the recess, only the glass surface covering the real label is exposed to the action of the air or of fluid running down the side of the bottle; these bottles attracted a considerable share of attention. Others exhibited by Poths and Co., with burnt-in labels, also unaffected by spirit or acids, were much admired, as well as some porcelain grease-proof jars for ointments, with similar labels. Cheap wooden hollowed-out blocks for sending bottles by post, and flat pill boxes with an overlapping rim, so that the lid cannot easily be crushed in by pressure, and coloured inks in powder were other useful and curious articles shown by the same firm.

Messrs. Bourne and Taylor exhibited absorbent cotton wool, spray producers, improved feeding bottles, clinical thermometers, etc., and a very useful little article, made of boxwood, for extracting stoppers which have stuck fast in bottles. Messrs. Erhardt and Co. showed tinfoil of remarkable thinness and polish, five thousand sheets being not more than an inch in thickness. Some pliable vegetable parchment exhibited by the same firm also seemed to be generally approved of, and the request on the label, "Please take a sample," was very generally complied with.

Among other articles of interest were Cowan's vaccination shields, for preventing the clothes from touching the part of the arm which has been vaccinated and thus preventing irritation. Cauty's poultice bags, exhibited by Messrs. Ayrton and Saunders, consist of an indiarubber bag with a spongio-piline surface and capable of containing hot water. These were of different shapes, one of the most generally approved of which appeared to be in the form of a collar for the neck, to be used for mumps, bronchitis or sore throat, etc. Messrs. Gabriel and Troke's capsuled horse balls consisted of a gelatine capsule with a gelatine label, containing the ingredients in a somewhat softer and more readily soluble state than could be possible if not enclosed in a capsule.

A VISIT TO THE NATIVE CINCHONA FORESTS OF SOUTH AMERICA.*

BY HENRY S. WELLCOME.

(*Concluded from page* 1002.)

All barks enter the market bearing certain brands, such as "J. P.," or "T. B." These brands gain a reputation according to the quality of bark they represent, but it is sometimes the case that as soon as a brand has established a good name the dealer sophisticates with inferior grades.† No large buyers of Europe or America purchase cinchona barks without first making careful assays; but, even with this precaution, they are sometimes deceived, on account of the adroit manner in which the barks are mixed.

The points of shipment for Ecuadorian barks are Guayaquil and Esmeraldes; for the barks of Northern Peru, Payta; from Southern Peru and Bolivia, Arica, Islay, Iquiqui and Callao. A limited quantity of Bolivian bark is exported by way of the Amazon to Para.

The greater portion of the bark produced in the northern and eastern districts of the United States of Colombia reaches the market by way of Carthagena and Barranquilia, on the Caribbean coast, but that collected in the State of New Grenada is mostly shipped from Buenaventura, on the Pacific coast.

Venezuela furnishes very little bark,* and that is sent from Puerto Cabello.

As regards the prospects for future supplies of cinchona barks from the native forests of South America, the outlook is exceedingly discouraging; the greatly increased use of cinchona alkaloids during the past few years, with the consequent demand for larger supplies of bark, has caused a very thorough working of the old forests and energetic seeking for new ones. The discoveries of paying forests are becoming more and more rare every year, and the new forests are found at greater distances from the shipping ports and more difficult of access.

The tract of country yielding the cinchona is not so unlimited as some writers would lead us to believe, nor is the supply inexhaustible; it is a fact recognized by natives and dealers, who are well informed about the extent and resources of the cinchona-bearing districts, that if the present ruinous system of destroying the trees is continued and no effort made to propagate new growths, they will before many years be practically exterminated from their native soil.

With the abundance of seeds yielded by the cinchonas one would naturally expect young plants to spring up in great numbers, but such is not the case; the light-winged seeds mostly fall upon and adhere to the ever-moist foliage, where they quickly germinate and decay; or if, perchance, they fall to the earth, it is almost impossible to gain a rooting, as the soil is covered to the depth of ten to twenty inches with loose, decaying leaves. Beyond all doubt the cinchonas might be successfully cultivated in their native country, especially in the localities of the exhausted forests; but the natives show no enterprise and foreigners receive no encouragement from the Government to attempt it.†

Two Germans have made a venture at cultivating cinchonas near the city of La Paz, Bolivia, but as yet the plants are not sufficiently developed to determine the results.

The almost continuous revolutions and wars in those South American countries so unsettle everything as to render investments hazardous; the roads and ports are sometimes blockaded for months, preventing the importation of goods or shipment of barks, often entailing heavy losses upon the dealers.‡

In case of war or revolution every Indian peon is subject to military duty, and if required is forced to enter the army; sometimes it is impossible to obtain sufficient cascarilleros to make it pay to enter the forests; hence it is that political troubles in those countries so greatly influence the price of bark and quinine.

We have no reliable history of the discovery of the medicinal virtues of cinchona bark, and the question as to whether or not its therapeutic value was known to the Indians before the Spanish conquest is still a subject of controversy. Of the several legends extant regarding its discovery and early history, one is of a certain saint who saved the life of a very holy padre§ by divulging to him the medical virtues of cinchona; this is told with several variations. The version which savours most of reality is that a padre was cured of fever at a small village, near Loja, by a decoction of cinchona bark administered to him by an Indian cacique.||

A legend which has gained wider circulation—probably on account of its romantic character—is that while a

---

* From the 'Proceedings of the American Pharmaceutical Association,' 1879.

† I was told of one merchant who, thinking his brand sufficiently well established, made a very large shipment of high-grade bark, with which he mixed about one-third of inferior quality; but the trick was detected in the foreign market, and his entire lot could only be sold as inferior grade, causing a heavy loss and serving him a very just punishment.

* The tapering-off points of the Andes, as also of the cinchona-producing forests, are in Venezuela.

† The Dutch and British Governments have shown great wisdom in taking such energetic measures to insure against the possibility of the world's bark supply becoming exhausted, and happily their experiments in their Eastern plantations are proving successful.

‡ During a revolution the property of any person suspected of sympathizing with a rival party is liable to be confiscated.

§ Jesuit priest.

|| Priest of the worshippers of the sun.

body of Spanish soldiers* was passing through the forests, one of their number was attacked by fever and left by the way to die. To quench his thirst he drank from a pool of water in which grew a cinchona tree; very soon he recovered and joined his comrades, heralding his salvador.†

The Spanish priests endeavoured to destroy every relic of native civilization, giving as little credit as possible for the many valuable products which they obtained from the people, whom they reduced from wealth and thrift to the most degrading serfdom; defiling their magnificent temples of worship and forcing‡ upon them a form of religion§ which, to this day, they observe only as a ceremonial performance, hedged about as it is by superstition and ignorance.||

It was the policy of the conquistadors to appropriate to themselves all creditable things. This is undoubtedly the reason why we have no authentic history of the medicinal use of cinchona by the natives at the time of the invasion.¶ It may be that its use was not general among all the Indian tribes, as the forests of Ecuador and Northern Peru** were the only sources from whence bark was collected by the Spaniards for nearly a century after it was introduced into Europe. However, this may be attributable to the fact that the Indians were (and they are now) very secret about the source of their remedies.

Several eminent travellers state (from hearsay, I suspect) that the Indians could not be induced to take cinchona bark as a medicine, and that they would not believe it was sought by foreigners for other than dyeing purposes. If this be true, how is it that the term applied to cinchona bark by the Indians is quinia-quinia, which signifies medicine bark? Herndon and Gibbons state that the Indians of the Matto-Grosso country use an infusion of red cinchona bark, which they deem a very efficacious remedy for calenturas.††

Ecuadorian Indians told me that they regarded it as a specific for fevers.

I was informed that pieces of the bark had been discovered in some of the ancient tombs; but I was unable to have this verified by positive proof.‡‡ It is very probable that such relics have been found, as I obtained specimens of *Erythoxylon coca* leaf§§ from the old Inca tombs in Peru.

It is a general belief among the natives that cinchona bark was well known and highly regarded as a remedy by their ancestors long before the Spaniards, under the daring Pizarro, invaded their coast.

---

* After or about the time of the conquest of Peru.

† This legend is especially commended to the credulity of believers in high dilution.

‡ By establishing the Inquisition.

§ With all respect to the religion of Christ and its redeeming qualities.

|| It is told that a party of priests, borne on the backs of Indians, went as missionaries among the Napa Indians (a tribe that had never acknowledged the authority of the Spanish invaders), soliciting them to accept the religion of the cross, like the other nations (who after the fall of Atahualpa humbly accepted the yoke of oppression); but the heathen, shaking their heads and laughing with derision, said (pointing to the slaves bearing the Jesuit fathers), "And carry you on our backs? Oh, no. We don't want a god that will transform us into beasts. Our god is the sun; he smiles upon us, gives light, and makes men of us, not dogs."

¶ It was first introduced into Europe under the name of Jesuit's bark.

** At the time of the conquest the whole of Western and Northern South America was known as Peru; hence the name Peruvian bark.

†† Fevers.

‡‡ Experience teaches one to receive all statements made by the natives with due allowance.

§§ Coca was cultivated and used by the natives throughout the country; it is still cultivated, but its use is not so general as before the conquest; more is consumed in Bolivia than elsewhere.

MEDICATED PENCILS.*

BY M. LEGRAS.

The author has recently communicated to the Société de Thérapeutique the following formulæ for a series of medicated crayons intended for use in the treatment of affections of the eyes and face. They are enveloped in a wrapper of tinfoil to preserve them, and another of ordinary paper to prevent them softening through contact with the heat of the hand.

The Pharmaceutical Journal.

SATURDAY, JUNE 19, 1880.

THE USE AND SALE OF METHYLATED SPIRIT.

In speaking last week of the Bill introduced by the Government to consolidate and amend the law relating to the manufacture and sale of spirits we confined ourselves to stating what were the provisions contemplated by the Bill as it now stands. In most respects they amount merely to a reiteration of the provisions of former enactments, and so far may be regarded as presenting a correct view of what the law is at the present time. But in view of the possible passing of this Bill as a measure of consolidation, it must not be forgotten that in several particulars the law has been materially relaxed by various general orders of the Inland Revenue Board. This has been notably the case in reference to methylated spirit, and under the sanction of these general orders several things may be done with methylated spirit which are, according to the strict letter of the law, unlawful.

The prohibitions of the use of methylated spirit are all of such a nature as are requisite for preventing fraud on the Revenue by its application in preparing beverages or any articles that could be used as such, and all of them may be taken as having that object in view. Thus, for instance, the Act of August, 1866 (29 and 30 Vict., cap. 64), provides that neither methylated spirit nor any derivative of it shall be used in the manufacture, composition, or preparation of any article capable of being used either wholly or partially as a beverage or internally as a medicine. But in the application of this Act an exception has always been made in favour of certain preparations for external use, such as liniments, that are required to be made as cheaply as possible. Clause 131 of the new Bill, however, deals simply with the provision in the old Act, stating that if any person uses any methylated spirits or any derivative thereof in the preparation of any article capable of being used wholly or partially as a beverage or *internally as a medicine* he shall for each offence incur a fine of one hundred pounds.

With respect to this clause it may be remarked that it is not at all obvious how the words "internally as a medicine," which are precisely the words used in the existing Act, can be legitimately construed so as to include poisonous liniments and other similar medicinal preparations capable of being used externally only. Nevertheless, as will be remembered, the Council of the Pharmaceutical Society some time since had to use its influence to obtain the consent of the Inland Revenue Commissioners to the use of methylated spirit in the preparation of belladonna and aconite liniments in cases where it is not required that they should be prepared according to the British Pharmacopœia.

Here, then, is one important point in regard to which it will be necessary to embody in the new Bill a specific permission of the use of methylated spirit in making liniments and preparations for external application that are not required to be in strict accordance with the British Pharmacopœia.

Were it not for the importance of the interests involved in connection with this matter it would be almost unnecessary to point out that there are numerous instances in which it is an object to have such preparations as belladonna and aconite liniments made with the most inexpensive materials. Thus, for hospital use and in some kinds of medical practice large quantities of liniments made with methylated spirit are contantly employed, and a prohibition to use the cheaper article would be a great privation to the poorer classes and to charitable institutions.

It was upon the strength of this representation of the case by the Council of the Pharmaceutical Society four years ago that the Commissioners of Inland Revenue issued a general order authorizing the use of methylated spirit in making aconite or belladonna liniment as well as soap liniment and compound camphor liniment. In point of fact the use of methylated spirit for these purposes could not offer any opportunity for fraud upon the Revenue, and since the preparations in question could not be used as beverages, they ought to be quite outside the operation of the law for protecting the Revenue. The exception recognized by this general order ought, therefore, for this reason alone to find a place in the Bill now before Parliament.

But there is a still stronger reason why it should be made quite clear that the use of methylated spirit in making preparations for external use and not required to conform to the directions of the British Pharmacopœia is not unlawful. To make this clear we must revert to the circumstances which led to the representation made to the Board of the Inland Revenue by the Council of the Pharmaceutical Society. Under the influence of an impression that the law prohibited the use of methylated spirit in making preparations for external use, certain makers of such articles had been in the habit of obtaining from the Inland Revenue authorities special permission to use methylated spirit for those purposes. In the month of August, 1876, an official notification was sent to them to the effect that the Commissioners saw reason to withdraw this permission, and in consequence considerable inconvenience and embarrassment was experienced.

Upon reference to the Acts of Parliament bearing upon the matter, it turned out that the use of methylated spirit in making preparations for external application, such as the liniments above referred to, was not in any way unlawful, and that it was indeed quite outside the provisions of the Act relating to the use of methylated spirit. At the time it was pointed out in an article in this Journal that having regard to the object of the legislation concerning the use of the methylated spirit as being exclusively the protection of the Revenue from fraud, it would be contrary to the principle and spirit of the Act of 1866 that any restriction should be imposed upon the use of methylated spirit in preparing articles so incapable of being used as beverages as the liniments of aconite, belladonna, or even those of soap and camphor.

It was also pointed out that the Act itself merely provided that methylated spirit should not be used in the preparation of any article capable of being used as a beverage or internally as a medicine. This is the whole extent of the prohibition. Beyond this the Act provided that if any person sold or had in his possession any *such* article he should be subject to a fine of one hundred pounds. As was pointed out at the time this is clearly to be understood as not applying at all to preparations incapable of being used as a beverage or internally as medicine, and therefore leaving the liniments above mentioned quite outside the operation of the Act.

That was undoubtedly the purport of the Act of 1866, but it so happened that immediately after the Act was passed a general order was issued by the Board of Inland Revenue embodying the provisions of the Act, and in this document there was a clerical error which has given rise to all the misconception that has prevailed. This error consisted in the omission of the word "such," which we have italicized above. By the omission of this word it appeared to be illegal to sell or possess *any* article in the preparation of which methylated spirit had been used.

The circumstance that this general order was circulated by the Board of Inland Revenue may account for its having received more attention than the Act itself, and for the impression under which persons desirous of using methylated spirit in preparing liniments made application to the Board of Inland Revenue to be permitted to do so. Probably the increase of applications of this kind may have caused the Board some difficulty, and have led to the general withdrawal of the permission. That difficulty, however, was overcome by the representations made by the Council of the Pharmaceutical Society, and practically it was removed by the consequent decision of the Board to consent to raise no objection to the use of methylated spirit in the preparation of aconite or belladonna liniment.

But in the fourth division of clause 131 of the Bill now before Parliament the reading of the General Order of August, 1866, is adopted, instead of the words of the Act of that year. The qualifying word "such," as indicating articles capable of being used as a beverage or internally as a medicine, is there omitted, and consequently the scope of the provision as it stands is very different from that of the original Act and from what was really the intention of that measure. As these words stand, although the Bill would allow methylated spirit to be used in an art or manufacture it would appear to render it illegal to be in possession of a substance—a varnish, for instance—prepared under this permission.

Among the articles in the preparation of which methylated spirit is now allowed to be used is chloral hydrate, but it is not so specified in the second part of clause 131, which merely provides that it may be used in making sulphuric ether or chloroform.

In addition to these points there are some others which will probably require revision when the Bill comes before the House. Among these we may mention the provision by which a retailer of methylated spirit is restricted to having in his possession at one time no more than fifty gallons. We believe that under certain conditions this limit is sometimes largely exceeded in practice with the consent of the Inland Revenue Board; but we do not find in the Bill any reference to the conditions under which this may take place without involving liability to the penalty of fifty pounds for infringement of clause 127.

Another point that has been referred to by a correspondent is the difficulty of keeping a strict account of stock in the case of retailers who are often required to sell a few ounces of methylated spirit. In regard to this objection, however, we think it should be borne in mind that the permission to sell methylated spirit is a concession, and that it almost necessarily involves the adoption of such precautionary measures as will adequately prevent improper advantage being taken of it.

From what we have already said of this Bill it will be evident that its further progress through Parliament will have to be watched in the interests of the trade.

REGISTRATION OF FIRMS.

In a recent number (before, p. 778) attention was called to a Bill that was introduced into the late Parliament for the consolidation and improvement of the partnership law, which contained a provision as to the registration of firms that it was suggested might, if carried, be of assistance in carrying out of the provisions of the Pharmacy Act. A similar Bill has now been introduced into the new House of Commons. But it is worthy of notice that the schedule of trades to which it provides that the term "trader" in the Bill shall apply does not contain "pharmacist" or "chemist and druggist," although it does contain "apothecary." It is moreover curious that the word "trader," although defined as applying to persons mentioned in this schedule, is not used in the Bill.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of this Association will be held on Thursday, June 24, at 8.30 p.m., when the chair will be occupied by the President, Professor ATTFIELD, F.R.S. A paper will be read on "The Green Extracts of the Pharmacopœia," by Mr. W. A. H. NAYLOR, F.C.S. A Report upon Organic Chemistry will be made by the Secretary.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

June 16, 1880.

Present—Mr. Greenish, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, T. E. Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

Dr. Greenhow was also present, on behalf of the Privy Council.

MAJOR EXAMINATION.

Nine candidates were examined. *Five* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Chapman, Joseph George ......Binfield.
Evans, John ....London.
Holmes, William Albert ....Kendal.
Jones, William ....Oswestry.

MINOR EXAMINATION.

Eighteen candidates were examined. *Six* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barnett, John Arthur ....Salisbury.
Bryant, Richard William ......Swansea.
Butler, Christie Havelock ......Tooting.
Carter, William ....St. Neots.
Court, Sydney ....Colchester.
Coverdale, George.................Leeds.
Davidge, Henry Ernest Fredk...King's Lynn.
Davis, Ifor..........................Dowlais.
Dickinson, David ....Boston.
Fitzjohn, Francis ....Whittlesea.
Francis, Matthew Robert ......London.
Leicester, Thomas.................Chester.

MODIFIED EXAMINATION.

One candidate was examined but failed to pass.

June 17, 1880.

Present—Mr. Greenish, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, T. E. Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Ten* failed. The following *fifteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Griffith, Philip ....Weston-super-Mare.
Jackson, William Hodgkinson...Crediton.
Joy, Francis John Jessop ......Cardiff.
Leigh, Harold Malcolm ....Dover.
Martell, Richard ....Portsmouth.
Mason, Joseph Robert............Workington.
Moore, Jonathan Reuben ......Kettering.
Parker, William ....Sessay.
Porter, John Thomas ....Coalville.
Rowe, John Bullen ....Ilfracombe.
Simpson, Samuel ....Gosport.
Trible, Edward.....................Launceston.
Vertue, Ernest Sutherland ......Ely.
Wallis, George ....Ryde.
Wilcock, James William.........Brighouse.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's Examination:—

Certificates of the University of Oxford.

Hoare, William Herbert.........Windsor.
Kirton, William Henry ....Boston.

Certificates of the University of Edinburgh.

Hislop, James Andrew............Hawick.
Robison, Ebenezer ....Hawick.

Certificate of the University of Glasgow.

Dalziel, John Logan...............Grahamston.

Certificates of the College of Preceptors.

Gummow, James Freeman ......London.
Haward, George Robert ....Lowestoft.
Hemens, Enoch John ....Banwell.
Morrison, John William Thos. Upper Holloway.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, June 2, 1880.

Present—Dr. Aquilla Smith, Vice-President, in the chair; Sir George Owens, M.D., Dr. Collins; Messrs. Bennett (Kingstown), Brunker, Goodwin, Hayes, Holmes, Oldham, Simpson.

The minutes of the meeting held on May 5 were read and signed.

Read a letter from William S. B. Kaye, LL.D., Clerk to the Privy Council, requesting on the part of a Committee of that Council that in the resolution relating to a course of practical chemistry the names of all the schools intended to be included in the resolution be submitted to them, and the words "and such other schools as may be approved by the Council" be omitted.

The Registrar was instructed to comply with the request.

Read a letter from Mr. John P. Harold, M.P.S.I., of Dublin.

The Registrar to inform him that his letter has been read, and that the Council will give it their consideration.

Read the following report:—

"The Committee appointed for the purpose have inspected the laboratory of the St. Cecilia Street School of Medicine, and beg to report that it appears to be furnished with sufficient appliances and conveniences for teaching practical chemistry."

Thomas Collins, *Chairman.*

The report was received and adopted, and the above school was ordered to be placed on the list of those recognized.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, June 10. Mr. H. Allen, Vice-President, in the chair.

The Secretary read a paper by Mr. R. W. Houghton, of Hong Kong, on "Cinchonas forwarded to India." The paper described the condition of some cinchonas during their voyage to India. The plants, which were in the charge of the Curator of the Royal Botanical Gardens, Calcutta, were destined for the Neilgherries and Darjeeling and were packed in Wardian cases. There were six Calisaya de Santé Fé (soft Columbian) and four Carthagena Crown Plants. The author was given to understand that the former were the first of the kind sent to India, and it is anticipated that a larger yield of quinine will be obtained from them than from the better known barks. The young shoots kept up well till in the vicinity of Port Said, when a parasitic fungus formed on the centre of the stem and they began to droop. On nearing Ceylon, however, there was an improvement, and on reaching Point de Galle there was every indication of their being landed alive in India. The author has since learnt that they have been planted in the Neilgherries. The four Carthagena plants grew perceptibly during the voyage and received no check whatever, being finally deposited at Darjeeling. Mr. Houghton suggests that when parasitic fungi appear on the stem of cinchonas a solution of sodium hyposulphite should be brushed over the fungoid growth; also that delicate cinchonas, Calisaya de Santé Fé for instance, should be less tightly packed than more hardy plants; and further that the route *viâ* the Cape be selected to forward the plants to India, so as to avoid the Suez Canal and the Red Sea.

A vote of thanks was passed to Mr. Houghton for his paper.

Mr. R. H. Parker then read the following paper on "Chian Turpentine."

Chian Turpentine.

BY R. H. PARKER.

Chian turpentine may now be added to the list (much lengthened of late) of remarkable remedies; a remedy claiming considerable antiquity,—for Theophrastus and Dioscorides were acquainted with this and other products of *Pistacia terebinthus*, L.; a remedy long ago subjected to therapeutical examination and found to possess exactly the properties of the pinic turpentines; still described in our most recent works on materia medica as "obsolete in British medicine," and suddenly, like some startling American invention, flooding the country with astonishment as to its curative properties, and in all probability destined to share in a short time the fate of transatlantic wonders and to sink into greater disuse than ever.

Professor Clay, of Birmingham, prescribed this oleoresin combined with sulphur in cases of cancer, and met with remarkable cures, and a communication of his results to the *Lancet* (March 27, 1880), set almost every physician writing prescriptions for Chian turpentine and sulphur, until the commodity threatens to be unobtainable.

The sulphur seems to have been originally used as an excipient for the remedy when administered in the pilular form. It was added to the emulsion of Chian turpentine because it was not thought desirable to omit any ingredient of the medicine that had been found to give such good results. We can only infer from this that the prescribers were not certain whether it was the turpentine or the sulphur, or the combination of both that had wrought the cures. Indeed, Dr. Battye* seems inclined to attribute this remarkable "melting away of cancerous growths" to the silica, which has been stated by Professor Rodgers to exist in Chian turpentine in the small proportion of ·78 per cent. With such evidence as this, medicine can scarcely be called an "exact science."

The analysis as given by Dr. Battye is as follows:—

Resin and volatile matter . . .	98·06
Ash	1·94
	100·00

The ash after burning was composed of—

Silica	·78
Alumen, iron and silicate of iron .	·029
Lime	·52
Residuum, chiefly fine sand . . .	·62
	1·949

The analysis of the ash seems rather remarkable, for the amount of silica present is given as ·78, while there appears a "residuum" of fine sand of nearly equal quantity, ·62.

Again, "alumen" is a curious ash constituent, and why this should be bracketed with iron and iron silicate does not seem evident. Possibly a typographical error occurs here.

An obsolete remedy having been so suddenly called to the front, it is not surprising that its botanical and geographical sources and all recorded information bearing on the drug should have been sought out and collected.

* *Lancet*, May 1, 1880.

The result is that nearly every journal claiming any connection with medicine or pharmacy has published papers on Chian turpentine. This drug, as every one is now well aware, is derived from *Pistacia Terebinthus*, L., growing profusely on the islands and shores of the Mediterranean and in varying forms throughout Asia Minor, Syria, Palestine, Beluchistan, and Afghanistan. These forms, *P. palæstina*, *P. cabulica* and *P. atlantica*, are considered by Hanbury simply as varities of *P. Terebinthus* produced by development under widely differing conditions.

The tree is not difficult to cultivate; it grows vigorously in the botanic gardens of this country. It is not known in the wild state at present,* although said to have been found wild in 1858.†

Secretion.—Unlike the analogous oleoresins produced by the coniferæ, the secretion of Chian turpentine takes place in the bark only; this accounts for the very small produce, since a large tree will only yield 10 or 11 ounces annually, while as many pounds of oleoresin, or more, are obtained from some pines.

Chemistry.—The proximate constituents of Chian turpentine do not appear to have been separated and subjected to individual analysis. Some light is thrown on the subject by analyses recently made by Wigner,‡ but the constituents given by him appear to have been named only from an examination of their solubilities and general physical characters. Genuine Chian turpentine, he finds, has a sp. gr. 1·050 at 60° F., melts in boiling water and becomes lighter than it, dissolves freely in hot alcohol 60 o. p., but a portion of one of the resins separates on cooling. The small residue from the hot alcoholic solution consists of earthy matter and sand, not of silica which had been in a state of combination as indicated by Dr. Battye in the analysis made by Rodgers.

The composition according to Wigner's results is:—

Volatile oil	9·2 to 12·1	per cent.
Alpha resin of mastic	79 to 81	„
Gamma resin of benzoin	4 to 6	„
Benzoic acid . . .	traces.	
Impurities	2 to 7·3	„

An obviously adulterated sample contained 26 per cent. of volatile oil; its sp. gr. was 1·000. Another, 16·3 per cent. volatile oil and sp. gr. 1·025. The oil distilled from each of these samples differed materially from the true oil in odour, and especially in its rotary action on polarized light.

In conclusion, Wigner says:—"The practical test which results from all these facts is the specific gravity. Genuine Chian turpentine should float in a solution containing 8 per cent. by weight of concentrated sulphuric acid, and should sink as soon as this is diluted. On the other hand, the adulterants used being lighter than water the spurious samples will float in this acid even after it has been diluted, say to three times its volume, and will sometimes even float in pure water. This test is perfectly easy to apply."

This is certainly a somewhat extraordinary conclusion, to isolate the specific gravity as a crucial test; for in an authentic specimen Flückiger and Hanbury found nearly 14½ per cent. of essential oil, sp. gr. 0·869, while Wigner found in one case 9·2 per cent. Probably greater extremes than these might be found among old and new specimens, and since a constituent of specific gravity 0·869 may be present in an oleoresin of sp. gr. about 1·050 in such varying proportions, it is evident that the sp. gr. must have considerable latitude, and cannot, except in extreme cases, be considered proof of adulteration.

Determination of Purity.—Since the annual produce of Chian turpentine is so small (according to Maltass 850 pounds), and the trade is monopolized by the Jews, who

‡ *Lancet*, May 29, 1880.

dispose of the greater part of it in the Turkish Empire, we are prepared to learn that very little finds its way to English markets, and as a consequence, adulteration and sophistication may be expected.

It has been stated that very little of the genuine drug can be obtained. Professor Clay said that out of a large number of samples submitted to him not more than 5 per cent. were genuine; but he does not say by what evidence he proved the discarded specimens to be adulterated. It has been even suggested that the drug originally used by that physician gave evidence of admixture with Canada balsam.

In the midst of so much probable sophistication it is essential that we, as pharmacists, should make ourselves intimately acquainted with the distinctive features which characterize the pure drug. The chemistry of Chian turpentine has not been carried far enough to supply chemical tests indicating its purity; we have, therefore, to rely for evidence of adulteration on its physical characters, viz., the taste, odour, solubility, etc.

The taste is feeble, only slightly aromatic and terebinthinate, entirely devoid of bitterness and acridity. One sophisticated sample which came under my notice had an extremely persistent bitter taste; adulteration with even a small proportion of such a specimen could not escape detection by the taste.

The odour of the true drug is very characteristic, and has been compared to fennel and elemi; but is, I think quite distinct from either. It is pleasantly aromatic, very feebly terebinthinate. The odour is not powerful, and should be observed by triturating the specimen in a warm mortar; under these conditions the coniferous oleoresins are easily detected. It is, of course, impossible for the odour to be diagnosed from a written description; but after making a few batches of pills with this drug, the olfactory nerve becomes perfectly acquainted with its distinctive peculiarities.

In some of the descriptions of true Chian turpentine which have been published of late, considerable stress is laid on its *consistency*. This is absurd, because at the present time samples can be found quite hard and brittle, while others are of nearly treacly consistence, the latter acquiring the former condition by age in consequence partially of resinification and partially of volatilization of essential oil. Either may be used for medicinal purposes; we cannot even say which is preferable, for the therapeutist has not yet told us whether the medicinal activity resides in the resin or in the oil, or whether both are alike good.

Chian turpentine is rarely free from a considerable trace of impurity consequent upon the paucity of its production and the necessary careful scraping when being collected.

Important data may be obtained by making a microscopical examination of the *débris* left from the ethereal or alcoholic solution, since the detection of the pitted tissue so characteristic of coniferous wood is tolerably certain evidence of adulteration.

The solubility of the drug in alcohol is important to observe. It dissolves in one volume of warm rectified spirit (sixty over proof), leaving only earthy impurities, etc.; the solution is not quite bright, but does not deposit to any large extent on cooling. Many of the coniferous oleoresins may be detected by this solvent. It dissolves freely in ether, acetone, benzol, etc., but these solvents do not distinguish it from analogous bodies.

The taste, odour and solubility are perhaps sufficient tests for pharmaceutical requirements, but more certain evidence of adulteration and the extent to which it occurs may be obtained by examining the optical powers of the oleoresin and its constituents with reference to polarized light.

An idea of the optical powers of some oleoresins and their constituents may be gained from the following table, constructed on data furnished by 'Pharmacographia':—

	Tereb. Chio.	Tereb. Canaden.	Tereb. Venet.
Oleoresin .	2 in 1 of acetone 7° right.	4 in 1 benzol 2° right.	2 in 1 benzol 9·5 right.
Resin . . .	Probably left.	2 in 1 benzol 8·5° right.	2 in 1 acetone 12·6 right.
Essential Oil.	12·1° right.	Distilled at 160 F., 5·6° left. Distilled at 170° F. 7·2° left.	6·4 left.

The French and American turpentines vary very much in their optical powers, but most of them are lævo-rotatory, while a few, such as obtained from *Pinus Tæda* and *P. australis*, are dextro-rotatory, while some have no rotary action at all on polarized light.

It will be observed in the foregoing table that the essential oil of Chian turpentine is strongly dextro-rotatory, while those of most other turpentines are lævo-rotatory; also that the *resins* from the coniferæ are dextro-rotatory, while that of Chian turpentine is probably lævo-rotatory, since the essential oil is much more powerfully dextro-rotatory than the oleoresin.

Observations on the optical powers of these bodies are of course only of value when made with the same instrument and the same solutions, comparing the results with parallel experiments conducted with authentic samples of Chian turpentine.

The pharmacy of Chian turpentine is perhaps what concerns us most. At present the drug is administered in two forms, viz., in pills and emulsion. Professor Clay's formula for the pills is, 3 grains of Chian turpentine and 2 grains of sulphur.

A tolerably firm sample of the drug must be used, or the pills will require much hardening excipient, and be inconveniently large. When fresh it is said to be of the consistence of honey. This would be useless for pills, and should be exposed in shallow vessels in a warm air chamber until sufficiently inspissated. Such procedure, of course, entails loss of volatile oil, but a sample hardened by old age could not be objected to; moreover the medicinal activity would probably vary far less than that of some of our potent official extracts, *e.g.*, belladonna, nux vomica, etc., with their varying degrees of consistence and composition.

The Chian turpentine being fairly hard it is easily made into pills by the use of a warm mortar or slab, the sulphur being incorporated with the addition, if necessary, of a little powdered liquorice or marsh-mallow, to enable the pills to retain their form. If the pills are to be coated they should be made tolerably hard, and allowed to stand some time, with occasional rounding, and then covered with very fine French chalk by means of thin mucilage of tragacanth or white of egg.

The emulsion is made with a solution of Chian turpentine in ether of such strength that 2 fluid ounces contain 1 ounce of the turpentine. Professor Clay's formula is:—

Solution of Chian turpentine .	℥ss.
Mucilage of tragacanth . . .	4 ozs.
Syrup	1 oz.
Sublimed sulphur	40 grains.
Water to	16 ozs.

Dose: 1 ounce three times a day.

The mucilage should be quite fresh, but the tragacanth must be thoroughly diffused. As the formula stands the best *modus operandi* is to dilute the mucilage with about half of the water, throw in the whole of the turpentine solution, agitate gently, add the remainder of the water and the sulphur, previously rubbed down with the syrup.

If the mucilage be not fresh, or the sulphur be added before the turpentine, the latter will aggregate into a sticky mass with the sulphur and adhere to the side of the bottle.

Another method is to triturate the turpentine solution in a mortar with powdered tragacanth, gradually add the water and other ingredients as above. This gives a good result but scarcely better than that obtained by the first process.

Almond mixture gives a far nicer emulsion, and if sweetened with spirit of chloroform keeps well; for this suggestion I am indebted to Mr. Branson. With this excipient it should be made as follows:—

℞	Compound almond powder	℥ss.
	Solution of Chian turpentine . . .	℥ss.
	Spirit of chloroform	ʒiv.
	Sublimed sulphur	gr. 40.
	Water to	16 oz.

Triturate the powder with a little of the water, add the solution of turpentine and the remainder of the ingredients.

The facility with which emulsions are made with gum-resins induced me to try to make an artificial gum-resin of Chian turpentine, by incorporating with it while in a fluid state in a hot mortar, a sufficient quantity of powdered acacia gum to render it hard and pulverizable when cold. By triturating this powder with water an emulsion is produced in which the tendency of the oleoresin to aggregate is completely overcome, and even if largely diluted, the resin subsides as a white sediment, which may be readily diffused by gentle agitation.

The addition of a small quantity of powdered tragacanth with the *acacia* is perhaps an advantage, as it gives an emulsion in which there is less tendency for the resinous particles to subside. The requisite quantity of powdered gum must of course vary with the consistence of the oleoresin. The following are the proportions I used:—

Tereb. Chiæ.	ʒj.
Pulv. tragacanth.	ʒss.
P. acaciæ.	ʒiiss.

The mixture should be allowed to remain for some time until thoroughly set, so that it may be easily reduced to a fine powder. It is then made into a thin paste with a little water and triturated until perfectly emulsified. This emulsion is by far the most perfect of any produced.

The tasteless character of Chian turpentine would indicate an electuary as a very convenient form for its exhibition. The following formula gives an elegant preparation:—

℞	Tereb. Chiæ.	ʒj.
	Spirit. Rectif.	ʒij.
	Pulv. acaciæ	ʒj.
	Pulv. glycyrrh	ʒj.
	Conf. rosæ caninæ	ʒj.

The dose may be from half to one teaspoonful.

The oleoresin is dissolved by warming with the alcohol and triturated in a mortar with the powdered gum; the liquorice is then added and finally the confection of hips.

The emulsion made from the artificial gum-resin and the electuary are decidedly the best forms for its administration. The emulsion with almond mixture is the most convenient for dispensing, that with the artificial gum-resin being somewhat tedious. Pills of almost entirely resinous composition are always of doubtful solubility, especially if hard, as these must be in order to retain their form.

A discussion followed in which the Chairman, Messrs. Branson, Hardwick, Hooper and James took part.

Mr. D. Hooper then gave his Report on Botany, being a paper on the "Medicinal Flora of Afghanistan." The author first gave a description of the country of Afghanistan and its climate, and then proceeded to describe the flora, arranged according to the natural system, giving the history, properties and botanical origin of the drugs which are mentioned in the Pharmacopœia, also many of those which constitute the bazaar medicines in India. The paper was illustrated by numerous specimens.

A discussion followed the reading of the paper, after which the meeting adjourned.

SOCIETY OF ARTS.

The Chemistry of Bread-Making.*

BY PROFESSOR GRAHAM, D.SC.

Lecture II.

(*Continued from page* 926.)

I think I have now gone through the more important properties by which we may recognize starch, dextrin, sucrose, maltose, dextro-glucose and lævo-glucose, and I have, therefore, done for the present with the description of the properties of these important carbohydrates.

I have been somewhat lengthy in my remarks on these carbohydrates, and I daresay there are some few here who are very well acquainted with the properties of those bodies, but of course, in lecturing to a public audience, one must consider the audience in general, not those who may happen to have studied chemistry for some considerable period, and are tolerably familiar with these things; but I am bound to deal with these matters in this way, because, if we take a general audience, we shall find there are many who have not had the opportunity of studying chemistry sufficiently long—or perhaps not even at all—to have acquired a knowledge of these bodies. Manifestly, when we come to consider what goes on in the important process of panification, and in the more important process of fermentation, we shall only be groping in the dark if we have not previously laid a solid foundation of knowledge connected with the important properties of these bodies that have to enter into the composition of the bread.

I now revert to the consideration of the phenomena that occur when certain albuminoid ferments act upon starch paste. I pointed out at our last meeting the valuable researches of Mr. O'Sullivan, the chemist for Messrs. Bass and Co., of Burton-on-Trent. It is some few years since he pointed out (not that he was the first, because it was Dubrunfaut who first clearly recognized and named it), a new sugar, to which he gave the name maltose, and, even before O'Sullivan, Musculus gave an explanation of the hydration products brought about by the action of albuminoids on starch paste which was not in accordance with the previous views on the subject.

Six or seven years ago, when I had the honour to address an audience here, I was aware of what had just been published, but it was too late to alter my tables and statements; nor was I prepared to adopt Mr. O'Sullivan's researches in their entirety, so that, even then, I spoke of glucose and dextrin as being the products of the action of albuminoid ferments upon starch and sugar. We now know, however, thanks to the researches of O'Sullivan and to the later works of Musculus and Grüber, and also to those of Brown and Heron, corroborated by other chemists, that under no circumstances does malt infusion ever produce either dextro-glucose or lævo-glucose, but only maltose and dextrin, and, consequently, maltose and dextrin are the products of the action of that important ferment on a solution of starch.

These equations† represent, according to Mr. O'Sullivan, the nature of the reaction. At about 140° Fah. the reaction consists in one molecule of water being added on to a molecule of starch. The molecule I have here made very much larger than I have represented it in a previous table, where it was C_{12}. Here I have multiplied that 12 by six, the value I have given to the n, and the molecule represented here is C_{72}. We have, then, one molecule of maltose formed, and this complex molecule of a dextrin. Under other circumstances, a lower heat and a longer time, two molecules are added on, a similar lesion of the compound molecule takes place, by which two molecules of maltose sugar are formed and β dextrin No. 1. Under still more favourable conditions, four molecules of water are added to the complex molecule; a lesion takes place, by which four molecules of maltose sugar and a less

* Cantor Lectures: Delivered November and December, 1879. Reprinted from the *Journal of the Society of Arts.*

† See before p. 806.

complex molecule of β dextrin No. 3 are formed. Lately, Messrs. Brown and Heron have communicated to the Chemical Society the result of very long researches on the action of malt infusion on starch paste; and they find that, at a temperature of 60 degrees Centigrade, the following set of phenomena occur. They agree with O'Sullivan in the main, but not altogether. In the first place, if you take the molecule of starch, as they have here taken it, to consist of ten times C_{12}, in other words, if you give to that unknown n the value of 10, what occurs, according to them, is this:—

Hydration Products of Soluble Starch. (*Brown and Heron.*) [*a.*]

	j. 3·86	k. 3·86	Resulting Dextrin.
Soluble Starch.	216·0°	0	
(1) $C_{12}H_{20}O_{10}$	209·0°	6·4	Erythro-Dextrin α
+ (2) $C_{12}H_{20}O_{10}$	202·2°	12·7	" " β
+ (3) $C_{12}H_{20}O_{10}$	195·4°	18·9	Achroo-Dextrin α
+ (4) $C_{12}H_{20}O_{10}$	188·7°	25·2	" β
− (5) $C_{12}H_{20}O_{10}$	182·1°	31·3	" γ
− (6) $C_{12}H_{20}O_{10}$	175·6°	37·3	" δ
(7) $C_{12}H_{20}O_{10}$	169·0°	43·3	" ϵ
+ (8) $C_{12}H_{20}O_{10}$	162·6°	49·3	" ζ
(9) $C_{12}H_{20}O_{10}$	156·3°	55·1	" η
(10) $C_{12}H_{20}O_{10}$ (Maltose.)	150·0°	61·0	"

A solution of soluble starch, at first, when examined by a saccharometer, indicates a right-handed rotation of the plane of polarized light of 216 degrees, and the reducing power on Fehling's liquid is nothing. In the course of a few minutes they find that the mixture, when acted on by a solution of iodine, indicates a brown colour. Of course, so long as there is soluble starch, the reaction with iodine would have given a blue colour, but after a few minutes at that temperature the solution indicates a brown colour, with a right-handed rotation of 209°, and 6·4 action on Fehling's solution. In the course of two or three minutes longer there is still a brown reaction, indicating what has been termed by Grüber erythro-dextrin. After that, however, at the particular period, where the right-handed rotation is 195° and the reduction of Fehling's solution 18·9, they find that there is no coloured product, but they obtain an achromatic dextrin. I will not go through the whole of this table, but the ultimate action, when carried out for a considerable length of time, is that no dextrin is left, and that the whole has been converted into maltose sugar, having a right-handed rotation of 150° and a reducing power on Fehling's solution of 61 per cent., that is to say, 100 parts by weight of maltose sugar only reduces Fehling's solution as much as 61 parts by weight of dextro-glucose or lævo-glucose. According to them, what occurs is this:—This very complex molecule, $10C_{12}H_{20}O_{10}$, is hydrated and a lesion occurs, by which the first $C_{12}H_{22}O_{11}$ is cut off, that is, maltose sugar and the complex body which is left has nine times C_{12} in its molecule. The next hydration product is where another C_{12} is cut off. At the successive steps successive molecules are cut off, all these being separate molecules of maltose, till finally, when this hydration process has been prolonged for sixteen to eighteen hours, the whole of the dextrin has been converted into maltose sugar, and the action then upon polarized light is +150°. The sign + on the table indicates that these different reactions, 2, 3, 4 and 8, having a corresponding action upon the ray of polarized light and a corresponding reducing power on the sulphate of copper, have been well established. They think, also, that the reactions indicated by 5 and 6 have been fairly well established, but the lower two have not been so.

Now, you may say to me, what is the practical meaning of all this? What does it matter whether three or four molecules of dextrin are formed, or whether there are a great many? We shall see. The practical result, I take it, is this. You must remember that Brown and Heron, precisely like O'Sullivan, have acted on starch paste, which is the representative of the boiled potatoes of the bakers, with a very powerful hydrating agent, and Heron indicates that, even though he uses so powerful a hydrating agent as a malt infusion, there are a series of dextrins formed, and that, practically, the amount of maltose that is formed at a low temperature with a hydrating agent of weak power, as the albuminoids of wheat, manifestly must give us bodies very rich in dextrin and particularly poor in maltose sugar. Possibly some of you may have forgotten, what I have already mentioned, that the yeast organism converts maltose into carbonic acid and alcohol, but the yeast organism has a very slight action on dextrin. Dextrin is a very stable body. It is so stable, as regards the power of the yeast organism upon it, that the German brewer, for example, and even the English brewer who wishes to imitate him, does all he can to try and obtain, in his infusion before fermentation, as much dextrin as possible from the hydration products of the barley. Now the dextrin is of no use to the baker; on the contrary, the more dextrin the baker forms in the panification process, either by employing bad flour, as I shall have hereafter to point out, or a bad process of fermentation—the more dextrin he forms in a given unit of time—whether it be six hours or twelve hours, the worse colour his loaf will be, because when you put dextrin bodies in the presence of moisture into an oven they are converted into highly-coloured products, and the object of the baker, therefore, must be to find out some method by which he will get as much maltose formed and as little dextrin as possible.

Then, I think, the next point we have learned, not merely from these researches of Heron and O'Sullivan, but from all previous studies, is this—that yeast has a considerable action on flour paste, but that yeast has a still greater action on soluble starch. I shall have to refer to these matters again.

(*To be continued.*)

Parliamentary and Law Proceedings.

PROSECUTIONS UNDER THE PHARMACY ACT, IRELAND, 1875.

In the Northern Division Police Court, Dublin, on June 5, 1880 (before Mr. A. J. O'Donel), James Haughton, carrying on business at 12, Rathmines Terrace, was summoned by the Pharmaceutical Society of Ireland, for compounding a prescription, he not being qualified or registered in accordance with the requirements of law.

Evidence was given that the defendant had made up a prescription, and Mr. H. J. Fennell, the Registrar of the Society, proved that defendant's name was not on the register of the Pharmaceutical Society.

The case was adjourned in order that defendant might have professional assistance, and be prepared with a legal defence.

He stated that he had let the compounding department to a Mr. Newbold. Mr. Newbold was at present absent, and he (defendant) was acting for him.

Mr. O'Donel suggested that Mr. Newbold, who was said to be in Dingle, might be communicated with, that the nature of the agreement might be laid before the court.

In the Southern Division Police Court, on the same day, before Mr. J. W. O'Donnell, a summons against Mr. Joseph Brownrigg, carrying on business at 46, South Richmond Street, Dublin, as Keily and Co., came on for hearing. He was charged by the Pharmaceutical Society of Ireland with illegally compounding a prescription without having been duly qualified or registered. Mr. J. C. Ennis appeared for the Society, and stated that the defendant was fined on a previous occasion for a similar offence, committed when he was carrying on business at Talbot Street. Evidence was given that a prescription was made up at defendant's establishment on the 27th of April last, but the case was allowed to stand adjourned in order that evidence might be produced showing who had made up the prescription. Defendant did not appear.

On June 12, the above cases, which stood adjourned from the previous week, were called on for hearing. Mr. Edward A. Ennis appeared for the Society. The Registrar, Mr. Hugh James Fennell, was also in attendance.

Mr. James Haughton appeared, and submitted to the judgment of the court.

In this case Mr. Ennis stated that as the defendant had promised to abstain from illegally compounding in future, the Society would be satisfied with the infliction of a nominal fine, defendant agreeing to pay the costs of the prosecution.

The court ruled accordingly.

In the case of Mr. Joseph Brownrigg, before Mr. Exham, the defendant did not appear.

The informations were read over, and evidence was given identifying Mr. Brownrigg as the person who had made up the prescription. The Registrar proved that the name of the defendant was not on the register of pharmaceutical chemists.

Evidence having been given that the prescription was written by a duly qualified physician, Mr. Exham, the presiding magistrate, considered the offence fully proved, and fined the defendant £5.

The Proprietary Rights in "Gum Extract."

On Thursday, June 10, 1880, before Vice-Chancellor Sir C. Hall, an application was made in the action of Bush *v.* Young to commit the defendant to prison for disobeying an injunction whereby he had been restrained from selling, imparting or publishing a recipe, which is an infringement of a certain patent known as "Gum Extract," the property of the plaintiff, which is used in the mineral water trade for giving a creamy head or foam to ginger beer and other beverages; the defendant having published and sold a recipe for the preparation of the same compound under the name of "Compound Fluid of Saphacarnium" to be used for the same purpose. The defendant resisted on the ground that the bark used by him was not the same as that used by the plaintiff, being known as "Panama Bark."

The plaintiff, however, proved that this was in fact the same, and the court granted the injunction. The defendant also threatened to publish the recipe unless it were bought up by the plaintiff.

His lordship made an order that in default of defendant paying the costs of the former applications and five guineas for those of the present motion, he should stand committed.

Obituary.

WILLIAM WALTER STODDART, F.I.C., F.G.S.

Mr. William Walter Stoddart, whose death we had recently to record, was born February 24, 1824, at Freshford, near Bath. On leaving school, at the age of sixteen, he was first placed in a carpet manufactory with his father, at Kidderminster, where he learned the usual routine of weaving and dyeing. This, however, was soon given up for chemistry, of which he was especially fond, and he then became the pupil of Mr. Hodgkinson, now a member of the firm in Aldersgate Street. For six years he remained with Messrs. Steele and Smith, of Bath, and soon after leaving them, commenced business for himself in Bristol.

Most of Mr. Stoddart's time for recreation was spent in scientific pursuits, and he occasionally contributed papers to various publications. Amongst others may be specially mentioned "A Singular Compound of Iodine and Quinine," and "The Growth and Nature of Sarcina Ventriculi." He also paid special attention with regard to the potable waters of Bristol, and the air of town dwellings. Geology was with him a favourite study, and he read a paper on "The Lias Formation of the Bristol Neighbourhood" before the Geological Society of London, and those who were present at the meeting of the British Pharmaceutical Conference in Bristol, in 1875, will remember the reading of his interesting paper, entitled "Pharmaceutical Experiments on the Bristol Rocks," which was avowedly a supplement to the series of papers from his pen on Bristol Pharmacology, which appeared in this Journal and were devoted mainly to the plants of the district.

In 1853, Mr. Stoddart joined the Pharmaceutical Society, and in 1868 he was elected a member of the Council. He performed the duties of this office for several years, but eventually the demands upon his time became so excessive that, in 1875, he was obliged to relinquish the seat. Whilst a member of the Council, he was, in 1873, requested by his colleagues to deliver the Inaugural Sessional Address to the students.

Mr. Stoddart was, for two years, Preident of the British Pharmaceutical Conference, at Liverpool and Edinburgh in 1870 and 1871, and at its meeting at Sheffield last year he read a paper on the subject of his latest researches with regard to the growth of ergot, which were unfortunately interrupted by his health giving way.

Mr. Stoddart's services to pharmacy in prominent representative positions were not allowed to prevent his help being extended to young pharmacists in the more limited sphere of his immediate district. He took an active part in the management of the Bristol Pharmaceutical Association, and in connection with it he for some years conducted classes in his favourite subjects of materia medica, botany, etc.

Mr. Stoddart for several years held the appointment of public analyst for the city and county of Bristol, and the county of Somerset, and afterwards was elected for the city of Salisbury, and the boroughs of Bridgwater, Chard and Devizes.

A few months since his health began to fail, and his death took place on May 30, in the fifty-seventh year of his age. He was buried at Stoke Bishop on June 3.

Besides the papers already mentioned, and his Presidential Addresses, the following by Mr. Stoddart have also appeared in this Journal:—"Commercial Sulphate of Quinine" (1864 and 1865); "Nature and Properties of Heat Practically Applied" (1866); "Use of the Microscope and its Crystallographic Application" (1867); Honey, its Formation and Changes" (1868); "Lemon Juice and its Decomposition" (1868); "The Air of Bristol and its Analysis" (1869); "Application of Spectral Analysis to Pharmacy" (1869); "Chemistry of Sugars" (1870); "Modification of Liebig's Volumetric Process for the Estimation of Phosphoric Acid" (1874); "Horsley's Lactometer" (1874); "Physics of Filtration and Evaporation" (1876); "Colouring Matter of *Crocus Sativus*" (1876); "Impurity in Zinc Oxide" (1877); and, in conjunction with Mr. Tucker, "Wines and Tinctures of the Pharmacopœia" (1872).

Notice has also been received of the death of the following:—

On the 4th of April, 1880, Mr. Charles William Wallace Crook, Chemist and Druggist, High Street, Hungerford. Aged 25 years. Mr. Crook was a Associate in Business of the Pharmaceutical Society.

On the 26th of May, 1880, Mr. Francis Clarke Barrow, Chemist and Druggist, Dalton Street, Barrow-in-Furness. Aged 36 years. Mr. Barrow became an Associate in Business of the Pharmaceutical Society in 1869.

On the 7th of June, 1880, Mr. Edwin Constable, Chemist and Druggist, Green Lanes, Small Heath, Birmingham. Aged 65 years.

On ths 11th of June, 1880, Mr. Thomas Livesey, Chemist and Druggist, Everton, Liverpool. Aged 57 years.

On the 14th of June, 1880, Mr. Harrison Thompson, Chemist and Druggist, Moor Street, Sunderland. Aged 64 years.

Dispensing Memoranda.

Replies.

[413]. I have made a considerable quantity of solution of acetate of morphia for hypodermic injection, simply by dissolving morphia acetate, for a local physician, taking care that the solution is perfectly neutral; and it has always answered quite as well as that made by the complicated B.P. process, although of double the strength.

South Norwood. J. H. Baldock.

[415]. In answer to "Disputant," I should certainly send out a ℥xx lotion, which is in my opinion correct.

If he will refer to the *Pharm. Journal* of March 29, 1879, p. 809, he will find a most satisfactory explanation given by G. H. L. which thoroughly settles the whole matter.

Patrington, Yorks. Twaddell.

[415]. I think it is difficult to lay down a rule as to whether Oj means 16 or 20 ounces. In my experience I have known both intended by different writers.

South Norwood. J. H. Baldock.

[415]. If "Disputant" will refer to the appendix to the Pharmacopœia he will see that the symbol O means a pint, and he will further find that a pint is 20 fluid ounces.

H. K.

[417]. I see no difficulty in this prescription. If the quinine be dissolved in the acid and a little water, then the bicarbonate of potash dissolved in this, the mucilage added, and then the guaiacum tincture, filling up the bottle with water, a very presentable mixture is produced, of a light chocolate colour, having but slight tendency to separate. Of course a label "Shake the bottle" should be put on.

South Norwood. J. H. Baldock.

[418]. This is a very frequent form of prescription, and the deposit is pretty sure to be formed sooner or later. It is due to the formation of a basic salt containing iron, consequent on there being an insufficient quantity of acid present to retain the whole of the quinine and ferric oxide in solution.

South Norwood. J. H. Baldock.

Queries.

[419]. Ol. Santal. Flav.—*R. F.* wishes to learn of a method of dispensing ol. santal. flav. so that it shall be tasteless.

[420]. What is the best method of dispensing the following formula?—

℞	Ferri Sulph.	gr. xxiv.
	Camphoræ	gr. xxiv.
	Gum Acaciæ	q. s.
	Ol. Cinnam.	♏ vi.
M.	Ft. pil. xxiv.	

F. G.

[421]. I should be glad to be informed what appearance lotions of zinci chlor. B.P. should present. Ought they to be clear like water, or is a certain amount of the zinci chlor. insoluble? And if so, should this insoluble portion be sent out in the bottle with a "Shake the bottle" label attached, or should it be filtered out through paper?

Tyro.

[422]. I had the following presented to be dispensed. It is written exactly the same as the original.

Sulphate of Zinc . . . . ʒj.

Ft. pulv. iv.

Will some readers kindly say what they think of it, and how they should have sent it out? I sent four powders of 15 grains each, and labelled, "The powders. Poison. To be used as directed."

Bdfrd.

[423]. A short time since I had the following to dispense?—

℞ Hydrarg. c. Cretæ . . . . gr. $\frac{1}{3}$.

Ft. pulv. j; ter die sumend.

Was I justified in adding $\frac{2}{3}$rds of a grain of sacch. lactis to each powder, so as to be able to weigh them out correctly? If not, will some readers kindly say how they would have managed.

Bdfrd.

Notes and Queries.

[656]. Starch Glaze is a mixture of borax and starch, both in fine powder. The proportions vary.

Liverpool. R. Parkinson.

[657]. Liq. Ammon. Acet. Conc. has generally been understood to mean a neutral combination of acetic acid and carbonate of ammonia.

Liverpool. R. Parkinson.

[657]. Your correspondent, Mr. Page D. Woodcock, has not answered this question at all, because he does not state what strength his solution is; while your other correspondent, "Twaddell," has, I think, answered it incorrectly. Taking the strong acetic acid of the B.P. (containing 28 per cent. of anhydrous acid), which I consider the only acid practically available for the purpose, and neutralizing it with Howard's volcanic ammonia, a solution is obtained of about 1 to 6 or rather less, and not 1 to 7, and is so generally indicated in the price currents of the wholesale houses. The sp. gr. of acetic acid of the B.P. is 1·044 corresponding to the old Dublin strength; while that of the P.L. was 1·048, so that it is not clear where "Twaddell" got his gravity of 1·038 from. (See a paper on this subject by Mr. J. C. Thresh, [3], vi., 781).

J. H. Baldock.

[657]. I presume your correspondent who wrote for a process for making liq. ammon. acet. conc. 1 to 7 wishes to make it so that when diluted with water it should make a solution of B.P. strength. This cannot be done with B.P. acetic acid (acid. acetic. fort.). When this is neutralized with carbonate of ammonia a solution results of six times the B.P. strength. 80 ♏ of it are required to make ℥j liq. ammon. acet. B.P.

Acetic acid B.P. should contain 28 per cent. of anhydrous acetic acid $C_4H_6O_3$ and glacial acetic acid 84 per cent., so that the latter is three times as strong as the former, and thus a neutral solution of acetate of ammonia made with the glacial acid would be eighteen times the B.P. strength. By diluting 1 part of this with $1\frac{1}{4}$ parts of water, the solution obtained will be of the required strength, viz. 1 to 7. In working it would be best before neutralizing to dilute the glacial acid with an equal volume of water and then to make up to the $2\frac{1}{4}$ parts.

Debutant.

[657]. LIQ. AMMON. ACET. CONC.—1 to 7.—I should like Mr. Woodcock to explain how he makes his formula to be eight times the strength of the B.P. formula. The B.P. product is only six times the quantity of the acid used, so that to use undiluted acid, as Mr. Woodcock suggests, will be only six times the strength (1 to 5). The quantity of am. carb. is, in each case, to neutralization.

"Twaddell" gives a form (from Cooley, I presume) still further from the mark. He orders an acid of s. g. 1·038, whereas the B.P. acid is s. g. 1·044; so that the liq. would be to that extent weaker. He certainly qualifies his remarks by adding the letters P.L., but it is a preparation eight times the strength of the B.P. form that is required.

H. K.

[657]. LIQ. AMMON. ACETATIS CONC. 1 to 7.—
Glacial Acetic Acid sp. gr. 1065. . . . 5
Aq. Destill. 7

Neutralize with volcanic carb. of ammonia in the usual way.

Replies of last week I think would result in 1 to 5 solutions.

T. S. Minett.

[658]. COMPOUND TINCTURE OF MYRRH.—A "Veterinary Traumatic" is prepared as follows:—

Myrrh	2 lb.
Barb. Aloes	2 lb.
S. V. R.	Oiss.
Aquæ	Ois.

Digest fourteen days and filter. ('Gray's Supplement,' 1848.)

Liverpool. R. Parkinson.

[658]. COMP. TINCT. MYRRHÆ.—

℞ Gum. Myrrhæ,	
Aloes Barb.	āā ℥iv
Sp. Vini. Rect.	Oiij.
Aquæ	Oj.

Macerate for fourteen days, and strain (Gray's form).

Potens.

A similar answer has been received from Mr. Jessop.

[658]. TINCT. MYRRHÆ COMP. is the old tinct. myrrh et aloes of the 'Edinburgh Pharmacopœa,' 1744, but I have reason to believe that many pharmacists of the present day use proof spirit instead of rectified as ordered in the original formula.

Lavandula.

Correspondence.

Viviparous Plants.

Sir,—Doubtless there are a few readers who, like myself, are somewhat puzzled as to the nature and origin of viviparous plants and would like to be more familiar with them. With this reason I trespass, if I may be allowed, on such space as can be allotted to me for inquiries. On reading the paragraph in the Journal entitled "The Month," reference is made to viviparous plants, specimens of which are to be seen at Kew and Regent's Park. My interest being excited, I made a special journey to Kew, having hitherto not seen such examples, which were very evident to a marked degree in the plant named, namely, *Cypella gracilis*. My curiosity, thus gratified, was further aroused and in consequence I searched further for other specimens, on the principle that much wants more. The search was compensated in the fern house, where two instances of a somewhat different nature presented themselves. In the first instance the fronds and pinnæ of the fern (*Dipsonia obtusifolia*) were loaded with a number of young plants developed on the upper surface of the frond, so much so that the frond itself was overburdened with the weight and was in consequence supported by means of a prop; in the second instance, instead of the plants being developed on the frond and pinnæ generally, the mid-rib was prolonged analogous to the prolongation of the petiole of the leaf, and instead of producing, as in case of the leaf, a pitcher or ascidia, a complete plant was developed forming several smaller fronds and a very small rhizome. Having thus far explained the external appearances presented, I wish to know:—

(1.) The nature and cause of such developments.

(2.) Would they arise from cultivation on such plants upon which they would in their natural condition be abnormal?

(3.) Would they be regarded as parasites, since they must necessarily derive their nourishment from their parents? Could young plants of the same genera and species as that upon which they grow be regarded as parasites?

According to the Journal, the first question would be answered, in case of the *Cypella*, that the young plants were developed from the inflorescence, the abortive ovary remaining.

Thomé's 'Botany' states that it is not uncommon for a leaf or flower bud to be transformed into fleshy bodies, with scale-like leaves and a very short, fleshy axis. These buds, which often serve as reservoirs for the reception of reserved materials, very commonly grow when "detached" from their parent plants into independent plants; such plants are viviparous, and he states that such phenomena occur normally on *Polygonum viviparum*, *Poa vivipara* and are not uncommon in *Lilliaceæ*, *Graminaceæ*, etc.

I should like to be clear as to how the young plant could arise from the inflorescence. Taking it for granted the ovary is abortive, would the force or nourishment essential for the maturity of the ovary exert any power or influence in the formation of the young plant? In reference to those young plants on the frond of the fern, drawing the analogy between the ovary and sori, then it follows that the sori were abortive and would likewise exert some influence on the formation of the young plants. Assuming such might be the case, I cannot trace any analogy in the case of the second fern, viz, a species *Adiantum*, to that of the former, since the plant is developed in a different position.

W. Ralph Dodd.

T. Marshall.—We can only undertake to communicate the information through the medium of the Journal, so that it may be available for other readers.

T. S. Minett.—We agree with you to some extent; but we are not responsible for the form in which the author chose to convey his information to the American Pharmaceutical Association.

"*Amicus Tyronis.*"—The question is not suitable for insertion in this Journal; it would be more appropriately put to a medical practitioner.

"*Acries.*"—(1) We believe not. (2) Apply for a copy of the Regulations to the Registrar of the Medical Council, 315, Oxford Street.

J. W. B.—The words have been evidently written or copied incorrectly.

"*Molar.*"—The decision does not lie with the Dental Association but with the Medical Council. If your friend's name had been on the Register of Chemists and Druggists it would have been evidence that he was engaged in the practice of pharmacy. But the Dental Act does not specify that such registration shall be the only acceptable evidence of the fact.

H.—(1) *Salvia verbenaca.* (2) *Rhamnus Frangula.* (3) *Luzula Forsteri.*

"*Vance.*"—See the answer to "*Molar.*"

Erratum.—On p. 1011, col. ii., line 37, *for* moisture *read* moisten.

Communications, Letters, etc., have been received from Dr. Wright, Messrs. Robinson, Elliman, Logsdail, Van der Weyde, Chichester, Hyne, Palmer, J. A. T., R., Jek, Sufferer from Outrageous Competition, Tyro, Oxygen, Pharmakon, Inquirer.

"THE MONTH."

Just a twelvemonth ago there was snow in Scotland and hail in London and the blossom had not made its appearance on the elder tree (*Sambucus nigra*). At present the elder is more abundantly covered with blossom than for some years past, and the season may therefore certainly be said to be in advance of last year. How far this is the case may be judged, also, from reports received from Cornwall, the Isle of Wight, Dorsetshire and Kent, according to which it would appear that many plants are at least three weeks earlier in blossoming than last year. From Cornwall, in the first week in June, a correspondent sent ears of wheat in full bloom, and a similar state of things was mentioned in the *Echo* as occurring in the Isle of Thanet. Another Kentish correspondent mentions wild henbane and belladonna as being in flower early in June. Mr. Romans' inference that because the lily of the valley was not in blossom at a certain date, the season was therefore later than last year is not perfectly legitimate. Those who have cultivated this little favourite know well that the same individuals do not flower regularly every year under ordinary circumstances. In the woods near Dartford, Greenhithe and Canterbury it remains without any flowers at all in some seasons, or perhaps only two or three here and there.

As might be expected from the recent abundant rains and warm atmosphere, vegetation has made amazing progress during the past month, and the student of botany needs to work hard to keep pace with the prodigality of nature. Aconite, actæa, belladonna, dulcamara, digitalis, henbane, hemlock, buckthorn, mustard and many other medicinal plants are now in blossom in botanical gardens. At Kew, a fine specimen of arnica in blossom may be seen in the Herbaceous Ground. The caraway, angelica, alkanet and horseradish may also be observed in bloom.

One curious plant, growing in waste sandy places and flowering at this time of year, is deserving of a brief notice, as it has recently been reported to have proved fatal to cattle which had eaten it. The hound's tongue, *Cynoglossum officinale*, as might be supposed from its Latin name, was formerly used in medicine. According to Sowerby's 'English Botany,' "It is narcotic and astringent (and antispasmodic), and has been given with advantage in scrofulous complaints in the form of decoction and as an external application, but its disagreeable odour has caused it to be discarded from modern practice." Sir W. Coles, in his 'Art of Simpling,' tells us that it "will tye the tongues of houndes so that they shall not bark at you if it be laid under the bottom of your feet, as Miraldus writeth." The plant has a strong, disagreeable odour, likened by some to that of mice, but by Gerarde to dog's urine, to which he says "there is not anything smelleth so like as the leaves of this plant doe," a fact which is also expressed in the Dutch name for the plant. The seeds, or rather pyrenes, which are large for the size of the plant, are covered with short hooked spines and adhere to animals or to the clothes, and the plant evidently thus effects its distribution. If the statement be true of cattle being poisoned by it, the reputed narcotic properties of the plant would seem to demand investigation.

It is not surprising that the term viviparous, used in the last "Month," should suggest inquiries from correspondents such as have appeared in the last two numbers of the Journal. The term may be looked for in vain in the index of some of our best botanical text-books, including Sachs's, Prantl and Vines's, Balfour's, Bentley's, Henfrey's and Brown's; nor do such excellent works as 'Hooker and Decaisne,' Lindley's 'Vegetable Kingdom,' the 'Treasury of Botany,' Masters's 'Vegetable Teratology,' or Cooke's 'Dictionary of Botanical Terms' index the word. In Webster's 'Dictionary,' however, it is explained thus:—"In *botany*, producing its offspring alive, either by bulbs, instead of seeds, or by the seeds themselves germinating on the plants, instead of falling as they generally do." Asa Gray, in the glossary to his botanical text-book, defines viviparous as "germinating or sprouting from seed or bud whilst on the parent plant." It must be obvious, however, that there are cases in which the seed sprouts on the parent plant, and yet the parent could scarcely be called viviparous. Thus, during the wet autumn of last year grains of wheat sprouted on the ear in many fields, yet no one would think of calling wheat a viviparous plant. The term must almost of necessity be restricted to those plants which have acquired a constantly viviparous character as above defined. The chief cause which appears to determine this development is inability to ripen seed from some cause or other. Most plants appear to have two means of reproducing themselves, viz., either by gemmation (*i.e.*, reproduction from buds) or fructification (*i.e.*, reproduction from seeds or their representatives), and when one is curtailed the vigour of the plant appears to set in the direction of the other. Thus on mountains, where there are constant mist or moisture and cold air, many plants tend to form viviparous growths. This appears to be the case with *Polygonum viviparum*, bulbils replacing flowers in the lower part of the inflorescence, and in *Poa vivipara*, *Festuca vivipara*, etc. Any conditions which would arrest the process of fructification would probably tend to the production of buds instead of flowers. If the flower bud be regarded as a modification of a leaf bud for the purposes of reproduction by cross-fertilization (a process which is well known to give increased vigour to the resulting individuals) then the reason why viviparous growths occur on the inflorescence when the plant is unable to ripen fruit becomes evident. A tendency in this direction also appears occasionally when the apical growth of the inflorescence is curtailed, as in *Allium vineale*, *A. Babingtonii*, *A. sphærocephalum*, and other species. The formation of buds on the rachis of a fern seems analogous to the formation of adventitious buds on various trees, and it may be the result of excessive nutrition, combined with a sudden stoppage of the main axis or axes of growth, as indicated in Mr. Wall's letter on p. 1052. The formation of buds, as in the *Adiantum*, at the end of the frond, probably indicates a tendency to root at intervals, as in the runner of the strawberry. Viviparous growths appear also to take place in abnormal positions in some naturalized plants in which the conditions are different from those occurring in their native country. Thus *Scirpus Holoschœnus*, which never appears to ripen fruit in England, when it sweeps the damp sand with its almost terminal inflorescence produces young plants on the inflorescence which root and propagate the species. The horseradish also, which does not ripen fruit in this country, produces numerous buds on the root. It may be regarded as questionable how far the term viviparous can be properly applied to such plants as produce deciduous buds which do not grow on the parent into young plants, such as *Dentaria bulbifera* and various species of *Begonia* and *Lilium*. A "parasite" is defined as a plant which is without the means of elaborating crude into proper sap and which consequently derives its nourishment from a plant of another kind or species, and this term cannot, therefore, properly apply to the young produced on a viviparous plant since these are capable of forming true roots and obtaining nourishment for themselves when detached from the parent plant. How far viviparous growths would "arise from cultivation on such plants upon which they would in their natural condition be abnormal" is open to experiment. In case of a common scarlet geranium from which the flowers were picked off their pedicels as soon as the corolla withered it has been observed that one of the membranous bracts at the top of the peduncle developed into a green leaf. The nutriment which would have gone to ripen the ovary here appeared to have been diverted towards producing a vegetative organ. This mode of procedure may perhaps serve as a clue for "viviparous" correspondents to follow up by experiment.

Most of our readers who have attended botanical lectures in London are probably familiar with the handsome bell-shaped flower of *Cobœa scandens* and its remarkable disk. In *Nature* for June 17, p. 149, Mr. A. Ernst, of Caracas, gives a most interesting account of the fertilization of a closely allied species, *C. penduliflora*, Hook. f. He found that the disk only secreted nectar immediately after the anthers burst, and that it was then produced in considerable quantity, and that unless the plants were cross fertilized the same night either by moths or artificially the fruit was not developed. "As soon as the corolla has fallen off the peduncle withdraws slowly amongst the dense foliage where the fruit develops protected from all kinds of injury."

Some interesting observations have been made by Herr Stahl (*Verhandl. der phys.-medic. Gesellsch. in Wurzburg*, Bd. viii.) on the motion caused by the effect of light on some minute algæ, belonging to the Conjugatæ. He finds that *Closterium moniliferum*, one of the Desmids, under diffuse daylight of little intensity, presents its longitudinal axis to the light rays, one-half of the cell being alternately attracted and the other half repelled, so that both halves are equally exposed to light. When the intensity of the light was increased the cells changed their position, and placed themselves at right angles to the incident light.

Dr. S. Vines read last month, before the Royal Society, a paper on "Aleurone Grains," which was a continuation of his investigations on this subject, as recorded in the 'Proceedings of the Royal Society,' in 1878 (vol. xxviii., p. 218). He finds that the aleurone grains of the peony are readily soluble in distilled water, but contain myosin-globulin only, and apparently no vitellin-globulin; but hemialbumose, a substance allied to the peptones, is present in considerable quantity. In the seeds of the castor oil plant, the grains are composed, like those of the lupin, of both globulins and of hemialbumose, and enclose a crystalloid of proteid substance and a globoid which consists of inorganic matter. These crystalloids in the aleurone grains of *Linum usitatissimum* are similar to those of *Ricinus communis*, in being slowly soluble in a 10 per cent. solution, and readily soluble in a 20 per cent. solution of chloride of sodium after treatment with alcohol. The author believes that the caseins which Ritthausen has extracted from various seeds consist largely of precipitated hemialbumose.

An interesting experiment upon the fixity of chemical composition of the ash of plants has been made by Mr. H. Pellet (*Chem. News*, June 18, p. 283). He found that specimens of *Soja hispida*, grown in China, Hungary and France, yielded phosphoric acid and potash with very little variation in quantity, these constituting three-fourths of the ash. The proportion of soda, lime and magnesia was, however, more subject to variation. In other experiments made with the potato he finds that there is a great difference in the proportions of the chief alkalies, but that there is equivalent substitution of one for another, so that the proportion of sulphuric acid remains the same.

In the *Bulletin Mensuel de la Soc. Linnéene de Paris* (No. 32, p. 256), Professor Baillon describes a new Strychnos from French Guiana, which he believes likely to be a curari plant. He has named it after its discoverer, *Strychnos Melinoniana*. It differs from other allied species in being erect and not climbing, in having short and rigid opposite branches, and in having no trace of hooked spines. The leaves are lanceolate, smooth and leathery. The young ovary is two-celled and has many ovules; but the baccate fruit differs from that of nux vomica in being oval instead of round; it is not larger than an olive and usually contains only one seed, which is more elliptical than that of nux vomica.

The report comes from Uruguay of a new potato which possesses the great advantage of preferring a low and moist soil. It is well known that the potato is a native of a remarkably dry region, and that it therefore is under unnatural conditions of life in a damp soil. But the new potato flourishes well in marshy ground near rivers, and much land hitherto of comparatively little use for other purposes may now be turned to profitable account by the introduction of this new vegetable. A favourable account of this plant (which seems not yet to have received a botanical name) has been published in the *Bulletin Mensuel de la Société d'Acclimatisation*, May, p. 127.

Some years ago an attempt was made to introduce eucalyptus trees in the Campagna of Rome, and it was anticipated that by the growth of these trees a considerably beneficial influence would be exercised upon the climate of that district. A recent correspondent of the *British Medical Journal*, writing from Rome, gives a very unfavourable account of the result of this experiment. He states that in the majority of cases the young trees which had been planted in considerable numbers have been killed during the cold nights of the winter season, and in his opinion there is but little probability of rearing the eucalyptus in the Campagna to any such extent as could be hoped to produce a sensible effect upon the climate of that district. The account given by this writer is not without some indications that in describing the result of the attempted cultivation of the eucalyptus his wish was father to his opinion, since he seems to think that the peculiar character and charm of the Campagna would be destroyed by the introduction of trees.

Mr. C. Roberts has suggested, in the same journal (p. 949), that probably the seeds obtained by Prince Troubetskoi from plants cultivated in the south of France would yield hardier plants. The same writer also states that he has "found a soap containing the essential oil of *E. citriodora* a most soothing application in irritable skin diseases, and it is no doubt to a certain extent antiseptic, like thymol soap, with the additional advantage of possessing a pleasant perfume." A specimen of essential oil prepared from one of this genus (*E. citriodora?*) has been recently seen, the odour of which was scarcely distinguishable from citronelle.

Baron Mueller is now issuing an important work on the genus Eucalyptus, under the name of 'Eucalyptographia,' published in this country by Messrs. Trubner and Co., which is in fact a descriptive atlas of the species found in Australia and the adjoining islands. Great confusion exists as to the products of these trees, and Baron Mueller will do good service to the colonies in describing the distinctive characters of the various gums, oils, etc., and pointing out those which are likely to prove most important in the arts and medicine. In this work a table is given of the yield of essential oil by the different species which have been experimented on by Mr. J. Bosisto, from which it appears that the quantity obtained varies exceedingly in different species, *E. melliodora* yielding only 7 ounces from 1000 pounds of leaves and twigs, while *E. globulus*, *E. oleosa* and *E. amygdalina* give respectively 120, 200 and 500 ounces from the same quantity of plant.

In Japan, where natives suffer after inundations from a kind of fever unknown in Europe, over which quinine has no control, the cultivation of *Paulownia imperialis* in the infected districts is recommended, instead of that of eucalyptus, by E. Baelz and Kawakami (*Virchow's Archiv.*, Band. 78). This tree is said to possess many advantages over the eucalyptus.

In the *Lyons Médicale*, May 23, it is stated that Dr. Bouchard finds the administration of pure charcoal powder in typhoid fever very favourable, that it causes the fetid odour of the stools to disappear, prevents absorption of putrid matter, cleanses intestinal ulcers, and does not cause hæmorrhage or other accident. The dose given is a tablespoonful every three hours.

In the *Louisville Medical News*, May 1, Dr. Springer states that salicylic acid is readily soluble in effervescing Vichy or Seltzer water, the former, from containing an excess of alkaline carbonates, being preferable. The acid is put into a tumbler first and mixed thoroughly with a small quantity of water to prevent its floating, and the glass then filled with the effervescing water and the liquid drunk off. When perfectly dissolved it is said to have a very pleasant, exhilarating, pungent and sweetish taste.

The same journal takes exception to the orthography of the name salicylic, remarking that "nearly all writers, pharmaceutical and medical, put it salicylic, though such of them as know anything of language and terminology must know that it is wrong. We should like to know by what rule of orthography, analogy, reason or common sense the word salicilic is spelt with a 'y'? Is the genitive of salix salycis? Do we write silycic or silicic as the adjective of silix? With as much propriety we may say sulphuryc, muriatyc or nitryc." The writer of the above remarks is evidently unaware why the "y" occupies the position it does, and that the name salicylic is derived from the hypothetical radical salicyl and not from salix. Were it from the latter word it should be salicic, and not salicylic acid. He does not even seem to remember that the "y" in salicylic occurs in the third instead of the second and fourth syllable. There is a trite saying about letting well alone which might be worthy of the attention of the discoverer of this mare's nest.

In the *New York Medical Record*, May 1, attention is called by Dr. Andrew Smith to the oxalate of cerium as a remedy in certain forms of chronic cough, in doses of 10 grains three times a day, commencing with 5 grains. He found it to relieve nausea and improve digestion. He remarks that different samples met with in commerce are not equal in value.

Dr. Sawyer, of Birmingham, calls attention to the use of chloride of calcium (not chloride of lime, from the administration of which one of his patients has suffered) in phthisis. He gives 10 grains, dissolved in a drachm of water and a drachm of glycerine, with a wineglassful of milk, twice daily, immediately after meals. This substance has an old reputation for the cure of strumous glandular swellings.

A remedy which this gentleman introduced into notice some years ago, as a remedy for neuralgia, has lately been the subject of an editorial article in the *British Medical Journal* (June 5), under the name of *Gelseminum sempervirens*, which the writer of the paper adopts in preference to gelsemium, apparently in ignorance that the name gelseminum was given to the plant when it was supposed to be a true jasmine, an opinion which no botanist holds at the present day, nor indeed, has held since the time of Linnæus. Uniformity of name is always desirable, and the name gelseminum, which is that adopted in the United States Pharmacopœia and in Bentley and Trimen's standard work on 'Medicinal Plants,' has surely sufficient weight of authority on its side to secure its universal acceptance. In the same article no allusion is made to the statement of Sonnenschein that gelseminic acid is nothing else but æsculin.

Mr. J. T. Clover, in a lecture delivered at University College on May 19, and reported in the *British Medical Journal* of May 29, made the following remarks on ethidene chloride, which have some points of interest for those engaged in dispensing medicines:—"Ethidene chloride, as now found in the market, has not an uniform boiling point. It can be divided by fractional distillation into two or more substances. That which I have lately been using has a sp. gr. of 1·225 and boils at 115°, the temperature rising to 140°, at which it boils steadily and is nearly all dissipated. I am told there are greater difficulties in the way of procuring the dichloride now than last year, in consequence of the waste products in the manufacture of chloral, from which it was made, having been used up. At all events, the price has more than doubled within a year, and some of the samples I have examined have had a disagreeable after-odour. Hitherto it has nearly all been imported from Germany, but some of our English chemists are trying to make a purer drug, and I hope they will succeed. Ethidene dichloride mixes freely with alcohol, but only slightly with water, enough to flavour it only, but less than chloroform, which it resembles in taste and smell. It is less inflammable than alcohol. A piece of paper saturated with it does not readily take fire; but air passed through the liquid takes up a vapour which makes it burn at a jet like coal gas."

Mr. Clover has administered this anæsthetic to 1877 individuals with only one fatal case, which was complicated with heart disease. Occasionally, only, has he found it to cause alarming depression of the pulse.

The use of bromide of ethyl as an anæsthetic was discussed at a recent meeting of the Paris Société de Chirurgie, and the opinions expressed seemed to be in favour of its use for producing local anæsthesia only. M. Nicaise stated that he thought it was the only local anæsthetic which could be used concurrently with the actual cautery.

Herr E. Jahns, whilst examining some genuine oil of *Thymus Serpyllum*, has made the observation (*Arch. d. Pharm.*, xvi., 277) that the thymol in it was prevented from solidifying by the influence of another body belonging to the class of phenols until the temperature was depressed far below (—32° C.) that at which either of the bodies solidified. This property seems to be characteristic of the phenols, for a mixture of thymol and carbolic acid behaved similarly, remaining liquid at $-20°$. It will be remembered that some time since Mr. A. W. Gerrard reported (*Pharm. Journ.*, [3], viii., 646) that he had failed to obtain thymol from a commercial specimen of oil of thyme, and inferred therefore that the thymol had been removed from the oil before it had been sent into the market. Presuming that Mr. Gerrard was not working upon a factitious sample of oil, it may be that his failure to separate thymol finds a partial explanation in this influence which the phenols appear to exert in the mutual depression of their solidifying points.

According to C. Winkler (*Schw. Wochenschr. f. Pharm.*) pure hydriodic acid may be prepared by dissolving iodine in carbon bisulphide in a tall glass cylinder, adding water, which forms a distinct layer on the top, and passing through the iodine solution a current of sulphuretted hydrogen. The hydriodic acid formed is absorbed by the water, whilst the separated sulphur dissolves in the carbon bisulphide. The conversion is complete when the lower layer, originally violet, acquires a wine-yellow colour. The layers are then separated and the aqueous solution of hydriodic acid is boiled a few minutes to expel any sulphuretted hydrogen that may be present.

A new organic acid, to which the name of borocitric acid has been given, has been recently described by Herr Scheibe (*Pharm. Zeit. f. Russl.*, xviii., 25). It may be prepared by boiling together in water, with constant stirring, one part by weight of boracic acid and seven parts of citric acid until a clear solution is produced. The acids unite in the proportion of two molecules of citric and one of boracic acid, and upon evaporating an aqueous solution to dryness the borocitric acid is obtained as a greyish solid amorphous mass, easily soluble in water and strong alcohol. But it may also be obtained as a light snow-white crystalline mass by allowing a very concentrated solution to evaporate slowly. Borocitric acid forms with the alkalies salts that are soluble in water, but the salts of the heavy metals are only partially so. All the salts turn turmeric paper red-brown, similarly to boracic acid, and they are decomposed by the stronger acids with a separation of boracic acid.

The magnesia compound with this new acid has been alleged to exercise a solvent action upon stone in the bladder and to be useful in cases of vesical catarrh. But Professor Ludwig, of Vienna, who has carried out a series of experiments to test this statement, reports (*Wiener med. Blatt.*, 1880, No. 4) that he has obtained only negative results.

The synthesis of citric acid has at last been effected, by MM. Grimaux and Adam (*Comptes Rendus*, vol. xc., p. 1252). The steps of the process are briefly as follows:—Dichlorhydrin was prepared by means of glycerine and chloride of sulphur, and then oxidized by bichromate of potash and sulphuric acid. The resulting dichloracetone was purified by combination with bisulphite of sodium and heated in a water-bath with concentrated hydrocyanic acid. The cyanodichloracetone formed was not isolated, but treated with hydrochloric acid, then distilled in a vacuum and the product exhausted with ether. The ether upon evaporation left a thick syrup which after some days yielded a crystallization of dichloracetonic acid, differing from citric acid in containing two atoms of chlorine in the place of two groups of CO_2H. This by saturation with soda and heating with two molecules of potassium cyanide in concentrated solution was converted into dicyanacetonate of soda. The liquor was then saturated with gaseous hydrochloric acid gas, heated in a water-bath and distilled in a vacuum. From the residue the citric acid was obtained as a lime salt by treatment with milk of lime. The lime salt and the citric acid obtained from it are said to have presented characters agreeing entirely with those of the natural products. But the acid is represented as crystallizing with two molecules of water.

In a paper in the *Bulletin* of the Bordeaux Pharmaceutical Society for April M. Carles calls attention to the inconvenience sometimes resulting from the presence of lime in sugar. His attention was directed to the subject by having submitted to him specimens of chocolate that when boiled with water formed an abnormally thick liquid, and when boiled with milk caused it to curdle. The presence in the ash of a considerable quantity of carbonate of lime induced the suspicion that the peculiar reaction might be due to sucrate of lime derived from an imperfectly refined sugar used in the manufacture of the chocolate. Experiments were therefore made with a mixture of sucrate of lime and a pure sugar which showed that always when the sugar contained an excess of lime it had the property of curdling milk similarly to acids, but coloured the serum yellow. This observation is of some hygienic and industrial importance and is also confirmatory of opinions that have been expressed by more than one observer as to the noxious influence that imperfectly refined sugars may exercise upon certain pharmaceutical preparations, such as powders containing calomel, syrups of the phosphates, etc.

In the same journal M. Carles recommends the use of carbonate of ammonia as an effective means of cleansing the worms of stills. The carbonate of ammonia is mixed with water in the still and being slowly carried over in the gaseous condition with the vapour of water during distillation it penetrates to every part of the apparatus, attacking resins, fatty bodies, sulphuretted products, etc., and after about an hour only a perfectly inodorous limpid water flows from the worm.

Lecturers on chemistry may be glad to know that Dr. T. Schurhardt, of Goerlitz, has succeeded in preparing metallic potassium in fine large octahedra, 1–11 centimetres long; also metallic sodium in smaller crystals, and metallic chromium in small regular octahedra. The specimens are preserved in hermetically sealed tubes in an atmosphere of hydrogen.

It is announced in *Nature*, May 27, p. 87, that Dr. Dodel Port, of Zurich, has just issued two parts of a new botanical work that promises to be of considerable interest, called 'Illustrirtes Pflanzen Leben.' In part I. the lower fungi are described in a popular manner, and it includes illustrations of the form, size, and mode of propagation, and points out the danger arising to the human race from these minute organisms. The question of potable water is becoming an important one at the present day, and the only question that suggests itself is, that if a knowledge of these organisms is popularized, whether people will not give up water altogether as a drink, and take other more harmful liquids as a substitute.

How would the authorities on potable waters class the one which gave rise to the following observation, chronicled in *El Siglo Medico* of Madrid? The excessive dryness of the summer of 1877 caused the inhabitants of a certain village to use the water of a spring for which a colony of leeches also had a predilection; the result was a perfect epidemic of implantation of the annelids in the palates and throats of the villagers. In most cases these were easily removed by the use of vinegar, salt, tobacco, and other means. But in one the leech lay beyond the reach of these remedies, and the patient, a strong woman of forty, was so reduced by loss of blood that after tracheotomy had been thought of and abandoned it was decided to try the effect of various insecticides. Fragments of sulphur were accordingly thrown upon burning coals and the patient was placed so as to be compelled to breath the sulphurous vapour. After two or three inspirations a cough was provoked which brought up a large leech more dead than alive. The same remedy was afterwards frequently employed successfully, and one young man is said to have been relieved from an objectionable quantity of this form of albumenoid ammonia that had fastened upon his œsophagus, the inhalations of sulphur being caused to pass downwards to the stomach without creating any inconvenience.

In the Botanical Gardens at Regent's Park a new jelly fish, about half an inch in diameter, was discovered on June 10 by Mr. W. Sowerby, which has created no small stir among the zoological celebrities of the metropolis. It has already received two names, one from Professor Allmann and the other from Professor Ray Lankester, and has formed the subject of two papers, one at the Royal and the other at the Linnean Society. Hitherto no jelly fish has been found in fresh water, and therefore the discovery of this species is the more remarkable. Professor Lankester concludes that it is a tropical species, as it is active only at a temperature of 90° F., becoming sluggish at 60° F. It comes nearest to a Brazilian species, and one might therefore suspect that it came originally with the *Victoria regia*. As the tank is cleared out every year, and this water lily has been grown for several years from seeds ripened at the gardens, it seems singular that the animal should not have been observed before if such were its source. Professor Lankester thinks it may have been introduced from the West Indies.

At the meeting of the Academy of Sciences on the 24th of May a communication from M. Mouchut was read stating that he has definitely succeeded in his experiment in the industrial utilization of solar heat in Algeria. With mirrors of 0·80 m. he is able to carry on operations requiring not more than 400 to 500° C. of temperature, and he mentions among those that have been successful the fusion and calcination of alum, the preparation of benzoic acid, the purification of linseed oil, the concentration of syrups, the sublimation of sulphur, the distillation of sulphuric acid and the carbonization of wood. With his largest solar apparatus, in which the mirror has an insolation surface of 3·80 m., M. Mouchut distilled, even in mid-winter, on the 24th of December, 25 litres ($5\frac{1}{4}$ gallons) of wine in ninety-five minutes with a yield of 4 litres of eau-de-vie. Small alembics have also been perfected that can be used in the distillation of essential oils. But perhaps the most important success is the mechanical utilization of the solar heat in the driving of a horizontal engine under a pressure of $3\frac{1}{2}$ atmospheres. This result is said to be obtained constantly from 8 o'clock in the morning until 4 o'clock in the afternoon, and is not modified sensibly either by the strongest winds or passing clouds.

When Mr. Crookes delivered his celebrated lecture upon Radiant Matter, it became evident that his interpretation of the results of his investigation pointed to the existence of matter in a form that had not hitherto been recognized. He has now definitely put forward this theory, and in reply to a challenge from Dr. De la Rue has enunciated, in a letter addressed to the President of the Royal Society and read at the meeting on the 10th inst., his arguments in favour of there being "a fourth or ultra-gaseous state of matter." Curiously enough his arguments after all point rather to the paradoxical conclusion that matter—in the ordinary acceptation of the term—is not matter at all, but that all the so-called "forms" of it are really forms of motion, true matter being intangible, invisible, and possibly inconceivable. This is not altogether a new position, and, in fact, when Mr. Punch replied some time ago to the question "What is matter?" with the answer "No matter," he was only anticipating Mr. Crookes's conclusions. A brief epitome of the letter will be sufficient to justify this statement. True matter, according to Mr. Crookes, consists of individual disconnected molecules, built up of atoms and governed by the opposing forces of attraction and motion. In solids these molecules are separated by spaces, which are large relatively to their diameters, but nevertheless still so small that the force of attraction is preponderant, so that it prevents the molecules from travelling about irregularly and gives them cohesion and fixity of position about their centres of oscillation. In liquids the force of cohesion is relatively very much reduced, and the centres of oscillation have no fixity of position. When liquids are heated the force of motion preponderates as the temperature rises until at last cohesion is broken down, and, released from control, the molecules fly off into space with inconceivable velocity and in every conceivable direction, and then constitute gaseous matter. In this state, with enormous numbers of molecules still crowded together into a given space, collisions are infinitely numerous, and the mean free path of the molecules is exceedingly small as compared with the dimensions of a containing vessel. The gaseous state is therefore pre-eminently a state dependent on collisions. But when by great rarefaction the chance of collision is nearly extinguished and the free path of the molecules can consequently become so long as to be comparable to the dimensions of the containing vessel, or when by some extraneous force the molecules are reduced to order and coerced into a methodical rectilinear movement—akin to what takes place in the polarization of light—the molecules then, in Mr. Crookes's opinion, assume the fourth condition of "radiant matter." It therefore follows that what Mr. Crookes says of solidity may be said of liquidity, gaseity, and the radiant state, that they are merely the effect on our senses of the motion of the discrete molecules among themselves. If this inter-molecular movement were to stop, matter as known to us would cease to be, though the molecules might remain; but of their nature as little is known as of that of the interspaces through which they are supposed to travel.

The introduction of new remedial agents will necessarily create fresh difficulties for the dispenser, and in doing so will tax his resources to the utmost, and the same will equally apply to old remedies exhibited under a new aspect. These instances are not by any means rare. There is one striking illustration in the resuscitation of that very old and long disused drug, Chian turpentine. The pharmacy of this substance either alone or combined with sulphur, has brought forth numerous letters from advocates of the several modes of combining Chian turpentine to form an emulsion, presentable, and at the same time palatable, in fact, a suitable method of administering this very scarce, and consequently very valuable drug. Happy must that pharmacist feel, who, with a veneration for old pots and their contents, has preserved his genuine Chian turpentine for the benefit of suffering humanity and a considerable advance on its normal cost.

The question of extemporaneous pill coating has often occurred in these columns, and the apparatus for that purpose shown at the Exhibition and illustrated in the Journal may be studied with advantage by dispensers. Those appliances, if not perfect, may at least be considered a step in the right direction and an advance towards a solution of those difficulties which have hitherto presented themselves in connection with this subject.

The first prescription demanding notice is that of No. 412, where a mixture is prescribed with very clear directions in English, "two teaspoonfuls every six hours." The writer asks if that was the dose the physician intended the patient to take. It must be assumed that the physician did intend the patient to take just that quantity at each dose which he has ordered, and the dispenser must direct the medicine accordingly. The dose, if for an adult, is smaller than that usually prescribed, but if an error it is one in the right direction, that is, of the smaller dose. At the same time it may very properly create a doubt; but, unless the prescription can be referred to the writer, there is no alternative but to give the directions as written.

In reply to question No. 413, it may be stated that had a simple solution of morph. acet. been as suitable for hypodermic injection as the solution made according to the B.P. process, that formula would, in all probability, never have found its way into the Pharmacopœia. Mr. Baldock says that he has supplied it to a local physician, taking care that the solution is perfectly neutral. This is an important proviso, and requires careful attention. With this precaution the one may, in some instances, answer as well as the other, and may suit the requirements of one practitioner; but for the prescriptions of the medical profession generally such a deviation is not safe, and consequently not one that could be recommended for adoption.

The emulsion made from prescription No. 414 is not a perfect one; with mucil. of tragacanth, the result is not satisfactory. This mucilage is useful when the object is merely suspension, but when an emulsion is required it is not so suitable for the purpose as mucil. acaciæ. Tragacanth is not dissolved in water, but swells and is diffused, differing in this respect from gum arabic, the better qualities of which dissolve and make perfect emulsions with oil and other similar substances. The partially emulsified mixture very soon separates and presents an inelegant appearance, which may be obviated by the substitution of mucilage of acacia for that of tragacanth.

In prescription No. 415, the question is asked, should the "Oj" be dispensed as ℥xx or ℥xvi. A reference to the appendix of the B.P. will decide the question. Under "measures of capacity" the following will be found "1 pint O=20 ounces." In the *Pharmaceutical Journal*, February 22, 1879, p. 706, No. 264, the same question is found, and replied to in "The Month," of March 29, p. 797. It is there stated that physicians frequently write Oss. when they intend the mixture to be 8 ounces; but when nothing is known to the contrary the octarium should be dispensed as 20 ounces.

The combination of carbolic acid with an excipient so as to form pills has on previous occasions been referred to, but in those instances there were other ingredients besides the carbolic acid. In No. 416 the carbolic acid is alone, with pulv. acaciæ as an excipient. The carbolic acid of the Pharmacopœia is described as being crystalline; this carbolic acid, therefore, should always be used. Pulv. acaciæ is not a suitable excipient; but if ordinary wheaten flour be substituted, the 2 grains of carbolic acid with 1½ grain of flour can be formed into a firm solid pill, requiring careful manipulation, but giving a satisfactory result, and there being no addition to the ingredients of the prescription the pills are not larger than is absolutely necessary. When, therefore, carbolic acid is ordered in a pill it must be used in a solid condition, and as an excipient wheaten flour in about the proportion of three-quarter grain to every grain of the acid.

The mixture, No. 417, may be dispensed as indicated by Mr. Baldock. It varies in colour from a light grey to a chocolate, depending much on the condition of the tinct. guaiac. ammon. The mixture is a very satisfactory one with little tendency to separation.

In combining the ingredients of No. 418 there is a deposit, and probably it is that which Mr. Baldock says is also due to the cause stated by him, an insufficient quantity of acid. That change will take place if the ingredients be in those proportions, but a few drops of acid. hydroch. dil. will either prevent the deposit, or dissolve it when formed. When an opportunity offers that addition may be suggested to the writer, who will probably be unaware how unsightly the mixture is when made in strict adherence to his formula.

R. F. wishes, in No. 419, "to learn of a method of dispensing ol. sant. flav. so that it shall be tasteless."

So desirable a result has never been published; should he succeed, however, in discovering such a method, many others will be glad to know the process through the medium of this Journal.

In No. 420, F. G. requires the best mode of dispensing a pill of ferri sulph. and camphor with a few drops of oil of cinnamon. The glycerine of tragacanth has been so often recommended as a good general excipient, and a very special one for ferri sulph. and camphor, that it should not be necessary to repeat it in this instance. There is no excipient so generally useful as glycerine of tragacanth, for which a formula has been given in the earlier pages of this Journal, and it will combine many ingredients that with most other excipients are perfectly intractable.

Solutions of zinci chlor., B.P., are generally a little opaque. Zinci chlor. is described in the B.P. as being "almost entirely soluble in water." Flückiger, in his 'Pharm. Chemie,' gives the composition of the precipitate as $ZnCl_2$, 9 ZnO, 3 H_2O, an oxychloride of zinc soluble in hydrochloric acid. It should not be filtered, but there is no necessity to use a "Shake the bottle" label.

With regard to prescription No. 422, the question is asked how it should be dispensed. The difficulty that presents itself is with the Latin. This subject was explained in "The Month," June 28, 1879, p. 1058, No. 304, and it is only necessary here to refer "Bdfrd" to that number.

The dispenser, in No. 423, was not justified in adding sacch. lactis to the hydrarg. c. cretâ. With efficient dispensing scales, which demand more care and better treatment at the dispensing counter than they generally get, and which a dispenser should take pride in keeping in good condition, there would be little or no difficulty in weighing these powders without the addition of anything extra to the prescription. Now that the Weights and Measures Act is in force, pharmacists should look well to their scales and weights equally with their measures on the dispensing counter. Even with average care the former soon get out of order, but in careless hands the transition is very rapid; whilst the measures, which are not given to change, in too many instances were never more than an approximation to average correctness.

THE DIGESTIVE FERMENTS, AND THE PREPARATION AND USE OF ARTIFICIALLY DIGESTED FOOD.*

BY WILLIAM ROBERTS, M.D., F.R.C.P., F.R.S.

Lecture III.

(*Concluded from p.* 1000.)

Peptonized Gruel.—Gruel may be prepared from any of the numerous farinaceous articles which are in common use—wheaten flour, oatmeal, arrowroot, sago, pearl barley, pea or lentil flour. The gruel should be very well boiled and made thick and strong. It is then poured into a covered jug and allowed to cool to a temperature of about 140° F. Liquor pancreaticus is then added in the proportion of a tablespoonful to the pint of gruel and the jug is kept warm under a cosey, as before. At the end of a couple of hours the product is boiled and finally strained. The action of pancreatic extract on gruel is twofold: the starch of the meal is converted into sugar and the albuminoid matters are peptonized. The conversion of the starch causes the gruel, however thick it may have been at starting, to become quite thin and watery. The bitter flavour does not appear to be developed in the pancreatic digestion of vegetable proteids, and peptonized gruels are quite devoid of any unpleasant taste. It is difficult to say to what extent the proteids are peptonized in the process of digestion by pancreatic extract. The product, when filtered, gives an abundant reaction of peptone; but there is a considerable amount left of undissolved material. Most of this, no doubt, consists of insoluble vegetable tissue, but it also contains some unliberated amylaceous and albuminous matter. Peptonized gruel is not generally, by itself, an acceptable food for invalids, but in conjunction with peptonized milk (peptonized milk gruel), or as a basis for peptonized soups, jellies and blanc-manges it is likely to prove valuable.

Peptonized Milk Gruel.—This is the preparation of which I have had the most experience in the treatment of the sick and with which I have obtained the most satisfactory results. It may be regarded as an artificially digested bread and milk and as forming by itself a complete and highly nutritious food for weak digestions. It is very readily made and does not require the thermometer. First a good thick gruel is prepared from any of the farinaceous articles above mentioned. The gruel, while still boiling hot, is added to an equal quantity of cold milk. The mixture will have a temperature of about 125° F. (52° C.). To each pint (550 cubic centimetres) of this mixture two or three teaspoonfuls of liquor pancreaticus and twenty grains of bicarbonate of soda are added. It is then kept warm in a covered jug under a "cosey" for a couple of hours and then boiled for a few minutes and strained. The bitterness of the digested milk is almost completely covered in the peptonized milk-gruel, and invalids take this compound, if not with relish, without the least objection.

Peptonized Soups, Jellies and Blanc-manges.—I have sought to give variety to peptonized dishes by preparing soups, jellies and blanc-manges containing peptonized aliments. In this endeavour I have been assisted by a member of my family, who has succeeded beyond my expectations. She has been able to place on my table soups, jellies and blanc-manges containing a large amount of digested starch and digested proteids, possessing excellent flavour, and which the most delicate palate could not accuse of having been tampered with. Soups were prepared in two ways. The first way was to add what cooks call "stock" to an equal quantity of peptonized gruel or peptonized milk gruel. A second and better way was to use peptonized gruel, which is quite thin and watery, instead of simple water, for the purpose of extracting shins of beef and other materials employed for the preparation of soup. Jellies were prepared simply by adding the due quantity of gelatine or isinglass to hot peptonized gruel and flavouring the mixture according to taste. Blanc-manges were made by treating peptonized milk in the same way and then adding cream. In preparing all these dishes it is absolutely necessary to complete the operation of peptonizing the gruel or the milk, even to the final boiling, before adding the stiffening ingredient. For if pancreatic extract be allowed to act on the gelatin the gelatin itself undergoes a process of digestion and its power of setting on cooling is utterly abolished.

Peptonized Beef Tea.—Half a pound of finely minced lean beef is mixed with a pint of water and 20 grains of bicarbonate of soda. This is simmered for an hour and a half. When it has cooled down to about 140° F. (60° C.) a tablespoonful of the liquor pancreaticus is added. The mixture is then kept warm under a "cosey" for two hours and occasionally shaken. At the end of this time the liquid portions are decanted and boiled for five minutes. Beef tea prepared in this way is rich in peptone. It contains about 4·5 per cent. of organic

* The Lumleian Lectures, delivered before the Royal College of Physicians.

residue, of which more than three-fourths consist of peptone, so that its nutritive value in regard to nitrogenized materials is about equivalent to that of milk. When seasoned with salt it is scarcely distinguishable in taste from ordinary beef tea.

The extreme solubility of digested products, whether of starch or of proteids, detracts from their acceptability to the healthy. To them they appear thin and watery; they miss the sense of substance and solidity which is characteristic of their ordinary food. But to the weak invalid, without appetite, this sense of substance or thickening is generally an objection, and they take with more ease an aliment which they can drink like water. The jellies and blanc-manges, on the other hand, give to invalids of more power that sense of resistance and solidity which is desired by those of stronger appetite.

Nutritive Value of Peptonized Food.

At the outset of this inquiry we are met with the question, Is it certain that the ultimate products of digestion are of equal nutritive value to the mixed transitional products which are produced in succession, and probably absorbed as the food is gradually transformed in the alimentary canal. In other words, are maltose and peptones alone as valuable to the economy as a mixture of these substances with the several dextrines and hemipeptones which are presented to the absorbent surfaces in the course of natural digestion?

With regard to the products of starch digestion, no direct experiments have been made on the nutritive value of maltose, and we can do little more than conjecture that the intermediate dextrines have an usefulness of their own. That they are absorbed seems proved (as might have been expected from their known diffusibility), for they have been detected in the blood, and especially in the blood of the portal vein.

With regard to peptones, we have more information. It was naturally assumed by the earlier observers, who identified peptone as the chief ultimate product of digestion, that this was the form under which proteids were taken up by the absorbents and introduced into the blood for the nutrition of the tissues. But, ten years ago, doubts were cast on this conclusion. It was alleged by Brücke and Voit that the nutrition of the tissues was maintained, not by peptone, which was unfitted for this purpose, but by soluble albumen, which was absorbed in the undigested state from the *primæ viæ*; and that the office of peptone was a subordinate one, resembling that of gelatin, and consisted in aiding to preserve the tissue-albumen from too rapid destruction. Direct observations on the nutritive value of peptones have, however, shown this paradoxical view to be untenable. As the point is one of importance, I will endeavour to lay before you the proofs which have been already adduced of the food value of peptones, and I will supplement these by some observations by myself.

P. Plosz (Pflüger's *Archiv für die ges. Physiologie*, 1874, p. 323) was the first to put this question to the test of direct experiment. He fed a puppy dog weighing 1302 grams with an artificial compound made of fat and sugar, in imitation of milk, but in which the casein was replaced by artificially digested fibrin. In the course of eighteen days of this diet, the dog grew and increased 501 grams in weight.

R. Maly (*Ibid.*, p. 585) performed a similar experiment on a pigeon. He first fed the pigeon for several days on a regulated quantity of wheat, until he had ascertained the quantity requisite to keep the bird in a state of nutritive equilibrium, in which it neither gained nor lost weight. He then made an artificial corn from starch, fat, gum, salts and water, but in which the gluten was replaced by fibrin-peptone, and fed the pigeon on the same quantity of this artificial corn as he had before given of the natural corn. Under this novel diet, the bird, after a short apprenticeship, not only maintained its weight, but actually put on flesh. This experiment seemed to show that peptone was even superior to natural gluten as a nutriment.

It was, however, objected to these experiments that they did not rigorously prove that peptone could build up the tissues, inasmuch as the increase of weight might have been due to an excessive accumulation of fat or of water, and that there might have been not an increase, but a decrease of the structural elements which contained nitrogen.

To meet these objections, Plosz and Györgyai (Pflüger's *Archiv*, Band x., 1875, p. 536) instituted a third set of experiments on a dog weighing 2753 grams. He was first brought down by a diet of simple water to a weight of 2531 grams. He was then fed on a mixture composed of sugar, starch and fat, and containing, in addition, 5 per cent. of purified peptone. Of this mixture, about 400 grams were daily administered to the animal for a period of six days In these six days, the dog took in with his food 14·45 grams of nitrogen; but the total of the nitrogen excreted by the urine and fæces only amounted to 13·46 grams, so that nearly 1 gram of nitrogen had been retained in the body of the animal, which had increased in weight 259 grams. This experiment went to prove that peptone served to repair the wear and tear of the nitrogenized structural elements, and even contributed something to the increase of weight.

Adamkiewicz (*Natur und Nahrwerth des Peptons*, Berlin, 1877), by a still more rigorous method, in a laborious series of experiments on a dog which was fed on a diet wherein the only possible source of nitrogen was peptone prepared from blood-fibrin, arrived at the conclusion that peptone supplied nitrogen to the solid tissues, and that it possessed a nutritive value equal to albumen, or even slightly superior; and that, therefore, it could not be looked on as a bye-product of digestion, but as the chief resultant of the transformation of proteids in the alimentary canal.

The experiments above cited seem sufficient to settle definitely the question raised by Brücke and Voit, and to establish the nutritive value of peptone as a source of nitrogen to the tissues. It seemed, however, desirable to obtain direct proof of the nutritive value of peptonized milk, as compared with the natural article. My observations led me to the conclusion that it was far easier to get a supply of peptonized aliment suitable for invalids by the artificial digestion of milk by pancreatic extract, than by any other method; but, in so important a matter as the feeding of invalids, inference and conjecture seemed hardly a sufficient basis for actual practice.

The questions I proposed to myself were: 1. Is artificially digested or peptonized milk alone sufficient to sustain nutrition? and 2. Is it as efficient in this respect as natural milk? For the purpose of answering these questions, I procured four kittens, of the same brood, eight weeks old. Kittens at this age thrive perfectly on an exclusively milk diet. Two of the kittens were fed on natural milk, and the two others on milk previously digested by pancreatic extract. The digestion of the milk in the latter case was carried out to full completion—that is to say, until the milk became greyish and bitter, and no longer gave any precipitate with acetic acid, nor even with nitric acid. The animals were permitted to have as much of their respective foods as they could consume. The experiment was continued for a period of twenty days. The quantity consumed by each pair was as nearly as possible the same. All four continued in perfect health, and took their nutriment greedily. I was surprised to find that the pair fed on peptonized milk showed no repugnance to the bitter taste of their food, but appeared to relish it quite as well as their companions did their natural milk. The following table exhibits the gain in weight at the end of twenty days by each of the four kittens. The weights are given in grams, and in round numbers.

Diet.		Initial weight.	Weight at the end of 20 days.	Increase of weight.	Increase of weight percent.
Natural milk. .		No. 1—338	514	176	52
		„ 2—558	838	280	50
Fully peptonized milk		„ 3—403	626	223	55
		„ 4—371	562	188	50

The table shows that the percentage increase of weight was very nearly alike in all four animals. No difference could be perceived in the sleekness of their coats, nor in the vivacity of their gambols. The experiment proves that peptonizing the milk in no degree spoils its nutritive value. It also shows, as might have been expected, that in healthy animals, with abundance of digestive power, there is no advantage to be gained from the administration of food in a predigested state. The quantity of food which is taken and absorbed appears to be regulated not so much by the quantity which can be digested as by the quantity which can be assimilated. This experiment had an interesting sequel. After Nos. 3 and 4 had been fed on *fully* peptonized milk for a period of twenty days, they were fed for a period of ten days on *partially* peptonized milk. By using a less quantity of the pancreatic extract in proportion to the milk, and by allowing the process of artificial digestion to go on for not more than half the time allowed in the previous experiments, only a partial conversion of the casein was effected. As nearly as I could judge by the precipitate caused with acetic acid, the casein was digested to about the extent of one-half. In these circumstances, I certainly expected that Nos. 3 and 4 would gain weight as before, and would continue to thrive as well as Nos. 1 and 2. It might have been anticipated that, in these new conditions, the proper digestive powers of Nos. 3 and 4 would come into play and complete with ease the unfinished work of the artificial process; but events did not pass exactly as I anticipated. The annexed table shows the actual results. The weights, as before, are given in grams.

Diet.	Initial Weight.	Weight on 3rd day.	Weight on 5th day.	Weight on 7th day.	Weight on 10th day.
Natural Milk .	No. 1—514	551	570	593	618
		gain 37	gain 19	gain 23	gain 25
	2—838	900	936	993	1063
		gain 62	gain 36	gain 57	gain 70
Half-peptonized milk .	3—626	693	687	681	693
		gain 67	loss 6	loss 6	gain 12
	4—562	645	638	648	683
		gain 83	loss 7	gain 10	gain 35

No interval was allowed to elapse between the two sets of experiments, so that the initial weights in the second set were the same as the terminal weights in the first set. The abrupt alteration in the diet of Nos. 3 and 4 produced a marked disturbance in their nutrition; but there was no declension in their general wellbeing, and they continued to take their modified diet with the same avidity as before. In the first three days, Nos 3 and 4 showed an unusual increase of weight—an increase quite out of proportion to that of their companions. Then came a check; in the next four days, they not only showed no gain, but showed even a slight loss of weight. In the last three days, they began to gain weight again, and were evidently recovering from the temporary check caused by their change of diet. The explanation of this series of events which has presented itself to my mind is the following; but I by no means wish to lay stress on its accuracy. It seemed as if the enforced rest imposed on the digestive organs for a period of twenty days, during the use of fully predigested food, had temporarily diminished their natural vigour, just in the same way as the disuse of a limb diminishes for a time the strength of its muscles. During this first period, immediately following the change of diet, the unemployed digestive powers were suddenly called upon to resume their wonted activity; but, owing to their enfeeblement from disuse, they were unable to respond to the call with due promptness, and undigested materials accumulated in the intestine. This accumulation accounted for the unusual increase in weight during the first period. During the next period, the digestive embarrassment made itself felt, and gave a check to the processes of growth and nutrition, and the animals ceased to grow and gain weight. During the last period, the temporary enfeeblement of the digestive organs was passing away, in proportion as renewed exercise was restoring them to their original vigour, and growth and increase of weight again commenced.

Whether this explanation be trustworthy or not, the lesson indicated by it is probably a true one; namely, that, except in extreme cases, when the digestive power is wholly lost or in complete abeyance, it is more advantageous to use a food which has been subjected to partial artificial digestion than a food in which the process has been carried out to completion. If the patient possess any digestive power at all, it is better that that power should be kept in exercise, than that it should be permitted to deteriorate still further from total disuse. This is in agreement with the rule we apply in other cases of enfeebled function, according to which we endeavour to combine partial rest with moderate exercise.

Clinical Experience of Peptonized Food.—The extreme difficulty of arriving at reliable conclusions in regard to the effect of therapeutical agents is well known to every sober-minded inquirer. The difficulty is not less, but probably greater, in judging of the effects of dietetic means. I have now had a considerable experience, extending over a period of two years, of the use by invalids of peptonized milk and peptonized milk-gruel; and it would be an easy task for me to recite a string of cases in which improvement and recovery followed the use of these articles of diet. But evidence of this sort would be wholly delusive unless checked by such an analysis of the circumstances of each case as would enable me to isolate the influence of the dietetic means. In the immense majority of cases, such an analysis would be obviously impossible; the conditions to be taken into account would be too numerous, and their relative influence too difficult to determine. In a question of this kind, one is obliged in a large degree to fall back on general impressions, and on deductions based on physiological considerations. Nevertheless, there are certain cases—most of them cases of incurable disease—in which the conditions are sufficiently simple to permit direct trustworthy conclusions to be drawn.

I found that peptonized milk-gruel was generally preferred, as being more agreeable to the palate, to simple peptonized milk; and by far the larger number of my observations were made with the former preparation. I was also soon satisfied that, with most rare exceptions, peptonized milk-gruel was perfectly acceptable to the invalid's stomach; and that a diet composed exclusively of this article could be used for many consecutive weeks without the slightest sign of failure of nutrition.

The cases in which the use of peptonized aliment appeared to produce the most striking benefits were those in which complete anorexia prevailed, and those in which the stomach was intolerant of food and immediately rejected every form of nutriment. A brief review of the results obtained in cases of this kind will, I think, prove instructive.

Uræmic Vomiting.—In advanced Bright's disease, incessant vomiting is sometimes a distressing and intract able symptom. In some cases of this class, I have seen the vomiting at once and permanently allayed by the use of peptonized milk-gruel. The downward course of the disease may not have been a moment checked; but the relief to the dying patient was great.

Gastric Catarrh.—That form of gastric catarrh which is the Nemesis of alcoholic excess often yields immediately to the use of peptonized food. In the later periods of cirrhosis, there frequently prevails severe intolerance of every kind of food—the stomach rejecting even beef tea and diluted milk in the smallest quantities. The relief afforded by the use of peptonized milk-gruel in some of these cases is most striking; the vomiting ceases almost from the first, and the intolerable sense of distension diminishes.

Crises of Cardiac Disease.—Persons suffering from cardiac dilatation and valvular incompetency usually encounter one or more crises which are susceptible of relief, before finally succumbing to their disorder. These crises are marked by a general venous stagnation, with severe congestion of the lungs, liver, and kidneys, and rapidly rising dropsy. Associated with these symptoms, there is generally almost complete inability to take food, and sleeplessness. In this condition, I have seen marked relief follow the use of peptonized aliment. I have long observed, as I doubt not have many of you, that the condition here described is often alleviated in the most striking manner by the use of exclusively liquid nourishment—such as milk or milk-gruel, given in small portions subcontinuously, or sippingly, as it were, throughout the waking hours; the patient being never permitted to take a distinct meal, nor a particle of solid food. As my practice has been to direct, in cases of this class, the administration of the peptonized aliment in this sipping fashion, the gratifying results noted have been partly due to the mode of administration; but I have been convinced by more than one example, when the same liquid nourishment in the natural and in the predigested condition has been used in succession, that there was a distinct superiority in the predigested article.

Pernicious Anæmia.—In the earlier periods of this singular disorder, I am inclined to hope that predigested aliment may prove a valuable resource. In cases where the aliment, although fully declared, was still of comparatively recent origin, I have in the last eighteen months seen the disorder checked under the use of peptonized milk-gruel. In one case, owing to the irritability of the stomach, the milk-gruel was at first administered *per rectum* with pancreatic extract, but was afterwards tolerated by the stomach. In three of these cases, the amelioration went on to complete restoration. In cases of longer standing, I have failed by the same means to obtain the slightest improvement.

Gastric Ulcer.—The use of an exclusively liquid nourishment, given subcontinuously in the manner before indicated, is a well-known and most efficacious mode of treatment in these cases; but, since adopting the plan of giving peptonized milk-gruel, I think I have perceived that the results were distinctly better than before, especially in cases associated with epigastric pain. The almost absolute rest procured by this food for the ailing organ appeared to be an additional advantage. I may be permitted to mention one case. The patient had suffered from copious and repeated hæmatemesis, and from severe epigastric pain. The irritability of the stomach was such that the simplest nourishment, given in the smallest quantities, was immediately rejected. Peptonized milk-gruel was, however, tolerated at once; vomiting only occurred two or three times during the first two days of the treatment, and then ceased, as did likewise the epigastric pain. This patient used no other food for a period of six weeks, and took daily from two to three quarts, with steady recovery of flesh and strength.

Pyloric and Intestinal Obstruction.—Peptonized aliment would appear to be especially suitable for use in these cases; but, so far, I have been somewhat disappointed in the results. The vomiting has generally been effectually controlled; but I have not been able to convince myself, in cases of pyloric stricture, that the fatal event was delayed even a single day. When the obstruction has been temporary, and due to a removable cause, the results have been, of course, more satisfactory.

I should be glad to see a further trial made of peptonized, or partially peptonized, milk in the gastric and intestinal catarrh of infants. In one severe case of this class, a favourable result was immediately obtained; in another case, there was greater tolerance of food, and more comfort after it, than with the use of simply diluted milk. It would be interesting, also, to have experience of the use of peptonized aliment in typhoid fever and in old age. The greater variety which can now be given to this form of food by the preparation of peptonized soups, jellies, and blanc-manges, will obviate the monotony sometimes complained of under the continuous use of peptonized milk-gruel.

The Use of Pancreatic Extract as an Addition to Food shortly before it is eaten.

The administration of pancreatic extract with or immediately after a meal can, I think, have only a limited utility. On entering the stomach, the pancreatic ferments encounter the acid of the gastric juice; and, when this rises above a certain point, the activity of the ferments is destroyed. Still a not inconsiderable interval of time must elapse before this point is reached; and during this interval the pancreatic ferments can accomplish a certain amount of work. I have repeatedly administered pancreatic extract in this way; but I am unable to say positively that I have seen benefit from this mode of administration. There is, however, a modification of this plan, which I have lately put in practice, that promises better results. It is to add the extract to the food fifteen or twenty minutes before it is eaten. Certain dishes commonly used by invalids—farinaceous gruels, milk, bread and milk, milk flavoured with tea or coffee or cocoa, and soups strengthened with farinaceous matters or with milk—are suitable for this mode of treatment. A teaspoonful or two of the liquor pancreaticus should be stirred up with the warm food as soon as it comes to table. And such is the activity of the preparation that, even as the invalid is engaged in eating—if he eat leisurely, as an invalid should do—a change comes over the contents of the cup or basin; the gruel becomes thinner; the milk alters a shade in colour, or perhaps curdles softly; and the pieces of bread soften. The transformation thus begun goes on for a time in the stomach; and one may believe that, before the gastric acid puts a stop to the process, the work of digestion is already far advanced.

This mode of administering pancreatic preparations is simple and convenient. No addition of alkali is required, and of course no final boiling. The only precaution to be observed is that the temperature of the food, when the extract is added, should not exceed 150° F. (65° C.). This point is very easily ascertained; for no liquid can be tolerated in the mouth, even when taken in sips, which has a temperature above 140° F. (60° C.). If, therefore, the food is sufficiently cool to be borne in the mouth, the extract may be added to it without any risk of injuring the activity of the ferments.

Pancreatic Extract as an Addition to Nutritive Enemata.—Pancreatic extract is peculiarly adapted for administration with nutritive enemata. The enema may be prepared in the usual way with milk-gruel and beef tea; and a dessert-spoonful of liquor pancreaticus should be added to it just before administration. In the warm temperature of the bowel, the ferments find a favourable medium for their action on the nutritive materials with which they are mixed; and there is no acid secretion to interfere with the completion of the digestive process.

I have now had some experience in this method of alimentation, and have been satisfied with its success. In one case, a patient suffering from postpharyngeal abscess which entirely occluded the œsophagus, was nourished exclusively for a period of three weeks (until the abscess broke) on enemata of milk-gruel mixed with pancreatic extract.

METHODS FOR THE QUANTITATIVE DETERMINATION OF THE ALKALOIDS IN PLANTS.*

BY A. LOESCH.

A. Methods for the Determination of the Solid Alkaloids.—1. The method of Stas, perfected later by Erdmann and Uslar, Dragendorff and others, and used for chemico-legal investigations, consists in extraction with water acidulated with hydrochloric acid, addition of ammonia to alkaline reaction, repeated extraction with continually renewed portions of ether, chloroform, amylic alcohol or benzole, separation of the watery liquid from the solution of the alkaloid, extraction of the latter by shaking with acidulated water, and repetition of the treatment, until the solution of the alkaloid is colourless. It is then evaporated in a weighed vessel, and the residue dried at 100—110° C. Instead of treating the plant with acidulated water, the author treated it with 99 per cent. alcohol, acidulated with hydrochloric, oxalic, tartaric, phosphoric or sulphuric acids, and evaporation and re-solution in water, before treating with ammonia, etc. By this means, the mucus, starch, gum and albuminoids remained undissolved in the residue from the extraction with alcohol. While this method affords the alkaloids in a very pure state, it is attended with a large loss, and is, in the presence of certain viscid substances and albuminoids, both difficult and tedious.

2. The method of Claus† for the estimation of theine and quinine. In the first case, the tea leaves are extracted with ether, the latter removed, for the most part, by distillation, and the residue extracted with water acidulated with sulphuric acid, until it no longer tastes bitter. The acid liquid is mixed with excess of burnt magnesia, evaporated to dryness in the water-bath, the residue pulverized and extracted with ether. In the determination of the quinine, the pulverized bark is thoroughly exhausted with water acidulated with sulphuric acid, the extract evaporated to dryness with excess of burnt magnesia, and extracted with ether. This method gives satisfactory results and can, without doubt, be employed in the quantitative determination of all other solid alkaloids; it does not, however, yield the alkaloids in a pure condition.

3. The methods of R. Wagner, Sonnenschein,‡ Husemann, Marmé and Schultz, are based on the precipitation of the alkaloids by iodine and potassium iodide, phosphomolybdic and phosphotungstic acids, or potassiomercuric iodide, from the extract obtained with acidulated water. The precipitates, according to their nature, are decomposed with barium hydrate, hydrogen sulphide, or a mixture of stannous chloride and caustic alkali, and warming, and the alkaloids dissolved out with ether. These methods are not only attended with a large loss, but yield impure products.

4. F. J. Mayer recommends titration with a standard solution of potassiomercuric iodide. This method gives inexact results, owing to the necessity of decolorizing the solution, and consequent loss of substance, and to the difficulty of determining the end of the titration.

The method of the author is as follows:—the cut, or coarsely powdered, vegetable substances are twice warmed for three hours in the water-bath, with 90 per cent. alcohol acidulated with hydrochloric acid, then pressed and washed with 90 per cent. alcohol. The volume of the collective alcoholic liquids is then reduced, by distillation, to two-thirds, the cold residue filtered, washed with alcohol, and the filtrate concentrated on the water-bath to the consistence of an extract. The residue is warmed with twice the weight of the original substance of water acidulated with sulphuric acid, cooled and filtered. The filtrate is mixed with thrice its volume of cold, saturated solution of alum, ammonia added in slight excess (*i.e.*, more than necessary to precipitate the alumina), evaporated to dryness on the water-bath, the residue pulverized, and exhausted with the solvent suited to the alkaloid to be extracted, *e.g.*, quinine is extracted with ether, and then cinchonidia with 90 per cent. alcohol. The residue from the leaves and roots of *Atropa belladonna*, from the leaves and seeds of *Hyoscyamus niger*, and the leaves of *Aconitum Napellus*, with ether; that from rad. ipecac., with 90 per cent. alcohol, etc. The ethereal or alcoholic solutions of the alkaloids are evaporated to dryness, dried at 110° C., and weighed. The alkaloids are thus obtained as perfectly colourless crystals, leaving no residue when heated on platinum foil. The results obtained by the author, with the foregoing methods, are given in the following table:—

Material.	Alkaloid.	Percentage Extracted. Method I.	II.	III.	IV.	Method of the Author.
Peruvian Bark, *yellow*	Quinine	2·735	3·175	2·460	2·570	3·250
	Cinchonidine	0·194	0·250	0·187	0·175	0·285
,, ,, *red*	Quinine	1·105	1·195	1·085	1·005	1·235
	Cinchonidine	0·425	0·500	0·400	0·395	0 525
,, ,, *brown*	Quinine	0·895	0·950	0·825	0·800	0·975
	Cinchonidine	2·485	2·975	2·350	2·300	3·075
Leaves of Hyoscyamine	Hyoscamine	0·099	0·145	0·085	0·074	0·175
Seeds of ,,		0·197	0·225	0·180	0·100	0·285
Leaves of Atropa belladonna	Atropine	0·115	0·197	0·100	0·090	0·235
Roots of Atropa belladonna		0·300	0·325	0·275	0·225	0·375
R. Ipecac	Emetine	0·720	0·800	0·550	0·475	0·875
Folia Aconiti	Aconitine	0·300	0·395	0·265	0·220	0·425

In the case of substances of unknown nature, the residue of the evaporation with ammonia and alum must be successively treated with the different solvents, *i.e.*, first with ether, then with chloroform, then with amylic alcohol, and finally, with 90 per cent. alcohol. It is by this means not only possible to extract the entire amount of alkaloids, but also to effect a separation of those of different solubilities in cases where more than one are present.

The special precautions for the successful conduct of the foregoing method are: 1. The alcohol must be completely expelled from the alcoholic extract, by evaporation on the water-bath. 2. Both the alcoholic and aqueous liquids must be filtered cold. The author finds, as the result of numerous experiments, that the best solvent for the alkaloids, in general, is amylic alcohol; then follow ether, chloroform and benzole, which latter, except in a few cases, dissolves the smallest quantity.

B. Methods for the Determination of the Liquid Alkaloids.—In the methods hitherto in use the vegetable substances are either distilled with potassium or calcium hydrates, the distillate saturated with hydrochloric acid, evaporated to dryness on the water-bath, and the residue distilled with potassium hydrate; or they are exhausted with acidulated water, the filtered liquid evaporated, and then distilled with potassium or calcium hydrate. As all plants contain not only ammonia, but nitrogenous substances which evolve ammonia when warmed with alkalies, the distillate, after neutralization with hydrochloric acid, is evaporated to dryness, and the residue exhausted with strong alcohol; the ammonium chloride remains undissolved, the alcoholic solution is evaporated to dryness, and the residue exhausted by shaking with solution of potassium hydrate and ether. The ethereal solution is then evaporated, at first at ordinary temperatures, and then over calcium chloride, or hydrate, to remove the moisture. In quantitative estimations, the clean ethereal solution is shaken with a measured volume

* *Pharm. Zeitschr. f. Russland*, 18, 545. Reprinted from the *Journal of the American Chemical Society*.

† *Vierteljahresschrift f. prakt. Pharm.*, 13, 414.

‡ *Zeitschr. f. anal. Chem.*, 4, 387.

of standard hydrochloric acid, the ether evaporated off at the lowest possible temperature, and the excess of acid determined by titration. The disadvantages of the foregoing method are: 1. Ammonium chloride is not absolutely insoluble in strong alcohol. 2. A certain proportion of the hydrochloric acid volatilizes with the ether, at temperatures even below 50° C. The error of the method is, therefore, one of excess.

The following method of the author permits an easy and exact determination of the liquid alkaloids:—

A weighed quantity of the substance is boiled out with water acidulated with hydrochloric acid, the residue pressed, and washed with water. The collective solutions are evaporated to one-quarter, and the residue distilled with calcium hydrate (under careful cooling of the distillate). The distillation is continued until the last portions of the distillate gave no alkaline reaction with sensitive litmus paper. Potassium and sodium hydrates cannot be used, owing to their destructive effects on the alkaloids. The colourless distillate is exactly neutralized with sulphuric acid, evaporated to dryness in the water-bath, the residue pulverized and exhausted with 90 per cent. alcohol. The ammonium sulphate remains entirely undissolved, the alkaloid sulphates pass into solution. The solution is evaporated to dryness, the residue shaken out three times with ether and solution of potassium hydrate, the ethereal solution treated with a measured quantity of standard sulphuric acid, the ether distilled off, and the excess of sulphuric acid determined in the residue by titration.

The following determinations of coniine and nicotine were made by the foregoing methods:—

KOUMYS.*

BY L. WOLFF, M.D.

A very interesting article in the *American Journal of Pharmacy*, 1874, p. 570, from the *Pharmaceutical Journal and Transactions*, gives a very excellent description of the koumys cure, and the preparation of koumys, as practised by the Tartars on their native steppes, but it leaves the distant pharmacist at this side of the Atlantic, where no Tartar mares nor mares' milk can be had, at a loss as to how to reproduce it in this country.

H. and N. Schultz, of Berlin (*American Journal of Pharmacy*, 1875, p. 68), direct an addition of sugar of milk to cows' milk, and its fermentation by brewers' yeast; anyone that has tried has probably succeeded as little in making koumys according to their directions as I have. Schwalbe, in the same article contributed by Dr. A. W. Miller, uses condensed milk, dissolved in water, to which he adds lactic acid and rum, puts it in a Liebig's bottle, and charges the whole with carbonic acid gas, and sets it in a warm room until fit for use.

In another article of the Journal, 1875, p. 261, the Russian method of fermenting mares' milk by a home-made yeast is quoted, while still another one, 1875, p. 83, from the *Allgem. Med. Centralzeitung*, 1874, p. 1108, recommends milk, grape sugar and fresh beer yeast to be fermented together at a temperature of 88° F. until fermentation has set in, when it is to be bottled, and shaken every fifteen minutes for the next forty-eight hours (not a very pleasant job).

In 1876 I formed the acquaintance of a Russian gentleman, visiting Philadelphia, who had made koumys in his native country, and together we experimented, but with very indefinite results, until we imported, at considerable expense, some of the original ferment from Russia, and with it prepared koumys, which certainly effervesced very much, had a rich, creamy appearance, did not coagulate in heavy curd, was slightly acidulated, but possessed a rank, acrid taste, which I attributed to the ferment, whose odour was certainly not very inviting. The consequence was that the koumys, which had been made at a considerable outlay, never enjoyed the reputation it ought to have acquired, and the costly ferment was gradually left to die out.

As the demand for it again increased, I was sorely puzzled how to make a koumys that would be all that is required of it, and that would possess all its virtues and properties. I tried in vain all the above-given methods, but invariably obtained sour milk with a heavy curd as a result, indifferently effervescing, while the taste was enough to cure any hankering the patient may have had after the coveted milk wine.

When considering the nature of koumys and its peculiar features, it appears evident that its properties must be largely due to the nutritious quality of the milk, along with the alcohol produced by the fermentation of its sugar, while its rich effervescence makes it readily digestible even to weak and enfeebled stomachs. The cause of success in its manufacture from mares' milk is undoubtedly due to the large amount of sugar of milk contained therein, which is 80 parts in 1000 to 40·37 in cows' milk; while the albuminates in the former are but 16·41 to 54·04 in the latter (Ranke's 'Physiology'), so that the object in view seems to be to increase the amount of sugar in the milk while decreasing the albuminates, should the latter be required.

As the sugar of milk when added to milk is not directly induced to fermentation by ordinary yeast fungi, I was soon led to substitute grape sugar for it, into which the former has to be changed before undergoing vinous fermentation, and which, though not in the same quantities, yields by fermentation the same results—carbonic acid gas and alcohol. But still while following the directions of some of the above quoted authorities, I found my koumys soon to curd and sour—a most unsightly article, whose acetous odour forbade its use.

As I was inspecting, one day, the fermenting rooms of one of our larger breweries, I was struck by the low, icy temperature maintained there, and on inquiry was informed that if the temperature were allowed to rise the fermentation would be sure to prove wild, signifying sour or acetous fermentation. This showed me at once the reasons of my former failures, and when I applied the principle involved to my own koumys, I had the satisfaction of drawing from my bottles a rich creamy, homogeneous liquid, slightly acidulated, foaming like the choicest soda water, of an agreeable taste, such as I exhibit here a specimen of, and some of which has been used by many physicians in their practices with excellent results, proving a sustaining nutriment which was readily borne by even the weakest stomachs.

In concluding, I give the formula employed by me, by which I am certain every pharmacist can produce a good and reliable article, at a reasonable cost, which, with a remedy consumed in such quantities as this, is of no small importance, and I have no doubt that nothing would bar even its dispensing as a beverage at our soda fountains.

Take of grape sugar ½ an ounce, dissolve in 4 ounces of water. In about 2 ounces of milk dissolve 20 grains of Fleischman's compressed yeast, obtained at any grocery store, or else well-washed and pressed out brewers' yeast. Mix the two in a quart champagne bottle, which is to be filled with good cows' milk to within 2 inches of the top; cork well, and secure the cork with strings or wire, and place in an ice chest or cellar at a temperature of 50° F., or less, and agitate three times a day. At the expiration of three to four days at the latest, the koumys is ready for use, and should not then be kept longer than four or five days.

It should be drawn with a champagne syphon tap, so that the carbonic acid gas may be retained and the contents will not entirely escape on opening the bottle.

* From the *American Journal of Pharmacy*, June, 1880.

The Pharmaceutical Journal.

SATURDAY, JUNE 26, 1880.

THE REVISION OF THE PHARMACOPŒIA.

To any one about to attempt a novel or difficult task it is always a great assistance to be able to look round upon the proceedings of other persons who have undertaken similar things, and thus to gain from their experience and example a knowledge of what is most desirable to be kept in mind for ensuring success. It is for this reason that we have often referred to the circumstances connected with the revision of the United States Pharmacopœia, as having in this sense a peculiar interest for British pharmacists now that there is growing up among them a desire to take an active part in the work of revising their own Pharmacopœia.

The reasons why the requisite periodical revision of a Pharmacopœia should be carried out under the guidance or, at least, with the assistance of the pharmacists' special knowledge and practical experience have been frequently stated in the pages of this Journal, and it has further been urged that since pharmacists are subject to the law of the Pharmacopœia, they ought, in accordance with modern principles of government, to have through the representatives of their order a considerable voice in the determination of what that law is to be.

Though pharmacopœias were originally framed by Colleges of Physicians, they were at that period intended rather to indicate the particular kinds of drugs and chemicals which were regarded by the medical profession as being the most important medicinal agents. In this respect their preparation came especially within the province of medical men, and in regard to such pharmaceutical skill as was required in carrying out the various operations of compounding according to formulæ, medical men were then proportionately so much more conversant with pharmacy than is now generally the case that there was little reason to object to their preponderating influence in the construction of pharmacopœias.

But of late the practice of pharmacy has become so far separated from medical practice, and such considerable advance has been made in the art of preparing medicinal remedies, that there is need for the co-operation of practical pharmacists with medical men in the work of revision to which pharmacopœias must necessarily be submitted from time to time.

In the United States of America the need of such joint action of both classes has always been recognized, and the most cordial relations have existed between medical men and practical pharmacists in regard to their respective functions in the revision of their Pharmacopœia. By mutual and voluntary consent this work is performed by representatives of incorporated medical and pharmaceutical colleges and societies, and now that the time for carrying out the decennial revision of the Pharmacopœia of that country has arrived we find the work being conducted by a Convention that has recently met at the National Medical College in the city of Washington.

Having regard to the views put forward at various times in this Journal, as to the propriety of giving pharmaceutical representatives a position of equality with medical men in the body entrusted with the duty of revising the British Pharmacopœia, and bearing in mind Mr. Hampson's motion to that effect at the Council meeting of the Pharmaceutical Society last December, we now propose to draw the attention of our readers to an account of the constitution and proceedings of the American Convention, as being likely to furnish suggestions as to the mode in which a similar course might be adopted in this country.

At the meeting held last month of the Sixth Decennial Convention the business was commenced by the nomination and election of Dr. James E. Morgan to act as Chairman, as being the only surviving officer of the Fifth Decennial Convention. After he had, on behalf of the medical profession and pharmacists of the district of Columbia, welcomed the attendants at the Convention, a Committee was constituted for the purpose of examining the credentials of the delegates who had been deputed to respond to the call of the Convention. The test of eligibility to act as a delegate in conducting the work of revision appears to have rested upon the fact of the institutions sending delegates to the Convention being incorporated bodies teaching medicine or pharmacy. If that were proved the several institutions were entitled to full representation. In regard to this point a question was raised as to whether the Pennsylvania College of Pharmacy was an incorporated body, and it was stated on the authority of the Secretary of the Commonwealth of Pennsylvania that there was no such incorporated institution other than the Philadelphia College of Pharmacy; subsequently, however, it was shown by Mr. Roche, the delegate from this College, that it did possess a charter, and though this charter was originally granted to a "College of Mines," it had been granted with authority to change the name of the College, a privilege which had been acted upon by making it a College of Pharmacy. In the discussion of a similar question as to the Philadelphia County Medical Society, Professor H. C. Wood remarked that the U. S. Pharmacopœia originated in the city of Philadelphia, and on behalf of the Society in question said that it wished to do all it could to make the Pharmacopœia as good as possible; that they were not assembled to subserve the interests of any individual institution, but rising above petty jealousies and sectional feelings, to do what, in their opinion, was best for the profession throughout the entire country, not to represent Philadelphia or any local institution, but to try and raise the Pharmacopœia out of the slough into which it had fallen. Hence, he urged that if any society of good standing sent delegates in accordance with the spirit of the call it was their duty to receive them, since he believed the profession of the United States would hold them responsible if they narrowed their representation by the exclusion of delegates who came in good faith. The question was then put to the vote and carried by a considerable majority.

A committee, consisting of one member from each of the bodies entitled to representation, and consisting in all of thirty-eight members, twelve of whom were pharmacists, was then appointed for the purpose of considering and deciding as to the general principles to be recommended for adoption in the revision of the Pharmacopœia.

Its first business was to elect a president and the officers of the Convention, Dr. ROBERT AMORY, of Brooklyn, Mass., being chosen as President, Dr. BUSEY, of Washington, and Professor BEDFORD as Vice-Presidents, Dr. CASTLE, of New York, as Secretary, and Dr. KLEINSCHMIDT as Assistant-Secretary.

In the report consequently presented at a later sitting of the Convention various recommendations were offered, of which the following is a brief *résumé*:—

That all measures of capacity should be abandoned and quantities expressed only in parts by weight.

That the text of the U.S. Pharmacopœia should be written in the English language; but that the titles of officinal substances and preparations should be given as heretofore both in Latin and English.

That the present division into materia medica and preparations be abolished, and all articles arranged in a continuous alphabetical order, retaining such headings as Extracta, Decocta, Infusa, etc., wherever it may be found useful to give general directions applying to the whole class, but making all formulæ for the preparation of the single members of each class complete in themselves.

That the different headings be accompanied by a list of synonyms in common use and in a manner not interfering with the perspicuity of the text of the formulæ.

That at the end of each article a short paragraph be added, giving the names of all the preparations into which the substance or preparation treated of in the article enters.

That concise but complete descriptions of all crude drugs be given, sufficient to indicate distinctive characters visible to the naked eye, or, when necessary, under a lens magnifying about ten diameters. Where such description is insufficient to characterize properly a substance it should be further defined by physical and chemical properties. Botanical names of plants to be accompanied by the name of the author, but all therapeutical discussion to be omitted. All minerals or chemical preparations to be described and defined by concise tests of identity and purity, without giving processes, except where differences in process produce different results. Processes for preparation of morphia, quinia, etc., to be omitted, but the articles opium and cinchona to be accompanied with detailed processes of assay for the respective alkaloids.

That chemicals of definite composition have their primary rational formulæ added, according to the old and new notation, and distinguished by different type, together with their atomic or molecular weights.

That in case of chemical preparations where different processes yield different results the process to be followed be described in detail.

That all tinctures, wines, etc., in which slight variation of dose is of no importance, be made as nearly as possible of a uniform percentage strength, viz., 1 part of the drug in 5 or 10 parts tincture, as the case may be. For highly active preparations, the present strength to be retained as nearly as possible, but in the liquid opium preparations, except paregoric, the strength of 10 per cent. be adopted if found advisable.

That the quantities or parts by weight of the ingredients of a composition be expressed in the simplest possible terms, and whenever possible in centesimal ratio.

That temperature be expressed in degrees Fahrenheit and Centigrade.

That varieties and degrees of colour, consistence, transparency, fineness of powders, etc., be defined as closely as possible.

That a uniform method of taking specific gravities of liquids be prescribed.

That whenever it is necessary to employ definite expressions of weight, as for instance, when a pill mass is to be divided into pills containing a certain weight of one or more ingredients, that weight be expressed in metrical as well as apothecaries' weight.

That in the formulæ (for syrups, infusions, elixirs, etc.) in which fixed quantities of ingredients are directed to be combined under circumstances involving possible partial loss of ingredients, the weight of the intended finished product be specified, and when practicable brought up to 100 parts, as, for instance, where a variable amount of water may be lost by evaporation.

That all doses be omitted from the Pharmacopœia.

That the following tables be appended to the Pharmacopœia:—a list of new additions; a list of articles dropped from the last Pharmacopœia; a list of changes of Latin officinal names; a list of changes of English officinal names; tables of weights and measures; table of solubilities of official chemicals in water and alcohol at 15·5° C. (=60° F.), and at the boiling points; an alcoholometric table; acidimetrical tables according to specific gravity: a list of reagents, qualitative, quantitative and volumetric, of fixed strength, with a brief statement of their use; a table of elementary substances, with symbols, atomicity, atomic weight, etc.; a weight and volume table; and, to facilitate the use of parts by weight in compounding, prescribing and dispensing, a table exhibiting the relationship between weight and measure of a given volume of any liquid preparation, and containing all officinal liquids in alphabetical order; a table of specific gravities of officinal liquids for each degree between 10° and 25° C.; a table comparing the strength of powerful galenical preparations of foreign pharmacopœias with those of the U. S. Pharmacopœia; a table exhibiting differences in strength of preparations made according to the present and the new U. S. Pharmacopœia; a table of thermometric equivalents; an index of all the synonyms, with marks of accent to indicate pronunciation; a table of saturations.

The Committee which made the foregoing report was also authorized to appoint a permanent committee of revision and publication, having power to provide for the publication of the new Pharmacopœia, to employ skilled experts to make such trials and investigations as may be necessary to enable the Committee to pass intelligent judgment upon the details of the work before it, to publish a supplement after five years, or oftener if deemed expedient, and to turn over to the future Convention of 1890 all the papers relating to its proceedings when the time arrives for making another decennial revision of the Pharmacopœia.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

Meeting of Executive Committee.

June 17, 1880.

Present—W. Southall, Esq., President; Messrs. Benger, Brady, Carteighe, Ekin and Greenish, and Professors Attfield, Bentley and Redwood.

The minutes of the previous meeting were read and confirmed. These included a discussion on the advantages and disadvantages of continuing to hold the annual meetings in the same town as that at which the meetings of the British Association were held, and practically at the same time. The following is a summary of the remarks on the subject made at that and at the present meeting.

Mr. Carteighe alluded to the difficulties experienced by local officers who were on the organizing committees of both bodies, the inconveniences felt by members of the two bodies on the Conference excursion day, and the frequent failures to get adequate hotel accommodation, especially by members of the Conference who did not wish to remain in a town for the Association meetings after the Conference meetings were over.

Mr. Schacht thought that the time and town of meeting of the Conference had become to be so generally understood as the time and town of meeting of the British Association that the whole organization of the Conference would be much upset by a change. The simultaneous character of the gatherings was one of great convenience to many men, though it might be the opposite to others. It was not easy to work up local pharmaceutical enthusiasm, but even that was less difficult of accomplishment when a whole town had been fired with the idea of entertaining a big body like the British Association than in the absence of such an impetus.

Mr. Brady reminded the Committee that this matter had been brought before them in previous years by himself and by Mr. Hanbury. There was a great deal to be said on both sides. He thought that before the Swansea meeting was held the opinions of members should be invited through the medium of any Report of Committee proceedings that might be published.

Professor Attfield had made many inquiries on the subject and had corresponded with several former local secretaries and other gentlemen, including Messrs. Clark (Plymouth), Grose (Swansea), Groves (Weymouth), Hayes (Dublin), Kinninmont (Glasgow), Maleham (Sheffield), Pitman (Bristol), and Reynolds (Leeds). A few influential members preferred the existing practice, with all its disadvantages. Their meetings would probably suffer in point of number of members attending, both as regarded local and visiting members, if the meetings were held at times other than those just preceding and overlapping the times fixed for the meetings of the British Association, for many visiting members would not care to go twice to a town within a month or so, and local members preferred to have the Conference at the least busy times of the year, which were just the times selected for the visit of the British Association. They might, of course, meet at the same date or about the same date in a more or less distant town, but members wishing to economize time would object to such an arrangement, and there was the increased difficulty of exciting enthusiasm already mentioned by Mr. Schacht. Teachers contributed men and papers to the Conference and would probably only attend during August or September. At whatever time during either of those months the meetings were held it would fit in with the holiday arrangements of some men and clash with those of others.

The following resolution was proposed by Mr. Ekin, seconded by Mr. Brady, and carried:—"The Committee again having had under consideration the desirability of holding the annual meetings of the Conference at times other than those just preceding and overlapping the times of the meetings of the British Association, or of holding them in towns other than those visited by the British Association, and having received opinions on the subject from local secretaries and other members of the Conference, conclude that any immediate alteration of the existing practice as regards times and places of meetings is undesirable."

Professor Attfield reported that, in accordance with instructions from the Committee, he had obtained an estimate of the probable cost of converting the ten indexes of the published 'Year-Books' (1870 to 1879), into a single index, and of printing such a general index. The printers of the 'Year-Book' had put the price of compilation at £35, and of printing 2500 copies of a nearly 200 page index at £75; total, £110. If the general index of the six numbers of 'Proceedings' (1864 to 1869), compiled, printed and issued to members in 1869, were incorporated with such a general index of the 'Year-Books,' some person being employed to check and, if possible, amplify the whole, the total cost probably would not be less than £150. Postage, wrapping, addressing, etc., would cost an additional £40. Probably every member of the Conference could be supplied, gratis, with a good general index to the sixteen annual publications of the Conference for somewhat less than £200.

Mr. Brady thought that the issue of such a general index would redound to the credit of the Conference, especially if copies were freely distributed to all the public libraries to which 'Year-Books' were now annually presented.

Professor Bentley said that he had often wanted such an index.

The matter was fully discussed, but decision postponed.

A complete set of 'Year-Books' was ordered to be presented to the Pharmaceutical Society of Ireland.

The consideration of probable changes amongst the staff officers of the Conference, and of a list of officers to be recommended for election by the members at the approaching meeting at Swansea (August 24 and 25) was, on the motion of Mr. Ekin, seconded by Professor Attfield:—"Deputed to Messrs. Brady, Carteighe and Schacht, as a Sub-committee, with instructions to report to the next meeting of Committee."

Professor Attfield reported the work done since the previous meeting of Committee, including the publication and delivery to members of the 'Year-Book' for 1879; distribution of the list of subjects for research; collection of subscriptions, and arrangements for the approaching meeting at Swansea. The balance for the year of income over expenditure would, he estimated, be £150. The amount already standing in Consols from previous years was about £350, besides the Bell and Hills Library Fund.

The Editor reported that he was making good progress with the MS. of the 'Year-Book' for 1880.

Eighty-one candidates were elected to membership of the Conference.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, June 17, Professor H. E. Roscoe, President, in the chair.

The following certificate was read for the first time:—A. C. Hawkes.

During the evening a ballot was taken and the following gentlemen declared duly elected Fellows of the Society:—P. S. Brown, H. Brown, K. Lal Dey Rai Bahadour, G. H. Hughes, H. A. Lawrance, F. E. Mathews, E. Moritz, R. S. Marsden, E. A. Reilly, Tarapwsanna Roy, C. Rawson, B. Symons, T. Taylor, H. K. Tompkins, R. G. Watts and A. Wingham.

The following papers were read—

On Pentathionic Acid. By T. Takamatsu and Watson Smith.—The authors at the suggestion of Dr. Roscoe have examined the proofs for and against the existence of this substance advanced by Wackenroder, Spring, Stingl and Morawski, Kessler, etc. The acid was originally prepared by Wackenroder by passing hydrogen sulphide into a saturated solution of sulphurous acid. Spring obtained what he thought was the potassium salt of the acid in an alcohol-ether solution and proved it to be merely tetrathionate. Stingl and Morawski proved by qualitative and quantitative results that an acid containing more sulphur than tetrathionic acid exists in Wackenroder's solution. Spring also asserts that the alleged solution of pentathionic acid contains a mixture of tetrathionic and hyposulphurous acids. The authors have confirmed results obtained by Kessler in the investigation of the reaction of Wackenroder's solution with mercuric cyanide $H_2S_5O_6 + Hg(CN)_2 + 2H_2O = 2H_2SO_4 + HgS + 2HCN + 2S$ the ratios between the S in the sulphuric acid to that in the HgS to that existing in the free state were 2·01 : 1 : 2·08, whereas tetrathionic acid would give 2:1:1. They have also investigated the statement of Spring that the Wackenroder's solution is not decomposed by alkaline hydrates, but yields a solution containing tetrathionate without separation of sulphur. The authors prove that a decomposition really occurs, and that sulphur is separated, but its separation is masked, because as fast as it is precipitated it is redissolved by the alcohol-ether solution. They also prove that no hyposulphurous acid is present in the Wackenroder solution. They finally synthesized both tetrathionic and pentathionic acids by acting upon lead thiosulphate, in the first instance with a moderately strong solution of iodine in hydriodic acid, when tetrathionic acid was produced, and secondly by acting on lead thiosulphate by as strong a solution of iodine in hydriodic acid as could be obtained, when pentathionic acid was formed—$3(PbS_2O_3) + 2HI + 2I_2 = H_2S_5O_6 + 3PbI_2 + SO_3$. Analyses of the products are given. The authors conclude that pentathionic acid exists and recommend the reaction just given as a convenient and expeditious method of preparing it. They hope to be able to prepare some of the pentathionates, which under ordinary conditions are less stable than the acid. In conclusion they contrast the reactions of the thionic acids, pentathionic acid being distinguished by giving an immediate precipitate of sulphur with caustic potash, redissolving gradually on standing, and an almost immediate brown coloration, becoming black on warming with ammoniacal silver nitrate.

Preliminary Note on some Orcinol Derivatives. By J. Stenhouse and C. E. Groves.—Some years ago halogen derivatives containing 5 atoms of bromine and chlorine were described (*Proc. Roy. Soc.*, 20, 72), and it was found that both the hydrogen atoms in the HO groups were displaced, giving rise to the substance $C_6MeBr_3(OBr)_2$. The reaction was subsequently examined by Liebermann and Dittler who admitted the correctness of the above empirical formula, but regarded the corresponding resorcinol body as a compound formed by the addition of 2 atoms of bromine to tribromoresorquinone, $C_6HBr_3O_2$. If the tribromoresorquinone had the above constitution it seemed probable that it would be formed by oxidizing tribromresorcinol, $C_6HBr_3(HO)_2$. The reaction was investigated in the case of trichlororcinol, but the above compound was not obtained.

The authors conclude that in orcinol the CH_3 group occupies the meta position with respect to the two HO groups and that it has the constitutional formula HO : HO : Me :: 1 : 3 : 5.

On the Determination of Carbon in Soils. By R. Warington and W. A. Peake.—The authors have examined the various methods which have been proposed. Oxidation by chromic acid suggested by Wolff; this gives but 79 per cent. of the carbon present. Oxidation by permanganate; 10 grams of the soil with 5 grams KHO in 25 c.c. of water and solid permanganate are digested in a salt-bath for an hour. The mass is then treated with H_2SO_4 and the CO_2 evolved absorbed. This method gives 92 per cent. of the total carbon. The best method is that of combustion in oxygen with oxide of copper after treatment with sulphurous acid.

Note on Camphydrene. By H. E. Armstrong.—The author sharply criticized a recent paper by Dr. Letts, in the *Berlin Berichte*, in which Dr. Letts repeats an assertion, made some months ago at this Society, that the chief product of the action of sodium on the solid hydrochloride from turpentine oil is apparently homogeneous, as it has a constant boiling point and soon attains a constant melting point on recrystallization from alcohol, and that its formula is $C_{10}H_{17}$, the mean only of ten analyses being given, which corresponds closely with $C_{10}H_{17}$. Dr. Armstrong asked whether these ten analyses were the same as those brought before this Society and which were widely discordant. Dr. Armstrong has also repeated the experiments of Montgolfier and completely confirms his conclusions that a mixture of camphene, $C_{10}H_{16}$, and of the camphydrene, $C_{10}H_{18}$, is produced from this mixture; the latter substance can be isolated by agitation with 2:1 sulphuric acid and steam distillation, thus a larger yield of the hydrocarbon can be obtained than by Montgolfier's process.

On the Action of Nitric Acid upon Diparatolylguanidin. By A. G. Perkin.—This substance dissolves in strong nitric acid, specific gravity 1·5, with rise of temperature. From the product, ammonia, after dilution and filtration, precipitates a new base having the formula $C_{15}H_{15}N_5O_4$, dinitrodiparatolylguanidin, melting at 205°, soluble in cold alcohol, insoluble in water; it crystallizes in red prisms. Treatment with tin and hydrochloric acid yields a new base which is under investigation. By mixing an alcoholic solution of the nitrate of ditolylguanidin with its own volume of nitric acid specific gravity 1·4, and heating until chemical action ensued, another substance crystallizing in primrose needles was obtained which proved to be dinitrodiparatolylurea, melting with decomposition at about 233°. On boiling this substance with alcohol acidulated with hydrochloric acid and tin diamidodiparatolylurea was obtained in minute crystals. Orthoditolylguanidine when treated with fuming nitric acid also forms a nitrobase which the author is at present investigating.

On some Higher Oxides of Manganese and their Hydrates. By V. H. Veley.—In order to avoid any possible contamination with alkalies the author proceeded as follows— A solution of manganese chloride was precipitated with ammonium sulphide; after washing this was dissolved in acetic acid and diluted, and a current of chlorine passed for a limited time at 52° C. Black glistening scales were precipitated, which were air dried. This substance is a hydrate, $MnO,11MnO_2$. After heating to 200°—250°, it was found that the oxide did not lose weight even when heated for several hours, and that the loss of weight of the oxide did not agree with the gain in weight of the drying tube. The oxide dried for many hours at this temperature retained a small but constant quantity of water; this constant oxide was found to be a monohydrate of a high oxide, $MnO,11MnO_2$. The loss of water during the heating of the substance to 200° in dry air is simultaneous, but not necessarily dependent upon the absorption of oxygen. Experiments were made to determine the various hydrates of the oxide, and the lowest temperature at which oxidation begins in air and in oxygen. The oxide was heated in a slow current of air at intervals of 10° from 60°—210° and the loss of the water determined; each experiment lasting two hours. In air the principal standpoints were 60°—100° for $MnO,5MnO_2,2H_2O$; at 120°—130° 2 (Mn_6O_{11}), $3H_2O$; at 200° $Mn_{12}O_{23}H_2O$. On repeating the experiment with oxygen, instead of air, further oxidation took place, and an oxide $MnO,23MnO_2$ was obtained. In no case was the dioxide formed.

On a New Method of Preparing Dinitroethylic Acid. By E. Frankland and C. C. Graham.—This substance was first prepared by the action of zinc ethyl upon nitric oxide. The process was, however, difficult and inconvenient (*Phil. Trans.*, 147, 59). The authors have adopted the following plan, which works well:—100 grams of pure zinc ethyl are introduced into a tubulated distilling flask, and enough sodium added to convert all the zinc ethyl into the compound $ZnNaEt_3$, taking care to keep the temperature down. When all action has ceased 100 c.c. of benzene are added, and the nitric oxide passed over the solution, the flask being shaken from time to time. When the absorption has ceased, some commercial ether is added to the cooled contents. The zinc ethyl is thus gradually decomposed, and finally the decomposition is completed by adding first some alcohol and then water. The zinc is precipitated by carbonic anhydride, and the filtrate evaporated to dryness. On treating the residue with absolute alcohol the sodic dinitroethylate alone dissolves out. It is purified by conversion into the copper salt. In some cases a yield of 50 per cent. of pure copper salt was obtained. A further study of the reactions of this acid is promised.

On the Action of Organozinc Compounds upon Nitriles and their Analogues. III. Action of Zinc Ethyl on Phenylacetonitrile. By E. Frankland and H. K. Tompkins.—The phenylacetonitrile employed was prepared by digesting benzylic chloride with a solution of crude potassic cyanide in dilute alcohol. In one experiment, while preparing this substance on the large scale, 2000 grams of the chloride being used, a substance was observed to distil over above 300°. The distillation was stopped, the residue solidified on cooling, and was found to contain tribenzylamine. The authors were unable to obtain phenylacetonitrile perfectly pure, and they therefore employed the portion of the distillate boiling 200°–230°. On treating it with zinc ethyl a reaction immediately began, and had to be checked by cooling. Towards the end the temperature had to be raised to 130°. The product is decomposed by alcohol, and finally extracted with that liquid. The crystals thus obtained contained two substances, the least soluble fusing at 170°–171°, crystallizing in silky acicular tufts; the second fused at 150°, and crystallized in rhombohedra. The first substance has the same empirical formula as phenylacetonitrile, but differs from it in all its physical properties. From analogy its formula should probably be tripled. The authors propose to call it cyanbenzine. It is sparingly soluble in hot alcohol. Glacial acetic acid, benzene, and carbon disulphide dissolve it readily. Analyses of the second substance indicated the formula $C_{32}H_{27}N_3O$. The authors have named it benzacin; it is a neutral body. The mother liquor from these two bodies contained a high boiling point oil, which the authors have not yet succeeded in satisfactorily isolating and purifying.

On the Action of Benzoyl Chloride on Morphine. By C. R. A. Wright and E. H. Rennie.—The authors prove by various analyses and other quantitative measurements, that by heating benzoyl chloride and morphine in sealed tubes to 100°—110° for several hours, the end result is invariably dibenzoyl morphine $(C_{17}H_{17}NO)\ (OC_7H_5O)_2$, morphine being for simplicity's sake regarded as $C_{17}H_{19}NO_3$, and that the product thus formed is identical with that formed by the action of benzoic anhydride on morphine. The conclusion recently arrived at by Polstorff (*Chemical News*, May 27, 1880, p. 220), that a tribenzoylated base is formed is shown to be utterly without foundation, Polstorff's own analytical figures rather indicating that the substance examined by him was the dibenzoylated base, whilst no determination at all of the molecular weight or of the quantity of benzoic acid regenerated by saponification was made as a check. Morphine contains two-thirds of its oxygen in the form of hydroxyl and one-third functioning in some other way, as has been shown by C. R. A. Wright in conjunction with J. H. Beckett.

On an Examination of Terpenes for Cymene by means of the Ultra-Violet Spectrum. By W. N. Hartley.—In a previous paper (*Proc. Roy. Soc.*), the author and Professor Huntington have shown that cymene gives a well marked absorption spectrum, which is not entirely obliterated by dilution with 5000 volumes of alcohol, if a layer of 15 mm. in thickness be used. The author has in this way tested samples of orange oil, French turpentine and Russian turpentine, received from Dr. Armstrong, for cymene. The first two substances contained no cymene, the Russian turpentine contained less than 4 per cent. The author concludes that the cymene found in these oils by Dr. Armstrong was formed by the chemical treatment to which they were subjected. The author examined the so-called terebene, which is also free from cymene.

Notes on the Purple of the Ancients. By F. Schunck.—The author has examined a sample of cotton recently dyed with the juice of a species of shell fish, *Purpura patula*, obtained through Herr Von Stralendorff, from the east coast of Nicaragua, where this method of dyeing is still practised by the natives. The purple was dull and not so brilliant as was expected; it was dissolved out of the fabric by boiling anilin, and was found to have all the properties of the punicin previously obtained by the author from the *Purpura lapillus* of the British coasts. It is characterized by its extreme stability, especially with regard to powerful oxidizing agents. It dissolves in concentrated sulphuric acid, yielding a dull purple solution, having an absorption band between D and E; on heating this solution and allowing it to stand the colour changes to a bright green, and the band disappears. This green solution gives with water a purple precipitate.

The Society then adjourned over the summer recess.

SOCIETY OF ARTS.

The Chemistry of Bread-Making.*

BY PROFESSOR GRAHAM, D.SC.

Lecture II.

(*Continued from page* 1029.)

I pass now, then, to the consideration of the albuminoids. Their general composition is given in this table:—

Average Composition of Albuminoids.

Carbon	53·3
Hydrogen	7·1
Nitrogen	15·7
Oxygen	22·1
Sulphur	1·8
	100

Hypothetical formula, $C_{72}H_{112}N_{18}SO_{22}$.

If you consult various works on the subject you will find some slight discrepancies from the numbers given here, but this will fairly indicate the general nature of the albuminoid bodies:—Carbon, 53·3; hydrogen, 7·1; nitrogen, 15·7; oxygen, 22·1; sulphur, 1·8. Now, these are the analytical results given by the chemist, Lieberkühn, and he converts the centesimal ratios of these elements and gives us this hypothetical formula, $C_{72}H_{112}N_{18}SO_{22}$. I say hypothetical, because if starch has hitherto been too difficult for us to elucidate clearly the exact composition of its molecule, I need hardly say that the albuminoids are even more difficult.

The albuminoids of wheat flour differ very much from those of the other starches. We have on the table the composition of the various flours.

On looking at the table, you will see that of albuminoids 10·9 is given to old wheat, 13 to barley, 16 to oats, 8 to rye, 8·9 to maize, 7·2 to rice. Oats

* Cantor Lectures: Delivered November and December, 1879. Reprinted from the *Journal of the Society of Arts*.

and barley are very rich in albuminoids, and probably most of you have considered that wheat is preeminently rich in the protein bodies, as they were called by Mülder, and that the value of any given sample of wheat flour would depend entirely on the total quantity of albuminoids in the wheat. I think I shall be able to demonstrate to you that such analyses as are given in this table, where all the albuminoids are put together under

Average Composition of Cereals. (*Flour.*)

	Old Wheat.	Barley.	Oats.	Rye.	Maize.	Rice.
Water . .	11·1	12·0	14·2	14·3	11·5	10·8

one head, are utterly useless, and give us no idea whatever as to the value of a given sample of flour for the purpose of making bread. If you take good wheat flour and knead it with water—you all know the experiment—you will gradually get rid of the starch and the gluten will cohere in a sticky adhesive mass. Of course, if you wash it sufficiently long you get rid of the whole of the starch, and what remains is called crude gluten. The crude gluten, when moistened with water, coheres—its particles join together with considerable force. Here is a sample, and you will notice the peculiar tenacity of the elastic tough mass.

The value in bread-making of this peculiar property is no doubt manifest to all of you. If you have a body of such an elastic nature it will entangle the carbonic acid produced by the action of the yeast on the starch, and the carbonic acid, being entangled in this way, will raise the whole mass. An abundance of these albuminoids is, therefore, necessary to good bread-making.

Crude gluten consists of four-fifths of fibrin and one-fifth of an albuminoid body called glutin, spelt with an "i," in order to indicate the difference between that and the whole mass, which is called gluten. These are left in the kneading process, and such a paste as you have just seen consists of the fibrin and glutin. On the other hand, in kneading flour and water there passes into the solution, along with the starch, an albuminoid body, that has been called sometimes casein and sometimes legumin. Now, if we take this gluten, we shall find that when it is freed from water it has no taste, and in addition to having no taste it is translucent. These biscuits, buns or loaves, which you see before you, have been made with the gluten of flour, and I would like you to examine them after the lecture. I am indebted to Mr. Bonthron, of Regent Street, for the different samples I have on the table here. He prepares the flour in such a way that he can separate all the starch on the one hand from the crude gluten on the other. In this bag on the table there is the crude gluten containing very little starch. In this other bag there is pure starch, and in this third bag the flour from which these two products are obtained.

This kind of bread is used for diabetic patients, when the object of the physician is to restrain as much as possible the use of starch in the food. Formerly, this diabetic bread came from Vienna. There is one sample, a pleasant soft bread, not intended to last a very long time, I suppose about ten days or a fortnight; so that patients living in different parts of England can readily obtain this kind of bread; whereas this other sample, dry, glistening, porous biscuit, will keep an indefinite length of time, doubtless for many years. I said just now that gluten was tasteless. I see Mr. Bonthron has also supplied me with some little cakes, something like gingerbread. They are flavoured a little with ginger, in order that for lunch one may not always be driven to eat this tasteless mass. Some of these are prepared with almonds and others with various flavouring materials, that the patients can have a little variety in their diet.

I ought to mention that one reason I have for bringing this before your notice is that these particular kinds of glutinous bread are made at about one-fourth or one-sixth the price of what they are sold at when brought all the way from Vienna.

Crude gluten is, then, a dry, tasteless, translucent body, where free from water; and we have seen that the crude gluten may be conveniently divided into glutin and fibrin. Glutin is slightly soluble in cold water and much more so in hot water. Glutin dissolves in spirit of wine. I say spirit of wine, because if you were to take this product of Mr. Bonthron's and act upon it with absolute alcohol it would fail to dissolve out the glutin; but if you use spirit of wine it would dissolve out all the glutin in time. Having thoroughly digested this crude gluten in spirit of wine, we have nothing left but the fibrin, and this fibrin is manifestly, therefore, not soluble in alcohol. Although fibrin is insoluble in water and in alcohol, yet, if we were to take fibrin and mix it with water and allow it to be acted on at the ordinary temperature for a little time it would gradually undergo putrefactive decomposition and ultimately produce offensive products; but long before that occurred, in undergoing putrefactive fermentation, the complex nature of the fibrin would be broken down and some soluble albuminoids would be formed. This degrading action takes place when grain or flour has been damaged by water and this kind of fermentation process occurs; and, instead of obtaining the powerful elastic gluten we have a material that has very little tenacity.

The soluble albuminoid bodies are the legumin and albumen. I prefer to call it legumin rather than casein, because legumin is found mainly in the seeds of the *Leguminosæ:* beans, peas, tares and such like seeds. It is soluble in water and in alcohol; it is precipitated by acetic acid, but the aqueous solution of legumin is not precipitated on boiling.

The next member that is soluble in water is the albumin. Albumin is precipitated by alcohol and also upon boiling a solution containing it. You all know that occurs also with ordinary animal albumen—that a solution of albumen, when heated, coagulates, as occurs when you boil an egg for some little time. One of the most delicate reactions to distinguish a small quantity of albumen, whether vegetable or animal, in solution, is to add to it some ferrocyanide of potassium and acetic acid. While Mr. Lewis is performing that experiment, I will pass on to the consideration of the last of the albuminoids to which I wish to draw your attention.

In the husk of wheat, that which one separates under the name of bran, occurs another albuminoid body called cerealin. Now cerealin has a very marked action upon starch; in other words, it acts as the so-called diastase. It acts like malt infusion, and the object of its being there, gathered together mainly in the bran, is for the purpose of enabling the young germinating plumule to obtain a large supply of nutriment, not entirely from the starch, but to a great extent from the cellulose structure of the outward layers of the corn. The cerealin, like many of the albuminoids, is precipitated by alcohol and also by acids. Now these soluble bodies, legumin, albumin and cerealin, one or more of them, occur in all seeds, and the reason that they occur in seeds is that they thereby present, under the germinating process, precisely what all chemists use in the researches upon starch, a material that has the power to convert the starch, and even the cellulose, into soluble materials, because you will remember that starch and cellulose are insoluble in water, whereas when converted into various sugar bodies they dissolve, and can be absorbed by the cells of the young growing plant. Now, the amount of this is somewhat increased by the process of sprouting or germination. I have here an analysis of the albuminous substances found in barley and malt.

Albuminous Substances.

	Barley.	Malt.
Glutin (soluble in alcohol)	0·28	0·34
Coagulable by heat	0·28	0·45
Non-coagulable	1·55	2·08
Insoluble albumin	7·59	6·23
	9·70	9·10

In the case of barley, it is 9·7, and in malt 9·1, but there has been a considerable reduction in the amount of the insoluble albuminous bodies. They were 7·5 in barley, but they are only 6·2 in the case of malt, with, of course, a corresponding increase in the quantity of the soluble albuminoid bodies. Sprouting increases, first of all, the quantity of the soluble albuminoid bodies; but, while that is noticeable enough, it is by no means so remarkable as the peculiar change that has taken place. Ordinary soluble albuminoids, in a well germinated and well garnered barley or wheat corn, are not very active in their action upon starch, whereas if sprouting has taken place at all, in other words, if the germinating process has taken place, then there is a very marked increase of action.

I find time is passing so rapidly, that I must defer some matters to our next meeting, and I will just draw your attention to the character of the albuminoid bodies in the other cereals. Passing to barley flour, the chief difference in barley flour, as compared with wheat, is not in the amount of the albuminoid bodies, but in their character. If you take barley flour and knead it with water, as one often does, with flour, you would, after washing for some time, find that there was a very small quantity of this crude gluten left, and that barley flour would be a very inappropriate material to form a good loaf with. Of course, I know that barley flour has been used for ages, but if anyone present has been in the habit of eating barley bread, he will know to what I refer—it is a heavy, sticky, doughy sort of mass. It is more like wheat treated by the boiling process than by the oven process.

Rye flour, very rich in the total quantity of albuminoids, is so deficient in crude gluten that when you knead it with water there is practically nothing left, the whole of it passes away along with the starch; not that it is soluble, but it is not coherent, and therefore does not form that tough, elastic mass, which is so characteristic of wheat under the same conditions.

Precisely the same may be said of oat flour. I do not know whether anyone present has ever seen oat flour fermented with yeast in the ordinary way; but it is a heavy mass, and practically the same may be said of maize. Now rye flour is very much used in the North of Europe for the purpose of making bread; and it is with rye flour chiefly that the leaven process is employed, and those who have travelled in the northern parts of Europe will remember perfectly well the dark kind of bread that rye, fermented by leaven, gives. To a great extent the same remarks as to the want of cohering elastic gluten would apply to oats or barley, or any other cereal than wheat.

Wheat, then, is pre-eminently fitted for the purpose of making bread by the fermentation process, since it is so rich in this tough elastic gluten, which holds in the carbonic acid and enables you to have a light, aerated bread.

(*To be continued.*)

Parliamentary and Law Proceedings.

THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* WRIGHT.

This action, which was for the recovery of penalties under the 15th section of the Pharmacy Act, was tried before the judge of the Liverpool County Court on Monday the 21st instant, and resulted in a verdict for the Society for £5 and costs.

The defendant applied for leave to appeal, but the judge refused to grant it.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[415]. The symbol O signifies a pint, 20 fluid ounces. Therefore a pint mixture or lotion should invariably be dispensed in a 20-ounce bottle.

SAMUEL LAWRENCE.

[419]. A very good mixture of ol. santal. flav. is made as follows:—

℞ Ol. Sant. Flav.		ʒvj.
Mucilag. Acac.		℥j.
Syrup. Simp.		℥j.
Tr. Aurantii		ʒvj.
Aq. Cinnam.	ad	℥vj.

M. ft. mist. ℥ss ter die sumend.

EMBRYO.

[420]. I think F. G. will find the best way of dispensing his pills as follows:—

Rub the camphor in dry with the ferri sulph., previously powdered; pulv. acaciæ, gr. xxiv.; conf. sennæ, gr. xx. Mass altogether along with the ol. cinnam. This makes a very nice pill mass. If it breaks in rolling, mass in warm hands.

W. F. W. KEENE.

[421]. In the evaporation of solution of zinc chloride for the production of the solid compound used in pharmacy, an uncertain quantity of hydric chloride is driven off, the result being that the solid contains a certain though variable amount of zinc oxychloride. When it is attempted to redissolve the solid in water, for the preparation of lotions, etc., part is always found to be insoluble, the proportion depending on the amount of oxychloride present. This insoluble matter is readily dissolved by a few drops of dilute hydric chloride, though of course in dispensing this must not be done. The solution should either be left as it is or filtered. The quantity, if collected and dried, is in any case but small and may be practically disregarded. "Tyro" will find some information in Gmelin's 'Handbook,' vol. v., p. 31.

South Norwood, S.E. J. H. BALDOCK.

[422]. I should have had no hesitation in dispensing four powders each containing 15 grains sulphate of zinc, the dose of which is 1 to 3 grains as a tonic and 10 to 30 grains as an emetic. Probably the powders were intended for the latter purpose, or for dissolving in water to form a lotion or injection. It was quite unnecessary of "Bdfrd" to label "poison."

SAMUEL LAWRENCE.

Notes and Queries.

[657]. LIQ. AMMON. ACET. CONC.—Page D. Woodcock finds it will not do to bring his old formulæ into the light of modern chemistry. He took the ℞ from his old working book of forty years since. He then had the superintendence of a wholesale warehouse, and that was the way it was done. By using the very strongest ordinary acid, in the manner indicated, a solution of very nearly 1 to 7 was obtained. P. D. W. is not sorry he gave the ℞ as it has led to the discussion of a very valuable medicine.

[657]. LIQ. AMMON. CONC.—In regard to liq. amm. acet. conc., what objection would there be to use liq. ammon. fort. in place of ammon. conc.? One of the difficulties in getting a neutral sol. is the quantity of carb. acid in the sol., and difficulty of applying sufficient neutral to drain it off.

Many years ago, Dr. Pereira suggested the use of liq. am. in his lectures, which I have adopted with fair results with aid of ice.

AN OLD STUDENT.

[658]. COMPOUND TINCTURE OF MYRRH.—In the reply printed on p. 1032 as having been sent by Mr. R. Parkinson, of Liverpool, some errors crept in through a misreading of the copy, which were overlooked. The recipe should have been:—

Myrrh	2 oz.
Barb. Aloes	2 oz,
S. V. R.	Ojss.
Aquæ	Oss.

Digest fourteen days and filter.

VIVIPAROUS PLANTS.

Sir,—Mr. Dodd's letter in last week's issue, called my attention to that paragraph in "The Month" on viviparous plants.

I have what I believe to be a specimen of the *Polystichum angulare*. Two fronds seem by some means to have become suddenly interrupted in their growth, so as to present an abruptly pinnate appearance, and from the extremity of the rachis, a small fleshy protuberance is formed, from which a young frond is produced. At the bases of other fronds, there are similar growths, one on either side of the rachis from which young plants are produced. Young plants are formed, too, on the stumps from which old fronds have been cut.

It is our practice to propagate this fern by means of these young plants produced in this viviparous manner, and I was not aware this fern bore sori at all, till on examination I found the oldest frond covered with sori with a peltate indusium.

I have also an asplenium which is viviparous; but in this case the young plants are produced on the upper surface at the base of the pinnules. This latter species is now presenting several small excrescences of a lighter colour than the other parts of the frond, from which in a short time young plants will be produced.

Having several plants of the polystichum, I shall be most happy to supply Mr. Dodd, or any other botanist who may be desirous of pursuing the subject, with specimens of this fern in its extraordinary growth, on written or personal application.

82, Cricketfield Road, Lower Clapton, E. WALL.

CLAY'S TURPENTINE MIXTURE.

Sir,—Having to dispense this mixture very frequently, I find the following method answer very satisfactorily:—

The sulphur having first been reduced to a very fine powder is rubbed down smoothly in a mortar with half the mucilage of tragacanth, water is then added and the mixture put into a bottle. A separate emulsion of the Chian turpentine is then prepared by adding the ethereal solution of the turpentine gradually to the remainder of the mucilage in another bottle, shaking well after each addition of the turpentine solution, then adding the syrup and water. The sulphur mixture is then gradually added to the emulsion, shaking thoroughly after each addition.

Take of—

Sublimed Sulphur	20 grains.
Mucilage of Tragacanth	1 ounce.
Distilled Water	3 ounces.

Mix.

And add this to the following emulsion:—

Ethereal solution of Chian Turpentine	2 drachms.
Mucilage of Tragacanth	1 ounce.
Syrup	½ ounce.
Distilled Water	to make 4 ounces.

If any separation of resin takes place the mucilage should be increased.

Middlesex Hospital. S. R. CHALLICE.

THE COUNCIL ELECTIONS.

Sir,—I can vouch for one error Mr. Hall made, that although I nominated Mr. Symes (too late, for someone had done it before me) I did not plump, but gave, I trust, an intelligent vote for the major part of the present Council, who (whether metropolitan or provincial) have done their work loyally, so as justly to evoke well-merited eulogy.

Liverpool. J. A. J.

Sir,—I would just like to point out that the statement of Mr. Hall's, as reported in the Journal of May 22, page 945, to the effect "that all the Liverpool members of the Pharmaceutical Society 'plumped' for one candidate at last year's election of Council," is simply incorrect. I, as a voter, certainly did no such childish thing, and I firmly believe that it is in my power to name others who did not. For my own part I voted for the full number required (14), and my intention has on each occasion been to do the same.

Liverpool: RICH. PARKINSON.

E. J. Cox.—No insect could be discovered in the extract when it was received.

"*Euretes.*"—(1) A public analyst is not required to pass a series of examinations. The Act provides that he must be of "competent knowle[illegible], skill and experience," and the Local Government may require satisfactory proof of such competence. (2) [illegible]ply to the Secretary of the Statistical Society.

"*Country Chemist.*"—Blaine's 'Outlines of the Veterinary Art.'

A. P. B.—There is a Pharmacy Act for the Colony of Victoria, the board of examiners under which are empowered to receive the certificates of the Pharmaceutical Society of Great Britain in lieu of an examination (see vol. viii, p. 589. Up to the latest advices this is the only legislation of the kind that exists in the Australian Colonies.

E. Coleman.—(1) *Sagina procumbens.* (2) *Alchemilla vulgaris.*

A. B. Macfarlane.—The sticky fly papers, according to Cooley, are made by covering paper with a factitious bird lime, prepared by boiling linseed oil, either with or without a little resin, until it forms a viscid stringy paste when cold.

G. D. R. Robinson.—Bunsen's work is the best on the subject; but if this be not available, consult the article on gas analysis in Watts's Dictionary.

Associate.—The solution should be a clear one.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Tunley, Brown, Bisset, Williams, Stone, Minor, Jacque, Square, A. A. F.

Several correspondents have failed to comply with the regulation as to anonymous communications.
