Dissolve the gelatin and gum in the acetic acid with the aid of a water-bath, then add the other ingredients, and mix. If the coating solution is to be used with needles alone, substitute for the gum two drachms more of gelatin. Keep securely corked in a wide mouth bottle. Make the pill mass a very little softer than ordinarily; use as little powder as possible in rolling out; when the mass is nearly brought to the proper length for cutting, lay a thread long enough to reach over the sides of the machine before the pill mass, then roll to the proper length and form pills by the machine. With some masses it may be necessary to cut with a sharp knife a slit in the top of the roll, then lay the thread in the slit and close by rolling. If the mass is of proper consistency and the machine handled right, every pill will be nicely formed and all connected *by the thread.* Then take hold of each end of the string of pills, shake off powder if there is any adhering, dip in the coating solution and twirl as though it was a toy buzz-wheel, which will throw off excess of coating; then hang up by placing pins through each end of the thread and then into wood, and expose to as cool a draught of air as possible. When hard enough to place in the box, cut the thread close to each pill with a pair of scissors or sharp knife, thus leaving no hole in the coating; the little piece of thread in each pill in length equal to the diameter of the pill should do no harm.

Pills can be coated in this way, I think, in less time than by any other method. They compare favourably in appearance, solubility, etc., with pills coated with any other substance, or with the same substance in any other and longer way. With sufficient practice, every pill can be caught on the thread and neatly rolled without touching with the fingers; twenty-four pills, or more, according to the size of the machine, can thus be coated as easily as one by the needle, as ordinarily used, and as a matter of course they dry quicker, as in coating with the needle the last pill coated will not be hard when the first is ready for the box. Even if at first only half the number of pills adhere on the thread, they may be coated as easily as one, and the remainder can be coated on the needles until the manipulator improves.

Some of the advantages of this coating are that it is always ready for use—and thus injury caused by repeated heating is prevented—it does not mould or decompose, it drys or hardens quickly, can be applied to pills as soon as made, and when applied is more soluble than gelatin alone.

I would say, in conclusion, that I have been able by practice to make the thread work successfully on my machine, but there is, perhaps, enough of trouble in learning how, to make it doubtful that this method will be of general use; still it is an idea which is freely given for what it may be worth. The coating may not be entirely new to others, but it is to me, and, as far as has been possible, I have reviewed the pharmaceutical literature on this subject. It may be capable of improvement; and for such purpose, and for a trial of what I believe to be its advantages over other coatings, it is now placed before the profession.

CALCIUM PHOSPHITE.*

BY R. ROTHER.

When sugar is added to saturation to a solution of calcium hypophosphite, the latter is precipitated. This fact is not generally known, and hence it is highly probable that a dense syrup of the mixed hypophosphites contains little if any of the calcium salt. Therefore, only a moderately thin syrup is certain of representing the requisite amount of calcium as one of the components of the compound syrup of the hypophosphites. In the presence of iron a precipitate also forms, but the proportion of sugar has apparently no share in this change. The statement is circulated, but it is not clear on what authority, that ferric hypophosphite, when contained in such a syrup, easily reverts to the ferrous form by reason of the reducing action of the hypophosphorous acid. In view of this supposition, it was proposed to substitute the very soluble ferrous salt for the uncertain and difficultly soluble ferric hypophosphite. This compound syrup is not, however, much in vogue. The writer once prepared such a syrup, but found, contrary to expectation, that the ferrous salt readily oxidized, even in the presence of sugar forming the dark green and very soluble ferroic (ferro-ferric) hypophosphite. Now, if the ferric salt suffered a reduction, it seems that this intermediate ferric compound would result without yielding a precipitate, unless the latter were occasioned by the generated phosphoric acid as calcium phosphate. The fact is, that ferric hypophosphite occurs in several modifications, of which the crystalline variety is next to insoluble in hypophosphorous acid, and hence it is this compound which deposits from the syrup. Having on hand a quantity of this sediment, the writer attempted to regenerate it by reducing it to the ferrous condition by the intervention of sulphurous acid. This treatment, however, resulted in an altogether unexpected reaction, wherein the sulphurous acid was decomposed into sulphuric acid, sulphur and oxygen; the latter, reacting upon the hypophosphorous acid of the sediment, converted it into phosphorous acid. The same result was obtained by mixing sulphurous and hypophosphorous acids together. In moderate concentration the precipitation of sulphur was instantaneous, but in dilute solutions this was preceded by a transient yellow coloration of the liquid. When solutions of calcium hypophosphite and sodium sulphite are mixed calcium sulphite is precipitated. The addition of chlorhydric acid to this mixture redissolves

---

* From the *Pharmacist* for August, 1879.

the calcium sulphite; but no further reaction sets in until both the hypophosphorous and sulphurous acids are entirely freed by the addition of enough chlorhydric acid. The evidence of the resumption of change appears in the production of the deep yellow solution above mentioned; this persists for about five minutes, more or less, according to the degree of concentration, and is then followed by a copious deposit of sulphur, mixed with calcium sulphate. The yellow coloration is by no means due to nascent sulphur in solution. It is caused by the intermediate formation of hyposulphurous acid, H_2SO_2 (not the thiosulphuric acid, $H_2S_2O_3$, formerly called hyposulphurous). The decomposition of the sulphurous acid is complete in six or eight hours. The solution, after filtering off the sulphur, is but mildly acid, and yields, on the addition of ammonia, a crystalline precipitate of calcium phosphite. This precipitate, however, contains less than half of the phosphorous acid generated, owing to the fact that hypophosphorous acid is monobasic, whilst phosphorous acid is dibasic, and also that a small loss of calcium is incurred as sulphate. Therefore, the liquid filtered from the calcium phosphite, on being treated with calcium chloride, gives an additional precipitate of calcium phosphite. But if the liquid filtered from the sulphur be treated with calcium carbonate, a much larger amount of calcium phosphite is thrown down than with ammonia. If after several hours the mixture is filtered, and to the neutral filtrate calcium chloride be added, a further precipitation of calcium phosphite takes place. The addition of a very little ammonia to the precipitate, with calcium chloride, always causes this to become more distinctly crystalline and to subside more rapidly. The calcium phosphite is most speedily and conveniently washed by decantation.

Calcium phosphite is a white crystalline powder, which, when heated in a test tube, evolves spontaneously inflammable hydric phosphide, accompanied by slight detonations. When raised to a certain temperature it suddenly becomes incandescent for a moment and then leaves a residue of calcium phosphate.

When 60 grains of calcium hypophosphite are converted into phosphite by the addition of 180 grains of sodium sulphite, 120 grains of chlorhydric acid and 4 fluid ounces of water, filtration after a lapse of six or eight hours, exposure of the filtrate to dissipate excess of sulphurous oxide and final addition of ammonia, the yield is only 40·75 grains; but the amount of phosphorous acid present is sufficient to produce 97·4 grains of the salt, as follows:—

$$CaH_4(PO_2)_2 + O_2 = CaH_4(PO_3)_2, \text{ or } CaHPO_3 + H_3PO_3, \text{ and}$$
$$CaH_4(PO_2)_2, (170) : CaHPO_3OH_2, (138) :: 60 : 48{\cdot}7,$$

and as the quantity of calcium contained in the hypophosphite, as seen from the above, is only half enough to neutralize the phosphorous acid, giving theoretically but 48·7 grains of the phosphite, it is evident that the introduction of the requisite amount of calcium will afford double this, or 97·4 grains. The difference between 48·7 and 40·75 grains is loss attributable to calcium sulphate and solubility of the phosphite. It appears that no phosphoric acid is generated, as decomposition of the precipitate with oxalic acid and treatment of the filtrate with ammonio-magnesian sulphate fails to give the characteristic precipitate.

SPECIFIC GRAVITIES OF FATS, RESINS, ETC.*

BY DR. H. HAGER.

The author first describes a simple method for determining these specific gravities. This consists in melting the respective fat, dropping it into a flat-bottomed vessel containing alcohol, in such a manner that the point from which the drops are allowed to fall is not over three centimetres distant from the surface of the alcohol, and that each drop be allowed to fall on a different spot. The fat globules thus deposited at the bottom are then removed to a liquid, consisting of either alcohol, water or glycerin, or mixtures of these, until after careful stirring and reduction or increase of the density, by the addition of one or another of the above liquids, the fat globules are held in equilibrium in any part of the liquid. The specific gravity of the latter is then determined, and this is, of course, at the same time the specific gravity of the fat. The author then gives a list of specific gravities, which is here reproduced:—

	Sp. gr. at 15—16° C.
Butter Fat, clarified by settling	0·938 – 0·940
„ „ several months old	0·936 – 0·937

RADIANT MATTER.*

BY WILLIAM CROOKES, F.R.S.

To throw light on the title of this lecture I must go back more than sixty years—to 1816. Faraday, then a mere student and ardent experimentalist, was twenty-four years old, and at this early period of his career he delivered a series of lectures on the General Properties of Matter, and one of them bore the remarkable title, *On Radiant Matter*. The great philosopher's notes of this lecture are to be found in Dr. Bence Jones's 'Life and Letters of Faraday,' and I will here quote a passage in which he first employs the expression *Radiant Matter*:—

"If we conceive a change as far beyond vaporization as that is above fluidity, and then take into account also the proportional increased extent of alteration as the changes rise, we shall perhaps, if we can form any conception at all, not fall far short o Radiant Matter; and as in the last conversion many qualities were lost, so here also many more would disappear."

Faraday was evidently engrossed with this far-reaching speculation, for three years later—in 1819—we find him bringing fresh evidence and argument to strengthen his startling hypothesis. His notes are now more extended, and they show that in the intervening three years he had thought much and deeply on this higher form of matter. He first points out that matter may be classed into four states—solid, liquid, gaseous, and radiant—these modifications depending upon differences in their several essential properties. He admits that the existence of Radiant Matter is as yet unproved, and then proceeds, in a series of ingenious analogical arguments, to show the probability of its existence.†

If, in the beginning of this century, we had asked, What is a Gas? the answer then would have been that it is matter, expanded and rarefied to such an extent as to be impalpable, save when set in violent motion; invisible, incapable of assuming or of being reduced into any definite form like solids, or of forming drops like liquids; always ready to expand where no resistance is offered, and to contract on being subjected to pressure. Sixty years ago such were the chief attributes assigned to gases. Modern research, however, has greatly enlarged and modified our views on the constitution of these elastic fluids. Gases are now considered to be composed of an almost infinite number of small particles or molecules, which are constantly moving in every direction with velocities of all conceivable magnitudes. As these molecules are exceedingly numerous, it follows that no molecule can move far in any direction without coming in contact with some other molecule. But if we exhaust the air or gas contained in a closed vessel, the number of molecules becomes diminished, and the distance through which any one of them can move without coming in contact with another is increased, the length of the mean free path being inversely proportional to the number of molecules present. The further this process is carried the longer becomes the average distance a molecule can travel before entering into collision; or, in other words, the longer its mean free path, the more the physical properties of the gas or air are modified. Thus, at a certain point, the phenomena of the radiometer become possible, and on pushing the rarefaction still further, *i.e.*, decreasing the number of molecules in a given space and lengthening their mean free path, the experimental results are obtainable to which I am now about to call your attention. So distinct are these phenomena from anything which occurs in air or gas at the ordinary tension, that we are led to assume that we are here brought face to face with Matter in a Fourth state or condition, a condition as far removed from the state of gas as a gas is from a liquid.

Mean Free Path. Radiant Matter.

I have long believed that a well-known appearance observed in vacuum tubes is closely related to the phenomena of the mean free path of the molecules. When the negative pole is examined while the discharge from an induction-coil is passing through an exhausted tube, a dark space is seen to surround it. This dark space is found to increase and diminish as the vacuum is varied, in the same way that the mean free path of the molecules lengthens and contracts. As the one is perceived by the mind's eye to get greater, so the other is seen by the bodily eye to increase in size; and if the vacuum is insufficient to permit much play of the molecules before they enter into collision, the passage of electricity shows that the "dark space" has shrunk to small dimensions. We naturally infer that the dark space is the mean free path of the molecules of the residual gas, an inference confirmed by experiment.

I will endeavour to render this "dark space" visible to all present. Here is a tube (Fig. 1), having a pole in the

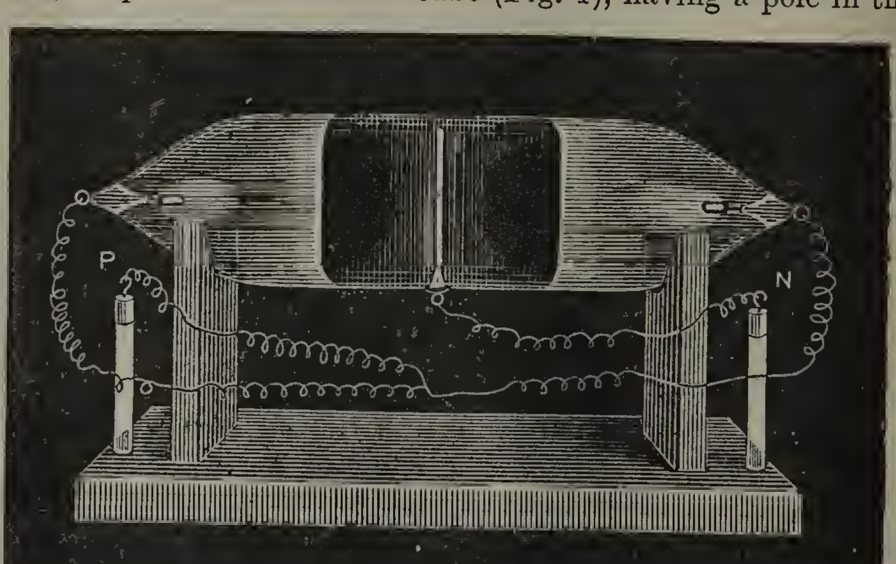

Fig. 1.

centre in the form of a metal disk, and other poles at each end. The centre pole is made negative, and the two end poles connected together are made the positive terminal. The dark space will be in the centre. When the exhaustion is not very great the dark space extends only a little

* A lecture delivered to the British Association for the Advancement of Science, at Sheffield, Friday, August 22, 1879.

† "I may now notice a curious progression in physical properties accompanying changes of form, and which is perhaps sufficient to induce, in the inventive and sanguine philosopher, a considerable degree of belief in the association of the radiant form with the others in the set of changes I have mentioned.

"As we ascend from the solid to the fluid and gaseous states, physical properties diminish in number and variety, each state losing some of those which belonged to the preceding state. When solids are converted into fluids, all the varieties of hardness and softness are necessarily lost. Crystalline and other shapes are destroyed. Opacity and colour frequently give way to a colourless transparency, and a general mobility of particles is conferred.

"Passing onward to the gaseous state, still more of the evident characters of bodies are annihilated. The immense differences in their weight almost disappear; the remains of difference in colour that were left, are lost. Transparency becomes universal, and they are all elastic. They now form but one set of substances, and the varieties of density, hardness, opacity, colour, elasticity and form, which render the number of solids and fluids almost infinite, are now supplied by a few slight variations in weight, and some unimportant shades of colour.

"To those, therefore, who admit the radiant form of matter, no difficulty exists in the simplicity of the properties it possesses, but rather an argument in their favour. These persons show you a gradual resignation of properties in the matter we can appreciate as the matter ascends in the scale of forms, and they would be surprised if that effect were to cease at the gaseous state. They point out the greater exertions which Nature makes at each step of the change, and think that, consistently, it ought to be greatest in the passage from the gaseous to the radiant form."—'Life and Letters of Faraday,' vol. i., p. 308.

on each side of the negative pole in the centre. When the exhaustion is good, as in the tube before you, and I turn on the coil, the dark space is seen to extend for about an inch on each side of the pole.

Here, then, we see the induction spark actually illuminating the lines of molecular pressure caused by the excitement of the negative pole. The thickness of this dark space is the measure of the mean free path between successive collisions of the molecules of the residual gas. The extra velocity with which the negatively electrified molecules rebound from the excited pole keeps back the more slowly moving molecules which are advancing towards that pole. A conflict occurs at the boundary of the dark space, where the luminous margin bears witness to the energy of the discharge.

Therefore the residual gas—or, as I prefer to call it, the gaseous residue—within the dark space is in an entirely different state to that of the residual gas in vessels at a lower degree of exhaustion. To quote the words of our last year's President, in his Address at Dublin :—

"In the exhausted column we have a vehicle for electricity not constant like an ordinary conductor, but itself modified by the passage of the discharge, and perhaps subject to laws differing materially from those which it obeys at atmospheric pressure."

In the vessels with the lower degree of exhaustion, the length of the mean free path of the molecules is exceedingly small as compared with the dimensions of the bulb, and the properties belonging to the ordinary gaseous state of matter, depending upon constant collisions, can be observed. But in the phenomena now about to be examined, so high is the exhaustion carried that the dark space around the negative pole has widened out till it entirely fills the tube. By great rarefaction the mean free path has become so long that the hits in a given time in comparison to the misses may be disregarded, and the average molecule is now allowed to obey its own motions or laws without interference. The mean free path, in fact, is comparable to the dimensions of the vessel, and we have no longer to deal with a *continuous* portion of matter, as would be the case were the tubes less highly exhausted, but we must here contemplate the molecules *individually*. In these highly exhausted vessels the molecules of the gaseous residue are able to dart across the tube with comparatively few collisions, and radiating from the pole with enormous velocity, they assume properties so novel and so characteristic as to entirely justify the application of the term borrowed from Faraday, that of *Radiant Matter*.

Radiant Matter exerts powerful Phosphorogenic Action where it strikes.

I have mentioned that the Radiant Matter within the dark space excites luminosity where its velocity is arrested by residual gas outside the dark space. But if no residual gas is left, the molecules will have their velocity arrested by the sides of the glass ; and here we come to the first and one of the most noteworthy properties of Radiant Matter discharged from the negative pole—its power of exciting phosphorescence when it strikes against solid matter. The number of bodies which respond luminously to this molecular bombardment is very great, and the resulting colours are of every variety. Glass, for instance, is highly phosphorescent when exposed to a stream of Radiant Matter. Here (Fig. 2) are three bulbs composed of different glass ; one is uranium glass (*a*), which phosphoresces of a dark green colour ; another is English glass (*b*), which phosphoresces of a blue colour ; and the third (*c*) is soft German glass—of which most of the

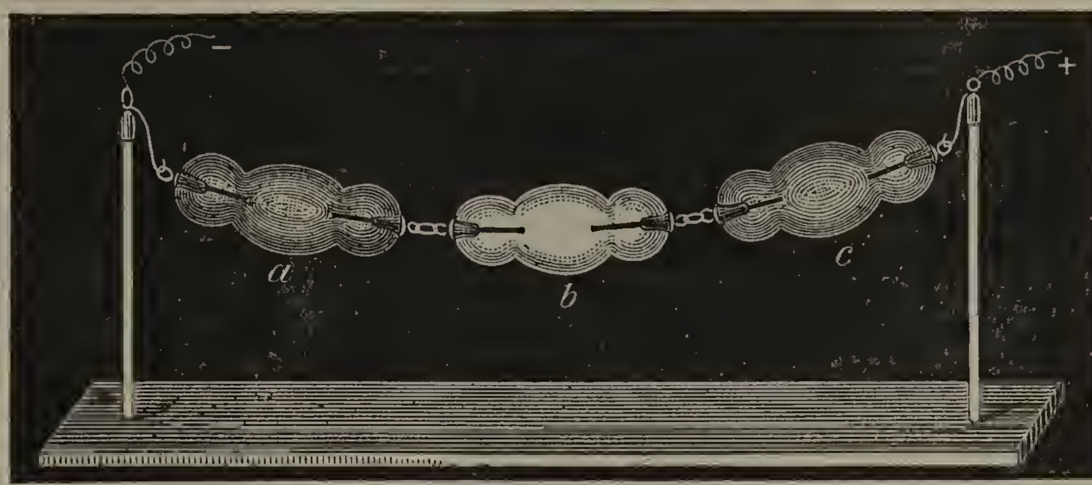

Fig. 2.

apparatus before you is made—which phosphoresces of a bright apple-green.

My earlier experiments were almost entirely carried on by the aid of the phosphorescence which glass takes up when it is under the influence of the radiant discharge ; but many other substances possess this phosphorescent power in a still higher degree than glass. For instance, here is some of the luminous sulphide of calcium prepared according to M. Ed. Becquerel's description. When the sulphide is exposed to light—even candlelight—it phosphoresces for hours with a bluish white colour. It is, however, much more strongly phosphorescent to the molecular discharge in a good vacuum, as you will see when I pass the discharge through this tube.

Other substances besides English, German, and uranium glass, and Becquerel's luminous sulphides, are also phosphorescent. The rare mineral Phenakite (aluminate of glucinum) phosphoresces blue ; the mineral Spodumene (a silicate of aluminium and lithium) phosphoresces a rich golden yellow ; the emerald gives out a crimson light. But without exception, the diamond is the most sensitive substance I have yet met for ready and brilliant phosphorescence. Here is a very curious fluorescent diamond, green by daylight, colourless by candlelight. It is mounted in the centre of an exhausted bulb (Fig. 3), and the molecular discharge will be directed on it from below upwards. On darkening the room you see the diamond shines with as much light as a candle, phosphorescing of a bright green.

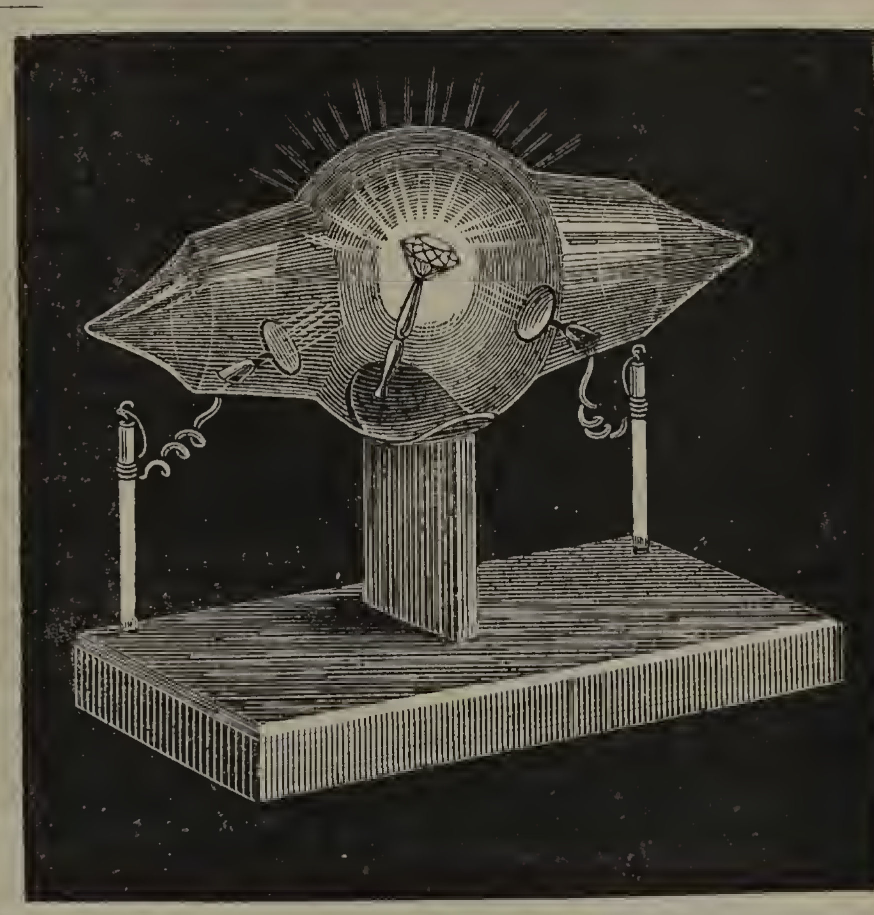

Fig. 3.

Next to the diamond the ruby is one of the most remarkable stones for phosphorescing. In this tube (Fig. 4) is a fine collection of ruby pebbles. As soon as the induction spark is turned on you will see these rubies shining

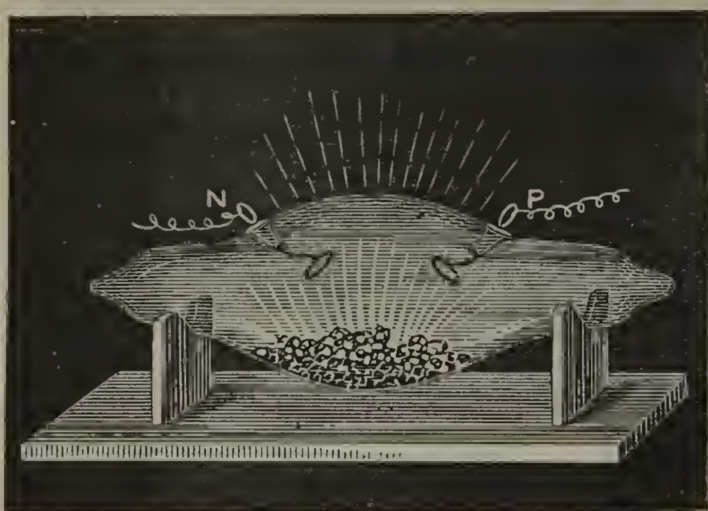

Fig. 4.

with a brilliant rich red tone, as if they were glowing hot. It scarcely matters what colour the ruby is, to begin with. In this tube of natural rubies there are stones of all colours—the deep red and also the pale pink ruby. There are some so pale as to be almost colourless, and some of the highly-prized tint of pigeon's blood; but under the impact of Radiant Matter they all phosphoresce with about the same colour.

Now the ruby is nothing but crystallized alumina with a little colouring-matter. In a paper by Ed. Becquerel,* published twenty years ago, he describes the appearance of alumina as glowing with a rich red colour in the phosphoroscope. Here is some precipitated alumina prepared in the most careful manner. It has been heated to whiteness, and you see it also glows under the molecular discharge with the same rich red colour.

The spectrum of the red light emitted by these varieties of alumina is the same as described by Becquerel twenty years ago. There is one intense red line, a little below the fixed line B in the spectrum, having a wave-length of about 6895. There is a continuous spectrum beginning at about B, and a few fainter lines beyond it, but they are so faint in comparison with this red line that they may be neglected. This line is easily seen by examining with a small pocket spectroscope the light reflected from a good ruby.

There is one particular degree of exhaustion more favourable than any other for the development of the properties of Radiant Matter which are now under examination. Roughly speaking it may be put at the millionth of an atmosphere.† At this degree of exhaustion the phosphorescence is very strong, and after that it begins to diminish until the spark refuses to pass.‡

I have here a tube (Fig. 5) which will serve to illustrate the dependence of the phosphorescence of the glass on the degree of exhaustion. The two poles are at *a* and *b*, and at the end (*c*) is a small supplementary tube

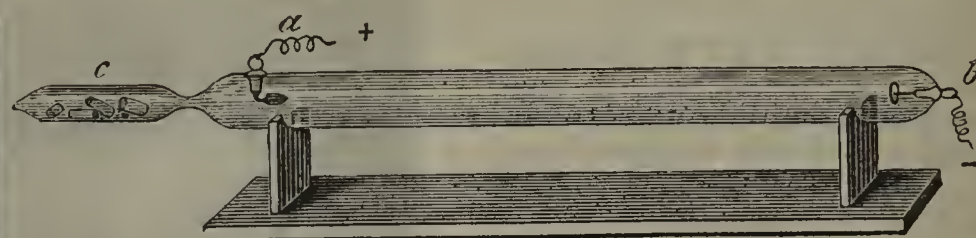

Fig. 5.

connected with the other by a narrow aperture, and containing solid caustic potash. The tube has been exhausted to a very high point, and the potash heated so as to drive off moisture and injure the vacuum. Exhaustion has then been re-commenced, and the alternate heating and exhaustion repeated until the tube has been brought to the state in which it now appears before you. When the induction spark is first turned on nothing is visible—the vacuum is so high that the tube is non-conducting. I now warm the potash slightly and liberate a trace of aqueous vapour. Instantly conduction commences and the green phosphorescence flashes out along the length of the tube. I continue the heat, so as to drive off more gas from the potash. The green gets fainter, and now a wave of cloudy luminosity sweeps over the tube, and stratifications appear, which rapidly get narrower, until the spark passes along the tube in the form of a narrow purple line. I take the lamp away, and allow the potash to cool; as it cools, the aqueous vapour, which the heat had driven off, is re-absorbed. The purple line broadens out, and breaks up into fine stratifications; these get wider and travel towards the potash tube. Now a wave of green light appears on the glass at the other end, sweeping on and driving the last pale stratification into the potash; and now the tube glows over its whole length with the green phosphorescence. I might keep it before you, and show the green growing fainter and the vacuum becoming non-conducting; but I should detain you too long, as time is required for the absorption of the last traces of vapour by the potash, and I must pass on to the next subject.

‡ Nearly 100 years ago Mr. Wm. Morgan communicated to the Royal Society a Paper entitled "Electrical Experiments made to ascertain the Non-conducting Power of a Perfect Vacuum, &c." The following extracts from this Paper, which was published in the 'Phil. Trans.' for 1785 (vol. lxxv., p. 272), will be read with interest:—

"A mercurial gage about 15 inches long, carefully and accurately boiled till every particle of air was expelled from the inside, was coated with tin-foil 5 inches down from its sealed end, and being inverted into mercury through a perforation in the brass cap which covered the mouth of the cistern; the whole was cemented together, and the air was exhausted from the inside of the cistern through a valve in the brass cap, which producing a perfect vacuum in the gage formed an instrument peculiarly well adapted for experiments of this kind. Things being thus adjusted (a smal wire having been previously fixed on the inside of the cistern to form a communication between the brass cap and the mercury, into which the gage was inverted) the coated end was applied to the conductor of an electrical machine, and notwithstanding every effort, neither the smallest ray of light, nor the slightest charge, could ever be procured in this exhausted gage."

"If the mercury in the gage be imperfectly boiled, the experiment will not succeed; but the colour of the electric light, which in air rarefied by an exhauster is always violet or purple, appears in this case of a beautiful green, and, what is very curious, the degree of the air's rarefaction may be nearly determined by this means; for I have known instances, during the course of these experiments, where a small particle of air having found its way into the tube, the electric light became visible, and as usual of a green colour; but the charge being often repeated, the gage has at length cracked at its sealed end, and in consequence the external air, by being admitted into the inside, has gradually produced a change in the electric light from green to blue, from blue to indigo, and so on to violet and purple, till the medium has at length become so dense as no longer to be a conductor of electricity. I think there can be little doubt, from the above experiments, of the non-conducting power of a perfect vacuum."

"This seems to prove that there is a limit even in the rarefaction of air, which sets bounds to its conducting power; or, in other words, that the particles of air may be so far separated from each other as no longer to be able to transmit the electric fluid; that if they are brought within a certain distance of each other, their conducting power begins, and continually increases till their approach also arrives at its limit."

REGISTRATION UNDER THE DENTAL ACT.

THE letter which appeared in this Journal some weeks since from Mr. MUSGRAVE, was not, in our opinion, either timely or judicious; but, having regard to the character of affording full opportunity for the expression of opinion, which we seek to merit by the insertion of letters in our correspondence columns, we allowed that influence to overrule the disposition to treat the letter in question as unsuitable for publication. As might naturally be expected the appearance of Mr. MUSGRAVE's letter has induced a number of correspondents to enter the lists with him for the purpose of controverting the opinions he has put forward. The publication of the letters which appear in the present number of the Journal has been unavoidably postponed, and since they were in type we have received many others, but as they are all very much to the same effect as those which have been published, it is unnecessary to occupy more space by inserting them also.

As regards the most prominent topic of Mr. MUSGRAVE's letter, viz., the claim of chemists' assistants to registration as dentists, we confess to having some considerable difficulty in coming to a decided conclusion whether or not chemists' assistants should be included among those who constitute the third class of persons described in the Act as entitled to registration under it. So far as concerns the present question, the persons who are there mentioned are such as were at the passing of the Act *bonâ fide* engaged in the practice of dentistry or dental surgery in conjunction with pharmacy. It may be contended that the common sense no less than the strict legal interpretation of those words should have reference only to those who were thus engaged in practice on their own account, and that consequently persons acting merely in the capacity of assistants to chemists and druggists who were engaged in the practice of dentistry would not be included in the terms of the Act and would not have the same right to registration as their employers. Certainly if this view of the matter were allowed to govern the admission to the Dental Register some very grave injustice would be done to many. It is quite conceivable that a chemist's assistant or apprentice may have acquired by application and experience in the dental operations that are usually performed by chemists, such skill and competence as to make him fit for registration in accordance with the spirit of the Act. As possessing the ability requisite for doing dental work, it would be a very hard case if such a person were denied registration upon the ground that his practice had not been *bonâ fide* because it had been carried on for someone else and not solely on his own account.

The hardship of such a case would be the greater, since the Dental Act does not contain any definite provision for admitting persons to registration by means of a modified examination, such as that provided to meet the case of chemists' assistants at the passing of the Pharmacy Act. One of our correspondents, writing from the same point of view as Mr. MUSGRAVE, lays great stress upon the significance of the term "*bonâ fide*," as being well understood by lawyers as one that, far from being lax or ambiguous, sweeps away all ambiguity. We fail altogether to appreciate in this way the import of the words "*bonâ fide*" as used in the Act, but on the contrary are disposed to regard these very words as constituting the difficulty to be encountered in reading the Act. The man who has by study and experience become skilful in the performance of dental operations and has carried them out successfully, as well as to the satisfaction of those operated upon, may well be said to have been "*bonâ fide*" engaged in the practice of dentistry. Whether he did this as a chemist in business on his own account, or whether he did it only as a pupil or assistant, does not much matter so far as the common sense view of the matter is concerned; nor do we think it much matters in regard to the true object and aim of the Dental Act.

We believe from what has been stated by some of our correspondents that many chemists' assistants who have had training and experience in dentistry in the way above mentioned, have sought and obtained registration under the Dental Act. Mr. MUSGRAVE's own inquiries have resulted in establishing the same fact. Of course we cannot undertake to say that in all cases the grounds upon which such registration was obtained were what they should have been, nor is it our business to attempt this; the settlement of any question that may be raised in regard to that point is in the hands of the Medical Council, by which body it will doubtless be conducted with just regard to all the circumstances of the case, rather than with the object of giving undue support to any attempted establishment of a monopoly in dental practice.

Meanwhile we would suggest to ardent reformers like Mr. MUSGRAVE that it is somewhat premature to talk and write so emphatically about "fraudulent registrations" and to flourish in such an aggressive manner the red flag of the 35th or penal clause of the Dental Act. We fully sympathize with them in their desire to make the practice of dentistry respectable by confining it to those who possess the requisite skill; it is but the other day such an undertaking was entered upon by our own body, and it would be ungenerous if we did not accord to dental reformers the same encouragement which pharmacists have been glad to receive from medical men. But these endeavours to effect reform must not be carried out with a high-handed disregard of antecedent conditions and their consequences. The first great work of the dental reformers is not to set up a graven image as the ideal standard to which all dentists must conform and to insist upon the immediate sacrifice of all that do not so. This achievement may be left for the dentistry of the future and present labour must be devoted to the making of a register. We cannot expect nor do we think dental reformers can hope that this will easily be made a satisfactory roll of persons entitled, in every sense of the word, to practise dentistry. It is in other ranks than those of chemists and druggists that are to be found the practitioners who have brought discredit upon the dental branch of the medical profession, and this is so well known that we are at a loss to understand the bitterness with which the dental practice of chemists has been fixed upon as a thing to denounce, and if possible to suppress.

Until dental practice shall have become, under the judicious administration of the Dental Act, a much better regulated occupation than it has been, we do not think there is much probability that Mr. Musgrave's idea of a dentist will correspond with more than a very small number of the registered persons who are legally qualified to practise dentistry and entitled to recover fees for so doing. We fully admit that from an ideal point of view the dentist should have been engaged in every branch of the dental art, able to undertake any operation and do any mechanical work that may be required for the mouth by the public; but there is no immediate prospect of the dental register being wholly occupied by such men. They must long be content to rank on a legal equality with many inferiors, just as the more accomplished pharmacist is still constrained to accept the legal level prescribed by the Pharmacy Act and trust to individual excellence for gaining greater recognition than that standard of qualification will afford.

As regards the general public and the existing order of things Mr. Musgrave's dentist is to a great extent, if not entirely, the dentist of the future, and as regards the dental practice of chemists, there is not a shadow of reason for accepting his definition of what a dentist should be in the eye of the law. He speaks of chemists that have been pointed out to him who have never done any dental operation beyond extracting a tooth, and he adds that they probably never saw the inside of a dental laboratory, know absolutely nothing of "dentistry" in his sense of the term, and he urges this is inconsistent with the fact that they are registered as having being in *bonâ fide* practice as dentists. We do not desire to question the good faith with which Mr. Musgrave puts forward this argument as an objection to the legal recognition of the chemist as a dental practitioner, and would only point out its fallacious nature by reference to the circumstance that drawing teeth is pretty well the extent to which dentistry has been practised by chemists, or to which they are generally called upon to practise dentistry. It was upon this ground that the Council of the Pharmaceutical Society applied for and obtained the insertion of a clause to enable chemists to continue as they had done mainly the extraction of teeth and some other operations of dentistry. But for that clause a chemist who drew teeth would have been to that extent practising as a dentist and by holding himself out as doing so by means of a notification on his window he would have been liable to a penalty.

In one and the same breath Mr. Musgrave expresses his contempt for this limited exercise of dentistry, and yet grudges the chemist the registration by which he is enabled to practise it lawfully. This seems to us unreasonable. The very limitation of the chemist's dental practice which he despises should be a reason for inducing him not to treat the tooth-drawing chemist as an opponent or a rival. At the same time drawing a tooth is a dental operation, and as the chemist who does it practises dentistry it seems irrational to leave him outside the operation of the Act by which it is sought to improve dental practice generally.

We understand the Dental Register has now been published and that the public, no less than the medical and pharmaceutical communities, will be able to know who is legally qualified to practise dentistry. That numerous amendments will have to be made necessitating the early publication of a new edition may be taken as certain, and if we may accept the intimation of some of our correspondents, the British Dental Association will soon be busy in its search for defective titles. That this should be done we admit is right; but judging from the spirit manifested in some of the letters we have received, it will not be at all less right to suggest that this work of purging the register should be conducted with discretion and justice, under the guidance of common sense rather than of high-flown ideas, and above all without a feeling of animosity against those members of the pharmaceutical body who have been brought into legal confraternity with dental practitioners more generally and exclusively engaged in the practice of dentistry.

The occasion of the retirement of Mr. G. S. Pedler, of Fleet Street, from the Court of Common Council of the City of London has furnished an opportunity to some of his fellow-citizens to show their appreciation of the services he has rendered to the ward and city generally during a period of upwards of forty years. The testimonial, which was presented on Monday week, took the form of a silver tea and coffee service and salver and a framed address, and was accompanied by a handsomely set gold ring for Mrs. Pedler.

Provincial Transactions.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

On Friday evening, September 26, a large number of pharmacists, assistants and apprentices, assembled at the Memorial Hall, Manchester, to hear a lecture on "Pharmaceutical Education," delivered by Mr. L. Siebold, F.C.S., under the auspices of the Manchester Chemists and Druggists' Association; Mr. G. S. Woolley presided.

Mr. Siebold, addressing himself chiefly to the younger members of the trade, who were present in large numbers, strongly urged upon them the necessity of making an early beginning with their scientific studies. He regarded their apprenticeship as pre-eminently the period for acquiring a sound fundamental knowledge of their calling, which they would then be in the best position to augment during their subsequent career, to their own immense advantage, and to the benefit of all they were called upon to serve. It was a mistake to suppose that their apprenticeship ought to be devoted solely to the acquisition of a practical knowledge of the trade, and that their scientific education should be reserved for a later period. Their practical training, no doubt was a most essential element, the importance of which he would be the last to underrate; but he did not see how it could be efficiently acquired without its being associated with a sufficient amount of scientific knowledge to impart life, thought, and intelligence to their daily work. Their practical and theoretical studies ought to be carried on together, and if this was judiciously and conscientiously done during a period in which learning was easier than ever afterwards, they would find themselves in a position when old enough to present themselves for the compulsory examination to satisfy all demands without any previous resort to cram, and by further exertions, under the guidance of competent and conscientious teachers, to obtain that higher distinction, which, he hoped, it would be the wish of most of them to attain. It was to him a matter of surprise that the apprentices in the larger towns, where courses of lectures were provided for their benefit, were so slow in availing themselves of the opportunities thus offered, and offered on terms which were certainly within the reach of the poorest of them. They would be in a position to attend such courses of instruction for several sessions during their apprenticeship, and if they were to do this, and to supplement the efforts of their teachers by a moderate amount of home work, they would obtain in a proper systematic manner an amount of knowledge which would benefit them for ever afterwards, and which would make their Minor examination a longed-for instead of a dreaded event. If it was then their intention to set apart an entire session for the acquisition of higher attainments, and for this purpose to enter the Pharmaceutical Society's school in London, as he most strongly recommended them to do, they would find their previous efforts still further rewarded, as the benefit they would derive from the great opportunities there afforded to them would be incomparably greater than if they entered unprovided with a sound foundation of knowledge. As it was, the majority of apprentices wasted much of their valuable time without any serious effort in a scientific direction, implicitly trusting to some future cramming process to make up for all. This process, however, despite all assurances and announcements to the contrary, failed in very many cases altogether, while where it succeeded in passing a man through the examination, it yet left him without the real knowledge required for the efficient discharge of his duties. He (Mr. Siebold) had the greatest faith in knowledge slowly and systematically acquired; such knowledge was permanent, and could be employed with advantage in the pursuit of one's calling. If, however, the earlier opportunity of the pharmacist had been neglected, and he had to face the necessity of gaining rapidly knowledge which would much better have been acquired by degrees, then it was all the more important that such a student should seek the aid of able and conscientious teachers, and avoid the unscrupulous crammer. There was this great distinction between learning and cramming, that the former process leads to a proper understanding of the facts committed to memory, enabling the student to make use of such facts for deducing other facts yet unknown to him, and to augment his store of knowledge, not merely by further additions from without, but also by his own reasoning and reflection; while the process of cramming (in the objectionable sense of the term) conveys to the students mere facts without any intelligible conception of their true meaning and the uses to which they may be applied. Such a system was intended not to impart real knowledge, but to get ignorant men through their examination; but he (Mr. Siebold) believed that in most cases it would fail to accomplish even that. He was quite aware of the fact that many passed their examinations after such a course of cramming; but he felt sure that in the great majority of such cases the success was due to previous honest efforts on the part of the candidates, and that the process would utterly fail with actual beginners. To those who did not wish to learn, but whose sole aim it was to endeavour by a show of sham knowledge to impose upon examiners—to those he had not a word to say. He trusted, however, that there would be an ever increasing number of young pharmacists anxious to obtain a sound scientific training, which he regarded as the surest means of winning for them the respect of professional men, and of raising them to a higher place in the social scale.

At the conclusion of the lecture,

The Chairman, in moving a vote of thanks to the lecturer, noticed with great satisfaction amongst the audience the large proportion of young men. He suggested to such of the latter as were engaged in study, that they might derive considerable inexpensive recreation from the formation of materia medica and botanical collections and the practice of qualitative analysis during a portion of their leisure time.

Mr. J. B. Payne seconded the resolution. He had listened to Mr. Siebold's remarks with great interest and very much pleasure. With reference to one of the remarks made by the lecturer at the commencement of his paper, in which he said that it was the duty of every employer to see that the apprentice committed to his care devoted some portion of his time to study, and which statement he cordially endorsed, Mr. Siebold did not tell them how that was to be accomplished in the case of those youths who showed themselves unwilling. He had had experience of both classes, those anxious to receive every assistance they could get, and those who utterly set it aside, and he must confess his inability to deal with the latter class. It was often a consideration with young men how to obtain possession of text-books and works of reference, and he took this opportunity of reminding those present that the Manchester Association had a good library, and that any youth on taking a note from his employer, who was a member of the Association, could have books for use at home by applying for them. He was sure also that the Council would whenever requisite be glad to make additions to the library, provided good use were made of the books.

Mr. Bostock, in supporting the motion, paid a tribute of respect to Mr. Siebold for his earnestness and enthusiasm in instructing his pupils.

The lecturer briefly acknowledged the thanks of the meeting, and the proceedings terminated.

Obituary.

Notice has been received of the death of the following:—

On the 30th of August, 1879, Mr. John Jackson, Chemist and Druggist, Northampton Street, Leicester. Aged 73 years.

On the 3rd of October, at Shanghai, China, of cholera, Mr. William Arthur Thirlby, Pharmaceutical Chemist, formerly of Ashby-de-la-Zouch. Aged 27 years. Mr. Thirlby had been a Member of the Pharmaceutical Society since 1874.

On the 7th of October, 1879, Mr. Thomas Croskell Blaymire, Chemist and Druggist, St. Ann's Square, Manchester. Aged 25 years. Mr. Croskell had been an Associate of the Pharmaceutical Society since 1871.

BOOKS, PAMPHLETS, ETC., RECEIVED.

Hospital Formulary and Posological Table for the Use of the Department of Public Charities and Correction of the City of New York. New York. 1879. From Mr. C. Rice.

Elements of Modern Chemistry. By Adolphe Wurtz. Translated and Edited from the Fourth French Edition by W. H. Greene, M.D., etc. London and Philadelphia. J. B. Lippincott and Co. 1879. From the Publishers.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[345]. Ought the following injection to be filtered or a "shake the bottle" label put on?—

℞ Zinci Sulphatis . . . . grs. v.
Liq. Plumbi Subacetatis . . . . . ʒj.
Aquæ . . . . ℥vj.
Misce. For injection.

Assistant.

[346]. When pigment. iodi. is ordered which should be sent out, the tincture or liniment of iodine?

"Juvenis."

[347]. I have had euonymin from several good wholesale houses. That which I get in Scotland is always distinctly green in colour, whereas that from London is as invariably a distinct brown, with slightly greenish tinge. Will some competent person kindly say which is as it should be, and by what tests it may be recognized?

Glasgow. Euryowie.

[348]. I had the following prescription handed me to-day. Will some of your correspondents give their opinion as to how it should be dispensed? Is the top ingredient meant for Ferri Am. Cit?—

℞ Ferri Ammoniæ Sulph. . . . . . . ʒj.
Syrupi Flor. Aurant. . . . . ℥v.
Aquæ Destil. . . . . ad ℥viij.
Cap ½ ter die.

Perhaps I may say I could not see the prescriber.

Mag. Carb.

[349]. The following prescription was presented to me a few days ago. Would some of your numerous readers inform me as to the best mode of dispensing it?—

℞ Ol. Copaibæ . . . . ♏ij.
Magnesiæ Ust. . . . . gr. ij.
Gum. Acaciæ . . . . gr. j.
M. Ft. pil. Mitte tales xxxvi.
Sig. Three pills to be taken thrice a day.

Junior.

[350]. How should the following be dispensed, and what appearance should it present?—

℞ Chloral Hydrat. . . . . gr. xx.
Pulv. Camphor. . . . . gr. v.
Syr. Tolut. . . . . ʒj.
Aq. . . . . ad ℥j.
M. ft. haust. Statim sd.

Tyro.

[351].

℞ Sodæ Bicarb. . . . . gr. x.
Pulv. Calumb. . . . . gr. x.
„ Zingib. . . . . gr. v.
M. Ft. pulv. j. capt. ter die.

℞ Potass Bromid. . . . . ʒss.
Acid. Tartaric. . . . . ʒiv.
Aquæ . . . . ad ℥vj.

A tablespoonful three times daily with one of the powders previously dissolved in two-tablespoonfuls of water, whilst effervescing.

Ought the mixture to be clear? It has been sent out turbid and bright, and with a heavy deposit (Pot. Bitart.), and still the patient is not happy.

"Country."

[352].

℞ Liq. Strychniæ . . . . ♏xxiv.
Ferri et Ammon. Cit . . . . . ʒiss.
Potass. Bromidi . . . . ʒj.
Magnes. Sulphatis . . . . . . ʒij.
Aquæ Flor. Aurantii . . . . . ℥vj.
M. Ft. mist.

The above produced a turbid mixture which was brought back by the patient the following day, who assured me that at Lucerne it had been dispensed a bright red and perfectly clear solution; moreover her physician had particularly requested to be allowed to see the first bottle before any was taken and expressed his surprise to find that it had been so scientifically dispensed. I made up another bottle in the presence of the lady, reversing the order in which I had mixed it the previous day, but with no better result. Afterwards I made several small quantities varying the *modus operandi* in every conceivable way, and testing the neutrality of the magnes. sulph., but without the success of my *confrère* at Lucerne. I would add that this is the second pharmacy in Paris in which it has been dispensed with a like result, and should be glad if some of your readers would explain the method of mixing, so as to obtain a perfectly clear and bright red mixture.

Paris. O. Rogers.

[353]. The following prescription was brought to me the other day and I had to make ten dozen of the pills. Should be glad to hear the opinion of some your correspondents on the best method of manipulation, and allowing for the difference in price of Howard's Quinine here (18*s.* 6*d.*) what they would consider a fair price to charge per doz.:—

℞ Quinæ. Disulph., Hwd's . . . . . ʒv.
Acid. Sulph. Dil. . . . . ♏xx.
Pulv. Phosphori . . . . gr. iss.
Strychniæ Sulph. . . . . gr. iss.
M. s. a. Ft. massa et divid. in pilul. LX. (in fol. auro involv.).

After finishing, the pills were of a large size but not larger than an ordinary six grains pill.

Orange, N. S. W. J. S.

[354]. Should this mixture be clear or turbid?—

℞ Potassii Iodidi . . . . ʒss.
Ferri Tart. . . . . ʒij.
Aquæ . . . . ad ℥viij.
M.

T. Brayshay.

[355]. Can a powder be made with these ingredients?—

℞ Pulv. Sodæ Phosphat. . . . . ʒiij.
Pulv. Zingiberis . . . . ʒij.
Potass. Citratis . . . . ʒiv.
M. Ft. pulv.

T. Brayshay.

---

[356].

℞ Castile Soap . . . . ʒj.
Camphor . . . . ʒiij.
Opium . . . . ʒiij.
Flowers of Benjamin . . . . . . ʒiij.
Oil of Aniseed . . . . ʒiij.
Ft. mass.

Can any reader of the Journal inform me the best mode of forming this into a nice mass? It was presented to me the other day. After I got them mixed up (without the oil of aniseed), they turned to be as soft as treacle.

A Student.

Notes and Queries.

[625]. ANILINE COPYING INK.—Dissolve a few grains of methyl aniline violet in methylated spirit (as little as possible), then dilute with about five or six times as much water, and add few drops of mucilage to make it a proper consistency for writing with.

J. Need.

---

[626]. TINCT. KINO. — Will some reader kindly state the best method of filtering tincture of kino? By means of filtering paper the process is exceedingly slow. A better method will greatly oblige

Minor.

---

[627]. JAPAN.—Can some reader give me a good receipt for best black japan which shall not turn opalescent with a bluish or greenish tinge on being varnished?

M. P. S.

---

[628]. STAINS FROM COCOA.—Would any of the readers of the Journal state their opinion as to the best mode of removing stains caused by cocoa on china, linen, etc.?

Ignoramus.

---

[629]. ROOKE'S GOLDEN OINTMENT.—Would any correspondent kindly oblige me with the recipe for making Dr. Rooke's Golden Ointment, as given by him some years ago?

Inquirer.

---

[630]. FERROUS OXALATE FOR PHOTOGRAPHIC PURPOSES.—Could some one through the medium of the Journal inform me how ferrous oxalate, suitable for photographic purposes, is prepared?

Hibernia.

---

[631]. FRENCH SALVE.—Can any correspondent kindly inform me what is the formula for "French Salve," and if not, where the preparation can be obtained? It is used for scurvy.

Gaul.

Correspondence.

Dental Registration.

Sir,—Having read with much interest the letters appearing in your columns about dental registration, I cannot refrain from adding a few remarks.

I think we shall all agree with Mr. Musgrave in doubting whether chemists' assistants or apprentices had any legal right to register, though if like "Lower Molar" they wrote to Mr. Miller asking the question and received the form of declaration in reply, we can hardly accuse them of a breach of common morality in thus registering, and that having been done, it would be rather unwise, despite Mr. Musgrave's solemn warning, to withdraw their names until the matter is legally decided.

Having had the advantage of a three years' dental training under an L.D.S., I can understand Mr. Musgrave's annoyance at seeing hundreds of men now legally entitled to claim all the advantages of the dentist with so little of the expense or trouble of a dental education, but the Act being now passed which renders their position perfectly legal, it would be better to recognize it with a good grace than show any perhaps natural jealousy.

All will agree with Mr. Musgrave that the Act was for the protection of the public; but how little he thinks of that when he says he would leave the operation of extraction, which he calls the least important part of the dentist's business, to the unregistered (dentally) chemist or his assistant, while he would reserve for the dentist the less surgical but more remunerative department of putting in reliable gold stoppings, etc.

I fear the public if they could speak on the matter would hardly appreciate Mr. Musgrave's kind consideration for them, but would prefer rather to be protected from the man who by a clumsy extraction fractures the tooth or the alveolus and causes them weeks of intense pain, than from him who puts in a gold stopping which proves unreliable.

In poor neighbourhoods, where the chemist and dentist generally does the most practice, the finer branches of the dental art (gold stopping, exposed pulp capping, etc.), are seldom or never required, the patients could not pay for even if they could understand the advantages of them; with them, if the tooth aches they go to the dentist with the firm determination of having it out, and they would have no faith in the man who recommended any other treatment. Mr. Musgrave may have his own definition of a dentist, but let me say that with the great majority of the public the extraction of the tooth is considered the primary and most important branch of the dental art, and if asked to describe their dentist they would say "the man who pulls out their teeth."

The chemist and dentist as a rule does not pretend to practise every branch of dentistry; if he has the knowledge he has not the time for it, but generally confines himself to the surgical part (extracting, stopping, scaling, etc.), getting the mechanical (artificial teeth, etc.) made for him by some working dentist, and Mr. Musgrave can hardly be astonished when he finds men who successfully perform most of the operations of dental surgery politely spoken of by the "professional dentist" as "dabblers in the art."

Unfortunately we have not all received Mr. Musgrave's kind advice in the spirit in which he says it was intended, and I am sure we shall all cordially hope that for the future he will have so much to do warming his irons in his own fire as to have no time for thrusting any into ours.

A. P. Penrose, *Ph. C. and Dentist.*

Amwell Street E.C.

Sir,—Mr. J. J. Musgrave in the Journal for September 27th, writes that the extraction of teeth is the least important part of a dentist's business.

In a lucrative sense it may be so, in a surgical and therefore dangerous sense it certainly is not so, and as regards skill I venture to think it requires to the full quite as much as that department of dentistry known as mechanical.

Something of the importance of purely surgical dentistry may be gathered from the reports of cases treated at the National Dental Hospital; thus for August 1st to August 31st, out of 1426 operations 995 are for extractions, 262 for stoppings, 119 for advice and scaling. I quote from the *British Journal of Dental Science*, September 15th.

York. Elevator.

Sir,—Neither Mr. Musgrave nor Mr. Clarke appears to be very certain on the points at issue, as to whether a chemist performing the simple extraction could claim to be put on the register; they evidently regard it as very questionable. Mr. Clarke speaks about the weeding out of the Dental Register by order of the Medical Council. I have never understood the Act gives them authority to demand legal evidence of fitness, else what is the declaration form for?

A weak point in that to my idea is the absence of a credible witness. My opinion is that a chemist actually in business performing the simple extraction before the passing of the Dentists' Act could legally claim to be registered, although perhaps not compelled to do so. I fail to see how either assistants or apprentices could conscientiously fill up the declaration form, however highly qualified they might be. It seems to me that a Dentists' Defence Association would be more likely to prosecute a chemist who was not on the register for extracting a tooth, rather than one who only performed the simple extraction, and had registered as a precautionary measure.

Respecting the capabilities of dentists, my experience is decidedly in favour of the chemist-dentist. I find as a rule they give more time and attention to their work, and in consequence the result is more satisfactory to the patient.

Walworth. F. W. S.

CREAM OF TARTAR.

Sir,—In commenting upon a prosecution for the sale of impure cream of tartar at Chertsey, you state that I totally ignored the fact that tartrate of lime is a natural ingredient of cream of tartar.

So far is this from being the case that I have invariably stated on my certificates given under the Sale of Food and Drugs Act, that a given sample of cream of tartar was a "good," "fair," or "inferior" specimen of cream of tartar (according to its quality), when the article consisted of acid tartrate of potash and tartrate of lime only. In no such case has a prosecution been instituted on my certificate. I must, however, point out that the B.P. in its description of cream of tartar gives a formula and a quantitative test, which distinctly contemplate an article which cannot contain more than a trace of lime salt.

Some months ago, I directed the attention of the surviving editor of the B.P., to the fact that the B.P. article was an impossible cream of tartar; and I also brought the matter under the notice of some of the leading firms in the drug trade.

Notwithstanding your strictures, I think that when a sample of cream of tartar contains a baryta salt, it is incumbent on the wholesale firm supplying the article to give some explanation of the presence of such impurity, other than mere accident. From the county of Surrey alone, I have, during the last three months, received seventeen samples of cream of tartar. Of these, no less than seven, or 41 per cent. contained sulphate of baryta in quantities varying from ½ to 4½ per cent. In other respects, the articles were of a very varied quality, and they were obtained from diverse sources—grocers as well as chemists and druggists. Surely some member of the drug trade can enlighten your readers as to the cause of this admixture.

THE ANALYST FOR THE COUNTY OF SURREY.

Sir,—I have read with much interest the report of the prosecution for the sale of cream of tartar at Chertsey, and also your leading article on the same subject. I shall be glad if you can spare me space for the following remarks.

It appears from the certificate of the analyst that the sample in question contained 11·7 per cent. of tartrate of lime and 0·6 per cent. of sulphate of baryta, and the case appears to have been dismissed chiefly owing to the evidence of Mr. William Hodgkinson that the above proportion of tartrate of lime was not abnormal. This witness stated that he had never heard of a sample of cream of tartar containing less than 7 per cent. of tartrate of lime, and that the usual proportion was from 10 to 20 per cent.

Mr. Hodgkinson's experience in cream of tartar seems to have been exceedingly unfortunate, and he cannot have gone very deeply into the matter or he would have found that the best authorities, Pereira among others, give amounts of tartrate of lime compared with which the minimum proportion he has heard of seems excessive.

According to R. Warington, a high authority on this subject, the proportion of tartaric acid existing as neutral tartrates in refined tartars varies from 1½ to 7 per cent. Taking these amounts as calcium tartrate, we may say that the proportion of that salt existing in cream of tartar is from 2·0 to 8·8 per cent.

In my capacity of public analyst, I have recently received from inspectors fourteen samples of cream of tartar, which have been considered genuine (in addition to an adulterated sample to be referred to subsequently). These were not all obtained in the same town or at places in the same neighbourhood, but at various small towns and villages in Derbyshire and the West Riding of Yorkshire, and their purchase has extended over some ten months. As one of the tests of purity I am in the habit of igniting a known weight of the sample, boiling the residue with water, filtering and again igniting the residue. This last product, when moistened with carbonate of ammonium, in the case of a pure sample, consists essentially of carbonate of calcium. It dissolves with effervescence in hydrochloric acid, leaving the faintest trace of residue. Evidently its amount represents the calcium in the original sample, and if its weight be multiplied by the factor 1·88, we obtain a very fair estimate of the proportion of calcium tartrate originally existing in the sample. Now in the fourteen samples referred to, the highest percentage of "insoluble ash" (= carbonate of calcium) found was 6·46 per cent., the next being 6·36, and no other above 4·68. The lowest amount was 2·60, and the mean of the whole fourteen was exactly 4 per cent. Multiplying these numbers by 1·88 we find that the highest amount of tartrate of lime met with was 12·14 per cent., the lowest 4·89, and the mean 7·52. Hence it appears that so far from commercial cream of tartar containing an average of 10 to 20 per cent. of tartrate of lime, as stated in evidence by Mr. Hodgkinson, in this part of the country at any rate the articles sold contain an average of only 7 or 8 per cent., and hence the cream of tartar commonly sold by country druggists and shopkeepers is equal in purity to the best specimen Mr. Hodgkinson ever heard of and is twice as pure as that commonly sold by his firm.

It appears to me that if it be admitted that cream of tartar is a preparation obtained by boiling crude tartar or argol in water, filtering, and crystallizing the salt from the clear liquid, the tartrate of calcium ought not to be present in more than a certain proportion, although it is true that it is far more soluble in solution of bitartrate of potassium than in pure water.

But it does not follow that because a high percentage of tartrate of calcium is present, that it is necessarily a legitimate constituent of the article. Any proportion beyond that readily soluble in boiling water cannot be regarded as proper. Now 20 parts of boiling water are amply sufficient to effect the solution of bitartrate of potassium, and any tartrate of calcium not soluble in this amount must be regarded with suspicion. Now, in the case of the two samples yielding 6·46, and 6·36 per cent. of "insoluble ash," I ascertained the amount of matter left on boiling the original sample with water, and found 3·15 and 3·35 per cent. respectively. These residues were soluble in hydrochloric acid, and, as far as my notes go, appear to have consisted of calcium tartrate. Hence if 3·15 be subtracted from 12·14 per cent., the total amount of calcium tartrate present, we have a residue of 9 per cent. legitimately present as a soluble constituent of the cream of tartar. This shows a close coincidence with Warington's highest result.

I am not prepared to stick at a difference of 1 or 2 per cent in the proportion of tartrate of lime, but when Mr. Hodgkinson states that 20 per cent. is a common and legitimate proportion, I would ask whether such samples are completely soluble in 20 times their weight of boiling water, and, if not, what right he has to regard them as genuine creams of tartar? (N.B.—Bitartrate of potassium is soluble in 15 parts of boiling water.)

But it may be asked, how does the excessive proportion of tartrate of lime get into the samples? In the case of crude tartars it is well known to be due to the addition of plaster to the wine, but this is not an explanation of an excessive amount in cream of tartar. In all probability such high amounts as are present in the samples known to Mr. Hodgkinson are due to adulteration of the specimens with compounds of calcium. Sophistication by chloride of calcium is said to have occurred, and there are authentic cases of adulteration by chalk and marble. In a cream of tartar sold near Pontefract, I recently found 20 per cent. of sulphate of calcium (probably as plaster of paris), and 2·3 per cent. of sulphate of barium. Of course, on treating such a sample with water a large quantity of calcium tartrate is formed. Hence it is clear that before we regard unusual proportions of tartrate of lime as normal, we must be quite sure that it is not a product of the decomposition of the tartrate of potassium with some adulterant.

How the barium sulphate occasionally gets into cream of tartar,—as in the sample which has called forth this letter —I am at a loss to imagine. It occurs too frequently for its presence to be the result of accident, as suggested by one of the witnesses for the defence. In a case at Huddersfield it was found in the form of crystalline heavy spar. Can any of your readers explain the occurrence of this curious impurity?

Sheffield. ALFRED H. ALLEN.

Sir,—With the view of preventing other pharmacists from occupying the unfortunate and unenviable position of Mr. Boyce, at Chertsey, whose case was reported in last week's Journal, and with whom I am sure we ought all to deeply sympathize, I should like to mention a simple and easy test whereby all may assure themselves of the comparative purity of this article when they receive it into stock. About 1 grain of the suspected sample should be shaken in a test tube with 6 or 8 c.c. of a 5 per cent. solution of potassic hydrate (the liquor potassæ of the official strength, provided it be free from lime, will answer every purpose); if the sample entirely dissolves barium sulphate is absent. The solution will, however, contain the calcium tartrate if any be present (and all samples of cream of tartar contain it to a greater or lesser degree), but on heating the solution to boiling, the calcium salt, being insoluble in hot solution of potash, will be thrown down, and its amount may be judged of comparatively by the bulk it occupies.* On cooling the solution the precipitate is again dissolved, so that for the purpose of comparing a number of samples I would recommend that after being well boiled they be kept hot in a water-bath, when, having been all allowed an equal time to settle, and using tubes of the same size, no difficulty will be found in estimating the comparative contamination. I merely put this forward as a rough test, and one which every pharmacist can quickly and easily employ. Of course, if it be wished to determine the actual amount of calcium tartrate present it will be necessary to take a weighed sample, incinerate and treat the residue with HCl, filter and add NH_4O and $(NH_4)_2C_2O_4$; the precipitated CaC_2O_4 may then be dried at 100° C. and weighed or ignited and weighed as $CaCO_3$; in either case its calculation into tartrate will be an easy matter.

It is unfortunate that the B.P., which should be our unfailing guide in this matter, is rather vague and ambiguous. We are told that cream of tartar, potassæ tartras acida and potassæ bitartras are synonymous, and that it is "an acid salt obtained from the crude tartar" (this crude tartar being evidently something quite distinct from cream of tartar). Among the characters and tests given is one which it has been stated provides for the presence of tartrate of lime. This runs as follows: "Heated in a crucible it evolves inflammable gas and the odour of burnt sugar, and leaves a black residue. This effervesces with diluted hydrochloric acid and forms a solution which . . . . when neutralized with ammonia is rendered slightly turbid by oxalic acid." It certainly does provide for a trace of tartrate of lime, but I think it will be admitted by those who know what a delicate test for lime oxalic acid is that the presence of only 1 or 2 per cent. would give something more than a slight turbidity when treated as above. But admitting for the sake of argument, that the presence of calcium tartrate is provided for by that test, what is the meaning of the next one? "188 grains heated to redness till gas ceases to be evolved leave an alkaline residue which requires for exact neutralization 1000 grain measures of the volumetric solution of oxalic acid." If it means anything it is that the sample shall contain 100 per cent. $KHC_4H_4O_6$ or absolute purity, and herein lies what I consider to be a contradiction. That cream of tartar does contain tartrate of lime is the experience of every one who has ever had to do with the examination of it, but that it should contain it in anything more than a trace I am by no means ready to admit. So far as my experience goes I have found samples to contain from 3 to 7 per cent., never so much as stated in your report last week, viz., 11·7.

If crude tartar is taken and ground and sold as cream of tartar, one can understand this large percentage, and this being the case it would be interesting to know how much tartrate of lime cream of tartar might contain and yet be still cream of tartar.

It has been a matter of some surprise to me that this article has not been selected by the zealous public analysts before now, and should some wholesale house consider it worth while to supply its customers with an article guaranteed to within, say, 5 per cent. of impurity, I have no doubt its efforts would be duly appreciated by pharmacists generally.

With regard to the presence of barium sulphate in the small quantity usually found, it cannot be looked upon as an intentional admixture, and the source of its contamination may possibly be from the stones in grinding

137A, *Aldersgate Street, E.C.* ALFRED E. TANNER.

* This is substantially the test I recommended when discussing this subject before the Liverpool Chemists' Association in November, 1877, and will be found with other remarks at p. 467, vol. viii., 3rd series, and I then ventured to predict that some unfortunate pharmacist would suffer prosecution for this impurity, and at the same time urged upon chemists the necessity of examining their stocks.

THE ADMISSION OF WOMEN AS MEMBERS OF THE PHARMACEUTICAL SOCIETY.

Sir,—I am one of those who consider the Council of the Pharmaceutical Society to be a representative body, and hence open to criticism by their electors; and I therefore venture to trespass upon your columns in order to express an adverse judgment upon the conduct of some of their number whom I voted for at the last election, trusting that they will take my remarks in the friendly spirit in which they are written. I shall not mention any names; but, sir, some of us who have advocated on principle the undesirability of the female (pharmaceutical) franchise will share the evident astonishment of some of our opponents at the "sudden conversion" of some in whom we had confidence at the last election as sound upon this question—a confidence supported by their speeches in and out of Council up to so late a date as the last Annual Meeting of the Pharmaceutical Society. What, then, has occurred between that time and the recent meeting of the Council to alter the opinion of these gentlemen on so important a question? There may, of course, be reasons not expressed in their speeches of Wednesday last; but, if so, I think we are entitled to know them, and the reasons there expressed for a charge they must really excuse my characterizing as shallow in the extreme.

I admit, sir, that it requires rather more courage to oppose two individual cases of application for membership than it does to advocate the broader question of the undesirability of the female franchise; and I feel quite to unite in the congratulations expressed in your leading article for this week, to these ladies upon the removal of a supposed grievance. But, sir, will it stop here? And will not the recent action of the Council weaken their own hands or those of some future-elected body in refusing admission to further application for membership from others of the fair sex, without drawing invidious distinctions? I am one of those who are sometimes accused of advocating a policy of "peace at any price," but not, sir, at the sacrifice of principle, and the action of some of these veteran Councillors reminds one too much of the conduct of the unjust judge in the parable (*vide* Luke xviii., 4 and 5), with this important difference that they were right in principle at the outset where he was wrong. Our venerable President seems to be the only man among them who holds to the courage of his convictions.

Scarborough. CHAS. FRYER.

Sir,—I was very much surprised to see by the *Pharmaceutical Journal* of Saturday last, that the Council at its meeting on Wednesday, had granted membership of the Society to two women, especially after having referred the question to the Annual Meeting, and that meeting had on two occasions voted by a small majority against their admission. True, the majority was small, still it was a majority, and I do not think the Council have acted wisely in thus ignoring the decision of the members.

If the Council did not mean to abide by the decision of the members they ought not to have sent the question to the General Meeting.

Probably the fact of the matter is that the Council were tired of the question, and (knowing it would in all probability be brought forward again at the next General Meeting) admitted the ladies rather than have any more trouble about it, notwithstanding the ladies have on two occasions been rejected by a General Meeting of the Members.

London, W. C. E. P.

THE COMPETITION OF CO-OPERATIVE SOCIETIES.

Sir,—Will you kindly afford me space in your columns for a few remarks on our position as druggists with regard to the competition of the co-operative societies? The competition of these societies to which we, in common with others, are exposed, and by which we are in many cases injured, makes it necessary that every means should be tried to lessen the evil. A great variety of suggestions have been made with this end in view, but the objection that has been fatal to most of them has been that they were impracticable. The evil still continues, and though in course of time I do not doubt that it will be greatly lessened, at present it rather grows than diminishes.

In combating this injurious competition the druggist finds himself somewhat handicapped; he does not stand on the same vantage ground possessed by those who deal in articles of food or clothing; he cannot in the case of the majority of articles in which he deals, by reducing the price offer an inducement to increased consumption. But I think he would by adopting more fully the leading principle of these societies, viz., cash payments, find himself in a better position to compete with them. There are certain practical difficulties in the way, which will occur to most; smallness of many of the transactions, for instance; but these would not, I think, prevent the general adoption of the system. There are very many articles in which the druggist deals which it would be easy to arrange for sale at two prices, viz., a cash and a credit price,—patent medicines, for instance. The customer would reap an advantage and the druggist would have the money in his desk to trade with instead of having it out at his customer's without interest; he would also have done something towards removing the manifest injustice under which the cash customer suffers in being called upon to pay as much for his purchase as the man does who has it booked for a twelvemonth or more. A great many of the articles in which the druggist deals might be listed without difficulty at cash and credit prices, and the adoption of the principle of distinguishing between the cash and the credit customer would, I feel sure, benefit both buyer and seller, and be the introduction of a sound principle into trade. The druggist could not supply medicines or dispense prescriptions at the prices charged at the "stores," nor should he attempt to do so. It is this part of his business that requires special qualification and is entitled to special remuneration; but even here the public would appreciate a move in the direction I have indicated, and with a difference between the cash and the credit price would be willing to pay something for the positive advantages offered by a personally conducted pharmacy as compared with the divided responsibility of the drug department of a general store.

I merely wish in this letter to bring the general question before your readers. The system may be carried out into practice by individuals, but I think it would be better if it became the subject of discussion among druggists generally, perhaps first through the pages of your Journal. By this means valuable opinions and much useful information may be obtained as to its probable working both generally and in particular localities. It is of no use to indulge in violent diatribes against co-operative stores, however satisfactory it may be to one's feelings to do so. Altered conditions of society and an overgrown credit system have produced them, and they can only be effectually checked by a return to sounder principles of trade.

K. K.

THE HEALTH OF THE DRUG TRADE.

Sir,—An interesting and important discussion has begun in your columns on the above subject, which would need to be handled with great caution. There is nothing so common as to draw sweeping conclusions from imperfect data, and I would warn your correspondents against making too hasty deductions from the meagre collection of facts at our command.

The statistics gleaned from the obituary of the Journal for three or four years will not justify any conclusion as to the healthfulness or unhealthfulness of our business throughout the United Kingdom. A satisfactory solution of the question can be determined only by a careful collection of facts gathered from a very large area. Speaking from my own experience and observation, extending over a period of more than forty years, I would decidedly deny that our business is more unwholesome than any other shop-keeping occupation. In my time I have had between fifty and sixty assistants and apprentices, and I do not remember a single instance of a breakdown traceable to the nature of our calling. On the contrary, boys somewhat delicate, have come to me who, under the invigorating influence of regular hours, and the frequent use of a sixteen pound pestle, developed into strong, active fellows. It is nonsense to say our well-known and gratefully-appreciated shop smell is unwholesome; as well say the blended odours of a flower garden will shorten life. Of course a dirty, ill-kept druggist's shop, where the inmates inhale nothing but a "villainous compound" of unsavoury smells, can neither conduce to comfort nor health; but that may be said of any place similarly circumstanced.

If a druggist's shop be properly ventilated and kept clean, and he himself be regular in taking out-door walking exercise, eschewing late hours and the use of tobacco in any shape, and as he sights forty or fifty years of age, using the milder stimulants, such as beer or wine moderately, I have no doubt his life will be of average duration and as enjoyable as that of any occupation. But our young men when they elect to follow pharmacy must not expect to go through life in a Pullman's car; like the rest of us, they must rough it in some shape, and as a result they will in due time exhibit the manly attributes of self-reliance and self-respect, and I hope men of experience who may have been soured by circumstances entirely unconnected with the business, will not darken the prospects of our young men by their gloomy and illogical deductions.

Montrose. GEO. BURRELL.

Sir,—I have read with much interest the correspondence appearing lately in your columns regarding the causes of the comparatively high percentage of mortality among chemists. The remarks made on the subject by "Sandford," in a recent issue, are very much to the point, and deserve careful perusal by every pharmacist who regards his health as something worth taking care of. A badly ventilated shop, the air in which has become impregnated with a heterogeneous mixture of foul odours and noxious gases, and where fresh air only admitted when the door is opened by customers entering and leaving, is not likely to produce an atmosphere best suited for respiratory purposes, during the greater part of the day. Undoubtedly impure air, coupled with insufficient bodily exercise, is a very important factor in bringing about the early fatal consummation so devoutly to be deplored.

Another reason hinted at by Mr. Nicol in drawing attention to the subject is also deserving of notice. It is the heavy strain which is daily imposed upon the mental faculties of the pharmacist by the peculiar nature of his occupation. The continual dispensing and handing of drugs, many of them demanding the concentration of all his faculties, and taxing his utmost ingenuity in their manipulation, impose a tax upon the brain, which, slowly it may be, but all too surely nevertheless, reacts unfavourably on the physical constitution.

The remedy in both instances is obvious. Let every possible means be employed to keep the air inside the shop pure and unadulterated, and instead of remaining on the rack for the space of ten and eleven hours out of the twenty-four, as is almost universally the case at present, let the number be reduced to nine at the very utmost. I have for a good many years been a strong advocate in favour of shorter hours being adopted by our profession, and have never yet discovered a single satisfactory reason why they should not be adopted. The petty jealousies and bad feeling which exist among ourselves are almost the only obstacles in the way of progress in this much desiderated direction, and so long as these obstacles remain, the present long hours system must remain also, and the high rate of mortality among chemists obtain as it has obtained in the past.

Edinburgh. OMNES MORIEMUR.

Sir,—On reading Mr. Nicol's remarks on the early death of chemists, and also the other correspondents on the subject, I felt a desire to make a few remarks. No doubt the locality in cities have much to do with our health, but I think our mode of living has more to do with the longevity of our lives than situation. As an instance, one chemist in this town carried on his business in a dense and low locality, and was never out of his shop from early dawn till very late at night; he is now retired, and if living he must be over eighty. Myself I am always at my post from soon till late, and have not been a day out of my shop for nearly twenty years, have never a day of sickness, and am now sixty-two years of age. Of course I always have plenty of air, both by door open, and also fanlight, and in winter very seldom close the door unless extremely cold. I think by constantly harping on the short lives of chemists, parties will imagine the calling is unhealthy for a young man. "Nothing of the sort;" essential cleanliness and the requisites for inducing health are all that are required to prolong our lives to the "allotted span."

VERUS.

Sir,—I notice a letter in the Journal of Saturday, September 6, by J. K. Nicol, regarding the health of the drug trade, in which he states that nearly 80 per cent. of chemists and druggists die at an early age.

Should this statement be correct it calls for serious consideration.

Impure air and close confinement are seemingly the two great evils.

We find a great many assistants with limited means starting business on their own account, and having recourse to long hours and assiduous attention to work to eke out a livelihood, and thereby utterly destroying their own constitution.

I would therefore suggest as reasonable business hours from 8 a.m. till 7 p.m., and should these hours be strictly kept sufficient time would be allowed for recreation, and doubtless the percentage of premature deaths would gradually decrease.

T. S. W.

How to Reduce our Death Rate.

Sir,—Allow me to throw out a few simple remarks on this subject. That our death rate is high, we can all easily believe, and we can as easily understand the reasons. Whether the percentage of those who die in their prime be quite up to what Mr. Nicol has found it, we may not be able exactly to determine; but certain enough it must be deplorably high. The reasons for it are plain, and the chief ones are these three: The comparatively stagnant nature of our work; the undoubtedly bad air we breathe, and, worst of all, the general long hours of the trade. If we are to reduce our high death rate, the great thing we must aim at is shorter hours, or more recreation and rest in one way or another. The nearer we can get, in fact, to that golden rule of eight hours to work, eight to play, and eight to sleep, the happier will our lives be, the lower our death rate. What each of us seems to be driving at in this go-ahead age is ever making a good business,—making money. In our zeal for these we forget health, or we give it but a third place in our thoughts. This must not be if we are to live longer lives. The order must be health, first, business, second, money, third. But the question will be asked, "How can chemists act up to this rule of eight hours to work, or where is the ordinary chemist who can carry it out?" I confess he is a *rara avis*, and in my travels of a dozen years, I have only met with two who had the good sense and courage to do it. One was a chemist in a small provincial town, the other was the chief of a large establishment in an important manufacturing town. I had noticed that the former took a great deal of recreation, and one day, about six years ago, I asked him how he was able to do it. He replied that he had simply made it a rule, almost from the first year he went into business, that he should not work more than eight hours a day on the average. He had stuck to this rule up to that time, and, I believe, he does so still. He did not work exactly eight hours each day, but between frequent holidays and short hours while he was at business, he made certain that his average was not more than that for each day of the year. It may be asked, and how did his business fare? He had always an assistant who was left in charge to do the best he could, and when the chemist returned from a holiday, the assistant got out to have his turn. He was always sure of getting more recreation time than the most of such assistants get.

In this way did this small chemist enjoy life, and keep himself healthy, while he also gave the health of his assistant a due amount of consideration, and in this way he also kept his business going at a fair pace. No doubt, had he stuck as closely to it as most chemists on his level do, he might now have had a better business, and a little more money saved for his old age (that is if he had lived to see it); but was it not wiser of him to enjoy life as he went along, to keep himself healthy, and to be content with a smaller business? I have always thought this man one of the most sensible chemists I ever met, and he certainly was one of the jolliest and healthiest. This, then, is one good model for chemists to go by, and it is happily one from the humble rank. The other I referred to was a noble specimen in every sense of the word. He had, I believe, made it a rule during the most of his business life of nearly fifty years, to work only about eight hours a day, going to business at 10 a.m., and leaving at 5 or 6 in the evening. He lived in vigorous health almost to the last week of his life, and died beyond the three score and ten, leaving a large business and a large fortune. He also thought of his assistants, the hours for ten out of twelve of them being from 10 a.m. to 8 p.m., with a break of three quarters of an hour for dinner. This made the day's work fully nine hours, but as each assistant got a fortnight's holiday in the year, that reduced the average day's work to little over eight hours, which was all that could be desired. This man was one of Nature's noblemen.

Chemists may be divided into three classes. First, those who are not able to keep an assistant and who can do little more than make a living; second, those who keep from one to four assistants and who make an income of from £300 to £600 a year; third, those who are able to employ half a dozen assistants or more and whose income is beyond £600. It is, no doubt, the first class who do most to swell up our high death rate. We have pity for these men in their lives and we regret their fate if they go to the ground in their prime on account of the confined life they have led.

I would, I think, prefer the life of Mr. Barnaby's niggers, for in all likelihood they would have the free pure air to breathe and work in and companions to toil beside, which would do much to brighten and lengthen life, slave life though it might be called. I would, however, recommend the chemists of this class, who must remain in the business they have chosen, to live as carefully, economically and contentedly as they can, doing their best to improve their condition; and wherever it can be done, let them shorten the day's work by an hour or two. Let them take what little exercise and recreation they can; a day or two, or a week or two occasionally in the country, according as their circumstances will admit, by getting a temporary assistant to take charge. They should see well to the proper ventilating of their shops. A current of air should always, if possible, be allowed to go right through the shop during the night, especially in winter time, when the air must be foul with the burning gas and closed doors. Rather let a fanlight remain open that might allow a burglar to get in, than entirely shut up that vicious air, to have to go into it again in the morning; for the burglar, if he go in, can at best but steal away a few shillings or pounds, while the other will assuredly steal a few years of life.

As men of this class have so little exercise, they should, during winter, wear a good layer of lamb's wool from neck to toe, which will help greatly to keep heat in and cold out, and it will enable them to do with less gas stove or fire heat. This is an important matter though it may be lightly thought of; and those who want proof of it will find it in Combe's 'Constitution of Man,' in which work many other valuable hints may be got for the preservation of life. Hufeland's 'Art of Prolonging Life,' is another book from which many good hints may be got. It would be well for chemists who aspire to long lives to give a little more attention to such books as these and less to their chemistries.

The second class of chemists can have almost no excuse if they do not keep near to this rule of the three eight hours. Instead of admiring men of this class for their industrious ways, or, in other words, for making slaves of themselves to business, we should look upon them with contempt. If such men die in their prime, we should have little sympathy for them; we should rather be thankful they have gone, o that others like them, working as they done, may take warning and do otherwise.

Little requires to be said about the chemists of the third or highest class. If any of them die in their prime, we know well what we should style them. It is to this class we look for the example of shorter hours, and it is very gratifying indeed to notice that some of the principal London houses are closing much earlier than they did a few years ago. Assistants in these houses, I have also observed remain much longer, and work more contentedly than they did when the hours were longer.

One word to assistants: They must not imagine that they are to do nothing and masters all to bring about this short hour system, and to reduce this high death rate. They must make up their minds to take a moderate salary for a situation in which the hours will be short, and be certain to ask for the highest where the hours are long.

Shorter hours throughout the trade, and a lower death rate we certainly will have as we get more enlightened. Chemists will not always be such fools as to sell their lives at such a rate for the mere glory of business or money; a happy and healthy long life they will look to first. There are signs of better times coming, now that the doors of some good west end houses begin to close at 7 o'clock; but if 80 per cent. are still dying in their prime, we may well raise a cry for the rest to lower their hours as far and as fast as they can, and let it ring right down to the poorest of the line.

A Sawney.

Nitrate of Pilocarpine.

Sir,—I acknowledge to have overlooked part of Mr. Martindale's remarks at the Sheffield Conference on the purification of nitrate of pilocarpine; therefore, I will set aside my letter published in the Journal on September 20, and start afresh with a desire to be strictly accurate and give credit to whom it is due.

The process spoken of by Mr. Martindale was first made public by M. Petit, in the *Répertoire de Pharmacie,* for August 25, 1877, and no matter how long previously Mr. Martindale may have used the same process, he must know he is not justified in claiming it as his own discovery two years after its publication by another.

The merit of the process is due to M. Petit and to him it must be given.

University College Hospital. A. W. Gerrard.

Gelatinization of Tincture of Kino.

Sir,—In respect to Mr. Bamford's remarks, and those of others, on the difficulty of keeping this fractious tincture from "jellying," it is a curious fact that during my forty years' experience with drugs, etc., I have always found the above tincture very difficult to keep, but I have now in my possession some obtained from Messrs. Evans, Sons, and Co. five or six years ago, and still it is as good as ever. The bottle has been several times opened, it is placed behind others, and is perhaps shifted and dusted every week, and it is as perfect and liquid as the day it was made. How it is I cannot pretend to say, but it is the only tincture of kino that I have seen in my forty years' experience that has *not* "jellied."

Catechu.

Tincture of the Resin of Podophyllum Peltatum.

Sir,—This tincture is now ordered a good deal, and in the absence of an official formula we would take the liberty of suggesting that the following strength should be observed:—

Podophyllin (Resin)	gr. j.
Alcohol	ʒj.
M.	

Fifteen minims will thus represent one-fourth of a grain of the resin, and this when taken on lump sugar is quite a nice dose.

Only this morning a medical man was inquiring the usual strength of the tincture, and although we believe many houses prepare it of the strength indicated, yet we have found that others make it widely different, and as the drug is an active one it is of considerable importance.

35, *Baker Street, W.* Young and Postans.

Pharmacy in the Transvaal.

Sir,—Can any of your readers kindly favour us with any information respecting pharmacy in the Transvaal, the number of chemists, prices obtained, and mode of doing business? Are examinations compulsory, or is there any association whatever of chemists and druggists? How are assistants paid, and what are the hours of business? Any information respecting our profession either in Natal or New Zealand will greatly oblige.

An Emigrant.

"*Epsilon*" (who should have sent his name and address).—There are two alternate whorls, which really answer to the calyx and corolla, but in consequence of their being btoh of the same colour are termed the perianth.

"*Epipactis.*"—If you send such plants to the Journal Department, after you have yourself done what you can towards naming them, we shall be willing to help you. The works mentioned are of about equal authority.

M. P. S.—We understand that the firm in question has recently promised to discontinue the use of the title. Information respecting the sale of vermin killer containing strychnia by unregistered persons should be forwarded to the Registrar.

F. H. Fairweather.—(1) *Hypnum tamariscinum.* (2) *Hypnum triquetrum.* (3) *Hypnum loreum.* (4) *Neckera complanata.* (5) *Ramalina calicaris.* (6). *Usnea florida.*

W. H.—See the paper on "Pills and Pill Coatings," by Dr. Symes, in vol. viii. of the present series of this Journal, p. 461. Several other papers on the same subject may be found by reference to the Index. There is also one in the present number.

"*Acid.*"—The addition of borax with and without glycerine and other salts, to promote the solubility of salicylic acid has been recommended, but probably in all these cases new compounds are formed not possessing properties identical with the original one. See *Pharm. Journal* [3], vol. vii., pp. 103 and 429.

A. B.—We do not quite understand your question, as tincture of iodine is itself of a red-brown colour.

X. Y. Z. is recommended to communicate with the officer appointed by the local authority under the Explosives Act.

"*Orchid.*"—*Spiranthes autumnalis.*

J. H. Dingle.—(1) *Scirpus palustris.* (2) *Senebiera Coronopus.* (3) *Silene maritima.* (4) *Arenaria serpyllifolia.*

"*Fraxinus.*"—(1) *Poa annua.* (2) *Lolium perenne.*

"*French.*"—An advertisement in one of the French pharmaceutical journals would probably secure what you require.

"*Lindum*" is referred to the rule respecting anonymous communications.

"*Medical*" should address his question to the Secretary of the Royal College of Surgeons.

"*Bill.*"—We are not acquainted with a mineral answering to your description.

"*Sarniensis*" should examine the Calendar of the University of London or apply to the Registrar of that institution.

"*Fons et Origo.*"—"Crabs'-eyes" are concretions of carbonate and phosphate of lime found in the craw fish when about to cast its shell. They were formerly used as an absorbent and antacid remedy.

M. Leigh.—The Secretary of the Institute of Chemistry, Mr. C. E. Groves, Somerset House Terrace, W.C.

B. J. Kent.—A copy of the *Pharmaceutical Journal* containing all the information yet published on the subject has been forwarded to you.

Erratum.—On p. 265, col. ii., line 31, in the list of Associates elected, *for* "Goodall, Thomas Torby, Derby," *read* "Goodall, Thomas Sorby, Derby."

Communications, Letters, etc., have been received from Messrs. Pollard, Swenden, Young, Turner, Edwards, Lawon, Thresh, Quinæ Sulph., Theta, Epsilon, C.E.P.

ACONITUM HETEROPHYLLUM, WALL.*

BY DR. M. DUNIN V. WASOWICZ.

Some years ago the attention of European physicians resident in India was directed to a nodular root which was known to the natives under the names, "utees," "atees" and "atis," and was used in fevers on account of its antiperiodic effects. Closer examination showed that although the name "utees" was also applied to several other drugs, for instance, the root of *Convallaria Polygonatum*, Solomon's seal root, or a tasteless and inert root considered to belong to *Asparagus sarmentosus*,† and in Kunawar to the root of *Aconitum Napellus*,‡ which is there eaten on account of its tonic effects, still this name was principally to be understood as referring to that species of aconite which Wallich called *Aconitum heterophyllum*. This root is said to have no poisonous properties,§ and to be, in fact, a very valuable remedy for intermittent and other fevers. It is administered in ordinary intermittent fever in the form of powder in doses of 20 grains and as a simple tonic in doses of 5 to 10 grains three times a day.|| No information respecting this drug is extant, although, according to O'Shaughnessy,¶ it has long been famous among Indian drugs on account of its tonic effects.

Professor Von Schroff, sen.,** was the first to communicate some cursory observations upon this drug in 1866, which were supplemented in 1871 by Schroff, jun.,†† in regard to its pharmacognosy.

Professor Flückiger, in 'Pharmacographia,' made known that Broughton had succeeded in obtaining from the root an alkaloid which he had not closely examined. Upon the basis of a platinum salt analysis Broughton assigned to it the empirical formula $C_{46}H_{74}N_2O_4$, and he called it "atisine." In the same year Broughton published a note on this drug in which he stated that the amount of alkaloid was exceedingly small and that the hydrochlorate was the easiest preparation to obtain. At the end of the year, T. B. Groves, in preparing aconitine nitrate from German *Aconitum Napellus*, found that after separating that salt crystals were formed in the mother liquor differing in form from aconitine nitrate and not poisonous. On the basis of polarization experiments and similarity of reactions he came to the conclusion that these crystals contained a base identical with the atisine obtained by Broughton.‡‡ At the time Hanbury expressed a doubt as to the identity of the two substances and shortly afterwards§§ C. R. A. Wright showed that Groves' inactive base more probably had the formula $C_{31}H_{45}NO_{10}$, or $C_{30}H_{45}NO_{10}$, than that of Broughton's atisine.

Subsequently, Professor Flückiger succeeded in obtaining a quantity of this root and he entrusted to me the examination of it.

Aconitum heterophyllum, Wallich, grows in the mild districts of the Western Himalayas, in Simla, Kashmir and Kumaon, at a height of 8300 to 13,300 feet above the sea level. The finest and largest samples grow upon the mountains Choor, Shalma and Kadarkantar. The plant is from 1 to 3 feet high, with heart-shaped, acute, indistinctly 5-lobed,

Fig. 1.—Leaf.

or sometimes incised, radiate-veined, leathery leaves and racemes of large dirty yellow purple-veined or entirely blue flowers arranged in a panicle. The calyx is furnished with a semicircular ascending pubescent helmet; the spur is ovate and obtuse; the limb long and bent downwards; the stamens are arrow-shaped and winged; the five carpels and the bracts roundish or rather long.

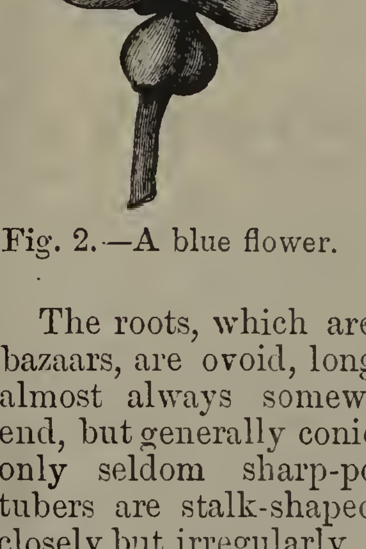

Fig. 2.—A blue flower.

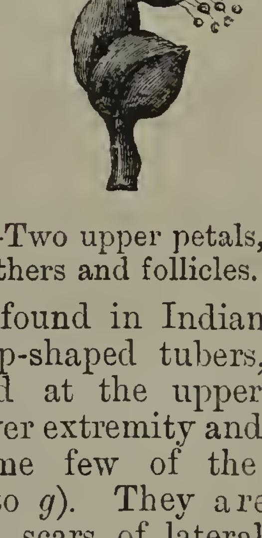

Fig. 3.—Two upper petals, with anthers and follicles.

The roots, which are only to be found in Indian bazaars, are ovoid, longish or turnip-shaped tubers, almost always somewhat flattened at the upper end, but generally conical at the lower extremity and only seldom sharp-pointed. Some few of the tubers are stalk-shaped (fig. 7 *a* to *g*). They are closely but irregularly covered with scars of lateral roots and here and there small remains of leaves are to

be found at the upper end of some roots. Externally the roots are pale yellowish grey, in some parts

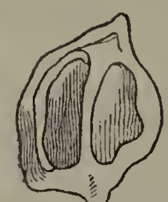

Fig. 5.—Seed.

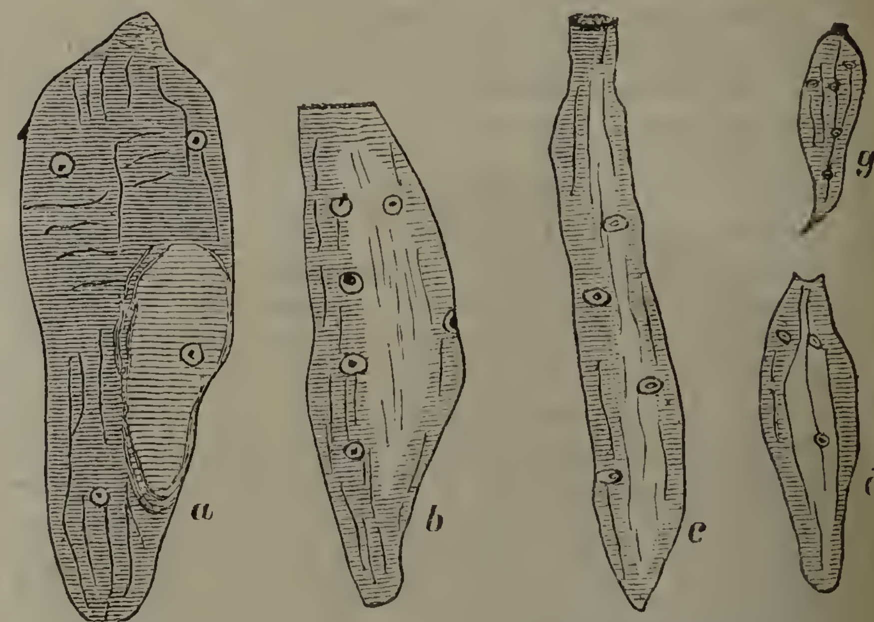
Fig. 4.—Capsule.

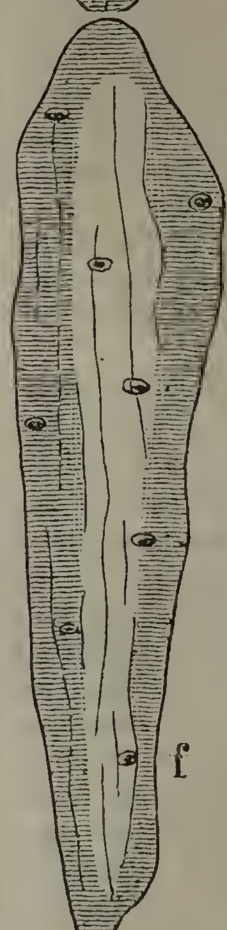
Fig. 6.—Portion of the stalk with tuberous roots.

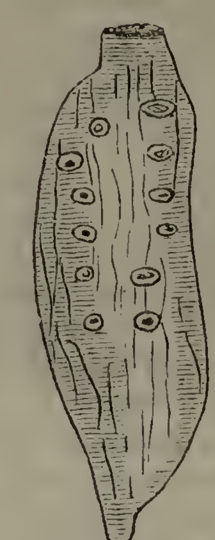
almost white, with numerous longitudinal wrinkles, and at the upper end from two to five transverse wrinkles, though only in some of the roots. In some cases there is a furrow or channel-shaped depression extending the whole length of the root. The roots are from $\frac{3}{8}$ inch to 3 inches long. The thickest diameter is from $\frac{1}{4}$ inch to nearly an inch, and they weigh from 7 grains upwards, the weight of most of the tubers varying between 38 and 90 grains. The fracture is almost even; within the tubers are clear white. The taste is mealy, somewhat mucilaginous and bitter, without any biting or acrid aftertaste. Digested in cold water for some hours the tubers swell up and after perfect drying become hard and horny. This is also the case when they are digested with hot water.

Under the microscope the pure white transverse section presents an almost uniform tissue, intersected with from three to seven rather yellowish coloured irregular bundles of vessels, situated in a scattered manner and enclosing an apparently large meditullium. Concentrated sulphuric acid colours the sectional surface reddish; solution of iodine in iodide of potassium colours it at first violet and then a dirty bluish black. Millon's reagent colours it only slightly reddish, and perchloride of iron does not alter it at all. Thin fragments, perfectly freed from starch by treatment with dilute acids and careful washing, give with alkaline solution of cupric tartrate, or with Millon's reagent, no reaction to indicate the presence of solid protein substances.

Fig. 7 *a* to *g*.—Roots, natural size.







Under the microscope the outer rind of the roots appears to be formed of four or five or six rows of somewhat rounded tabular cells crowded together and having their walls slightly brown-coloured. Next to this comes a rind consisting of five to twelve rows of elongated collenchymatous cells of uniform size and slightly thickened. This rind is separated from the rest of the tissue by a distinctly yellow-coloured zone. The cells of this zone are thin-walled and distinguished only by the yellow colour from those of the central portion of the root. The latter are rounded slightly thickened polyhedral cells of a parenchymatous nature of which the whole general mass of the tissue is formed. In this tissue there are generally very irregularly distributed vascular bundles, to the number of three or seven, which seldom consist of single vessels, but more frequently of three to nine, arranged in rows or groups. The latter are mostly scalariform, less frequently spiral, and their walls are yellowish, but much lighter coloured than those of the yellow zone. Round these vascular bundles the cells of the principal tissue are the smallest. These bundles surround a medilullium, which is almost always in the centre of the transverse section, but is not so big as it appears under the microscope. It consists also of rounded polyhedral cells, having only very small intercellular spaces and exceeding in size three or four times those of the principal tissue. The form of this tissue, consisting of large cells, varies very much; sometimes it is triangular, sometimes square, sometimes a circle or almost an ellipse, according to the number and situation of the vascular bundles above mentioned. Among the many transverse sections that I have examined from different parts of the root, by far the most of them presented the appearance shown in fig. 8. At the upper part of the root, where it is almost always flattened, the transverse section also presents such an appearance as is especially to be seen in the large-celled parenchymatous tissue. A closed cambium-ring was not to be detected either in the upper parts or at the ends of the roots. To-

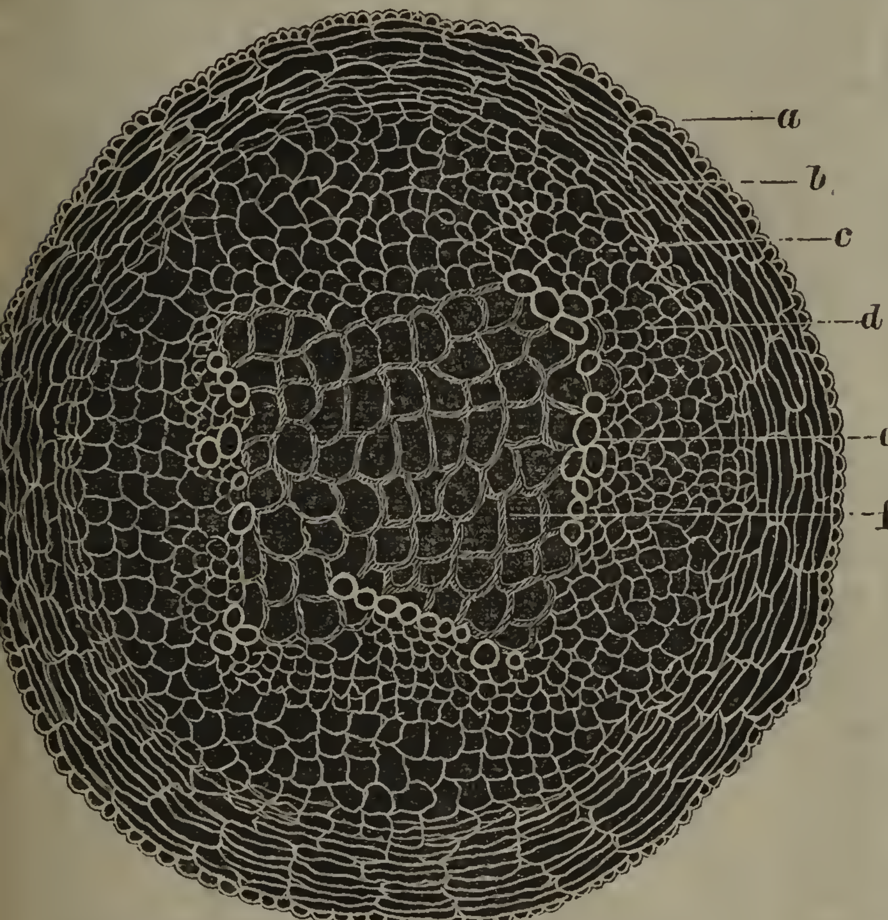


Fig. 8.—Transverse section of middle of root.

wards the conical-shaped end of the root the transverse section appears regularly arranged, and in almost all the sections presented the appearance shown in fig. 9. In the longitudinal section the

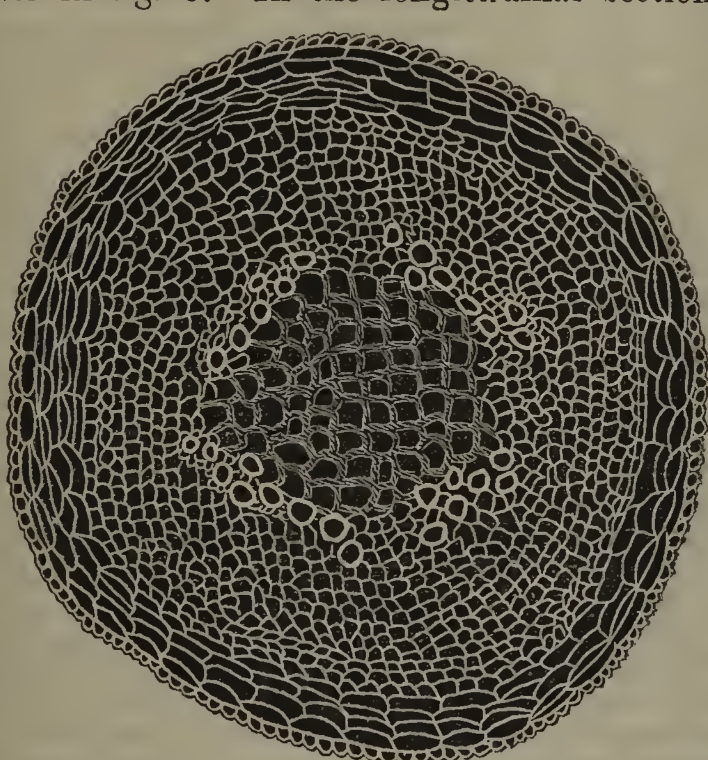

Fig. 9.—Transverse section towards end of root.

vascular bundles, or more correctly the single vessels, extend from the scars of the stalk to the opposite pointed end of the root, and though bent and curved, are always separate, and never anastomosing, and only here and there extending into a lateral root. Some vessels originate first in the centre of the root, as shown in fig. 10 *a*.

The lateral roots, so far as I could judge from their remains, have a comparatively thicker rind, consisting of longitudinally extended cells, which are rounded at both the narrow ends. The yellow zone appears distinctly also, as in the principal root, and separates the rind from the other tissues. This, as well as the vessels and the parenchymatous tissue, are formed in the same way as the corresponding parts of the principal root; but frequently the central tissue is not

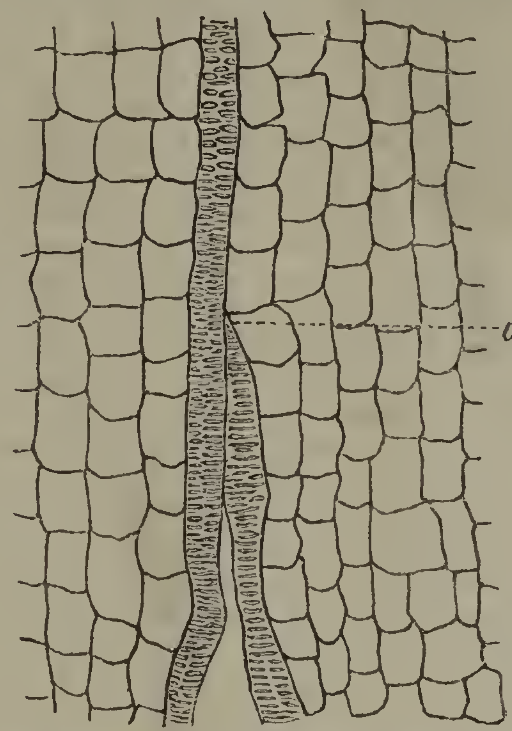

Fig. 10.—Longitudinal section: *a*, vessels originating almost in the middle of the root.

visible. Its place is then occupied by a bundle of seven to sixteen vessels. Frequently it is also comparatively very elongated longitudinally, and bounded by two vascular bundles which consist of several rows of vessels. Stony cells are altogether wanting both in the principal and the lateral roots. The contents of all the parenchymatous cells (with the exception of the empty collenchymatous rind cells) consist of single, simple or compound, or merely aggregated starch granules. The number of the parts of the granules amounts to from two to seven, more frequently from two to three. The appearance of the starch granules resembles sometimes the starch of *Phaseolus* and sometimes that of *Colchicum* (fig. 11). Some of them closely resemble the 4-partite granules of *Crocus* starch. They are comparatively small, about 15 to 18 m.m. at the most, and always somewhat larger than the granules of *Aconitum Napellus*. The starch granules of the principal are always bigger than those of the lateral roots.

PRELIMINARY NOTICE ON TEUCRIUM FRUTICANS.*

BY A. OGLIALORO.

This labiate plant, which is employed as a febrifuge, is called "olivetta" by the Italian peasants, from the resemblance of its leaves in colour to those of the wild olive. The fresh plant collected in June soon after flowering gave no essential oil when distilled with water; it was therefore dried in the sunshine, and treated with boiling alcohol in a continuous displacement apparatus for two days. On cooling, the extract deposited a deep green granular pasty substance. The partly exhausted plant was then treated for other two days with fresh spirit, and on cooling, a nearly colourless crystalline substance was deposited from the solution.

* From the *Gazzetta chimica italiana*, 8, 440—446. Reprinted from the *Journal of the Chemical Society*.

The green deposit from the first extract consists of two substances mixed with a large quantity of chlorophyll. When treated with boiling alcohol, a white crystalline substance is left undissolved, identical with the crystalline deposit from the second extract. The other compound, which is readily soluble in hot alcohol and in benzene, can only be freed from chlorophyll with difficulty. It is a nearly white somewhat soft substance, insoluble in water, and melting at about 80—85°. As it does not crystallize, and constant analytical results could not be obtained, the author is inclined to consider it as a mixture.

Teucrin.—The nearly colourless crystalline substance obtained from *T. fruticans* dissolves but very sparingly in any of the ordinary solvents, with the exception of glacial acetic acid, which affords the best means of purifying it. It crystallizes in slender prisms of a yellowish colour, which melt at 228—230° with decomposition. The results of the analyses accord best with the formula $C_{21}H_{24}O_{11}$, but the author reserves his opinion on this subject until he has more thoroughly investigated the nature of the substance. Teucrin is decomposed when heated with dilute nitric acid, leaving a residue of a red colour; on cooling, the solution deposits yellow crystals, which may be purified by recrystallization from boiling water. The new substance is thus obtained in long silky prisms (m.p. 180°) of a golden colour. It is of an acid nature, and yields a silver salt, rather soluble in water, but which is thrown down in splendid golden-yellow plates on adding alcohol or ether to a mixture of the ammonium salt with silver nitrate. The analysis of the acid itself and that of the silver salt points to the formula $C_8H_8O_3$ for the acid, which is that of hydroxytoluic acid; its fusion point also is nearly the same as that of Fittica's β-hydroxytoluic acid (*Ber.*, 7, 927). The nitric acid mother liquors, from which this acid crystallizes, contain oxalic and tartaric acids, indicating that the substance is a glucoside. Teucrin is decomposed when boiled with dilute sulphuric acid, leaving a yellow residue of an acid nature, the quantity of which was too small to establish its identity with the acid obtained by the action of nitric acid; the solution contains a substance of the nature of glucose, so that there can be no doubt that teucrin is a glucoside. Three 0·5 gram doses of teucrin administered to a dog caused a lowering of the temperature of the animal.

STATICE CAROLINIANA.*

BY EUGENE L. REED, PH.G.

Marsh rosemary is considered by Nutall, Torrey and other botanists as a mere variety of *Statice limonium*, of Europe, while others regard it a distinct species. It is indigenous to the Atlantic coast of the United States, and has a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, mucronate, smooth and on long foot stalks. They differ from the leaves of *S. limonium* in being flat on the margin, while the latter are undulated. The flower-stem is round and smooth, from a few inches to a foot or more in length, sending off near its summit numerous subdividing branches, which terminate in spikes, and form altogether a loose panicle. The flowers are small, bluish-purple, erect, upon one side only of the common peduncle, with a mucronate, scaly bract at the base of each, a five-angled, five-toothed caylx, and spatulate obtuse petals. The meadows in the vicinity of Atlantic City are made beautiful by the marsh rosemary when in flower. The delicate bluish-purple of its blossoms, which appear in August and September, produce a pleasant relief to the eye from the varying shades of green of the salt grases. It is the forerunner of the bright yellow and crimson tints of the pickle-weed, which later in the fall gives to the meadows such richness of colour. The marsh rosemary, or meadow lavender, is highly prized by those who collect grasses to ornament their homes in winter, and is placed above picture frames and in bouquets as one of their most attractive features. The root collected in October possesses medicinal properties in a higher degree than that collected later in the season. It is large and spindle-shaped, branched, fleshy, compact, rough and of a purplish-brown colour. Its length depends upon the nature of the soil, which varies from dark muddy to light sandy in numerous localities over the meadows. If found in sandy soil, the root is short and of a branching character, while that obtained from muddy soil is long, straight and less branching. It is bitter and very astringent to the taste, and in the fresh state is without odour, but a decoction kept in a warm place for several days ferments and has a molasses-like odour.

The fresh root is tough and not easily bruised except after the addition of a little alcohol. The tincture obtained with a mixture of one part of alcohol and two parts of water yielded a precipitate with acetate of lead, the filtrate from which contained sugar, gum and extractive matter. The precipitate was dissolved in alcohol, the solution decomposed by sulphuretted hydrogen, and the filtrate evaporated; it yielded 17½ per cent. of residue, consisting chiefly of tannin, which gives a greenish-black colour with solution of chloride of iron. Statice is powerfully astringent. In domestic practice it is freely used in some parts of the coast line as a remedy for diarrhœa and dysentery, to restrain morbid discharges from mucous surfaces, as a gargle in sore throat and aphthous condition of the mouth and fauces, and as a styptic in passive hemorrhages. If it were necessary to pay the cost of importation, statice would probably be held in as high estimation by the medical profession as kino and catechu. It can be tinctured and employed for all the purposes for which these popular remedies are given; it may also be given in decoction or infusion. Its abundance and valuable properties should cause it to be brought before the medical profession and to be more generally used.

* From the *American Journal of Pharmacy*, Sept., 1879.

CHLOROFORM AS AN ANÆSTHETIC.*

BY J. REGNAULD.

The purity of chloroform for anæsthetical purposes being very important, the following simple tests are recommended by the author.

If chloroform is dropped on paper and allowed to evaporate, the last portion on being inhaled has a characteristic pleasant smell, and leaves the paper perfectly dry and odourless; impure chloroform however possesses a disagreeable irritating odour, which it imparts to the paper.

Pure chloroform does not redden blue litmus or give even a cloudiness with silver nitrate. If it should do either, it contains hydrochloric acid or the products of decomposition of some other chlorides.

Pure chloroform remains perfectly colourless when boiled with potash; the presence of aldehyde causes a brown coloration.

When shaken with concentrated sulphuric acid and allowed to stand for half an hour, the two liquids should separate into two colourless layers. The presence of alcoholic chlorides produces a brown coloration.

The purity of chloroform may be judged by its constant boiling point, 60·8°. Impure chloroform may boil above or below according to the impurities it contains.

The sp. gr. of chloroform can hardly be used as a criterion of its purity, since its determination has been attended with conflicting results. Liebig has found the sp. gr. of pure chloroform to be 1·48 at 18°. Souberain shows that this number is too low, the sp. gr. at 12° being 1·496. Again, Remys (*Arch. Pharm.* [3], 5, 31) points out that the sp. gr. of pure chloroform is 1·5 at 15°, and moreover the presence of $\frac{1}{800}$ of alcohol lowers the sp. gr. ·002.

The purity of chloroform may to a certain extent be judged by the complete insolubility of Hofmann's violet in it: if it contains a trace of alcohol, the solution is coloured a beautiful purple.

The Pharmaceutical Journal.

SATURDAY, OCTOBER 18, 1879.

THE "SODA WATER" OF COMMERCE.

THE weakness that is indicated by the popular application to anything of the term "milk and water," seems to be still the prevailing characteristic of the proceedings of public analysts, and almost involuntarily they appear to be influenced by some verbal connection between the articles which first engaged their attention as a body and those which they from time to time undertake to inquire into now. From the milk of the cow they went on to "milk of sulphur," and from that have since advanced to "cream of tartar," as though subject to some kind of fascination. Though to a great extent the examination of water is outside the duty of a public analyst, the kind of aerated water known as "soda water," and commonly used as a beverage, has on several occasions been taken as the material for investigation and last week the Newport magistrates were occupied in hearing a case of prosecution under the Food and Drugs Act arising out of this exercise of the public analyst's skill.

The case we refer to is fully reported at page 312 of the present number of the Journal, and it was based upon the certificate and evidence of the Newport public analyst to the effect that a certain article called "soda water," supplied by Mr. DAVIS, a chemist, of Newport, was not of the quality and nature required by the purchaser, inasmuch as it did not contain bicarbonate of soda. According to that official, water charged with carbonic acid would not have the effect of neutralizing acidity in the stomach in the same manner that the soda water of the British Pharmacopœia would do, and apparently under the belief that soda water was drunk only by persons afflicted with acidity in the stomach, the Newport analyst followed the example of many of his brethren in arriving at the conclusion that the British Pharmacopœia furnished a standard for the composition of soda water,—that if it did not contain in the half pint 15 grains of carbonate of soda it was not of the nature and quality of "soda water."

In some form or other this mischievous delusion of regarding the British Pharmacopœia as a standard for the nature and quality of articles of ordinary daily consumption, has misled many public analysts, and has been a source of considerable unnecessary vexation to individual traders. We have on various occasions endeavoured to impress upon the minds of these official analysts that the British Pharmacopœia relates, like the Pharmacopœia of any other country, solely to the composition and strength of articles to be used as medicines, that it is intended simply to afford to the members of the medical profession and those engaged in the preparation of medicines, one uniform standard and guide, whereby the nature and composition of substances to be used in medicine may be ascertained and determined. In certain of the cases of prosecution where the public analyst has sought to make the British Pharmacopœia the standard by which to gauge the nature and quality of articles that it does not in fact refer to, the soundness of the principle we have sought to impress on the consideration of public analysts has been repeatedly endorsed by the magistrates or judges before whom the cases have been tried. But still the endeavour goes on to treat the chemist and druggist as though he never sold anything but physic, and hence we have such prosecutions got up as the one just disposed of at Newport.

Fortunately for Mr. DAVIS some of the magistrates before whom the case was brought were in the habit of drinking "soda water." They seem also to have had such a knowledge of the virtues of bicarbonate of soda and such a wise regard for the soundness of their internal economy, that they took care the soda water they drank contained no soda at all, and would not drink it if they knew it contained any soda. That is to say they would not think of drinking as a daily beverage the effervescing solution of soda of the British Pharmacopœia, notwithstanding the fact that this preparation may be very beneficial for persons with acidity in the stomach. In short, they drew a distinction between medicinal soda water and that ordinarily used as a beverage. Upon this ground they dismissed the summons, but as is usual, they refused to allow costs to the defendant, since the prosecution, however mistaken, was undertaken for the public benefit.

For our own part we regret that the defence of this case was not based upon an outspoken assertion of the principle by which the magistrates were spontaneously guided in deciding it, for in our opinion there is ample reason for the opinion that "soda water" for ordinary drinking purposes is far better when made, as it generally is, by merely charging pure water with carbonic acid gas, than it would be if it contained some bicarbonate of soda.

CHEMISTS' ASSISTANTS' ASSOCIATION.

ON Wednesday next, the 22nd inst., the Chemists' Assistants' Association will hold a Conversazione at St. James's Hall (Regent Street entrance), at which all interested in pharmacy are invited to be present. There will be an exhibition of microscopes, spectroscopes and other scientific apparatus of general interest, as well as the performance of a musical programme. Tickets (to admit lady and gentleman) may be obtained by letter from the Hon. Sec., 32A, George Street, Hanover Square, W.

THE HOWARD MEDAL.

THE subject chosen by the Statistical Society for the HOWARD Medal to be awarded in November, 1880, is "The Oriental Plague in its Social, Economical, Political and International Relations; special reference being made to the labours of HOWARD on the subject." This prize was instituted in the year 1873, the centenary of the appointment of JOHN HOWARD as High Sheriff of the county of Bedford. It consists of a bronze medal, and is adjudged by the Council of the Statistical Society for the best essay on some subject in Social Statistics. On this occasion a sum of £20 will be given in addition. The competing essays must be sent in on or before the 20th of June, 1880, and should not exceed in length 150 pages of the *Journal of the Statistical Society.*

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the thirty-first session was held at the Royal Institution on Thursday evening, October 9. The President, Dr. Charles Symes, in the chair. The minutes of the previous meeting having been read and confirmed, Mr. J. McCaig was elected a member; Messrs. T. Blyton, H. Edwards, J. Hallawell, A. Hughes and P. C. Williams were elected associates.

The President then delivered his inaugural address.

Inaugural Address.

After an interval of five years you have again done me the honour of electing me your President. When some few months since I consented to act in this capacity, my official duties were fewer than they now are, otherwise I might justly have hesitated in taking this further responsibility; nevertheless, seeing that those who have most to do, do the most, I am hopeful that with the support which I can fully rely on from the Council and from the members generally we shall have a successful session. This society has now an established position, a history extending over nearly one-third of a century, a dignity to maintain, a useful work to perform. It is a proverb of antiquity that "no man lives unto himself," and what is true of the individual is equally so of the body corporate. As individual members of this society we have helped to swell its numbers and have contributed to its funds; but we have done more, we have entered a brotherhood where the common weal should be our first thought, we have virtually pledged ourselves (one and all) to contribute to the common fund of information, to impart as well as to receive, to cull from our every day experience, from the work or reflections of our leisure, something, however small, which will help to add interest and profit to our evening meetings. As a society we represent the progress and interests of chemistry and pharmacy in this town and neighbourhood, and have our relations to the other scientific societies which meet in this institution and elsewhere. We are one (and I venture to think not the least important) of the societies established throughout the country for the fostering and development of these sciences, so that it requires but a moment's reflection to see how great is our joint responsibility, how necessary for us to maintain in its integrity the work of the founders and of those who have reared and brought the society to maturity. Passing from the society itself to the branches of science which it represents, and the relation of these to the numerous other branches, the mind of the most profound thinker is unable to grapple with the whole of the facts, deductions and theories which rise up before it, some real and substantial, others semi-ideal, some with so much of truth about them that they cannot be lightly dispensed with, others having barely a claim to recognition.

A connecting thought here, a missing link there, this clear exposition, that conflicting evidence, passing from arguments of solidity through the various grades of attenuation to the most ideal theories of the imagination. An interminable network of ramifications embracing all, from the commonplace things of every day life to the borders of infinity. But if the gravest philosopher is incapable of grasping the whole of this and of arriving at satisfactory generalizations, can it be expected that we, men of average minds and capabilities, shall be able to deal with them? Presumably not, but you will agree with me that it is well that we should dip sufficiently deeply into these things to enable us to realize the earnestness and reality of life and to penetrate beyond the mere surface of existence.

This probably will be best accomplished by limiting our sphere of inquiry and regarding more especially the chemist and pharmacist, and his environment, not in the broadest possible acceptation of the term; but contemplating more especially his surroundings, the accomplishments of the present and the work of the immediate future. Next to what Carlyle calls "the vestural tissue," around the chemist are his chemicals, balances, burettes, beakers, to an almost endless list; his laboratory. Around the pharmacist his measures, mortars, medicines, an ever increasing multitude; his pharmacy. These are the surroundings within which he, as a rule, gains experience and acquires the means by which he is sustained and enabled to impart energy to the mind, that mind by which he is or should be judged as regards his social position and capabilities for usefulness to mankind.

It is not however the mere possession of, but the practical application of knowledge which determines the environment outside that already mentioned, and chemistry provides abundant scope for this, seeing that it is at the very foundation of our knowledge of things.

Professor Allman, in his recent presidential address to the British Association, pointed to the conclusions of Max Schultze, which are now generally accepted as being correct, viz., "that the *same* protoplasm lies at the base of all the phenomena of life, whether in the animal or vegetable kingdom," and further, that although in all probability *chemically* the same, it differs in some unknown physical property. Here, then, chemistry is called on to decide a most important question, a fundamental principle in biology, and this single illustration will suffice to show the importance of and necessity for exactness in the results of its operations. Great as this exactness already is, workers in this field are constantly aiming at new or improved methods for the acquirement of greater accuracy, and while this work is steadily progressive, the facts or subject matter of chemistry remain constant and immutable to all time. Not so the theories by which these facts are explained; within comparatively few years these have undergone a complete revolution, and the student who twenty years ago took special pains to ground his knowledge thoroughly in the principles on which chemical phenomena were generalized, has, if desirous of keeping pace with the times, been compelled to unlearn and consider erroneous much of what he then regarded as incontrovertible fact, and to begin *de novo* to acquire the modern system.

The work of the professional chemist is not materially affected by these theoretical considerations, but inasmuch as he seldom enters this profession simply on account of the amount of remuneration it yields, but rather because his taste lies in this direction; because he takes pleasure in his occupation, and delights in unravelling these mysteries surrounding the primary and complex conditions of matter, he will be induced at every step to go beyond the mere requirements of his work. Chemical occupation has considerably increased in modern times; within a comparatively short period a small army of public analysts has been created, which, with its vassals, is pledged to guard the public against the baneful influences of adulteration, a very desirable object and one in which undoubted good has already been accomplished. That some unqualified, over officious and even unprincipled men should have entered the ranks is not at all surprising, seeing that the demand sprang suddenly into existence without the years of necessary preparation for supplying it efficiently, but the position is becoming elevated and the evil which has existed in some localities (happily not in ours) viz., where the public analyst has been a terror equally to the unjust and the just, will doubtless soon cease; a consummation greatly to be desired and by none more so than by the conscientious and efficient members of the body. In addition to the various chemical works throughout the country there are many manufactures, the conduct of which involves some chemical knowledge, and in some instances this is sufficient to justify the employment of one or more chemists on the premises. This is a growing occupation for chemists and one which must necessarily increase in direct proportion to the enlightenment of the age. I have in my mind at the present moment one or two large manufacturing firms who, to my personal knowledge, by using their laboratories as guides in their operations, are enabled even in these trying times to compete successfully with what would otherwise be overwhelming competition. Belonging to this department of technical chemistry are certain manufactures in which huge chemical processes are involved.

Those of us who attended the recent meeting of the British Pharmaceutical Conference at Sheffield had an opportunity of witnessing one of these in the Bessemer process of manufacturing steel, the grandeur of which produced an effect on the minds of many which will not readily be effaced. The Hollway process of rapid oxidation and the use of sulphides as fuel is of so recent a date as to be scarcely perfected, at least as regards working details, but it is a grand conception, the ultimate effects of which cannot at present be estimated. Ores so poor as not to be worth working on account of the cost of the fuel which would be consumed, are by this process made to produce their own fuel and can be worked at a profit. These are two instances of applied chemistry, but many others might be quoted if time permitted.

Beyond this we have the more attenuated environment of chemical physics, in which we gradually pass from experimental demonstration to deductions, theories and hypotheses; here rapid strides have been made during the last few years, and still there is room for work. Quite recently we were startled by the announcement that oxygen, hydrogen and nitrogen had been liquefied; but the other day it was more than hinted that chlorine had been dissociated, and now Mr. Crooks opens up a new field of inquiry into the chemistry of "radiant matter." So far he finds that even in this attenuated condition the molecules retain their chemical characteristics; if, however, the character of the molecules can be modified by physical influences, or if it is possible for the atom to exist in a free and uncombined state, it seems probable that the most favourable condition for such existence will be found in this direction.

Having thus gone over in outline some of the surroundings of the chemist as a professional and scientific man, let us contemplate shortly but more especially the environment of the pharmacist. I have already mentioned the close proximity of the pharmacy, its medicinal contents and the instruments and utensils by which the latter is dispensed; but seeing that drugs, etc., have to undergo selection and certain processes of manufacture before they are fitted for use in the pharmacy, some amount of skill is required to enable the operator to accomplish these things satisfactorily. But comparatively few years since only one school of pharmacy (to the best of my knowledge) existed in this country, now there are probably a score or more. Books and other facilities for education have been multiplied, all of which are, or should be, healthy signs; and I think it cannot be denied that the pharmacist of to-day is a decidedly more accomplished man in his calling than he was even twenty years ago. But whether pharmaceutical education has kept pace with the provisions made for it is somewhat doubtful; if young men trust too much to the "short cuts" so temptingly provided and neglect systematic training and home study, the knowledge gained will be exceedingly evanescent and will be of little real use to them; it might perhaps suffice to enable them to pass an examination or two, but it should be borne in mind that examinations are not the aim and end of our existence, they are but the portals through which it is necessary to pass in order to enter into the real business of life, first as assistant and then as principal, during which transition views of things often undergo considerable modification. The chemistry of the pharmaceutical laboratory is not so exhaustive as that previously referred to; many of its operations are mechanical and can be performed in detail by less skilled labour, but that both knowledge and judgment of no mean order are involved in the direction of these, no one with personal experience in the matter will doubt. But chemistry does not stand alone; some knowledge of botany, a sound knowledge of materia medica and of the various operations and requirements embraced by the broad and comprehensive term of pharmacy are absolutely necessary, and if these are faithfully acquired it is not at all surprising that those who conduct a business involving proficiency in such sciences should lay claim to a professional status. Many, however, find it impossible or inexpedient to conduct their business on a purely professional basis; hence we have the existing state of things well known amongst us, viz., pharmacy as a combination of profession and trade. The social position of the pharmacist has been so recently and so ably dealt with by the President of the Conference that very little from me on this point will suffice.

There can be no doubt but the public regard pharmacy as something above an ordinary trade, and the pharmacist as a man of superior intelligence; but he is a shopkeeper, and with the superficial portion of society this militates considerably against him. Yet if my experience is worth anything, it indicates that those who have the most substantial claims to position themselves, readily accord to us our proper status. Still, an anomaly does exist, and this social environment of the pharmacist is a problem not easily solved.

It has occurred to me in this relation, as it probably has to others, that there is something in a name, and if we, after continental fashion, were to educate ourselves and the public to speak of our places of business as *Pharmacies*, and to regard our charges for dispensing—however small or large—in the light of fees or payment for professional work—*which they really are*, and added to this, if we put forth a general effort to improve the tone of our business, we shall have done, not all, but something toward the accomplishment of our aim, which must necessarily be a work of time. Progress will of course be less rapid in times of general depression than it would in those of prosperity, and far as I am from believing in the perpetuity of "bad times," if only half one hears is true, it would be useless denying their existence at present. But as a picture cannot consist entirely of background and shadows, but must have its high lights and half tones, so the evil cannot exist without some attendant good; the refining process rarely fails to produce better metal, and I believe these trying times have their salutary influences, inasmuch as they are calculated to stimulate our capabilities, to test the strength of our mental resources and to develop our best energies. Our latent powers are doubtless greater than we should ever be aware of but for the necessity which calls them into action, and if we add to these fortitude and patience, there can be no doubt but the end will be worthy the means. The present time is one in which we should most thoroughly appreciate an association like this, which brings us together for friendly intercourse, for mutual help by the exchange of ideas, tending to render more perfect the sciences we profess, and to make us better capable in our respective spheres of serving our day and generation, so that when called on to give place to others, we may leave Chemistry and Pharmacy something better than we found them. There is much uncultivated ground to work; much that remains to be done. Truly, at first sight, it appears as though every atom of the universe, every molecule of which it is built up had been twisted and turned by scientists in every conceivable or possible direction; but going somewhat more deeply into our subject we find that so vast is the prospect which opens up before us that we are overcome by the contemplation of how little it is possible for one individual in a lifetime to accomplish. The amount of partially developed ideas and unfinished work by which we are surrounded is very considerable; versatility of talent and the wide range of operations seem to tempt workers to pass on to new subjects and new inquiries, and to leave the old ones with still much to be done for their completion.

There are still many vacant places in the tables of homologous substances. Synthesis of the alkaloids is merely commenced, inasmuch as with only two or three has it been accomplished. Not until within a few weeks since were we furnished with reliable information on the chemistry of so common a substance as ginger.

Perusal of the blue list published by the British Pharmaceutical Conference, and of the list of queries given by the American Pharmaceutical Association, at once suggests the incompleteness of our knowledge in many chemical subjects and pharmaceutical processes, and reminds us that there is more work than there are workers.

Gentlemen, let us, as members of this Association, resolve that during the present session we will do something toward working out the numerous problems which lie around us for solution, and so contribute something to the common stock of chemical and pharmaceutical knowledge.

One word to the students now entering on a new session, and I have done. Let your work be *thorough*. You have examinations to pass and must of necessity work in a direction to acquire the requisite education; but if you work solely for this, with no higher or broader aim, then, however successful you may be in passing, you utterly fail to accomplish the object for which examinations exist. It is not by spasmodic efforts, but by persistent study—*Nulla dies sine lineâ*—that you can gather in a rich harvest of knowledge and thereby gain the approval of your own consciences and are enabled more thoroughly to serve the interests of your fellow men.

A cordial and unanimous vote of thanks, proposed by Mr. R. Sumner, seconded by Mr. Davies and supported by Mr. Mason, having been accorded Dr. Symes for his able and instructive address, the meeting terminated.

CHEMISTS AND DRUGGISTS' TRADE ASSOCIATION OF GREAT BRITAIN.

A meeting of the Law and Parliamentary Committee of the Association was held at the office of the Association, 23, Burlington Chambers, New Street, Birmingham, on October 8, 1879, at 1 p.m., Mr. Thomas Barclay, President, in the chair. Present—Messrs. Andrews (London), Churchill (Birmingham), Cross (Shrewsbury), Hampson (London), Holdsworth (Birmingham), Jones (Leamington), Symes (Liverpool) and the Solicitor of the Association. The minutes of the previous meeting of the Committee were read and confirmed.

The Secretary said that in compliance with the instructions of the Committee he had issued circulars to influential members of the trade asking for well-authenticated instances in which fatal results had followed the sale of scheduled poisons under cover of the patent medicine stamp, with a view to obtain information and suggestions that would prove to the satisfaction of the Legislature that the present system of unregistered persons vending poisons under cover of the patent medicine stamp was dangerous to the general public.

A large number of replies to this circular were laid on the table, and extracts from some read.

The President said the Committee at its last meeting spent a considerable amount of time in endeavouring to devise some means of carrying out the wishes of the Executive in procuring information to aid them in dealing with that question. As had been seen from the minutes of that meeting, several suggestions had been considered, and a resolution passed instructing the secretary to issue a circular. They had to consider whether the replies to that circular contained adequate information or whether it would be advisable to adopt other means to that end.

Mr. Hampson said they had heard in one of the letters read by the Secretary a statement to the effect that it made little difference who sold patent medicines containing poisons, as they were not supposed to know the contents of such medicines. Such remarks had from time to time been applied to poisons sold uncovered by the stamp, but he was of opinion that it did make a considerable difference in whose hands the sale of such poisons was placed. He believed that the fact of the public being compelied to go to particular shops for the purchase of poisons was in itself an advantage to the trade. The public knew that they must go to registered persons to obtain poisons; if those poisons were obtainable at every shop they would be ranked with groceries and such like goods. It was thought wise—the Legislature thought it wise—to restrict the sale of certain poisons to registered persons, and he failed to see any distinction, or any very important distinction, between the sale of poisons covered by the patent medicine stamp and the same poisons sold uncovered by the stamp. He considered that the sale of all scheduled poisons covered or uncovered by the stamp should be restricted to chemists and druggists, and he thought the efforts of the Association should be directed to that end, and that it was their duty to aid the Executive in accomplishing that object.

Mr. Symes said he supported Mr. Hampson's views; it was an opinion he had long held. If the sale of patent medicines containing scheduled poisons were placed in their hands exclusively, it would, to a certain extent, increase their responsibilities, but he thought in the present state of affairs they must be prepared to accept those increased responsibilities.

The President said it had been already decided by the Executive to endeavour to restrict the sale of poisons under cover of the patent medicine stamp to chemists and druggists.

After further discussion it was unanimously resolved:—"That the Secretary be empowered to take such steps as he deems expedient, by conference or otherwise, to collect information and suggestions on the sale of patent medicines, with a view to bring about modifications in the Pharmacy Act, 1868, to restrict the sale of scheduled poisons under cover of the patent medicine stamp to registered chemists and druggists."

The case of a member of the Association, against whom proceedings had been taken under the Sale of Food and Drugs Act, for the sale of soda water, was discussed at considerable length, and after mature deliberation, it was unanimously resolved:—"That the Solicitor be instructed to defend a member of the Association prosecuted for the sale of soda water, under the Sale of Food and Drugs Act, and to employ the services of Professor Attfield and Mr. Stoddart."

The Secretary reported that in compliance with a resolution passed by the Committee at its last meeting, he had taken out summonses against three illegal traders for infringements of the 17th section of the Pharmacy Act, 1868, and that a fine was in each case imposed by the magistrates. He said they would probably have observed from a leader in the last number of the *Pharmaceutical Journal* that the Editor attributed that action on the part of the Association to an intimation furnished by the Solicitor of the Pharmaceutical Society at the hearing of a recent case of prosecution under the same section of the Act, undertaken by order of the Pharmaceutical Council. The Editor had, he presumed, forgotten that the Association carried to a successful issue three cases, proceedings in which were taken under that section so long ago as June, 1877.

The Secretary further reported having forwarded to the Secretary and Registrar of the Pharmaceutical Society particulars of eight cases of infringements of the provisions of the 15th section of the Pharmacy Act, in which he had collected evidence. Communications were read from the Secretary and Registrar of that Society acknowledging the receipt of that letter, and detailing the course he had adopted in dealing with each particular case.

A letter was read from a member of the Association stating that there were ten or twelve illegal dealers in poisons carrying on business in and around the town in which he resided.

It was unanimously resolved:—"That the Secretary be instructed to take proceedings from time to time against illegal traders under the 17th section of the Pharmacy Act, 1868, in such cases as in his opinion, and that of the Solicitor, it is expedient."

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The first meeting of the second session of the above Association was held in the rooms of the Pharmaceutical Society (North British Branch), 119A, George Street, on Wednesday evening, October 8.

The minutes of the final meeting of last session having been read and adopted,

The President, Mr. D. McLaren, proceeded to read the opening address. In thanking the members of the Association for the honour they had conferred upon him in electing him as their President, he assured them of his willingness to do his utmost in furthering the interests of the Association; but remarked that it was the exertion of individuals alone which would constitute the *sine quâ non* in carrying out that end. In referring to the relationship existing between the medical profession and chemists, he argued that while it was the care of the physician to ascertain the nature and seat of disease and to prescribe the appropriate remedies, it was the province of the chemist to collect, compound and dispense these remedies. While the exercise of the duties of a physician demanded a much higher standard of qualification than was requisite to the discharge of the duties of a chemist, yet the application of much care and dexterity, as well as a considerable acquaintance with scientific knowledge, was demanded of him also. In speaking on the subject of counter prescribing, he discountenanced the practice of chemists assuming to themselves on all occasions the responsibility of properly qualified practitioners, but maintained that on many occasions, and more especially where the poorer classes were concerned, it was necessary, if not incumbent, upon the chemist to give advice in the treatment of minor ailments. Admitting that there was thus a tendency on the part of the chemist to encroach upon the rights of the doctors, yet the keeping of an open shop by doctors, was, he affirmed, no less an encroachment on the rights of the chemist. After briefly noticing the various essays to be delivered during the session, as stated in the syllabus, he expressed his opinion that members would derive not only much pleasure, but also valuable information from their attendance on these meetings.

At the close of the address, a discussion was entered into as to the best means to be adopted for the shortening of business hours in those shops which remained open later than 8 p.m. A Committee, consisting of the President, Vice-President, Secretary and Treasurer, was finally appointed with powers to take such steps in the matter as might be thought desirable.

A very cordial vote of thanks was awarded to the President for his interesting and instructive address, to which, having briefly replied, the meeting was brought to a close.

Proceedings of Scientific Societies.

AMERICAN PHARMACEUTICAL ASSOCIATION.*

The twenty-seventh annual meeting of this Association was called to order in the Supreme Court Room, in the city of Indianapolis, Ind., on Tuesday, September 9, at 3 p.m., by its President, Mr. George J. Luhn, of Charleston, S. C.

President Luhn read the annual address which is usually expected from the retiring President. The address was replete with information as to the work, objects, and success of the Association in the past, as also the present attainments of pharmacy, made necessary through the working of the laws relative to pharmacy in many of the States, and the examinations of the Boards of Pharmacy under these laws. This advance is being greatly aided by the formation of State Pharmaceutical Boards, and of these several have been established during the past year. Allusion was made to the work of the officers, as also the several committees authorized by the Association. Among the other subjects commented upon were the time at which the meeting was held, the finances of the Association, and the centennial fund. The President advised that the meetings should be held earlier in the year; when in the Southern States, it should be as early as April or May, and when in more northern latitudes, not later than August. Regarding the finances, he named some plans for the relief of the debt the Society owed, and said that definite measures should be adopted at this meeting for that purpose. The centennial fund, which had now held over for two years, had made slow progress, as but one-third of the necessary amount had as yet been collected. At the conclusion of the address it was, on motion, referred to a committee.

The Committee of Credentials reported that they had received the credentials of delegates of various associations.

Invitations to attend the meetings of this body were extended by the Business Committee, on behalf of the Association, to the following:—The Governor and State Officers, Judges of the Supreme Court, Mayor, Medical College of Indiana, Central College of Physicians and Surgeons, and the Marion County Society of Microscopists.

The names of fifty-four persons were read, and of these fifty-two were elected, two names being withdrawn for the present. At subsequent sessions, other members were elected, including the two names temporarily withdrawn, making eighty-five new members elected at this meeting.

Some discussion arose as to qualifications for membership, as to time of service in the business, and the following resolution was offered by E. H. Sargent, of Chicago:—"That a committee of three be appointed to report at our next session what changes may be desirable in our bye-laws to make definite and uniform the balloting for members, and also to report on the requisite qualifications of candidates for membership in this Association."

The Chairman of the Executive Committee, Mr. G. W. Kennedy, read his report. The main facts may be briefly stated as follows:—Total number of members at present, 1106. This is a decrease from last year, as the number of members elected at Atlanta in November last was exceeded by the number lost by various causes, of which 8 were by death, 13 by resignation, and 61 from other causes; total 82. The report was accepted and directed to be published.

The delegates present then named one from each delegation, and to this the President added five others, and these gentlemen were constituted the Committee to Nominate Officers for the ensuing year.

The President appointed a Committee on Exhibits; and, after this, the Secretary called the roll of members present.

The Association then adjourned until 9 o'clock Wednesday morning.

SECOND SESSION.

The meeting was called to order shortly after 9 o'clock, when the Secretary read the minutes.

T. Roberts Baker, of Richmond, Va., then read the report of the Nominating Committee; immediately after which followed the election of all the gentlemen named by the Committee. The principal officers were as follows:—President, George W. Sloan, Indianapolis;

* Abstract of the report in the *Druggists' Circular and Chemical Gazette*, October, 1879.

First Vice-President, T. Roberts Baker, Richmond, Va.; Second Vice-President, Joseph L. Lemberger, Lebanon, Pa.; Third Vice-President, Philip C. Candidus, Mobile, Ala.; Treasurer, C. A. Tufts, Dover, N. H.; Permanent Secretary, John M. Maisch, Philadelphia, Pa.; Reporter on the Progress of Pharmacy, C. Lewis Diehl, Louisville, Ky.

The Committees appointed included the Executive Committee, Committee on Drug Market, Committee on Papers and Queries, Business Committee, Committee on Prize Essays and Committee on Legislation.

The retiring President then introduced Mr. G. W. Sloan, of Indianapolis, the new President, who briefly acknowledged the honour conferred upon him.

Prof. Maisch then read his report as Permanent Secretary. The topics discussed were mainly the expenses incurred in publication of proceedings, and suggestions as to where in future there might be some retrenchments as to expenses, as also how it might be possible to increase the income. Alluding to the delay in issuing the last volume of proceedings, it was stated that it was due in part to the delay in obtaining the wood-cuts to illustrate the work as desired. The total expenses of issuing the volume were 3,823.42 dollars. The expenses of various years were compared, showing that, considering the increased volume of the proceedings, it has cost the Association much less, proportionately, than in the past six years. Although the organization is practically in debt, the Reporter did not favour an assessment, but rather decreased expenses and an effort to largely increase the membership. A resolution was passed some years ago that the subscription to the various papers and periodicals received for the Reporter on the 'Progress of Pharmacy" is thought to be an unnecessary tax on the body, and it was suggested that it be left discretionary with the Executive Committee and the Permanent Secretary. It was also suggested that in localities where more than three or four members reside, authorized agents of this Association be appointed to extend its interests.

The report was accepted, and subsequently referred to committee.

The Treasurer, Charles A. Tufts, M.D., of Dover, N. H., then read his report. The total receipts for the year are 4,849.12 dollars; the disbursements were 4,730.45 dollars, and a cash balance on hand of 980.98 dollars. This balance of cash on hand represents in part dues of members paid in recently, while there are some heavy bills still due for the publishing of last year's volume. The Association has actually incurred expenses in the past more rapidly than it has provided ways and means for their payment.

The report was received and referred to an Auditing Committee, named by the chair.

After some considerable discussion relative to the finances, and the two reports just read, it was, on motion, referred to a Special Committee appointed by the chair.

The subject of the Centennial Fund was brought to the notice of the members, and on motion of Prof. Diehl, the chair named three members to act with the Chairman of the Executive Committee to endeavour to secure the balance of the amount necessary.

The Committee appointed at the previous session to suggest such revision of the bye-laws as might be thought desirable relating to membership and election of new members, made a report recommending alterations in the bye-laws, adding to the duties of the Executive Committee, by requiring that the names of candidates shall be read at one session and balloted for at the next session, and that a vote of two-thirds shall elect; the Executive Committee to hear and decide upon any objections that may be offered to any name presented; and no names to be balloted for until they have been approved by the Committee.

The Committee suggested the advisability of so changing the bye-laws that all matters relating strictly to business be brought before a Business Council, and thus devote much more time to the reading and discussion of papers than is now possible under the present rules.

The consideration of the proposed changes was laid over till the next session, when the resolutions offered by the Committee were adopted, and the necessary alterations of the bye-laws will be made in accordance therewith.

It was stated by the President that it was now in order to receive suggestions as to where the next annual meeting should be held.

Prof. Maisch read an invitation signed by the druggists of Kansas City, Mo., and Prof. Bedford read an invitation signed by the druggists resident at Saratoga Springs, N. Y., as also one signed by the proprietors of the several mineral springs of Saratoga.

Prof. C. L. Diehl then read the introductory to his report on the progress of pharmacy.

The Association adjourned shortly after the reading of the introductory of this report.

THIRD SESSION—WEDNESDAY AFTERNOON.

Soon after 3 o'clock the meeting was called to order by the President, the minutes of the previous session read, and then, in accordance with a motion previously offered, Prof. Remington was named as the reader for the Association.

Prof. Maisch read the report of the Committee on Legislation. The principal new facts related to the minor modification of the law of New Jersey, and the fact that a law has been enacted which relates to the sale of medicines and poisons in King's County, N. Y.

The remaining portion of the afternoon was occupied by the reading of scientific papers, after which the meeting adjourned until Thursday morning at 9 o'clock.

FOURTH SESSION—THURSDAY MORNING.

The Association was called to order at 9.30 by the President, Mr. George W. Sloan.

The Committee appointed to examine the reports of the Secretary and Treasurer, with a view to ascertain what changes may be recommended for the advantage of the Association, reported the following recommendations:—

1. That local agents be appointed in all places where more than three members reside.
2. That delegates from the various bodies be in future required to pay initiation fees.
3. That the volume of proceedings be reduced in size, as the judgment of the Executive Committee may determine.
4. That the Secretary be empowered to sell such of the pamphlets which are used for the Committee on the Progress of Pharmacy, as in his judgment are of no further use.
5. That the Treasurer present annually a tabulated statement of all receipts and expenditures.
6. That the fiscal year begin with January 1, instead of September 1.

The report, after a very brief explanation, was adopted, and Prof. Remington was requested to alter the bye-laws accordingly.

In the absence of Mr. Charles Rice, the Chairman of the Committee on the Revision of the U. S. Pharmacopœia, Prof. Diehl, one of the Committee, read the introductory report offered by Mr. Rice.

The report was a very voluminous one, and well represents the untiring industry of the Chairman of the Committee and his efficient co-labourers. The desire of the Association, as expressed in the resolution by which this Committee was reconstructed in 1877, was that at the present meeting the Committee should have their report completed and ready to present at the meeting of the Pharmacopœial Convention in May next. This seems to be an absolute impossibility; the most that can be hoped for is to publish as much as can be prepared by that time. The various members of the Committee have taken up departments of the work, and others have aided liberally in giving valuable time for careful experiments.

FIFTH SESSION—THURSDAY AFTERNOON.

The Association met at 3 p.m.

The Business Committee then called up an amendment to the constitution proposed by Mr. Joseph T. Remington to strike out the words "the United States," and insert in place thereof "America," so as to make the sentence read as follows:—"Its aim shall be to unite the educated and reputable Pharmaceutists and Druggists of *America* in the following objects." This was, with a brief explanation and discussion, adopted.

SIXTH SESSION—FRIDAY MORNING.

The meeting was called to order, and the usual business disposed of.

The President returned his thanks to the Association for their consideration, and then put the motion that the Association do now adjourn, to convene in Saratoga Springs, N. Y., on the second Tuesday (the 14th) of September, 1880, at 3 o'clock, which was adopted.

The following papers in replies to queries were read during the intervals of business:—

Eriodictyon Californicum is receiving attention for its action in lung diseases and bronchial affections. What is its therapeutical value, and to what is its activity due? Make a chemical examination of it. By Charles Mohr.

The writer made a very full examination of the plant, and the action of the various solvents in regard to the amount and quality of extractive matter. The properties are believed to be due chiefly to the resinous matter, which is best extracted by alcohol, to which it yields nearly 11 per cent. of its weight. It yields an ethereal extract of 15 per cent. and an aqueous of 19 per cent., but that which is taken up by alcohol seems more satisfactorily medicinal in its character.

Its apparent action is as an astringent and tonic to the bronchial tubes, but as a remedial agent in consumption the author thinks it no better than many other panaceas whose uselessness was long ago proved.

Fluid Extract and Syrup of Seneka.—Should it not be prepared with an alkaline menstruum? By George W. Kennedy.

The writer stated that for the past seven years he had used an alkaline menstruum in making both the fluid extract and syrup of seneka, and has never during that time noticed a single instance of gelatinization, and in but very few instances any precipitate whatever. It also furnishes handsome and brighter looking preparations, and is apparently more acrid and stronger. For 16 troy ounces of seneka root 3 fluid drachms of aq. ammonia are sufficient, and this amount is added to two pints of dilute alcohol. The finely ground drug is prepared for percolation, and after the first 12 ounces of percolate have been obtained, the percolation is continued to exhaustion. The second percolate is evaporated to $3\frac{1}{2}$ ounces, to which is added $\frac{1}{2}$ ounce of alcohol, and this is added to the reserved percolate of 12 fluid ounces. In making syrup of seneka, this alkaline liquid is used, but otherwise the process of the Pharmacopœia is followed.

Mr. S. Campbell thought a stronger alcoholic menstruum with glycerine answered as well. Mr. Lloyd spoke of the fact that seneka root yields both salicylic acid and oil of wintergreen under certain conditions, though in very small quantity.

Can any of the Decoctions or Infusions of the United States Pharmacopœia be satisfactorily prepared from the Fluid Extracts of the United States Pharmacopœia, and in what particulars do they differ from infusions and decoctions prepared in the prescribed manner? By William Saunders.

This paper gave many detailed experiments, and the results of preparing infusions and decoctions from fluid extracts. In the author's opinion when the fluid extracts are made with a menstruum of *dilute* alcohol, they may readily and satisfactorily be used to prepare both of the above weaker remedies; but when the solvent used is *stronger* alcohol, and this be diluted with water to make it the same strength as an infusion or decoction, the general result is a persistent cloudiness or milky appearance, rendering it objectionable in dispensing.

The affinity of Glycerin for water is well known; to what extent will officinal glycerin attract moisture on being exposed to a damp atmosphere? By George W. Kennedy.

The author exposed to the atmosphere of a damp cellar, glycerin of specific gravity 1·23 and 1·26 in vessels of broad shape, also in narrow mouth bottles, weighing the vessels at frequent intervals. In the first ten days the vessels of broad, open space had absorbed 4 per cent. of moisture, and this had continued until, at the end of ten months, the increase had amounted in the glycerin of 1·23 sp. gr., to $55\frac{1}{4}$ per cent., and in the denser variety to $57\frac{1}{2}$ per cent.

REVISION OF THE U. S. PHARMACOPŒIA.

Several papers were presented on this subject.

The introductory by Mr. Charles Rice was an admirable review of the subject, discussing the work already done and in process, and alluding to the changes in the character of the work itself. The proposition of the committee is to arrange the contents in alphabetical order, without any regard to the present division into materia medica and preparations; to do away with any mention of weights, substituting *parts by weight*, arranging these in the simplest ratios possible.

In preparing medicated waters, precipitated phosphate of calcium is proposed in place of carbonate of magnesia, for the purpose of diffusing volatile oils and similar materials for better solution in water.

Prof. J. P. Remington presented a very full report upon the tinctures, giving detailed formulas, some involving modifications, but all arranged upon the plan of simplifying processes as much as possible. The paper was accompanied by numerous specimens of tinctures made as proposed, as also by the residues of the exhausted drugs.

PHARMACEUTICAL EXHIBITION.

Masonic Hall, situated on the opposite side of the street from the Supreme Court Room, was the place selected for the exhibition of articles connected with pharmaceutical interests.

The large room was literally crowded to repletion with beautiful products of the art of the chemist, pharmaceutist, manufacturer, artizan and perfumer; and in many cases the crude materials from which they are prepared.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held at George Street, Hanover Square, on Wednesday evening, October 8.

The inaugural address was read by the President (Mr. F. W. Branson), who after alluding to the rise and progress of the Association and the large increase of new members, touched upon several topics of general interest, and concluded by noticing how useful a large and varied source of knowledge was to the pharmacist, and recommending as recreative studies a more intimate acquaintance with the vague separation of the animal and vegetable kingdoms and geology, which especially recommended itself by being a healthy as well as a scientific study.

A vote of thanks to Mr. Branson was proposed by Mr. Snow, and seconded by Mr. Naylor.

Mr. Ernest Cardwell, the late Honorary Secretary, was then presented with a complete set of Dickens's Works, together with an illuminated address, as a slight token of esteem on his severing his connection with the Association.

Mr. Branson then referred to the approaching Conversazione to be held at St. James' Hall, on Wednesday next, October 22, and expressed his opinion that it would be a great success.

Parliamentary and Law Proceedings.

The Nature and Quality of Soda Water.

IMPORTANT PROSECUTION UNDER THE SALE OF FOOD AND DRUGS ACT.

At the Newport (Mon.) Borough Police Court, on October 10, 1879, before Dr. Woollett (chairman), and Messrs. Charles Lewis and Henry Phillips, Mr. Eleazer Davis, chemist and soda water manufacturer, of 55, Dock Street, Newport, was charged under the Sale of Food and Drugs Act, 1875, for that he did in the said borough "sell a certain article, called soda water, not of the quality and nature asked for."

Mr. Line (Deputy Town Clerk) conducted the prosecution, and Mr. Henry Glaisyer, instructed by the Chemists and Druggists' Trade Association of Great Britain, appeared for the defendant.

Mr. Line said this was a somewhat important case, and the facts were these:—On the day in question, September 15 last, the public officer went to the defendant's shop and asked for six bottles of soda water, which were supplied to him. The ordinary course was adopted by the officer as to the division of the samples. Two of these bottles were sent to the borough analyst, whose certificate states: "I, the undersigned, public analyst for the borough of Newport, do hereby certify that I received on September 16, 1879, from Mr. T. H. Jones, a sample of soda water (bottle marked No. 125) for analysis, and have analysed the same, and declare the result of my analysis to be as follows:—I am of opinion that the same is a sample of water charged with carbonic acid gas, and I am of opinion that the said sample contained the parts as under, or the percentage of foreign ingredients as under:—Total solid residue, 14·63 grains per gallon; metallic impurity equivalent to $\frac{1}{20}$ grain of lead per gallon. Observations:—This sample is ordinary water charged with carbonic acid gas, and does not contain added bicarbonate of soda, and is not 'soda water.' The metallic impurity is not considerable, but care should be taken no lead pipes or solder joints containing lead are used in the apparatus employed in the manufacture. As witness my hand September 23, 1879. (Signed) J. W. Thomas, F.C.S., Mem. Inst. Chem." The question to be considered was whether water simply charged with carbonic acid gas and containing no soda is soda water within the meaning of the Act. The defence would perhaps endeavour to show that this article without soda was soda water, but he submitted that a person going to a chemist's shop would expect to get a different article from what he would expect to get if he asked for the same thing at a restaurant. Soda was a highly important medicine.

Mr. Glaisyer: You are not going into the question of a drug, I suppose. We are not summoned on that.

Mr. Line: I am not; it is a question of a food. It is not the article of food which a person going into a chemist's shop would expect to receive when he had asked for soda water.

Mr. Glaisyer: Why into a chemist's shop?

The Chairman of the Bench: Is it an article of food?

Mr. Line: It is an article of food sold by chemists, and I submit in this case the chemist is selling as soda water a water not containing soda, and that consequently the defendant has not supplied the article asked for and expected. We do not drag this person here as an ordinary malefactor. If you hold that in getting this particular water the inspector has obtained what he may have reasonably expected to get, then, sir, of course you will dismiss the summons; if, however, you hold otherwise, I shall be satisfied with a small penalty.

By the Bench: Have you selected Mr. Davis especially as being a chemist? You seem to dwell very much on the fact of his being a chemist.

Mr. Line: Soda water is, of course, a medicated water.

Chairman of the Bench: Then that takes it out of the category of its being a food: you would not go to the chemist's shop to buy a food?

Mr. Line: Chemists sell many goods that are not medicines or drugs; for instance, pomade, tooth-powders, and such like things.

By the Bench: We must shut our eyes to the fact that it is a chemist who is the defendant in this case.

Mr. Glaisyer: I am very glad to hear that remark from the Bench, as it has anticipated some observations I was about to make.

Thomas Henry Jones, called, sworn and examined by Mr. Line, said he was the officer appointed under the Sale of Food and Drugs Act in the borough. He went to the defendant, who is a chemist and druggist and soda water manufacturer, residing in Dock Street, on September 15 last, and asked for six bottles of soda water. He told defendant the soda water was to be analysed by the public analyst, and offered to divide it into three parts, which offer was accepted. Witness handed two bottles to the defendant and took two to Mr. Thomas, the public analyst, at Cardiff, the following day. Defendant said, "This is soda water, there are about three grains to each bottle." When he asked the defendant for soda water he expected to get water containing soda. Could not say what proportion of soda he expected to get in it. Did not expect to get a medicine of nauseous taste and highly alkaline, but should expect to get a soapy-tasting article. Knowing there were two kinds sold, he did not ask especially for any particular kind.

Mr. Glaisyer: The provisions of that section of the Act which relate to the division of the sample intend, that by such division a portion of the purchase shall be retained by the defendant, another portion shall be sent to the analyst, and a third shall be retained by the purchaser, and that all these portions shall be identical in their constituents. From the division which has been made in the present case this result is impossible, because by the process which the defendant adopts in the manufacture of his soda water each bottle necessarily contains a variable quantity of soda, from this simple fact, which I am prepared to prove, that the soda is introduced into each bottle separately; and consequently the only way in which the purchase in this case could be satisfactorily divided to meet the intention of the Act of Parliament would be by an actual division of each bottle of soda water.

By the Bench: According to your argument it would be impossible in any case to properly divide the samples.

Mr. Glaisyer: You could divide any article purchased into three parts.

Chairman of the Bench: Is it a matter of fact that the soda is put into each bottle separately?

Mr. Glaisyer: Yes; and I submit it is a point of law as to whether this sample has been properly divided or not.

Mr. Line: I submit the sample has been properly divided. The section referred to is the 14th section of the Act, which is as follows:—"The person purchasing any article with the intention of submitting the same to analysis shall, after the purchase shall have been completed, forthwith notify to the seller or his agent selling the article his intention to have the same analysed by the public analyst, and shall offer to divide the article into three parts, to be then and there separated, and each part to be marked and sealed, or fastened up in such manner as its nature will permit, and shall if required to do so proceed accordingly, and shall deliver one of the parts to the seller or his agent. He shall afterwards retain one of the said parts for future comparison, and submit the third part, if he deems it right to have the article analysed, to the analyst." Well, I say, sir, the article purchased by us consisted of six bottles. If we had made six distinct purchases, then each bottle must have been separately divided, but such was not the case. I think in this case it will be found that the only active principle in the soda water was the gas, which would have vanished had the bottles been opened.

Mr. Fox (Magistrates' Clerk): You must assume, then, that supposing there were three grains in each of these two bottles, and none in the others, you would then have had a portion of alkali in each bottle.

Mr. Line: There have been hundreds of cases in which the samples have been divided as in this case.

Mr. Glaisyer: This particular point has never yet been raised.

The Bench conferred and decided that the case had better go on.

Mr. J. W. Thomas, called, sworn and examined by Mr. Line, said he was public analyst for the boroughs of Newport, Cardiff, and the county of Monmouthshire. On September 16 last, he received from inspector Jones two bottles of soda water, No. 125. They were sealed with the official seal of the borough of Newport. He took particular notice that the rubber was not destroyed in any way; it was moist, and the wax did not adhere to it in the slightest. Both bottles were analysed, and his certificate referred to both. Soda water containing a reasonable amount of soda, if taken internally, would have the effect of neutralizing acidity in the stomach. Water charged with carbonic gas would not have that effect. 30 grains of soda to the pint was the Pharmacopœia standard, and a bottle of half-pint ought to contain 15 grains. In his analyses of soda waters he found they generally contained soda.

Chairman of the Bench: I must say that the soda water I generally drink contains no soda at all.

Cross-examined by Mr. Glaisyer: You say Pharmacopœia soda water contains 30 grains to the pint?—That is so.

But there is another kind of soda water?—Not to my knowledge.

Then whenever soda water is asked for the British Pharmacopœia preparation should be supplied?—I didn't say that.

Then there is more than one kind of soda water?—No; I did not admit that.

Will you explain your answer then?—It depends upon the quantity of soda added; I cannot say it differs in kind.

Well, if a half-pint bottle contains 15 grains of soda, what do you say that is?—Soda water.

Supposing it contains only 3 grains?—It would still be soda water.

Supposing it contained half a grain?—Then it would probably be an impurity in the water from which the soda water was made. I may say I think the standard of the Pharmacopœia is too high.

Would not Pharmacopœia soda water be dangerous if taken too frequently?—I cannot say.

Would it not be injurious if taken in large quantities? —That is a medical question I cannot answer.

You say you have examined many samples—with what result?—They contained soda—from 5 grains to 15 grains per bottle.

You have never had a sample containing less than 5 grains?—No.

Is the British Pharmacopœia soda water such a preparation as the public would drink?—It is not very palatable.

Is it not very nauseous?—Well, it is not palatable.

Have you had soda water submitted to you for analysis which contained, as you say this sample contained, no soda?—I have had samples submitted to me as soda water which I do not admit it to be soda water.

Your certificate is an analysis of both bottles submitted to you?—Yes, taken separately, and the analyses agree in every particular.

There was a trace of soda present?—No, not of added soda: it had an alkaline residue.

Is the residue of all water alkaline?—In the majority of instances it is.

Have you examined Newport Waterworks water?—Yes; the residue is slightly alkaline.

To what extent?—Only a very moderate trace; about the same as in this soda water.

Is the alkalinity due to soda?—To a certain extent it may be.

Do you know whether it is or not?— I am not absolutely certain.

Do you recollect from your analysis of Newport water what the amount was?—It is stated on my certificate that this soda water contained 14·63 grains of solid residue per gallon, and the town water contains from 13 to 15 grains per gallon, according to the state of the weather.

Have you frequently had samples to analyse?—No, not very frequently.

There may be only 13 grains of residue per gallon?—Yes, possibly.

And there may be one grain to the gallon of added matter in this soda water?—Yes, but not of carbonate of soda.

How so?—Because I should have been able to estimate it in the residue.

How did you estimate the alkalinity?—By the standard tests.

Did you test both bottles for alkali?—I tested both residues.

You say in your certificate that there was a metallic impurity amounting to one-twentieth of a grain of lead to the gallon: now would that amount be injurious to health?—No.

Perfectly innocuous?—No, I do not say that.

How do you test the water for lead?—By sulphuretted hydrogen.

How do you account for the presence of lead?—From the pipes in the manufacture.

Could it not have got in in any other way?—Well, I don't think it could.

By the Bench: Do you think it is likely to have come from the apparatus?—Yes.

Mr. Fox: What is the smallest quantity of bicarbonate of soda you could have traced in the soda water?—I could readily have detected half a grain.

By the Bench: Then if half a grain of soda had been added to the water of each bottle you would have detected it?—Yes, sir.

Mr. Line: That is my case.

Mr. Glaisyer: The case, as far as I am prepared to carry it, is this—that soda water has been largely manufactured for use as an agreeable beverage, and that as such it should be as free as possible from medicinal properties. It is well known that the article in general use is a very different article from that prepared according to the formula of the Pharmacopœia, and I think I shall produce evidence to prove to you that the Pharmacopœia soda water would be injurious to health if drunk constantly. The case seems to have shaped itself simply into the question whether the defendant did sell soda water with or without soda, and I think I may keep the Pharmacopœia preparation out of the question.

Chairman of the Bench: Quite so; what is soda water of commerce?

Mr. Glaisyer: Then I shall call the defendant and the boy that assists him in the soda water department of his trade, and they will tell you that the water is charged with carbonic acid gas, and that the soda is added to each bottle separately before being filled with aerated water. I shall call as witnesses Professor Attfield and Mr. Stoddart, both eminent analysts, and they will both tell you that soda was present in the samples they analysed, and, therefore, you will see the force of my objection which I previously urged as to the division of the sample, and I think in the end you will either be satisfied to dismiss the case upon the technicality I have raised—and which is really something more than a technicality in this case—or to dismiss the case upon the consideration that the defendant did actually supply the soda water of commerce.

Mr. E. Davis, called, sworn, and examined by Mr. Glaisyer, said: I am a chemist and druggist and a soda water manufacturer in the borough, and have been in business thirteen to fourteen years. I have manufactured soda water between four and five years.

Do you make the British Pharmacopœia preparation?—I made it once, one bottle for my own use.

Have you ever had it asked for?—Never.

What is your process of manufacture?—Whiting is placed in a leaden generator, sulphuric acid is added, and the carbonic acid gas evolved is conducted by means of piping into a gasometer; it is then pumped into a soda water machine and forced from thence through the bottling machine into the bottles. Previous to the bottles being placed in the machine for charging each bottle has a certain amount of bicarbonate of soda placed in it.

Is that done under your superintendence?—When it is not done by myself it is done under my immediate superintendence.

Describe the manner in which the soda is placed in the bottles?—Cases containing the bottles are arranged side by side along the bottling machine, the bottles are placed in rows consecutively, then the soda is added to one bottle after another.

By the Bench: Is that always done?—Yes, invariably. A little soda is taken on the point of a knife and dropped into the neck of each bottle.

Mr. Glaisyer: Is it not weighed?—No.

You use one make of bottles, I believe?—Yes, only one make—Codd's patent.

By the Bench: What is the smallest quantity you would put into each bottle?—Well, about 1¾ or 2 grains.

Would it be more than a grain?—Yes; I did not think it was necessary to be very distinct or definite as to the amount, so long as some was put in.

Cross-examined by Mr. Line: Witness said he considered it necessary, in order to comply with the provisions of the Act, to put some soda in. The generator in which he made the gas was of lead.

Chairman of the Bench: Then I would advise you to alter it, as lead is pretty sure to come over with the gas.

Albert Harvey, examined by Mr. Glaisyer, said: I assist the defendant in his business by helping him to make soda water. I put the soda into the bottles by means of a knife, putting a little into each bottle.

Professor Attfield, called, and examined by Mr. Glaisyer.

What in your opinion is soda water?—There are two kinds of soda water in trade now. There used to be three. First, medicinal soda water, and the present official strength of that is 15 grains of bicarbonate of soda to the bottle of half a pint, and it was this medicinal soda water that gave the name to the article. This medicinal soda water always contained carbonic acid gas, and was aerated soda water. This aerated soda water created a demand on the part of the public for "soda water" that had no "soda" in it; created a demand for aerated water, in fact. Created a demand for aerated water which the public always continued persistently to call soda water. To meet this demand for a beverage manufacturers used commonly to make soda water, so called by the public, without any soda in it, but some manufacturers put a dash of soda in it to warrant the name. But since prosecutions have been instituted about soda water nearly all, practically all, manufacturers put at least a dash of soda in it, just to warrant the name, and I may say to meet the requirements of officials under the Act.

Can you say anything as to the quantity of soda to meet this?—That varies very much.

By the Bench: Say how much?—It varies from a fraction of a grain to three or four grains per bottle. This is according to my experience as an analyst, and the reason of its varying is, in my opinion, because the boys and the work-people put the soda in, as has been described in this case, rapidly instead of with care. And it is important for commercial purposes that it should be done rapidly, in which case it is impossible for such boys to be very accurate as to the amount employed, that is to say, in the cases of those makers who adopt this rough-and-ready mode of adding the soda.

Mr. Glaisyer: Have you had an official sample?—I have. This is the label of the sample which I received on October 3, and it corresponds with that of the sample produced.

By the Bench: Then you have analysed one of the sealed samples?—Yes.

Mr. Glaisyer: Tell us the result of your analysis.—I found bicarbonate of soda in that bottle.

And what would you term the liquid you analysed?—There being soda there, it was of course soda water. There was enough soda to warrant the name.

By the Bench: Soda in what quantity?—It was about a quarter of a grain per bottle.

By the Bench: Was it added or was it in the water used?—I can only say from my knowledge of the waters in this district, which I believe to be mainly sandstone waters, that——

By the Bench: Some water here comes from limestone; many natural waters would contain soda in the quantity you have found, I take it?—Some waters would contain that quantity, others contain traces only, and others really none at all; and as such waters as are supplied to this district contain, practically, none at all, therefore, in my opinion, this quarter of a grain of soda I found was added carbonate of soda.

Mr. Glaisyer: Did you examine the bottle in which the water was sent to you?—Yes.

Now how do you account for the small quantity of soda found in that bottle of water?—On account of the rapidity of the manipulation of the work by the boy in putting the soda into the bottles, I should certainly expect the quantity to vary from, say, a ¼ of a grain to 3 or 4 grains. I have seen this work done by boys, and I am certain the amount of soda must almost necessarily vary in the bottles.

Is it also possible for a portion of soda to be forced out after being put into the neck of the bottle?—That question I have gone into, and have made experiments myself in bottling soda water from a machine. The soda dropped into one of these patent bottles falls on the glass ball—sometimes partly and sometimes mainly; and then, when the water charged with gas is driven by the machine into the bottle, air and gas escape from the neck of the bottle, and with that air nearly always comes out some spray, and with that spray might come a certain amount of the soda.

Did you make a further analysis of anything that came with the sample?—Yes. When I proceeded to open my sample I found it extremely difficult to get out the whole of the wax with which the bottle was sealed. I knew as a chemist that even if a fiftieth part of a grain of the colouring matter of the wax got into the bottle it might contaminate the water; and, although I took especial care, I found it impossible to get all the wax out. The fact of the pressure of the glass ball acting on the centre of the indiarubber ring in the neck of the bottle caused the inner edge of that ring to curl up and I found it utterly impossible to get all the wax from beneath, although I myself tried with a penknife, but I found I could not do so. I then pressed down the ball and got out the liquid, and found lead therein. I immediately examined the particles of wax for lead, and there found lead in considerable quantity.

By the Chairman of the Bench: Do you think the lead would get there from the lead generator?—I have examined many samples of soda water, the gas for which was made in a leaden generator. Some contained lead, others no lead. I have sometimes found that lead does come from the pipes; at other times I have been sure it could not have come from that source. Very minute traces of lead might come over with the gas, notwithstanding one or two washings of the gas. I am of opinion that it is just possible for lead to be present from that cause.

Mr. Glaisyer: Could any other substance be used instead of lead for the generator of the gases?—Makers of soda water apparatus are turning their attention to that subject now, but up to a short time ago lead has been almost universally used.

Do you consider the lead in this sample innocuous?—Perfectly; such a minute quantity must be.

Cross-examined by Mr. Line, witness said a large quantity of the soda water he had examined contained only small quantities of soda, which would not practically have any effect at all, but was put in to make it the so-called "soda water" of commerce; it was the fault of the public that this term is kept up. There was no question of cost in the matter. The contentions in these soda water cases were mere contentions about names. Some makers had called this beverage "aerated water," others "carbonated water," but the public did not take kindly to these names; they seem to prefer their old term, "soda water," and it practically caused no confusion, except to officials under the Act.

Mr. W. W. Stoddart, called, sworn, and examined by Mr. Glaisyer, said he was public analyst for the city of Bristol. He had had a sample of this water sent to him for analysis bearing the official seal of the borough. He found 1 and 1-10 grain of bicarbonate of soda in it. He had examined three samples of Newport water. In one he found total solids about 8 grains to the gallon, in another about 13 grains to the gallon, and in the third about 14 grains to the gallon. There was no soda in Newport water. If a quarter of a grain were found there it must have been added. He found a small trace of lead, which he thought came from the generator in which the gas was made. One-twentieth part of a grain of lead would not be serious.

Mr. Line, addressing the Bench: I would call your attention to the second section of the Act. "The term 'food' shall include every article used for food or drink by man, other than drugs or water." Soda water is neither a drug nor is it water, and therefore it is an article of food.

Mr. Glaisyer: I admit that.

Mr. Line: My point is this, that a person going into a chemist's shop——

Mr. Fox: I may say I have all my soda water from Mr. Young, a chemist, in quantities of six dozen at a time. I would not drink soda water if I knew it contained any soda.

Mr. Line: I submit that a large number of persons going into a chemist's shop for soda water would expect to get water containing soda.

Chairman of the Bench: The defence have proved that this water did contain soda.

Mr. Glaisyer: I admit that it is a food, which ends that point.

Mr. Line: I go still further.

Mr. Glaisyer: I must protest against this.

Mr. Line: I am arguing a question of law.

Mr. Glaisyer: What question of law?

Mr. Fox: It is admitted on all hands this should have soda in it; is that so or not?

Mr. Line: I say, sir, the Legislature never intended that the Act should be evaded by such a small quantity as a ¼ grain of soda being added to each bottle on the point of a knife.

Chairman of the Bench: When this Act was passed it was intended to apply to stronger drinks than soda water.

Mr. Line: If ¼ grain only was in the water it is nothing substantial, nothing material.

By the Bench: The defence have proved there is something material in the water.

Chairman of the Bench: I have drunk soda water for many years, and I must say if I thought there was any quantity of soda in it I should never have drunk it.

Mr. Line: It is ridiculous to argue that you can make soda water by putting ¼ grain of soda into the water, or that the water contains it as a natural constituent.

Mr. Fox: It makes no difference whether the soda be added, or whether it be present as a natural constituent of the water. In either case it will be soda water.

Mr. Line: Take the case of a member of the general public suffering from gout or rheumatism: he asks for soda water and expects to get some soda in it.

Chairman of the Bench: Then let him ask for medicinal soda water.

The magistrates conferred.

Chairman of the Bench: We think this soda water was the ordinary soda water of commerce, and we shall not inflict any penalty; in fact we dismiss the summons.

Mr. Glaisyer: Do you award costs?

By the Bench: This action was taken on public grounds; they are a public body who are prosecuting. No costs will be awarded.

Chairman of the Bench (addressing Mr. Line): Do you propose proceeding with the other two cases?

Mr. Line: No, sir. This case will govern the others, as the charge is the same in each instance.

Deaths from Chloroform.

On Monday last an inquest was held at Ashton-under-Lyne, by Mr. Price, the district coroner, on the body of a young lady named Mary Handford. The deceased had been suffering from a tumour upon her breast, and by the advice of her medical attendants, Dr. Gardiner and Mr. E. Lund, professor of surgery at Owens College, Manchester, she consented to have it removed. The two gentlemen named attended at her house on Saturday for this purpose, and Dr. Gardiner administered the chloroform in the form of vapour by means of an inhaler. She had inhaled the anæsthetic for only about two minutes, and had not passed into the second stage of narcosis when her pulse became feeble and she died. Both medical men had previously given it as their opinion that she was a fit subject to receive chloroform, and no blame was attributed to them by any person. The verdict was one of death by misadventure.

On Wednesday, also, Dr. Hardwicke held an inquiry at the University Hotel, Grafton Street, Tottenham Court Road, as to the death of Harry Knowlton, aged six years, son of a smith, living at 61, Bemerton Street, Islington, who died in University College Hospital on Friday while under the influence of chloroform. The evidence showed that for two years past he had been under treatment in different hospitals for contraction of the sinews of the legs. On the 6th inst. he was taken to the University College Hospital. On Thursday, Mr. Marshall, the senior surgeon, performed an operation on him, and the next day it was decided that splints should be placed on his legs. Chloroform was given to the child, and he was about to be operated on when it was noticed that he had ceased to breathe. Artificial respiration was resorted to, but without success. The jury returned a verdict of "Death from misadventure."

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[345]. I think that the injection mentioned ought to be filtered, as the precipitate (sulphate of lead) could not have been intended on the part of the prescriber.

NEMO.

[345]. "Assistant" should put a "Shake the bottle" on this.

J. C.

[345]. This injection should be sent out with a "Shake the bottle" label on. The ingredients must be carefully rubbed up in a mortar with distilled water.

ST. RULE.

[346]. In answer to "Juvenis," I beg to state that it is usual to give the tinct. iodi when pigment is ordered.

NEMO.

[346]. Liniment. iodi should be used.

J. C.

[346]. There are four formulæ for pigmentum iodi in Squire's 'Hospital Pharmacopœias.' I should be inclined to use "King's" ʒj. iodin. to ℥j. s. v. r.

W. WILKINSON.

[348]. I should use ferri ammon. cit. without troubling the prescriber, even if I knew him. It is evidently a slip of the pen.

W. WILKINSON.

[348]. Ferri ammoniæ sulph. is iron alum, and I should think that was meant.

J. C.

[348]. "Mag. Carb." will find that it will be as well to explain his difficulty to the patient and offer to dispense it with ferri am. cit., which I have no doubt was intended by the prescriber.

NEMO.

[348]. The top ingredient is ferri ammoniæ sulph. It is a double salt, frequently used in photography, very seldom employed as a therapeutic agent, but as such it acts as a powerful astringent in uterine cases. It is sometimes difficult to get from the wholesale dealers.

ST. RULE.

[350]. Rub the chloral and camphor together into a smooth semi-fluid paste; rub with this ʒss. to ℈ij. mist. acaciæ, then add the syrup, and afterwards the water gradually. This produces a milky looking emulsion in which the camphor is suspended; if the gum is not put in the camphor separates in the form of a greasy substance floating on the water.

W. WILKINSON.

[351]. In regard to this mixture my opinion is this, "that it should be filtered before sending out." Supposing the prescriber's intention be to order hydrobromic acid, which this mixture undoubtedly represents, we have the authority of Dr. Fothergill for removing by filtration the pot. bicarb. precipitate.

WM. LYLE.

[352]. I cannot understand how this recipe should produce a turbid mixture, and do not see any particularly scientific dispensing in producing a bright red or rather a dark reddish-brown and perfectly clear solution. There is no need for any especial care in mixing, for if the ingredients are all put into the bottle and the aq. aurant. added the result is just the same as if each is dissolved separately and afterwards mixed, viz., a clear dark solution.

Can the difference be in the French and English ferri am. cit.?

W. WILKINSON.

[355]. So far as an assistant's knowledge and experience direct me, I find no difficulty in dispensing this prescription, and am at a loss to discover grounds for Mr. Brayshay's doubts. Further than that, the salts are very deliquescent, it is a very good powder as a diuretic and aperient, and taken in doses of half to one teaspoonful. We send it out in W. M. bottles. I think Mr. Brayshay should have stated his difficulty.

W. LYLE.

[357]. The following prescription was handed to me the other day for dispensing. Will any of your correspondents inform me as to the best mode of preparing it? I digested two quantities with different pepsin of well-known makers, from ten to twelve hours each at 100° Fahr., but failed to get a clear mixture as ordered in the prescription.

Perhaps some one may have had a similar prescription and was more successful in preparing it, if so will he kindly give me particulars?

New Milk . . . . Oj.
Pure Pepsine . . . . gr. 100.
Dilute Hydrochloric Acid . . . . ♏ 80.

Mix and digest in a water-bath at a temperature of 100° Fahr. When the mixture has become quite clear, neutralize the acid with bicarbonate of soda.

T. E.

[358]. How should the following prescription be dispensed?—

℞ Quiniæ Sulph. . . . . gr. xxiv.
Sp. Ammon. Fœtid.,
Tinct. Aurantii. . . . . . āā ʒvj.
Aqua . . . . ad ℥xij.
Ft. mist.

Take a twelfth part three times a day.

QUINIÆ SULPH.

[359]. I shall feel obliged if any reader of the Journal will give me the correct mode of dispensing the following:—

Ol. Olivæ . . . . ʒij.
Ext. Belladonæ . . . . ʒij.
Ft. lin.

I endeavoured to mix in a mortar, but finding it, as I thought, impossible, I used lin. belladonæ instead. This not having the desired effect was sent back.

APPRENTICE.

[360].

℞ Codeiæ. . . . . gr. iij.
Acid. Carbolic. . . . . gr. ½.
M. Ft. pil. j. Mitte xxxvj.

What is the best method of dispensing the above so as to make the pills as small as possible?

A. W.

[361].

℞ Pulv. Calaminæ . . . . ʒiss.
Zinci Oxyd. . . . . ʒiss.
Glycerine . . . . ʒj.
Liq. Carb. Deterg. . . . . . . ʒj.
Ol. Olive . . . . ʒiss.
Aq. Calcis . . . . ℥ij.
Aq. Rosæ . . . . ad ℥vj.
M. Ft. lotion.

How can I dispense this elegantly? The way I proceeded to do it was to rub the calamine and zinci oxyd' together with the glycerine, then adding a little rose-water. I then mixed the oil and lime water, and lastly, the liq. carb. deterg. After standing a few minutes a thick white scum collects at the top, and is not dispersed by frequently shaking. It was dispensed in the same way at Apothecaries' Hall, but two other West End houses sent it out with a sediment only at the bottom. How is it done?

C. W. LAWTON.

[362]. Can any one supply information as to how the following should be dispensed? It comes from the pen of Dr. A. A. Biermann, L'Hiver, San Remo, and was last dispensed in that town:—

℞ Acid. Muriat. Conc. 2/0
Tr. Aurantii 18/0
M.S. 10—15 mma. 18·11·78.

NEMO.

[363]. A prescription of the following formula was dispensed by me the other day, and after standing forty-eight hours or so it changed from clear pale to turbid brick-red:—

℞ Sodæ Bic. . . . . ℈ij
P. Acid. Tart. . . . . ℈ij
Potass. Iod. . . . . ℈j
Potass. Brom. . . . . gr. x
Tr. Aconiti . . . . gtt. x
Sp. Camph.,
Ess. Menth. P. . . . . . . āā ♏ x
Aq. . . . . ad ℥vj

Can any one account for the difference in the mixtures? I have kept it for weeks, and it has not changed previously.

NEMO.

[364].

℞ Acid. Phos. Dil. . . . . ʒj.
Glycyrrhini . . . . ʒj.
Aquæ . . . . ℥ij.
Sig. One teaspoonful every two hours.

What is meant by the second article in above prescription?

PYRETHRUM.

Notes and Queries.

[626]. In answer to Mr. Elton's inquiry, coins can be quickly cleansed by immersion in nitric acid (fort.), then speedily washed with water. If very dirty, or corroded with verdigris, it is best to give them a rubbing with paste or with the following, which of course entails a little "elbow grease" and a little time:—

℞ Pu. Potass. Bichrom. . . . . . . ℥ss
Acid. Sulphuric.,
Aq. Fort. . . . . āā ℥j

Rub over, wash with water, wipe dry, polish with rotten stone or chalk.

W. LYLE.

[629]. This I believe to be merely the unguentum hydrargyri oxidi rubri (B.P.).

ST. RULE.

[630]. In answer to "Hibernia" the following is from the 'English Mechanic,' and is Captain Abney's process. To prepare the ferrous oxalate developer, make a saturated solution of neutral potassium oxalate, and in this dissolve as much ferrous oxalate as it will take up; allow it to stand and pour off the clear red solution, and dilute with one quarter its bulk of water. It should be kept in air-tight bottles with corks luted with paraffin.

THE CREAM OF TARTAR OF THE PHARMACOPŒIA.

Sir,—In a letter from Dr. Stevenson, the analyst for the county of Surrey, and also in some other communications which appeared at the same time in your Journal, reference is made to the description of cream of tartar as given in the Pharmacopœia, and in the former of these it is said that my attention was some months ago directed to the fact "that the B.P. article was an impossible cream of tartar." I have no recollection of such remark, and have been somewhat puzzled to conceive what it should mean; but I presume the difficulty Dr. Stevenson may have experienced in interpreting the Pharmacopœia must have arisen from the way in which chemical names and formulæ are used in that work to represent commercial articles which are rarely or never in a state of chemical purity. Thus, the name acid tartrate of potash is given to the article formerly called bitartrate of potash, but more commonly known as cream of tartar, and this is followed by a chemical formula which precisely represents what the composition of the article would be if it were chemically pure. The definition thus far is such as would be given in a purely chemical work. But the subsequent description shows that the salt is not required or expected to be chemically pure. There is certainly some appearance of inconsistency in this, and it has been suggested that chemical formulæ might with advantage be omitted on account of their too great precision. The same objection, however, might be taken to the use of chemical names. But these objections, in my opinion, are greatly outweighed by advantages which the use of known chemical names and formulæ afford in defining the articles referred to. Chemical formulæ are used in the Pharmacopœia not only for explaining chemical names, but also for shortening and facilitating the description of products, while "characters and tests," when these are appended, serve further to define the nature of the substances named, and often to qualify what the name and formula, if used alone, would indicate. These must, therefore, be taken altogether, the context as well as the text. In the case of cream of tartar, the lime salt, the presence of which is indicated by the test, being variable in quantity, the specified indication of it is made to refer to a minimum rather than a maximum quantity, and it is probable that the average is greater now, since plastering wines has become so largely practised, than it was twelve or thirteen years ago, when the Pharmacopœia was constructed. Tartrate of lime has always been recognized as a legitimate, because necessary, constituent of cream of tartar, from which it could not be made perfectly free without augmenting the price to an extent that would practically prohibit its use. Pereira says, "as found in commerce it usually contains from 2 to 5 per cent. of tartrate of lime, and sometimes a little sulphate of lime. . . This is of no material consequence in a medicinal point of view."

For the presence of sulphate of barium, I know of no legitimate excuse; but it may possibly arise from the use, in plastering wine, of mineral matter containing both barium and calcium salts. I am informed by a large Spanish wine maker that in the district in which he lives they plaster wine by the use of earth found in the locality of the vineyards, without reference to its special composition. It is not known as gypsum, or by any name representing sulphate of calcium, but merely as an earth that answers the wine makers' purpose.

Some remarks made by Mr. Tanner on this same subject have surprised me. He thinks the description of cream of tartar in the B.P. is "rather vague and ambiguous," and as far as I can gather from his remarks, the ambiguity lies in the statements that cream of tartar is obtained from "something quite distinct from cream of tartar," namely the *crude tartar* which is deposited during the fermentation of grape juice; that this cream of tartar when tested gives evidence of the presence of what he calls *a trace* of tartrate of lime, and that the ash resulting from the incineration of 188 grains of the salt requires for its neutralization 1000 grain measures of volumetric solution of oxalic acid. He thinks this last test would prove that the salt was a pure potash salt! and he observes, "that cream of tartar does contain tartrate of lime is the experience of every one who has ever had to do with the examination of it, but that it should contain it in anything more than *a trace*, I am by no means ready to admit." He then suggests that it should be guaranteed not to contain more than 5 per cent. of impurity, which may be supposed to be what he represents as a trace. Surely all this indicates ambiguity somewhere else than in the B.P.

Again, I am at a loss to understand how anyone could suppose that crude tartar on being ground would form cream of tartar, or anything like it, as apparently assumed by Mr. Tanner. The cream of tartar alluded to by Mr. Hodgkinson, at the hearing of the case, was represented by Mr. Allen, the grinder, as having been obtained by a delivery order for "cream of tartar, in its crude state," which, of course, means the usual roughly crystallized cream of tartar, a very different thing from crude tartar or argol.

October 15, 1879. T. REDWOOD.

CREAM OF TARTAR.

Sir,—Now that the presence of a little calcium in commercial cream of tartar is being made a rock of offence by public analysts, it may not be out of place to direct attention to a point which appears to have escaped notice in the discussion which has arisen with regard to this subject.

In every prosecution which has occurred the adulterant has been reported to be so much "tartrate of lime." Is this statement a matter of fact, or of assumption? If the former, it is certainly a striking coincidence; if the latter, the cream of tartar has probably been credited with nearly twice the amount of impurity which it actually contained. Cream of tartar may, and not unfrequently does contain a small proportion of sulphate of lime. If, therefore, the estimation of the calcium is made (as is frequently the case) by solution of the bitartrate in hydrochloric acid, and precipitation by alkali, the whole of the calcium will be thrown down as tartrate, and its amount consequently largely over estimated

The same error would, of course, follow even if the calcium is precipitated as oxalate, and thus the presence of little more than 6 per cent. of calcium sulphate would figure in the report as 13 per cent. of "tartrate of lime." So seriously indeed does the presence of the former salt affect the analysis, that, according to Scheurer-Kestner, "in the presence of calcium sulphate only an approximation can be made of the relative amount of potassium bitartrate and calcium tartrate, and even this is not possible when the sample contains other acid substances besides tartaric acid."

For the homœopathic proportion of baryta, it seems to me that the "yeso," or the "Spanish earth," previously added to the wine may fairly be held responsible. Knop and others have found barium salts in Nile mud and in the ashes of plants grown therein. The conjecture, therefore, that the presence of traces of these substances in cream of tartar may result from one or more of the elegant processes adopted by the Spanish vintner is not more wild than is the supposition that six-tenths of a per cent. of sulphate of barium is wilfully added as an adulterant by the British wholesale druggist.

Holloway, N. F. W. FLETCHER.

THE RIGHT OF REGISTRATION UNDER THE DENTAL ACT.

Sir,—I scarcely know which to despise most, the select stupidity of all dentists in the way they have conducted their affairs, or the assurance of over two thousand odd chemists. Dentists first allow every one and any one to register, and then when the opportunity is taken, roundly abuse. But be that as it may, still I am a dentist of over thirty years' practice, yet was struck with amazement at the assertion of chemists that any man is a *bonâ fide* dentist, or was in actual practice at the passing of the Dentists Act as a dentist, who had extracted a tooth. Pray let me ask chemists to be just a trifle more consistent. Would, for instance, any man have been registered as a chemist, under the Pharmacy Act, simply and solely because he had made up a prescription? Certainly not! But surely, sir, if a man is a dentist simply because he has taken out a tooth, then it follows as logically that any one is a chemist because he has made up a prescription. Again there is no value in the Dentists Act or the necessity of registration, if extraction is the sole qualification of a dentist. The argument is rankly absurd on the very face of it. What then is a *bonâ fide* dentist? Why a man who can do with his hands whatever in or appertaining to dentistry he may be called upon or asked to do, viz., anything from lancing the gums to making an artificial set of teeth or palate. A dentist who cannot make a set of artificial teeth, palate, etc., with his own hands, though he can extract and fill, is not a true dentist, but a nondescript, or at the best a surgeon of a very limited order of surgery. Thus it is the ability to construct artificial teeth, palates, regulation plates with filling that constitutes a *bonâ fide* dentist; but there is a very wide difference between all this and extraction. I know four barbers, two farriers and a butcher's slaughterman, who are indeed first class extractors of teeth. But who would call them dentists? The truth is any simpleton can extract, that is pull, and in the majority of cases the tooth must come and without breaking. I should indeed despise my skill as a dentist if it consisted simply of extraction.

Permit me, sir, to further disprove the assertion of chemists, and show by their own acts and deeds, and also those of medical men, that they had no right on principle to oppose the Dentists Act, much less to register. Listen, sir. In 1814 the Medical Act came in force, but is there a word in it relative to dentists or dentistry? No! Later on came the Pharmaceutical Act, is there a word in it relative to dentists or dentistry? No! But why not if dentistry is a branch of medicine and pharmacy, as the opposition of medical men and chemists implied? But let us admit that dentistry is a branch of medicine and pharmacy; still how comes it that medical men after the Medical Act of 1814, and chemists after the late Pharmaceutical Act, permitted unqualified men by the hundreds to practise a branch of their several callings, if it be a branch. The truth is, not only were dentists after the passing of the Medical and Pharmaceutical Acts permitted to practise without any diplomas or qualifications whatever; but a Dentists Act was needed, years after the other two named, to legalize dentists themselves with medical men and chemists and to legalize dentistry as a profession. But surely no such Act was needed if dentistry be a branch of medicine and pharmacy. Also medical men and chemists having Acts of their own surely did not need another just to confirm a mere branch. The whole thing is highly absurd on the very face of it and proves incontestibly that dentistry—not the extraction of teeth, which was the actual right of both medical men and chemists—is a special and peculiar calling and has no more to do with medicine and pharmacy, or with with medical men and chemists, than electricity or photography, though the one is somewhat allied to medicine and the other to chemistry. In fact the very passing of the Dentists Act was proof positive that dentistry is not merely the extraction of teeth, but a profession special and distinct, or the Dentists Act never could have become law. It is sheer folly and nonsense to argue otherwise. Now the reason that it passed in the manner it did was owing to the gross incapacity, apathy, supineness and imbecility of dentists themselves in general and the late Dental Reform

Committee in particular. We dentists, sir, ought decidedly to take to Dr. Pangloss's last title, viz., the A.S.S., for we have really earned it. It is also far too late to scold and whine now the die is cast, and we must grin and bear it as best we can. In America there is a matchless dental profession, independent of medical men and chemists; in this United Kingdom it is—well a branch of medicine and pharmacy, a branch of anything in fact. In conclusion, let me humbly advise chemists, that advice is—*Ne sutor ultra crepidam*. Translate it, my brother chemists-dentists, and lay it to heart, for they are words of wisdom. Thus far more in sorrow than in anger that we dentists have so egregiously sold our dear profession and its independence. However, fools must pay for their folly.

185, *Oxford Street, W.* GEORGE WARD, S.D.

Sir,—As one who has lent his aid to the passing of the Dentists Act, I beg to thank you for your timely and temperate article on "Registration under the Dentists Act" in your issue of the 11th.

I believe I know the disposition and intentions of the promoters of this Act, and feel sure that their views are of the most liberal nature regarding the scope of registration privileges, and that nothing but the most urgent sense of duty towards the public—for whose protection the Act was primarily framed—and the dental profession will ever induce them to put the penal clause of the Act in force against anyone.

I feel sure of the support of every promoter of the Dentists Act when I say that I most heartily endorse the concluding sentence of your article, and I assure you, sir, that there is no feeling of animosity existing against "those members of the pharmaceutical body who have been brought into legal confraternity" with us. It is well known to all that many of those gentlemen are much more professional in their views and conduct than many who have come upon the register with the undoubted right to call themselves dentists pure and simple. Moreover, many pharmaceutical chemists and dentists have used their interest and freely given of their means to help the passing of the Dentists Act, and I think that such men, as well as all who can establish their *bona fides*, would have reasonable cause of complaint if the Dentists' Register becomes a refuge for those who cannot find a place on your own special register.

I do not think that a youth who has been engaged in bottle washing and in sweeping a chemist's shop, and who might have learned to do a little dispensing, could be considered eligible for the Pharmaceutical Register even at the most liberal period of its existence, and I may be permitted to doubt how far the Pharmaceutical Society has not had cause to regret past liberality, though it may have been more or less due to a want of power to be more strict.

You say truly that it is quite conceivable that a chemist's assistant or apprentice may have acquired such skill and competence in dentistry as to make him fit to register under the Act, and in such a case you recognize a probability of hardship. I submit that it is hardly possible to frame a law which in the commencement of its operations may not inflict hardship of a limited kind. From the alteration of the rules of an examining body up to an Act of Parliament such always has been and will be the case, and to legislate for what is conceivable is, I think, beyond the most comprehensive law-making intellect. But I would ask how far we are right in admitting this speculative ability of acquiring skill into our calculations. Such exceptional skill must be rare indeed, and the possessor, if his ambition be in that direction, will find little difficulty in attaining the position to which he aspires by means far more satisfactory than by taking advantage of a side door, supposed to have been left open by an Act of Parliament. If such skill be common, then the demands of the Pharmaceutical Society and of the Dentists Act in reference to apprenticeships are excessive, I do not speak now of Preliminary examinations, but if a youth, say a chemist's apprentice, be able to spare so much of his time from the period during which he has to learn the nature of drugs and the business of compounding them, and all the technicalities which belong to the practice of pharmacy, surely both pharmacy and dentistry are much more easily acquired than some authorities would have us believe.

From what I can gather, many chemists and druggists have registered from diverse motives. Some have done so not so much for the sake of practising dentistry as to avoie jury serving and such inconveniences. Others, and thesd are mostly young men, have registered so that they may have dentistry to fall back upon should pharmacy fail them; and others have come upon the register with a view to continue the practice of dentistry to the same limited extent as before the passing of the Act. With regard to this last class, it is a common thing to see announcements in the shop windows of chemists and druggists, to the effect that teeth are scaled or extracted or stopped as need be. Now I am perfectly sure that the framers of the Dentists Act never contemplated interfering in anyway with these most useful men. Hundreds have done so hitherto without calling themselves dentists, and there is not a word in the Dentists Act which seeks to interfere with their doing so still. I know that certain medical journals sent the chemists and druggists in force against the Dentists Bill on that ground. These journals knew how they had been embarrassed in their abortive attempts to prevent counter practice and they hoped to produce a like embarrassment for the promoters of the Dentists Act, but in doing so they were only trying to serve their own end and in no way to benefit the chemists and druggists. I repeat the Dentists Act only interferes with unqualified persons using certain titles; the chemist and druggist may extract or scale or stop teeth as heretofore, but he may not call himself a dentist. With regard to the other two classes named, I think it cruel to encourage young men to think that having the power to assume a title will ever enable them to successfully compete with the educated class of men who will arise along with them, and I can but say, regarding the third variety, that it is not fair to make the Dentists' Register a refuge for those who are unable to place themselves elsewhere.

Referring to the uncertainty of the meaning of the term *bonâ fide*, your correspondent who says it is designed to sweep away all ambiguity certainly gives the view of a very high legal authority. Whether his view be exact or no, is not for me to say. I can only as a layman repeat the opinion as laid down by those who are supposed to understand those matters.

There is yet another point which is worthy of the consideration of those who may have registered on rather slender claims, viz., what is the meaning of the term "in connection with medicine, surgery or pharmacy?" When a man wants to prove himself a doctor or a surgeon, he must appeal to the Medical Register, so I presume the same condition applies to one who wishes to prove himself a pharmacist.

In conclusion, sir, I am sure that the spirit in which the expurgation of the Dental Register will be carried out will be such as to meet with your approval, and that the confidence shown in the Dental Reform Committee by a large number of most excellent men who have practised dentistry in connection with pharmacy will not have been misplaced. I trust to your kindness to give this letter a place in your Journal if you think fit, and apologize for its great length.

A MEMBER OF THE DENTAL REFORM COMMITTEE.

FRIEDRICHSHALL WATER.

Sir,—We are in receipt of a communication from the secretary of the Apollinaris Company, the agents of the Hunyadi Janos Bitter Water, in which he complains that an advertisement of the Bitter Water of Friedrichshall, which appeared in the *Pharmaceutical Journal* of September 27, contains an erroneous translation of a testimonial of Professor Virchow. We herewith send you a copy of the certificate in the German language, with the rendering which should have appeared, and side by side with it, the misleading translation, which was inserted in the advertisement columns of the *Pharmaceutical Journal* through an oversight on our part.

German original.

"Auf ihre gefällige Mittheilung erwidere ich, dass ich das natürliche Friedrichshaller Bitterwasser seit Dezennien kenne und anwende und dass ich die vortrefflichen Eigenschaften desselben nach wie vor schätze. Es ist nicht meine

Absicht gewesen, indem ich mich über ein anderes Bitterwasser günstig aussprach, dadurch das Friedrichshaller herabsetzen zu wollen, und ich bezeuge daher recht gern, dass es mir fern gelegen hat, irgend ein anderes ähnliches Wasser als das unter allen Verhältnissen vorzuziehende und als das absolut beste zu empfehlen.

"*Berlin*, 8 *Juli* 1879." RUD. VIRCHOW.

Correct Translation.

"To your polite communication, I reply that for upwards of twenty years (seit Dezennien) I have known and employed the natural Friedrichshall Bitter Water, and that now, as heretofore, I appreciate its excellent qualities. In giving a favourable opinion of another Bitter Water, I did not intend thereby to depreciate the Friedrichshall Water, and I quite willingly affirm that it was far from me to recommend any other similar Water as that which is to be preferred under all circumstances and as the absolutely best.

"Signed RUD. VIRCHOW

"*Berlin*, 8 *July*, 1879."

Incorrect Translation.

"I have known and used the Friedrichshall Bitter Water for a long time, and experience has proved to me its many excellent properties. Although I do not wish to undervalue the merits of other Bitter Waters, I feel that in justice to the Bitter Water of Friedrichshall, I must record my opinion that it is the best and most useful of the Bitter Waters, and as such I can confidently and gladly recommend it."

We are, sir,
Your obedient servants,
J. AND A. CHURCHILL.

HEALTH OF THE DRUG TRADE.

Sir,—I was very much struck with the correctness of the statements made by "Junius," and consider that we may trace with ease the apparently short life of the chemist to those three causes—confinement, want of recreation, and the vitiated atmosphere in which he lives.

The greatest evil of the three is late closing, and one which is deserving of immediate attention.

Should we not, at a time when examinations are compulsory, endeavour to raise ourselves and the business to which we belong to something better and higher than what it was before such things were thought or heard of?

If chemists as a body would unanimously agree, we might without any difficulty close our respective shops at a reasonable hour, and by so doing I feel certain that it would tend to raise us in the estimation of the public, and be beneficial to the health of both assistant and master.

At a meeting held recently in our largest town, the question was very seriously discussed as to whether they might close at 10 instead of 11 p.m. When we know that such a miserable state of affairs exists, can we reasonably wonder that we are not men of strong constitution and long lives?

Bootle. CAMPHORA.

A SIMPLE STANDARD.

Sir,—It may perhaps be new to the majority of your readers, as it was to myself, when the advantages of this standard were first pointed out to me by a friend, and on this ground I have taken the liberty of troubling you with my few remarks, with the hope that they may prove useful to those, who, like myself, are in the habit of dispensing from solutions of various salts.

There can be no doubt whatever that in such cases where the salt does not undergo any change by being kept in solution, this practice is not only allowable, but preferable to weighing the dry salts, especially in such establishments where much dispensing is done and where time is necessarily valuable.

I have usually made my solutions ʒj ad ℥j, and this strength answered very well in most instances, but for simplicity it is not to be compared with that which I now desire to bring before your notice, viz., 1 in 6, the advantages of which will be quite apparent on a careful examination of the following examples:—

Strength 1 in 6.

No. of grains ordered.		No. of drachms of solution.
1 grain	equals	·1
2 grains	,,	·2
3 ,,	,,	·3
10 ,,	,,	1·0
12 ,,	,,	1·2
15 ,,	,,	1·5
20 ,,	,,	2·0
25 ,,	,,	2·5
40 ,,	,,	4·0
ʒj or 60 ,,	,,	6·0
ʒij ,, 120 ,,	,,	12·0 or ℥iss
ʒiv ,, 240 ,,	,,	24·0 ,, ℥iij
℥j ,, 480 ,,	,,	48·0 ,, ℥vj

On glancing at the above title it will be noticed that the figures in both columns are the same, with the addition of the decimal point (·) in the second column; thus the number of grains, ordered in a prescription, indicates the number of drachms of solution necessary to use, 10 grains requiring 1·0 drachm or ʒj, etc. It may be thought by some, that where an odd number of grains is ordered, the calculation will be difficult, but this need not be so, if the principle of the standard be grasped. ·1 drachm means $\frac{1}{10}$ drachm= ♏vj; ·2 must then = ♏xij; ·5 = ʒss, etc. The placing of the decimal point (·) it should be noticed is fixed by the number of grains ordered, 10 grains requiring 1·0 drachm or ʒj.

In conclusion, I trust that my endeavour to make known a simple remedy for a common want may be a sufficient excuse for me venturing to trespass so much upon your valuable space.

Sunderland. ROBT. H. MUSHENS.

TINCTURE OF YELLOW JASMIN.

Sir,—As the above tincture is frequently prescribed, I would respectfully ask, through the medium of the *Pharmaceutical Journal*, of what strength it ought to be? Every wholesale house has its "Tinct. Gelsem. Sempervirens" (in some instances the word "Special" or the maker's name follows), but the strength is seldom if ever given.

When large doses are prescribed it is absolutely necessary that we should know whether we are on the safe side or not, in dispensing them, as the drug is comparatively little known. I think it would be a good plan if every wholesale house stated the strength of the tincture and the dose, and abolished the favourite terms which follow the name, and which frequently have to be paid extra for.

ABERDAWE.

H. Waistell.—A recipe for stamping ink will be found on p. 80 of the present volume.

G. H. Morgan.—We do not think you should assume that the statement made by your customer is correct, but should communicate with the chemist and druggist in question.

R. Hardy should address his question to the editor of a medical journal.

R. Grant.—For a description of the way in which koumiss is made by the Tartars, see vol. v. of the present series, p. 325.

"*Fraxinus.*"—(1) *Holcus mollis.* (2) *Festuca gigantea.* (3) *Dactylis glomerata.*

F. Gale.—*Artemisia vulgaris.*

J. H.—The arms are the property of the Society as an incorporated body, and cannot be used legally by any individual.

"*Student.*"—(1) The question of the dispensing of "chloric ether" has been fully discussed recently in the "Dispensing Memoranda." See vol. viii., pp. 19, 38 and 67. (2) The swelling of the pills is probably due to the decomposition of the oxide of silver.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Rogers, Wills, Willmott, Deck, J. Squire, Siebold, Wilkinson, Swinn, Sub Umbra Floresco, Jek, Progress is Life, Forceps, Apprentice, T. E., R. H. R.

"THE MONTH."

"Chill October" well deserves its name this year, the cold but delightfully bracing north-east winds having effected a marvellous change in a few days and brought autumn so suddenly upon us that flowers are disappearing from our gardens and hedges all too quickly. At the Kew Gardens several families in the Herbaceous Ground still present a sufficient number of plants in flower to illustrate their characters. Among those which still linger thus are the *Leguminosæ*, *Compositæ*, *Scrophulariaceæ*, *Malvaceæ*, *Polygonaceæ*, *Boraginaceæ*, *Linaceæ*, *Geraniaceæ*, *Onagraceæ* and *Loasaceæ*. Of medicinal plants few remain in blossom. Several varieties of tobacco, the camomile, alkanet, melilot, and most beautiful of all, the colchicum, still remain in blossom. Several species of the last mentioned genus now present quite a bright appearance, while close by the rare British species, *Crocus nudiflorus*, which also flowers without the leaves, is scarcely to be distinguished by external appearance, and it is only when the inside of the flower is examined that the six stamens and the different character of the stigma is perceived. The shining black berries of the belladonna, the bright red ones of the woody nightshade and the prickly fruits of the thornapple, almost alone represent the Solanaceæ, just a few blossoms of *Solanum nigrum*, and some scattered panicles of the graceful *Solanum jasminoides*, being all that are left to represent this family at the present time. A species of *Datura*, to which the name of thornapple in this case is most inappropriate, for the capsule is quite smooth, may now be seen in fruit.

Among a few other Rosaceæ, the *Agrimonia odorata* still remains in blossom. Although by some botanists it is distinguished as a species, there are scarcely sufficient permanent characters by which to separate it specifically from large specimens of *A. Eupatoria*, the distinguishing features being that the stems are 3 or 4 feet high, the furrows on the fruit rudimentary or even quite undistinguishable, and the calyx wider at the mouth than in the other species. *A. Eupatoria* is occasionally used by herbalists in this country in affections of the liver, and in fact, it has had a reputation for complaints of that organ since the time of Dioscorides, who says it is "a remedy for them that have bad livers and for such as are bitten with serpents," and as Gerarde translates it "the leaves being stamped with old swine's grease and applied, closeth vp vlcers that be hardly healed." This reputation may perhaps explain a discovery recently made by Dr. Brinsley Nicholson, who, in a paper in the *Medical Times and Gazette*, speaks very highly of the value in scurvy and tapeworm of a plant called by the Caffres "Uhlinga," a species of *Agrimonia* (*Agrimonia Eupatoria*?), which has succeeded in his hands in the latter complaint even where turpentine failed. In eighty-six cases tried by the author the remedy acted effectually as a tænicide or tænifuge in nearly all.

The violet may almost be called an autumn as well as a spring flower, for almost every year a few blossoms may be found during the autumn where the plant grows freely, especially in sheltered spots in gardens. One of this genus has recently been examined by Dr. J. Konig, who finds as much as 21 per cent. of zinc oxide in the ash of the plant. This plant, which is by many botanists considered to be a variety of *Viola tricolor*, receives its name of *Viola calaminaria*, from the fact that it appears to be restricted to soil containing zinc, and thus serves to indicate the presence of the metal in the soil, where it might not otherwise have been suspected. Sufficient attention has perhaps not been paid to the influence of the chemical constituents of soil in producing variations in plants, nor to the value of such varieties in indicating the nature of the soil. Probably many of our readers have noticed with regard to the common violet, *Viola odorata*, how rare it is to find plants with blue flowers on a limestone soil, the prevailing colour being white. With regard to *Viola tricolor*, of which *Viola calaminaria* is probably a variety, Sowerby's 'Botany' makes the following statement:—"Some years ago a writer in the *Medical Journal* called attention to the heartsease as a valuable remedy for the cutaneous disease called *crusta lactea* in children. For this purpose half a drachm of the leaves or a handful of the fresh herb boiled in milk was to be given every night and morning and poultices made of the leaves, to be applied externally." When distilled with water it gives a volatile oil having an odour something like peach kernels, which may be also observed on chewing a leaf or portion of the stem. The possibility of the relation of this oil to the odour of violets, might be worth investigation.

An account of poisoning by fungi of a boy, three years of age, is given in the *Lancet* for October 11. The child had eaten some small fungi which he had gathered in Hyde Park, specimens of which were shown to the medical man by the child's sister. The child recovered next day. As the symptoms were somewhat peculiar and the name of the fungus or fungi eaten could easily have been ascertained at the Botanical Department of the British Museum, or by application to anyone of our numerous fungologists, it is to be regretted that such an opportunity of adding to our knowledge of the little-known properties of the plants of this interesting class was allowed to pass by. Four other cases of fungus poisoning during the first few days of October were admitted into Middlesex Hospital. In these cases the symptoms were those caused by a strong intoxicant, and in two cases accompanied by violent delirium. They all eventually recovered. In these cases also no mention is made of the species which produced these results.

Fungi probably possess properties as dissimilar in different groups, or even in species of the same genus, as those which are found in different species of aconite among the flowering plants; thus a species of *Amanita*, *A. rubescens*, which differs from the deleterious *A. muscaria* in having a pale drab-coloured cap, and flesh reddening when bruised, is edible. No opportunity of ascertaining the pecularities of poisonous species should, therefore, be neglected.

While speaking of fungi it may be mentioned that Dr. B. Crowther, of Hobart Town, calls attention, in the *Lancet*, to the use of hyposulphite of sodium in zymotic diseases, and states that it is a potent remedy in certain intractable acute and chronic ulcers, whose origin and continuance seem due to some local irritant of a fungoid or bacterioid nature. He further adds, "From the vast number and varied class of diseases over which it exercises a controlling influence, it is destined to hold the first position as a specific in our Pharmacopœia." It may be dded that it possesses the advantage over the bisulphite of having a less disagreeable taste.

A curious illustration of the fact that all knowledge is useful at some time or other has recently occurred in the discovery of diatoms in the gooseberry preserve of commerce. The study of the Diatomaceæ has generally been looked upon as comparatively useless, although the beauty of the forms of these plants renders it a very delightful one. M. Ch. Menier, professor of materia medica at the School of Medicine and Pharmacy at Nantes, in examining a specimen of gooseberry preserve from Paris, recognized that its gelatinous consistence was due to algæ, by finding in it a very beautiful diatom, *Arachnoïdiscus japonicus*, which is known to occur in "Japanese isinglass."* Probably the gelose came from the French colony of Cochin China. The colouring matter was due in part to cochineal, as determined by analysis, and in part to the petals of the Rose Tremière (a dark-flowered variety of *Althæa rosea*), as indicated by the pollen grains characteristic of the Malvaceæ, which in consequence of the union of the petals to the androphore would be almost sure to be present.

At the recent drug sales several packages of calabar beans were offered; these have been rather scarce for some months, and as this is about the time of year when they become ripe, an abundance may soon be expected. Zanzibar aloes, having an opaque appearance like Natal aloes, but as usual packed in monkey skins, was observed. There was also a quantity of fine-looking yellow bark, which would probably pass as Calisaya, but contains generally only traces of cinchonidine and a small percentage of quinine. Rose geranium oil from Algeria, Dalmatian insect powder, Siam benzoin in fine tears, Samovey book isinglass, German camomile flowers (*Matricaria Chamomilla*) and patchouli leaves were among those of less frequent occurrence.

At a sale, in London, during the early part of this month, a number of small gourds of curari were exposed for sale and labelled *aloes*! They were tasted by several people, who fortunately, owing to its bitterness, probably ejected their saliva immediately afterwards, for had the mucous membrane of the mouth been in any case abraded, the consequences must have been disastrous. It was well for the public that the gourds were of so small size, that they would, probably in any case, have been purchased merely as curiosities. As soon as the true nature of the drug was known it was immediately withdrawn.

According to Gehe's report curari is already going out of favour owing to its want of uniformity. Some time since, M. Preyer in the endeavour to obtain an active principle of definite strength from curari, prepared a crystallized sulphate of curarin; this substance, which was stated by the discoverer to be twenty times stronger than curari, was afterwards found by Theodor Sachs† to be composed of phosphate and carbonate of lime with a little adherent curari, sufficient only to produce a weak physiological action.

There now appears a possibility of a definite principle having the properties of curari being procurable at no distant date. An important discovery has recently been made by M. Jobert, whose investigation of the source of curari was noticed in this Journal on a former occasion,‡ and will probably call renewed attention to the drug. He has found that *Strychnos castelnæ* and *Strychnos toxifera* are by no means the only species which yield a poison similar to curari; but that so far as experiments have gone, the South American species are distinguished from the Asiatic by possessing properties resembling those of curari rather than strychnia. He considers that the most active of what may be called the curari-yielding species of strychnos is *S. rubiginosa*, Piauhy, and the least toxic, *S. triplinervia*, Gaertn; indeed in so slight a degree does the latter possess toxic properties that it is employed for fevers by the natives. In another number of the same journal, MM. Couty and De Lacerda give an account of the extraction of the active constituents of the latter plant and the physiological action of the extract. They found that the extract made from the bark of stems of moderate size was more active than that of the root, and although much less powerful than curari. M. Jobert states that the Peruvian Indians mix the juice of a menispermaceous plant which has a poisonous action on the heart with the curari, and that only the pure extract of the strychnos should therefore be used in order to obtain definite physiological results. In *Strychnos triplinervia*, we have, according to MM. Couty and De Lacerda, an agent which can easily be obtained of a definite strength and offers the advantages that the valuable physiological effects of curari can be obtained in a few moments and that the symptoms can be arrested at different periods as may be required.

Dr. W. Murrell, in an article in the *Practitioner* this month, states that he has found picrotoxin afford great relief in the night-sweating of phthisis, having had only one case of failure out of twenty, and even then the remedy did some good at first. The strength of the solution used in his experiments was at first 1 part in 180, but as some of the picrotoxin crystallized out a solution of 1 part in 240 of water was afterwards adopted. Of the former solution, 1 drachm in an eight-ounce bottle of water was prescribed, the dose ordered being in most cases a teaspoonful, or in other words, about one ninety-sixth of a grain.

In the severe diarrhœa which often occurs in the course of the same disease, Dr. J. B. Yeo has found that the fluid extract of coto bark in doses of 5 to 8 minims, arrests or checks it even in its severest forms, and he remarks that he is quite sure that coto bark is a valuable remedy which ought rapidly to come into general use. Dr. Yeo also calls attention to the very important fact that when administered in the form of pills or with the mistura cretæ, B.P., it appeared inert, and that he found a resinous element was precipitated in tough masses when the fluid extract was carelessly mixed with water, but that when given in combination with tincture of cardamoms and mucilage it was very effectual. He also makes the very pertinent observation that "this is probably the fate of many valuable medicines which appear to fail, not from want of virtue in themselves, but from want of patience and attention in their mode of administration."

In the *Indian Medical Gazette*, Mr. A. L. Deb recommends the root of *Hedysarum gangeticum* in dysentery. The fresh root is given three or four times a day in the form of pulp, ground down and mixed with water, to the extent of thirty or forty grains each time for adults. He considers it to stand next in value to *Ixora coccinea* and to be especially adapted for acute dysentery of moderate severity.

* Ser. [3], vol. ix., p. 1056.

‡ Ser. [3], vol. viii., p. 581.

In the United States the bark of *Piscidia erythrina*, or Jamaica Dogwood, is being tried as an anodyne and soporific. Some years ago Dr. W. Hamilton, of Plymouth, called attention in the *Pharmaceutical Journal* to this drug. The strength used is 4 oz. of the bark to 16 oz. of rectified spirit, and the dose taken to ease pain and procure sleep is 1 drachm for adults.

Dr. L. Mann, of California, has recently been experimenting upon the Californian laurel (*Oreodaphne Californica*?) and finds that the odour of the leaves causes in some persons a severe frontal headache when they stand under a tree. Apparently this suggested a use of the remedy in nervous headache, in the treatment of which he has found the bruised leaves, used as an inhalation, very successful. The taste of the leaves is exceedingly pungent and to some persons disagreeable, and the plant seems to be one likely to possess some useful properties. The odour is said to be disliked by mosquitos and other insects.

During the last few weeks *Hamamelis virginica*, which is well known as the chief ingredient in Pond's Extract, has attracted some attention in the correspondence columns of the *Lancet*. The writers appear to be unaware that a formula for the tincture has already been published, and as uniformity in unofficial preparations is very desirable it may be useful to some of our readers to know that a formula may be found in the last edition of Squire's 'Companion to the Pharmacopœia.' Medical practitioners would obtain much more satisfactory and uniform results from the use of unofficial preparations than is sometimes the case if they would indicate in their prescriptions the strength of tincture intended to be used.

Dr. E. Schrader, in the *Chemiker Zeitung*, describes a new method of making varnish, which consists in causing ozone to act on linseed oil, by which it is bleached and brought to the proper consistence, without the aid of fire.

In the same journal, M. A. Tschirch calls attention to the fact that in almost all the bottles of magnesium sulphate and in some of calcium sulphate solutions in the laboratory of Berlin University, algæ belonging to the *Palmellaceæ* and developing chlorophyll have made their appearance.

Recently there was noticed in these columns an interesting announcement that Herr Ladenberg had succeeded in recombining tropic acid and tropin to form the alkaloid atropine of which they were the products of decomposition. It is now announced that a similar feat has been performed with respect to milk sugar by M. E. Demole (*Comptes Rend.*, lxxix., 481). Upon treating with boiling anhydrous acetic acid the mixture of galactose and lactoglucose into which milk sugar is converted in contact with dilute acids, an octacetyle ether is formed resembling that obtained by Schutzenberger with dextroglucose. An alcoholic solution of this ether poured into baryta solution and kept for a few minutes at a temperature of 90° gives off acetic ether, and after exact neutralization with sulphuric acid, evaporation to dryness, and re-dissolving in water, is by several recrystallizations aided by alcohol obtained as a crystalline body having all the properties of sugar of milk. "Octacetic saccharose" similarly treated with alkalies is said to have yielded cane sugar, but the crystallization was not successful.

Another investigator in this direction, M. A. Michael, has effected even more interesting results in the synthesis of two glucosides and has indicated a probable method by which a large numbers of others may be produced and investigated. Of M. Michael's two products the more interesting at present to pharmacists is undoubtedly "helicin," a glucoside described by Piria and produced by the action of dilute nitric acid upon salicin and reconvertible into salicin by the action of nascent hydrogen. The relation between these two glucosides is shown by the following equation:—

$$\underset{\text{Salicin.}}{C_{13}H_{18}O_7} + O = \underset{\text{Helicin.}}{C_{13}H_{16}O_7} + H_2O$$

The medium used by M. Michael for the introduction of the molecule of glucose is a compound called acetochlorhydrose obtained by the reaction of chloride of acetyle upon glucose. Equivalent quantities of acetochlorhydrose and salicylite of potassium were dissolved in absolute alcohol, mixed in the cold and left to stand; there was evolution of acetic ether and formation of a precipitate of chloride of potassium, the reaction being completed in about three days. After filtration the alcohol was allowed to evaporate spontaneously, when there was left an oily substance that solidified after ten days, and which when purified gave upon analysis the composition of helicin and was also identical in its other properties. Helicin so produced is slightly soluble in cold water, and very soluble in hot water, from which it is deposited on cooling in white arborescent crystals. Boiled with dilute sulphuric or hydrochloric acid it splits up into salicylic aldehyde and glucose, and the same decomposition is induced by the action of emulsin. The other glucoside was obtained by the reaction between acetochlorhydrose and phenate of potassium; it does not correspond with any known natural substance, and has been named phenol glucoside. Acetochlorhydrose appears to be endowed with considerable powers of substitution. It acts upon levulose with the evolution of gaseous hydrochloric acid and acetic acid and the formation of a small quantity of crystalline matter which may prove to be dextrolevulose (cane sugar). Other compounds have also been obtained by its use that have yet to be examined and described.

After a considerable amount of writing suggestive of the mythical there appears to be at last some prospect of the properties long attributed to the papaw tree undergoing scientific investigation. In the paper published in the Journal for the 11th inst. (p. 283), Messrs. Wurtz and Bouchut describe a substance having the properties of an energetic digestive ferment which they have separated by precipitating with alcohol an aqueous solution of juice from the stem of the papaw, and named "papaïne." Curiously enough almost simultaneously Dr. Peckholt, of Cantagallo, Brazil, has published in the *Zeitschrift* of the Austrian Apotheker-Verein a long and interesting account of the *Carica Papaya*, in which he describes under the name of "papayotin" a substance apparently identical with "papaïne." Dr. Peckholt's researches appear to have been carried out some ten years since, and only to have been published now because of the revived interest in the subject. Notwithstanding Dr. Peckholt's long delay in publishing, due probably to his residence in Brazil, and the fact that he disclaims any intention to claim priority, it would appear that he really is entitled to do so, since his paper appeared in the Austrian journal for the 20th of August, whilst M. Dumas' communication was not read in the Academy of Sciences until five days afterwards.

Last month there appeared in this Journal a letter from Messrs. Baildon and Son, stating that after following out Mr. Thresh's formula for making soluble essence of ginger (before, p. 193) they had failed to obtain a clear preparation. Mr. Thresh replied recommending a reagitation with silica and filtration. It may be useful to mention that a second letter has been received from Messrs. Baildon stating that upon carrying out the suggestion a bright preparation was the result. The wide-spread interest in this subject is illustrated by the fact that a few days since a letter was received from Jacksonville, Florida, U.S., attesting the practicability of Mr. Thresh's process.

It is now officially announced that the day on which this Journal is published is to be the day upon which the India Museum will be finally closed. Whatever may have been the circumstances which have induced the authorities to take this step—whether simply in consequence of the expense, or that in addition to other causes—only regret can be expressed at such a necessity having arisen. In distributing this fine collection among other institutions no doubt care will be taken to select the most fitting recipients, and it may be hoped that a large portion of the materia medica, including the essential oils, will find its most suitable resting place in the museum of the Pharmaceutical Society.

The annual report of the Director of Kew Gardens, which has just appeared, contains an unusually large amount of matter interesting from a pharmaceutical point of view. This includes information concerning the introduction of Columbian barks into India, the success of cinchona cultivation in Jamaica, African dragon's blood, lignaloes, or eagle wood, olibanum and myrrh. Extracts from this report will probably appear in future numbers of this Journal.

The Dentists' Register, which has appeared during the past month, has no doubt, ere this, been scanned through spectacles variously tinged according to the wearers' views of what such a Register ought to contain. It appears to be carefully compiled, and is prefaced by a "table showing the number and qualifications, with percentage of the total of persons registered." From this it appears that the total number of names on the Dentists' Register on the 1st of August was 5289. The Licentiates in Dental Surgery of different medical bodies who have been registered number 483. Of persons registered on their own declaration as having been in *bonâ fide* practice before the passing of the Act, 2707 have claimed to have carried on dentistry separately, 2049 in conjunction with pharmacy, 17 in conjunction with medicine, 11 with surgery, 20 with medicine and surgery, and two with surgery and pharmacy. There have also been two persons registered as doctors of dental medicine of the University of Harvard.

The third part of Dr. Dodel-Port's valuable 'Atlas der Botanik' will be published in a few days. It will contain figures of *Spirochæte Obermeieri*, the contagium of a certain typhoid disease; also the whole development of the carbuncle fungus, *Bacterium anthracis*, as investigated by Professor Nägeli and the author of the atlas; the development of the prothallium of the fern genus *Aspidium* from the spore to the formation of the embryo; the fertilization of *Polysiphonia subulata* by the aid of animalculæ, and other recent observations of great value.

Pharmacists will be glad to learn that a new and thoroughly revised edition of 'Pharmacographia' will be published during the coming season by Messrs. Macmillan. The first edition has been out of print for some time, and much additional matter has appeared since the date of its publication which will doubtless be represented in the clear and condensed manner for which the work is so remarkable.

"A little knowledge is a dangerous thing." The *British Medical Journal* of the 18th, in an editorial paragraph, refers to the paper of Mr. Fahnestock, on "The Valuation of Blistering Beetles," which was recently (vol. ix., p. 1038) reproduced in this Journal from the *American Journal of Pharmacy*. In doing so it credits the author of that paper with saying that the fresh powder of the "potato beetle" yields about $1\frac{1}{3}$ per cent. of pure cantharidin, and remarks that this is a large product, and that "no doubt these pests will be increasingly used as a source of this drug." But it further ventures to prophesy that mankind will hardly be prevailed upon to desist from vigorous efforts to exterminate the insect because it is now shown to be capable of acting effectually as a physical as well as a moral blister. Perhaps a taste of this insect's power in the moral blister direction will be realized by the writer if he turns to the original paper, where he will find that the author does not speak of the Colorado "potato beetle" (*Doryphora decemlineata*), but of the potato bug (*Cantharis vittata*).

The power of ridicule is acknowledged, and there is no doubt it may be utilized in making impressions upon the memory. In connection with the New York College of Pharmacy there is a conversational class, in which the office of "quiz" is a recognized institution. Banter appears, in fact, to have been so useful in correcting errors in past sessions that the Board of Trustees have at the commencement of the present one formally appointed two gentlemen to the office of "quiz masters."

The meeting of the American Pharmaceutical Association at Indianapolis, a report of which has appeared during the past month, seems to have been a success in point of attendance, but showed a marked falling off in the number of papers read. A large amount of time was taken up in considering the rules of the Association, whilst some reports in respect to the next edition of the United States Pharmacopœia naturally absorbed much of the attention of the men by whom that book will have to be used when it appears. One alteration in the rules, in which the word America is substituted for United States, throws open the eligibility for membership to Canadians, Mexicans, Chilians and citizens of other South American States. One little *contretemps*, whilst amusing, shows how easily the "best laid plans" may "gang oft agee" on such occasions. It appears that when assembling for the "banquet," the Secretary, Professor Maisch, four past Presidents of the Association, and about a score of old members stood on one side to give precedence to their juniors. These flocked in in such numbers, however, that the room was filled and the doors were closed, leaving still outside the seniors, who were fain to comfort themselves at a neighbouring restaurant.

As usual with the American Pharmaceutical Association, the reports were a good feature. In one of them Mr. H. S. Wellcome stated that he had not been able to find "any drugs now cultivated here which were formerly obtained from foreign countries," with perhaps the exception of valerian, now cultivated in Vermont. In another report upon the market of San Francisco, Mr. Steele gave an account of the manufactures of his section, one of the most remarkable among which was that of 25,000 gallons of castor oil per annum. A specimen of a new salt, salicylate of cinchonidia was exhibited by the secretary. It crystallizes in well defined prisms, is sparingly soluble in water, and dissolves freely in weak and in strong alcohol.

The extent to which colour blindness is prevalent amongst railway servants has been the subject of an official inquiry in Germany. It is reported that on the State lines 1 *employé* in 125 is colour blind, whilst on the companies' lines only 1 in 250 is so affected. Probably this difference in the figures is due to a difference in the standard adopted, and it is noteworthy that they approach closely to the numbers recently published by the English Board of Trade, of 1 in 230 partially affected and sent back for further trial and 1 in 150 finally rejected.

According to the *Pharmaceutische Zeitung für Russland* the Russian armies were well supplied with all manner of drugs during the recent war, as much as eighty waggonfuls of unused drugs having been brought back with the army from Bulgaria. Some of the quantities used by the armies on active service are given as follows:—cinchona bark, 1083 lbs.; quinine hydrochlorate, 2358 lbs.; quinine sulphate, 5083 lbs.; chloroform, 3088 lbs.; opium, 1546 lbs.; morphia, 52 lbs.; castor oil, 25,953 lbs.; rhubarb, 1138 lbs.; ipecacuanha, 1820 lbs.; carbolic acid, 5597 lbs.; camphor, 6771 lbs. It is further stated that in the years 1877 and 1878 the medical department of the Russian war office purchased altogether 260,350 ounces of quinine sulphate and 194,700 ounces of quinine hydrochlorate at an expenditure of two and a half millions of roubles.

"Physicians' prescriptions accurately prepared" is the dispenser's motto, but to accomplish this with neatness and facility certain requirements are almost essential in a pharmacy. The letter of Mr. Mushens in last week's Journal, page 320, on a simple standard for solutions of salts daily and hourly required in dispensing, directs attention to one series; others will in due course be referred to. Opinions may differ as to the relative proportions of the salt in solution, but there can be but one opinion as regards the value of the principle, and its application may be left to the judgment of each dispenser. An "endeavour to make known a simple remedy for a common want" needs no apology, and the readers of this Journal will be indebted to those whose efforts are successful.

The first prescription requiring notice is that of No. 343, where sp. chlorof., without any quantity being given, forms part of the prescription. Judging from the size of the mixture and from its dose, that it was for a child, ʒss. sp. chlorof. would be a fair quantity. The next article sacc. ust. is only a colouring matter and must be left to the dispenser's discretion.

No. 344 contains a solution of Cheltenham salts. The writer of a prescription sometimes severely tries a dispenser's resources. To confine a prescriber to the Pharmacopœia would tend to check therapeutic progress, but there should be some limit to erratic prescribing. A teaspoonful or a quarter of an ounce of Cheltenham salts is the dose recommended for occasional use; one ounce and a half, therefore, in the twelve ounce mixture would give that proportion to each dose. A dispenser is required to keep the preparations of the B.P. ready for use in his pharmacy, but the Cheltenham salts have not yet occupied that position. It may assist "Dispenser" to give him Beasley's formula for artificial Cheltenham salts, which would be supposed to represent the saline and tonic characters of the Cheltenham waters:—Sulphate of soda 16 oz., sulphate of magnesia 8 oz., muriate of soda 1 oz., sulphate of iron 8 grs. Dissolve in the smallest quantity of hot water, strain and evaporate to dryness.

It is not usual to filter an injection such as No. 345, neither should a "shake the bottle" label be put on. A decomposition takes place, acetate of zinc is formed and remains dissolved, whilst sulphate of lead is precipitated. The writer may wish the deposit to remain at the bottom of the bottle, as he does not direct it to be filtered, or he may not desire it to be used with the fluid, as would be indicated by a "shake the bottle" label. The deposit is not considered an essential part of the remedy or one that possesses any value; the dispenser therefore has nothing to justify him in ordering the bottle to be shaken.

Pigment. iodi is prescribed in No. 346, and "Juvenis" wishes to know whether tinct. or linim. iodi should be dispensed. There is no formula for a preparation of iodine with the name pigment. iodi in the B.P., but on reference to the formula of the Throat Hospital, for pigment. iodi, the linim. iodi is directed to be used. This circumstance will be a guide to the dispenser, and a sufficient justification for the use of linim. iodi when pigment. iodi is ordered.

The question No. 347 refers to the varying appearance of different samples of enonymin. For several of these remedial agents from the United States, and recently introduced into this country, there is no published form, and there being more than one maker, it is but reasonable to conclude that each has his own particular method of manufacture. On reference to some papers which have at different times appeared in this Journal on the preparation of podophyllin, it will be observed how the appearance of the product is affected by very slight differences in the process of deposition from its solution. From what has been stated the difficulty or rather impossibility of furnishing a safe test of quality, or a test by which one of these vegetable products, probably of a resinoid character, may be recognized must be apparent.

It is difficult to say what the writer of No. 348 meant when he wrote ferri ammoniæ sulph. If he cannot be referred to, the dispenser will be quite safe in using ferri ammoniæ sulph., a salt formerly much used in photography, but little known in medicine. The remarks of St. Rule, p. 316, are very much to the point, but he would have made them more valuable if the source of the information that ferri ammoniæ sulph. acts as a "powerful astringent in uterine cases" had been appended. It will be observed that many correspondents assume ferri ammoniæ cit. to have been intended by the writer, but this is by no means certain. "J. C." states that ferri ammon. sulph. is iron alum; this is an error, iron alum is a *ferric* sulphate with sulphate of ammonia or potash; ferri ammon. sulph. is a *ferrous* sulphate with sulphate of ammonia.

The pills in prescription No. 349, may be made by the addition of a very small quantity of soap to the ingredients ordered; with the assistance of the soap a satisfactory mass may be obtained, firm, and capable of being rolled into pills. "Junior" is referred to remarks on the combination of similar ingredients in some of the preceding "Months."

The chloral hydrate and camphor in No. 350 may be so combined as to form a milky emulsion by following the directions of Mr. Wilkinson, p. 316, on this prescription. Care should be taken to rub the chloral hydrate and camphor till they become semi-fluid, before the addition of the mucilage, or the emulsion may be imperfect and gritty from the presence of free camphor.

There will necessarily result, from the mixture of bromide of potassium and tartaric acid, ordered in No. 351, a deposit of acid tartrate of potash with a supernatant clear solution of hydrobromic acid. Of this decomposition the prescriber may not have been aware, or he may have been aware of the decomposition, but considered that on the addition of the deposited acid tartrate of potash to each dose of the sodæ bicarb. in the powder, a potassic tartrate of soda would be formed; the dispenser should therefore direct the mixture to be shaken so that each dose of it may contain a definite relative quantity of the sediment. The dispenser would do well, however, to suggest to the prescriber that a more elegant combination would result by combining the sodæ bicarb. with the potass. bromid., and then putting the acid. tart. into the powder. Effervescence would equally take place and there would be little, if any, formation of acid tartrate of potash; the result would be more elegant, and probably just that which was intended. Of course this would depend upon whether the prescriber intended to give his patient bromide of potassium or hydrobromic acid.

The turbidity resulting from the mixture, No. 352, is due to the presence of the magnesiæ sulph. On that salt being added there is a separation of brown, flocculent matter; without it, the other ingredients may be combined so as to form a mixture free from deposit, and tolerably bright. The alkalinity or otherwise of different samples of ferri et ammoniæ cit. may have a bearing on the change which with some samples certainly takes place. It is, of course, impossible to say how the mixture may have been prepared to show such different results.

The prescription, No. 353, contains pulv. phosphori, and from the dose being the same as that of the strych. sulph., it may be presumed that the amorphous variety was not intended. The combination is not suitable for retaining phosphorus in an unoxidized condition; however, it should be dissolved in a little bisulphide of carbon before being mixed with the other ingredients. and then probably the best excipient will be the glycerine of tragacanth. With regard to the price, that must be left to individual judgment, its discussion is not suited for these columns. A paper on the subject of prices charged for dispensed medicines, by the late Daniel Hanbury, will be found among 'Science Papers' (p. 453), and may be read with advantage.

The mixture, No. 354, will become turbid soon after being mixed, and there will be a considerable amount of deposit on standing.

The powder, No. 355, becomes moist, due to the water of crystallization of the sodæ phosphas. A better result would ensue if the phosphate of soda be deprived of a part of the water before being mixed with the potass. citrat.; but as written it will not retain its condition as a powder, and is not an elegant combination.

The ingredients of recipe No. 356, with the exception of the oil of aniseed, can be very well combined as a powder if each be in a dry condition, but the addition of the oil of aniseed makes the mass too soft. It is a piece of veterinary practice, and probably oil of aniseed quan. suff. would be more suitable to form the other ingredients into a manageable mass.

The prescription, No. 357, becomes difficult from the remark of the writer "when the mixture has become quite clear." The digestion of the ingredients at the temperature indicated will result in a curdling of the milk, and subsequent deposit of the clot, but the supernatant liquid will not be clear except in comparison with the milk. It is probable that this is the condition it is intended the mixture should be in when adapted for neutralization by bicarbonate of soda.

The quinine mixture with ammonia, No. 358, is in principle similar to others which have been previously commented on, so that "Quiniæ Sulph." must be referred to those. Mucilage should be used as there indicated, to retain the quinine in suspension.

The mixture of ol. olivæ with ext. of belladonna, as in No. 359, may be satisfactorily made by rubbing the ext. bellad. with a little water, on a warm slab, to a smooth paste, gradually adding the oil. If care be taken to reduce the extract with a suitable quantity of water, an elegant ointment may be made from this prescription, but lin. bellad. should not have been used.

The carbolic acid, No. 360, should be used in a crystalline state, and then there will be little or no difficulty experienced in making the pills. Reference may be made to carbolic acid in pills commented on quite recently.

In the lotion, No. 361, aq. calc. and ol. olivæ in equal proportions emulsify very satisfactorily, but if other water, or even more liquor calcis be added, there is a separation of some of the partially saponified oil, though on standing this is absorbed. Mr. Cairnie's process, in this week's Journal, is probably the best that can be adopted.

The prescription, No. 362, it is presumed, was intended to be dispensed just as written:—2 parts by weight, acid. muriatic conc. with 18 parts tr. aurantii, 10–15 minims for a dose; the subsequent figures most probably bear reference to the date of the prescription.

It is difficult to account for a change of colour in the mixture, No. 363; there is no reason why there should be one. Such a mixture may be dispensed with great uniformity of result. The decomposition alluded to can only be referred to impure iodide of potassium or careless dispensing.

The second ingredient in No. 364 is evidently intended for glycerine; but there would seem to have been some little confusion in the mind of the writer between the Latin of glycerine and that of liquorice.

In reviewing the prescriptions referred to in this "Month," it can scarcely be said that the inquiries are not fair and reasonable, and it will be observed that most of them owe their origin to errors or incompatibles on the part of the writers of the several prescriptions.

THE GLUCOSIDE OF LIQUORICE.*

BY F. SESTINI.

An aqueous extract of the root, on being evaporated to dryness after treatment with animal charcoal, yields a product from which absolute alcohol extracts asparagine. The residue dissolves in dilute spirit, and when burnt leaves an ash containing lime, alkalies, and a trace of sulphuric acid. From these results, it is evident that glycyrrhizin does not exist in the root in the free state, but in combination with bases, chiefly lime. An examination of the commercial extract, or "liquorice," shows that it contains free glycyrrhizin in small quantity, liberated, apparently, from its combination by the acids formed during the evaporation of the juice. Roussin (*Jour. Pharm.*, 1875) imagined that the glycyrrhizin existed in the root as an ammonium compound containing 0·14 per cent. nitrogen; but, as the author points out, the method by which he obtained this compound (precipitating the glucoside with sulphuric acid, and treating it first with alcohol and ether, and then with an alcoholic solution of ammonia), affords no evidence that it existed in the root as such, and moreover it is not very probable that the substance obtained by Roussin is a definite compound, as it would contain 26 or 27 molecules of glycyrrhizin to one of ammonia.

The glucoside dissolves in dilute potash solution, and is precipitated again unaltered by acids, but the potassium compound formed could not be isolated. Better success attended the attempts to prepare the calcium and barium compounds. *Calcium glycyrrhizate*, prepared by adding calcium chloride to a solution of the glucoside in the smallest excess of potash, washing the precipitate with water, and drying at 100°, forms a brown shining mass. By dissolving glycyrrhizin in milk of lime, filtering, separating the excess of lime by carbonic acid, and evaporating, a residue is obtained, which when treated with alcohol of 50 per cent. and evaporated, yields the glycyrrhizate in amorphous yellowish scales. This glycyrrhizate is hygroscopic, and has a sweet taste: it is almost insoluble in dry alcohol, but dissolves tolerably well in dilute alcohol.

It is only sparingly soluble in water, but more readily in presence of calcium hydrate, which points to the existence of a basic compound.

Dried at 110° and analysed, it gave numbers corresponding with the formula $3CaO + 5C_{24}H_{36}O_9$, adopting Gorup-Besanez' formula, $C_{25}H_{36}O_9$, for glycyrrhizin.

Barium glycyrrhizate, $3BaO + 5C_{24}H_{36}O_9$, obtained in a manner similar to the calcium compound by dissolving glycyrrhizin in baryta water, passing carbonic anhydride, and evaporating, forms yellowish scales. All the compounds of glycyrrhizin with bases have a sweet taste; glycyrrhizin itself when first placed on the tongue is insipid, but as it dissolves in the alkaline saliva, it acquires a sweet taste.

The ordinary method of preparing glycyrrhizin by exhausting the root with water and precipitating with sulphuric acid, gives very unsatisfactory results, as the product is small and highly coloured, and there is great difficulty in separating the adherent sulphuric acid. The author prefers to exhaust the root four or five times successively with boiling water and a little milk of lime, and to precipitate the concentrated extract with acetic acid. The brownish gelatinous precipitate, after being washed with water is dissolved in spirit of 50 per cent., decolorized by animal charcoal, and evaporated on the water-bath until the alcohol is expelled. On cooling, it solidifies to a gelatinous mass, which is dissolved in alcohol, mixed with twice its volume of ether, filtered and evaporated. The gelatinous glycyrrhizin is then pressed and dried over sulphuric acid. The author regards the crystalline substance obtained by Habermann (*Pharm. Journ.*, before, p. 46) as an alteration product.

In order to determine the amount of glycyrrhizin in the root, it is extracted eight times successively with boiling water rendered alkaline by calcium hydrate, and the solution concentrated to a syrup is precipitated with 10 per cent. acetic acid, which has been previously saturated with glycyrrhizin, as is also the dilute acid (2 per cent.), and water used for washing. The precipitated glycyrrhizin is then dissolved in alcohol, and the solution evaporated after treatment with animal charcoal. In this way the fresh root containing 48 per cent. water yields 3·271 per cent. glycyrrhizin, or 6·318 on the dry root.

ESSENCE OF ROSEMARY.*

BY M. BRUYLANTS.

The quantity of the essential oil yielded by the plant *Rosmarinus officinalis* depends on the latitude in which it is grown; that from the neighbourhood of Paris yielding only 1·4 to 1·6 grams per kilo., whilst that grown in the south of France yields 3 grams per kilo. When freshly prepared, it is a colourless liquid, but on keeping it darkens in colour and becomes thick; it is miscible in all proportions with alcohol of 85 per cent. It smells strongly of rosemary, its taste is hot and camphorous; sp. gr. at 12° is 0·885; it turns the plane of polarization to the left. It begins to boil at 150°, and the temperature gradually rises to 200°, where it remains stationary a short time, and finally rises to 260°. By fractional distillation, it may be separated into three portions, boiling from 150° to 180°, from 180° to 210°, and from 210° to 260°.

Fraction boiling between 150° *and* 180°.—By repeated distillation and rectification over sodium, a liquid is obtained boiling at 157—160°, which is lævogyrate. Its vapour-density corresponds with the formula for terpene, $C_{10}H_{16}$. This terpene combines with iodine, and on distilling the product, it decomposes into hydriodic acid and cymene, $C_{10}H_{14}$; by the action of nitric acid, it yields γ-toluic acid.

Fraction boiling between 180° *and* 210°.—By careful distillation, a liquid boiling at 200—205° is obtained, which on cooling deposits crystals melting at 176°, and boiling at 204°. They possess all the properties of laurel camphor. The mother liquor boils at a lower temperature, and on distillation yields a second crop of crystals and some terebene. Repeated distillation results in the complete separation of these two bodies.

Fraction boiling between 210° *and* 260°.—By cooling this fraction in a freezing mixture, a large quantity of borneol is separated, which when treated with phosphoric anhydride, yields a hydrocarbon of boiling point 160°, and having the vapour density 5·23 (Air = 1). This when treated with iodine, yields cymene and hydriodic acid. Amongst the products of the action of nitric acid are borneol, and a crystalline body which melts at the same temperature as camphor.

When distilled with acetic anhydride, the borneol yields a product boiling at 230°, which is decomposed by potash, with formation of a hydrocarbon, $C_{10}H_{16}$, and potassium acetate.

Essence of rosemary therefore contains—

A hydrocarbon (lævogyrate), $C_{10}H_{16}$	80 per cent.
A borneol camphor, $C_{10}H_{18}O$	4 to 5 „
A camphor, $C_{10}H_{16}O$	6 to 8 „

When acted on by concentrated sulphuric acid, essence of rosemary yields a mixture of cymene (b. p. 175°), and terpene (b. p. 16°), and on oxidation with chromic mixture, it yields a small quantity of camphor, some formic and acetic acids, and terephthalic acid.

The author gives no analysis.

RADIANT MATTER.*

BY WILLIAM CROOKES, F.R.S.

(*Continued from page* 290.)

Radiant Matter proceeds in Straight Lines.

The Radiant Matter whose impact on the glass causes an evolution of light, absolutely refuses to turn a corner. Here is a V-shaped tube (Fig. 6), a pole being at each

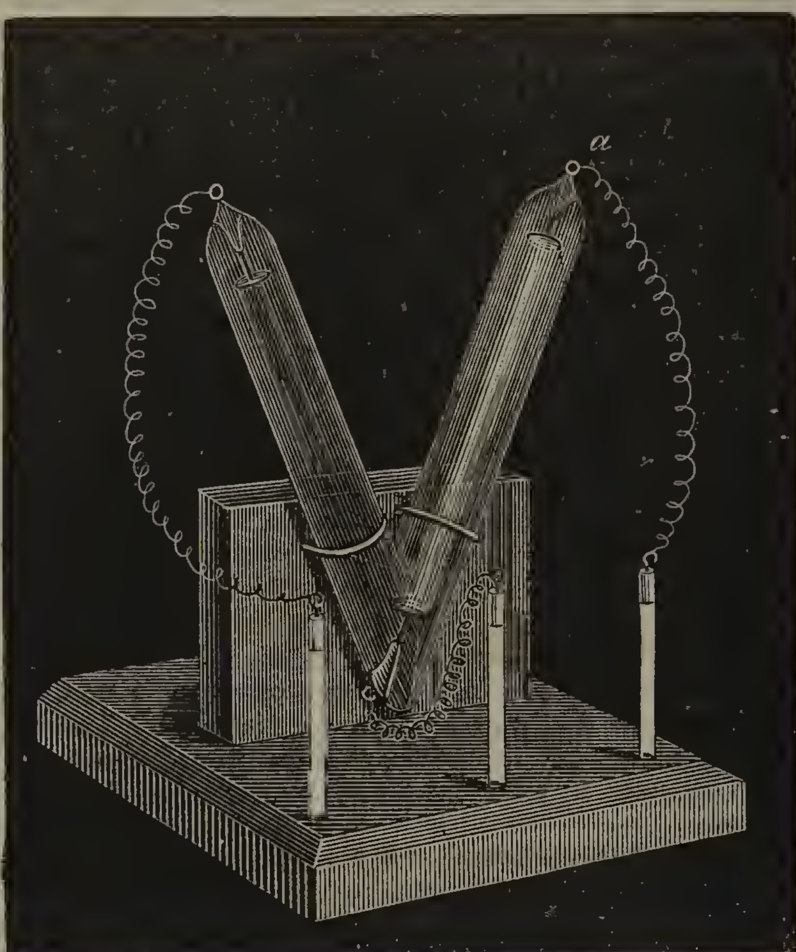

Fig. 6.

extremity. The pole at the right side (a) being negative, you see that the whole of the right arm is flooded with green light, but at the bottom it stops sharply and will not turn the corner to get into the left side. When I reverse the current and make the left pole negative, the green changes to the left side, always following the negative pole and leaving the positive side with scarcely any luminosity.

In the ordinary phenomena exhibited by vacuum tubes—phenomena with which we are all familiar—it is customary, in order to bring out the striking contrasts of colour, to bend the tubes into very elaborate designs. The luminosity caused by the phosphorescence of the residual gas follows all the convolutions into which skilful glassblowers can manage to twist the glass. The negative pole being at one end and the positive pole at the other, the luminous phenomena seem to depend more on the positive than on the negative at the ordinary exhaustion hitherto used to get the best phenomena of vacuum tubes. But at a very high exhaustion the phenomena noticed in ordinary vacuum tubes when the induction spark passes through them—an appearance of cloudy luminosity and of stratifications—disappear entirely. No cloud or fog whatever is seen in the body of the tube, and with such a vacuum as I am working with in these experiments, the only light observed is that from the phosphorescent surface of the glass. I have here two bulbs (Fig. 7), alike in shape and position of poles, the only difference being that one is at an exhaustion equal to a few millimetres of mercury—such a moderate exhaustion as will give the ordinary luminous phenomena—whilst the other is exhausted to about the millionth of an atmosphere. I will first connect the moderately exhausted bulb (A) with the induction-coil, and retaining the pole at one side (a) always negative, I will put the positive wire successively to the other poles with which the bulb is furnished. You see that as I change the position of the positive pole, the line of violet light joining the two poles changes, the electric current always choosing the shortest path between the two poles, and moving about the bulb as I alter the position of the wires.

This, then, is the kind of phenomenon we get in ordinary exhaustions. I will now try the same experiment with a bulb (B) that is very highly exhausted, and as before, will make the side pole (a') the negative, the top pole (b) being positive. Notice how widely different is the appearance from that shown by the last bulb. The negative pole is in the form of a shallow cup. The molecular rays from the cup cross in the centre of the bulb, and thence diverging fall on the opposite side and produce a circular patch of green phosphorescent light. As I turn the bulb round you will all be able to see the green patch on the glass. Now observe, I remove the positive wire from the top, and connect it with the side pole (c). The green patch from the divergent negative focus is there still. I now make the lowest pole (d) positive, and the green patch remains where it was at first, unchanged in position or intensity.

We have here another property of Radiant Matter. In the low vacuum the position of the positive pole is of every importance, whilst in a high vacuum the position

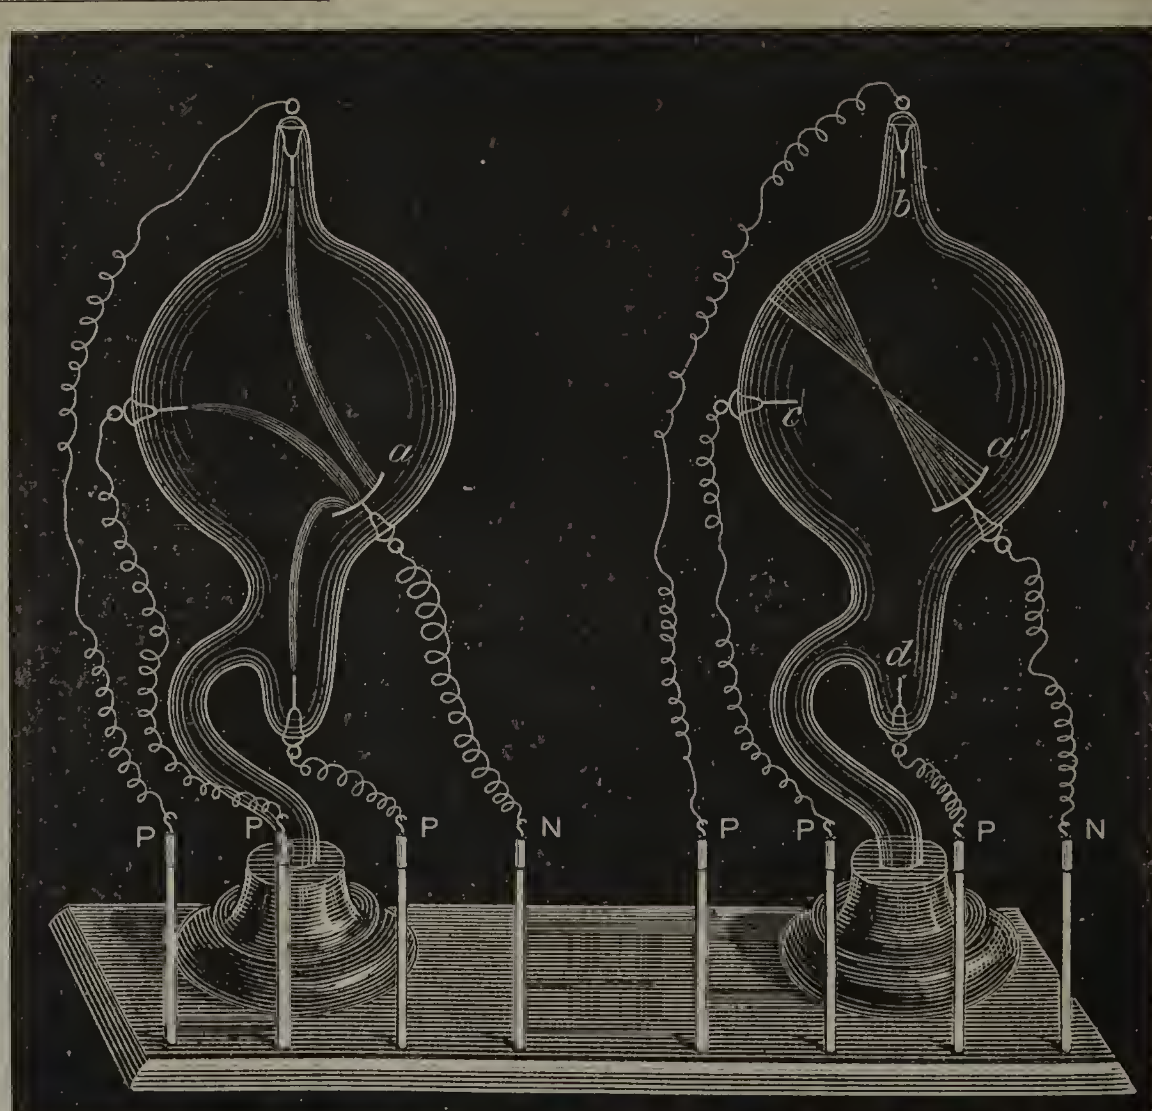

Fig. 7.

* A lecture delivered to the British Association for the Advancement of Science, at Sheffield, Friday, August 22, 1879.

of the positive pole scarcely matters at all; the phenomena seem to depend entirely on the negative pole. If the negative pole points in the direction of the positive, all very well, but if the negative pole is entirely in the opposite direction it is of little consequence: the Radiant Matter darts all the same in a straight line from the negative.

If, instead of a flat disk, a hemi-cylinder is used for the negative pole, the Matter still radiates normal to its surface. The tube before you (Fig. 8) illustrates this property. It contains, as a negative pole, a hemi-cylinder (*a*) of polished aluminium. This is connected

Fig. 8.

with a fine copper wire (*b*), ending at the platinum terminal (*c*). At the upper end of the tube is another terminal (*d*). The induction-coil is connected so that the hemi-cylinder is negative and the upper pole positive, and when exhausted to a sufficient extent the projection of the molecular rays to a focus is very beautifully shown. The rays of Matter being driven from the hemi-cylinder in a direction normal to its surface, come to a focus and then diverge, tracing their path in brilliant green phosphorescence on the surface of the glass.

Instead of receiving the molecular rays on the glass, I will show you another tube in which the focus falls on a phosphorescent screen. See how brilliantly the lines of discharge shine out, and how intensely the focal point is illuminated, lighting up the table.

Radiant Matter when intercepted by Solid Matter casts a Shadow.

Radiant Matter comes from the pole in straight lines, and does not merely permeate all parts of the tube and fill it with light, as would be the case were the exhaustion less good. Where there is nothing in the way the rays strike the screen and produce phosphorescence, and where solid matter intervenes they are obstructed by it, and a shadow is thrown on the screen. In this pear-shaped bulb (Fig. 9) the negative pole (*a*) is at the pointed end. In the middle is a cross (*b*) cut out of sheet aluminium, so that the rays from the negative pole projected along the tube will be partly intercepted by the aluminium cross, and will project an image of it on the hemispherical end of the tube which is phosphorescent. I turn on the coil, and you will all see the black shadow of the cross on the luminous end of the bulb (*c*, *d*). Now, the Radiant Matter from the negative pole has been passing by the side of the aluminium cross to produce the shadow; the glass has been hammered and bombarded till it is appreciably warm, and at the same time another effect has been produced on the glass—its sensibility has been deadened. The glass has got tired, if I may use the expression, by the enforced phosphorescence. A change has been produced by this molecular bombardment which will prevent the glass from responding easily to additional excitement; but the part that the shadow has fallen on is not tired—it has not been phosphorescing at all and is perfectly fresh; therefore if I throw down this cross — I can easily do so by giving the apparatus a slight jerk, for it has been most ingeniously constructed with a hinge by Mr. Gimingham—and so allow the rays from the negative pole to fall uninterruptedly on to the end of the bulb, you will suddenly see the black cross (*c*, *d*, Fig. 10) change to a luminous one (*e*, *f*), because the background is now only capable of faintly phosphorescing, whilst the part which had the black shadow on it retains its full phosphorescent power. The stencilled image of the luminous cross unfortunately soon dies out. After a period of rest the glass partly recovers its power of phosphorescing, but it is never so good as it was at first.

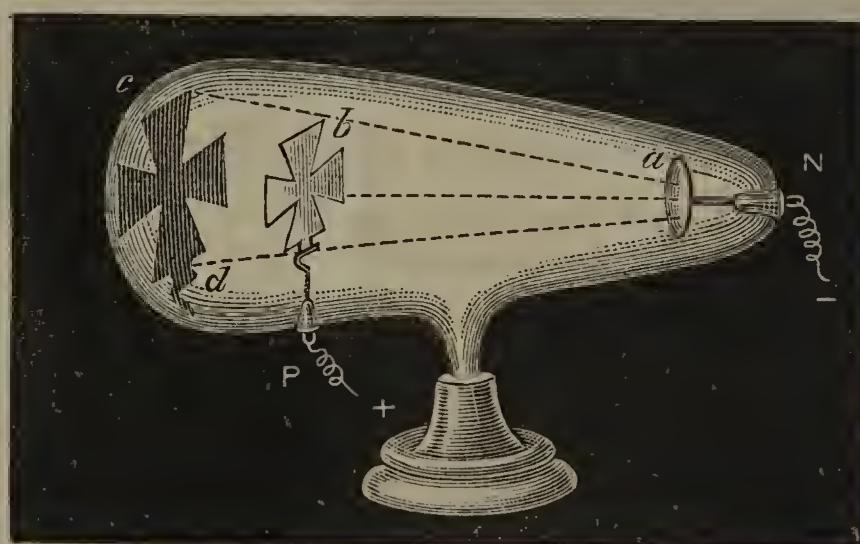

Fig. 9.

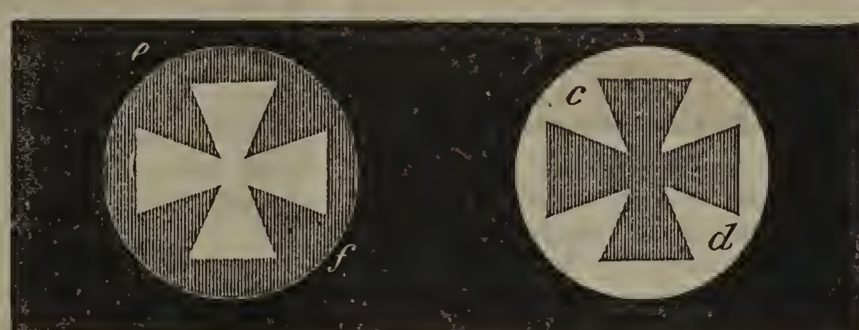

Fig. 10.

Here, therefore, is another important property of Radiant Matter. It is projected with great velocity from the negative pole, and not only strikes the glass in such a way as to cause it to vibrate and become temporarily luminous while the discharge is going on, but the molecules hammer away with sufficient energy to produce a permanent impression upon the glass.

Radiant Matter exerts strong Mechanical Action where it strikes.

We have seen, from the sharpness of the molecular shadows, that Radiant Matter is arrested by solid matter placed in its path. If this solid body is easily moved the impact of the molecules will reveal itself in strong mechanical action. Mr. Gimingham has constructed for me an ingenious piece of apparatus which, when placed in the electric lantern, will render this mechanical action visible to all present. It consists of a highly-exhausted glass tube (Fig. 11), having a little glass railway running along it from one end to the other. The axle of a small wheel revolves on the rails, the spokes of the wheel carrying wide mica paddles. At each end of the tube, and rather above the centre, is an aluminium pole, so that whichever pole is made negative the stream of radiant matter darts from it along the tube, and striking the upper vanes of the little paddle-wheel causes it to turn round and travel along the railway. By reversing the poles I can arrest the wheel and send it the reverse way, and if I gently incline the

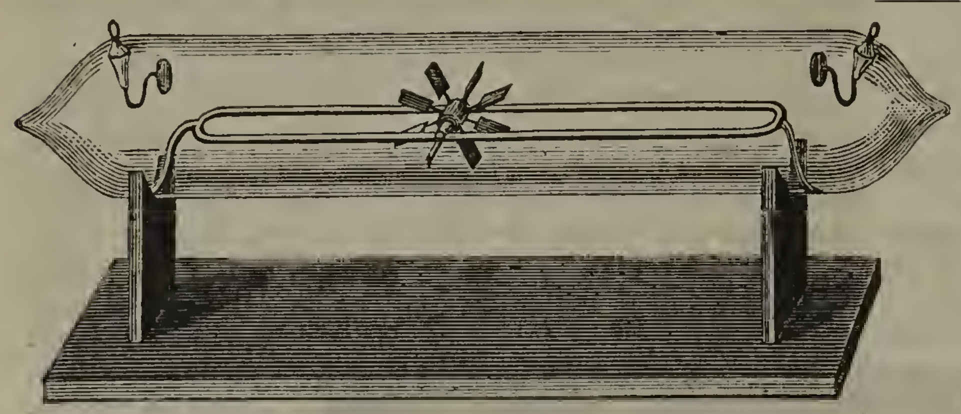

Fig. 11.

tube the force of impact is observed to be sufficient even to drive the wheel up-hill.

This experiment therefore shows that the molecular stream from the negative pole is able to move any light object in front of it.

The molecules being driven violently from the pole there should be a recoil of the pole from the molecules, and by arranging an apparatus so as to have the negative pole movable and the body receiving the impact of the Radiant Matter fixed, this recoil can be rendered sensible. In appearance the apparatus (Fig. 12) is not unlike an ordinary radiometer with aluminium disks for vanes, each disk coated on one side with a film of mica. The fly is supported by a hard steel instead of glass cup, and the needle point on which it works is connected by means of a wire with a platinum terminal sealed into the glass. At the top of the radiometer bulb a second terminal is sealed in. The radiometer therefore can be connected with an induction-coil, the movable fly being made the negative pole.

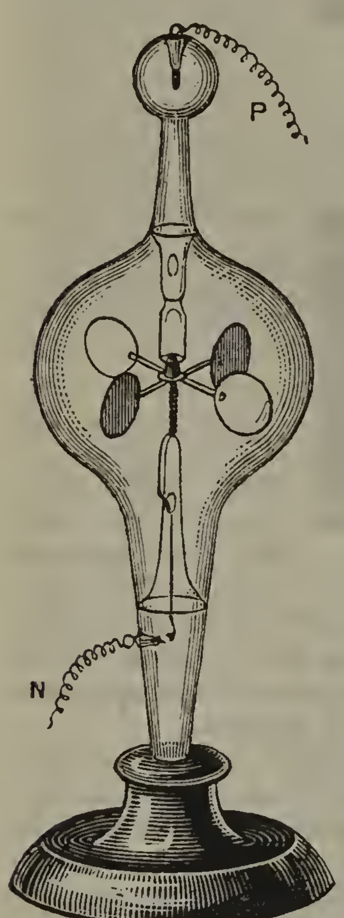

Fig. 12.

For these mechanical effects the exhaustion need not be so high as when phosphorescence is produced. The best pressure for this electrical radiometer is a little beyond that at which the dark space round the negative pole extends to the sides of the glass bulb. When the pressure is only a few millims. of mercury, on passing the induction current a halo of velvety violet light forms on the metallic side of the vanes, the mica side remaining dark. As the pressure diminishes, a dark space is seen to separate the violet halo from the metal. At a pressure of half a millim. this dark space extends to the glass, and rotation commences. On continuing the exhaustion the dark space further widens out and appears to flatten itself against the glass, when the rotation becomes very rapid.

Here is another piece of apparatus (Fig. 13) which illustrates the mechanical force of the Radiant Matter from the negative pole. A stem (*a*) carries a needle-point in which revolves a light mica fly (*b b*). The fly consists of four square vanes of thin clear mica, supported on light aluminium arms, and in the centre is a small glass cap which rests on the needle-point. The vanes are inclined at an angle of 45° to the horizontal plane. Below the fly is a ring of fine platinum wire (*c c*), the ends of which pass through the glass at *d d*. An aluminium terminal (*e*) is sealed in at the top of the tube, and the whole is exhausted to a very high point.

By means of the electric lantern I project an image of the vanes on the screen. Wires from the induction-coil are attached, so that the platinum ring is made the negative pole, the aluminium wire (*e*) being positive. Instantly, owing to the projection of Radiant Matter from the platinum ring, the vanes rotate with extreme velocity. Thus far the apparatus has shown nothing more than the previous experiments have prepared us to expect; but observe what now happens. I disconnect the induction-coil altogether, and connect the two ends of the platinum wire with a small galvanic battery; this makes the ring red-hot, and under this influence you see that the vanes spin as fast as they did when the induction-coil was at work.

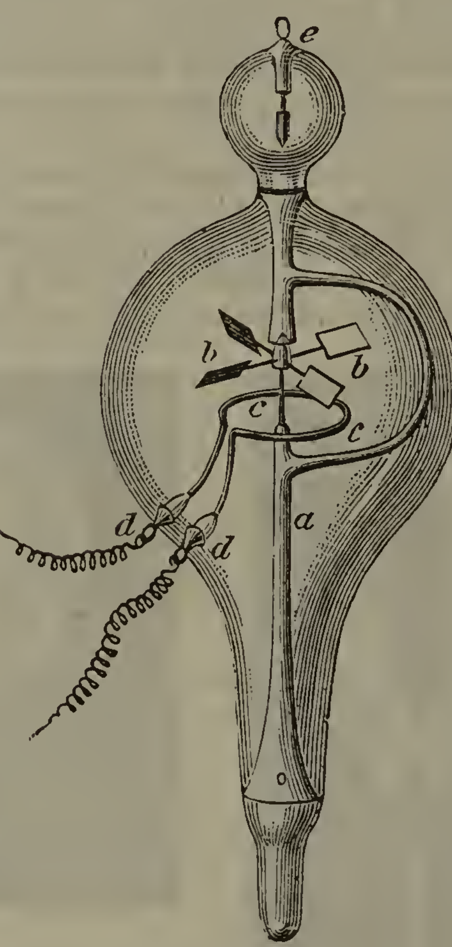

Fig. 13.

Here, then, is another most important fact. Radiant Matter in these high vacua is not only excited by the negative pole of an induction-coil, but a hot wire will set it in motion with force sufficient to drive round the sloping vanes.

(*To be continued.*)

EXTRACT OF YLANG YLANG.

True.

Extract of jasmine	8 ounces.
,, rose	16 ,,
Tincture of orris root	8 ,,
,, civet	4 ,,
Oil of ylang ylang	4 drachms.
Alcohol	2 pints.

Artificial.

Tincture of tonka beans . . .	3 ounces.
,, musk	4 ,,
Extract of tuberose	4 ,,
,, cassia	4 ,,
Tincture of orris root	8 ,,
Oil of orange (fresh)	2 drachms.
Neroli	½ drachm.
Alcohol, sufficient to make . .	4 pints.

Can. Ph. Journ.

A BRILLIANT PURPLE FOR SHOW BOTTLES.

Sulphate of copper	2 drachms.
Water	2 ounces.
French gelatine	1 drachm.
Boiling water	2 ounces.
Solution of potassa	2 pints.

Dissolve the copper salt in the water and the gelatine in the boiling water. Mix the two solutions and add the liquor of potassa. Shake the mixture a few times during ten hours, after which decant and dilute with water.

THE APPLICATION OF THE FOOD AND DRUGS ACT IN NEW DIRECTIONS.

WE have so often had occasion to complain of the vexatious manner in which the Sale of Food and Drugs Act has been had recourse to as a means of instituting frivolous prosecutions that it is with much satisfaction we are enabled to speak of some recent cases with approval, and also to express the opinion that if the line of action taken in those cases is followed up, some real service may be done in the public interest as well as in the furtherance of the objects contemplated by the Pharmacy Act.

Reports of the cases we now refer to will be found in the present number of the Journal at page 336. In one of these cases a person described as a druggist, of 229, Stirling Road, Glasgow, was charged with having sold to the food inspector of the district a quantity of powders—purporting to be dispensed according to the prescription of a medical practitioner in Glasgow—that were not what was ordered by the prescriber.

In the first place, we may state that the person against whom the prosecution was instituted is not upon the Register of Chemists and Druggists of Great Britain, and that he is therefore presumably as unqualified to dispense the prescriptions of medical men as he is disentitled to use the designation of druggist. That such was the case may be inferred from the manner in which the powders were prepared on account of which he has been charged with a breach of the Food and Drugs Act. The prescription ordered salicylate of soda 5 grains and pulv. ipecac. co. 6 grains, with the direction in Latin that eight such powders should be supplied. The person dispensing the prescription does not appear to have been acquainted with the usual mode of writing such directions and consequently to have divided the quantities of the ingredients ordered into eight parts, so that each of the powders was deficient in quantity to the extent of seven eighths.

It is unnecessary to comment upon the nature of this proceeding from a pharmaceutical point of view, but having regard to the provisions of the 7th section of the Sale of Food and Drugs Act, that no person shall sell any compounded drug which is not composed of ingredients in accordance with the demand of the purchaser, there seems to be no question that it involved a breach of the law, and that it rendered the seller of the powders liable to the penalty of £20 imposed by the 7th section of the Food and Drugs Act.

It appears that there was no attempt at defence, and that the defendant at once pleaded guilty, and thereupon a fine of £5 was imposed by the sheriff, who remarked that though he was satisfied there was no fraudulent intention, the powder had evidently been dispensed by a person ignorant of the medical formulæ used in prescriptions.

The further offence of improperly using the designation "druggist" is one to be dealt with under the Pharmacy Act. As this proceeding is under some pretext or other common in Glasgow this case will probably receive further notice.

The other two cases were both prosecutions of grocers in Derbyshire, for the sale of an adulterated drug as it was technically stated, the article referred to being "paregoric," that was not of the quality demanded, inasmuch as it was found on analysis to be devoid of opium, the most important ingredient of that preparation. An attempt was made to defend both cases on the ground that "paregoric" was a preparation that had no place in the British Pharmacopœia, and consequently that there was no standard by which its composition should be judged of. Hence it was contended that the Court had no power to deal with the cases under the Food and Drugs Act for the deficiency, while at the same time the absence of opium from the preparation sold as "paregoric" protected the seller from liability to a penalty under the Pharmacy Act, 1868. The untenable nature of this defence is too apparent to require argument, and we cannot avoid expressing our deep regret at finding from the statements made that such a defence should, as it appears, have been suggested by members of the pharmaceutical body, and that such irregular sales of medicinal preparations should have been in any way encouraged by them.

Whether the term "paregoric" has a place in the British Pharmacopœia or not seems to be, in our opinion, a matter of very little importance, since it is so familiarly known as being a popular synonym for the preparation that is in the Pharmacopœia, and just as we should contend that a person asking for "milk of sulphur" should be supplied with the preparation that name is most frequently understood to represent, so we should contend that any person asking for "paregoric" ought to be supplied with a preparation containing opium. It may be that as there is now no recognition of the term "paregoric" in the British Pharmacopœia the preparation of that article may be carried out according to various private formulæ, but still in its general character it ought to conform closely to the standard of strength as a mild opiate that appertains to the Pharmacopœia preparation which it represents.

We think, therefore, the magistrates exercised a very wise discretion in rejecting the defence offered and holding that persons who sold "paregoric" should sell what was properly to be understood by that name, and nothing else which they or the persons who supply them may imagine to answer the purposes of trade without incurring the penalties resulting from infringement of the Pharmacy Act. But we cannot go the length of agreeing with the magistrates' suggestion that if the Pharmacy Act does not permit unregistered persons to sell "paregoric" with opium in it, they should sell an article under that name without opium in it, even under the condition of putting upon the bottle a label stating that it is "minus the opium." Such a proceeding would be, we think, very objectionable and we should have laudanum without opium, and perhaps other potent preparations sold without the ingredient to which their medicinal as well as poisonous energy is due, and the confusion thus created between the preparations that possessed their proper character and those that did so only in name might readily lead to the most disastrous consequences.

There has been lately much dissatisfaction among members of the drug trade because of the irregular sales of medicines and drugs by grocers and other small dealers in country places, and we have reason to believe that there is too much probability that in some cases such a trade is promoted by individuals without due regard for the general interests of the body to which they belong. Whether that trade be carried on so as to constitute a punishable breach of the Pharmacy Act, or under the belief that it can be done with impunity by making use of the patent medicine stamp, or, worse still, by selling to the public articles which have no virtue beyond assuming the names of the preparations they are pretended to be, it is certainly time that some vigorous and united action should be taken by those who have the common welfare of the business at heart with the object of putting an end to practices so detrimental to the credit of pharmacy.

We regret to have to record the death, on the 16th inst., of Dr. Arthur Leared, Senior Physician of the Great Northern Hospital. It appears that only a few days previously he returned home unwell from a holiday tour, having contracted typhoid fever in Portugal. Dr. Leared on more than one occasion showed his interest in the Pharmaceutical Society by taking part in its Evening Meetings, and he also contributed an interesting collection of Morocco drugs to the Society's Museum.

The death is also announced of Mr. Alfred Henry Garrod, Fullerian Professor of Physiology at the Royal Institution, at the early age of 30 years. The deceased was a son of Dr. Alfred Baring Garrod, and had already attained a considerable prominence in the scientific world.

Transactions of the Pharmaceutical Society.

PRELIMINARY EXAMINATION.

At a meeting of the Board of Examiners for England and Wales, held in London, on Wednesday, October 22nd, 1879, the report of the College of Preceptors on the examination held on October 7th, was received.

Three hundred and eighty-seven candidates had presented themselves for examination, of whom *one hundred and eighty-three* had failed. The following *two hundred and four* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

(Arranged alphabetically).

Abbott, Thomas Henry	Bradford.
Akerman, John William	Bath.
Allan, Alexander Fergusson	Greenock.
Allan, Charles Joseph	Tadcaster.

The questions for examination were as follows:—

Time allowed: Three hours for the three subjects.

I. LATIN.

1. Translate the following passages into English:—

A. Quibus rebus cognitis, cum ad has suspiciones certissimæ res accederent, quod per fines Sequanorum Helvetios *traduxisset*, quod obsides inter eos *dandos* curasset, quod ea omnia non modo injussu suo et civitatis, sed etiam inscientibus ipsis *fecisset*, quod a magistratu Hæduorum accusaretur, satis esse causæ *arbitrabatur*, quare in eum aut ipse animadverteret, aut civitatem animadvertere *juberet*.

B. Hæc cum pluribus verbis *flens* a Cæsare peteret, Cæsar ejus dextram *prendit*; consolatus rogat finem orandi faciat; tanti ejus apud se gratiam esse ostendit, uti et rei publicæ injuriam et suum dolorem ejus voluntati ac precibus condonet. Dumnorigem ad se vocat, fratrem adhibet; quæ in eo reprehendat ostendit, quæ ipse intelligat, quæ civitas *queratur*, proponit; monet, ut in reliquum tempus omnes suspiciones *vitet*; præterita se Divitiaco fratri condonare *dicit*.

2. Give the present, perfect, and infinitive of the verbs in italics.

3. Parse *either* "*non modo injussu suo et civitatis*," *or* "*consolatus rogat finem orandi faciat*."

4. Compare *certus*, and give three adverbs formed from the superlative degree of adjectives. Decline *obsides*.

5. Decline, singular and plural, the pronouns *ego*, *tu*, *ille*, *qui*.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

6. Of twenty-one people, thirteen lose £116 7*s*. 8*d*. each, and eight lose £93 0*s*. 9*d*. each. What is the average loss per man.

7. Find the weight of 5 dozen spoons, each weighing 2 oz. 4 dwt.

8. Multiply $3\frac{3}{20}$ by $15\frac{5}{7}$, and divide $\frac{2}{3\frac{3}{4}}$ by $\frac{2\frac{3}{4}}{3}$; and add together the sum and difference of these results.

9. What do the digits 5, 7, 3 represent in the decimal ·573? Reduce $\frac{6}{7}$ of £1 + $\frac{3}{8}$ of a guinea + $\frac{3}{560}$ of 6*s*. 8*d*. + $\frac{1}{14}$ of half-a-crown, to the decimal of £100.

10. How long will it take 17 men to earn £50, if 12 men in $6\frac{1}{2}$ days can earn 13 guineas?

III. ENGLISH.

11. Decline in full the pronouns *I*, *thou*, *he*; and give their corresponding possessive forms.

12. Explain what is meant by *weak* and *strong* verbs; give one example of each. Show, by example, how intransitive verbs may become transitive.

13. Parse fully each word in the following sentence:—

"She never told her love;
But let concealment, like a worm i' the bud,
Feed on her damask cheek."

14. Write a short composition upon *one* of the following subjects:—"Knowledge is Power," "The Zulu War," "Thrift," "The advantages of Travelling," "Some modern invention with which you are acquainted."

The following is a list of the centres at which the examination was held, showing the number of candidates examined at each centre and the result:—

	Candidates. Examined.	Passed.	Failed.		Candidates. Examined.	Passed.	Failed.
Aberdeen	26	5	21	Lancaster	8	5	3
Birmingham	23	9	14	Leeds	23	12	11
Brighton	4	2	2	Lincoln	15	10	5
Bristol	17	7	10	Liverpool	7	4	3
Cambridge	2	2	0	London	54	26	28
Canterbury	3	1	2	Manchester	26	12	14
Cardiff	6	6	0	Newcastle	8	4	4

Inverness	4	3	1	York	7	4	3
Jersey	1	0	1				

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, October 1, 1879.

Present—Charles R. C. Tichborne, LL.D., Ph.D., President; Dr. A. Smith, Vice-President; Sir George Owens, M.D., Dr. T. Collins, Dr. Whitaker (Belfast), Messrs. Allen, Bennett (Kingstown), Brunker, Doran (Bray), Goodwin, Hayes, Hodgson, Holmes, Oldham, Payne (Belfast), Pring (Belfast), Simpson.

The minutes of the meeting held on September 3 were read and signed.

A letter was read from the Secretary of the Société de Pharmacie de Constantinople, informing the Council of the formation of that Society, and requesting the aid of the Council in carrying out the work which it had undertaken. A copy of the first number of the Society's Journal accompanied the letter.

The Registrar was instructed to acknowledge with thanks the receipt of the letter and Journal, to forward in return a copy of the Calendar, and to state that this Society would lend any aid that might be in its power towards furthering the aims of the new Society.

Read a letter from Mr. Robert Barklie, F.C.S., Chemical Teacher in the Belfast Working Men's Institute, renewing the application made by him in March last that the Council should recognize the instruction in practical chemistry given in the Institute by him.

Resolved that Mr. Barklie's letter be considered at next meeting.

Read a letter from Mr. William Dowling, of Killarney, praying the Council to recognize the Preliminary examination of the Apothecaries' Hall, which he had passed in 1876.

The Registrar to write, informing him that there is a notice of motion upon this subject to be considered at the next meeting.

Read a letter from Mr. William Prott, of Belfast, asking, as a pharmaceutical chemist and member of the Pharmaceutical Society of Great Britain since 1852, that he be allowed to go forward to both the Preliminary and Practical examinations now, or be admitted to such special examination as the Council may deem necessary. The writer stated that it was his intention to commence business as a chemist in Belfast.

The Registrar to send him a copy of the same reply as he had been instructed to send Mr. Dowling.

Proposed by Mr. Oldham, seconded by Mr. Goodwin, and resolved—

"That a Hektograph be purchased for the use of the Society."

Proposed by Mr. Hayes, and seconded by Mr. Payne,—

"That this Council is of opinion that after this year it is not desirable to retain the College of Science on the list of Schools from which certificates are received."

The motion was rejected on a division.

The following candidate for membership, who was proposed by the President at the September meeting, and seconded by Mr. Brunker, was now elected a member—

Mr. Thomas Batt, 48, Fontenoy Street, Dublin.

The examination for the licence as pharmaceutical chemists was held on this day, but had not concluded when the Council rose.

There were five candidates for the examination.

ANNUAL MEETING OF THE PHARMACEUTICAL SOCIETY OF IRELAND.

Monday, October 6, 1879.

The fourth annual meeting of this Society was held at the College of Physicians, Dublin, at 4 o'clock p.m., on the above date. The following members attended:—Professor Tichborne, President, in the chair; Dr. A.

Smith, Vice-President. *City members*—Messrs W. N. Allen, jun., Atkinson, Batt, E. J. Boileau, Brunker, Collins, Galwey, Goodwin, Grindley, Hayes, Hodgson, Holmes, Murphy, Oldham, Park, Simpson, James Wells, W. F. Wells, jun., H. Whitby. *Members from the Provinces:*—Dr. Hodges (Belfast), Messrs. Beggs (Dalkey), Bennett (Kingstown), Carter (Naas), Doran (Bray), G. Hardy (Tandragee), R. L. McAdam (Kingstown), Minchin (Athy), Murray (Clones), Sterling (Kilkenny), Vance (Bray).

Mr. W. N. Allen, jun., moved, in accordance with notice sent to the Registrar a few days previously, that the voting papers of all members who had not paid their subscription for the preceding year be rejected, in accordance with rule 8 on page 54 of the Calendar.

The motion was seconded by Mr. Grindley.

The President declined to put the motion—the effect of which, if carried, would be to reject the votes of the original members named in the Pharmacy Act; and he stated his opinion that those members were entitled to record their votes, and that the regulations relating to subscriptions applied to elected members only.

The Vice-President and Dr. Hodges, Belfast, with some others, also held the same opinion.

The President stated that if Mr. Allen, or any other member, thought his ruling was wrong, they could appeal to the Privy Council, and have the question decided for them.

The voting papers which had been returned, 57 in number, were laid on the table, and the President appointed Messrs. Bennett, Goodwin and Minchin, as scrutineers, to count the votes.

The Treasurer laid on the table the annual statement of accounts, audited by Messrs. Allen and Hayes, showing a balance to credit of the Society of £81 0*s.* 4*d.* in Bank, and £307 12*s.* 8*d.* in New 3 per cent. stock.

The annual list of members who had paid their subscriptions for the year ending September 30, 1879, was laid on the table.

On the motion of Mr. Doran, seconded by Mr. Grindley, the statement was received and adopted.

The scrutineers of the voting papers now brought in their report. Fifty-seven voting papers had been returned, of which two had been rejected, one being unsigned, and the other from a member whose subscription was unpaid. The following were the number of votes obtained by each of the candidates for a seat on the Council.

OUTGOING MEMBERS OF COUNCIL.

Aquilla Smith, M.D., 51 votes.
William Goulding, M.P., 34 votes.
John Thomas Holmes, 49 votes.
Sir George B. Owens, Kt., M.D., 43 votes.
Henry Bennett, 45 votes.
John Chilcott Charles Payne, 44 votes.
Henry Whitaker, M.R.C.S.E., 41 votes.

In addition, Mr. William N. Allen, jun., obtained 25 votes, and Mr. William F. Wells, jun., 2 votes. Mr. Wells, however, stated that he was not a candidate for the office.

The President hereupon declared the seven outgoing members of Council to have been re-elected.

The meeting then proceeded to the election of officers for the ensuing year.

Charles R. C. Tichborne, LL.D., Ph.D., was re-elected President, on the motion of Mr. E. M. Hodgson, seconded by Mr. Hayes.

Dr. Aquilla Smith was re-elected Vice-President on the motion of Mr. Holmes, seconded by Mr. Goodwin.

Mr. E. M. Hodgson was re-elected Treasurer, on the motion of Mr. Brunker, seconded by Mr. Murray.

Mr. Hugh James Fennell was re-elected Registrar, on the motion of Mr. Oldham, seconded by Mr. Simpson.

The present Examiners, viz.:—

In Latin, English, and Arithmetic: Edward W. Collins, A.B., M.D., Dublin, M.R.I.A.;

In Materia Medica and Botany: Walter G. Smith M.D., Dubl., F.K, and Q.C.P.I.;

In Pharmaceutical and General Chemistry: Harry Napier Draper, F.C.S.; and

In Practical Pharmacy: Robert Montgomery, L.H.A., Dubl., M.R.C.S., Engl.,

were re-elected for one year, on the motion of Mr. Bennett, seconded by Mr. Doran.

The Finance Committee of last year, viz.:—Messrs. Thomas Collins, John Goodwin, John Thomas Holmes, and Stanley Oldham were re-elected, on the motion of Mr. Simpson, seconded by Mr. Hodgson.

The present Auditors, Mr. William Allen and Mr William Hayes, were re-elected, on the motion of Mr Grindley, seconded by Mr. W. F. Wells, jun.

The meeting then proceeded to the consideration of—'The report of the Committee on the Pharmacy Act, Ireland, 1875, as amended by the Council,' (printed in the *Pharmaceutical Journal* for June 14, 1879, page 1025,) a copy of which had been forwarded to each member of the Society in September, asking their opinions on the various points touched on. A large number of letters from country members in response to this request were laid on the table.

The clauses were now considered *seriatim.*

Clause 1 was agreed to.

Clause 2 was struck out.

Proposed by Mr. Brunker, seconded by Mr. Hodgson, and resolved:—

"That it is desirable that the Pharmaceutical Council should seek powers which will enable them to compel all persons who under section 31 have their right to sell poisons preserved to them, to register their names."

On the motion of Mr. Brunker, seconded by Mr Simpson, Clause 3 was amended to read as follows:—

"To compel all chemists or druggists actually engaged in the sale of poisons, or poisonous drugs, at the passing of the Pharmacy Act, 1875, on making a declaration to that effect, and giving reasonable proof thereof, to be registered on payment of a fee not exceeding three guineas, and that such persons shall be styled 'registered druggists.'"

Clause 4 was struck out, on the motion of Mr. Holmes, seconded by Mr. W. N. Allen, jun.

Proposed by Mr. Murray, seconded by Mr. Beggs, and resolved:—

"That clauses 5 to 9 remain as they are, the words 'and examination' being omitted in Clause 9."

Clause 10 was adopted on the motion of Mr. Brunker, seconded by Mr. Hayes.

Clauses 11 and 12 were adopted, on the motion of Mr. Hayes, seconded by Mr. Sterling.

Additional Clause.

Proposed by Mr. Sterling, seconded by Mr. W. F. Wells, jun., and resolved:—

"That the Council be instructed to insert a Clause to have an examination instituted for assistants to pharmaceutical chemists."

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting held at 32A, George Street, on October 15, 1879, a paper was read by Mr. Parkinson, on the "Preliminary Examination."

Mr. Parkinson began by saying that the subject of education had been discussed so much of late years, that he felt he owed an apology for bringing it forward once more. He conceived its importance justified him in so doing. He should not attempt to grasp the wider phases of the subject, but would confine himself to education as gauged by the Preliminary examination, which he described "as the three R's with a little Latin thrown in." He expressed his surprise that so very modest a standard of accomplishment should have satisfied the framers of the regulations, especially when he considered how very varied a range of duties the pharmacist was called upon to perform. In his opinion no education it was possible for a boy to receive was too elaborate. He drew attention to the preliminary examinations of other bodies, and said the time had come when pharmacists ought seriously to consider whether a higher standard ought not now to replace the present one. The defects of the present standard were the very moderate amount of Latin required and the total absence of Greek and mathematics. He pointed out some of the advantages in education of an acquaintance with those subjects, and said it was a cruel kindness to decoy youths into the trade by so easy an examination, and contended that justice to them was a sufficient reason for raising the standard, though many others might be found. The matriculation examination of the London University was the one that ought to be aimed at, and when, as a start, that was obtained, it might be hoped that pharmacy would assume the higher aspects, which had been so well described by one of pharmacy's ablest sons in another place.

An animated discussion followed, and though the majority of the speakers looked upon the matriculation examination as impracticable at present, a decided preponderance of opinion favoured increasing the stringency of the Preliminary examination.

A vote of thanks to Mr. Parkinson having been proposed and carried, the meeting terminated.

Parliamentary and Law Proceedings.

Prosecution under the Sale of Food and Drugs Act for Improper Dispensing of a Prescripton.

On Thursday, October 16, before Sheriff Spens, Alexander Beaton Chalmers, druggist, 229, Stirling Road, Glasgow, pleaded guilty to a charge, at the instance of the Sanitary Department, of having sold to W. T. Armstrong, food inspector, a quantity of powders prescribed for a patient by Dr. Neil Carmichael, South Portland Street, Glasgow, in which the ingredients were defective in quantity to the extent of seven-eighths in each powder. His Lordship imposed a penalty of £5, and remarked that while he was satisfied there was no fraudulent intention on the part of the defender in dispensing these powders, it was quite clear they were made up by a person in his employment, ignorant of the medical formula, for whom he was responsible.—*Glasgow Herald.*

[We have been supplied by a correspondent with what purports to be a copy of the prescription. It is written in pencil and is as follows:—

"℞ Sodæ Salicylat. . . . . gr. v.
Pulv. Ipecac. Co. . . . . gr. vj.
M.
Mitte tales viij.
S. One every 3 or 4 h.".

Ed. Ph. J.]

Prosecutions for Sale of Paregoric devoid of Opium.

At the Chesterfield County Police Court on Saturday, October 11, Lieutenant Colonel Shortt, charged Richard Hollingworth, grocer, of Newbold Moor, with selling adulterated drugs at Newbold Moor, on September 5, to wit, 3 ozs. of paregoric, not of the quality demanded.

Colonel Shortt said that on the day in question he visited the shop of defendant. He demanded 3 ozs. of paregoric for which he paid 7*d*. The defendant supplied the drug himself. The inspector then told the man that he required the sample for analysis, under the Drugs Act, and divided and labelled it as usual, and forwarded one sample to the analyst, labelled "962." On October 1 the analyst sent a certificate of analysis, on which he said, "I certify that I received a sample of a fluid called 'paregoric,' marked 962, which sample was devoid of opium—the most important constituent. There should be 1½ or 2 grains in the fluid ounce." The inspector said that the practice of selling the so-called paregoric without opium was very dangerous. Persons went and purchased the article minus the opium, and, as it would be very ineffective, they would go in all probability to another shop, where the mixture would contain a proportionate amount of the opiate.

The Defendant said that he obtained the article from Mr. Greaves, who had told him that the Bench had no power to deal with the case as the preparation had no place in the work known as the Pharmacopœia, which contained the components of all standard medicines. As the mixture (which was an effectual remedy in cases of slight cough) had no place in that work he contended that the Bench had no power to deal with the case.

The case of James Walmesley, of the same place was heard, which was a very similar offence.

Mr. Walmesley admitted the charge, but said he sold it as supplied by Mr. Oldfield. This sample contained a very small amount of opium, considerably under the quantity laid down by the Pharmacy Act.

Mr. Oldfield, chemist and druggist, of New Square, Chesterfield, said the mixture was a thing kept in all chemists' and a great many small shops. He had supplied this article, and it had a [*sic* in report, ? no] place in the Pharmacopœia. The Pharmacy Act says that "no person other than a chemist and druggist shall deal in, or have in his shop for sale any article containing opium;" in consequence, chemists sold the paregoric minus the opium, and he considered it was as effectual without as with it for what it was chiefly used for. The bottles containing "paregoric," so called, for shopkeepers should, properly, be labelled "minus the opium," and had been so in the past, but remarkable to say, this was an oversight by one of his *employés* in the packing house. He was very sorry for the omission.

Mr. Barnes: Well, we have decided in these two cases to fine you the very nominal fines of 1*s*. each and the costs, and you must clearly understand that, if you sell anything for "paregoric," it must be "paregoric" and nothing else. If the Act does not allow you to sell the article with the opium in it, then you must label it "minus the opium," or, in fact anything you like, but you must not sell it as in the past.—*Derbyshire Times.*

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[345]. This injection ought to be filtered as "Nemo" surmises, as the insoluble sulphate of lead irritates the mucous membrane of the surface to which the preparation is applied. It is true that some prescribers make the combination in ignorance of the incompatibility of the salts, which separately have similar therapeutic effects; but that circumstance should not excuse the absurd practice of dispensing it as "J. C." and St. Rule recommend.

J. B. L. Mackay.

[345]. The injection of liq. plumbi and zinci sulph. shou d not be filtered.

F. STEVENS.

---

[346]. Though tincture of iodine is often applied externally in domestic medicine it is not strong enough for reducing glandular enlargements, hence the introduction of the liniment into the B.P., whilst the tincture is intended for internal administration. As neither physicians nor dispensers are supposed to be conversant with the multitudinous formulæ of the Hospital Pharmacopœias, it is best to supply lin. iodi, B.P., when iodine "paint" or "pigment" is ordered.

J. B. L. MACKAY.

[346]. When pigment. iodi is ordered it is customary to send the liniment or a solution stronger than the tincture.

F. STEVENS.

---

[348]. Ferri et ammoniæ sulphas ought to be supplied as ordered in the prescription. This salt is erroneously called iron alum (there being no alumina in its composition) while the double sulphate of iron and potash bears the same name.

To dispense ferri et am. cit. would be to exceed the dispenser's bounds. If the latter was really meant the fault rests with the prescriber and no blame would be attributable to the dispenser who used the former salt.

J. B. L. MACKAY.

[348]. Here ferri et ammon. cit. is evidently intended.

F. STEVENS.

[348]. I should use ferri ammon. sulph. as it is ordered. I cannot see why ferri ammon. cit. should be used.

T. J. R.

---

[349]. This makes a good mass, rubbed together with a little thick mucilage.

F. STEVENS.

---

[351]. This is indeed a difficult case and likely to puzzle many. The prescriber ought to be seen, for possibly it was his intention that bromide of potassium should be exhibited in the form of an effervescing tonic mixture, but then the proportions for neutralization are not correct. There is no *evidence* that hydrobromic acid was intended.

J. B. L. MACKAY.

[351]. In this mixture I think the deposit should be allowed to remain and the bottle shaken.

F. STEVENS.

---

[352]. I see no reason why this mixture should present a turbid appearance. My experience is that it does not, even after standing several days. Why Mr. Rogers has failed I cannot say.

F. STEVENS.

---

[355]. It is impossible to produce a dry powder with these ingredients as the potassium citrate is so deliquescent. Not long since I had to dispense a prescription containing lithium and potassium citrates with sugar. With the permission of the patient I made a solution of it.

F. STEVENS.

---

[357]. This mixture would not become quite clear, the opacity of milk being due to the suspension of minute globules of *fat* on which pepsine has no action whatever. Two hours was ample time for the change to take place, in other words, for the artificial digestion of the caseine contained in the milk.

J. B. L. MACKAY.

---

[358]. Rub the quinine to a fine powder, shake up with the tincture and add the fetid spirit of ammonia last. Had the proportions been different, it would be dissolved in the tincture with the aid of heat and the ammonia finally mixed therewith.

J. B. L. MACKAY.

[358]. "Quiniæ Sulph." should rub his quinine to powder with a portion of the water, add tinct. aurant. and spt. ammon. fœt. and remainder of the water. A "shake the bottle" label should be put on.

C. F. W.

[358]. I think "Quinæ Sulph." should prepare the prescription as follows:—Dissolve the quinine in the tr. aurantii by the aid of heat, then add the water, and lastly the spt. am. fœtid.

FERRI CIT.

[358]. Dissolve the "quinine" in the "sp. ammon. fœtid" and "tr. aurant.," afterwards adding it to the water.

T. J. R.

---

[359]. Rub the extract with a drop or two of glycerine and water and gradually incorporate with the oil without heat. A slab should be used. It was not permissible at all to employ lin. belladonnæ instead.

J. B. L. MACKAY.

[359]. Carefully dry the ext. belladonnæ at a gentle heat, reduce to powder, sift through muslin, and then rub together with the oil.

The alcoholic extract is tolerably miscible with oil, but as there seems to be some doubt as to its relative strength its employment may be objectionable.

D. D. CAIRNIE.

[359]. Rub the extract in a mortar with a few drops of water to soften it, then add the oil. It may be sent out in a pot or wide-mouthed bottle.

F. STEVENS.

[359]. "Apprentice" might rub in a mortar the ext. belladonnæ with a few drops of boiling water, then gradually add the olive oil and send out in a small W. M. bottle.

J. M.

[359]. I should say the prescriber must mean ℥ij of olive oil. Heat the oil to the boiling point and rub the extract belladonna in it until dissolved.

FERRI CIT.

[359]. Rub the ext. of belladonna down into a smooth paste with a little water, and then add the oil. It will require a "shake the bottle" in sending it out.

T. J. R.

---

[360]. Codeia and carbolic acid can be made into pills with bread crumb and mucilage. F. STEVENS.

---

[361]. If Mr. Lawton had added the detergent along with the glycerine, then the saponified oil, and lastly the rose water in successive portions he would have succeeded better. J. B. L. MACKAY.

[361]. If this lotion has been sent out with "a sediment only at the bottom," the oil must have been omitted.

F. STEVENS.

[361]. If Mr. Lawton will triturate the oil in a mortar with just sufficient lime water necessary for saponification, then add the powders, then the remainder of the lime water and the rose water, and lastly the glycerine and liquor carbonis detergens, the result will be an elegant flesh-coloured lotion without any supernatant indispersible "scum."

D. D. CAIRNIE.

---

[362].

℞ Acidi Hydrochlorici 2·0 = drachmam dimidiam . . . . } By weight.
Tincturæ Aurantii 18·0 = drachmas quatuor et dimidiam . . . . . }

Misce, signa: 10—15 minima = guttas (sumenda sunt).

November 18, 1878.

Dr. Biermann resides during the summer season at Baden-Baden, during the winter season at St. Remo.

W. H. LANGBECK.

A similar reply is sent by T. J. R.

---

[363]. The turbidity and coloration are due to the separation of iodine probably caused by impure iodide of potassium. The presence of iodate would account for the change. Tartaric acid would not liberate free iodine from either the iodide or iodate alone, but when both are present iodine is set free.

J. B. L. MACKAY.

[363]. Nemo should test his iodide of potassium. It evidently contains iodate, which is decomposed by the excess of tartaric acid used, iodine being set free.

C. F. W.

[363]. The prescription contains more tartaric acid than required to neutralize the bicarbonate of soda. The remaining acid acts upon the bromide and iodide of potassium, liberating slowly parts of the bromine and iodine, therefore the change of colour.

H. W. LANGBECK.

---

[364]. The second article "glycyrrhini" is glycerine.

F. STEVENS.

[364]. The word is simply mis-spelt and one need have no hesitation in dispensing glycerine.

J. B. L. MACKAY.

[364]. I would have no doubt about dispensing glycerine in "Pyrethrum's" case.

J. M.

[364]. The prescriber appears to have made a mistake in spelling. I should read it glycerini.

C. F. W.

[364]. Glycyrrhini should be glycerini, for if glycyrrhizini were intended a much smaller quantity would have been ordered, as the dose of the latter is 1—2 grains.

H. W. LANGBECK.

---

[365]. Would any reader of the Journal inform me whether it is possible to prepare the following so as to produce a white ointment?—

℞ Ung. Hyd. Ammon.,
Ung. Pot. Iodidi. . . . . āā ℥j.
Misce. Fiat unguentum.

The above was dispensed with ointments prepared strictly according to B. P., but did not answer the expectation of the prescriber, whereupon he took it to a chemist known to him, and he produced a creamy ointment.

I should be glad to hear the opinions of those who can explain what result they would expect from the above.

UNGUENTUM.

---

[366].

℞ Acid. Carbolic. . . . . ʒij.
Ext. Opii . . . . ʒij.
Ol. Olivæ . . . . Oss.
Misce bene. To be used as directed.

How should the above be dispensed?

APPRENTICE.

---

[367]. Could any reader mention a convenient mode of forming pills, each to contain 5 grains of black pitch?

SUB UMBRA FLORESCO.

Notes and Queries.

[629]. ROOKE'S GOLDEN OINTMENT.—The ℞ given by Dr. Rooke in his 'Anti Lancet' several years ago, was ung. hyd. nit., and the reason he afterwards assigned why he began to prepare it himself was the number of complaints he received of a total want of uniformity in the article sold by the trade (*vide* fol. 113).

RUSTICUS.

---

[632]. CHLORAL HYDRATE.—Will some of your readers give me their experience of the above in solution in distilled water. Some draughts 25 grains to ℥iss appear to have undergone some change from keeping. What is the change that occurs chemically?

THE CREAM OF TARTAR OF THE PHARMACOPŒIA.

Sir,—In reply to Professor Redwood's remarks on a portion of my letter contained in your issue of October 11, and to which he appears to take exception, I think it must be evident to most of your readers that "vagueness and ambiguity" lie in the direction I there indicated and not "somewhere else," the Professor's remarks to the contrary notwithstanding; and I think, further, that he has slightly misunderstood what I intended to convey by the first portion of my remarks. When I stated (parenthetically) that "this crude tartar" was evidently something quite distinct from cream of tartar, it was intended to refer not to any ambiguity on the part of the Pharmacopœia description, but to the evidence of Mr. Hodgkinson, reported in the Journal of September 27, p. 257, viz., that "cream of tartar was sent to this country from Spain and France, and came in a state that was known as argol. . . . . . The argol was generally taken from the docks by the grinders. . . . . . Argol, or cream of tartar, was the natural product of the fermentation of the juice of grapes."

If, therefore, Professor Redwood is "at a loss to understand how anyone could suppose that crude tartar on being ground would form cream of tartar or anything like it," probably the evidence quoted above will convince him that such a supposition is entertained by some; but at the same time I wish it to be distinctly understood that I never assumed or affirmed anything of the sort, knowing perfectly well that ground argol, whether red or white, is quite a distinct thing from cream of tartar.

With reference to the tests given in the Pharmacopœia for ascertaining the purity of cream of tartar (and it is here that the "ambiguity" I mention lies), the first one provides one for the presence of a trace of calcium salt, the next points to the absolute purity of the article; if it does not, may I ask Professor Redwood why 188 grains are taken and why the residue obtained on heating this to redness till gas ceases to be evolved requires for exact neutralization (exact neutralization being not always required in the application of the Pharmacopœia tests) 1000 grain measures of volumetric solution of oxalic acid. If this is not intended as a quantitative test for the amount of potash salt, of what use, may I ask, is the test at all? I am quite aware that the calcium carbonate in the residue would consume the oxalic acid equally with the potassium salt, but I scarcely think anyone would apply the test without first washing out the soluble potassium salt on a filter.

My suggestion that some wholesale house should send out an article guaranteed to within 5 per cent. of impurity had no reference whatever to the Pharmacopœia description, neither did I give, so far as I am aware, any reason for the supposition on Professor Redwood's part that the above quantity was what I meant by a "trace" of impurity; this suggestion was made solely with the idea that it would represent a product commercially attainable, and not an impossible one, such as the Pharmacopœia indicates.

137A, *Aldersgate Street*. ALFRED E. TANNER.

P.S.—In my letter of October 11, line 8, "1 grain" is a misprint for "1 gramme."

Sir,—Professor Redwood's letter in your last issue asserts that "in the case of cream of tartar, the lime salt, the presence of which is indicated by the test, being variable in quantity, the specified indication of it is made to refer to a minimum rather than a maximum quantity."

I do not know whether Professor Redwood makes this assertion on his own authority alone, but I certainly cannot think that the Council of the Pharmaceutical Society, composed of gentlemen practically acquainted with the drug trade, would endorse such an erroneous statement.

According to this statement of Professor Redwood's, the presence of any proportion of lime salts, even 90 per cent. would not constitute a violation of the "characters and tests" of the Pharmacopœia, while acid tartrate of potash chemically pure would be in direct violation of such "characters and tests."

Professor Redwood's connection with the Pharmacopœia can certainly give him no right, after it has been published, to pretend to read between the lines and say that the tests for impurities refer to minimum, rather than to maximum quantities, and therefore, until his statement is adopted by others, it would rank simply as the expression of an individual opinion; but if it is so endorsed, the value of the Pharmacopœia, as a standard, is at an end, since every analyst will have a perfect right to put any possible or impossible interpretation that he may think fit upon all the "characters and tests." If it is permissible to make one alteration, it is obviously impossible to draw the line there, and further alterations must be permitted.

By all means let every error which exists in the Pharmacopœia be set right, but this must be done in a proper way, and after full discussion, and not by tampering with the plain and common-sense meaning of the words used.

The particular subject of cream of tartar is of small importance compared with an attempt like this to destroy the only existing standard, and therefore as far as that substance is concerned, I content myself with saying that though tartrate of lime may be, and doubtless is, a necessary ingredient of commercial cream of tartar, and the admixture of small proportions of it would therefore be wisely overlooked by the public analyst, yet until the Pharmacopœia is amended it is not a "legitimate" constituent of the drug, except in "traces only."

79, Great Tower Street, E.C. G. W. Wigner.

Dispensing Memoranda.

Sir,—The astonishingly divergent opinions finding expression under the above heading in your issue of the 18th inst., give four most important indications:—

1st. The very varied manner in which a prescription is handled at different pharmacies.

2nd. The limited character of the libraries of some pharmacists, or else the inability of the latter to make proper use of standard works of reference.

3rd. That questions, which to some minds appear palpably absurd, should not be excluded from the "Dispensing Memoranda."

4th. The absolute necessity that every pharmacist should utilize some means of intercourse with other members of the trade in order to promote unanimity of opinion.

In the issue referred to, Mr. Wilkinson gives the correct answer to No. 346 (pigmentum iodi). In such cases the name of the prescriber should be ascertained, from the signature, and that of the hospital where he studied. The intended preparation will probably be found in the Pharmacopœia of that hospital.

After reading his reply to No. 346, I was surprised to notice his answer to No. 348 (ferri ammon. sulph.); since by using ferri am. cit. he takes a most unwarrantable liberty, unless he is furnished with data not supplied in the prescription (such as a personal knowledge of the idiosyncrasies of the prescriber). The *modus operandi* indicated by "Nemo" is even more objectionable. It is impossible, in this case, to state definitely what the prescriber intended, for there are two double sulphates of iron and ammonia containing iron in the ferrous and ferric states respectively, viz., the ordinary photographic salt, $Fe''SO_4, Am_2SO_4, 6H_2O$, mentioned by "St. Rule," and iron alum, $Fe'''_2 3SO_4, Am_2SO_4, 24H_2O$, referred to by J. C. But the ambiguity does not extend beyond these two salts, and if the prescriber cannot be consulted, either might be used, and a note made on the prescription to indicate which was dispensed for the guidance of subsequent dispensers. Since "iron alum" is more frequently used in medicine and the ferrous double salt finds its chief application in photography, it is, perhaps, more than likely that the former was meant. It would certainly be a doubtful compliment to a pharmacist's education for him to plead ignorance to his customer, as "Nemo" recommends. He ought to know either that he does not keep in stock the ingredient ordered, or that the prescriber has omitted indispensable data.

In reviewing these varied opinions, it is important that we should trace out the cause of the discrepancies, and endeavour to indicate the remedy. The primary cause is the carelessness of the prescriber in using ambiguous nomenclature. The ever-expanding fields of information recorded in every branch of science render it a necessary consequence that a man wishing to become eminent must confine himself to a branch of study, to the exclusion of other sections of science. For this reason scientific men are rarely good scholars, and, on the other hand, good scholars have, as a rule, but a partial familiarity with science; so also eminent medical men are rarely good chemists or pharmacists, therefore chemistry and pharmacy should find their devotees amongst pharmacists. Prescribers, then, would render a great service to pharmacists, saving them from much undeserved mistrust and ignominy, if they were to avoid dabbling in doubtful synonyms, and for substances, etc., contained in the British Pharmacopœia, to use the precise nomenclature there employed. For galenical preparations not included in the B.P., the initials of the Pharmacopœia, or other standard works, where the formula may be found, should be appended. For non-official chemical preparations, they should inquire of a pharmaceutical chemist (one who has studied the science, and not one who has been simply crammed for his examination) whether there is any doubt about the name he uses.

Having pointed out one cause and its remedy from the prescriber's point of view, I proceed to append remedies from the dispenser's standpoint.

Firstly, careful perusal of the "Dispensing Memoranda," inserting notes of incompatible mixtures, etc., and expressing opinions on the questions raised. An adverse opinion was recently expressed on the ground that it would excite want of confidence among medical men and others reading the divergent opinions; but I consider that the removal of the cause of mistrust far outweighs an objection of that sort, and I am sure that a medical men of any perception would see the cause, and appreciate the cure. In fact, the medical profession has found a similar need, and applied a parallel remedy in the column of the *British Medical Journal* headed "Our Confessional."

Secondly, I would urge upon all chemists, assistants and apprentices, the value of forming associations at the meetings of which all such difficulties could be discussed.

Thirdly, that chemistry proper should be more stringent at the "Minor," and that an acquaintance with other pharmacopœias than the British should be required.

In conclusion, I would express my opinion that the "Dispensing Memoranda" is doing a great and good work, but I trust that it will not be trifled with by correspondents sending in absurd questions "as a joke," or without having previously made endeavours to solve them.

R. H. Parker.

Sir,—May I suggest that in the case of answers to the questions on dispensing, the name of the writer should appear, and not a "nom de plume," which in many cases hides a lamentable ignorance. This would give your readers some idea of the value of the opinions, and would, I venture to think, save your space for more trustworthy information.

C. Parkinson.

Registration under the Dental Act.

Sir,—The large amount of (in many cases) intemperate correspondence respecting the right of a chemist extracting teeth and performing the minor operations in dental surgery to use the title of "dentist" is truly absurd.

Turning to the dictionary, we find the definition of a "dentist" as "an operator on the teeth." (N.B.—It does not say "a maker of artificial teeth.")

If extracting a tooth is not an operation in dental surgery, what is it?

If the *bonâ fide* dentist is to be only the man who can do both the mechanical and surgical work, it is quite evident that many old respected practitioners must give up.

How many of the great guns could make a piece decently if they tried?

Most dentists put out their work to mechanical men. It is not considered the province of the medical profession to make crutches or wooden legs, and I believe there are many *bonâ fide* dentists who can extract, scale, stop, take impressions and fit, who never made a set in their lives.

To what end did the Pharmaceutical Society obtain the terms of "dentistry in conjunction with pharmacy" if it was not to cover the existing rights of those chemists who extracted teeth, etc., to use the title of dentist and to continue their operations? And if, as some affirm, it is not necessary to register to perform dental operations if you do not call yourself a dentist, perhaps some one can explain why there are separate clauses, "in conjunction with medicine or surgery," "in conjunction with pharmacy"? Let the chemists hold their own.

DEFENCE, NOT DEFIANCE.

Hours of Trading.

Sir,—The unnecessary late closing of some chemists' shops is a scandal. I say unnecessary, because I feel convinced that a great deal of the trade done after 8 p.m., or whatever times the shttters are put up, might be got through before that time, if chemists in their respective towns would agree amongst themselves to discourage the late shopping of some of their customers. I wish I had the power to persuade my brethren in the trade to cultivate a little friendly co-operation amongst themselves to this desirable end. I agree, therefore, with the remarks by "Camphora" in to-day's Journal.

Referring to the letter of "Verus" in the Journal of Oct. 11, I cannot see that the fact of his not having been a day out of his shop for "nearly twenty years," is worthy of boasting about. There must be a serious risk of the man becoming very narrow minded who confines himself for so long a period to the limits of a chemist's shop. Or I may be wrong. The "contented mind" may be the "continual feast."

16 and 17, *Cliffe, Lewes.* W. T. MARTIN.

The Drug Trade in South Africa.

Sir,—Enclose please find extracts from letters I have received from a friend in the drug trade in South Africa, Orange River Free State. I have no doubt they will be read with interest by others as well as emigrants; they give a fair idea of what this man had to contend with. He had a good notion of insinuating himself into the good graces of those with whom he came in contact. He went out on "spec," taking with him a lot of meerschaum pipes, which he sold well. How a person would do there now is a problem. The results of the late war are to be felt.

October, 1877.

"Teacher, barman, farmer, brickmaker, and now back to the old trade again. Get £6 a month and all found. Just moved into a very fine shop to-day; have soda water machine, and do a roaring trade, sell large quantities of Dutch drops to the Boers. The bases are valerian, ether, turps, camphor, assafœtida, etc. The governor has done well up here, visits, performs surgery, midwifery, etc., and charge slap up. The Boers think him a demigod. Patents, are 13½*d.*, 2*s.* 6*d.*, !2*s.* 9*d.*, 5*s.* 6*d.*, and so on. Mixtures 4*s.*, 7*s.*, and often more.

"I had rough times at first, and have slept on the grass many times, with clothes wet, and no blanket, under waggons and in barns, walked all day, and lain down at night, and have met better men worse off.

"I cannot recommend emigration indiscriminately. You see many a man rubs along at home, with his own family connections, etc., and passes for a good sort, who if placed in a strange country, with no social influence to check him, would go to the very lowest. That is my idea, I give it for what it is worth. I think it is a side of the question which is not often put forward, but it should be."

Extract March 20, 1879.

"The dullness of a small colonial town is intolerable, so I gave up my berth. When the terrible news came of the loss at Isanhlawana I could stand it no longer, so I joined the Transvaal Volunteers. Our pay is 12*s.* a day, out of which we pay our expenses, expected to be 3*s.* or 4*s.*"

Letter dated May 16, 1879.

"Unless a person comes to a situation he must make up his mind to rough it, or at least to turn schoolmaster, which is the only thing open for strangers who are not mechanics, and have not coin enough to start farming on their own account. . . . A situation is easily obtained from advertisements in the *Chemist and Druggist* and *Pharmaceutical Journal.*"

J. S.

Sir,—Of pharmacy in the Transvaal I know nothing, not having been there, but I know that many of the Dutch Boers, during their annual visit to Maritzburg to dispose of their produce, buy their medicines there, and seem to keep a stock. The prices obtained are generally large, but trade is chiefly done by barter, the merchants buy their produce, and supply them with goods, and any they do not keep they either get for them, or if they recommend any customer, the chemist has to allow a commission, which I consider a very rotten state of trading. A knowledge of Dutch is absolutely necessary in Transvaal. There is a nominal examination to pass by a Medical Board before anyone can commence business in Natal. I think they accept the pharmaceutical certificates in lieu of examination.

There were about nine or ten chemists in Durban and Maritzburg when I was there, the hours of business being generally from 7 in the morning till 5 p.m., the days varying only about two hours in the year. Salaries vary from £70 in the house to £100, and about £150 out-door. There are some in business who have done very well; but I should say that Natal now (just after the war) will be very dull for some time, as merchants have bought largely during the war, and they are now forcing their goods on to the market at any price.

The trade there is similar to here, except that all the medical men send their prescriptions to the chemist. There is a large trade done in cooling drinks. I know one chemist in Maritzburg (who does a large business with the military officers) who must have coined money during the war.

A RETURNED EMIGRANT.

"*Kenbaan.*"—The question of "official" *v* "officinal" has been frequently discussed in this country and the United States, and probably it will not be lost sight of when the time comes for the revision of the British Pharmacopœia.

"*Ferri Cit.*"—Recipes for Glycerine Jelly will be found in the Journal for November 30 last (vol. ix., p. 462).

"*Theta.*"—The second word is the Spanish word for "English," but we do not recognize the first. It might be equivalent to "kino."

T. J. R.—The double salt is more stable.

T. W. G.—See a paper on the colour of podophyllum resin, by Messrs. Senier and Lowe, in vol. viii., p. 441.

"*Surrey.*"—We should require to see a specimen before accepting the statement.

"*Inconvenience.*"—We believe the Catalogue is now being compiled.

"*Triplex.*"—The Dental Act was printed in vol. ix., p. 52. The Registrar under the Act is Mr. W. J. C. Miller, Medical Council Office, 315, Oxford Street, W.

"*Carey.*"—The subject of the strength of Orange Flower Water was discussed during the meeting of the Pharmaceutical Conference in Dublin last year. See *Pharm. Journ.* [3], vol. ix., p. 249.

"*Gwendoline.*"—No. 6 is probably *Festuca gigantea.* The other five are correctly named.

Erratum.—On p. 320, col. ii., line 19, *for* "On glancing at the above title," *read* "On glancing at the above table."

"*Juror.*"—The 12th section of the Juries Act, 1870, provides that "No person whose name shall be in the Jury Book as a juror shall be entitled to be excused on the ground of any disqualification or exemption, other than illness, not claimed by him at or before the revision of the list by the justices of the peace."

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mayhew, Hughes, Simcock, Kent. Long, Warneford, Leigh, Rainer, Postans, Student, Isograph, Nigel, Cumberland, Sub Umbra Floresco, Delta, Olibanum, Tinctura.

TARTRATE OF LIME IN CREAM OF TARTAR.

BY B. H. PAUL, PH.D.

Having regard to the recent discussion as to the amount of lime existing in the state of tartrate in cream of tartar, it may be of interest to make known the following results of some experiments carried out with the object of determining the extent to which cream of tartar prepared in the usual way might contain lime combined with tartaric acid.

Tartrate of lime was in the first instance prepared from tartaric acid and carbonate of lime, using such proportions as would furnish a salt having the composition represented by the formula $C_8H_{10}CaO_{12}$. The boiling solution deposited on cooling, crystals, which by analysis were proved to contain 21 per cent. CaO, instead of 16·6 per cent., which would be the amount in a true acid tartrate having the formula above mentioned. This salt was not therefore a bitartrate, though the conditions were suitable for the formation of that compound. Neither was it a neutral tartrate, $C_4H_4CaO_6$, for in the anhydrous condition this salt contains 29·7 per cent. of lime.

However, on adding the crystallized tartrate of lime to a boiling solution of bitartrate of potash, prepared by neutralizing 5 grams of tartaric acid with carbonate of potash, and then adding another 5 grams of tartaric acid, the tartrate of lime was dissolved, and after some few minutes the liquid was filtered while near the boiling point. On cooling, crystals were deposited having all the external character of bitartrate of potash; but on analysis this salt was found to contain a considerable amount of lime, though forming a perfectly clear solution.

It is therefore evident that the ordinary method of preparing cream of tartar is not capable of effecting the entire separation of the potash salt from the lime salt, which is so frequently a constituent of "argol," both as of normal origin from the grape juice itself, and also in part produced by the reaction of gypsum added to the must in the process of wine making.

As a necessary consequence tartrate of lime must be looked upon as necessarily forming some part of the "cream of tartar" met with in commerce, as an extraneous matter with which the drug is unavoidably mixed in the process of preparation, not as an impurity or adulterant according to the terms of the Food and Drugs Act. The extent to which this substance extraneous to bitartrate of potash may be present in "cream of tartar" will appear to be somewhat different, according to the nature of the compound that a certain determined percentage of lime is assumed to represent. Taking the salt referred to above, for example, if the amount of neutral anhydrous tartrate of lime would be 7·6 per cent. the amount of the same salt in a hydrated condition would be 10·5 per cent. and the amount of bitartrate of lime would be 13·6 per cent.

The amount of water in neutral tartrate of lime is here taken as being four molecules; but there are diverse statements on this point, and therefore it would perhaps be best to state the amount of extraneous material in terms of anhydrous tartrate of lime. If sulphate of lime also be present, as it sometimes is in small amount, allowance must be made for this in calculating the quantity of tartrate of lime from the lime found by analysis.

As regards the presence of sulphate of lime in "cream of tartar," it would appear that this can only be the case when adulteration has been practised, unless the amount of sulphate of lime be very small, for it is improbable that such a quantity as 20 per cent. of sulphate of lime can be introduced into "cream of tartar" during the ordinary preparation of that article and remain as such in it. More likely there would be decomposition of the sulphate together with the production of tartrate of lime and sulphate of potash, and in this way the greater part of such an amount of sulphate of lime would be got rid of. But if the sulphate of lime be added in the state of powder to the "cream of tartar," it is to be understood that its presence would be indicated by analysis.

ACONITUM HETEROPHYLLUM, WALL.*

BY DR. M. DUNIN V. WASOWICZ.

(*Continued from page* 303.)

In the chemical examination of the roots I first prepared an infusion, and then a clear decoction with 50 grams to 250 grams of liquid, and applied to these the following tests:—

(A.) The watery infusion filtered slowly but clear. It was yellow coloured, had a bitter taste, reddened blue litmus paper, frothed considerably, became covered after a time with a thin pearly film, and after two or three days became turbid. Perchloride of iron produced neither in the cold nor after heating any precipitate or turbidity. Tannic acid solution produced at once a dirty white turbidity that disappeared completely by gentle warming and reappeared on cooling. Nitrate of silver produced a slight white turbidity, and after a time a flocculent yellow precipitate. Acetate of lead produced a dirty white precipitate that did not disappear on boiling. With basic acetate of lead the precipitate was more voluminous and dark yellow coloured. Tartrate of antimony and sulphate of copper did not produce either precipitate or alteration of colour. Gelatine solution did not produce either alone or by addition of hydrochloric acid, any precipitate, even after the liquid was allowed to stand or by boiling. Solution of iodine in iodide of potassium produced a deep yellow coloration that soon became blackish blue, and after some time a dirty brownish black precipitate. Potassio-iodide of mercury and potassio-bromide of mercury produced a white turbidity.

(B.) The decoction was darker coloured, filtered very slowly, soon became turbid, and behaved generally like the infusion, except that the reactions were more distinct. A quantity of both liquids was precipitated with basic acetate of lead, and—

(1) The precipitate was decomposed by sulphuretted hydrogen. In the filtrate, which had a distinctly acid reaction and tasted but slightly bitter, gelatine solution produced no precipitate; perchloride of iron coloured it blackish (not green); mercurous nitrate produced a white precipitate.

(2) The liquid separated from the precipitate and from excess of lead was acid, very bitter, and gave at once considerable precipitates with tannic acid solution and potassio-iodide of mercury. Portions of the extracts were boiled with lime water and became at first reddish and after longer boiling dirty green coloured, from which I inferred that decom-

* *Archiv. der Pharmacie*, vol. xi., p. 19

position must have taken place. This observation induced me to avoid the use of alkalies and alkaline earths and to adopt the following mode of treatment.

The coarsely cut roots were extracted with alcohol of 85 per cent. with gentle heat and the filtered extract distilled to remove the alcohol. The residue, having the consistency of thin syrup, deposited after twelve hours standing in the cold an apparently crystalline mass, having a fatty feel. This was separated by filtration from the liquid portion, which was diluted with a large quantity of water and evaporated on a water-bath until all the alcohol was got rid of. After cooling, a further small quantity of the above mentioned brown fatty mass separated upon the surface and was removed from the liquid, which when filtered had a dark brown colour, an acid reaction, and a very bitter taste. It was mixed with basic acetate of lead until nothing more was precipitated. The dirty yellow precipitate was washed with water until sulphuric acid gave no further reaction with the washings. In this process there were obtained for further examination:—

(A.) A brown apparently crystalline fatty mass.

(B.) The precipitate produced by basic acetate of lead, probably containing the acids separated.

(C.) The liquid filtered from the lead precipitate, in which bitter substances and alkaloids were to be sought.

(A.) *The brown, apparently crystallizable, substance* did not dissolve in water or alcohol, and was only partially soluble in boiling water or ether, but dissolved completely in amylic alcohol to a clear dark brown liquid. The ethereal solution was of a brownish colour, and was without any action upon red or blue litmus paper. The solution in amylic alcohol had a slight acid reaction.

After evaporating the ether there remained a slight brownish apparently crystalline residue, which was completely volatilized when heated on platinum foil, giving off an odour like burnt fat. Being convinced that I had to do with a vegetable fat, the entire quantity of the brown substance was several times treated with ether, and the solution thus obtained was shaken with water acidulated with sulphuric acid until it no longer became coloured. After distilling off the excess of ether I again obtained a brown coloured substance that was again dissolved in ether, and shaken with acidulated water. As this no longer became coloured the residue left after evaporating off the ether was mixed with animal charcoal, and after some time again extracted with ether. The solution thus obtained was considerably paler. A portion of it was rapidly concentrated and saponified with soda solution—sp. gr. 1·11—the yellow-coloured soap, separated with salt, dissolved in boiling water, digested with animal charcoal, the boiling solution filtered, and then decomposed with dilute sulphuric acid. The fat acids thus separated were converted into soda and then into lead salts; the latter treated with ether appeared to consist chiefly of oleate. I did not succeed in detecting glycerine in the mother liquor.

Another portion of the ethereal solution was allowed to evaporate slowly in the cold. After two days there remained a soft yellowish-white mass that asted at first mild and afterwards somewhat acrid. This was partly soluble in absolute alcohol. It melted at 32° C., and did not again solidify to a uniform mass, but remained partially liquid. The liquid portion had a distinctly acid reaction, and did not solidify until cooled below zero. The purified fat burnt with a slightly smoky flame, giving off a distinct odour of burning wax. Its specific gravity at 15° C. was ·895.

When exposed for some time in an open vessel to the action of the air the fatty mass separated into two layers. The upper oily rancid-smelling dark coloured layer had a distinctly acid reaction, and dissolved readily and completely in 95 per cent. alcohol. The lower layer, after washing with alcohol, appeared as a white apparently crystalline mass that dissolved readily in boiling alcohol and in ether. It crystallized out from the ether in small needles that melted at 62° C., and accordingly was palmitic acid.

It then remained to ascertain whether the fat contained stearic acid. For that purpose I prepared from the liquid portion of the fat soluble in cold spirit a lead salt, under the impression that the oleic acid might be mixed with stearic acid, since stearic acid is soluble in cold alcohol. The lead salt thus obtained did not dissolve completely in ether, so that I conjectured that stearic acid was also present, although in very small amount.

More minute chemical examination was scarcely possible, since the whole quantity of material did not exceed three grams.

The circumstance that I was not able to detect glycerine in the mother liquor was not to be regarded as a proof that the fat was only a mixture of the three acids, and not a glyceride, as it is well known that glycerine is difficult to detect in such small quantities, and if the fat were not a glyceride the original ethereal solution should have had an acid reaction.

(B.) *The lead precipitate* was thoroughly washed, suspended in water while still moist and decomposed with sulphuretted hydrogen. The filtrate from the sulphide of lead was evaporated, after separating the sulphur to the consistence of an extract. The residue was readily soluble in water and the solution was more or less dark coloured according to strength. It had a very slight bitter taste, reddened blue litmus paper, did not give a precipitate with gelatine, acquired a blackish colour with perchloride of iron, did not become turbid with tannic acid solution, but gave with the double iodide of potassium and mercury a slight curdy precipitate, and deposited after long standing warty crystals in very small quantity. This solution was again precipitated with basic acetate of lead and the precipitate treated as above described. In the solution of the extract thus obtained double iodide of mercury and potassium no longer gave a precipitate.

The extract thus purified was thoroughly extracted with ether. The yellowish solution had a sourish taste and left after evaporating off the ether, a yellowish indistinctly crystalline mass, completely soluble in ether, alcohol and water. The aqueous solution of it, digested with animal charcoal, deposited after some days an almost colourless warty crystalline mass. This had a sour taste, was free from odour, melted at 165° C., and charred when more strongly heated, but did not volatilize.

The conjecture that this substance was aconitic acid was readily confirmed. The aqueous solution gave with mercurous nitrate a white flocculent precipitate; nitrate of silver gave no precipitate. The neutral soda salt gave with nitrate of silver a white precipitate that soon became black, and perchloride of iron gave a reddish-brown precipitate. The rest of the acid was crystallized again from ether and burnt. I thus obtained from 0·1823 gram of dried substance:—

$0·2756\ CO_2 = ·07515\ C = 41·223$ per cent. C.

$0·061\ H_2O = ·0066\ H = 3·620$,, H.

For $C_6H_6O_6$	Calculated.	Found.
C. . .	41·379	41·223
H. . .	3·447	3·620
O. . .	55·173	

The portion of extract insoluble in ether, and constituting the greater part of it had still an acid reaction. Its taste was at first mild and afterwards disagreeably astringent. It was dissolved in a little water, mixed with animal charcoal, evaporated to dryness, and extracted with dilute alcohol. The solution had a brownish-yellow colour, slight acid reaction and was coloured black by perchloride of iron. When boiled with ferrous sulphate no change took place, but after adding acetate of soda in solution the liquid immediately become black. The solution did not reduce Fehling's liquor, but when a large quantity of the alcoholic solution was evaporated to a syrupy consistence, and then boiled with a solution of oxalic acid, cuprous oxide was at once separated.

Basic acetate of lead therefore precipitates from the watery extract of the root aconitic acid, a peculiar form of tannic acid, grape sugar and mucilage.

(*To be continued*).

FUCUS VESICULOSUS.*

The subject of obesity and its treatment has of late years received much attention both from doctors and their patients. The interest excited by the appearance of Mr. Banting's 'Letter on Corpulence' will not be readily forgotten. The medicinal agents most commonly employed in the treatment of this condition are acids,—chiefly in the form of lemon-juice and vinegar,—strong alkalies, and iodide of potassium. Of late, however, a preparation known as "anti-fat" has been extensively advertised, both in this country and in America, possessing, if we may accept the statements of the proprietors, very remarkable powers in removing that superabundance of fat which is so frequently a source of anxiety and discomfort to those who indulge too freely in the pleasures of the table. Anti-fat is said to be a fluid extract of *Fucus vesiculosus*, a common sea-weed, known in this country as sea-wrack or bladder-wrack, and in France as Chêne marin or Laitue marine. It is largely employed on the coasts of Scotland and France in the preparation of kelp; whilst in Ireland, curiously enough, it is found to be invaluable for fattening pigs. It contains, as might be expected, large quantities of iodine, chiefly, according to Gaultier de Claubry, in the form of iodide of potassium.†

Fucus vesiculosus was at one time officinal in the Dublin Pharmacopœia, and is by no means a new remedy. Pliny describes it under the name of *Quercus marina*, and says it is useful for pains in the joints and limbs. In the eighteenth century it was largely employed by Gaubius, Aunel, Baster, and others, in the treatment of scrofula, bronchocele, and enlarged glands, and even for scirrhous tumours. Its charcoal, known as *Æthiops vegetabilis*, was used in the same class of cases. The fucus has also been found useful in skin diseases and asthma. On the discovery of iodine, in 1811, by Courtois, the saltpetre manufacturer of Paris, it for a time fell into disrepute. In the year 1862 its use was revived by Professor Duchesne-Duparc, of Paris, who whilst using it experimentally in the treatment of psoriasis, found that it possessed the singular property of causing the absorption of fat.

The fucus can be taken either as an infusion, made by steeping half an ounce or a small handful in a pint of boiling water, or in the form of pill or liquid extract. The dose of the infusion is about a cupful, but it is so abominably nasty that few people can be induced to take it. The pills contain each three grains of the alcoholic extract; and, to begin with, one is taken in the morning, an hour at least before breakfast, and another in the evening, about three hours after dinner. The dose is increased by a pill a day, until the patient is taking ten every morning and evening. It is directed that the ten pills should be taken *dans la même séance*, and that a greater interval should not be allowed to elapse between each pill than is necessary for the process of deglutition. The fluid extract may be given in drachm doses, and it is said that the best results are obtained when both the solid and liquid extracts are taken. In favourable cases the sufferer may expect a reduction in weight of from two to five pounds in the week. Unfortunately, however, the fucus appears to be somewhat tardy in its action, and the patient should lay in a good stock of the drug before commencing treatment. In successful cases one of the earliest effects is an excessive diuresis, and the urine is said to become covered with a film of a beautiful nacreous aspect. In one carefully recorded case the patient did not observe this, but noticed that his water was very high-coloured, and that its odour was extremely offensive. The next action of the drug is usually on the bowels, and the patient has many calls to relieve himself, without, however, being able to pass anything more than a little mucus. Sometimes the feet and body exhale a peculiar fusty smell, so that the patient is a nuisance both to himself and friends. After this, as a rule, the reduction in weight takes place. Occasionally, however, the opposite effect is produced, and the patient gets stouter than ever; in fact, fucus has been recommended as an "anti-lean."

By some authorities it is stated that the fucus should be gathered at the period of fructification, about the end of June, and that it ought to be rapidly dried in the sun; whilst other and equally eminent authorities insist that it should be gathered only in September, and that it should be allowed to dry slowly in the shade, a high temperature, according to them, destroying its active properties. It is generally agreed, however, that the roots and stalks should be rejected, and that the fucus gathered on the west coast is superior to that of the east. We understand that as a matter of fact most of our fucus comes from Billingsgate market, it being extensively employed for packing fish.

It must be confessed that we know little or nothing of the mode of action of this remarkable drug. We are told that it "stimulates the absorbents," but that is throwing very little light on the subject. What we want is a real sound systematic study of its uses and properties, both in the physiological laboratory and at the bedside. When it has been thoroughly and carefully worked out, as so many drugs have been of late years—pilocarpine and gelsemin, for example,—we shall be able to form an opinion as to its value, but at present we are quite in the dark.

* From the *Lancet*, October, 25, 1879.

† *Fucus vesiculosus* is one of those seaweeds which yield an ash containing the smallest amount of iodides. See *Pharm. Journ.*, ix., p. 303.—Ed. Ph. Journ.

CARICA PAPAYA AND PAPAYOTIN *

BY DR. THEODOR PECKOLT.

The papaw tree belongs to the family of the Papayaceæ, which in this country (Brazil) is represented by only two species. It is called by the Pupi Indians "ambapaya" and by the Brazilians "mamao." The trees are diœcious and hermaphrodite, the hermaphrodite tree being distinguished by the people as the "mamao macho" (male mamao), and the fruit-bearing tree as the "mamao femea"

* From the *Zeitschrift d. allg. österreichischen Apotheker-Vereines*, vol. xvii., pp. 361 and 373 (Aug. 20 and Sept. 1, 1879).

(female mamao); further a cultivated variety of the latter is known as the "mamao melao" (papaw bearing mamao).

In the hermaphrodite tree the young plants have the leaves alternate, but these fall off after a short time, leaving only the leaves of the crown; the petioles are divergent, 27 to 32 inches long; the leaf which is disposed like a shield is rounded, about 14 inches broad, divided into seven lobes, and these lobes again into seven sub-divisions. Inflorescence male and female, disposed in racemes; flowers pale yellow, or white, with a pleasant odour, faintly resembling jasmine, differing in appearance from those of "mamao femea" and "mamao melao" in the flower stalk being 8 inches long. The first flowers of a nine months old hermaphrodite tree are always male only. Six months subsequently the development of numerous carpels may be seen, and these gradually continue to be formed. The fruit-bearing flowers which always commence from below, bloom and then bear fruit uninterruptedly throughout the whole year until the death of the tree, which usually takes place after four or five years.

The stems are elegant, and notwithstanding it is stated in some works that the *Carica Papaya* is without branches, this is not the case in Brazil with the hermaphrodite tree; for in the second and third years it throws out abundant branches which bear at first only male flowers.

The fruit of the hermaphrodite tree is considerably smaller than that of the "mamao femea." It is as large as a fist, pear shaped, light yellow when ripe, irregularly furrowed into seven perceptible divisions, and has an average weight of ten ounces. The seeds, when planted, yield both kinds of trees.

The fruit-bearing papaw ("mamao femea") has larger leaves and large perfect separate flowers which are situated immediately above in the crown between the leaf stalks and the stem itself. The flowers are yellowish, 2 inches long, ⅜ inch wide, recurved and revolute, delicate as a wax flower and have a more powerful odour than the preceding. The fruit attains almost the size of a walnut before the flower falls off; in the ripe condition it is as large as a small gourd, but rounder, not so pear-shaped, and provided with a wart; it is of a yellow colour and often weighs a kilogram or more.

The kind improved by cultivation, the "mamao melao," has the same habit, but yields fruit larger than a human head, orange yellow in the ripe condition and weighing from 4 to 6½ pounds. The fruit of the *Carica Papaya* contains over a hundred small polished wrinkled brown seeds, about twice the size of linseed.

The stem of a full grown tree is about 13 to 17 feet high and frequently 12 to 20 inches in diameter; the hermaphrodite tree is often branched above, the diœcious tree always branchless. Stem cylindrical; bark smooth, grey at the lower part of the stem, and greenish above, woody, fibrous, and easy to cut; beneath is a layer the thickness of a finger, of a herbaceous substance like a cabbage stalk; all the remainder is hollow, but has internal partitions at the rings, like the bamboo, which are very porous and easily penetrated.

This herbaceous tree is in Brazil a constant companion of the banana, and is never wanting near the huts of the natives. And rightly do the Indians honour this useful and most grateful tree, specially selected by Providence for a people averse to any cultivation, for without the slightest care or labour after a few months' growth it yields harvests the whole year through.

Notwithstanding that in respect to nutritive value the fruit cannot compete with the banana, its use makes a refreshing change, and as will be seen subsequently by the analyses it is not so very poor as a food stuff.

The *Carica Papaya* is in the present day hardly absent from any tropical country in Asia and Africa, and it appears to have been shown that like the maize the papaw tree has spread from west to east, or rather from America to Africa and then to Asia. Marcgraf states that he found it growing wild in the primitive forests of Brazil; other authors think it had its origin within the tropical portion of the American continent; certain it is that it was found domesticated near the dwellings of the Indians when Brazil was discovered.

Dr. Heinrich Barth states that in Central Africa the fruit bears the name of "gónda-n-masr," equal to the Egyptian "gonda," which appears to indicate that it has been introduced within historic times through Egypt. But I believe that this tree of a four or five years' life, which like maize, can only be continuously cultivated by means of seed, requires no "historic time" in order, even more rapidly than maize, to become naturalized in all the tropical countries of the world, and the more so because the seeds, unlike those of maize, are not destroyed by insects or beasts, but are in fact more rapidly spread by them. In the northern districts of the Soudan Dr. Barth found the papaw but seldom; on the other hand in the districts between Kátsena and Nyffi, as well as in the southern parts of Kano, Pangónda and Gudjeba, southward to Benuë, scarcely anything else than the papaw tree was usually found. By the Fulde it is called "dukudje" and by the Kanori "bambus masarbe." Both Dr. Barth and Dr. Rohlf speak of the refreshing taste of the fruit, which would also be noticeable in Brazil, if it were not for the possession of a large number of other delicious tropical fruits.

In Brazil the tree is scarcely cultivated, or with but little care, its continued planting, like that of the banana, being self-effected, but with this difference that instead of shoots from the roots it is done by the seeds of the fruit rotting on the ground. The tree is simply left to stand where the seed has been planted either by the use of the fruit as manure or by the agency of birds; the tender young plants brave all weathers and are very tenacious of life, are not eaten by animals, and after becoming ten inches high are not prevented by injury to leaf or bark from growing luxuriantly and almost perceptibly to the eye, even more rapidly than the banana.

On the 20th of February, 1867, I set a young plant, 3 inches high, from a seed of the "mamao femea," in the pathway from the house to the garden, a place where it was exposed to injury from continual passers-by and poultry, and very unfavourable to the development of a fruit tree. On the 20th of November—nine months subsequently—the first inflorescence appeared; the tree was then nearly 5 feet high; at the lower end the stem was 1½ inches in diameter, and branchless; the crown had twelve leaves, and in the angles of nine leaves were the long stalked racemes of flowers of the hermaphrodite tree. The lowest raceme, with nine flowers, opened first, always from below upward; the topmost raceme had only seven flowers. The whole of the flowers were male; the first perfectly developed diœcious flowers were developed at the end of fourteen months, and always below first.

A "mamao femea" which bore fertile flowers from the commencement, flowered first when fourteen months old, also beginning from below. The stem at this time had a height of 17 feet 4 inches.

The improved "mamao melao," which yields fruit as large as a pumpkin, is treated with somewhat more care, and its management may even be called cultivation. The seeds are planted, together with the flesh of the fruit, in a light soil, not too moist and containing abundance of organic matter; if they be planted without the flesh of the fruit only trees that yield the original fruit of the uncultivated kind are obtained. I had doubts respecting this, but have satisfied myself of its correctness by numerous experiments.

When the plants are about 3 to 4 inches high they are transplanted, and for this a lighter soil is selected, which is not too shady, and too much watering must be avoided; this is usually left to the weather. After fourteen to eighteen months the tree-like plants bear fruit through the entire year without cessation. After four or five years of this fruit-bearing existence the top commences to decay and it dies from above downwards, the stem being eventually completely destroyed by the wind if not previously removed by man.

The fruit, like the banana, is collected in the full grown, but still green condition, so as to ripen in the house. If perfectly ripe when taken from the tree the flesh, especially in the neighbourhood of the skin, is bitter; moreover, the ripe fruit is difficult to secure against destruction by birds.

During my seventeen years' residence in the interior of the province, from 1851 to 1868, I examined almost the whole of the Brazilian fruit and food plants; this work is published in here by Messrs. C. and H. Laemmert, under the title 'As Plantas nutritivas e do gozo do Brazil,' but has not yet reached the letter M. In my manuscript of 1868 occurs the examination of the fruit, seeds and milk of the *Carica Papaya* and the discovery in the milk of a white amorphous substance, which in my notice I described as "papayotin." This same substance I found also in the leaves, and although I knew that the leaves had been used from time immemorial by the Indians for rendering meat tender, it did not occur to me that my "papayotin" might be a pepsin-like substance, until I saw in the Austrian Society's Journal, a short time since, notices of the work of Herr Wittmack and Dr. C. G. Roy, which induced to me to look up my notes and make some experiments with papayotin, when I found the solubility of meat in a solution of papayotin confirmed, and therefore publish my investigation. I do not thereby make the smallest claim to priority and do not even desire that the name should be adopted, but only to invite a further and more perfect investigation of this interesting substance, and by the making known of my own imperfect experiments to become useful as a guide and to save several useless experiments.

Analysis of the Fruit.

In 100 grams of fresh fruit, freed from rind, taken from the three kinds of "mamao," I found the following substances:—

	1. Mamao femea.	2. Mamao melao.	3. Mamao macho.
Caoutchouc-like Substances	—	—	0·046
Soft Yellow Resin . . .	0·165	—	—
Reddish-yellow Fat . . .	—	0·020	—
Albumenoid Substances .	1·070	0·500	0·753
Sugar	3·238	3·580	4·333
Pectinous Matter	1·315		
Tartaric Acid } combined with Bases.	0·075		
Citric Acid . } combined with Bases.	0·020	0·480	2·332
Malic Acid . } combined with Bases.	0·083		
Dextrin, Extractive Matter, etc.	5·503		
Water	85·351	92·500	89·445
Cellulose	3·180	2·920	3·091

100 grams of fresh fruit flesh of the "mamao femea" gave 1·239 grams of ash, and 100 grams of it dried gave 8·457 grams.

In a kilogram of pure ash from the flesh of the fruit I found—

Carbonic Acid	140·945
Chlorine	56·013
Sulphuric Acid	52·401
Phosphoric Acid	71·573
Soluble Silicic Acid	165·340
Insoluble Silicic Acid	5·423
Ferric Oxide	19·504
Maganous Oxide	0·277
Alumina	38·576
Lime	23·438
Magnesia	47·878
Potash	63·248
Soda	315·332
Loss	0·007

The milky juice, which is contained in the unripe fruit in considerable quantity, disappears upon the ripening of the "mamao macho" fruit almost entirely, and then there is found in the flesh of such fruit traces of a caoutchouc-like substance, which doubtless originates from the small quantity of milk. On the other hand, the milk disappears from the fruit of "mamao femea" and "mamao malao" entirely on ripening, but the caoutchouc-like substance is in the "mamao femea" replaced by a yellow soft resin, and in the cultivated "mamao melao" by a dark reddish-yellow fatty oil. Both the latter sorts have a more delicate taste, and the "mamao melao" has actually a melon flavour. However, it is not to be denied that the taste is insipid and not particularly refreshing, as the prized free acids are entirely wanting in the fruit and only a trace of an aroma is present. The milk in the ripe juice is rich in free acid, but this disappears in the ripening.

I am at present engaged during my little spare time in the examination of the unripe fruit in different stages, and will return to the subject subsequently.

The seeds are frequently used as a vermifuge, and information as to the manner of administering them will be given at the close of this paper.

The examination of the seeds was unfortunately not completed; they deserve a perfect analysis, for which I can supply sufficient materials.

In my notes I have the following entries:

I. 500 grams of dried powdered seeds were repeatedly extracted with 90 per cent. alcohol, distilled, and the residue treated with hot distilled water as long as the water was coloured. Residue insoluble in water (A).

The watery solution, evaporated to the consistence of a thin syrup, and allowed to stand some time, yielded 0·803 gram of crystals, which proved to be a compound of lime with an organic acid. The mother liquor, upon evaporation gave 3·250 of extractive, having an unpleasant taste, and coloured dark brown by perchloride of iron.

The residue insoluble in water (A) consisted of an oil containing resin. It was carefully separated from the resin and weighed 73·333 grams; it was of a dark brown colour, and of the consistence of castor oil, odourless, and having a disagreeable flavour with long persistent acrid after-taste. In ether it was only partially soluble, and was preserved for further investigation as *papaya oil.* The resin weighed 3·833 grams and formed a tasteless and odourless dark brown powder.

II. 500 grams of finely pounded seeds were digested in a still at reduced pressure with caustic potash and 80 per cent. alcohol, strained and pressed; and the residue again treated in a similar way with alcohol. The united liquor was filtered and distilled, then evaporated to about 800 grams, when the separation of crystals was noticed and in consequence it was set aside for a time. It was then separated from the crystals, further evaporated, and allowed to stand for a longer time in a cool place. No crystallization or other separation was noticed, and it was now warmed and saturated with acetic acid in small excess. After a long time a brown oil separated; removed from this and carefully further evaporated a dark brown resin separated, which will be described further on. The liquid was separated from the resin and repeatedly shaken with ether. The ethereal solution evaporated gave 2·315 grams of an oil-like substance, having a peculiarly disagreeable taste and smell, which was easily soluble in ether and alcohol. Heated upon platinum it burnt with a smoke irritating to the eyes, and clear flame, and left no residue. This was preserved for examination as *caricin.* The liquid separated from the ether was evaporated and gave 14·722 grams of a nauseous tasting extract.

The crystals, etc., weighing 3·704 grams of a dazzling white fat acid, similar to palmitic acid, were preserved as *carica fat acid.*

The oil β, weighing 38·426 grams, behaved similarly to the papaya oil obtained in the first experiment.

III. 500 grams of finely pounded seeds were treated with caustic lime and distilled water as in the preparation of santonin. The impure precipitate thrown down by acid, was dissolved in alcohol and evaporated, then treated with boiling water, and separated by filtration from resinous substances. The watery solution, evaporated to a syrupy consistence and stood in a cool place, yielded after a long time granular crystals, which when dried weighed 8·722 grams. Heated upon platinum the substance melted to a clear liquid, and volatilized leaving only a trace of a black residue. In cold water it appeared insoluble, in boiling water and in cold alcohol soluble. The solution scarcely reddened litmus paper, and it had a cool bitter taste. It was preserved as *papayic acid* (?).

The resin acid was purified by repeated solution in alcohol and formed after evaporation a brownish substance that could be rubbed to a light brown powder. This had a bitter taste, with a pepper-like biting after-taste. On platinum it burnt with a smoke irritating to the mucous membrane to a small carbonaceous residue. It was insoluble in water and ether, and readily soluble in alcohol and alkalies. From a solution of carbonate of soda it was precipitated by acids in yellow flocks. The alcoholic solution of the resin slightly gelatinized with ammonia; it gave with acetate of copper a dark green precipitate and with acetate of lead and tincture of galls no reaction. Preserved for further experiments as *papaya acid resin*.

IV. 100 grams of dried seed powder were extracted with ether, alcohol, water, acids, and alkalies, and besides the above mentioned products there was obtained 0·220 gram of soft resin, very similar to the soft resin found in the flesh of the fruit of "mamao femea." The fatty oil was yellow coloured, and by ether only 5 per cent. of oil was obtained from the seeds.

The oil, the so called "caricin," and the resin acid were used against intestinal worms; all three products were active, but the most favourable results were obtained with the resin acid in doses of from 0·02 to 0·04 gram.

(*To be continued.*)

THE VALUE OF ALTHÆA AS A PILL EXCIPIENT.*

BY W. WALLACE BEITENMAN, PH.G.

The use of althæa as an excipient was suggested from the fact that it contains a large amount of mucilage, and in endeavouring to determine its value as such, I found it to answer admirably in every respect but one, which I shall shortly state.

The proportion of mucilage contained in good althæa is from 25 to 35 per cent. This it readily yields to boiling water, together with about the same amount of starch, some pectin, sugar, etc., which are also present. Treated with cold water, the mucilage, without the starch, is extracted, the infusion becoming ropy.

In experimenting with the althæa, it was used, however, only in the form of a fine powder. With some few substances, by using simply the powder with a little water or simple syrup, a pilular mass was readily obtained; but with most substances the amount of powder required was such as to render the pills too large. To remedy this, combination with other substances was resorted to. Tragacanth, acacia, syrup, solution and syrup of acacia, glycerin, etc., were tried, using them in different proportions and with various results. The best combination was produced by mixing six parts of althæa with one part of powdered tragacanth, and simple syrup sufficient to give the required consistence. By using a smaller proportion of tragacanth the adhesiveness was decreased; while on the addition of a larger proportion it was not materially changed. The use of either solution or syrup of acacia instead of simple syrup did not improve the mixture; while with glycerin the adhesiveness was much lessened. But by mixing about three parts of tragacanth with six of althæa, and then with glycerin, a mixture was obtained nearly as good as the first. In this the adhesiveness, without doubt, was due more to the tragacanth than to the althæa. Acacia used instead of tragacanth, either in the same or in larger proportions, was found far inferior to the latter. In short, in no way could I improve on the combination first mentioned. Giving that in definite quantities, we have the following formula:—

℞ Powd. Althæa	ʒi.
„ Tragacanth	grs. x.
Simple syrup	f ʒii.

Mix well.

This is easily and quickly prepared, is ropy, plastic, and of such adhesiveness that with heavy, inert substances, such as reduced and dried sulphate of iron, a small quantity will give a mass capable of being easily and thinly rolled out.

With quinia and other cinchona alkaloids it answers well, forming with them, either with or without the use of acid, masses of good consistence and plasticity; and, as but a small amount of excipient is required, the white colour of the alkaloids, which for elegance the pills ought also to have, is not perceptibly changed. In speaking of the colour, I may here state that in mixing the ingredients of the excipients it becomes of a pale somewhat dirty yellow colour. In comparing it with several excipients that have met with considerable favour, it was found that for adhesiveness and plasticity it was fully equal if not superior to the best.

Thus, then, for reasons already mentioned, and for its general adaptability, it would undoubtedly prove a valuable addition to the prescription counter were it not for one great objection, viz., that pills prepared with it soon become hard and insoluble.* This seems due mostly to the althæa itself; for with pills prepared with an excipient in which other substances were substituted for the tragacanth and syrup, and especially where althæa and water were used to make a mass, the effect was just about the same. Failing to remedy this tendency to harden, its value practically is naught.

In France althæa is said to be much employed in the preparation of pills and electuaries. On inquiring as to the manner in which it is there used, I was informed that in the preparation of pills it is never used as an excipient or ingredient, but simply to dust or place among them for the same purposes that we use lycopodium, powdered liquorice and rice flour, and when used in the preparation of electuaries, etc., only to give them bulk and consistence.

Here some prefer althæa to powdered liquorice in the preparation of blue pill. In this I fail to see the advantage, as it produces no change other than making the mass somewhat harder in consistence. In conclusion, to show the adhesiveness of the mixture of althæa, tragacanth and syrup, I subjoin a list of some substances made into pills, stating opposite each the amount of excipient required to form a mass:—

	grs.	Excip., grs.	No. of pills.
Pyrophosphate of iron . . .	45	5	15
Dried sulphate „ . . .	30	3	15
Quevenne's iron	30	4	15
Sulphate of quinia	20	2	20
„ cinchonidia . .	20	2	10
Calomel	50	3	10

* From the *American Journal of Pharmacy*, October, 1879.

* Pills made with powdered marshmallow root soon become dry and hard in consequence of the absorbent power of this powder for liquids; but we do not believe that they become insoluble, because marshmallow is capable of absorbing a large amount of liquid, and pills made with it are readily disintegrated.—*Editor Amer. Jour. Pharm.*

RADIANT MATTER.*

BY WILLIAM CROOKES, F.R.S.

(*Concluded from page* 330).

Radiant Matter is deflected by a Magnet.

I now pass to another property of Radiant Matter. This long glass tube (Fig. 14) is very highly exhausted; it has a negative pole at one end (*a*) and a long phosphorescent screen (*b*, *c*) down the centre of the tube. In front of the negative pole is a plate of mica (*b*, *d*) with a hole (*e*) in it, and the result is, when I turn on the current, a line of phosphorescent light (*e*, *f*) is projected along the whole length of the tube. I now place beneath the tube a powerful horseshoe magnet: observe how the line of light (*e*, *g*) becomes curved under the magnetic influence waving about like a flexible wand as I move the magnet to and fro.

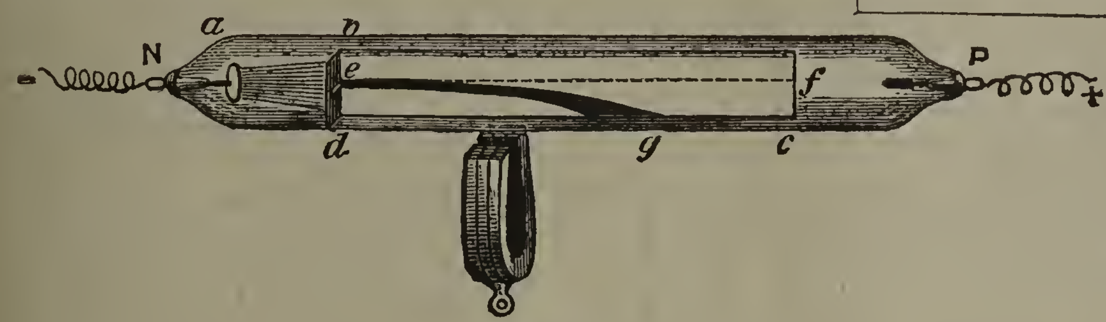

Fig. 14.

This action of the magnet is very curious, and if carefully followed up will elucidate other properties of Radiant Matter. Here (Fig. 15) is an exactly similar tube, but having at one end a small potash tube, which if heated will slightly injure the vacuum. I turn on the induction current, and you see the ray of Radiant Matter tracing its trajectory in a curved line along the screen, under the influence of the horse-shoe magnet beneath. Observe the shape of the curve. The molecules shot from the negative pole may be likened to a discharge of iron bullets from a mitrailleuse, and the magnet beneath will represent the earth curving the trajectory of the shot by gravitation. Here on this luminous screen you see the curved trajectory of the shot accurately traced. Now suppose the deflecting force to remain constant, the curve traced by the projectile varies with the velocity. If I put more powder in the gun the velocity will be greater and the trajectory flatter, and if I interpose a denser resisting medium between the gun and the target, I diminish the velocity of the shot, and thereby cause it to move in a greater curve and come to the ground sooner. I cannot well increase before you the velocity of my stream of radiant molecules by putting more powder in my battery, but I will try and make them suffer greater resistance in their flight from one end of the tube to the other. I heat the caustic potash with a spirit-lamp and so throw in a trace more gas. Instantly the stream of Radiant Matter responds. Its velocity is impeded, the magnetism has longer time on which to act on the individual molecules, the trajectory gets more and more curved, until, instead of shooting nearly to the end of the tube, my molecular bullets fall to the bottom before they have got more than half-way.

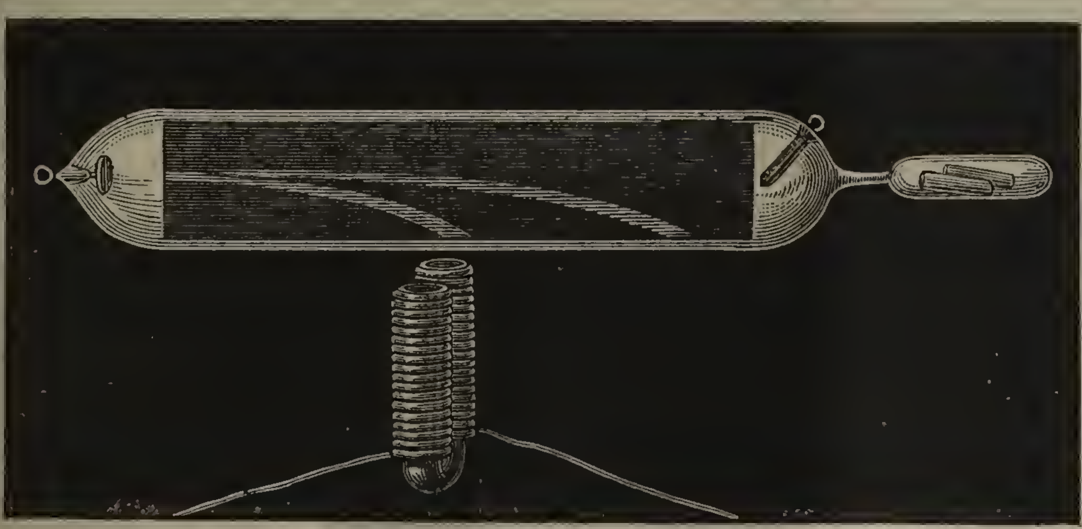

Fig. 15.

It is of great interest to ascertain whether the law governing the magnetic deflection of the trajectory of Radiant Matter is the same as has been found to hold good at a lower vacuum. The experiments I have just shown you were with a very high vacuum. Here is a tube with a low vacuum (Fig. 16). When I turn on the induction spark, it passes as a narrow line of violet light joining the two poles. Underneath I have a powerful electro-magnet. I make contact with the magnet, and the line of light dips in the centre towards the magnet. I reverse the poles, and the line is driven up to the top of the tube. Notice the difference between the two phenomena. Here the action is temporary. The dip takes place under the magnetic influence; the line of discharge then rises and pursues its path to the positive pole. In the high exhaustion, however, after the stream of Radiant Matter had dipped to the magnet it did not recover itself, but continued its path in the altered direction.

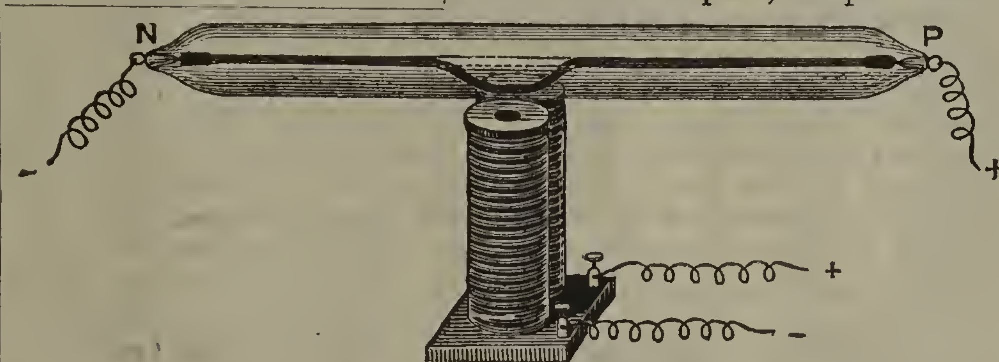

Fig. 16.

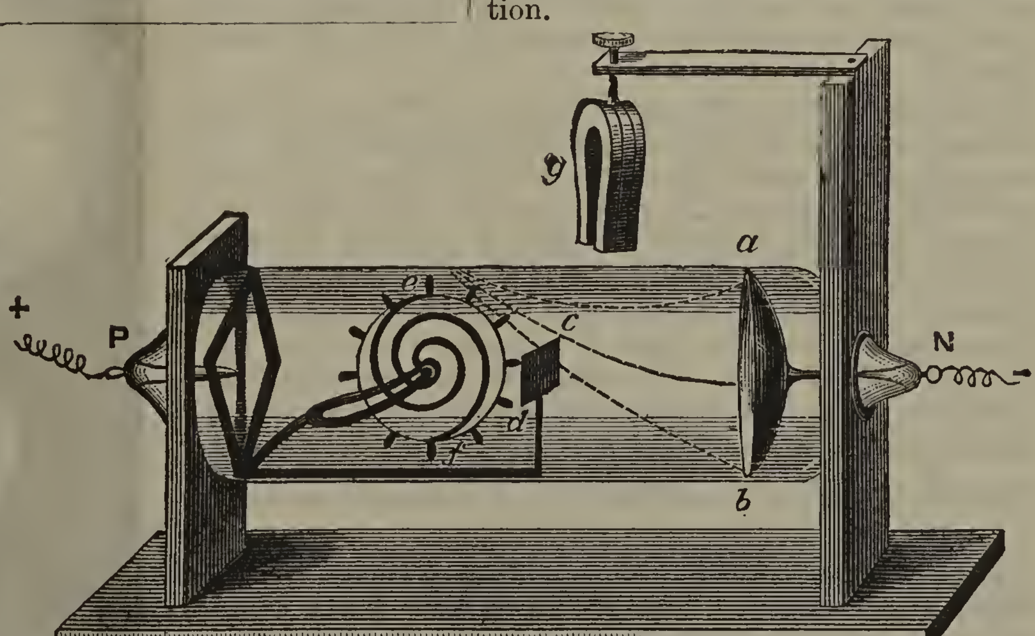

Fig. 17.

By means of this little wheel, skilfully constructed by Mr. Gimingham, I am able to show the magnetic deflection in the electric lantern. The apparatus is shown in this diagram (Fig. 17). The negative pole (*a*, *b*) is in the

* A lecture delivered to the British Association for the Advancement of Science, at Sheffield, Friday, Aug. 22, 1879.

form of a very shallow cup. In front of the cup is a mica screen (*c*, *d*), wide enough to intercept the Radiant Matter coming from the negative pole. Behind this screen is a mica wheel (*e*, *f*) with a series of vanes, making a sort of paddle-wheel. So arranged, the molecular rays from the pole (*a*, *b*) will be cut off from the wheel, and will not produce any movement. I now put a magnet (*g*), over the tube, so as to deflect the stream over or under the obstacle (*c*, *d*), and the result will be rapid motion in one or the other direction, according to the way the magnet is turned. I throw the image of the apparatus on the screen. The spiral lines painted on the wheel show which way it turns. I arrange the magnet to draw the molecular stream so as to beat against the upper vanes, and the wheel revolves rapidly as if it were an over-shot water-wheel. I turn the magnet so as to drive the Radiant Matter underneath; the wheel slackens speed, stops, and then begins to rotate the other way, like an under-shot water-wheel. This can be repeated as often as I reverse the position of the magnet.

I have mentioned that the molecules of the Radiant Matter discharged from the negative pole are negatively electrified. It is probable that their velocity is owing to the mutual repulsion between the similarly electrified pole and the molecules. In less high vacua, such as you saw a few minutes ago (Fig. 16), the discharge passes from one pole to another, carrying an electric current, as if it were a flexible wire. Now it is of great interest to ascertain if the stream of Radiant Matter from the negative pole also carries a current. Here (Fig. 18) is an apparatus which will decide the question at once. The

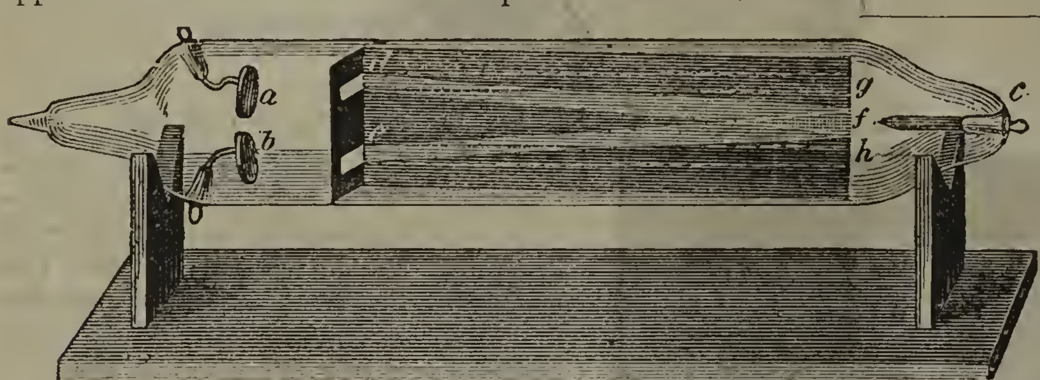

Fig. 18.

tube contains two negative terminals (*a*, *b*) close together at one end, and one positive terminal (*c*), at the other. This enables me to send two streams of Radiant Matter side by side along the phosphorescent screen—or by disconnecting one negative pole, only one stream.

If the streams of Radiant Matter carry an electric current they will act like two parallel conducting wires and attract one another; but if they are simply built up of negatively electrified molecules they will repel each other.

I will first connect the upper negative pole (*a*) with the coil, and you see the ray shooting along the line (*d f*). I now bring the lower negative pole (*b*) into play, and another line (*e*, *h*) darts along the screen. But notice the way the first line behaves; it jumps up from its first position *d*, *f*, to *d*, *g*, showing that it is repelled, and if time permitted I could show you that the lower ray is also deflected from its normal direction: therefore the two parallel streams of Radiant Matter exert mutual repulsion, acting not like current carriers, but merely as similarly electrified bodies.

Radiant Matter produces Heat when its Motion is arrested.

During these experiments another property of Radiant Matter has made itself evident, although I have not yet drawn attention to it. The glass gets very warm where the green phosphorescence is strongest. The molecular focus on the tube, which we saw earlier in the evening (Fig. 8) is intensely hot, and I have prepared an apparatus by which this heat at the focus can be rendered apparent to all present.

I have here a small tube (Fig. 19, *a*) with a cup-shaped negative pole. This cup projects the rays to a focus in the middle of the tube. At the side of the tube is a small electro-magnet, which I can set in action by touching a key, and the focus is then drawn to the side of the glass tube (Fig. 19, *b*). To show the first action

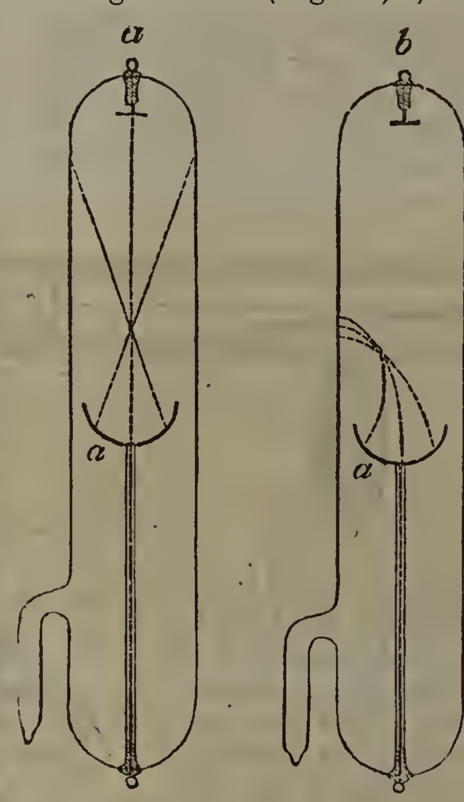

Fig. 19.

of the heat I have coated the tube with wax. I will put the apparatus in front of the electric lantern (Fig. 20, *d*: *vide* next page), and throw a magnified image of the tube on the screen. The coil is now at work, and the focus of molecular rays is projected along the tube. I turn the magnetism on, and draw the focus to the side of the glass. The first thing you see is a small circular patch melted in the coating of wax. The glass soon begins to disintegrate, and cracks are shooting starwise from the centre of heat. The glass is softening. Now the atmospheric pressure forces it in, and now it melts. A hole (*e*) is perforated in the middle, the air rushes in, and the experiment is at an end.

I can render this focal heat more evident if I allow it to play on a piece of metal. This bulb (Fig. 21) is furnished with a negative pole in the form of a cup (*a*). The rays will therefore be projected to a focus on a piece of iridio-platinum (*b*) supported in the centre of the bulb.

I first turn on the induction-coil slightly, so as not to bring out its full power. The focus is now playing on the metal, raising it to a white-heat. I bring a small magnet near, and you see I can deflect the focus of heat

Fig. 21.

just as I did the luminous focus in the other tube. By shifting the magnet I can drive the focus up and down, or draw it completely away from the metal, and leave it non-luminous. I withdraw the magnet, and let the molecules have full play again; the metal is now white-hot. I increase the intensity of the spark. The iridio-platinum glows with almost insupportable brilliancy, and at last melts.

The Chemistry of Radiant Matter.

As might be expected, the chemical distinctions between one kind of radiant matter and another at these high exhaustions are difficult to recognize. The physical properties I have been elucidating seem to be common to all matter at this low density. Whether the gas originally under experiment be hydrogen, carbonic acid, or atmospheric air, the phenomena of phosphorescence, shadows, magnetic deflection, etc., are identical, only they commence at different pressures. Other facts, however, show that at this low density the molecules retain their chemical characteristics. Thus, by introducing into the tubes appropriate absorbents of residual gas, I can see that chemical attraction goes on long after the attenuation has reached the best stage for showing the phenomena now under illustration, and I am able by this means to carry the exhaustion to much higher degrees than I can get by mere pumping. Working with aqueous vapour I can use phosphoric anhydride as an absorbent; with carbonic acid, potash; with hydrogen, palladium; and with oxygen, carbon, and then potash. The highest vacuum I have yet succeeded in obtaining has been the 1-20,000,000th of an atmosphere, a degree which may be better understood if I say that it corresponds to about the hundredth of an inch in a barometric column three miles high.

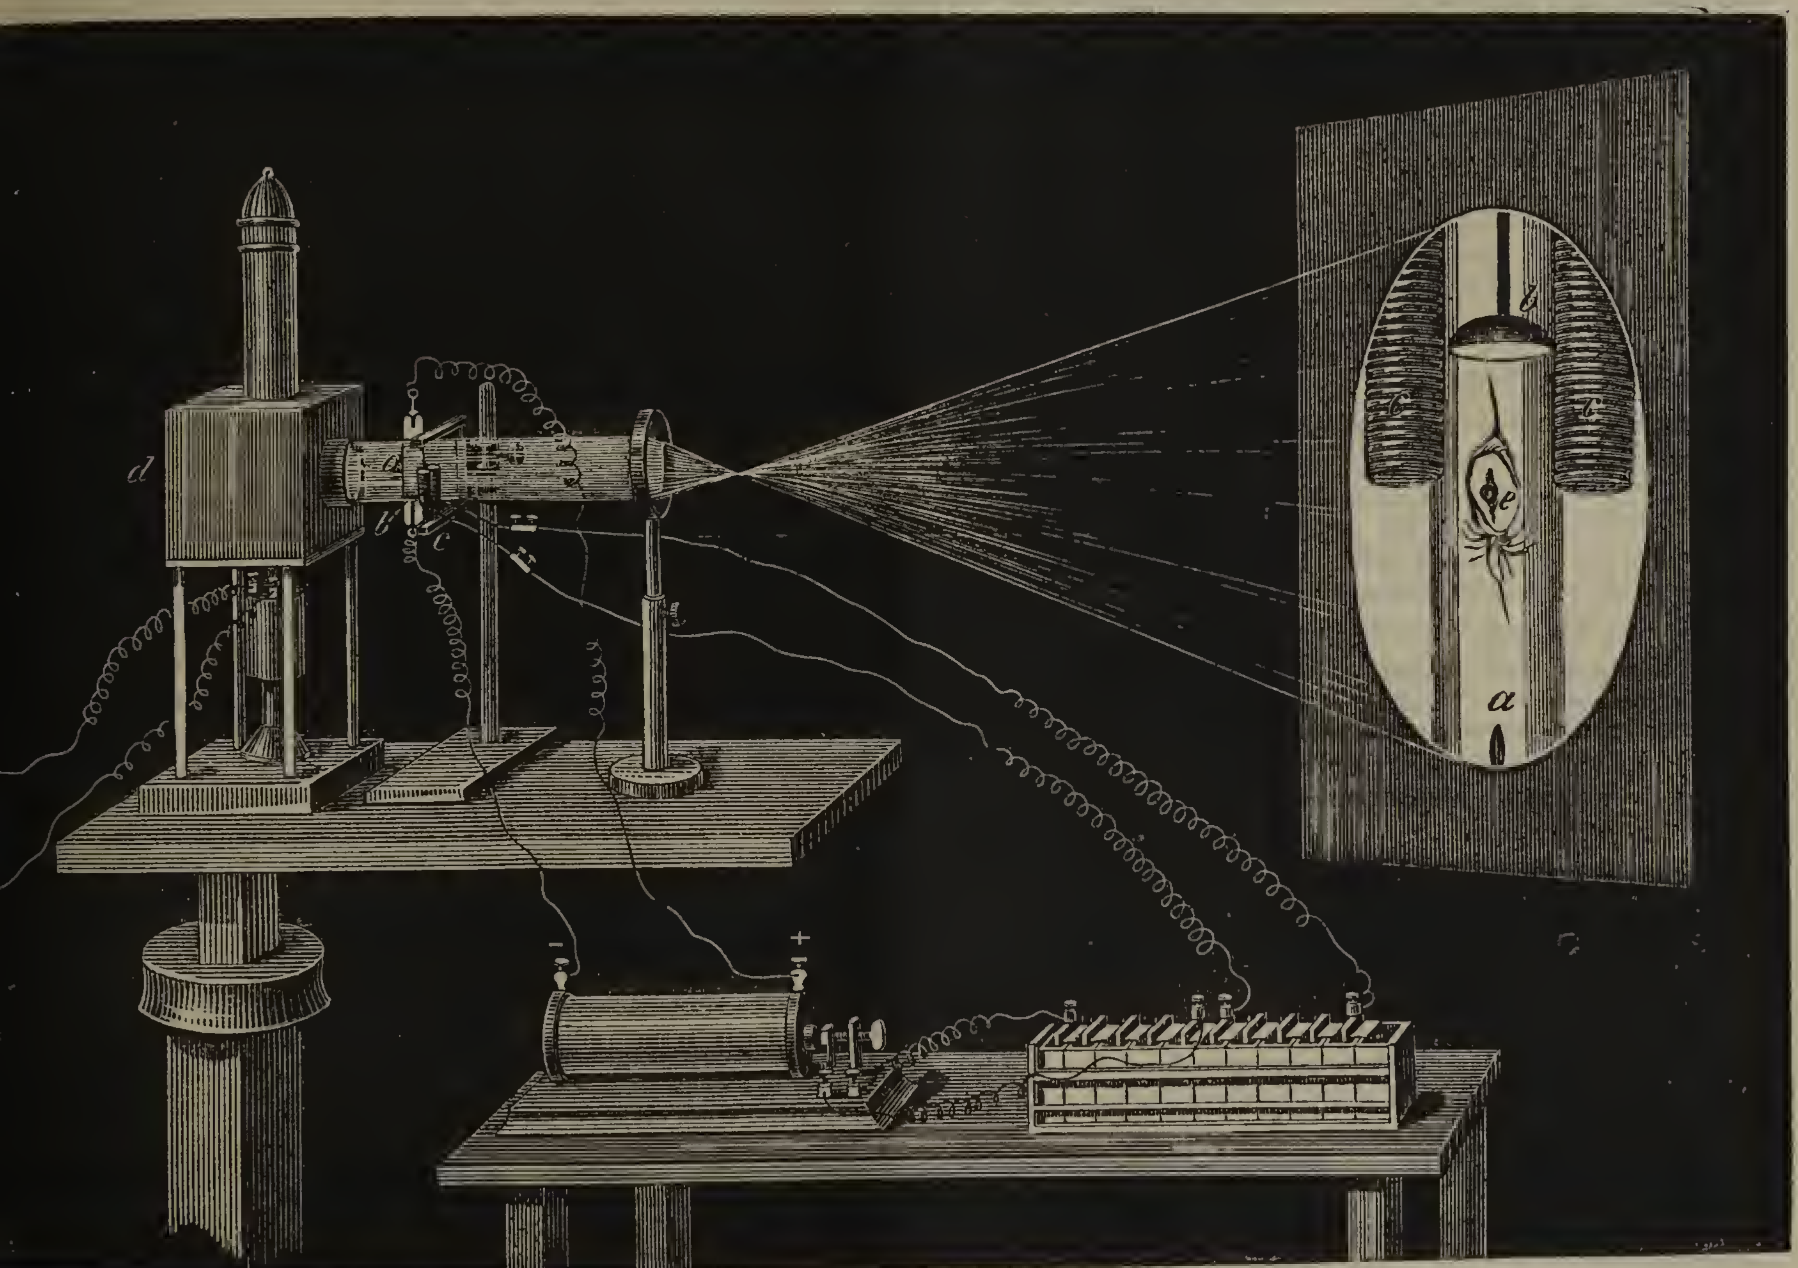

Fig. 20.

It may be objected that it is hardly consistent to attach primary importance to the presence of *Matter*, when I have taken extraordinary pains to remove as much Matter as possible from these bulbs and these tubes, and have succeeded so far as to leave only about the one-millionth of an atmosphere in them. At its ordinary pressure the atmosphere is not very dense, and its recognition as a constituent of the world of Matter is quite a modern notion. It would seem that when divided by a million, so little Matter will necessarily be left that we may justifiably neglect the trifling residue and apply the term *vacuum* to space from which the air has been so nearly removed. To do so, however, would be a great error, attributable to our limited faculties being unable to grasp high numbers. It is generally taken for granted that when a number is divided by a million the quotient must necessarily be small, whereas it may happen that the original number is so large that its division by a million seems to make little impression on it. According to the best authorities, a bulb of the size of the one before you (13·5 centimetres in diameter) contains more than 1,000000,000000,000000,000000 (a quadrillion) molecules. Now, when exhausted to a millionth of an atmosphere we shall still have a trillion molecules left in the bulb—a number quite sufficient to justify me in speaking of the residue as *Matter*.

To suggest some idea of this vast number I take the exhausted bulb, and perforate it by a spark from the induction coil. The spark produces a hole of microscopical fineness, yet sufficient to allow molecules to penetrate and to destroy the vacuum. The inrush of air impinges against the vanes and sets them rotating after the manner of a windmill. Let us suppose the molecules to be of such a size that at every second of time a hundred millions could enter, How long, think you, would it take for this small vessel to get full of air? An hour? A day? A year? A century? Nay, almost an eternity! A time so enormous that imagination itself cannot grasp the reality. Supposing this exhausted glass bulb, indued with indestructibility, had been pierced at the birth of the solar system; supposing it to have been present when the earth was without form and void; supposing it to have borne witness to all the stupendous changes evolved during the full cycles of geologic time, to have seen the first living creature appear, and the last man disappear; supposing it to survive until the fulfilment of the mathematical prediction that the Sun, the source of energy, four million centuries from its formation will ultimately become a burnt-out cinder ;* supposing all this—at the rate of filling I have just described, 100 million molecules a second—this little bulb even then would scarcely have admitted its full quadrillion of molecules.†

But what will you say if I tell you that all these molecules, this quadrillion of molecules, will enter through the microscopic hole before you leave this room? The hole being unaltered in size, the number of molecules undiminished, this apparent paradox can only be explained by again supposing the size of the molecules to be diminished almost infinitely—so that instead of entering at the rate of 100 millions every second, they troop in at a rate of something like 300 trillions a second. I have done the sum, but figures when they mount so high cease to have any meaning, and such calculations are as futile as trying to count the drops in the ocean.

In studying this Fourth state of Matter we seem at length to have within our grasp and obedient to our control the little indivisible particles which with good warrant are supposed to constitute the physical basis of the universe. We have seen that in some of its properties Radiant Matter is as material as this table, whilst in other properties it almost assumes the character of Radiant Energy. We have actually touched the border land where Matter and Force seem to merge into one another, the shadowy realm between Known and Unknown which for me has always had peculiar temptations. I venture to think that the greatest scientific problems of the future will find their solution in this Border Land, and even beyond; here, it seems to me, lie Ultimate Realities, subtle, far-reaching, wonderful.

"Yet all these were, when no Man did them know,
Yet have from wisest Ages hidden beene;
And later Times thinges more unknowne shall show.
Why then should witlesse Man so much misweene,
That nothing is, but that which he hath seene?"

NEW CEMENTS FOR DENTAL AND OTHER PURPOSES.‡

Charles Sylvester Rostaing di Rostagni, of Philadelphia, has procured patents for preparing cements for dental and other purposes, which are compounds of pyrophosphates.

A mixture of acid or neutral calcium phosphate is fused in a crucible together with zinc phosphate, or 1 part of calcium phosphate is fused with 10 to 30 parts of oxide of zinc, and enough ammonium phosphate to saturate the zinc oxide. The solidified, glassy mass is dissolved in dilute phosphoric acid; to the solution may be added a little magnesia or oxide of cadmium. The solution is evaporated, and when wanted for use the mass is dissolved in a little distilled water.

The inventor also prepares mixtures of phosphate of zinc, or magnesium, or cadmium with the above mass.

Another cement is prepared from 3000 parts oxide of zinc, to which are added 5 to 50 parts of boracic acid dissolved in alcohol or water. The oxide of zinc may partly be replaced by lime, magnesia or baryta. The mixture is heated for several hours to a white heat, and if desired coloured, a sufficient quantity of an aqueous solution of the characteristic metallic salts used for producing coloured beads may be previously added.

Zinc silicate, prepared by double decomposition of sodium or potassium silicate with a soluble zinc salt, may also be employed.

* The possible duration of the Sun from formation to extinction has been variously estimated by different authorities, at from 18 million years to 400 million years. For the purpose of this illustration I have taken the highest estimate.

† According to Mr. Johnstone Stoney (*Phil. Mag.*, vol. 36. p. 141), 1 c.c. of air contains about 1000,000000,000000,000000 molecules. Therefore a bulb 13·5 centims. diameter contains $13{\cdot}5^3 + 0{\cdot}5236 + 1000{,}000000{,}000000.000000$ or 1,288252,350000,000000,000000 molecules of air at the ordinary pressure. Therefore the bulb when exhausted to the millionth of an atmosphere contains 1,288252,350000,000000 molecules, leaving 1,288251,061747,650000,000000 molecules to enter through the perforation. At the rate of 100,000000 molecules a second, the time required for them all to enter will be

12882,510617,476500 seconds or
214,708510,291275 minutes, or
3,578475,171521 hours, or
149103,132147 days, or
408,501731 years.

‡ From *New Remedies*, October, 1879.

THE HANBURY MEMORIAL FUND.

A meeting of the Committee of Organization of the Hanbury Memorial Fund was held at 17, Bloomsbury Square, on Thursday, October 23.

The Secretaries reported that in accordance with the instructions of the General Committee at its final meeting on February 19, 1879, as reported in the *Pharmaceutical Journal* of March 8, 1879, the Pharmaceutical Society had been requested to act, by its Council, as trustees of the fund, biennially requesting adjudicators to award the medal, and afterwards presenting the medal so awarded. The Council had accepted the duties. £400 stock in consols had been purchased in the name of the Society. The adjudicators were to be "the respective Presidents for the time being of the Linnæan, Chemical and Pharmaceutical Societies, and of the British Pharmaceutical Conference, together with one pharmaceutical chemist, who shall, prior to each award, be nominated by the last named two Presidents."

Specimens in wax of the dies of the medal were laid before the Committee together with the following letter:—

"Plough Court, Lombard Street,
"August 12, 1879.

"Dear Professor Attfield,—Accept my thanks for a sight of the impression from the die for the memorial medal of my late cousin, Daniel. As now finished, it appears to be admirable, and the likeness excellent. It is remarkable that it should have been rendered so well.

"Yours very truly,
"Cornelius Hanbury."

Mr. H. B. Brady proposed, and Mr. T. H. Hills seconded a resolution to the effect that the dies be accepted, and be handed over to the custody of the Council of the Pharmaceutical Society, and that the costs be paid. Carried unanimously.

The draft deed of declaration of trust, as kindly drawn up by Mr. Flux, and as revised by the members of the Sub-Committee, was read and considered, and a resolution was proposed by Mr. M. Carteighe, seconded by Mr. G. F. Schacht, and carried,—"That the deed as drafted be accepted, that it be engrossed, and that the costs of engrossing and stamping be paid."

Instructions were given to the Secretaries to prepare a cash account and balance sheet for publication so soon as all costs were paid.

On the motion of Mr. W. Southall, the thanks of the Committee were voted to Professor Attfield for his labours in connection with the collection and organization of the Fund.

CHEMICAL SOCIETY.

The first meeting of the Chemical Society for the new session will be held on Thursday, November 6, when the following papers will be read:—On Alizarin Blue, by G. Auerbach. The Transformation Products of Starch, by C. O'Sullivan. Note on the Formulæ of the Carbohydrates, by H. E. Armstrong. A New Method of Determining Sulphur in Coal, by T. Nakamura. The Bromine Derivatives of β Naphthol, by A. G. Smith. Notes on the Dissociation of Ammonia Iron Alum, by J. S. Thomson.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 1, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

KEW GARDENS REPORT.

SOME of the most interesting material in the annual report of the Director of the Royal Gardens at Kew is the collection of reports from various parts of the world where attempts are being made to introduce the cultivation of plants that are useful as yielding drugs or other substances capable of being employed for technical purposes.

This year, a number of medicinal plants are mentioned, among which cinchona may be allowed to hold the first place. In British India, we learn that the introduction of Columbian species of cinchona into India is contemplated, and that Mr. CROSS has collected in New Grenada a number of plants of those species that yield the varieties of bark known as "Soft Columbian" and "Hard Carthagena," which are so largely used for the manufacture of quinine. Samples of bark corresponding to the different kinds were brought home by Mr. CROSS and examined by Mr. J. E. HOWARD, who reported that the soft Columbian variety known as Calisaya of Santa Fé was of the very best description, such as indicates the probability of a much larger production of alkaloid in the bark of more mature trees, and he is of opinion that if the young plants can be safely conveyed to India and established there, the bark obtained from them in the future may prove second to none. Among the plants of the "Hard Carthagena" kind one considered by Mr. HOWARD to be especially worthy of attention is from Coralis Inza, in the Magdalena Valley, yielding 4·75 per cent. of alkaloids, of which 1·88 was quinine and 1·18 cinchonidine. If it proves to be, as he thinks likely, a free grower, this plant might be well worth naturalizing in India.

These plants have been placed at Kew, under the care of Mr. CROSS, and he has reported to the Under-Secretary of State for India that though the number of Calisaya Santa Fé plants is somewhat reduced, fifteen of them are growing and rooting, and he is convinced they will soon become good established plants. Of the Magdalena Valley plants ten are now growing, but some of them are good, and he considers the fate of both sorts as being quite safe.

In Ceylon, cinchona cultivation has had to contend with very unfavourable weather; many old trees have died, and great numbers of cuttings have been destroyed, so that it will be necessary to establish fresh nurseries for rearing young plants. The bark of the trees cut down when they showed signs of bad health has sold well in the London market, and most of the stumps are again sending up fresh shoots.

According to recent accounts the cultivation of cinchonas in Ceylon has quite recovered from the discouragement produced during last year, and as it is stated that returns can be obtained from a cinchon plantation almost as soon as from one of coffee or tea it is probable that the enterprise will be carried out so as to add largely to the wealth and prosperity of the island. It may here be mentioned that one deficiency is the want of a supply of moss for covering up the trees during the growth of renewed bark, and there is an opportunity for introducing some other material as a substitute.

From Jamaica also there is news of success in the cultivation of cinchona. Mr. THOMPSON, late superintendent of the Botanic Gardens, and in charge of the cinchona plantations, reports that the trees, though growing at the low elevation of 2000 feet, are very healthy and well developed.

In some instances the trees of *Cinchona succirubra* in Jamaica have been found to be affected with a disease, apparently caused by the mycelium of a fungus permeating the cambium layer and the bark; but the number of trees thus attacked is small, and it is believed that the disease will be best met by at once felling the trees which appear unhealthy, securing the bark and carefully burning all the *débris.* The base of the stem will generally "coppice," or throw out fresh shoots.

Some of the bark sent to England from Jamaica last year realized a good price as compared with similar bark from India and Ceylon, and there are some thousands of acres of land in the parish of Manchester, having an elevation of about 3000 feet, that is said be especially well adapted for the cultivation of cinchona. At Gordon Town the results obtained show that cinchona cultivation would be very profitable in Jamaica, and the Government has therefore authorized the extension of the plantation by a hundred acres.

The use of the mixed alkaloids prepared from East Indian red bark appears now to be more successful. Dr. KING reports that increased experience has served to establish confidence in it, and there are now but few complaints of the nauseating effect which was at first objected to. Possibly the product sent into the market, or supplied for use in the hospitals, has been improved and made less objectionable. Considering also the high price that quinine has for some time past commanded, there will probably always be a field for the advantageous use of this mixed alkaloid if it continues to be manufactured in a sufficient state of purity.

Among the numerous interesting contributions to the Kew Gardens by persons living abroad, a fine plant of the Dracæna that yields the dragon's blood of

Socotra has been sent by Mr. W. Wykeham Perry, of H.M.S. "Undaunted," which was stationed at Aden during the past year. By the aid of Captain Hunter, Assistant Resident at Aden, it has been ascertained that the tree grows only at an elevation of about 1500 feet, that it is diœcious and that the plants of both sexes yield gum. To obtain the dragon's blood the bark is scraped and after some days the exudation is collected.

Among other plants sent to Kew by Mr. Wykeham Perry are several living specimens of the trees yielding the gum resin olibanum, and from the information furnished respecting the sources of olibanum it seems evident that much remains to be done before our knowledge of this subject is placed upon a thoroughly satisfactory footing. Unfortunately, the zealous collectors of Her Majesty's Customs made the collection of authentic specimens of frankincense brought home by Captain Hunter quite useless for study by hopelessly mixing the contents of the several boxes. Surely it might be possible in a case of this kind to allow such packages to pass through unopened, or at least, to have them examined in the presence of an officer of the institution such specimens are intended for.

Myrrh is another drug to the defective natural history of which Mr. Perry and Captain Hunter have made important contributions by sending to Kew Gardens a set of plants yielding the several kinds of myrrh known in Eastern commerce.

THE UNIVERSAL PHARMACOPŒIA.

Amongst the reports presented to the International Medical Congress, recently held in Amsterdam, was one by Professor Gille, of Brussels, from the International Commission nominated two years before at Geneva to deal with the subjects of uniformity in medicine and the construction of an universal pharmacopœia. This report is interesting in several respects, and especially because it discloses something like an abandonment of the idea of an international pharmacopœia in some pharmaceutical quarters.

It will be remembered* that the principles agreed to at the previous International Medical Congress, held in Geneva in 1877, as suitable for the basis upon which to construct such a work, were closely in accord with those adopted at the last International Pharmaceutical Congress, held in St. Petersburg in 1874. This fact was accordingly communicated to the St. Petersburg Pharmaceutical Society, to which body the carrying out of the decisions of the Pharmaceutical Congress appear to have been entrusted, through its President. This, however, led to no response. On the other hand, the St. Petersburg Society is said to have decided in March last to take no part in the next international pharmaceutical congress, which was to have been held this year in London, and, in July, to have sent back to M. Mehu, without a word of explanation, the scheme for an universal pharmacopœia elaborated by the Paris Society of Pharmacy, which had been referred to a committee of pharmacists to report upon.

Under these circumstances the present reporters think that it devolves upon the medical profession to take up the question of the universal pharmacopœia, and to apply the stimulus necessary to arouse the flagging interest of pharmacists. The report proposes that the commission should be authorized to select a Government to which application should be made to open negociations with other Governments, with a view to the nomination of an international commission to deal with the subject, utilizing as far as possible the work already done. This commission it is proposed should commence its labours immediately after its nomination, and the members of it to report progress to their respective Governments every two years, the subjects upon which they are not in accord being reserved for further investigation.

The report and its recommendations were agreed to by the Medical Congress, and it was decided that the scheme of the Paris Society should be printed in the official proceedings of the meeting at Amsterdam. It was also decided to add to the members of the Geneva Commission, Messrs. Sayre, of New York; Dechambre, of Paris; Ernest Hart, of London; Warlomont, of Brussels; Goye, of Amsterdam; and Palasciano, of Naples.

* See *Pharmaceutical Journal* [3], vol. viii., p. 261.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION

The opening meeting of the above Association for the present session will be held at 17, Bloomsbury Square, W.C., on Thursday, November 13, at 8.30 p.m., when the President, Professor Attfield, will occupy the chair, and the election of officers will take place.

We learn from a colonial newspaper that Mr. C. R. Blackett, the President of the Pharmaceutical Society of Victoria, has been elected a member of the Legislative Assembly for Fitzroy. Mr. Blackett has for some years occupied a prominent place among the pharmacists of Victoria, and in his former office of Honorary Secretary of the Pharmaceutical Society took an active part in the obtaining of the existing Act to regulate the practice of pharmacy in that colony. It appears that Mr. Blackett's popularity was sufficient to secure his election, notwithstanding that the influence of the Government was brought to bear on behalf of another candidate.

We have been requested by Mr. R. Hampson, of St. John Street Road, and Mr. W. M. Covell, of Hackney, to warn our readers against the representations of a man who is going about London soliciting charity with a petition purporting to bear their signatures which have been added without their authority.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 22, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Plowman, Southall and Taylor.

Dr. Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Seven candidates were examined. *Four* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Arnfield, John Cash..............Ashton-under-Lyne.
Bevan, William....................Ipswich.
Cook, William Richard ....Bath.

MINOR EXAMINATION.

Fifteen candidates were examined. *Five* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Austin, Alfred ....Birmingham.
Ballard, William ....Hammersmith.
Blower, Joseph ....Shrewsbury.
Bond, Peter Gillard ....Kingsbridge.
Brown, John ....Pontefract.
Cann, James ....Dorking.
Cheal, Harry Alexander ....London.
Chipp, James..........................Newport, I. W.
Clarke, Henry ....Whitehaven.
Constance, Sidney William......London.

MODIFIED EXAMINATION.

Four candidates were examined. *Two* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Carter, James ....London.
Jones, Thomas ....London.

October 23, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Plowman, Southall and Taylor.

MAJOR EXAMINATION.

Eight candidates were examined. *Five* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Gascoigne, Charles ....Hurworth.
Gibbons, Walter ....Manchester.
Howse, Charles Turk ....Cheltenham.

MINOR EXAMINATION.

Eighteen candidates were examined. *Nine* failed. The following *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cole, Edwin Henry ....Dorking.
Field, William ....Shoreham.
Fowler, William ....Sunderland.
Fryer, Charles Harry ....Leeds.
Godfrey, Henry......................Godalming.
Gordon, John ....Bradford.
Gould, Henry Thomas............Newport, I. W.
Greenwood, George ....Grantham.
Haden, Walter Edward ....Lichfield.

October 24, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Plowman, Southall and Taylor.

MINOR EXAMINATION.

Twenty-four candidates were examined. *Twelve* failed. The following *twelve* passed, and were declared qualified to be registered as Chemists and Druggists:—

Hearnshaw, John William ......Spalding.
Hessell, James ....Rye.
Hewlett, James......................Northwich.
Hoad, Frank ....Rye.
Hopkins, William..................Warwick.
Hornby, Charles Haycock ......Stockport.
Hutchin, William Francis W...Maidstone.
Jones, Henry.........................New Milford.
Jones, Llewellyn ....London.
Jones, Nathaniel Stevens ......Fulham.
Kilner, Frederick James.........Bristol.
Mason, Frederic Silvester ......Leicester.

October 29, 1879.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Plowman, Southall and Taylor.

Dr. Greenhow was present on behalf of the Privy Council.

MAJOR EXAMINATION.

Eight candidates were examined. *Five* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Laxon, Matthew ....Wisbeach.
Leach, Isaac ....London.
Mason, William Brandwood ...Bolton.

MINOR EXAMINATION.

Sixteen candidates were examined. *Eleven* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Moody, Lewis ....Lincoln.
Morgan, Alfred William.........Rochester.
Morris, Humphrey ....Dolgelly.
Parker, Charles......................Lancaster.
Powrie, Percival Chamberlain...Mossel Bay.

October 30, 1879.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Plowman, Southall and Taylor.

MINOR EXAMINATION.

Twenty-three candidates were examined. *Twelve* failed. The following *eleven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Reid, William ....Aberdeen.
Richardson, Arthur ....Epworth.
Sedgwick, John ....Blackpool.
Tanner, Herbert ....Wendlebury.
Thompson, John Tatham ......Scarborough.
Thompson, Thomas Clay.........Bedworth.
Watkinson, James ....Farnworth.
Watson, Robert John ....Market Rasen.
Wilding, George James ....Preston.
Williamson, Bamford ....South Shields.
Willson, Robert ....Boston.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the Royal College of Surgeons of England.

Beesley, William ....Banbury.
Buxton, Alfred ....Stafford.

Certificate of the Faculty of Physicians and Surgeons of Glasgow.

Burrows, Richard..................London.

Certificate of the Society of Apothecaries.

Sharman, J. Schultz Wm. E....Norwood.

Certificates of the University of Cambridge.

Eastes, Ernest John ....Deal.
Hall, Robert Edward ....Camborne.
Readman, Edward James ......Newport Pagnell.
Youngman, William Edward...Bury St. Edmunds.

Certificates of the College of Preceptors.

Atkinson, Robert B..............Pontefract.
Barritt, Ernest Henry...........Colchester.
Brown, Ernest Ansell ....Margate.
Lugton, Peter ....Manchester.
Thew, Thomas William ....Sunderland.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting of the thirty-first session was held at the Royal Institution, on Thursday evening, October 23, the President, Charles Symes, Ph.D., in the chair.

The minutes of the previous meeting were read and confirmed.

The following donations were announced:—The current number of the *Pharmaceutical Journal*, the 'Proceedings of the Liverpool Geological Society' for two sessions 1877–8 and 1878–9, and the *Canadian Pharmaceutical Journal.*

Messrs. J. Barker Galloway and Albert Kehlstadt were elected members.

The President called attention to some remarks of Professor E. Pollaci, published in the *Italian Chemical Gazette*, relative to the process technically known as "Plastering Wines." It was there stated that if gypsum were added to wine during fermentation the proportion of alkaline sulphates dissolved might reach 5 or 6 grams per litre; in fact, the sulphates and tartrates were present to such an extent as to render the wine a saturated solution of them. The public are now demanding a greater state of purity in articles of food, drugs, etc., and he thought it well that *connoisseurs* should be made aware of the fact that under the name of wine they might possibly be drinking a "saturated solution of plaster of paris." This had also a special interest for pharmacists seeing that it might account for some of the impurities in cream of tartar.

Mr. Symes then gave a short discourse on "Radiant Matter." He thought it would be of special interest to the members, now that Mr. Crookes's Sheffield lecture was being published in the *Pharmaceutical Journal*, to have the subject illustrated by experiments. He briefly summarized the characters of the three conditions of matter commonly known, viz., the solid, liquid and gaseous, and then passed on to compare the latter with the ultra-gaseous condition. The mean free path of the molecule, lines of molecular pressure, were experimentally illustrated by means of a series of beautifully illuminated tubes.

Mr. Thomas Johnson, F.I.C., F.C.S., made a communication, which he illustrated with diagrams and experiments, on—

Some Recent Improvements in Burettes, Siphons, Reagent Bottles, and Apparatus for taking Specific Gravity.

The first was *A New Apparatus for taking Specific Gravities of Solids* by means of the volume of water displaced. The apparatus consists of a cylindrical vessel containing water. The top of the cylinder is covered with a brass lid, through the centre of which a needle can be screwed till the point touches the surface of the water contained in the jar. When the substance is dropped into the water the needle is screwed up till the point again rests on the surface of the water, and the displacement is shown on a scale, or the water is drawn off to its original level in an accurately graduated tube.

An Apparatus for Estimating Nitrates by Pelouze's Method.—A flask is fitted with a hollow stopper; a conical glass rod fits into the bottom of the stopper; the funnel-shaped stopper is filled with alkaline solution. On boiling the contents of flask, the steam lifts up the little rod and escapes without allowing the alkaline solution to enter the flask; when the boiling is finished the conical rod is sucked tightly against the opening of the stopper, so no air can enter the flask and vitiate the results.

The glass bead key, a piece of glass in the form of an egg, is introduced into an indiarubber tube, connected with some vessel containing liquid. On gently pressing over the bead with thumb and fore finger, the liquid will flow as required through the tube.

Apparatus for Decanting Liquids.—A bottle without a bottom is inverted and the liquid poured in, a cork fits the neck of the bottle through which passes a glass tube connected by an indiarubber tube to an inner tube which slides up and down. To decant the liquid the inner tube is drawn downwards till the orifice is just above the surface of the sediment.

A New Reagent Bottle.—This bottle is fitted with a hollow glass stopper, filled with cotton wool to exclude dust; a bent glass tube fits in a hole drilled in the shoulder of the bottle, as in an ordinary wash bottle. On placing the forefinger on the opening of the hollow stopper and inclining the bottle no liquid will flow, but on removing the finger the liquid flows instantly, continuously or in drops as required.

Bottles containing standard solutions can be fitted as above, and if it is desirable to exclude atmospheric air from them they can be kept in an atmosphere of carbonic acid. The apparatus for this consists of two bottles which swing on a pivot. When the bottle generating the gas is raised, the acid liquid flows into the other bottle below and the gas ceases to be produced; on raising the other bottle again the acid flows into the generator containing the carbonate of lime and more gas is produced.

A New Burette Float.—This is made square instead of round, so as to diminish the friction against the sides of the burette.

The next communication was on—

A Factitious Sample of Powdered Scammony.

BY M. CONROY, F.C.S.

Writing on scammony, Pereira said "It is adulterated to such a large extent by the peasants who extract, and the Jew dealers who export it, that it is hopeless to seek for a pure specimen except in pharmaceutical museums." This remark is as true to-day as when it was first penned twenty-five years ago, for the difficulty of obtaining gum that will yield even the minimum percentage of resin is exceedingly great, and it is consequently with the greatest difficulty that wholesale houses are able to guarantee their virgin scammony to contain 80 per cent. of resin. Although adulterated samples are, unfortunately, so plentiful, they rarely get into use without their real value having been ascertained, for as a rule, all wholesale houses analyse samples before buying, and buy and sell according to the amount of resin which the sample contains. The most common adulterant is wheaten flour, but occasionally wood ashes, lampblack, gum, etc., are met with.

It is not, however, an adulterated sample that I intend bringing before you this evening, but an entirely factitious one, made up of wheaten flour and resin of scammony. It was purchased from a wholesale house as fine Aleppo powdered gum, but the purchaser doubting its genuineness, sent it to be analysed, and for that purpose it came into my hands. Fine Aleppo scammony is, as you are well aware, commercially known as a kind inferior to the "virgin," and, so far as my experience goes, contains usually from 50 to 70 per cent. of resin. Its odour is, like that of the virgin quality, pleasant and cheesey, but it is considerably tougher, breaks with a rougher fracture, and its powder is generally much darker in colour.

This sample, you will notice, is of a pale buff colour, is entirely devoid of even a trace of the cheesey odour of the gum, but possesses in a marked degree the strong peculiar odour of the resin prepared from the root.

Having satisfied myself by a careful ocular and nasal examination that it was an entirely factitious sample, I exhausted it with ether and obtained 15 per cent. of resin, the remaining matter insoluble in ether consisted almost exclusively of wheaten flour.

The gummy matter found in genuine scammony was entirely absent, as were likewise the usual impurities, such as particles of the root, sand, etc.

From these facts the only conclusion that can be drawn is that the sample is an entirely artificial one, and the sublime simplicity of a wholesale firm attempting to pass off such an article as this for fine Aleppo scammony is certainly very amusing. I am informed that the addition of resin of scammony is frequently resorted to, as a means of bringing up inferior powder to the official standard, but I must say that I have never myself met with any such samples. Such an addition, however, can be readily discovered by the nose, for the odour of resin of scammony is so characteristic and powerful that anyone possessed of a keen sense of smell could discover the presence of even 2 or 3 per cent.

While on this subject, it would, perhaps, be interesting to some of our younger members and associates were I to give a *modus operandi* for the assay of this gum. The Pharmacopœia simply states that ether should remove from 80 to 90 per cent. of resin; but as there are so many ways by which this could be done, some giving more accurate results than others, I will just explain the one by which I work myself, and which I can safely say gives thoroughly accurate results.

50 grains of moderately fine powdered gum, mixed with about double its bulk of powdered glass, is placed in a small percolator: the one which I have here answers admirably; it is the tube of a 2 oz. glass male syringe having a plug of glass wool so placed as to prevent any particles from getting into, or passing through the neck. On the glass wool is placed powdered glass, to the depth of about a quarter of an inch, and on to this the mixture of powdered glass and scammony is placed. Ether is then passed through, until the whole of the resin is extracted, which is seen by the ether passing through colourless. The ethereal tincture is collected in an accurately tared beaker, of about 2 fluid ounces capacity, and placed in the drying oven, which has been previously heated, and the gas extinguished to avoid the ether vapour firing. The heat of the oven will be sufficient to drive off the ether in about ten or fifteen minutes, when the gas may be relit, and the drying completed at 212° Fahr. Towards the end of the process, if the resin be not stirred, it will rise in the beaker in the form of a light, spongy mass, in which condition it rapidly dries. The net weight is then taken, and this multiplied by 2 gives the percentage of resin.

Interesting discussions followed each communication, in which the President, Messrs. Conroy, Davies, Johnson, Hallawell and Watt took part.

LEEDS CHEMISTS' ASSOCIATION.

The annual social meeting of the members, associates and friends was held on Wednesday, October 22, 1879, at the Green Dragon Hotel, Guilford Street, where dinner was provided at eight o'clock p.m.

The President, Mr. Councillor Stead, occupied the chair, and the Vice-President, Mr. S. Taylor, acted as croupier.

After dinner, the usual loyal toasts of "The Queen," "The Prince and Princess of Wales and the Royal Family," were proposed by the Chairman, and drunk with honours.

Mr. S. Taylor proposed "The Town and Trade of Leeds," referring to the steadiness which characterized the trade of the town, due no doubt to the great variety of manufactures carried on in it.

Mr. P. Jefferson briefly replied.

Mr. T. Fairley, F.R.S.E., proposed "The Leeds Chemists' Association," an institution which had done much good, and was calculated to be of service hereafter, especially if the unpleasantness caused by the reduction in some cases of the usual retail prices was overcome.

In responding, Mr. E. Yendall pointed out the advantages which the Society offered, and expressed an opinion that the impression which many of the apprentices of the present day had that it was impossible to study and attend to the duties of the shop was a fallacy, and that instead of leaving over the preparation for their examination until they could place themselves under some London crammer, by systematic study any youth might easily prepare himself without any fear of the consequences.

The Chairman said that as the population of towns increased the necessity would arise for greater facilities by which the youths of successive generations should be educated, and he was glad to refer to the manner in which these demands had been met, the last addition being the Yorkshire College. He had therefore great pleasure in proposing "The Scientific and Educational Institutes of the Town," coupling with the toast the names of Mr. R. Reynolds, F.C.S., and Mr. George Ward, F.C.S.

Mr. Reynolds acknowledged the toast on behalf of the Philosophical Society and the Yorkshire College, accrediting the Chairman with the happy thought which had resulted in this dinner. He rejoiced to be able to say that several members of the Society were attending the day classes of the College, and that there was every promise of success attending the scheme. Last year the expenditure of the College consequent upon the number of professors and assistants, was over £4000, and towards this sum £1500 had been received in fees, a result which he thought was very encouraging in such a young institution.

Mr. George Ward, Lecturer upon Chemistry at the Mechanics' Institute, urged a better attendance at the meetings of the Society. There was nothing chilled the ardour of a lecturer more than a meagre attendance, and upon some occasions there had been a very small number.

A vote of thanks to the Chairman and Vice-Chairman brought an agreeable evening to an end.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION AND SCHOOL OF PHARMACY.

The eleventh annual meeting of this Association was held on Tuesday, October 28. Mr. W. Wilkinson, Vice-President, in the chair.

The following annual report of the council was presented:—

"The past year has been uneventful in the history of our Association. The ordinary winter meetings were held at the Memorial Hall, tea being provided. At some of these meetings scientific subjects were brought before the members, whilst others afforded opportunity for the discussion of important trade questions now occupying the serious attention of chemists and druggists.

"Your committee regret that the usefulness of these meetings is not more generally recognized by members, and that so few realize the importance of their individual interest in the aims of the Association.

"The attendance at the classes held in connection with the Association was smaller than usual; this being attributed by the lecturer mainly to the fact that the fees demanded were somewhat high, whilst the ability to pay on the part of students has been adversely influenced by the depression of trade prevalent in the district.

"In order to meet this condition of things, your committee have this year made a considerable reduction in the fees, and have applied to the Council of the Pharmaceutical Society for a grant of money to supplement the fees as remuneration to the lecturer.

"Your committee have much pleasure in informing you that the sum of £35 has been granted by the Pharmaceutical Society in answer to this application.

"In order that the classes may be made as widely useful as possible, a resolution will be proposed for acceptance by the present meeting abolishing the associates' subscription to the Association, and throwing the classes open to all connected with the trade as assistants or apprentices.

"Your committee trust that this endeavour to restore the Manchester School of Pharmacy to its former scale of usefulness may be cordially seconded by parents and employers, without whose co-operation very limited success can be hoped for.

"In conclusion, your committee again ask the support of all engaged in the practice of pharmacy in this district, and venture to urge those members who have hitherto only contributed to the funds of the Association, to add the encouragement of their presence to the forthcoming winter meetings."

The Treasurer, Mr. G. S. Woolley, having presented his statement of accounts, the report and balance sheet were adopted by the meeting.

A resolution moved by Mr. J. B. Payne, and seconded by Mr. Jas. Botham:—"That the associates' fee be no longer charged," was carried unanimously.

The concluding business of the meeting was the election of officers for the session 1879-80. The following gentlemen were appointed:—

President, Mr. W. S. Brown; Vice-Presidents, Mr. J. T. Slugg, F.R.A.S., and Mr. W. Wilkinson; Treasurer, Mr. G. S. Woolley; Hon. Secretaries, Mr. F. Baden Benger, F.C.S., and Mr. H. Woolley; Council, Messrs. Blain (Bolton), Boor, Botham, Bowden (Patricroft), Hargraves (Oldham), S. Kay (Stockport), B. Robinson, Ralph Robinson (Rochdale), Slack, Westmacott.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held at the Cross Keys Hotel on Thursday evening, the 23rd inst., the President, Mr. James Oldham, in the chair.

The report and balance-sheet, having been read and discussed, were unanimously adopted. Votes of thanks were accorded to the officers for the valuable services they had rendered to the trade during the past year. A ballot was then taken for officers, with the following result:—President, Councillor Myers; Vice-President, Mr. J. Grindell; Hon. Secretary and Treasurer, Mr. C. B. Bell; Committee—Messrs. Hammond, Oldham, Stoakes and Hayles. Regret was expressed that Mr. Stoakes had decided not to accept the office of hon. secretary, as during the three years he had held that position he had been most efficient, and had given universal satisfaction.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual conversazione of this Association was held at St. James's Hall, on October 22. A numerous company assembled, amongst whom were noticed several well-known pharmacists.

The programme, consisting of vocal and instrumental performances interspersed with recitations, seemed highly appreciated by the audience and was carried out in a very creditable manner.

Scientific apparatus and objects of interest were kindly lent by various firms. Amongst others we may mention those by Messrs. Maw, Son and Thompson, Messrs. Jackson and Co., and Mr. Rimmel. A splendid assortment of microscopes was exhibited by Messrs. Ladd, Pillischer and Swift, and some rare and new chemicals by Messrs. Hopkin and Williams.

A large amount of attention was given to the collection of Dr. Muter, which consisted of very fine vacuum tubes, microspectroscope, saccharimeter, telephones and microphones, spectroscopes, etc.; and the value of this exhibit was greatly enhanced by the able manner in which the various pieces of apparatus were demonstrated by Dr. Muter and his assistants.

Parliamentary and Law Proceedings.

PROSECUTION FOR SALE OF PAREGORIC DEVOID OF OPIUM.

John Boar, of Ashover, was charged with selling as paregoric a preparation which was entirely destitute of opium.

Colonel Shortt, inspector of weights and measures, said on September 2 he went to defendant's shop for three ounces of paregoric. Defendant served him and he paid 8*d.* for the three ounces. He then told defendant he had purchased it for the purpose of having it analysed. He divided it into three parts in the presence of defendant and sealed each part. He gave defendant one, kept one himself, and sent one to Mr. Allen, the public analyst of Sheffield. Mr. Allen had reported that the preparation was entirely wanting in opium, of which there should be two grains to the ounce.

Defendant said he purchased it of Greaves and Sons, of Chesterfield, and that they informed him he was right in selling it as a mixture free from opium.

Colonel Shortt said he had consulted Mr. Allen on this point, and had received the following reply:—"'Paregoric Elixir' always was, and always is, understood to contain opium. No one objects to shopkeepers selling a common domestic medicine (free from poison), if they will do it under such a name as not to cause mistakes. Dangerous and even fatal results are continually happening owing to the preparation, destitute of opium, being sold under the name of 'Paregoric.' Its failure to produce the intended effects leads to an increase in the dose, and then when the genuine article is obtained, as it will be if a druggist is asked for it, poisonous effects are produced. . . . I am strongly of opinion that the sale of paregoric destitute of opium ought to be put a stop to. It is an abuse similar to the selling of children's gunpowder, warranted not to go off. P.S.—You are at liberty to make any use you like of this letter. I may say that my attention was first called to the importance of the question by medical men and druggists. (Signed), Alfred H. Allen, Sheffield."

Mr. J. S. Robinson, pharmaceutical chemist, of Alfreton, was then sent for by the magistrates, and having consented to give what information he could about any drug, was put on oath and said that paregoric according to the standard should contain two grains of opium to the ounce. A nominal fine of 1*s.* was inflicted, with costs 11*s.* 6*d.*—*Derbyshire Courier.*

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[345]. This injection appears to have given rise to a difference of opinion, as to whether the mixture should be filtered or sent out (with a "Shake the bottle" labe

on) containing the insoluble sulphate of lead. I write from practical experience, not from theory. I have dispensed and seen others dispense, both here and in London, dozens of injections similar to the one mentioned, but have never known one yet to be filtered. Mr. J. B. L. Mackay says that "Some prescribers make the combination in ignorance of its incompatibility." I have only to add that the formula of Dr. Ricord (without doubt the most celebrated physician in the world for sexual maladies) contains the same precipitate, as also does the well-known "Injection brou." The fact is that sulphate or acetate of zinc prescribed alone is more apt to produce stricture, which is avoided by the soothing properties of the insoluble sulphate of lead.

Injection Astringente (Ricord)—
Sulfate de Zinc,
Acétate de Plomb. . . . . . āā 1·0
Eau de Roses . . . . 200·0

Il y a production d'un précipité de sulfate de plomb, *qu'on laisse dans la préparation.—L'Officine* (*Dorvault*).

WILLIAM FOX.

14, *Rue de la Paix, Paris.*

[365]. The two ointments should be freshly prepared, the ung. potas. iodid. to contain double at least the quantity of potas. bicarb. ordered in the B.P. By this method a white creamy ointment will be produced; but on keeping a short time, mercuric iodide will form and change the colour of the ointment, showing what affinity the one element has for the other.

LAVANDULA.

[366]. Dissolve the carbolic acid in the olive oil, then rub the ext. opii with a little distilled water, to a smooth paste, then gradually add the oil and affix "Shake the bottle" label.

LAVANDULA.

[367]. Pitch can be made into very good pills by simply soaking in warm water until sufficiently soft, and rolling out quickly on a slightly warmed machine.

J. F. THURSFIELD.

[368]. Would some of your readers kindly give me their opinion on the following:—

℞ Sp. Ammon. Arom. . . . . . . ʒij.
Tinct. Zingib. . . . . ʒiss.
Sp. Æther Nit. . . . . ʒij.
Pot. Bicarb. . . . . ʒiss.
Aq. . . . . ad ℥viij.
M. ft. mist.

I dispensed it with tr. zingib., B. P., it was returned with the remark that it was not so strong and very much more milky than it was when dispensed in Scarboro'. I afterwards used the soluble essence with satisfactory results. Which was right?

LEO.

[369]. May I call the attention of skilled dispensers to the following prescription recently handed to me with the caution that I would dispense it carefully, as the doctor had warned the patient that it could not otherwise be made takeable?—

℞ Camphor . . . . grs. 50.
Ammon. Carb. . . . . grs. 50.
Spt. Æther. Nit. . . . . . . ♏ 50.
Liq. Ammon. Acet. . . . . . ♏ 100.
Glycerini,
Aquæ Rosæ, part. æqual. . . ad ℥x.
Take ℥j every half hour.

After proceeding to the best of our ability, conscientiously abstaining from making any alteration or addition whatever, we obtained but an unsightly mixture, the camphor separating to the top.

This was returned with a request that we would try and mix it better, as others had done (the prescription bore the stamps of two other chemists), the doctor having stated that he could mix it perfectly.

We thereupon loosened the reins of our conscience with a much more satisfactory result; but I would ask those gentlemen who insist upon strictly "faithful dispensing," how they would proceed in the present case? I would also call attention to the large dose of camphor, 5 grains "every half hour."

F. R. BESSANT.

[370]. Would any dispenser inform me how to dispense the following, and if it ought to be filtered or not?—

℞ Liq. Strychniæ . . . . ʒj.
Sp. Myristicæ . . . . ʒss.
Tinct. Ferri Perch. . . . . ʒij.
Aq. Destill. . . . . ad ℥viij.
M. Ft. mist.

CUMBERLAND.

Notes and Queries.

[629]. ROOKE'S GOLDEN OINTMENT.—In a private letter to a friend a few years ago, Dr. Rooke gave the following formula for his ointment:—

℞ Hydrarg. Perchlor. . . . . gr. ij.
Acid Hydrochlor. pur. . . . . . ♏x.
Hydrarg. Nitr. Ox. (levigated) . . . ʒj.
Adipis . . . . ℥viij.
M.S.A.

C. PARKINSON.

[633]. LIN. SAPONIS.—*Delta* in making the lin. saponis, P.B., has, he supposes, exceeded the temperature, viz., 70°, and the soap has gelatinized. Can any of your readers recommend him what to do with it, as in its present state it is quite useless?

[634]. COLOURING FOR WAX.—Can any reade of the Journal inform me of a deep red colouring to use for bees'-wax melted in oil of turpentine?

"EPSILON.'

Obituary.

Notice has been received of the death of the following:—

On the 18th of September, 1879, Mr. Thomas Henry Morris, Chemist and Druggist, St. Asaph. Aged 32 years.

On the 20th of September, 1879, Mr. Morley Thompson, Pharmaceutical Chemist, Princes Street, Rotherhithe. Aged 66 years. Mr. Thompson had been a Member of the Pharmaceutical Society since 1864.

On the 25th of September, 1879, Mr. George John Haddock, Chemist and Druggist, North Street, Brighton. Aged 36 years.

On the 5th of October, 1879, Mr. William Bentley, Chemist and Druggist, New Basford. Aged 47 years.

On the 14th of October, 1879, Mr. John Sneed, Chemist and Druggist, High Street, Keighley. Aged 51 years.

On the 15th of October, 1879, Mr. James Keith, Pharmaceutical Chemist, Union Place, Aberdeen. Aged 69 years. Mr. Keith had been a Member of the Pharmaceutical Society since 1853.

On the 20th of October, 1879, Mr. William Swarbrick Blackhurst, Chemist and Druggist, Poulton Street, Kirkham. Aged 42 years. Mr. Blackhurst had been a Member of the Pharmaceutical Society since 1874.

On the 23rd of October, 1879, Mr. John Morris, Chemist and Druggist, Brecon Aged 64 years.

On the 27th of October, 1'879, Mr. William Field, Pharmaceutical Chemist, Regent Street, W. Aged 51 years.

On the 27th of October, 1879, Mr. William Frederick Wright, Chemist and Druggist, Regent Street, Leamington. Aged 36 years. Mr. Wright had been a Member of the Society since 1872.

BOOKS, PAMPHLETS, ETC., RECEIVED.

ANNALS OF CHEMICAL MEDICINE, including the Application of Chemistry to Physiology, Pathology, Therapeutics, Pharmacy, Toxicology, and Hygiene. Vol. I. By J. L. W. THUDICHUM, M.D. London: Longmans, Green and Co. 1879.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE CREAM OF TARTAR OF THE PHARMACOPŒIA.

Sir,—As Mr. Tanner wishes me to state the purpose for which the neutralizing test for cream of tartar is given in the Pharmacopœia, if it be not to prove the absolute purity of the article as a potash salt, I may inform him, although I am sure he does not need the information, that while it admits and credits in the estimation the tartrate of lime which the previous test has recognized, it excludes other impurities, such as sulphate of barium or sulphate of calcium. If he still sees ambiguity in this, I can only say I am sorry for it. To me it seems sufficiently clear and consistent.

I find from his explanation that I misunderstood what he meant by first saying he was not prepared to admit that there should be more than a trace of tartrate of lime in cream of tartar, and then suggesting that guaranteed samples may contain 5 per cent. I presume it might be otherwise put, that ten or twelve years ago the Pharmacopœia description was applicable to the best commercial samples, but that it has ceased to be so, owing to the increased quantity of lime salt now generally present. If this be his meaning I think he may be right. But as far as we know, the proportion of tartrate of lime has always been variable, and as the Pharmacopœia test was obviously made to apply to what was the minimum proportion formerly, reasonable men may be supposed to apply it in the same sense now, without necessarily condemning as adulterated samples that contain a larger proportion, such as the maximum in good commercial samples, seeing that this variation results from the mode of producing the article, over which the manufacturer of cream of tartar has no control. Mr. Wigner has thought proper to put a construction upon what I have previously said on this point, which, as it involves an absurdity, could hardly be supposed to be, and certainly is not, what was intended to be conveyed; but at this demonstration I am not surprised.

October 28, 1879. T. REDWOOD.

"PAREGORIC MINUS THE OPIUM."

Sir,—Permit me to thank you for your outspoken remarks upon the above case, which appeared in your last week's issue.

The specious defence made by the two chemists concerned is, as you say, too plain to need any argument. But there is another view of the matter to which I think you did not allude, namely, that when such a defence is set up by a member of the pharmaceutical body—a defence, technically right perhaps, but certainly morally wrong—it cuts the ground from the feet of the unfortunate chemists who happen to be subjected to a really vexatious prosecution under the Adulteration Acts, in which they are morally right but technically wrong. If once magistrates and the general public were to get the impression that we chemists had loose notions in these matters, we should find the principle of *nullum iniquum in jure præsumendum est* more honoured in the breach than in the observance. It is deplorable that any chemist should for paltry pecuniary motives show such an absence of *esprit de corps* as was here exhibited, and I can only suggest to the local secretary for the district to have his wits about him; a wholesale chemist who will supply a petty shopkeeper with "paregoric minus the opium" (we shall have simple syrup minus the sugar next!) would not require much temptation to supply it with the opium, to the detriment of his brother chemists and the safety of the public.

CRITICUS.

MEN'S WORST FOES ARE THOSE OF THEIR OWN HOUSEHOLDS.

Sir,—In your article on "The Application of the Food and Drugs Act in New Directions," reference is made to some of the druggists promoting the sale of drugs and medicines amongst grocers and country shopkeepers "without due regard for the general interests of the body to which they belong."

We beg to enclose a label taken off a bottle brought into our shop casually for some laudanum. Size of the bottle, 3 oz. The government stamp had been upon it, its contents had been tinct. opii, and we have no doubt the firm puts it up in that form specially for country shopkeepers. That we should have such black sheep amongst us is, we think, simply disgraceful. Imagine a respectable firm sending out laudanum with a government stamp upon it, and on the label, in adddition to the name of the firm, the dose. with the additional words, "N.B. This preparation has the same properties as laudanum, and may be used for outward application." Save us from our friends!

36, *Watergate, Grantham.* JNO. COX AND SON.

REGISTRATION UNDER THE DENTAL ACT.

Sir,—The question as to whether a man may legally call himself a dentist unless he is able to undertake all the branches of the profession has been raised, and is now being freely discussed in this Journal, and I have thought that perhaps the following extracts from "The History of Dental and Oral Science in America," quoted by T. Stack, Esq., M.D., Dublin, in an article entitled, "The New Dental Act in its Relations to the Licensing Bodies and the Profession," which appeared in the *Medical Press and Circular*, may throw some light upon the disputed point. In alluding to the present position of dentistry in America, it says, among much other interesting matter, "Besides I have never known, with a single exception, any one individual to excel greatly in both these departments of our arts (*i.e.*, surgical and mechanical).

"It is here, as in Europe, the practice of most of our best educated dental surgeons to employ mechanics to do their artificial work, who never see the patient. . . . Therefore while, on the one hand, I would persuade our well educated men to confine their practice chiefly to operations on the living teeth. I would as earnestly dissuade the mechanical dentist from all attempts at operations in the surgical department. . . . In all large cities, or places, having the requisite facilities, the question is virtually settled by the employment of specialists for most of what is known as 'artificial work.'"

Dr. Stack, furthe on in the article, fully confirms this view, and says that a man should be a surgeon first, and dentist after, and that a man may be entrusted to know whether he is fitted by his mechanical taste to undertake the speciality of dentistry.

By these it will be seen that both here and in America many of our bes men differ from some of your correspondents.

GEORGE JAS. GOSTLING.

Sir,—In the Journal of the 18th inst., Mr. G. Ward states that "In America, there is a matchless dental profession independent of medical men and chemists." I enclose a cutting which illustrates that statement, from *Lloyd's* of the 26th inst. Perhaps it also may operate as a caution to those who use arsenic as a nerve cautery.

"The *New York Times* states that Mr. G. A. Gardiner, nephew by marriage of Prescott, the historian, died in Brooklyn, on the 27th of September, in great agony, after two weeks of indescribable suffering. It is said by his attending physician that his death was caused by arsenical poison placed by a dentist in one of his teeth for the purpose of killing an aching nerve."

Bell Scholarships for the Ladies.

Sir,—My friend, Mr. G. S. Taylor, in his usual happy manner, has done good service by drawing attention again to the smallness of the number of candidates who annually compete for the Jacob Bell Memorial Scholarships, and I think he would have placed the Society under still greater obligation to him had he thought well to invite the lady aspirants to pharmacy to compete for these eligible positions, inasmuch as the Council have decided that the term "person" shall henceforth mean men and women, and I doubt not in the future examinations gentlemen candidates will find the ladies pressing hard on their heels for these most serviceable, as well as valuable and much to be coveted, relics of one of the greatest men pharmacy has known.

Trading by Government Clerks.

Sir,—In the Journal for October 4, a letter appeared from "A Looker-on," upon trading by government clerks. I have felt somewhat surprised that that letter has elicited no response, as I must say, without exception, I have seen no statement which has so fairly and temperately laid the case before retail traders, and I hope its being passed over in silence is not due to the fact that retailers have settled down into a state of helpless apathy, vainly trusting that the fates will do for them what they ought to do for themselves.

I took occasion to submit the letter to a legal friend, who pronounced it very well written, but contended that it did not meet the case; he based his objection upon the hackneyed argument that if a servant fulfils his contract he can employ his spare time as he thinks proper. "But," said I, "suppose your head clerk during his spare time takes a little practice on his own account, which in all probability would come to you?" "Why," he replied, "I'd kick him out of the place of course." He at once admitted the justice of the argument. "But," said he, "how would such restrictions apply to the Army and Navy Stores?" I replied that they would not be interfered with provided that they confined their transactions to the members of the service; but they would certainly have to be prohibited from supplying Her Majesty's ships or any institution of a public character. He replied, then retailers have justice and equity on their side and it is their own fault if they don't secure an Act to make trading by crown servants illegal.

For my own part, laying aside all personal or trading interests and looking at it as a question of principle, I consider this system of public trading by the government clerks one of the most flagrant and dishonourable evasions of social obligation which has taken place in modern times, and that by a class who are supposed to be gentlemen, and whom the public have always looked upon as such; beside their conduct is setting up a spirit of discord and retaliation between different classes of the community which have always been on the best of terms with each other; if it goes on it is calculated to produce very bad results socially, and if not checked at once the system will be established as a precedent.

Now, sir, by way of putting a stop to such a system, I have to propose that a central committee be formed in London, consisting of the chairmen or presidents of the different trading associations (chemists and druggists to be represented by the President of the Pharmaceutical Society), that they have the letter by "A Looker-on," with the following letter or any modification of them which may be thought desirable, printed in every trade journal and issued to every retailer in the kingdom. This will educate retailers upon the question and will give them to understand what to request and their reason for so doing when brought face to face with the candidates for future parliamentary honours. Education upon the subject is essential, as I hear retailers complaining in all directions and I have never met with one who understood the case beyond the effect which it produced upon his business. Further, I would suggest that the same letters be printed in the form of a circular and sent at once to each member of Parliament or candidate for future membership. Members are now amongst their constituents and they would have opportunity for calmly discussing the subject. If chemists do not feel themselves sufficiently aggrieved to take the matter up, I hope that it will be brought before other branches of trade, and as soon as I see action commence, I will send 10*s.* towards a fund for defraying expenses.

Justice.

"To ——————, M.P.

"Sir,—We, the representatives of the retail traders of the United Kingdom, beg respectfully to call your attention to the conduct of the clerks in the government offices and others in the service of the state, in forming themselves into trading companies under the disguise of Mutual Benefit Societies, with the avowed object of dealing with the public outside their own immediate class. Now, sir, this is felt by retail traders to be an illegitimate and dishonourable innovation upon their vested interests, inasmuch, as they are taxed to pay the salaries of such officials and public servants, and further, that length of service is acknowledged in declining years by pensions paid out of the earnings of the public. Under such circumstances the salaried and pensioned servants of the state, although not under the immediate control of the public, are in every respect the servants of the public; in fact they occupy precisely the same position towards each other as individuals do in the case of employer and employed, and in such capacity they are morally, if not legally, bound to do nothing which shall in any way injure the interests of any class of the community. In the case of individuals, such conduct would be considered dishonourable and breach of faith and would not be tolerated, and retail traders feel that they are asking nothing unreasonable nor assailing any legitimately vested interests in asking that such conduct shall be prohibited on the part of those employed in the public service.

"Retail traders have no wish to interfere with legitimate competition in business, nor do they in any way wish to interfere with the liberties of those in the service of the state by placing upon them any restriction to prevent them supplying themselves with the necessaries of life at the least possible cost; all they ask is that those whose salaries and pensions are paid out of the earnings of the public shall be prohibited either individually or collectively from entering into business or taking service in any form of such a nature as to be detrimental to the interests of any class of the community.

"Having explained exactly the nature of our grievance and also exposed the injustice of such action on the part of the servants of the state, we beg respectfully to inform you that at the coming election the retail traders in your constituency will ask your promise of support to a measure to be introduced into the new Parliament, which shall prohibit and make illegal after a certain date, any action on the part of the pensioned or salaried servants of the state, either individually or collectively, which has for its object trading with the public outside their own immediate class.

"Trusting that you will admit the reasonableness of the request and that you will give the subject your favourable consideration and promise of support, we beg to remain on behalf of the retail traders of the United Kingdom,

"Yours very respectfully,

"The Central Committee, ——————
"London."

The Health of the Drug Trade.

Sir,—I am very glad to see that this matter is being ventilated in our Journal, that increasing interest is taken in it, and that the salvation army is gradually growing.

I intended to have written directly I saw Mr. Nicol's sensible letter, and beg you to kindly insert this, as my name has become identified with the subject.

The health of the mass is, of course, that of the individual atoms, and with us, as with every other occupation, the weakly will be weeded out, although that occupation may or may not have a direct influence on its followers; and also naturally strong persons will be able to combat influences that must kill the delicate.

It must be candidly admitted that hours used to be longer than happily they are generally now, but probably the conditions were more favourable. Fifty years ago, although light was dawning on the horizon, still there was not such a strain then, as at present, on our brains. It was becoming evident that we must have a better qualification for our duties if we wished to maintain our place in the ranks continually marching on, unless we were content to fall back to the rear; still the stock of the druggist was a perfect elysium of simplicity compared with what it is now, the duties were less onerous and enervating, the prescription was composed of articles contained in the Pharmacopœia, and neither contained so many deadly ingredients (which must always be a source of danger and anxiety to the dispenser), nor did they require so much acumen to prepare; also, I believe that we were held in higher estimation by the public, and that there was more business done of a more profitable nature and giving less anxiety. Now that is all altered. People as a rule take less physic than they formerly did, and are less willing to support the druggist, and what with increased expenses of salaries, wages, rent, rates (taxes I think are lighter), living and education for our children, to most of us comes the greater difficulty to make a living.

In my opinion it is even now the excessive hours we voluntarily (not necessarily) keep, that is the source of mischief. In many towns our brethren are united, close early (7 p.m.), and even have a half-holiday as well in London. Early closing is not a reality, because, although many shops, large especially, and small also, are closed earlier now, still business goes on much as usual and the public defer their orders till the whim takes them, knowing "they can always get anything at any time." Even in those shops where, to use the vulgar expression very prevalent, "more than one is kept," this is very inconvenient, because often times owing to selfish neglect there is a large amount of business thrown on the diminished staff, of whatever strength it may be, that was only intended to be left to attend to sudden illness and cases of unavoidable necessity, and this vile servitude deadens the moral faculties of those who have to submit to it. I am sorry that the original purpose of the Pharmaceutical Society was ever departed from,—the three examinations, the Preliminary for the apprentices, the Minor for the assistant, and the Major for the chemist. I am sure that which costs little is little appreciated, and that the Modified examination has produced a modified effect very injurious to the welfare of the trade. Mr. Burrell speaks of darkening prospects, but I think it should be addressed to the young men themselves. The late Mr. Deane was in favour of a good fee on apprenticeship, as unless a man was able to command a sufficient capital to pay it, he would not have sufficient afterwards to advantageously enter the business, and this is most true, for many young men without position or capital go into business and think their only chance of success is keeping open later than and underselling the old established chemists (as was pointed out by Mr. Corder last year), and Dr. Tilden this year has given us good advice. "Lighten the ship, cast overboard much of the superfluous and derogatory cargo." We must sell to get our living, but ours is something more than a mere trade; let us continue our educational efforts, elevate ourselves, protect our own interests against all comers, shorten the hours of labour and cease to be public slaves, then we shall live long and happily.

I close and have done for sixteen years at 8 p.m., and all day Sunday.

HENRY LONG.

48, *High Street, Notting Hill, London, W.*

Sir,—The discussion on the "Health of the Drug Trade," is very interesting, but I should like to ask your correspondents whether they have not jumped rather rashly to the conclusion that the majority of us pine away in the flower of our youth.

The average duration of life in the psalmist's time might be three score years and ten, but is it now?

C. PARKINSON.

LIQUID EXTRACT OF COTO BARK.

Sir,—In the "Month," page 322, it is stated that Dr. J. B. Yeo has found this preparation useful in the diarrhœa met with in phthisis, and suggests that it should be given in combination with tincture of cardamoms and mucilage.

Will you allow me to ask whether the simple or compound tincture is referred to?

It would be interesting, also, to know whether tincture of catechu given in a similar combination would not answer equally well.

OBSERVER.

[*** The compound tincture of the B.P. is intended.—ED. PH. J.]

FERRI AMMON. SULPH.

Sir,—Having read Mr. Parker's letter in last week's Journal with great interest, I think he has pointed out four very important indications. Speaking from my own experience I think the "Dispensing Memoranda" is a most valuable portion of the Journal, where opinions may be expressed, difficulties cleared, and the trade benefited.

Respecting ferri ammon. sulph., it was a fit subject to make inquiries into, as I was handed a similar prescription a few days ago. Being able to communicate with the prescriber, he said he meant ferri ammon. sulph., and thought it was a preparation generally kept, and that he had prescribed it before. Where I don't know, probably in some of the hospitals, where I am disposed to believe that it is used sometimes. I should be glad to know whether there is anything objectionable in ferri ammon. sulph. being used for medicinal purposes, and what is the dose of it?

COCHLEA TERRESTRIS.

CREDULITY IN MODERN TIMES.

Sir,—There has lately arrived amongst us at Birkenhead a strange phenomenon for this country—a lady doctor, who professes to be an Italian—Madame Enault. She has a magnificent turn out, a chariot all mirrors and gold, with three splendid horses, said to be worth a hundred guineas each; seated on the top of this imposing vehicle are six musicians, dressed in fancy costume, cavalier hats, boots and feathers. The lady herself is attired in a picturesque Italian costume, ornamented with dragons, stars, and other hieroglyphics. She also wears a gilded tiara and head-dress of beads, with flowing black hair. Just imagine the sensation she causes as she drives through the town with her band playing in the loudest strains, to the place where she is located, a piece of ground in Conway Street. This lady appears to cure every imaginable disease that human flesh is heir to—paralysis, extracting teeth, takes out encysted tumours, and all before the public almost instantaneously; but whether she does so in reality or not public opinion is divided. She is surrounded daily by a dense mass of two or three thousand people, including all classes of society, magistrates, merchants, shopkeepers and working men, all anxious and struggling to procure a bottle of a preparation that she calls "malachité," which she sells at 2*s*. per bottle. This she recommends almost for every complaint, for headache, toothache, neuralgia, etc., and to show what effect faith has in many cases of imaginary disease, I may mention that I have examined it, and believe it to be a mixture containing tincture of cannabis indica, together with glycerine and essential oils.

I send this short sketch thinking it may interest some of your readers and many pharmacists in Lancashire, who must have heard of Madame Enault, and to show the height credulity will reach in the nineteenth century.

TARAXACUM.*

BY CHARLES SYMES, PH.D.

When a short time since a trivial circumstance caused me to reflect on my experience with regard to the pharmacy of taraxacum, I was fully aware that the subject had received considerable attention from very able men in the earlier days of the Pharmaceutical Society, and that for some years past little had been written or said concerning it. This implied that the conclusions then arrived at were uniform, that the results were altogether satisfactory, and that it would be a fruitless task again to open up the subject. Reference, however, to the early volumes of the Journal seemed rather to indicate that the subject had been abandoned because high authorities differed, and not because perfect results had been arrived at.

I have therefore ventured to bring the matter forward anew so that it might receive further consideration, and trust that on the present occasion it will receive full discussion, so that with the experience of the days already mentioned, and the cumulative results of observation since that time, we may, when a new edition of the British Pharmacopœia goes to press, feel that as regards taraxacum we are walking in the light of to-day.

In the present edition of the Pharmacopœia, "taraxaci radix" is described as the "fresh and dried root of *Taraxacum Dens Leonis* gathered between September and February."

Now it is this *time of gathering* which presents the first difficulty, and is really the point at issue. Mr. Joseph Houlton, writing in the *Medical and Surgical Journal* of August, 1828,† after quoting several authorities says: "My own observations perfectly coincide with those of Bergius. In the month of March, the juice obtained from the bruised root by pressure is a thin, watery and brownish fluid, weak in flavour; whilst that procured by the same process towards the end of the summer is thick, opaque and cream-coloured, and in a few minutes after being expressed it sets to a much more solid consistence, becoming as thick as common paste; it is very bitter and saponaceous. This is the season in which I have chosen it for medical purposes, and from many years of observation upon this plant of disputed virtues, I have been led to a conviction that it has medicinal powers varying essentially according to the time of year in which it is gathered, and the mode in which it is prepared." Extending the period somewhat later in the year, viz., to the latter part of the autumn, these views were subsequently confirmed by Squire, Bell, Hills, Cracknell and others. Bentley, on the other hand, furnished some very convincing arguments in favour of the use of roots collected in the spring, and in support of his views related his personal experience not only as to the superiority of the preparations then obtainable from a pharmaceutical point of view, but also as to their greater medicinal efficiency.

Christison and, I believe, others entertained the same views. Giles considered the time which elapsed between collecting and using the roots was of the first importance, and the season at which they were collected quite secondary. The United States Pharmacopœia directs the roots to be collected in the autumn.

I am not aware that anything more definite than these varied opinions has been arrived at, and yet as a medicine taraxacum and its preparations are extensively used. If, however, this short, and I fear, imperfect paper, should elicit facts which will enable us to arrive at satisfactory conclusions on this and other points, or should start anew the investigation of the subject, it will have served some useful purpose.

My own experience, which has been derived from operating some years ago on several tons of the root and recently on smaller quantities, at various seasons of the year, points to November as the month in which taraxacum roots should be gathered for medicinal use, the period being extended to the beginning of December if the winter has not commenced early; or in other words, the later they are gathered, so long as they have not been subjected to the influence of frost, the better they will be. At this period it is true they contain a large quantity of inulin, but the active principle, or taraxacine is more fully developed (if bitterness is any criterion) than at any other season, and the inulin can be separated from the expressed juice far more readily than the saccharine matter which abounds in the spring. I have examined samples of the fresh juice late in the autumn which had comparatively little action on Fehling's solution, whilst at other seasons it is very marked and energetic. No sooner does the frosty weather set in than the roots become sweet, the starchy matter becoming converted into saccharine; a necessary condition of things before it can serve the useful purpose in the economy of the plant for which it appears designed, viz., for the nourishment of the root during the cold weather. This is probably brought about under the influence of a ferment which operates specially at low temperatures; but that starch, even in the absence of a ferment, and in the cold, may be gradually converted into dextrine has recently been shown by Riban (*Bull. Soc. Chim.*, xxxi., 10), and as regards the change in dandelion roots, no one who will take the trouble to examine them before and after a few sharp frosts will have the least doubt as to the increased sweetness. My first impression was that the bitter principle remained intact and was merely masked by the presence of the saccharine matter, but experiment led me to the conclusion that it became more or less altered in character and that its destruction probably went on *pari passu* with that of the inulin; and this conclusion became strengthened on the perusal of a paper by Morson, in the 1st vol. of the *Pharmaceutical Journal*, page 52, on "Vegetable Extracts," in which he writes as follows:—"The bulk of most extracts consists of sugar, starch, enuline, gum, and other inert substances, which although inoperative in themselves exert in combination with water a very destructive influence on the really active proximate principle of the plant." These remarks were doubtless founded on experiment and careful observation, and although here the conditions differ somewhat, inasmuch as the vital influence is absent, still the results appear to be the same.

As to the preparations of taraxacum, the solid extract is not regarded by medical men as an agent of much activity, except in large doses; the succus on the other hand is much prescribed, not unfre-

---

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, November 5, 1879.

† Reproduced in *Pharm. Journ.*, vol. i., p. 421, 1st series.

quently in too small doses, but when well prepared and moderately fresh is a good representative of the medicinal properties of the drug. When, however, it is kept for any length of time, and more especially in warm weather, it often becomes turbid, deposits, and sometimes ferments, losing most of its bitterness, and this will, as a matter of course, occur much more readily in the presence of a large quantity of saccharine matter than in its comparative absence. Reasons which it will be unnecessary to detail render it undesirable to increase the quantity of alcohol in any medicinal preparation of the kind, beyond the amount necessary for its complete and perfect preservation, but especially in that under consideration where the quantity administered is or should be comparatively large. But in the formula given a minimum of spirit is used at a risk of the stability of the preparation, and I would suggest an increase of say 5 per cent. of spirit as desirable, and the dose as regards bulk might be diminished by concentrating the filtered juice as soon as possible after expression from the roots.

There is a preparation of taraxacum officinal in the United States Pharmacopœia, but not in the British, viz., the fluid extract prepared from the dry root, with which many pharmacists are, I presume, acquainted. It is a concentrated, efficient, elegant and stable preparation. The sample No. 1, which possesses much of the bitterness and the peculiar odour of taraxacum, is in a perfect state of preservation, and is at least three years old. Sample No. 2 has been recently prepared from roots a year old, and No. 3 from roots collected and dried about ten days since; both these are very decidedly bitter.

Like most of the American fluid extracts the one under consideration is of such a strength that one fluid drachm represents 60 grains of the dry powdered drug; and as the best autumnal roots lose 75 per cent. of moisture in drying (spring roots about 80 per cent.), each fluid drachm represents at least four times the quantity of fresh root. The formula will be well known; the finished product contains one half its bulk of rectified spirit, one-fourth glycerine, the remaining fourth consisting of dissolved extractive and water. Liquid extract of taraxacum is not unfrequently prescribed in this country (the dispenser often being uncertain as to what is really intended), and I think this preparation would fill a want; and that it, or some modification of it, should find a place in the next British Pharmacopœia.

[*The discussion on this paper is printed at p.* 374.]

THE PREPARATION OF CASTOR OIL.*

BY ERNEST P. RAAB, PH.G.

From an Inaugural Essay.

Castor oil is obtained in the United States by the following method, as witnessed at the "Belleville Oil Works," owned by Messrs. Brosius and Son. The seeds having been thoroughly cleansed from the dust and particles of the pod, with which they are more or less contaminated, are placed in an iron reservoir and slightly heated. Great care is taken to prevent them from being scorched, the object being only to make the oil more fluid for expression. The pressing is now proceeded with by means of hydraulic presses, which are preferred on account of the great force exerted by them. Each piece has a series of movable plates and cylinders, of which each cylinder is filled, the plate pushed in, and then the power applied. The first quality oil is thus expressed, and runs into a large tank below. The pressed seeds are now heaped into a pile and allowed to remain for a day. Next day they are again heated in another iron reservoir, put into a series of cylinders, power is applied, and the second quality, or lubricating oil, is obtained. Messrs. Brosius and Son use a portion of their oil-cake for fuel, and send the remainder to the East, where it is utilized in combination with other matter to produce artificial guano. A Philadelphia firm, Messrs. Baeder, Adamson and Co., have resorted to bisulphide of carbon as a solvent for the press-cake, thereby obtaining a dark thick liquid. The process is similar to that carried on in France with alcohol, the product, however, being a very common lubricating oil, but without smell of bisulphide of carbon. The firm does not now manufacture any more.

The oil made by the process in use at the "Belleville Oil Works" is called cold-pressed, to distinguish it from any of the other methods in which more heat is employed. The cold-pressed oil without doubt deserves the preference, and is now extensively used. The yield per bushel after two expressions is sixteen pounds, or two gallons; the first expression yielding twelve pounds, the second four pounds. Sometimes a third expression is resorted to, but this oil is much coloured and the yield so very small that it hardly pays for the labour and expense incurred; the yield is from one to three pounds.

The process of purifying and clarifying the oil is accomplished in various ways, and is the specialty of every factory. The great point in purification as well as clarification to be noticed is the fact not to expose the oil too long to the air, as it is then liable to become rancid. The first expressed oil is clear white, or rather colourless, like water; the colour of the second expression is yellowish, like syrup of squills. Castor oil is remarkable for its power of mixing, in all proportions, with glacial acetic acid and with absolute alcohol without the aid of any other agent. It is soluble in four parts of alcohol, ·835 or ·850, at 15° C., and mixes without turbidity with an equal weight of the same solvent at 25° C. Its specific gravity is ·97 to ·98; it congeals at —12° to —13° C., and becomes solid at —40° C.

The oil of the first expression is used for medicinal purposes; that of the second for oiling leather, lubricating machinery, burning and various other purposes.

The oil-cake is either, by the addition of animal matter and other ingredients, made into manure, artificial guano, or is used for fuel. The latter is the customary practice in large oil mills, where a saving of from 40 to 50 dollars a week is effected thereby.

* From the *American Journal of Pharmacy*, October, 1879.

SOPHISTICATIONS OF OLIVE OIL.

The adulteration of this oil has become so prevalent that the French Minister of Agriculture and Commerce had requested the Academy of Sciences to ascertain the most trustworthy method for the detection of such frauds Among the procedures at present under examination by a special committee is the use of a diagometer, an instrument devised by Professor Luigi Palmieri, founded on the difference of the electric conductivity of oils. Seed oils are as a class better conductors than olive oil. At the same time every oil conducts the better the greater are its impurities. Linseed and cotton seed oil are among the best conductors, whilst the oils of pine seeds and of hazel nuts are almost as feebly conductive as the purest olive oil, known in commerce as virgin oil. Fortunately these two oils are too rare and costly to be used in the adulteration of olive oil. The use of the diagometer requires considerable manipulative skill.—*Chemical News.*

SOLICITATION OF VOTES BY CANDIDATES FOR THE BENEVOLENT FUND.

THE idea that, in the administration of relief from the Benevolent Fund, the most worthy candidates should have the advantage simply because they are most deserving is one that we cordially sympathize with, and to that extent we share with the mover and the seconder of the motion respecting canvassing cards and solicitation of votes in their desire to prevent, as far as possible, any advantage being gained by or for individual candidates through other means than that of having a preferential claim to relief from the Fund by reason of their actual circumstances and antecedents.

But having admitted thus much we cannot avoid adding that it is our conviction the object sought for cannot be attained by means of such regulations as it is proposed to establish, and we need not go far beyond the remarks made by those who supported Mr. SHAW's motion for evidence in support of this view. The Benevolent Fund of the Pharmaceutical Society is a feature of that Society which every member has reason to be proud of, not only by reason of the good it has done, but also on account of the good it is yet able to do. However, the good character of this Fund, like that of all other charitable funds, is not wholly unqualified. Even in its accumulation, and still more in its application, it affords opportunities for the exhibition of various tendencies of human nature not altogether admirable perhaps, or even pleasant, but still natural tendencies which it would be quixotic to quarrel with, or to attempt to put down arbitrarily.

It is upon the basis of these tendencies that the system of soliciting votes, of sending out circulars and cards, is carried on by candidates with the view of promoting their election, and it is from a sort of instinctive perception that voters are likely to be influenced more or less by such tendencies that this system is had recourse to. Looking at the practice impartially it may not be possible to avoid the admission that it is a great evil; one which, as Mr. HAMPSON said, is becoming more and more recognized by men who have thoroughly entered into the question. But when that admission is made, does it follow, as a logical consequence, that it is an evil to be done away with by such measures as those proposed in regard to solicitation of votes, etc.? Is it not rather one of those evils that have to be endured?

We admit it is to be deprecated that poor persons applying for relief and variously incapacitated from active exertion should come into competition with others, who in place of those conditions possess an habitual disinclination to take back seats anywhere. It is, we admit, wholly undesirable that the candidates for election should ever enter upon the candidature as a sort of race who should get in. Even in the absence of any inequality in power to compete in this way, such contest would be inappropriate and when such differences as those above referred to obtain it is next door to an injustice that the weakest must necessarily go the wall. This, however, is only the natural injustice which prevails in all worldly affairs, and we cannot see that it calls for special regulation in the administration of a charity more than in the regulation of the circumstances by which some people become prosperous, while others become unfortunate.

But there seems to be a further objection to the motion brought forward by Mr. SHAW and Mr. HAMPSON, and that is its being only a half measure at best. Mr. SHAW would not interfere with personal or written solicitations, but only with such proceedings as caused expense to the candidates, so that he would leave altogether unprovided against such an evil and such an undue advantage as might be gained by a person attacking the Benevolent Fund as a matter of business, able and willing to go about and solicit votes with plausibility and without compunction, so as to court success rather by such means than on the ground of any real merit. It is no libel to say that there are such persons, and that charitable institutions are sometimes successfully cultivated by them.

And in addition to these possible sources of injustice in the allotment of the gifts of charity there are the influences hinted at by the *Daily News.* For some of the supporters of charities there can be little reason to doubt that the part they play is one of business. They subscribe partly to satisfy their vanity by seeing their names in print, partly, also, to become conspicuous and for the sake of enjoying the sense of importance arising to some persons from the fact of being solicited to give their votes and from having the power to exercise patronage.

So long as such influences prevail with voters as well as with candidates for election to annuities we cannot entertain the hope that they will not have their effect irrespective of questions as to which of the candidates are the most deserving. As regards the point of relieving candidates from expense, the prohibition of printed cards would not relieve those who are weak or disabled from the greater disadvantage of active solicitation in this way by others better able to carry it out, for now that the reproduction of letters can be carried out rapidly and copiously, it would be easy for any able-bodied persons to prepare a large number of such copies and distribute them themselves.

A further objection to the prohibition of cards and canvassing for votes arises from the dislike some persons would have to be thus shut out from taking an active part in the election of annuitants, and it is quite possible that this feeling might have the effect of preventing some persons from subscribing. Moreover it would deprive some candidates from enjoying the advantage resulting from the assistance of friends who might be disposed to canvass for them, or even to defray the cost of printing and circulating cards. It is difficult to perceive that the handicapping of candidates in regard to such assistance by their friends would be less an evil than that which is assumed to result in some cases from canvassing.

Still it seems there are charities which are administered under conditions that are supposed to do away with the evil of canvassing. Mr. Shaw mentioned the Royal Albert Orphan Asylum as having been carried on without canvassing and the Medical Benevolent Fund as one in the administration of which canvassing was to be done away with in future, so that there is evidently a considerable amount of opinion in favour of the discontinuance of the practice.

Perhaps it may not be altogether useless to suggest a plan by which much of the difficulty arising from the difference of opinion upon canvassing could be got over. If those who disapprove of solicitation for votes were to have added to their names in the list of subscribers to the Benevolent Fund in the Society's Calendar the letters N.C., as indicating that they did not approve of canvassing, this plan would serve the purpose of notifying to candidates that those persons objected to be asked for their votes, and it may be assumed the candidates would abstain at least from applying or sending cards to them. In this way subscribers to the Fund would be able at once to exercise their influence towards preventing the practice of canvassing, and in time it would appear how far this desire prevailed among the subscribers. If this course were adopted by the majority there would then be a very strong argument upon which to base a motion in future similar to that brought forward by Mr. Shaw.

In any case some such individual action directed to the prevention or removal of the evil attending the system of canvassing appears to be most suitable for initiating the reform that is considered to be necessary, and we are of opinion that by attacking the subject in such a way there would be the greatest likelihood of securing a satisfactory result.

PHARMACOPHOBIA.

The pharmacophobia, of which Dr. Dupré has on previous occasions presented such distressing symptoms, has again taken possession of that amiable member of the Society of Public Analysts, and has impelled him, with the aid of his colleagues the editors of the *Analyst*, to deliver himself of a letter denouncing in one breath the Council of the Pharmaceutical Society, the Pharmaceutical Journal, Professor Redwood, Professor Attfield, Professor Tilden, and pharmaceutical chemists in general, for certain indications of heretical views on their part respecting a favourite dogma of Dr. Dupré's, that the British Pharmacopœia, as read by himself, is the sole and only standard of what drugs and medicinal preparations or articles of materia medica, etc., ought to be.

The editors of the *Analyst* characterize this letter as being "sufficiently outspoken in itself to require no comment" on their part, and certainly the arrogant assumption of infallibility it manifests would not require their help to establish an analogy with a Papal bull or an edict of excommunication.

But amid all the vehemence of Dr. Dupré's expression of displeasure, there is a faint sign of misgiving in his mind, that owing to his belonging to Carlyle's majority, he fails "to understand, either the chemistry, the sense, or the morality" of the matters which have so profoundly moved him, and Dr. Dupré, speaking with this sense of having "lime in his sack," really shows such symptoms of amendment, that though we might otherwise have been disposed to characterize this letter of his as another illustration of "*parturiunt montes*," we will, for the present, at least, entertain a hope that it gives some sign of his being possibly cured of "pharmacophobia" at a future time.

THE DIGNITY OF PHARMACY.

A correspondent sends us under this heading two cuttings from newspapers, stating in one instance that a person has bequeathed a legacy to the poor by sending to every chemist and patent medicine vendor a bottle of his nostrum for free distribution, and in the other that advice gratis on all diseases is given by the advertiser. For the special satisfaction of our correspondent, however, we can state that the names of neither of these advertisers are on the Register of Chemists and Druggists of Great Britain, and for his further consolation we refer him to the excellent letter in which Mr. John H. Wilson expresses his opinion of the harm that is done to pharmacy and to the real interests of the trade by promoting the sale of patent medicines.

In regard to this feature of the trade, we may mention that the detrimental influence it exercises upon the status of the pharmacist is being seriously felt even in Germany and in France, where the pharmacist occupies a more professional position than is generally the case here, and the German *Pharmaceutical Journal* speaking of Mr. Schacht's remarks on that subject in his address to the Conference at Sheffield, says they are of interest to German pharmaceutists, since they show that the status of the pharmacist will be inevitably reduced to the level of general trade and industry and will be regarded in that light by the public wherever the business of pharmacy does not advance scientifically in the same degree as other occupations.

Apropos of this subject we also refer our readers to the inquest recently held at Doncaster, as illustrating the mischievous consequences of the irregular sale of medicinal preparations by persons unqualified to deal in them and as furnishing further evidence in justification of the steps taken from time to time for enforcing the provisions of the Pharmacy Act.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, November 5, 1879.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Churchill, Frazer, Gostling, Greenish, Hampson, Hills, Richardson, Rimmington, Robbins, Shaw, Symes, Williams and Woolley.

The minutes of the previous meeting were read and confirmed.

Before commencing the business of the day,

The PRESIDENT said he must trespass on the Council for one moment on his own account. When the Council did him the honour in June last to elect him President, he expressed a fear that he should be unable to carry out the duties, and he did feel that those duties were too much for him. It was not altogether a question of time, but of wear and tear, which he found he could not stand, and therefore without saying more, he must beg that at the next meeting the Council would appoint his successor.

After a brief pause,

Mr. HILLS said he trusted that Mr. Sandford would continue to hold office for the present. He could quite enter into what was now stated, but at the same time this came upon the Council very suddenly. He was not anticipating anything of this kind, and he trusted Mr. Sandford would withhold his resignation for the present.

Mr. ATKINS said although a young member of the Council he could not help rising to second Mr. Hills' appeal to Mr. Sandford to reconsider his decision. He ventured seriously to think that however much some of the members of Council might differ on some points with Mr. Sandford, they all united in the most intense respect for him, and in a thorough admiration of his English pluck, and if it came to a discussion on questions of pharmacy few would venture to cross swords with him. He therefore hoped Mr. Sandford would not consider his decision as a Medo-Persian one, but give effect to their cordial regard for him, and their desire that he should retain office. The Council was confessedly passing through a period of considerable difficulty; it required men of long practical experience at the head of affairs, and could not afford to spare him.

The VICE-PRESIDENT hoped Mr. Sandford would not feel himself called upon to relinquish the post they were all so glad to see him occupy. If Mr. Sandford needed more rest he could only say that he would most gladly do everything in his power to lighten his load. He was sure that in ninety-nine cases out of one hundred he should be at one with him in his views, and he should be very pleased if he could bring himself still more into accord with him than he had sometimes been. He would only say that he placed himself entirely at his disposal if he could assist him in any part of his duties.

Mr. WILLIAMS said he understood Mr. Sandford had taken this step, not from any feeling of disagreement which had occurred on the Council, for all that had occurred had been in the most open and friendly manner. The members of Council had only disagreed in the way in which men must always disagree, and he understood that it was the strain upon Mr. Sandford's physical powers, involved in the Presidency, which he found to tell upon him. He could quite sympathize with him in that feeling, but he must say that anything like the resignation at which Mr. Sandford had hinted would be a most serious thing for the Society, and he trusted that he would if possible struggle against this feeling and continue to carry out those duties, which no one on the Council could fulfil so well.

Mr. FRAZER, as the only Scotch member present,—which he regretted, for he was sure Mr. Mackay would feel inxpressible regret at such an announcement,—trusted that some arrangement of the work could be made which would relieve the strain that Mr. Sandford felt too heavy for him, and that the Council would not be deprived of his services as President until the close of the current year of office.

Mr. ROBBINS hoped Mr. Sandford would withdraw his notice, because he was quite sure it would be considered as a loss to the Society almost irreparable. At the present time, especially, when there was a Pharmacy Bill under discusssion, there was no man on the Council who would be able to give so much assistance as Mr. Sandford. He knew the duties were very onerous, but some of them might surely be thrown on the shoulders of younger members.

Mr. GREENISH expressed his earnest hope that if it were compatible with Mr. Sandford's health he would not lay down the reins of office at present. It was a critical period; the Council had important business before it, and there was no man so capable of filling the chair as Mr. Sandford, and he was sure there was no one who would not be glad to save him any trouble or anything which might bring an extra strain upon him.

The PRESIDENT said he should not have risen again except to thank his colleagues for the kind expressions of feeling they had given. He must entirely disclaim any feeling of antagonism to any of his colleagues in retiring. All the members of Council honestly expressed and acted on their own opinions, as it was right they should, and he had always received the greatest kindness and courtesy from those whom he had most strongly opposed, not only during his present term of office but years and years ago. He knew they were all desirous of helping him, and they all had helped him, but the truth was, he had been so long mixed up with this Society that it had become almost a part of himself, and the anxiety was too much for him. He thought of it day and night, and he really felt that it was more than he could stand. However, there need be nothing further said on the subject at the present meeting.

Letters of thanks were read from the Manchester Chemists' Association for the grant of £35, made last month, and from the Chemists' Assistants' Association for the loan of specimens from the museum to illustrate a lecture.

THE WEIGHTS AND MEASURES ACT.

The PRESIDENT laid before the Council an Order in Council on the subject of the standards about to be issued to inspectors.

DIPLOMAS TO PHARMACEUTICAL CHEMISTS.

The following being duly registered as Pharmaceutical Chemists were respectively granted a diploma stamped with the seal of the Society:—

Arnfield, John Cash.
Bevan, William.
Cook, William Richard.
Gascoigne, Charles.
Gibbons, Walter.
Howse, Charles Turk.
Laxon, Matthew.
Leach, Isaac.
Mason, William Brandwood.
Presslie, Robert Dowell.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemist.

The following, having passed the Major examination and paid his subscription for the current year, was elected a "Member" of the Society:—

Mason, William Brandwood ...Bolton.

Chemist and Druggist.

The following who was in business on his own account before August 1, 1868, having tendered his subscription for the current year, was elected a Member of the Society:—

Cooke, Thomas.....................Holt, Norfolk.

ASSOCIATES.

The following, having passed the Minor examination and tendered or paid as Apprentices or Students their subscriptions for the current year, were elected "Associates" of the Society:—

Chambers, Herbert ....Haddenham.
Chipp, James........................Newport, I. W.
Constance, Sidney William......London.
Field, William ....Shoreham.
Fowler, William ....Sunderland.
Fryer, Charles Harry ....Leeds.
Godfrey, Henry.....................Godalming.
Hearnshaw, John William ......Spalding.
Hessell, James ....Rye.
Hoad, Frank ....Rye.
Hornby, Charles Haycock ......Stockport.
Hutchin, William Francis W...Maidstone.
Jones Nathaniel Stevens.........Fulham.
Kilner, Frederick James.........Bristol.
Mason, Frederic Silvester ......Leicester.
Moody, Lewis ....Lincoln.
Morgan, Alfred William.........Rochester.
Morris, Humphrey ....Dolgelly.
Parker, Charles.....................Lancaster.
Powrie, Percival Chamberlain...Mossel Bay, S. Africa.
Watkinson, James ....Farnworth.
Watson, Robert John ....Market Rasen.
Williamson, Bamford ....South Shields.
Willson, Robert ....Boston.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Chabôt, Frank ....London.
Chadwick, Thomas Edward ...Bradford.
Harrison, Jeremiah...............Clitheroe.
Nelson, Harry ....York.
Nettle, William Robert P.......Plymouth.
Orchard, Arthur Bishop C. ...London.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

The names of the following persons, who have severally made the required declarations and paid a fine of one guinea, were restored to the Register of Chemists and Druggists:—

George Arthur Cannell, 81, High Street, Queenborough, Kent.

William Shipley, 2, Haugh Lane, Lower Broughton, Manchester.

Alfred Wall, 37, Church Street, Woolwich, Kent.

Addition to Register.

The Registrar reported that—

Robert Charlton Turner, Victoria Street, Douglas, Isle of Man,

having made a statutory declaration that he was in business before the passing of the Pharmacy Act, 1868, and his declaration having been duly supported by a medical practitioner, his name had been placed on the register.

Mr. Rimmington and Mr. Robbins expressed the opinion that very few persons could be left who were really qualified for this registration and that stringent inquiry should be made in each case.

The Secretary explained that this was done.

Appeal from the Registrar's Decision.

A memorial was read from Mr. John Hardcastle, 23, Waterloo Road, Hunslet, Leeds, by way of appeal from the refusal of the Registrar to place his name on the register as having been in business prior to 1868. The memorial set out at length the applicant's case, which was that he had an interest in a business prior to 1868, though his name did not appear in it.

The Secretary stated that on writing to the medical practitioner who had signed the certificate, that gentleman had stated that he had no personal knowledge of the facts, and had only relied on the applicant's statement, believing him to be a respectable man. He therefore considered the certificate withdrawn and had declined to register the applicant.

Mr. Richardson thought that many men were being put on the register without due care to scrutinize their claims. Those who lived in the country constantly heard complaints of this kind, and it was felt to be a hardship on respectable chemists and druggists that men not duly qualified should be put on the register.

Mr. Woolley said the respectable portion of the drug trade must do what was right and just. The question in this case seemed to turn on what constituted a partnership.

After some further conversation,

The Vice-President pointed out that in this case the medical practitioner having withdrawn his certificate, the necessary preliminary to registration had not been complied with. The applicant must provide a certificate from some one who was able to support his statements from personal knowledge before his application could be entertained.

The Secretary was directed to write to the applicant to this effect.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

HOUSE.

This Committee's report referred to sundry matters connected with repairs to the house; but no recommendations were made.

BENEVOLENT FUND.

The report of this Committee included a statement by the Secretary to the following effect:—

338 persons who subscribed in 1878 have not subscribed this year, leaving a deficiency in subscriptions of about £150.

The following grants were recommended:—

£15 to a member, formerly in business, but now in greatly reduced circumstances.

£10 to the wife of an associate who is now in a lunatic asylum.

30 guineas to aid in securing the election of the youngest son of a late pharmaceutical chemist and member of the Society to the London Orphan Asylum.

£10 to a former member, aged 63, who has received five previous grants.

£10 to a pharmaceutical member from 1853 to 1877.

£5 to a registered chemist and druggist conditional on further inquiries by a member of the Council resident in his neighbourhood being satisfactorily answered.

£10 to the widow of a registered chemist and druggist who has had four previous grants.

£10 to a pharmaceutical member from 1868 to 1871. Applicant has had one previous grant.

£10 to the widow of a registered chemist and druggist who has had three previous grants.

£10 to the widow of a registered chemist and druggist who had a previous grant of like amount in July 1878.

One case the Committee had declined to recommend for relief and two others were deferred for further inquiries. One of these referred to the election of an orphan to an asylum.

The report and recommendations were received and adopted.

Mr. WILLIAMS trusted that attention would be called through the Journal to the desirability of friends who had votes for either the London Orphan Asylum, or British Orphan Asylum, reserving them for the two candidates whom the Council wish to see elected.

LIBRARY, MUSEUM AND LABORATORY.

The report of this Committee included the usual report from the Librarian, to the following effect:—

Attendance.		Total during Month.	Highest.	Lowest.	Average.
July	Day	441	23	7	16
	Evening	193	14	3	8
August	Day only	182	13	4	7
September (15 to 30)	Day only	125	12	6	9 nearly.

Circulation of books.	No. of entries. Town.	Country.	Total.	Carriage paid. s.	d.
July	152	59	211	17	0
August	48	30	78	19	9
September (15 to 30)	59	43	102	15	11

The following Donations to the Library had been received and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Aguiar (Dr. J. M. de), Memoria sobre a Araroba, 1879. From Dr. C. Symes.

Attfield (Professor J.), Chemistry, General, Medical and Pharmaceutical, 8 (U.S.) ed., 1879. From the Author.

Bath Royal Literary and Scientific Institution, Catalogue of the Library; with Catalogue of Books belonging to the Bath and West of England Society for the Encouragement of Agriculture, *etc.*, 1879. From the Institution.

Chemical Society of London, List of Officers and Fellows, 1879. From the Society.

Cooley (A. J.), Cyclopædia of Practical Receipts, 6 ed., 1879, pt. 14. From Messrs. Churchill.

Guy's Hospital, Reports, 1879, ser. 3, v. 24. From the Hospital.

Guy's Hospital, Formulæ, 1868 and 1879. From Mr. Henry Collier.

Imperial College of Agriculture, Tokio, Japan, Catalogue of Agricultural Products exhibited in the Sydney International Exhibition, 1879. From Professor E. Kinch, compiler.

Institution of Civil Engineers, Charter, Bye-laws and Regulations, and List of Members, 1879. From the Institution.

National Dental Hospital and College, Report, Prospectus, etc., 1879-80. From the Hospital.

New York City, Department of Public Charities and Correction, Hospital Formulary and Posological Table, 1879. From Mr. Charles Rice, compiler of the posological table.

Royal College of Physicians of London, British Dispensatory, a translation of the London Pharmacopœia, 1747. From Mr. John Saffery.

St. Bartholomew's Hospital, Statistical Tables of Patients during 1878. From the Hospital.

Smithsonian Institution, Annual Report of the Board of Regents for 1877. From the Institution.

Tommasi (Dr. Donato):

Sur la Non-existence de l'Hydrogène naissant, 1 partie, Réduction du Chlorate de Potasse, 1879.

Sulla Non-esistenza dell'Idrogeno nascente, parte 5, Riduzione del Perclorato Potassico, 1879. From the Author.

University College, London:

Catalogue of Books in the General Library and in the South Library, 1879, v. 1-2.

Calendar, 1879. From the College.

University of Durham College of Medicine, Newcastle, Prospectus for 1879-80. From the College.

University of Edinburgh, Calendar 1879. From the University.

University of Glasgow, Calendar 1879. From the University.

Waring (Dr. E. J.), Bibliotheca Therapeutica, 1878-9, 2 v. From the Author.

White (Dr. J. Walls), Salicylate of Iron, 1879. From the Author.

Yorkshire College, Leeds:

Fifth Annual Report, 1879.

Calendar, and Prospectus of the Leeds School of Medicine, 1879. From the College.

Pharmacopée universelle et Uniformité en Médecine; Rapport de la Commission internationale, 1879. From Professor Norbert Gille, reporter.

Dragendorff (Prof. G.):

Analysen zweier Äpfel, 1878.

Beiträge zur Chemie der Päonien, 1879.

Über Mannit als Nebenproduct der Milchsäuredarstellung aus Rohrzucker, 1879.

Haberkorn (T.), Das Verhalten von Harnbacterien gegen einige Antiseptica, 1879.

Keussler (E. v.), Untersuchung der chrysophansäureartigen Substanz der Sennesblätter und der Frangulinsäure nebst Vergleichung derselben mit der Chrysophansäure der Rhabarbers, 1879.

Sitzungsberichte d. Dorpater Naturforscher-Gesellschaft, 1 no., 1879. From Professor Dragendorff.

The Committee had recommended the purchase of the following books for the library:—

Cockayne (T. O.), Leechdoms, Wortcunning, and Starcraft of Early England, 1864–6, 3 v.

Edinburgh New Dispensatory, ed. by A. Duncan, jun., 1803.

Gray (Asa), Botanical Text-book, 6 ed., pt. 1: Structural Botany, 1879.

Répertoire de Pharmacie et Journal de Chimie médicale réunis.

Tyndall (J.), Fragments of Science, 6 ed., 1879, 2 v.

Wanklyn (J. A.) and E. T. Chapman, Water Analysis, 5 ed., 1879.

Wurtz (Ad.), Elements of Modern Chemistry, translated by W. H. Greene, 1879.

The Librarian had reported that in the annual revision which he had just completed the following 13 books were found to be missing:—

Attfield (J.), Chemistry, 7 (U.S.) ed., 1876.

Bevan (G. P.), Industrial Classes, 1876, vol. 2.

British Pharmacopœia, with Additions, 1877.

Burbidge (F. W.), Horticulture, 1877.

Bloxam (C. L.), Metals, 2 ed., 1871.

Canning (W.), Select Practical Notes and Formulæ, 1877.

Church (A. H.), Food, 1876.

Clendon (J. C.), Observations on Extraction of Teeth, 1843. (Lost by borrower.)

Cooke (M. C.), Manual of Structural Botany, 2 ed., 1865.

Cooley (A. J.), Pharmaceutical Latin Grammar, 1868.

De Crespigny (E. C.), New London Flora, 1877.

Flückiger and Hanbury, Pharmacographia, 1874.

Squire (P.), Companion to British Pharmacopœia, 10 ed., 1874.

The Committee had ordered that the list be published in the Journal, and recommended that a reward be offered for the detection and conviction of persons stealing books from the Society's library.

The Librarian had also presented a report of the meeting of the Library Association at Manchester on September 23, 24, and 25, which he had been directed to attend.

The Curator had reported that in August the average daily attendance in the museum had been 4; in September the average had been 17.

During the vacation the museum had been visited by Dr. Berge of Zurich; Professor Baudrimont of Paris, and Herr Wiarogorski, Apothecary, Warsaw.

He had also reported that he had received the following Donations to the museum, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimens of "*Matico Aromatica*" leaves. From Messrs. Allen and Hanbury.

Specimen of "*China Cuprea*" Bark, with analysis. From Dr. B. H. Paul.

Fine specimens of Sassafras Root. From Mr. W. H. Ferguson.

A number of specimens from Dr. Dymock of Bombay, including:—

"Rusa Oil" distilled under his own superintendence, and herbarium specimens of the grass from which it was obtained.

Herbarium specimens of *Garcinia pictoria* in flower and fruit.

Seeds of *Lobelia nicotianæfolia.*

Fruit of the Zanzibar Copal Tree.

Very fine specimens of Sarcocoll, with seeds of the plant from which it was obtained.

Specimen of the finest Yarkand Churrus.

Extract of *Myrica sapida.*

Judwar root (*Aconitum* species).

Resin of *Boswellia serrata*, gathered from the tree by Mr. J. E. Gibbs.

Root of *Gloriosa superba.*

Asgund root (not *Withania somnifera*).

Fruit of *Melia dubia.*

Fruit of *Martynia diandra.*

Bark of *Croton oblongifolium.*

Original package of Canton Oil of Peppermint.

Cake of Jaferabad Aloes.

A large number of small specimens from Mr. J. Dittrich, Apotheker, Prague.

Specimens of Crude Japanese Camphor, Pachyma Cocos, Demerara Copal and Peach tree bark, from China. From Mons. Chantre.

Specimens of Vanillon and of the fruit of *Luffa Ægyptiaca.* From Mr. H. W. Langbeck.

Specimens of the root of *Gentiana punctata*, gathered in Switzerland by Mr. O. Corder. From Mr. Corder.

Herbarium specimens of *Nardostachys jatamansi*, Dec. From Mr. T. Ware, of Hale Farm Nurseries, Tottenham.

Specimens of Barks, etc., from British Guiana, used by the natives in medicine. From Mr. F. S. Mason, Student of the Society.

Specimen of Maldon Salt obtained at Maldon. From Mr. C. J. Mead.

Seeds of *Cucurbita maxima*, grown at Porto Mauritzio for medicinal purposes. From Mr. F. R. Squire, San Remo, Italy (received through Mr. C. J. Mead).

Fine specimen of Pituri. From Dr. Bancroft, Brisbane (received through Mr. T. Christy).

The Curator had suggested the desirability of closing the museum for revision during the first fortnight in September in each year.

The Curator had also reported that room for about 500 specimens was required, the cases being already filled. The specimens in the cases in the materia medica museum were so crowded that it was impossible to clean the bottles, or remove them frequently for reference without great risk of breakage, and the specimens more frequently sought after by students could not on that account be displayed to advantage or in such a manner as to illustrate efficiently the materia medica of this country. He considered that the advantage of museum instruction, which to a certain extent is received through the eye, was necessarily lost, the great number of specimens tending rather to confuse the mind than to convey information. He also considered it would be advantageous to remove such specimens as are not official in the British, United States, or Indian Pharmacopœias to other cases, and to place in cases from which light is excluded, essential oils, and such other specimens as are injured and lose their characteristic appearance by exposure to light. It was suggested that this might be done by providing closed cupboards above those at present in use. The doors of such cupboards might be used for exhibiting the drawings of Bentley and Trimen's 'Medicinal Plants,' which had been presented by the artist.

The SECRETARY had presented estimates for printing the Journal Index and the 'History of the Progress of Pharmacy,' and the Committee had recommended with regard to the Index that Butler and Tanner's estimate be accepted and 5000 copies be printed.

An adjourned meeting of the Committee had been held on Wednesday October 28, when Professor Redwood had attended and reported that he had more students attending his class than in former sessions. He also suggested to the Committee that the 'Progress of Pharmacy,' so far as it was ready, should be put into type at once, and stated that if that were done, he thought the book might be ready for publication by the time of the next Annual Meeting.

The Committee recommended that this be done, that Messrs. Butler and Tanner's estimate be accepted, and that 5000 copies be printed.

The Committee also recommended that the suggestion of the Curator for closing the museum during the first fortnight of September in each year be adopted. A loan of certain specimens to illustrate a lecture given on the 29th October before the Chemists' Assistants' Association by Mr. Parker had been authorized.

A discussion arose with regard to the recommendation of the Committee to print 5000 copies of the Index to the Journal for the last ten years, and on the question whether copies should be sent to all members or only to those who applied for them, or whether they should be sold, great differences of opinion were expressed. It was ultimately resolved that 2000 copies should be printed, and distributed to those who applied for them.

A similar discussion arose with regard to the recommendation to put the Progress of Pharmacy in hand at once, and print 5000.

Mr. GOSTLING moved that the work be not put in hand until it was completed, but this motion was lost.

Mr. ATKINS proposed that only 2000 copies of the work be printed, but this proposition meeting with little or no support, he did not press it.

The report and recommendations of the Committee, were then received and adopted with the alteration above noted as to the number of copies of the Journal Index to be printed.

The Hanbury Memorial Trust Fund.

Mr. WILLIAMS said it would be in the recollection of all that the Council had undertaken to be custodian of this fund, and Mr. Flux had kindly drawn up a deed of trust, which was now ready to be signed and sealed. The amount invested was £400. He had now to resign his post as Treasurer of the Fund.

It was then resolved, on the motion of the PRESIDENT, that the deed of settlement of the Daniel Hanbury Memorial Fund of £400 Consols be stamped with the seal of the Society.

GENERAL PURPOSES.

The report of this Committee included the usual report from the Solicitor with regard to cases which had been placed in his hands. The only details admitting of publication are the following:—

The appeal in the case of London and Provincial Supply Association stood No. 46 in the list, and might come on during the present sittings.

John Mayo, 62, Bingfield Street, Caledonian Road, charged with illegally using the title of chemist and druggist, had confessed judgment without going to trial. In this case the Committee recommended that the penalty be not enforced on the costs being paid.

Eliza Hancock, Castle Road, Roath, Cardiff, a widow carrying on business, had also consented to judgment against her.

The Committee had considered various cases of alleged infringement of the Pharmacy Act, and in several recommended that the Solicitor be instructed to commence proceedings.

The Committee also recommended that the Special Committee to consider the Amendment of the Pharmacy Acts should hold a meeting during the present month and report to the Council in December; and that in the meantime the draft should be printed for the use of that Committee.

The Council went into Committee to consider the report.

On resuming, the report and recommendations of the Committee were received and adopted.

An application from Mr. Daniel Tudor Williams, of Aberdare, asking to be allowed to enter for the Modified examination, was refused, he not being duly qualified.

Elections of Annuitants.

Mr. Shaw moved, in accordance with notice—

"That the Council, desiring to protect the interests individually and collectively, and also to prevent unnecessary expenditure of money by the candidates for an annuity from the Benevolent Fund, order that no printed cards or circulars, asking or canvassing for votes, be permitted to be sent to any member, associate or subscriber to the said Fund."

"The Council will, as heretofore, and prior to the election, publish in the *Pharmaceutical Journal*, and also by the special circular, or voting paper to all voters, the full particulars of the merits of each case."

Mr. Shaw said this motion was one which was discussed some eighteen months or two years ago, and last October a discussion also took place upon the same question, when he had stated the desirability of prohibiting canvassing, but at the same time as he had not given notice of his intention of bringing the subject forward it was thought better to give notice so that it should be thoroughly discussed at some future meeting. The election would take place next month, and he should have been glad to have brought it forward last month, but it did not occur to him it was necessary to do so before any canvassing cards were issued. For some years he had been thoroughly convinced of the desirability of relieving if possible the poor candidates for annuities from the necessity of canvassing for votes, and he still retained the same conviction, and would briefly state his reasons. On the previous occasion he had received very important support from several members of the Council. Mr. Hills, Mr. Hanbury, and others had taken great interest in this subject, and desired that this canvassing should be prohibited. What drew his attention to it in the first instance was the fact that a poor widow, who had canvassed right and left for her children, made application to the Council asking to be refunded the money she had spent, and which she could ill afford. It struck him at that time that money spent in that way was quite unnecessary, and he had never since given up the idea of doing away with the practice. With regard to the administration of the Benevolent Fund it was, however, free from some evils which attached to other benevolent institutions; for instance, it was free from the trafficking in votes, from public polling days, where persons bid one against another, and where the rich, of course, succeeded in carrying the day. The Council also exercised a large amount of discretion in preparing the list of candidates. In many institutions everyone who chose to send in a claim was put on the list, and thus there might be forty or sixty candidates, not more than one-tenth of whom could be elected, so that they all had to spend a great deal of money, and perhaps in the end might be disappointed. This year there were only nine candidates for the annuities, and three to be elected, and he thought one-third was but a fair proportion in order to give the subscribers an opportunity of judging of the merit of each case. As to whether canvassing was an evil or otherwise, the discussion which took place in October last was almost conclusive. Mr. Williams then expressed himself that it would be very well to do everything possible to discourage the system, and that showed there must be some evil about it, because they never wished to discourage that which was good and right. The ex-Vice-President also agreed that there was great evil in the present system. If then there was a great evil in it by all means let the system be removed. With reference to other opinions outside of the Council he could not do better than read one or two from prominent members of society. The first was a distinguished member of the House of Commons, who a few months ago stated that canvassing was an unmitigated nuisance, and a system by which an immense deal of money was thrown into the gutter. And another prominent legislator, a member of the House of Lords, said, at a recent meeting, that there were a good many abuses in connection with charities, which it was desirable to sweep away, most of all the trafficking in votes and the public polling days. Another gentleman who had spoken very recently on the subject, Mr. Ernest Hart, said on this question nearly the whole of the profession was against the Council of the Royal Medical Benevolent Fund, which was opposing the abolition of canvassing, and he added that that was not the testimony of men of hasty judgment, but of such men as Sir William Gull, Sir William Rutherford, Sir Henry Thompson, Dr. Sievking, and almost every eminent man in the profession, most of whom had spoken strongly on the subject. All this testimony certainly should have some weight. Efforts had been made on different occasions to relieve persons to some extent of the annoyance to which they had been subjected by canvassing cards, and in the case, he believed, of the Royal Medical Benevolent Fund, and also of the British Orphan Asylum at Slough, those who objected to receive the canvassing cards might have their names put in a separate list. The reason for prohibiting this system was that the feelings of poor people thrown destitute on the world ought to be respected. Many of them had scarcely the courage in the first place to apply to the Council for assistance, but directly they had got over that difficulty they asked about the necessity for canvassing, and were apparently under the impression that if they did not resort to it they must be left out in the cold, at least for two or three years, because those who did canvass necessarily stole a march upon them. A case of that kind came before the Committee on the previous evening, when a gentleman interested in one case asked if anything could be done in the way of canvassing and applying for votes for the election. Some time ago, he had had a communication from a widow who informed him that the cost thrown upon her with regard to one of these elections came to £5 13*s.*, and he contended that that sum was perfectly lost. She said she would be very glad if some other plan could be suggested, because she found the expense very heavy. In another case, in connection with the Royal Benevolent Fund, he was informed that a person had spent £20 on one election and £15 on another. Now, if each of the nine candidates spent only £5, that was £45 in the whole, which was totally thrown away. Again, the most destitute and most deserving often failed in consequence of the unequal struggle, and he referred to the elections for the few previous years to show that those who canvassed really obtained the most votes, though it did not follow that they were the most deserving candidates. He had often asked himself, but had asked in vain, what was the difficulty in putting a stop to this system. With regard to personal or written solicitations he would not interfere with them; all he wanted was to relieve the candidates from the expense. It had been said that the subscribers naturally desired to be asked for the votes they were entitled to give, but he should hardly think they would stand on a ceremony of that kind. If papers were sent round with full particulars, as they always were, he could not see what additional reason there could be for any gentleman expecting or requiring to receive six or nine canvassing cards as well. The editor of the *Daily News* had said that it was whispered that there were persons who enjoyed the sense of importance of being canvassed, but he should hope that that was not one of the requirements which their subscribers insisted on. The impracticable arguments which had been made use of over and over again, he could not see the force of. Twelve months ago, he had alluded to the Royal Medical Benevolent Fund, and at the Annual Meeting in May last, he was glad to see that out of about 5000 subscribers, a resolution was passed by about 3000 voting for the abolition of canvassing which the Council had previously declined to carry out, so that in future it was to be swept away. He could not learn from the Secretary that any increase in subscriptions was ever noticed in connection with the sending out of cards, and his motion would not interefere with any subscribers obtained by personal solicitation or writing. There were about twenty institutions already in existence in which canvassing was prohibited on pain of disqualification. For instance, at the Royal Albert Orphan Asylum there were 220 orphans now being fed, clothed and educated, and that institution was entirely dependent on voluntary contributions and had been ever since the commencement conducted on the non-canvassing principle. If such an institution could carry on operations so successfully there could be no danger about the matter. He would not detain the Council longer, but would simply ask for a vote in favour of the proposition he had brought forward.

Mr. HAMPSON, in seconding the motion, said he had supported it before and felt it right to do so again. The first time the subject was brought before the Council he waited for arguments on the other side and having failed to find them he felt more thoroughly convinced that Mr. Shaw had adopted the right view on this matter. Mr. Shaw had very clearly and convincingly introduced his motion and had brought ample evidence to show that the abolition of canvassing cards and circulars was possible, because it was carried out in other institutions. The system of canvassing was a great evil and that evil was becoming more and more recognized by men who had thoroughly entered into the question, and it was in every sense a thing to be deprecated. But that which convinced him was simply this. In these elections they had a certain number of poor persons applying, some of whom were ill in bed, some were scarcely able to move about, and the majority were without friends and without funds. It was a sort of race for who should get in; and who was the most likely to get in? The person who had the most money and who was probably the least eligible, because he was most able to canvass and bring influence to bear on behalf of his own case. The weakest must necessarily go to the wall. He thought no other argument was required to show that canvassing was objectionable; it handicapped the weakest person, and in many cases votes which would have been given to the weakest and least able were given to those who less deserved them, or who might well have waited for another year. It was on behalf of those who required the aid of the Fund most that he supported Mr. Shaw's motion.

Mr. ROBBINS thought the motion would hardly accomplish the object Mr. Shaw had in view, because there was one great and unaccountable omission in it of any penal clause, and without that it would do a deal of mischief. It simply said the Council ordered that the candidates should not canvass; but supposing some of the candidates obeyed the order, which no doubt they would, others might disregard it, and their friends might disregard it, and they would thus steal a march on those who conformed to the order of the Council. Unless there were a penal clause such as that the election of any candidate who should be proved to the satisfaction of the Council to have resorted to canvassing should be declared null and void, it could not be stopped, and if one did it not only with impunity, but with advantage to himself, next year it would be copied by others. On the other hand if such a penal clause were introduced it might occasion a difficulty, because the candidate himself might keep in the background, but his friends might come forward. In fact now the expense was often incurred not by the candidate but by his friends.

Mr. ATKINS said his first objection to the motion was that it was thoroughly impracticable. He should say that by all means the Council should do what it could to discourage the practice, but it should not talk about prohibition, at least unless it introduced the penal clause, and if that were to be done it would require very careful consideration. Mr. Hampson talked of the poorest and weakest suffering, but he though that argument was capable of a two-fold application. They were just the persons who often by kindness of friends had their claims brought forward. Mr. Shaw would admit the writing of a private letter, but how could he draw a legal distinction between a private letter and a printed card? If instead of writing a letter to a dozen friends he used one of the many systems of manifold copying, would that be considered a breach of the regulation? He was frequently influenced in giving his votes by the private letters he received, and he feared if the Council were to prohibit this principle of recommendation it would interfere with those private letters. If the prohibition were carried he should feel great doubt whether he ought to write a letter in favour of A. or B. lest he might prejudice somebody else who was more deserving. If the Council did all it could to deprecate excessive advertising on the part of poor persons, which no doubt would be the result of that debate as it had been of previous ones, he believed it might do good, but he could not support the motion as it stood.

Mr. WILLIAMS thought the motion was most inconsistent and arbitrary. What right had the members of the Council to order such a thing, which affected not themselves only, but all the subscribers to the Fund? With regard to the expense, he had already received several private letters, written no doubt under the idea that it was improper to canvass with cards, but this was a far more expensive form of canvassing than that of having a few cards printed. He did not like cards, and he often said he should discourage their use as much as possible, and he thought what had been done on previous occasions would tend to discourage them. He had thought if the Council were to turn round and say that a person who did, either by himself or by friends, issue a circular or card or canvass for votes, that that person should be disqualified, it would be most absurd and would do a great deal of injury to the Fund. He supposed Mr. Shaw intended to follow up his present motion by another, of a penal character, because if the Council made an order it must take some step to secure the order being carried out. But he thought that anything of that kind was so absurd that the least reflection would convince the members that it would be most improper to do such a thing.

Mr. GREENISH said he sympathized with Mr. Shaw very much in this matter. He thought it very desirable that the money spent in canvassing cards should be saved to these poor people if possible, but he must confess he did not see his way out of the difficulty, nor did he think Mr. Shaw had made it very clear. Instances had come under his notice where, quite irrespective of the applicants, the case had been taken up by ladies, who had undertaken the printing and the distribution of the cards, and had taken the whole of the trouble and expense upon themselves; in fact he was not sure that the applicant was even aware of it at the time. Mr. Shaw and Mr. Hampson had said that under those circumstances the weakest went to the wall, but they had no proof to that effect, and he did think that rather than pass this motion things had better remain as they were.

Mr. CHURCHILL was very sorry to see the benevolent gentlemen on each side of him opposing Mr. Shaw's motion, especially as the matter was not new to them. He could understand gentlemen of conservative tendencies being at first opposed to such a motion, but he could not see the difficulties in the way that they saw. It had been argued that it would be very arbitrary on the part of the Council to issue such a regulation, but he saw no more difficulty in issuing such a regulation than there had been in issuing those which were already in force with regard to the disposal of the Benevolent Fund and the election of annuitants. Such a provision as the following added to the regulations would, as he thought, be a simple and practical way of working the measure :—

"That the election of any annuitant shall be void who shall have canvassed for votes by means of cards, circulars or advertisements, or on whose behalf any person shall have canvassed by means of cards, circulars or advertisements."

The PRESIDENT asked if Mr. Churchill moved that as an amendment?

Mr. SHAW said he should be most happy to add it to his motion.

Mr. CHURCHILL said all the members of Council knew the very little effect on their judgment which those circulars sent out broadcast produced, and he believed that almost all members who took any trouble to consider the election at all voted for those whom they knew and for those whom they believed to be the most afflicted, and the necessities of each could be perfectly well set forth in a few lines in a circular prepared by the Council. He could see no difficulty at all, if their hearts were in the matter and they really wished to discourage canvassing, in passing such a motion as that.

Mr. FRAZER asked if he understood Mr. Shaw to accept Mr. Churchill's suggestion.

Mr. SHAW said, yes, he did.

Mr. FRAZER said if so he pitied the Benevolent Fund. Assuming that to be accepted the Council might order the candidates, but it could not order their friends over whom it had no control, and the friends might issue cards, and yet it was proposed to disable these worthy objects, it might be the very best people in the whole of the applicants, because of this arbitary law, and they would just be excluded through the injudicious action of their friends. Besides, if this were stopped private canvassing could not be. This already went on to a large extent through the representatives of large London houses and it would be carried on with redoubled force if such a motion were passed.

Mr. HILLS suggested that Mr. Shaw should withdraw his motion altogether as it could not be used now for the next election. There would then be more time to think of it and devise a more perfect means of conducting elections. He did not think the machinery for carrying it out was altogether settled, and therefore he thought it would be well to withdraw the motion for the present, especially as next May there would be an election of the Medical Benevolent Institution under the new plan, from which valuable experience might be gained.

The PRESIDENT said he could not vote on this question without expressing the opinion he had often expressed before on the same subject. Mr. Shaw had put the Council in possession of certain facts, as he described them, and said in some institutions all applicants were admitted, which was very different to the case of this Fund, because here a selected list was prepared by the Council. He must remember that in orphan asylums all applicants were not admitted, but only those who were eligible, and he must also remember that those societies he referred to gave no relief except in one way; whereas in this case not only were the deserving candidates selected for annuities, but casual relief was also given. If the Council could pick out some deserving candidates and put them first on the list and give them some sanction, saying they were the ones who should be admitted, there might be some reason in Mr. Shaw's proposition, but it would be a very difficult thing without that. Mr. Shaw had quoted observations made by other members of the Council some time ago, but had not quoted them in full, or it would have been seen that they were not in favour of his proposition. Again, he spoke of a certain Medical Benevolent Society in which the Council resisted the desire of the members to abolish the present system. He should submit to Mr. Shaw that the Council was in the best position to judge—far better than the members outside who only received the cards. No doubt to many persons it was almost a nuisance to receive these cards, because they had so constantly to say "no," and to meet this difficulty Mr. Shaw said in another institution the names of those who did not wish to be canvassed were placed on a separate list; the same could be done here. If this motion were passed the candidates might write, or their friends might write, and the mere writing of the friends might invalidate the election of the candidates.

Mr. SHAW said it was the printing, not the writing, he objected to.

The PRESIDENT said if writing were excused it would give those who had friends,—and they were probably those who were least in want,—an advantage over others. There was also this great difficulty, that he did not know how the electors were to become acquainted with the different cases unless brought before them in some way by the candidates or their friends. He should attach rather more importance to Mr. Shaw's views if he had not heard him that day vote for a grant of thirty guineas to be applied for the election of a candidate to an orphan asylum, in January next, for he could not see how he could reconcile the one thing with the other. The Secretary had just put a letter into his hands dated 20th October, saying that Mr. —— would be obliged by receiving particulars of the subscriptions to the Pharmaceutical Society with a view of assisting a candidate at the ensuing election to which he wished to subscribe. That was exactly what the Council was doing with regard to the orphan asylum he had mentioned. Besides he did not think there was anything in the motion which would really prevent canvassing.

Mr. SHAW said he had accepted Mr. Churchill's addition, which would render the resolution operative.

Mr. WILLIAMS asked what there was to prevent an enemy issuing cards. For instance, if A. B. and C. were candidates, A. might issue cards for B. and C. in order to prevent them getting elected.

The VICE-PRESIDENT said it had been contended by Mr. Shaw that these cards were an unmitigated evil, but in his opinion it was not so. If he were only a subscriber to the Fund, and not a member of the Council, he should be much obliged for any information which anyone interested in the candidates chose to give, and he therefore deprecated altogether this condemnation of the system of cards. He could see there was something to be said for a system which put the entire election into the hands of the Council, and that plan was adopted by some charitable institutions; but there was, he thought, more to be said for the opposite system, which allowed the elections to be an occasion for stimulating subscriptions and keeping up interest and enthusiasm amongst the subscribers. It was possible a little miscarriage of justice occurred, but it could only be one of degree, because the Council took care only to nominate fit candidates. In his opinion it would be a great danger to the Fund if the Council cut away from the large body of subscribers the interest they naturally felt in the exercise of their privileges. To limit the canvassing to one particular form was most unphilosophical, and he thought Mr. Hampson could scarcely have realized what it meant when he spoke so strongly in favour of the proposition of nullifying the success of the candidate because some one had canvassed in his behalf.

Mr. SHAW said he would not take up any time by a reply; and the motion was then put to the vote with the ollowing result:—

For—Messrs. Churchill, Hampson and Shaw.

Against—Messrs. Frazer, Greenish, Rimmington, Robbins, Sandford, Schacht and Williams.

The motion was therefore lost.

Mr. Hills was present at the division, but did not vote.

Mr. SYMES said he would withdraw one motion of which he had given notice, seeing that it would throw further duties upon the President. He was convinced from what he had said to-day that he had already a great deal of work to undertake, and he would be the last to add to it, if the business could be got through in a satisfactory manner. With regard to a second motion of which he had given notice, he was afraid it was now too late to bring it on that day, as many gentlemen who had promised to support it had left, and if it could be understood that it would come on earlier at the next meeting it would be better to defer it. It was not the first time he had found matters of importance left to the end of the meeting, and voted on by quite a minority on account of gentlemen having to leave, and it had been suggested that notices of motion might come earlier in the agenda. He thought this would be an improvement, where such matters were of importance, and he would leave his motion for the next meeting.

Mr. FRAZER said he had no wish to interfere with Mr. Symes's decision as to postponing this important question, but it was only fair to remind him that as long as the present rule affected matters coming at the close of the regular business they must come on at the end of the day, and he might be in the same position next month.

Mr. WILLIAMS said the question was whether it would be right to postpone the regular business of the Society for notices of motion. If this were done there might be a long argument taking up much time, at the end of which there would hardly be a quorum left to transact the regular and necessary business.

REPORT OF EXAMINATIONS.

October, 1879.

ENGLAND AND WALES.

Candidates.

2 Royal College of Surgeons of England.
1 Society of Apothecaries.
4 University of Cambridge.
1 University of Edinburgh.

APPOINTMENT OF BOARD OF EXAMINERS.

The PRESIDENT reminded members that next month the Board of Examiners would have to be appointed, and therefore gentlemen should be prepared with names, if they had any to suggest.

PHARMACEUTICAL MEETING.

Wednesday, November 7, 1879.

MR. THOMAS GREENISH, TREASURER, IN THE CHAIR.

An evening meeting of the Pharmaceutical Society was held on Wednesday last. The chair was taken at half-past eight o'clock.

The minutes of the previous meeting having been read and confirmed—

The CHAIRMAN called attention to the large number of specimens, presented to the museum, which were displayed on the table, and invited the Curator to give some particulars with respect to them.

The CURATOR first drew attention to a valuable collection of essential oils. These specimens had been used to illustrate a paper on essential oils read before the School of Pharmacy Students' Association, by Mr. Bush, who afterwards presented them to the museum of the Society. Some of them were rare and costly, and they were of further interest on account of the rotatory power of several of them having been referred to in a paper read at the meeting of the Pharmaceutical Conference at Sheffield by Dr. Symes. See *ante*, page 211. A very fine collection of North American drugs, presented by the Philadelphia College of Pharmacy and comprising over one hundred specimens, was on the table. Among these might be noticed several which were of recent introduction. The specimens were remarkably characteristic and formed a valuable acquisition to the museum of the Society. This was more especially the case since there existed some difficulty in procuring many of the North American drugs, except in the compressed and comminuted form in which they were prepared by the Shakers of New Lebanon and in which state it was impossible to study the character of the bark. Another interesting specimen was that of a portion of the stem of the Arabian myrrh, and an account of which had already been published in the Journal, vol. ix. p. 893. Next there was a specimen of Mozambique opium, the cultivation of which had only recently been successfully commenced. It contained 4 per cent. of morphia and 4·3 of narcotine, with a large percentage of water. Another interesting specimen was an ostrich stomach, from South America, where it was used in the same way as pepsine. The ostrich of South America was the *Rhea Americana*, not the common ostrich (*Struthio Camelus*), from which it differed in having three toes instead of two. Whether the digestive power of the two birds was different he could not say, but with regard to the dried stomach of the South American ostrich, he had been told by a gentleman who had endeavoured to prepare pepsine from it, that it had hardly any digestive power. The Curator next drew attention to a number of specimens presented by Dr. Dymock, of Bombay, who had been for some time past a very liberal contributor to the museum.

One was a specimen of Jaferabad aloes, which was sold in the bazaars in India in the form of flat cakes. Dr. Dymock informed him that what had been recently sold in Bombay was fictitious, which accounted for his former statement that it had the same reaction as Barbadoes aloes. The specimen now sent would not turn red by nitric acid, whereas all the Aden aloes would. Another specimen was the gum called sarcocoll, which derived its name from the fact that it was formerly used for healing and cleansing wounds. Taken internally it was a somewhat dangerous purgative. There was also an original package of Chinese oil of peppermint from Canton. Menthol had lately attracted attention as an antiseptic, and Professor Flückiger had pointed out that the oil of Chinese peppermint differed from the English in its chemical reaction; the odour, also, was slightly different. Another of Dr. Dymock's specimens was some oil of ginger-grass, or rusa oil, prepared under his own superintendence, and also specimens of the grass from which it had been prepared. This grass, he had found on inquiry at the Kew Herbarium, was not the true ginger-grass (*Andropogon Schœnanthus*, L.). He had noticed that the oil had a slightly different odour to that of ginger-grass, almost as if oil of caraway had been mixed with it; and it was interesting to find from Dr. Symes's experiments that whereas the true oil had a very low rotatory power (+1°·72) the rusa oil of Dr. Dymock's was much greater (+39°·65)* There therefore would appear to be more than one grass yielding ginger-grass oil. Another specimen of some interest at the present time was the fruit of *Luffa ægyptiaca*, which was coming into extensive use as a flesh glove, for which it answered remarkably well, and was very lasting. Mr. Harold Senier had kindly lent a specimen of the perfect fruit, which had been grown at Clapham by Mr. R. Heath, from which it might be observed that the "Loofan" gloves were merely the fruit with the outer skin and seeds removed and the fruit slit open. From a botanical point of view the fruit was interesting on account of presenting an instance in which the parietal placentation characteristic of the Cucurbitaceæ could be readily seen. He next called attention to several specimens of spurious matico, which he had selected from some offered at the London drug sales in September, and had mounted for the herbarium. One of these specimens was *Artanthe adunca*, and another was a singular variety of the true matico (β. *cordulatum*, D.C.), which differed from the typical plant in having leaves which although hairy were nearly smooth, and had not the wrinkled appearance of the true drug. Whether it differed in medicinal or surgical properties from official matico he could not say. A third was a species of pepper, which had been imported under the name of "*Matico aromatica*," but which had appeared at the drug sales under the name of matico. It had a strong aromatic odour, somewhat resembling anise, and could not possibly be confounded with matico on account of the leaves being perfectly smooth and of a more ovate outline. Another interesting specimen was the *Nardostachys Jatamansi*, supposed to be the spikenard of Scripture, and was, he believed, the first which had blossomed in this country, and which had been grown at Mr. T. Ware's nursery at Tottenham. There was also a specimen in flower of a cinchona (*C. pubescens*), presented by Mr. J. E. Howard. Dr. Dymock had also sent a specimen of the *Garcinia indica*, or cocum butter-tree, specimens of which, he believed, were rare in herbaria in this country. Next came some white quebracho bark, which had recently been found to afford relief in dyspnœa. There were two kinds of quebracho, the white and the red, the latter being used extensively in America for tanning, and had lately been imported into France for the same purpose in considerable quantities. He would also draw attention to a valuable collection of minerals presented by Mr. Talling, of Liskeard, and to some absorbent cotton wool, prepared by an American firm, which would be found to sink in water immediately, whereas ordinary cotton wool would not.

A vote of thanks having been passed to the donors,

Dr. Symes, alluding to the ostrich stomach, said he had found next to no digestive power in it, and he had lately heard that a Paris chemist had made a similar report. It was, however, constantly prescribed and used in Buenos Ayres, which showed the power of imaginative remedies. Those who got their living there by killing oxen had but one meal a day, when they were in the habit of eating seven or eight pounds of roast beef, and naturally they wanted a digestive, and they often took a dose of this after a meal. With regard to the ginger grass oil, he mentioned at Sheffield that he had examined it, and found it did not agree with the statement in the 'Pharmacographia,' that it had no rotatory power, for he found this had a rotatory power of about 39°. Relying on the high authority of Dr. Dymock, he then said that the 'Pharmacographia' might be wrong, but it now appeared pretty plain that Dr. Dymock had been misled by a spurious grass.

Mr. Martindale said the Chinese oil of peppermint was mentioned by Christison as well as Pereira, under the name of po-ho-yo. It was sold on the Continent in little bottles under the name of Japanese drops and was supplied to the Japanese market by the Chinese. As formerly sold it generally contained a quantity of stearoptene, floating in the liquid, but specimens he had seen lately were clear. However, he noticed that the sample then shown had some sublimed on the cork. Chang, the secretary to the Chinese Legation, had told him that it was nothing but Chinese oil of peppermint or some species of mint, and was used for facial neuralgia.

Mr. Davies called attention to a series of specimens showing the results obtained in dispensing a prescription containing tincture of sumbul, carbonate of ammonia, sal volatile and camphor water, with tincture of sumbul, obtained from various sources. In some cases there had been a green coloration, due possibly to the presence of umbelliferon, and in others not, and there were other differences. The question he wished answered was whether true tincture of sumbul gave a green coloration with alkalies. He also showed specimens of the roots from which the tinctures had been made.

Professor Bentley said he had not seen the specimens of root, and should not be able therefore to give any opinion as to their nature. But it was well known that a good deal of false sumbul had been in the market, attention having been first called to it by Dr. Dymock, who particularly mentioned ammoniacum root as a common article of commerce in India. This at once led to the discovery that the Indian sumbul root of Pereira was really ammoniacum root coloured and scented. The question of the change of colour should be thoroughly investigated by a practical pharmacist, especially as sumbul was coming largely into use and there was a difficulty in getting it.

Mr. Holmes was glad that attention had been called to this subject and hoped Mr. Davies would continue his investigations. He had specimens of both the genuine and spurious root and could spare him enough to experiment upon. Mr. J. B. Allen had called his attention to the false sumbul root, some time before Dr. Dymock's paper appeared in the Journal, and it was also due to Mr. F. J. Hanbury to say that he first called attention to the fact that tincture prepared from this root had a strong taste and odour of ammoniacum. At that time he compared the false sumbul with the ammoniacum root in the museum, which had been previously presented by Dr. Dymock, and found that they were identical, so that there could be no doubt that the false sumbul was nothing but ammoniacum flavoured with musk. It differed in appearance by having a slight yellowish-red colour, whereas sumbul was always white. With regard to the specimens of the root which Mr. Davies had placed on the

* In the list on page 211, rusa oil appears under the name of ginger-grass and oil of ginger-grass as Turkish oil of geranium.

table, they had to him the appearance of having been heated, and as he believed that heat developed umbelliferon in roots which, like sumbul, contained it, that might account for the green colour of the mixture in some specimens; the tincture from false sumbul (ammoniacum) had a much darker appearance than that from true sumbul

Professor BENTLEY said he had now examined the root, and had no hesitation in saying that the principal part of it was true sumbul.

Mr. ALLEN said that more than twelve months ago, when dispensing a prescription similar to that mentioned by Mr. Davies, and using the tincture he had in stock, he found the colour of the mixture was not what it should be. On getting a fresh supply of the tincture he found the colour was much darker and the smell more distinct, and after consulting Mr. Holmes, he was of opinion that it was not genuine. With some difficulty, he obtained from the wholesale house a sample of the root from which the tincture had been made, and on submitting that to Mr. Holmes he thought it was spurious. On again writing to the manufacturers, they owned that probably the tincture had not been made from the genuine root, but said that at the time it was made true sumbul could hardly be obtained.

Mr. CLEAVER thought the questions brought forward by Mr. Davies were of great importance. The tincture of sumbul varied from a very light colour to very dark; and he had himself tried in vain to get a tincture which had the same appearance as tincture of sumbul used to have years ago. The root used to show a distinctly resinous appearance on the surface on being broken, but he never saw that now, and the odour was quite different from what it used to be. He believed genuine sumbul was hardly to be obtained. As to the green colour he hardly liked to venture an opinion, but from experiments made on a genuine sample some years ago, he believed it ought not to appear.

The CHAIRMAN suggested that Mr. Davies, in following out these experiments, with the help of Mr. Holmes, should obtain an unquestionable sumbul, make the tincture himself, and then experiment on it with the same mixture, and at some future time report the result to the Society.

Mr. DAVIES said he had made several tinctures from the roots now shown. For some time the colour did not appear, and even after being macerated for some seven or eight days the tincture came out nearly clear. Nearly all the tinctures were of different colour, and he should like to know whether they were generally made by maceration, as Mr. Squire recommended, or by the B.P. process, because possibly the difference in colour might be due to the method employed.

The CHAIRMAN said perhaps the amount of interest shown in the subject would induce Mr. Davies to make further experiments and bring the result before them in the form of a paper.

A paper was then read on—

TARAXACUM.

BY CHARLES SYMES, PH.D.

This paper is printed on page 361 and gave rise to the following discussion:—

Mr. NAYLOR said, in working on large quantities of taraxacum his experience coincided with that of Dr. Symes with reference to the time of the year at which the root should be gathered. He thought the preparations kept best if the root were gathered towards the end of November or even later. With reference to the addition of more spirit to the succus taraxaci, he did not quite agree with Dr. Symes or see any particular advantage to be gained by so doing, for he had always found the quantity prescribed ample, provided the roots had been gathered at the proper time, and that care was observed in the preparation. No doubt the liquid extract would be of great service, but he questioned whether it would retain its medicinal properties to the same extent as the succus.

Mr. POSTANS said it seemed curious that there should be so much difference of opinion with regard to the best time for gathering these roots. He had had some experience in the preparation, and was rather disposed to think that in the summer, or towards the autumn, was the more proper time. It was a generally accepted opinion that the milky juice became thicker and the bitter principle more bitter during the the heat of summer, and therefore if they were to take taraxacine as the active principle, from July to September would be the best time. He quite agreed that the quantity of juice obtained at this period might not be equal to that expressed later on, but he considered that it would contain in proportion more taraxacine. The Belgian and the old Edinburgh Pharmacopœias got over the difficulty by ordering that the whole plant should be used; but it seemed to him that in the absence of physiological experiments these differences of opinion might well exist, and he hoped Dr. Symes would continue his experiments in several forms. It would be useful if he could obtain some juice from roots gathered at different periods, and then enlist the co-operation of a medical man who would test them therapeutically. They had been told that the extract was a useless preparation, and that it was used chiefly as as excipient for pill masses. Why was that? It occurred to him that perhaps the heat used in the evaporation of the extract had a great deal to do with it. The Pharmacopœia ordered that the juice should be expressed, then heated to 212°, and subsequently evaporated to an extract at 160°, and it occurred to him that perhaps that temperature destroyed the taraxacine. Possibly they would get a better extract if the succus containing the spirit were itself evaporated at a low temperature. He did not agree with Dr. Symes that they should have a liquor. He thought the succus an excellent preparation; it answered every purpose, and it was undesirable to multiply liquors in such a way that it would be difficult for dispensers to know when the liquor was desired by a physician and when the succus. As they had at present only one official preparation he should imagine the succus was in all cases intended.

Mr. HOLMES said he had sometimes found that instead of the extract dissolving entirely in hot water, it left a large proportion, as much as 25 per cent., undissolved, which he believed to be inulin. Dr. Symes spoke of the root being sweet after a frost and said it was caused by the alteration of the starchy matter. He did not know whether starch was present in the root or only inulin. If there were only the latter he should be glad to know whether the sweet root still showed the presence of inulin, whether it had disappeared and given place to sugar, or whether the sugar was produced from altered gum. With regard to fresh and dried root, the milk contained a certain amount of caoutchouc which would be insoluble on drying, and he would be glad to know whether the dried root on that account might not present some advantages over the fresh.

Mr. UMNEY said those who had had practical experience in pressing large quantities of taraxacum root could have hardly failed to notice that at any rate with regard to the density of the juice the root collected in the month of November was far superior to any other. They had it on record by Professor Bentley that the juice prepared from roots collected in the earlier spring had a more delicate flavour, and perhaps contained an equal amount of taraxacine. That he was not prepared to contest, but he could not follow Mr. Postans in thinking that the root should be collected between July and September. He could not conceive that the proper time to gather a root was whilst it was in the greatest state of activity. However, his own observations convinced him that juice expressed in the autumn was superior, and that it then has a much greater specific gravity than that pressed at any other time; at that time the hydrometer would indicate 1·065 up to 1·075 specific gravity, whereas in spring it would be as low as 1·030. Dr. Symes had referred to the imperfect keeping power of the succus of the Pharmacopœia and every one must have been annoyed at times by its turbidity in spite of all precautions. Perhaps the chief cause of that was to be found in the constituents of the root itself; but there was one thing which should not be lost sight of. When a magma, and this crude juice and spirit was nothing less, was thrown upon a filter the difficulty of filtration was immense, and he had for years adopted the method of filtering the juice out of contact with air as much as possible; in this way acetification was prevented and evaporation of spirit reduced to a minimum, and the juice was obtained in the most elegant condition. For this purpose he always discarded the ordinary filtering paper and resorted to a canvas bag five or six feet long having a tin cylinder round it to keep away the air. When the juice was thus filtered there was very little difficulty in keeping it. In this country, for almost half a century, there had been a fluid extract of taraxacum quite different from the Pharmacopœia. One or two houses had certainly made it for twenty-five years by taking the dried root, macerating it with cold water, taking the aqueous liquid and raising it to boiling point to coagulate the albumen, evaporating down to a certain point and adding spirit of wine so that one fluid ounce of the resulting product was equal to one ounce of the root. Such a preparation was frequently sent out, although the quantity was small as compared with the succus. It was very dense, but from a medicinal point of view, an inelegant preparation, for he should say it consisted almost wholly of glucose. Some five or six years since, soon after the publication of the United States Pharmacopœia, when everything seemed to be embodied in glycerine, he exhibited twelve or fourteen fluid extracts, one of which was fluid extract of taraxacum prepared by that process, and they might remember some of the senior pharmacists considered it one of the most inelegant preparations they had ever seen. He must stand up for the old succus taraxaci of the Pharmacopœia. When properly prepared and one-third its volume of spirit added to it, it was an elegant preparation, but it required precautions in making. For instance, after the roots were crushed they must not, as was sometimes the case, stand five or six hours before pressing, but should be put into the press at once, the juice taken out and spirit added; otherwise the juice might be expected to turn sour, and when acetification had once commenced it was difficult to know where it would end.

Mr. Martindale said the preparations of taraxacum had always been troublesome to pharmacists. In the London Pharmacopœia there were three: the decoction, the compound decoction of broom and the extract. The fresh root was ordered for the decoctions, and he remembered as an apprentice being sent out to gather it when required; sometimes he had seen roots not at all genuine brought in,—species of hawkweed, etc. In the present Pharmacopœia they were ordered to make the decoction from the dry root, which had not the disadvantages of the fresh root, but unfortunately it was liable to be maggot-eaten. Then they had the succus, which Dr. Symes thought might be improved by concentration, but he questioned whether therapeutically taraxacum was really worth taking so much trouble with. Dr. Rutherford, who had conducted a series of experiments with it upon dogs, came to the conclusion that it was a very feeble biliary stimulant. Dr. Garrod also considered that its efficacy was very doubtful. He thought, therefore, it would fast fall into the category of obsolete drugs, and he had himself lately found very little demand for it. With regard to the concentrated preparation of the American Pharmacopœia, he thought there was rather too much concentration. One part in two fluid parts might be of service in some drugs, but in many of them one in one was not possible. It did not fairly represent the drug, especially if it were of an active character.

Mr. Postans said it would be useful to know whether Dr. Rutherford's experiments were continued with the isolated taraxacine, and if the results were the same.

The Chairman said it was sufficient for them that taraxacum held a place in the Pharmacopœia. They had better leave the question of therapeutics to medical men.

Professor Bentley said it was now nearly a quarter of a century since he brought before the Society his views on the collection of taraxacum. He then stated his reasons for thinking that spring was the best season, but he thought Dr. Symes must have misunderstood in one particular what he then said. He did not mean to say that the preparation made in the spring was superior from a pharmaceutical point of view, but that judging from the bitterness of the juice, and its greater activity, of which he had personal proof, he wished pharmacists to consider whether it would not be better to make the extract in the spring than the autumn. What he had also specially referred to was the period mentioned in the Pharmacopœia, for it seemed to him unquestionable that it could not be right to allow so long a period as from September to February. He had always said that however opinions might differ as to the period of collection, it could not be proper to gather it after a frost, because at that time the root became sweet instead of bitter. He was glad to find that on this point he had been confirmed by Dr. Symes. Mr. Holmes had called attention to the question whether the root contained starch or inulin, but he imagined Dr. Symes meant to convey that inulin had been converted into sugar. Overbeek had found as much as 2 ounces of inulin in a pound of the dry root in the autumn, but very little in spring, when it had doubtless been converted into saccharine matter. No one could doubt that the preparation had a more elegant appearance when made in the autumn, but he did not think it was yet settled whether that made from the spring root had not greater medicinal activity. It was not a question for them whether taraxacum was a good therapeutical preparation; it was largely used, and pharmacists were simply called upon to present it in the best form, and to advise physicians as to the best mode of administering it.

Professor Redwood congratulated the Society on having had so throughly pharmaceutical a paper, and on a subject on which he thought discussion might well be renewed. Although the matter had apparently fallen into abeyance after the discussions which took place many years ago, yet that had not been strictly the case. Hardly any preparation had received more attention from the Committee of that Society (of which he had the honour to be Secretary), which was appointed first on the recommendation of the College of Physicians, and subsequently of the Medical Council, to furnish the results of their practical experience on matters in the Pharmacopœia, than taraxacum. Whatever responsibility attached to the instructions given in the Pharmacopœia relating to either the time of collection or the preparation of the extract, rested mainly on that Committee. With regard to what had fallen from Professor Bentley, he must say the Committee took great pains to inform themselves on various points besides those which had been referred to. The most suitable time of collection was considered, and it was also deemed desirable to fix upon a period when the root was found to yield the juice in what was considered the greatest state of activity. But the further question was also considered of the practicability of getting the root at the times most suited for using it. It was well known that taraxacum was not cultivated specially; but that which came into the London markets was collected from ground otherwise occupied, so that it was necessary to fix upon a period when the roots could be taken up without disturbing the more important crops occupying the same ground. It was therefore considered that even if November were the best month for collecting the roots, it might not be practicable to get the supply required in that particular month, and that in the subsequent months of December and January equally good roots might be collected. It was therefore deemed advisable to give rather a wider range of time, because it was obvious that something depended on season and climate, and the period which might be most suitable in one part of the country might not be most suitable in another. The point he wished specially to mention was that the whole matter had been carefully considered by a Committee appointed by that Society.

Mr. CLEAVER said he could scarcely agree with Dr. Symes's statement that juice from roots collected in the autumn was very thick and almost immediately solidified, though it was certainly denser than that collected in the spring. He did not think it was so bitter, however. The latter was perfectly opalescent after a short time, and the bitterness was far more marked. With regard to preparations he feared that of late they had been drifting too much in the direction of elegance without due regard to efficiency. He had found that if taraxacum root were exhausted by water, by weak alcohol, and by strong rectified spirit, three entirely different preparations were obtained, which would keep for different lengths of time. That exhausted by water quickly changed into a sweet preparation; that with proof spirit had the odour of taraxacum, and kept for a considerable length of time; but with rectified spirit there was obtained a light coloured preparation, having little of the characteristic odour of fresh taraxacum, but which had a decided bitterness. If that were evaporated, a liquid was obtained which would, after a little time, deposit a substance which had been called caoutchouc, but the nature of which he did not know; the residue was bitter, and with the addition of a little spirit would keep bitter for almost any length of time; at any rate he had kept it for eight years without any alteration. With regard to the extract as at present ordered, when first made it had a very bitter taste; if treated with alcohol the result was a bitter preparation, and a sweet one was left behind. What it was would be for future pharmacists to determine. The succus if properly made was an elegant preparation, and one which kept for any length of time. In many places he believed it was made by merely expressing the juice without heating and adding alcohol, and though it might sometimes keep, at others it would acidify rapidly. The addition of alcohol caused a large coagulation of some matter which on exposure to air on the filter acidified and rapidly altered.

The CHAIRMAN thought the pharmacy of these preparations was very empirical until they knew the constituents of the substance on which they were operating. They had in taraxacum a bitter, and a peculiar substance, inulin, which did not turn blue with iodine, though it was related to starch and was found in the compositæ. It did not appear in grains like starch, it was soluble, and was found in this plant in spring, but much more largely in autumn. One of the most interesting papers on this subject was one which appeared in 1848 or 1849, by Dr. Wilson, of Edinburgh, founded on various experiments performed by Messrs. Smith, who obtained from the juice expressed a large quantity of mannite. Being desirous of ascertaining whether this existed in the dandelion root or was produced by fermentation, they sent out a man to dig some roots, and within six hours they were pressed, the juice reduced and spirit added In that juice mannite was not found; but if itw ere left. for even twelve hours, more or less mannite was found. Two German chemists had previously found mannite in the juice, but they were uncertain whether it existed in the root or was produced by fermentation. He thought there was a great deal of truth in Mr. Giles's opinion that the time which elapsed between the collection and use of the roots was of the first importance, and the season of collection rather secondary. There could be no question, however, that the root should be collected in November, as it then contained more of the bitter principle with a large amount of inulin, while in spring there was very little of the latter principle. He would rather qualify Mr. Giles's view, however, by saying that it was the time between the pressing and reducing which was of prime importance. The conversion of the inulin through fermentation into a saccharine substance was the real cause of the difficulty they had to meet.

Dr. SYMES, in reply, said his suggestion as to the addition of a little extra spirit was readily explained by Mr. Umney's remark, that by filtering in a closed vessel protected from the action of the air he saved loss of spirit. It was quite possible that the loss by evaporation in the ordinary way was the reason why he found an addition advantageous. He quite agreed that it was not the province of pharmacists to discuss the physiological action of taraxacum; but its great importance was shown by the fact of which he had been informed since his paper was in print, that one wholesale house, last year, between September 25 and November 28, pressed 129 cwt. of root, giving 641 gallons of strained juice. His informant, who was chemist to the house in question, also told him that he found November was the best season. He should not have quoted Professor Bentley's remarks of twenty-five years ago, but for his high authority, as anyone might change his opinions in that time, and Mr. Cleaver still held the same opinion that the spring was the best time, and he found the same thing stated in a very useful book, the Museum Catalogue. Again, they had the Pharmacopœia, giving a period from September to February, passing through those very months when there were severe frosts, which all agreed, was the least proper season. In using the term "starchy matter," he, of course, referred to inulin. Some years ago, he had tried to obtain taraxacine in the crystalline form, but had never succeeded, though he got it in a colourless solution very much concentrated. He found, as matter of experience, operating with large quantities, that the juice pressed in the autumn was very dense and abounded in inulin, which was capable of being filtered out and separated. On examining similar roots a month later he found they yielded much less inulin, there was more sugar and less bitterness, and further on in the winter and early spring he found that inulin had largely disappeared. Some of the inulin he had isolated as a buff-coloured powder. With regard to the fluid extract, he knew that extractum taraxaci fluidum was frequently prescribed and then the difficulty arose that they had no fluid extract; but probably the American preparation was meant. The succus could not be used certainly as a fluid extract. The chairman had remarked that they had not a very definite substance to deal with, and Professor Attfield had suggested to him that possibly some gentleman connected with the Conference might investigate the matter chemically, and he hoped that might be done, because those who were daily occupied in business had not time to follow out investigations requiring so much time.

A vote of thanks having been passed to Dr. Symes, the meeting was adjourned to December 3.

EXAMINATIONS IN EDINBURGH.

October 28, 29, *and* 30, 1879.

Present on each day—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was present on the 28th on behalf of the Privy Council.

MAJOR EXAMINATION.

October 28.

One candidate was examined, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Presslie, Robert Dowell ....Aberdeen.

MINOR EXAMINATION.

October 28.

Ten candidates were examined. *Four* failed. The following *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Chalmers, Thomas ....Lanark.
Chambers, Herbert ....Haddenham.
Cowie, George ....Glasgow.
Dow, William ....Kinross.
Easton, John ....Moffat.
Goddard, James Godfrey ......Great Yarmouth.

October 29.

Thirteen candidates were examined. *Eight* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Gould, William E. ....Birmingham.
Hardie, James Miller ....Dundee.
Heslop, Henry Hills ....London.
Hogg, Robert William ....Gateshead.
Mauchlen, Robert ....Glasgow.

October 30.

Eight candidates were examined. *One* failed. The following *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Pringle, George ....Pathhead.
Tatam, Saml. Blackmore Chas..Ottery St. Mary.
Taylor, Robert Allan ....Kingston, Glasgow.
Walker, Alexander ....Cullen.
Wallace, Andrew..................Edinburgh.
Waters, George.....................Alnwick.
Welford, Richard..................Blackburn.

MODIFIED EXAMINATION.

October 30.

One candidate was examined, and was declared qualified to be registered as a Chemist and Druggist:—

Campbell, William ....Manchester.

PRELIMINARY EXAMINATION.

The undermentioned was received in lieu of the Society's examination:—

Certificate of the University of Edinburgh.

MacGregor, William ....Edinburgh.

Provincial Transactions.

BIRKENHEAD CHEMISTS' ASSOCIATION.

A meeting of this newly formed association took place on the 29th of October at the Ranelagh Hotel, where the members dined together at nine o'clock p.m. Considering the recent formation of the Society and the somewhat unfavourable circumstances under which this meeting took place, the attendance was good. The principal chemists of the town and district were mostly in attendance or sent in apologies for absence, the others perhaps only waiting for the consolidation of the Society, or further information, before joining. The objects sought are chiefly more unity of action in all matters affecting the interests of the trade, mutual improvement and the strength of combination against the many assaults now made upon the legitimate business of chemists. The meeting, as well as the preceding ones, was perfectly unanimous and a very pleasant evening was spent, all the members feeling the better for social intercourse and separating with much higher opinions of each other than ever can be attained whilst unworthy selfishness and suspicion are allowed to prevail, a state of things which does not exist to the same extent in any other calling whatever, and which is inflicting the deepest injuries upon the best interests of chemists in general. The association is only in its infancy, but it has begun with every prospect of success, and the members look forward for the assistance of all the chemists in the town and district. In former years the chemists of Birkenhead were very closely united and very frequently met together for mutual benefit and social discussion; but the rapid extension of the town and sudden influx of many chemists from other districts had, unfortunately, an unfavourable influence upon the strong bond of unity, and serious loss to all has resulted.

Parliamentary and Law Proceedings.

Prosecutions under the 17th Section of the Pharmacy Act, 1868.

At the Hull Borough Police Court, on October 30, 1879, before Mr. E. C. Twiss (Deputy Stipendiary), William and Thomas Cussons and others, trading as the Hull and East Riding Supply Association at Lansdown Terrace, Beverley Road, Hull, were charged "that they did, on the 22nd day of October, 1879, unlawfully sell to William Frederic Haydon, secretary of the Chemists and Druggists' Trade Association of Great Britain, 23, Burlington Chambers, New Street, Birmingham, certain poisons, to wit, chloral hydrate and morphia, contained in certain pills enclosed in a bottle wrapped in certain papers, neither the bottle nor the wrappers of which poisons were labelled with the word 'poison,' nor with the names or addresses of the sellers of the same, contrary to the statute in such case made and provided."

Mr. Henry Glaisyer, solicitor, Birmingham, appeared on behalf of the Chemists and Druggists' Association for the prosecution, and Mr. Thomas Priestman, solicitor, Hull, for the defendants.

Mr. Glaisyer said this was a summons issued under the provisions of the Pharmacy Act, 1868. The 15th section of the Act prohibited all persons other than those registered under the Act from retailing, dispensing or compounding poisons, and from using or exhibiting certain titles, and the 17th section enacted "that it shall be unlawful to sell any poison either by wholesale or by retail unless the box, bottle, vessel, wrapper, or cover in which such poison is contained be distinctly labelled with the name of the article and the word 'poison,' and with the name and address of the seller of the poison, and that any person selling poison otherwise than is herein provided shall upon a summary conviction before two justices of the peace be liable to a penalty not exceeding £5 for the first offence, and to a penalty not exceeding £10 for the second or any subsequent offence, and for the purposes of this section the person on whose behalf any sale is made by any apprentice or servant shall be deemed to be the seller." On the 22nd of the previous month, Mr. Haydon visited Hull, and went to the defendants' establishment, situated in the Beverley Road, where he purchased a bottle of compound chloral pills. The pills were supplied to him in a bottle, upon which was not placed the word "poison," or the name or address of the sellers of the poison. Having made the purchase, he analysed the pills and found they contained chloral hydrate and morphia in considerable quantity, both being within the meaning of this Act.

Mr. Thomas Priestman, for the defendants, said they had no defence except ignorance of the law which, of course, was no valid defence. His clients had no intention of doing wrong, and they were quite prepared to withdraw from their stores everything they had no legal right to deal in, and they were sorry that they had offended against the law. He hoped only a mitigated penalty would be imposed, provided his clients at once give up selling such articles.

Mr. Twiss: What do these pills contain?

Mr. Glaisyer: They contain chloral hydrate and morphia.

Mr. Twiss: And these are poisons within the meaning of the Act?

Mr. Glaisyer: Yes, sir.

Mr. Twiss: I suppose that as a matter of fact there is poison in almost in all patent pills?

Mr. Glaisyer: The article sold in this case is not a patent medicine.

Mr. Twiss: You say, Mr. Priestman, that your clients have been selling these pills without a knowledge of the statute?

Mr. Priestman: Yes, sir; and they did not know the articles contained in the pills were poisonous.

Mr. Twiss: But if your clients deal in such things they must take the responsibility attached to their sale. Of course this case is taken up in the interests of the public, and I think under the circumstances I must fine the defendants 40*s*. and costs.

A penalty of 40*s*. and costs was inflicted.

Sale of Vermin Killer by Unregistered Persons.

At Walton-le-Dale (Lancashire) Police Court, on October 31, 1879, before Messrs. Whittaker (Chairman) and Thomas Whittaker, John Hayhurst, general dealer, Bamber Bridge, was charged "that he did on the 21st day of October, at Bamber Bridge, unlawfully sell to William Frederic Haydon, secretary of the Chemists and Druggists' Trade Association of Great Britain, certain poison, to wit, rat poison, a preparation of strychnine, in a certain packet, the cover of which packet did not set forth the name or address of the seller of the same, and that the said sale was effected, the purchaser being unknown to the seller and not introduced to the seller, and that the date of the sale, the name and address of the purchaser, and the name and quantity of the article sold, not being entered by the seller in a book kept by him for that purpose, in contravention of the statute in such case made and provided."

Mr. Glaisyer, solicitor, Birmingham, appeared for the prosecution, and the defendant appeared in person.

Defendant pleaded guilty, but said he had not had his attention called to the fact that he must not sell such poisons. He purchased them in the ordinary way of business, and did not know he could not legally sell them. He kept the poisons as a convenience both to himself and his neighbours.

Chairman of the Bench: It is pretty well known that poisons in a pure state may be sold only by chemists.

Magistrates' Clerk: You are not in the habit of keeping a book, I suppose, for the purpose of registering the sale of such poison?

Defendant: No, sir; I was not aware it was necessary for me to do so.

Chairman of the Bench: This kind of poison is pretty generally sold, I suppose?

Defendant: Yes, sir; such articles may be purchased in almost all the small shops in country districts.

Chairman of the Bench: You know as well as I do that there have been suicides from the taking of such preparation?

Defendant: I have heard of such things.

Chairman of the Bench: We shall fine you in the mitigated penalty of 10*s*. and costs. You must be more careful for the future.

Poisoning by Syrup of Poppies sold by an Unregistered Person.

On Wednesday, October 17, an inquest was held at the Guildhall, Doncaster, before Mr. Arthur J. Shirley, the borough coroner, on view of the body of a child, three months old, named Beatrice Cliffe. Emma Cliffe, mother of the deceased, identified the body. Deceased was a healthy child; it began to be unwell on Friday afternoon and was troubled with a cough. It was also sick. She gave it a little of Mr. King's cough mixture. She gave it a quarter of a teaspoonful with a little warm water and sugar, and repeated the dose two or three times. On Sunday, when she gave the child two doses of the medicine it became worse, and in the evening a neighbour named Mrs. Mawson told them she had a recipe which she thought would cure it. Next morning witness went for the recipe, which Mrs. Mawson had obtained from a neighbour, and she copied it in pencil. She gave the paper to her daughter and told her to go to Mr. Spight's for some medicine. When her daughter returned she sent to Mrs. Mawson's to inquire how the medicine was to be taken, as Mr. Spight had not put a label on the bottle. Mrs. Mawson came herself and told witness the dose was not quite a teaspoonful, which was to be repeated three times a day. Witness gave the child a dose and for about an hour the child seemed quite lively, but after that time she fell asleep and slept for two hours. Witness then took the child up, and after giving her the breast, gave her another dose of the medicine. After that witness put her on the sofa, and she fell asleep. About eight o'clock witness undressed her. While doing that, the child's arms dropped on one side and her face looked very pale. Getting alarmed witness sent for Dr. Wilson, who applied a mustard plaster to the child's chest. It seemed to revive a little, but did not thoroughly wake up, and died on Tuesday morning. The child had frequently slept a long time, but it had never had any medicine before. Her husband took a little of Mr. Spight's medicine on Monday night, and said it made him feel queer.

Dr. Wilson deposed that on Monday evening Mr. Cliffe's daughter came to his house and told him the baby was very ill, and they wanted him to see it. He got there soon after eight o'clock, and found the child lying on Mrs. Cliffe's knee, looking very pale and ill. Its cheeks were cold, and on examining its eyes he found the pupils were very much contracted. He asked what had been given to it, as there was every symptom of opium poisoning. He was shown a paper, containing the following prescription:—1 ounce cold drawn linseed oil, $\frac{3}{4}$ ounce syrup of squills, and $\frac{3}{4}$ ounce syrup of poppies. He asked what the dose was and was told a teaspoonful. The bottle was shown to him and he said there was no label on it, stating what it contained or how it was to be used. He said it was a very unsafe thing, as syrup of poppies varied considerably in strength. In the meanwhile various means had been adopted to rouse the child from the state of stupor in which it was, and for a while those means seemed to be successful to a certain extent. The child began to move about a little and open its eyes and looked a good deal better. He stayed about an hour, and as the child seemed to be improving, he left. He applied a large mustard plaster, and had the child's feet placed near the fire. The child was in a profound stupor, and but for the breathing, which was very faint, he would have thought it was dead. Before the child died, his opinion was that it had been poisoned by opium. On Tuesday morning, Mr. Cliffe came to his house and told him the child was convulsed, and when witness arrived at the house a little before ten o'clock, he found that it was dead. Speaking of the medicine, he said each dose would contain 15 drops of syrup of poppies. Syrup of poppies was such an uncertain preparation that he would never under any circumstances administer it to children; it was essentially opium and very often adulterated. It was a dangerous preparation and if used at all should be used with very great caution. On Wednesday morning, he, in company with Mr. Walker, house surgeon, at the Infirmary, made a *post mortem* examination of the body. There was a small quantity of mucus in the bronchial tubes showing a slight attack of bronchitis, and some portion of the lungs were slightly congested. The brain was also slightly congested. There was no disease discovered sufficient to account for death, the bronchitis being very slight indeed. If he had known nothing of the circumstances he would not have been able to say from the examination he made that the child had been poisoned.

In reply to a juryman witness said the medicine should have been labelled "poison."

Mr. Walker, surgeon at the Infirmary, confirmed the evidence of Dr. Wilson as to examination of the body after death.

The inquiry was adjourned until Tuesday afternoon for the purpose of having the remaining portion of the medicine analysed.

The adjourned inquest was held before the borough coroner, Mr. A. J. Shirley, on the 21st ult.

Mr. Hall watched the case for Mr. Spight, druggist.*

The evidence given by the witnesses at the last hearing was read over.

After the evidence of the little girl who fetched the medicine had been read, Mr. Hall said what he wished to put was this. Take it for granted that Mr. Spight made up the mixture (which he denied), that would be no offence. According to the ruling in the case of the Queen *v.* Pocock, there must not only be neglect, but the death must be an immediate result. It would not be sufficient for Mr. Spight to have made up the medicine, for the child's evidence was that she did not tell Mr. Spight for whom or for what the mixture was required.

The Coroner said Mr. Spight was not charged with anything at the present time, and he thought it would be best for the inquiry to proceed.

Replying to Mr. Hall, the girl said it was a week on Monday when she fetched the medicine from Mr. Spight—whom she pointed out in the court. There was a girl in the shop at the time she got the mixture. She only gave Mr. Spight the paper. She did not say anything as to what it was for.

Dr. Wilson, answering Mr. Hall, said that no druggist would be justified in making the mixture up, as there were no directions on the paper as to how it should be used. There was nothing as to this, however, in the books he had read. Supposing a child had bronchitis, the syrup of poppies would have more effect; would tighten instead of loosen the expectoration. Witness was not aware what the mixture (King's) was that was given to the child the day before, but it might, or might not, make the child more susceptible to the opium.

By the Coroner: There ought to have been a label on the bottle. The chemist would have been justified in making up the prescription if it had been initialed by a medical man.

The first witness examined to-day was George Cliffe, the father of the deceased. In addition to corroborating the main portion of the evidence of his wife, he said the reason they discontinued giving the child King's mixture was that it was rather hot, and the child did not take it well.

Sarah Ann Mawson, deposed to recommending the last witness to give his child the mixture contained in the prescription, as it had done her children good. On her bottle there was a direction on the label to give the mixture twice or three times a day. She got her medicine from Mr. Spight, and it produced no ill effects on her child.

Martha Snow deposed to recommending the prescription to Mrs. Mawson. She had given it to her children, and the one in court—a baby—had only a spoonful the last week. She had always got the mixture, till the last lot, from Mr. Spight, but the last time Mr. Spight told her child that he had not one of the things in stock.

By the jury: She had had the prescription made up by Mr. Spight several times.

Sergeant Thompson deposed to receiving the prescription and a bottle of cough mixture, with Mr. King's label on, from Mrs. Cliffe. This bottle of mixture, and the one containing the mixture said to have been got from Mr. Spight, witness took to Mr. Walker, analyst, of Sheffield.

Edmund Spight said he was a grocer and dealer in medicines. [The Coroner here said that witness was not obliged to answer any question unless he liked.] His shop was in Cemetery Road. He knew the little girl, Alice Ann Cliffe, from seeing her several times at his place. She had been for several little things. He believed he would be at home about nine o'clock on Monday night week. Mrs. Spight would be at home, too. He did not remember that morning the girl Cliffe coming to the shop, nor any little girl coming to the shop and giving him a paper. He did not keep at his shop syrup of poppies.

The Coroner: Do you keep any poisons at all?

Mr. Hall: You need not answer that question.

Witness, continuing, said he had never kept syrup of poppies. He did not know that he had seen the prescription produced, but similar ones had been brought to him to make up, and he substituted certain things—burnt sugar and simple syrup—for the syrup of poppies. He never sold syrup of poppies at all. Syrup of poppies was made by boiling poppy heads with sugar. He kept the linseed oil and syrup of squills, but not the syrup of poppies. He was quite certain the girl Cliffe never went to the shop on Monday week; nor did he to his knowledge see the prescription produced that week. It was not usual for people to sell burnt sugar and simple syrup for syrup of poppies. They did not do this where he was last employed.

By the jury: The label on the bottle produced (by Mrs. Mawson) was his, and he always labelled the bottles in which he supplied cough mixture. He had now at his place a bottle containing burnt sugar and simple syrup. He might have told Mrs. Snow that he had not one of the ingredients she wanted, but if he did it was because of its being the race week, and he would be busy. He would then have the same thing as he had now. He did not remember the girl coming at all, but if he had sold the mixture he usually sold, he should, as was his habit, put a label on the bottle. To his knowledge he had never had any syrup of poppies in his shop—at least, not for the last three years. On the day the child died he told the officer (Serjeant Thompson) that he had had the prescription brought to him.

Henry Herbert Walker, of Sheffield, and the analyst for the borough, said the two samples of medicine he received from Sergeant Thompson he had analysed. In King's mixture he found a small trace of opium, but not sufficient to be weighed. The other constituents were quite harmless—such as anise. The mixture said to have been obtained at Spight's he analysed, with the object of detecting opium, and he found two grains in the whole bottle—about 16 teaspoonfuls. There would be about a tenth of a grain in each teaspoonful, the teaspoonful to hold a drachm, or about 60 drops. In analysing he found both morphia and meconic acid—two of the constituents of opium.

By the jury: He did not analyse to estimate the other contents of the bottle, though he found traces of both the oil and simple squills. He should think that two grains of opium was a large quantity to find in three quarter ounces of syrup of poppies.

By Mr. Hall: He was told to examine the mixtures for deleterious substances. The officer might have told him to analyse for opium. He did not know whether one-tenth of a grain of opium would, or would not, kill a child. He made both analyses at the same time, but in separate vessels. It was by testing the substance that he found it was opium, but in testing it the quantity was so small, that he lost it.

Dr. Wilson, recalled, said that a tenth of a grain of opium in a teaspoonful of mixture given to a child, and repeated, would produce the symptoms from which this child suffered. His opinion was that the child died from opium poisoning.

By the jury: One-tenth of a grain of opium had been known to poison a child, though it was often given without producing ill effects.

By Mr. Hall: Although the child, was a healthy one, one-tenth of a grain given at ten o'clock, and another at three o'clock, would produce the symptoms he found. In his opinion, no prescription of this character ought to be given except by a medical man. Dr. Wilson explained that if there had been three-quarters of an ounce of syrup of poppies, it would contain three-quarters of a grain of opium, whereas the portion of mixture remaining was found to contain two grains.

* Mr. Spight is thus described in the report in the local newspaper, but there is no such name in the Register of Chemists and Druggists.—ED. PH. J.

This was all the evidence, and the coroner told the jury that the case resolved itself into two points. The first was the death of the child. Did it die a natural death, or from the administration of opium? If death was caused by the latter, then the question was where did the opium come from, and who was responsible for its being given to the child. After reading over the main parts of the depositions, he stated that the evidence of the mother, Dr. Wilson, and the analyst, all pointed to the fact that the child had not died a natural death. Then came the second point. Was there any person responsible for the death; that was if it had been caused by poison? The evidence of Mrs. Mawson and Mrs. Snow was that Mr. Spight had frequently made up this prescription, though their children had never suffered from it. The little girl had given her evidence remarkably well, though it was singular that her evidence should so much differ from Mr. Spight's. The girl remembered nearly everything, while on the other hand, Mr. Spight said she was not at his shop. Mr. Spight was on his oath, and they ought to give due weight to his evidence. First, then did the child die a natural death, or was its death caused by the administration of opium? If the latter was obtained at Spight's shop, and if so, was Spight justified in selling it as he did? If they found that the medicine was obtained from Spight's, and that the child's death was caused from the gross negligence, carelessness, or ignorance of Spight, they must say so. On the other hand, if they found that the death arose from the administration of opium, but there was no proof as to where it was obtained, then they must bring in a verdict of death from misadventure.

The jury retired, and after being absent about half an hour, they brought in a verdict that the deceased died of opium poisoning. The jury believed that the girl went to Mr. Spight's for the mixture, and obtained from him a mixture containing opium. The jury, however, found that Mr. Spight was not guilty of gross or criminal negligence, but that more care should be taken in supplying mixture.—*Doncaster Chronicle.*

A Question of Policy.

Sir,—Some years ago when "Allen's Hair Restorer" was introduced to the public, and boldly and skilfully advertised, chemists, tempted by the large profit offered to the retailer, "pushed" it with their utmost ability, and since careful people generally consult their chemist as to the innocuousness of such preparations, it may, with all due deference to the skilful methods of advertisement, be safely inferred that but for the recommendation of chemists, it would not have realized such an immense consumption.

The growth of stores and cutting houses has, however, taken the sale in a great measure out of the hands of the chemists; the chemist has sown that others may reap; for, once he has assured his lady clients that it is perfectly harmless and effectual, and they have become habituated to its use, at no time can he effectually retract that opinion, and he has therefore the pleasure of seeing the very customer who "sucked his brains" on the scientific and medical view of the preparation, obtain her supply at the store, and point at his exorbitant charges from that identical article. "Once bit, twice shy" used to be held a good proverb, but it seems of small value now, for I have just had placed in my hands an almanack for 1880, skilfully and ingeniously compiled by a gentleman, "who as a stranger in the land" commenced business a little more than a year ago in a cellar, or as he more euphoniously puts it "a sub-basement." Business energy, a believing public and the chemists as missionaries, have created for his article a sale almost unprecedented.

Remember, I make no complaint against this gentleman or his article, but simply take it as an example.

The almanack is graced with woodcuts, prominent among which is a portrait of a venerable dame, who if she be not as mythical as Mrs. Harris, would put to shame all the medical profession, botanists, and scientific discoverers in the world.

Out of the thirty testimonials from agents, I find some three from pharmaceutical chemists, thirteen from chemists and druggists, in company with eleven from persons not on the register, many of whom are herbalists, storekeepers and general hucksters.

Fancy a chemist being proud of the scores of bottles he has sold, while the very next testimonial tells of the sales of a "medical botanist," whatever that may mean.

By the time these energetic chemists and their select companions have helped to build up an immense sale for this article, the public will buy it at a discount at the stores.

Now, do the chemists of England hope to sell medicines like Dutch cheeses? and if they do not, let me ask them why they persist in helping to push a principle of quackery which will eventually kick its benefactors—why they put a rod in pickle for their own backs?

Surely chemists should stay their cry against their murderers when they themselves are following such a suicidal policy.

John H. Wilson.

P.S. It would be an interesting statistic of business cuteness to know how many chemists have sent up a list of the names and addresses of their corpulent customers to an enterprising American now located in London.

Paregoric minus Opium.

Sir,—The *exposé* of the Chesterfield firms is only one of the very many which ought to take place. We have amongst us a great number of men who do not care what their customers are (grocers or what not), or what their requirements may be; we have wholesale "pharmaceutical chemists" supplying grocers and shopkeepers with all manner of drugs, including scheduled poisons, also supplying the stores, thereby injuring the chemists who, I venture to say, are their oldest and most legitimate customers. Surely, sir, it is time the Pharmacy Act was more stringently enforced. I think any grocer selling scheduled poisons should be prosecuted at once without a warning letter, and that the party supplying him ought also to receive a certain amount of punishment, for grocers, etc., would soon obey the Act if they could not find parties willing and solicitous to supply them.

A. P. S.

E. O. Jones.—We cannot recommend any book as specially fitted for the study of the subject of a particular examination. There should be however no difficulty in obtaining a good and cheap manual of chemistry.

"*Inquirer.*"—The preparation is a proprietary one, and we are not aware that the formula used in making it has been published.

"*Bella.*"—It is beyond our power to assist you in respect to a recipe for the production of whiskers and moustache.

"*A Friend of Mr. Brown*" is recommended to address his question to the Registrar.

"*Borax.*"—The recipe for Boracic Acid Ointment (Lister) has already appeared several times in this Journal. It will be found in vol. viii. of the present series, p. 743, and some remarks on the manipulation on pp. 782 and 822 of the same volume.

C. T. Brooks.—The answer to your question would depend upon the nature of the salt you desire to obtain. In any case the information you require may be obtained by reference to any manual of chemistry.

R. D. Gibbs.—The Secretary of the Institute of Chemistry is Mr. C. E. Groves, and the address, Somerset House Terrace, W.C.

H. Layng.—For the removal of chrysophanic acid stains see vol. viii. p. 1018.

Communications, Letters, etc., have been received from Messrs. Pearson, Dingle, Baldock, Richards, Ward, Furness, Heath, Landerer, Hart, Allen, Toomey, Young, Bradshaw, Brookes, Stevens, Bell, Sec. Chemists' Assistants' Association, P. T. W., M. P. S., M. B., H. L., H. W., Excelsior, Jacques, Quidnunc, Juvenis, Lavandula.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 282.)

ZARÁWAND-I-GIRD (Pers. and Bomb.), ARISTOLOCHIACEÆ.

This is the imported root of *Aristolochia rotunda*, Linn., a small plant with slender stems and almost sessile, obtusely cordiform leaves. The flowers are solitary in the axils of the leaves, tubular, yellow without, and orange brown within. The whole plant is acrid, aromatic and bitter. The root is tuberous, placentiform, hard and heavy when dry, more or less mammellated; on the under surface of a reddish-brown colour; on the upper surface are the remains of several stems or small pits showing where they were attached; on the under surface one central scar marking the attachment of the rootlets. The substance is very hard and horny and has a bitterish somewhat aromatic taste, and camphoraceous odour. Zarawand-i-gird, or mudahraj is considered by Persian writers on materia medica to be the female of *Aristolochia longa*. Meer Muhammad Husain tells us that at Ispahan it is called Nukhud-i-alwandi. Mahometan physicians describe it as resolvent, stimulating, pectoral, stomachic, cephalic; they prescribe it in jaundice and gout.

ZARAWAND-I-TAWIL (Pers. and Bomb.), ARISTOLOCHIACEÆ.

This is the imported root of the *Aristolochia longa*, Linn., a plant much resembling *A. rotunda*, and having a similar habitat. It differs from the latter plant in having petioled leaves, yellow flowers striped with brown, and a cylindrical root which has much the same taste and odour as that of *A. rotunda*. Mahometan physicians describe it as resolvent, deobstruent, diuretic, emmenagogue, alexipharmic and vermifuge.

CROTON OBLONGIFOLIUM, *Roxb.*, EUPHORBIACEÆ. *The root bark. Vernacular.*—BARAGACH (Beng.), GANASUR (Bomb.), GONSURONG (Goa).

History, Uses, etc.—The medicinal properties of the root of this tree appear to be little known. I have been unable to find any notice of the drug in works on Indian Materia Medica. Roxburgh, though he describes the tree as common in forests near Calcutta, is silent upon the subject. Dalzell and Gibson in the 'Bombay Flora' (p. 231), remark that "the plant is used medicinally by the natives to reduce swellings." When on a visit to Goa in 1876, my attention was drawn by the native doctors to the root bark of a small tree as being one of the most valuable medicines they possessed; this plant, unknown to me at the time, proved on subsequent investigation to be *C. oblongifolium*. The Goanese and the inhabitants of the Southern Concon administer the bark in chronic enlargements of the liver and in remittent fever. In the former disease it is both taken internally and applied externally. As an application to sprains, bruises, rheumatic swellings, etc., it is in great request. In large doses it is said to be purgative. Flückiger and Hanbury ('Pharmacographia,' p. 5-10) state that the seeds are said to be sometimes substituted for those of *C. tiglium*. The tree is rare in the Bombay Presidency, and has only been found in the Southern Concon. In Goa it is common.

Description.—Trunk straight; bark ash-coloured and pretty smooth; leaves petioled, alternate, and thickly set about the ends of the branchlets, spreading or drooping, oblong, serrate, obtuse-pointed, very smooth on both sides, from 6 to 12 inches long; petioles round and smooth, with a lateral gland on each side of their apices; stipules small, caducous; racemes terminal, generally solitary, erect, shorter than the leaves; flowers solitary, a few female ones mixed with many male ones, small, of a pale yellowish green; bracts three fold, one flowered, on the inside of each of the small lateral bracts is a round permanent gland, as in *Sesamum Indicum;* male calyx deeply 5 cleft; petals six, smaller than the calyx, very woolly; filaments twelve, distinct, nine in the circumference and three in the centre, woolly towards the base; female calyx and cord as in the male; stamens none; germ globular; styles three, each divided into two very long, variously bent segments; capsules globular, fleshy, six-furrowed tricoccous (Roxb.). The root is twisted, often somewhat flattened, bark thickish, externally light brown and scaly, internally yellowish, mottled with brown, substance compact and resinous; odour terebinthinate and highly aromatic; taste peppery and camphoraceous; wood white, compact and hard.

Microscopic Structure.—Sections of the bark show that the epidermis consists of about five rows of elongated cells placed horizontally, their walls are much thickened by a dark brown deposit which produces a patchwork appearance. The parenchyma is loaded with large globular or oval highly refractive bodies of a yellowish colour; there are also numerous dark purplish brown particles which are sometimes single, but usually arranged in irregular concentric rows. They appear to be due to a deposit in the vascular system of a resinous nature.

EUPHORBIA NERIIFOLIA, *Linn.*, EUPHORBIACEÆ. *The juice and root. Vernacular.*—SEHUND, THOHAR (Hind.), MANSASIJ (Beng.), NEWERANG, MINGUT (Bomb.), ILAIK-KALLI (Tam.).

History, Uses, etc.—This plant, called Snuhi in Sanskrit, is sacred to Mansá, the goddess of serpents. In some parts of India in July and August, on Tuesdays and Thursdays, the natives approach this tree with offerings of rice, milk and sugar, praying to be delivered from snake-bites. They also employ the root mixed with black pepper as a medicine for the cure of snake-bites internally and externally. Dutt informs us that in Bengal, on the fifth day after the full moon of the month Srawan, it is planted in the courtyard of Hindu houses and worshipped. The plant abounds in an acrid milky juice which is a popular application to warts and other cutaneous affections. The native doctors purify arsenious acid by packing it in a hole made in a piece of the stem, closing the hole and exposing the stem to the action of fire until it is charred. The milky juice of *E. neriifolia* is described by Sanskrit writers as purgative and irritant; it is usually administered internally by soaking other purgatives and aromatics in it, so that by absorption of the juice their purgative properties become increased.

A similar method is adopted when the juice is applied externally, a tent or issue pea being prepared with some finely powdered drug and steeped in it. Ainslie tells us that the native practitioners prescribe the juice as a purge and deobstruent in those visceral obstructions and dropsical affections which are consequent of long continued intermittent fever, the quantity given for a dose being about one-fourth of a pagoda weight (20 grs.). Externally, mixed with margosa oil, it is applied to limbs which have become contracted from rheumatism (Confer. 'Mat. Ind.,' vol. ii. p. 97). In Bombay the root is mixed with country liquor to make it more intoxicating, and the juice is used to kill maggots in wounds. There is also a curious custom here in connection with this plant. At the time of the Diwali the Hindus cut a portion of the stem, hollow it out, and fill it with oil in which they place a wick. The little lamp thus formed is lighted and carried from house to house with the object of depositing it unextinguished in the house of some friend or acquaintance, saying at the same time, "a son-in-law for you." That is wishing them good fortune (Nevadunga). The people of the house pretend not to want it and try to extinguish the light by throwing water at it. These lamps are also placed upon little heaps of cow-dung and worshipped. The author of the 'Makhzan-uladwiya,' under the name of Zakoom (Euphorbia), describes four Indian species, which are probably *E. antiquorum*, Linn., *E. neriifolia*, Linn., *E. nivulia*, Buch., and *E. tirucalli*, Linn. The milky juice of the first, he says, is mixed with the flour of *Cicer arietinum*, roasted and administered in pills as a remedy for gonorrhœa. It has a strong purgative action. The juice of the second and third species is heated and dropped into the ear for the cure of ear-ache; heated with salt it is given as a remedy in whooping cough, asthma, dropsy, leprosy, enlarged spleen, dyspepsia, jaundice, flatulence, colic, calculus, tumours, etc. The fourth species yields a milky juice having similar properties.

Description.—Shrubby, often arboreous; branches sharply five-angled, stipulary thorns; twin leaves, subsessile, oblong, about 3 inches long, appear in the rainy season; flowers greenish-yellow, February—March. The root is thick, soft and woody, often of considerable size and much contorted. Bark thick, of a light brown colour, warty and fissured, rootlets numerous, juice milky. The milk dries into a greyish waxy mass if collected, and the bark shrivels up and becomes papery like that of some other milky shrubs.

Chemical Composition.—The milky juice of the euphorbias mentioned in this article does not appear to have been chemically examined, but it probably differs little from that of *Euphorbia resinifera*, which yields the euphorbium of commerce, an article which is always obtainable in the Bombay shops under the name of Farfizun, and the chemical composition of which is described in Watts's 'Dict. of Chemistry.'

PHYLLANTHUS EMBLICA, *Linn.*, EUPHORBIACEÆ. *The fruit. Vernacular.* — ANVULA (Hind.), AMLAKI (Beng.), AVALKATI, AWLA (Bomb.), TOPPI (Tam).

History, Uses, etc.—The emblic myrobalan (in Sanskrit Amalaki and Dhatri) is an important article of the Hindu materia medica. It is used both fresh and dried; in the former condition it is considered to be refrigerant, diuretic and laxative, in the latter astringent. A sherbet of the fruit, sweetened with sugar or honey, is a favourite cooling drink for sick people; it is said to be diuretic. Emblic myrobalans are an ingredient in many compound preparations described in Sanskrit works. A selection of these prescriptions will be found in Dutt's 'Hindu Materia Medica'; the following translated from Chakradatta may be taken as an example:—

Dhátri lauha.—Take of powdered emblic myrobalans 64 tolas, prepared iron 32 tolas, liquorice powder 16 tolas. Mix them together and soak in the juice of *Tinospora cordifolia* seven times successively. This preparation is given in jaundice, anæmia and dyspepsia, in doses of from 20 to 40 grains.

Mahometan physicians esteem this myrobalan equally with the Hindus; they describe it as astringent, refrigerant, cardiacal, and a purifier of the humours of the body. It is much prescribed by them in fluxes, and is also applied externally on account of its cooling and astringent properties. The Arabic name is Amlaj and the Persian Amala. Ainslie tells us that the flowers, which have an odour resembling that of lemon peel, are supposed by the Vytians to have virtues of a cooling and aperient nature, and are prescribed in conjunction with other articles in the form of an electuary ('Mat. Indica,' ii., p. 244). In the Pharmacopœia of India it is stated, upon the authority of Dr. Æ. Ross, that the root by decoction and evaporation yields an astringent extract equal to catechu, both for medicinal purposes and in the arts; the chips of the wood or small branches thrown into impure or muddy water, according to the same authority, clear it effectually.

Description.—Fresh emblic myrobalans are globular, fleshy, smooth, six-striated, of a yellowish green colour, and sometimes as large as a walnut; they contain an obovate, obtusely triangular, three-celled nut, each cell of which contains two triangular seeds. The taste of the pulp is acid, astringent and somewhat acrid. The dried fruit is the size of a hazel nut, sub-hexagonal, wrinkled, of a grey black colour if it has been collected when immature, but yellowish brown if mature; the latter upon pressure breaks up into six parts, each of which consists of a section of the pulp and nut and contains one triangular brown seed. Two kinds of Aunla are found in commerce, one entire and the other cut up and the nut removed.

Commerce.—The fruit is collected in many parts of India. Value Rs 32 per kandy of 7 cwt.

HIPPION ORIENTALE, GENTIANEÆ. *Syn.*, STEVOGLIA ORIENTALIS, *Grisebach;* CICENDIA HYSSOPIFOLIA, *W. and A. Vernacular.* — CHOTA KIRAYATA (Hind.), MAMEEJWA (Bomb).

This is common in moist situations in many parts of the country. In Western India it abounds in Guzerat, but is rare in the Concon. Where abundant it appears to be generally accepted as a useful bitter. According to Cleghorn it is much used by the natives of Madras as a stomachic, as, in addition to its tonic properties, it is also somewhat laxative ('Indian Annals of Med. Sci.,' vol. iii., p. 272). *H. orientale* is brought to Bombay from Guzerat along with other simples. The plant is collected when in flower and tied up in small bundles which contain a pound or more.

Description.—Six to eight inches high, stem ascending, simple, four-sided, leafy from the base; leaves opposite, subsessile, linear-lanceolate, or oblong, three-nerved; calyx with bracts; the lobes obtuse, longer than the capsule; flowers small, white, sessile in the opposite axils, do not fall when the plant is dried. Taste strongly bitter.

GUL-I-GHÁFITH, GENTIANEÆ.

This is the name under which the flowering top of a small gentian are sold in the Bombay market

The drug is imported from Persia. Under the name of gháfith, Arabian and Persian writers describe a plant which they say is called in Latin *Eupatorœ*; it is thorny and has long, broad, fleshy leaves. The stem is said to be hollow and rough and to rise from the centre of the leaves; it bears violet or purple flowers. The whole plant is extremely bitter; it grows in the hilly districts near Shiraz. As a medicine it is said to be attenuant and deobstruent, especially useful in hepatic and splenic obstructions. It is also a valuable tonic and febrifuge and is said to have anthelmintic and emmenagogue properties. Applied externally it promotes the healing of wounds and sores. The gháfith or ghafis of Bombay consists of quadrangular flower stalks two to four inches in length, terminating when perfect in five flowers; one of these is terminal, the remaining four are in opposite pairs and on longish peduncles, with bracts as long as the peduncles. The corolla is funnel shaped, about an inch in length, erect, five-partite; calyx five-partite; stamens five, alternate with the corolline segments; style single; stigmas, two; fruit three-fourths of an inch long, one-celled, containing numerous small seeds; calyx and corolla persistent. The lower portion of the plant is sometimes to be found; it has the leaves of a gentian. The entire plant must be from six to eight inches high; it is very bitter. It would appear that this drug has been adopted as a substitute for the original gháfith of the early Arabian writers, which is by some considered to have been the *Eupatorium cannabinum*, or hemp agrimony, a tall plant with unbranched stems, downy leaves, and terminal crowded corymbs of dull pale purplish flowers. The description given above agrees pretty well with that of hemp agrimony, if we take thorny to mean hispid, as it sometimes undoubtedly does in Persian descriptions of plants. Value annas 3 per lb.

Kanturiyun, Gentianeæ (?).

Under this name small woody stems, from the tops of which spring numerous round, slender, jointed branches, are sold in Bombay. They come from Persia and are supposed by the Hakeems to represent the lesser centaury of the Greeks (*Erythræa centaurea*).

The stems in question are certainly not those of *E. centaurea*. They are round with tumid joints, which are furnished with bracts and resemble the stems of a grass. Towards the upper part the stem becomes obscurely angular, and terminates in a single flower or capsule about one inch in length and very much like that of *Ophelia multiflora*. The leaves are linear, like those of a grass. The whole plant is intensely bitter. Value annas 3 per lb.

Jintiyana, Gentianeæ.

Under this name gentian root imported from Europe is sold in Bombay and is generally accepted by the Hakeems as representing the gentiana of Pliny and Dioscorides. Mahometan writers describe jintiyana as having purplish flowers, and give pakhánbed as the Hindi synonym. The pakhánbed of Bombay is apparently the root of an iris, and is quite distinct from gentian. European gentian root is obtainable in the Bombay market for about ¼ Re. per lb.

(*To be continued*).

CARICA PAPAYA AND PAPAYOTIN.*

BY DR. THEODOR PECKOLT.

(*Concluded from page 346.*)

The Milky Juice.

This occurs in all parts of the plant, but in large quantity only in the unripe fruit, from which it disappears on ripening. But it is extremely troublesome to collect from the root, still more difficult from the stem, and the leaf stalks yield only traces. It is also very scanty in the colder months, and can only be obtained in somewhat remunerative quantities in the months from August to April.

The fruit whilst on the tree is scratched to the point longitudinally and sufficiently deep to pierce the skin; the juice then oozes through in drops and as soon as the drops become scanty another place must be wounded. If the fruit be removed from the tree in order to collect the milk only a few drops at the most will be obtained and even these frequently coagulate on the surface of the wound.

The fruit from which the milk has thus been taken ripens much more quickly than the unwounded fruit, and tastes as sweet, but is almost without juice and the ripe seeds do not germinate. From a medium sized fruit the juice was carefully collected, and as on the following day it yielded no more, the product was weighed in the previously tared glass and found to be 33 grams. The fruit then taken from the tree weighed 785 grams; it yielded therefore about 4 per cent. of milk, and considerable trouble was required in order to obtain from 30 fruit of similar size about a kilogram of milk. The cost of the fruit was of little consequence, as in Brazil a ripe fruit can be purchased for about three pence; but each fruit requires uninterrupted attention, as the drops of milk soon coagulate in the incision and require to be assisted through by means of fresh scratchings; add to this the inconvenience arising from the height of the tree, and the collection will be seen to be a troublesome and thankless work.

The milk of the green fruit at the time of its exudation resembles sheeps' milk; it has a strongly acid reaction and with three times its volume of water gelatinizes. It is odourless, tastes astringent and slightly bitter and has a specific gravity of 1·023 at 26° C.

Analysis I.—33 grams of fresh fruit milk were repeatedly shaken with ether, until a portion evaporated without residue. The ethereal solution when evaporated left behind a white wax-like fatty substance—*Mamao wax*. The residue insoluble in ether was exhausted with absolute alcohol and then with 80 per cent. alcohol; the alcoholic liquid distilled and evaporated left a soft resin, a light brown resin and extractive matter. The portion insoluble in ether and alcohol formed when dried a snow white powder. A little dissolved in water rendered it turbid, through floating flocks. The entire residue was dissolved in a little water and filtered; on the filter was left a caoutchouc-like substance, soluble only in carbon bisulphide, and traces of an albumenoid substance.

To the watery solution absolute alcohol was now again added as long as turbidity was produced, the precipitate collected on a filter, well washed with alcohol and dried over chloride of calcium. This product, as well as the similar one obtained in the following analyses, I have preserved in my collection as *Papayotin*. I would only now remark that this substance can effect the solution of albumen and flesh, which property I did not light upon in the reactions that I carried out at that time, and I did not guess that the substance could have such therapeutic importance. I will refer to the reactions subsequently.

* From the *Zeitschrift d. allg. österreichischen Apotheker-Vereines*, vol. xvii., pp. 361 and 373 (Aug. 20 and Sept. 1, 1879).

The dried papayotin weighed 2·590 grams and formed a brilliant white light amorphous powder, similar to magnesia carbonica.

The alcoholic liquor filtered from the papayotin gave still a very small quantity of extractive matter containing sugar.

Analysis II.—A quantity of milk was perfectly dried and the loss of moisture estimated. The viscous resin-like residue was completely exhausted with ether, and then with absolute alcohol and rectified spirit, and the solutions examined and weighed. The residue insoluble in these formed when dried a light brown powder, having an unpleasant faintly turpentine-like smell and weighing 5·388 grams. Dissolved in water and mixed with absolute alcohol it also gave a precipitate which when separated and dried formed a light brown powder, but it had lost the unpleasant turpentine odour. The papayotin had in this case, through the influence of heat, formed a substance that I have preserved in my collection as *Parapapayotin*, the reactions of which will be described subsequently.

Analysis III.—82 grams of fresh fruit milk were treated with four times as much cold distilled water, filtered from the insoluble portion (*a*), and the aqueous solution mixed with absolute alcohol as long as any turbidity was produced. The precipitate separated by filtration, washed with absolute alcohol, and dried over chloride of calcium, formed 3·085 grams of snow-white papayotin, not quite so light as in No. I.

The residue (*a*) was now exhausted first with spirit of wine, and the portion insoluble therein treated with cold and then with boiling absolute alcohol, and finally the portion still insoluble treated with ether and with carbon bisulphide. Results were obtained similar to those in Analyses I. and II. The alcoholic liquid from which the papayotin had been filtered was treated with a spirituous solution of acetate of lead and examined.

Analysis IV.—50 grams of milk were several times extracted with warm water, the filtered watery solution evaporated by a gentle heat to a syrupy consistence, and after cooling and again filtering precipitated with absolute alcohol and the precipitate dried over chloride of calcium. The papayotin weighed 2·152 grams, but was slightly greyish-white.

Analysis V.—Some milk was completely exhausted with cold and warm distilled water, the solution precipitated with tribasic acetate of lead, and the filtered liquid examined. The white lead precipitate was suspended in water and freed from lead by sulphuretted hydrogen; it was then divided into two portions, one of which was precipitated at once with alcohol, the other evaporated to the consistence of a syrup and then precipitated. The results were similar, except that the papayotin precipitated without evaporation was somewhat whiter than the other. The yield was 3·530 per cent.

In 100 grams of fresh fruit milk I found the following substances:—

Caoutchouc-like Substance	4·525 grams.
Wax-like Fatty Substance	2·424 „
Soft Resin	0·110 gram.
Light Brown Resin	2·776 grams.
Albumenoid Substance	0·006 gram.
Papayotin (average)	5·303 grams.
Extractive Matter (with disagreeable taste)	1·283 gram.
Extractive Matter (containing sugar)	1·059 „
Organic Acid (Malic)	0·443 „
Pectic Substance and Inorganic Salts	7·100 grams.
Moisture	74·971 „

Analysis VI.—Milk from the Stem.—The stem yields extremely little milky juice at any time, but this milk has more consistence than that from the fruit and resembles cream. With much trouble I obtained 13 grams of milk, which was shaken with distilled water and filtered; the dried resinous residue, containing caoutchouc, weighed 1·430 gram.

The aqueous solution treated with absolute alcohol in the manner already described and the precipitate dried over chloride of calcium, gave 0·515 gram of shining white papayotin, or equal to 3·961 grams. The alcoholic liquid yielded 0·580 gram of extractive matter, etc.

These are the results which up to that time (1868) I had obtained with the *Carica Papaya.* But as I now hoped to obtain the papayotin in larger quantities, in order to use it therapeutically, before closing this paper I made some experiments with fresh leaves and green fruit, in order to prepare this product in an easier way than from the milk which is so troublesome to collect.

Analysis VII.—Green Leaves.—1400 grams of fresh leaves bruised to a paste in a marble mortar, and pressed in a small hydraulic press, yielded 460 grams of dark-green juice, or equal to 33 per cent. The juice was treated with absolute alcohol until no more turbidity was produced, allowed to settle and filtered. The precipitate, containing chlorophyll, was well washed with alcohol and allowed to drain completely, then again exhausted with cold distilled water. A sample of the filtered liquid gave immediately upon precipitation with alcohol a mass of dirty impure papayotin. The aqueous solution was therefore treated with tribasic acetate of lead as long as a precipitate was produced, the precipitate separated, well washed with water on a filter, suspended in water and freed from lead by sulphuretted hydrogen, filtered and the colourless liquid evaporated at a temperature of about 50° to about one-half, filtered and precipitated with absolute alcohol. The precipitate separated and dried over chloride of calcium gave 0·550 gram of snow-white papayotin: equal to 0·117 per cent.

Analysis VIII.—Unripe Fruit.—Three green fruits, freed from seeds, weighed 1550 grams. When rubbed to a paste upon a fine iron grater and pressed they gave 730 grams of juice, which was filtered and precipitated with absolute alcohol; the precipitate was redissolved in a little water and again precipitated. The precipitate collected upon a filter and dried over chloride of calcium gave 1·820 grams of white papayotin, or 0·117 per cent.

In the preparation of papayotin the use of strong heating is to be avoided, in order to obtain a good looking and active product. It should not be dried by means of heat; even in the air it often forms upon the filter a mass, and this happens especially when heat has been used in the preparation. Drying over chloride of calcium is therefore recommended.

Neutral acetate of lead does not completely precipitate papayotin, and the tribasic acetate of lead is preferable. The precipitate ought not to remain too long in the alcoholic liquid, or the papayotin will partially form a smeary mass.

From the different modes of preparation the following quantities of papayotin were obtained from 100 grams of material:—

I. Milky juice of fruit, with cold ether 7·848 grams of papayotin.

II. Milky juice of fruit, with warm ether 5·338 grams of parapapayotin.

III. Milky juice of fruit, with cold water, 3·762 grams of papayotin.

IV. Milky juice of fruit, with warm water, 4·304 grams of papayotin.

V. Milky juice of fruit, with warm water and lead, 3·540 grams of papayotin.

VI. Milky juice of stem, with cold water, 3·961 grams of papayotin.

VII. Fresh leaves, with cold water, 0·039 gram of papayotin.

Juice of leaves, with cold water, 0·119 gram of papayotin.

VIII. Green fruit, with cold water, 0·117 gram of papayotin.

Juice of green fruit, with cold water, 0·249 gram of papayotin.

The finest papayotin I obtained according to Nos. I. and III., and from the milk from the stem. The papayotin prepared from the leaves almost equalled these, as did that from the fruit juice. Notwithstanding the small yield, the preparation from the leaves is the most advantageous, because the alcohol can be recovered and used for other purposes, whilst the leaves are to be obtained without cost in large quantities. Subsequent experiments have also made probable the utility of the extract from the alcoholic liquid.

I have now taken up the subject afresh, in order to examine more completely the fruit, leaves (fresh and dry), and stem bark, and shall possibly make some more therapeutic experiments.

Papayotin forms an amorphous snow-white non-hygroscopic powder, without smell, sweetish, faintly saline, astringent, but almost tasteless. Upon platinum foil it burns to ash with a peculiar smell. It is insoluble in ether, alcohol, chloroform, petroleum spirit, as well as in volatile and fatty oils. In glycerine and in water it dissolves readily. The aqueous solution lathers when shaken similarly to a saponin solution, has an acid reaction, and becomes turbid after twenty-four hours.

An aqueous solution gave the following reactions:—With alcohol, acetate of lead, mercuric chloride, tannic acid and solution of carbonate of soda, a white precipitate. With silver nitrate a white turbidity, immediately becoming yellow; after twelve hours the precipitate is deep yellow, and the liquid brown. Chloride of sodium gives no reaction, but with alcohol a precipitate. Perchloride of iron after standing some time gave traces of a yellow precipitate. Solution of iodine a light brown precipitate. Phosphoric acid, only after standing twenty-four hours, a white precipitate. Commercial potash and soda also gave a precipitate, only after a long time; less time was required by ammonia. With acetic acid, lactic acid, cupric sulphate and iodide of potassium no reaction. Trommer's sugar test coloured it a beautiful violet-blue, which after boiling became red-violet; there was, however, no reduction of cuprous oxide. With starch it gave no reaction, and no sugar reaction when boiled with starch. With fat oils it gave no reaction, even after continued boiling together.

The dried papayotin behaves towards reagents as follows:—It does not dissolve in acetic acid either cold or when heated, or even when diluted with an equal volume of water, and it behaves similarly towards lactic acid. In ammonia it is insoluble, and becomes coloured yellowish after some time; in potash and soda ley it is also insoluble, becoming brown. In nitric, as well as in hydrochloric acid, it gives a clear solution in which water produces no change and alcohol no precipitation. In sulphuric acid it does not dissolve, but is coloured yellowish. In phosphoric acid it is insoluble, but is dissolved upon the addition of water.

0·28 gram of papayotin, No. III., dissolved in water and mixed with 0·2 gram of roasted meat in a test-glass, disintegrated the meat in two minutes to a pulp, and at the end of ten minutes had perfectly dissolved it without the use of heat.

Papayotin, No. VI., from the milky juice of the stem, and No VIII., from the juice of the fruit, behaved with equal activity. Papayotin, No. 1, behaved similarly, but required in the cold fifteen minutes for solution, as did also No. VII. from the leaves.

1·3 gram of papayotin, No. IV., was dissolved in water and mixed with 0·8 gram of roasted flesh. Only after twenty minutes the flesh formed a pulp, and after three-quarters of an hour a partial solution; with the aid of a gentle warmth it still required ten minutes for a perfect solution. Papayotin, No. V., behaved similarly.

0·7 grams of the substance I have named "parapapayotin" (No. 3) were added to 0·4 grams of cooked flesh. Although after about twenty-five minutes the flesh had become disintegrated to a pulp, no solution was effected even when heat was applied.

Papayotin prepared by direct precipitation from the watery solution by alcohol is the most active and dissolves an equal weight of flesh and albumen. On the other hand, papayotin in the preparation of which the smallest amount of heat has been used is much weaker.

The most powerful preparation I have yet obtained was one in which the milk was allowed to drop from the fruit into glycerine. The glycerine appears to retard the decomposition of the milk and to diminish the troublesome gelatinization; the papayotin is also precipitated whiter and there is a larger yield. The glycerine solution keeps very well, and I have frequently used it therapeutically, as the amount of papayotin in the milk can always be calculated more or less approximately. I have used it many times in ailments of the stomach where pepsine was indicated with good results. When I did not use the glycerine solution I gave the dried papayotin in doses of 0·2 to 0·25 gram at each meal-time.

Coagulation of Milk.—Messrs. Gehe and Co., having obtained from me some *Carica Papaya* milk, noticed especially the property it has of curdling animal milk immediately, which induced me to make the following experiments:—

Some drops of milky juice falling direct from the fruit into a glass of unboiled cow's milk coagulated the milk only after a quarter of an hour.

The aqueous concentrated and filtered solution of the fruit milk dropped into cow's milk caused immediate coagulation.

Concentrated solution of papayotin added to milk coagulated only after an hour.

Boiled cow's milk behaved similarly.

For the sake of comparison experiments were made with the milky juices of other Brazilian plants which I had at my disposal in my garden; for instance: *Euphorbia antiquorum*, L., *E. cereiformis*, L., *E. hypericifolia*, L., *E. brasiliensis*, L., *E. pulcherrima*, Willd., *Ficus repens*, *Curcas multifida*, Endl., *Artocarpus incisa*, L. fil., and *A. integrifolia*, L.

Generally, the milky juices having an acid reaction coagulated cow's milk similarly to that of *Carica Papaya* the milky juices having a neutral reaction effecting coagulation only after a longer time. An exception was the clear water-like juice of *Curcas multifida*, which reddens litmus paper strongly, but does not truly coagulate milk, the milk forming after mixing a thick cream-like fluid, as if the casein were in concentrated solution. Even after twelve hours there was no separation of serum; a small quantity of clear watery liquid passed through fine filter paper, and the residue formed on the filter a white butter-like substance, which in the air dried to an odourless white pulverizable mass.

Uses of Carica Papaya.—The ripe fruit is eaten raw and with sugar, similarly to melon, or made into a confection with sugar and lemon juice and boiled for jam. The unripe fruit is peeled, freed from seeds, well washed, finely grated and boiled with sugar to a pulp. It is also cut into pieces and preserved with hot vinegar like gherkins.

In the province of S. Paulo a syrup is made by boiling the juice expressed from ripe fruit with sugar, which has a reputation as a sedative and expectorant. Dose, a tablespoonful every two hours. The milky juice taken internally is said to cause intestinal inflammation; but it is given in small doses against worms, especially ascarides, where an aqueous solution is to be preferred, and I have used it with extraordinary results.

Used externally for spots and as a wash for freckles it is said to make the skin smooth and delicate.

The pungent cress-like tasting seeds are also used as a vermifuge.

The fresh leaves have been used by the Indians since unknown times to wrap flesh in, in order to make it savory and tender. Further they are used as a washing material in the purification of linen, and a paste as a poultice for unclean wounds. The leaf-stalks are used as pipe stems and the bast for cord.

The root has a nauseous stale radish-like taste. I have not yet examined this certainly interesting part of the plant.

DRUG SMOKING.

BY REGINALD E. THOMPSON, M.D.

The following remarks and formulæ are extracted from a paper on "The Therapeutical Value of Drug Smoking," especially in reference to asthma, which appeared in the *Practitioner* for August:—

The chief difficulty in treating an individual case of asthma arises from individual peculiarities, which makes the choice of the appropriate neurotic a matter rather of hap-hazard selection, numerous experiments being sometimes necessary before an indication is obtained as to the special drug required; one drug will have a so-called magical effect in one case which may prove inert when used in another, and hence in endeavouring to meet the exigencies of a number of individuals it becomes necessary to combine a number of remedies, and such a combination of drugs becomes more universal in its application in proportion to its complexity, the chance of its proving effectual in any individual case being greatly enhanced by such a composition.

It is a matter of some difficulty to analyse with any certainty those mixtures of vegetable and other substances which are sold as remedies for asthma, but an examination of them shows conclusively that they are composite, different leaves being found on submitting any sample to microscopical analysis; some of them contain opium, others do not; most of them contain lobelia, and it may be stated with some certainty that all of them have stramonium for their basis.

If such remedies are tried in a number of cases it is surprising how one remedy at one time appears to be of the greatest service, another at another time; much depends, doubtless, upon the method of preparation and preservation, and upon the care with which the drugs are selected, and the best secret remedy I know (Himrod's) is evidently well prepared and preserved, the leaves of which it is composed being fresh and green.

Remedies for asthma are supplied in three forms: a powder which is burnt and the fumes of which are inhaled, cigarettes composed of tobacco combined with various drugs, or of paper dipped in a solution of the drugs.

The best method of preparing drugs for the powder form of remedy appears to me to be this: the leaves of the vegetables used should be procured in good condition and perfectly fresh; they should then be soaked in a solution of nitre (25 per cent.), and the leaves then dried by gentle heat and powdered. I have made use of the various neurotics in this manner in asthma, first separately, in order to ascertain the individual value of the remedy, and then in combination, and the experiments have now been carried on for many months, and I am disposed to place them in the following order of merit:—

Opium.
Stramonium.
Cannabis Indica.
Conium.
Lobelia.

The three first on the list appear to be the most potent by fumigation, but when administered in the wet method (if I may use the term) cannabis indica is so uncertain and so apt to produce delirium, especially in women, that I prefer conium, a drug from which I have obtained extremely good results when administered by the mouth.

With belladonna I could not satisfy myself that any good results were to be obtained by fumigation, and I consider it far inferior to those given above in whatever way it is administered.

The powder may be used by those patients who are not accustomed or object to smoking cigarettes, or it may be added to the tobacco of those who prefer the use of the pipe.

As regards the composition of the powder, I have had good results from gr. ix. of stramonium and gr. i. of cannabis indica, this being a quantity, which will cover a shilling, sufficient for one fumigation.

But if the patient does not object to smoking, I much prefer to administer the remedies in the form described in my previous paper, namely, paper cigarettes impregnated with tinctures so that the dose may be accurately apportioned.

It will be understood that in suggesting remedies which serve to alleviate the spasmodic dyspnœa of asthma I do not consider that they constitute a mode of treatment calculated to improve the general condition of the patient, or that they are more than palliatives of an urgent symptom: constitutional treatment by ferruginous tonics and cod-liver oil, or it may be by iodide of potassium or arsenic, must be resorted to, if it be intended to give the asthmatic patient permanent relief from distressing disease. With acute conditions of the disease, with bronchial complications of such a nature as to contra-indicate the use of iron, there is probably no treatment better for a majority of cases than the use of iodide of potassium with stramonium; in many cases of like character I have derived very good results from the administration of hemlock in combination with the hypophosphite of soda, but for the prevention of the disease I know no treatment to compare with iron and cod-liver oil.

But for soothing and diminishing the dyspnœa, neurotics may be used with great effect, and the following combination is that which, up to this time, has given me the best results.

The same form of cigarette is used as described in my former contribution on this subject, and the paper is soaked in the following drugs according to the recipe here given:—

Extract of opium	gr. $\frac{1}{64}$.
Extract of stramonium	gr. $\frac{1}{32}$.
Tincture of Indian hemp	♏ $\frac{1}{2}$.
Tincture of hemlock	♏ $1\frac{3}{4}$.
Tincture of lobelia	♏ $1\frac{3}{4}$.
Tincture of tobacco	♏ 9.
Oil of anise	♏ $\frac{1}{8}$.
Nitre	gr. $\frac{1}{4}$.

Or for a sheet of Swedish paper sufficient to make sixty-four cigarettes the formula may be given thus:—

Tincturæ tabaci	ʒ x.
Tincturæ conii	ʒ ij.
Tincturæ lobeliæ	ʒ ij.
Tincturæ cannabis Ind.	♏ xxxij.
Extract. opii	gr. i.
Extract. stramonii	gr. ij.
Olei anisi	♏ viij.
Potassæ nitratis	gr. xvi.
Spir. v. r.	ad ℥ iiss.

This formula, which is a complex one, has only been obtained from repeated experiments, leading step by step to the addition of some effective remedy, and to the elimination of less effectual drugs.

As it is sometimes desirable not to give opium or Indian hemp, I have had cigarettes made with stramonium and lobelia only; so that altogether I have three different kinds for use: opium cigarettes containing a small quantity of opium and stramonium; a compound opiated cigarette containing the drugs given in the formula above, and a stramonium cigarette without opium.

CALOMEL AND CORROSIVE SUBLIMATE.*

Much has been said and written about the decomposition of calomel in such compounds as pills, powders and mixtures. We have been told that bichloride of mercury can be formed if calomel is mixed in the dry state with sugar, bicarbonate of sodium, sugar of milk, when such compounds are kept for months, or in less time in aqueous mixtures containing magnesia or bicarbonate of sodium. Others, again, have told us that experiments and researches had shown that in such compounds no bichloride was formed even after a long time.

What in most cases has been overlooked by the latter writers is the effect of the atmosphere.

The atmosphere in drug stores contains very often vapour of ammonia, etc., and may in one corner of the store be more moist or contain more fumes of ammonia, etc., than at other corners or sections of the room, and such vapours and gases may, under certain circumstances and when least suspected, affect compounds containing calomel.

Suppose a glass-stoppered bottle, containing a preparation of calomel, is opened for the purpose of dispensing some of its contents, air will be admitted into the bottle, and if such air is contaminated with ammonia, nitrous acid, ozone, etc., these gases will be brought into contact with the calomel.

Dr. H. Hager gives his opinion and the rules for keeping preparations containing calomel in the following:

"Calomel should be kept in well closed glass or porcelain vessels, protected against the light. Neutral or acidulous aqueous mixtures containing calomel should not be kept longer than one week. The presence of bichloride of mercury in powders of sugar and calomel has been proved after such powders had been kept for a longer time. Most vegetable substances show a more or less acidulous reaction, and therefore offer so much the greater a chance for the formation of corrosive sublimate.

"In trying to prove by experiments that no corrosive sublimate had been formed in such cases as above referred to, all the circumstances and the effect of the atmosphere have not been taken into consideration.

"It is unquestionable that prudence requires calomel in composition with organic substances to be kept no longer than one week, or such compounds kept longer than one week not to be dispensed.

"The transformation of calomel into corrosive sublimate will in dry compounds be restrained by the presence of carbonate of lime or carbonate of magnesia."

These rules should be observed and adhered to, but above all, attention should be paid to the preparing of powders and pills containing calomel or corrosive sublimate.

In making these pills a prolonged contact of the mass with iron vessels or spatulas should as much as possible be avoided. Too often such masses are left too long in an iron mortar, or in so-called porcelain-lined dishes, which are so defective that the porcelain lining is worse than none, if the lining ever was porcelain. Dishes and iron kettles are found too often to be lined with lead compositions instead of porcelain.

If the mass is beaten in a porcelain mortar, attention should be given to the spatula and the pill-cutting machine.

If calomel pills are divided with cutting plates of brass, just brightly polished, the calomel on the outside of the pill will always be decomposed, as every one can see on pills made of a white mass of calomel; black oxide of mercury and an amalgam of mercury with the metals of the brass being formed. The formation of black oxide of mercury on the outside of pills can be avoided to a great extent if no brightly polished brass cutting plates are used. The brass cutting plates should not be polished with any polishing powder; a good washing with water, or, if resinous substances are adhering to the brass, a washing with alcohol and a rubbing with a piece of cloth only, should be given.

It is evident that in pills which have not been dried out well the decomposition of calomel will proceed more rapidly than in such as have been perfectly dried. A carefully prepared pill, containing calomel, if perfectly free from moisture and properly protected by an outside coating against light and the action of the atmosphere and then enclosed in well corked bottles, may be as good after months as when first made.

If calomel powders are mixed in a porcelain mortar care should be taken not to use a spatula of iron or of steel which has not been properly tempered, for if the steel is too soft black stripes can be seen in the mortar where the soft iron or steel passed along, forming black oxide of mercury and metallic mercury in the calomel.

If pills of corrosive sublimate have to be made, too much care cannot be exercised in the selection of the utensils used for their preparing. A porcelain mortar and a horn spatula should be employed, and such pills should be divided on cutting plates made of wood or horn, and not used for any other but corrosive sublimate pills. It is a common thing to see a pill mass of corrosive sublimate scraped together with a steel spatula and cut on a brass cutting machine, or cut into pills on a porcelain or glass pill tile with a steel spatula. In all these cases black oxide of mercury and the metal itself can be seen on the steel and brass. Separate horn spatulas are the best for making calomel powders and pills, as well as pills of corrosive sublimate.

The decomposition of calomel has been deemed of such an importance that the eminent Dr. H. Hager has repeatedly written about it. We have quoted above from an article written by him in reference to calomel, and concluding these remarks we invite the earnest attention of all pharmaceutists to the matter.

Jolly has shown that corrosive sublimate was formed in a dry compound of calomel with sugar containing traces of lime. Vulpius found corrosive sublimate in a dry compound of calomel with carbonate of sodium and sugar of milk, and especially in compounds of cane sugar and bicarbonate of sodium, also in aqueous mixtures of the same. These researches prove that the atmosphere of a drug store, contaminated with ammonia and other gases, will not be indifferent to compounds of calomel, and the daily experience of the dispensing pharmaceutists shows that iron and brass should not be brought into contact with masses and compounds of corrosive sublimate or calomel.

* From the *Druggists' Circular and Chemical Gazette*, October, 1879.

FOLIA CAROBÆ.*

The *Pharmaceutical Zeitung*, Bunzlan, Berlin, publishe the following communication by Dr. Ottokar Alt, Hamburg:—

My attention was first called to this drug by Mr. Camillo Weber, licensed apothecary of Leipzig, Rio de Janeiro and Montevideo, who is now engaged in business in Hamburg. During his sixteen years' residence in Brazil and South America he has seen the carobæ employed by the resident physicians in the various forms of syphilis with the happiest results, and he induced J. von der Heide, apothecary of this city, to introduce it here (Hamburg). In my large practice I had ample opportunity to employ it, and I am so extremely well satisfied with the results that I take the liberty of calling the attention of my colleagues to this comparatively new drug. The results of the employment of the drug were favourable in all the forms of syphilis, but they were really surprising in old syphilitic eruptions, and with patients who had taken large quantities of mercury.

In cases which were accompanied by pains in the limbs the carobæ was borne well with an addition of iodide of potassium. In Brazil the carobæ is considered one of the best alteratives, diuretics and sudorifics, with most extraordinary tonic properties.

I will add a few words about the leaves. The drug

* *New Preparations*, reprinted from the *Pharmacist* for October, 1879.

which is known as corabæ comes from Brazil, and consists of long, ovate leaves, dark green above and light green beneath, and strongly veined.

The leaves are derived from a tree, which, according to Sprengel, is the *Jacaranda procera*, and belongs to the family of *Bignoniaceæ*. It attains a height of thirty to forty feet; its root is externally of a dark red, internally of a whitish-yellow colour; its stem is considerably branched; the flowers are red and white in beautiful terminal cymes and have an agreeable honey-like flavour; the fruit is a woody bivalved capsule, containing several winged seeds. The aborigines of Brazil, and more particularly their medicine men (called Curanderos), have long known the beneficial effects of this tree, and finally the attention of Brazilian physicians was called to it. Joan Alves de Canerio, an eminent physician, submitted it to the Academy of Medicine at Paris, upon which it was taken up in the Materia Medica. The various and elaborate experiments made by Drs. Carron de Villard, Bompani, Santo, Barros Pimental, and by Messrs. Level, Spicks and Martins (the latter of whom has given the tree the name of *Cybistas Antisyphilitica*), have been crowned with the most complete success. It was also found that the carobæ produces appetite: it was first given in the form of a decoction, 8 grams of leaves to 360 grams decoction *pro die*. Syphilitic ulcers were sprinkled with the powder of the leaves or painted with a concentrated extract. Diseases of the skin were treated by lotions or baths with simultaneous internal applications. I owe these communications to the above named Mr. C. Weber, who was called upon by Drs. Santo, Barros Pimental and Bompani to make a preparation that would keep and obviate the tedious manipulation of making an infusion. He thereupon made an aqueous alcoholic extract which was free from all inert matter likely to ferment; the preparation, which keeps well, contains in fifteen grams one half gram soluble extract matter. The small addition of alcohol gives it a pleasant, wine-like taste.

This extract is everywhere well received, and is also prepared here (in Hamburg). The dose is a tablespoonful three times a day in water.

NICOTINE AND NICOTINIC ACID.*

BY R. LAIBLIN.

The following modification of Schloesing's process for preparing nicotine is recommended:—Coarsely-cut tobacco is digested for a day with cold water, and the mixture subsequently boiled by injection of superheated steam, filtered, and the residue pressed. The same series of operations is repeated, and the mixed filtrates are evaporated to one-third of their volume. A quantity of lime, one-tenth of the weight of the tobacco used, is now added, and the mixture distilled by a current of steam as long as nicotine (recognized by its odour) comes over. The distillate is exactly neutralized by oxalic acid, the amount used being noted, and evaporated to a thin syrup. The exact amount of potash necessary to neutralize the oxalic acid is now added, and the crude nicotine which separates is collected. The remaining liquid is exhausted with ether, and the nicotine thus extracted added to that first obtained. That portion of the crude base which distils over below 250° is converted into oxalate by adding powdered oxalic acid to its ethereal solution; and the purified oxalate, which separates as a syrup, after being washed with ether, is disolved in water and again decomposed with potash as above. The product is finally heated to 110° for six hours by a paraffin-bath, and a slow stream of dry hydrogen passed through it to remove ammonia, ether, and water. The temperature is then gradually raised to 210° to complete the removal of the water, and on fractionally distilling the residue, pure nicotine comes over between 240—242°. It must be preserved in sealed tubes. One centner of tobacco thus treated yielded 600 grams of pure nicotine ($=1\frac{1}{2}$ per cent.), besides impure base.

Nicotine is not decomposed into well-defined simpler bodies by heating with hydrochloric acid at 280–300°. No addition product is formed by the action of nascent hydrogen on the brominated hydrobromide, $C_{10}H_{13}N_2Br_5$.

Nicotine is readily oxidized by potassium permanganate in the cold, but only when the salt is added to its solution as long as it is decolorized is it possible to obtain crystalline oxidation-products. By employing a suitable process, which is fully described, potassium carbonate and nicotinate are the sole products found. The nicotinate is dissolved out by absolute alcohol, and converted into silver salt by precipitation. Nicotinic acid may be obtained from this by decomposing it with hydrogen sulphide.

Nicotinic acid was first obtained by Huber, by oxidizing nicotine with chromic mixture, and was subsequently recognized by him as *carbopyridenic acid*, $C_5H_4N.COOH$ (*Ber.*, 3, 849). Weidel also (*Annalen*, 165, 328), by acting on nicotine with nitric acid, obtained an acid which he identified with Huber's and which the author, by a crystallographic comparison of salts, proves to be identical with his own; he, however, assigned to it the formula $C_{10}H_8N_2O_3$. By analyses of the acid and a variety of its salts (silver, calcium, potassium) and other compounds with hydrochloric acid and auric and platinic chlorides, the author decides in favour of Huber's formula. He also shows that when nicotinic acid is distilled with soda-lime, it yields a quantity of pyridene nearly equal to that which might be expected from a carbopyridenic acid. Moreover, nicotine yields carbopyridenic acid in almost molecular proportion.

Nicotinic acid forms crystalline compounds with hydrochloric and hydrobromic acids, of the formula,

$$C_6H_5NO_2.HCl \text{ and } C_6H_5NO_2HBr.$$

Ethyl chlorocarbonate acts violently on pyridene, but does not form ethyl nicotinate; the only products are ethyl chloride, ethyl carbonate, and pyridene hydrochloride. Neither is ethyl nicotinate formed by acting with ethyl iodide on silver nicotinate. When the compound of nicotinic chloride with hydrochloric acid (see below) is treated with absolute alcohol, a violent action occurs, and the product evaporated in a desiccator deposits crystals of nicotinic acid hydrochloride. The mother liquor from these crystals gives with caustic soda an oily liquid, probably containing the ether, which no doubt existed in combination with hydrochloric acid.

If nicotinic acid, or better, potassium nicotinate, is treated with phosphorus pentachloride, energetic action ensues, and a volatile crystalline compound sublimes, the analysis of which corresponds approximately with the formula $C_5H_4N.COCl.HCl$. This chloride is insoluble in ether, chloroform, benzene, and petroleum-ether. When heated with water it is reconverted into nicotinic acid; but no amide could be formed from it by the action of ammonia.

When the double chloride of zinc and nicotine,

$$C_{10}H_{14}N_2.2HCl + ZnCl_2 + 4H_2O,$$

is distilled with soda-lime, a large quantity of gas is given off, containing ammonia, methylamine, free hydrogen, and traces of hydrocarbons. The liquid distillate consists principally of nicotine, but contains also a considerable quantity of pyrrol, which was separated by fractional distillation, and analysed as the cadmium double salt. By carefully adding water to the fraction 245—270°, containing much nicotine, an oily liquid was separated, which, when dissolved in hydrochloric acid and fractionally precipitated by platinic chloride gave a carmine-red easily decomposable double salt, $(C_{10}H_{11}N.HCl)_2.PtCl_4$. The free base is a yellowish liquid of extremely penetrating and repulsive odour, boiling between 250—270°. The smallest quantity of it, dissolved in hydrochloric acid, gives an intensely red solution when boiled with platinic chloride. It is probably formed from nicotine by the direct separation of ammonia, $C_{10}H_{14}N_2 - NH_3 = C_{10}H_{11}N$.

* *Liebig's Annalen*, 129—182. Reprinted from the *Journal of the Chemical Society*, October, 1879.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 15, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

COUNSEL'S OPINION ON THE INTERPRETATION OF THE DENTAL ACT.

THE evident signs of party feeling manifested in the letters relating to the subject of "Registration under the Dental Act" render the encouragement of any further discussion of this subject as undesirable as it is, we think, unnecessary for the purpose of proving that the registration of chemists and druggists who had been in the habit of extracting teeth was but a wise precautionary measure for preventing their being interfered with for so doing after the Act came into force. Some addition, however, has lately been made to the opinions expressed on the provisions of the Act which it will be desirable to place before our readers for their information.

The British Dental Association has submitted to an eminent legal authority certain questions respecting some sections of the Act, and by the courtesy of MR. JAMES SMITH TURNER, the Honorary Secretary of that Association, we have been furnished with a copy of the answers to these questions. Perhaps the opinion which is of most import for consideration is the one to the effect that "the *occasional* performance of one class of dental operations, such as the extraction of teeth, does not constitute *bonâ fide* practice of dentistry." In regard to this opinion we would remark that it distinctly avoids the point of most importance in its bearing upon the claim of chemists and druggists to be registered under the Act, and this, we think, is shown by the use of the word we have italicized. The claim of chemists and druggists to registration was urged not upon the ground that they "occasionally" extracted teeth, but because they had habitually carried on that practice as part of their business. In doing so, they acted as "dentists," and having regard to the unquestionable object of the Dental Bill to restrict the practice of dentistry, there was good reason to apprehend the practice of extracting teeth by chemists and druggists might have been interfered with, if they did not become registered.

It is a mistake to suppose that the chemists and druggists so engaged ever offered any opposition to the Dental Bill: the fact is they merely claimed a recognition of their rights as having been engaged in the *bonâ fide* practice of dentistry long before the Bill was introduced into Parliament, and it was to provide such a recognition that the amendment relating to the practice of dentistry in conjunction with pharmacy was introduced into the Bill.

Chemists and druggists do not as a rule seek to compete with those dentists who claim to be perfect because they carry out all the mechanical and constructive operations connected with the art which in their opinion alone makes it worthy to be termed "dentistry." Some chemists and druggists may do even this much, however, with credit to themselves as well as satisfaction to others, but the great majority have little to do with the art of supplementing dental deficiencies, and they are essentially dentists only in the popular sense of extracting or stopping the teeth which have been acquired in the ordinary course of nature.

Another of the legal opinions given in reply to the questions of the British Dental Association is to the effect that a person, who—being at the passing of the Act engaged in the practice of dentistry, and also in some business not mentioned in the Act—declared himself to have been engaged in the practice of dentistry separately, is liable to have his name erased from the Register. That is to say he would, according to this opinion, be held to have obtained registration improperly. If, therefore, the amendment relating to the practice of dentistry in conjunction with pharmacy had not been made part of the Act, a person engaged in the business of a chemist and druggist could not have obtained registration and with that the right to call himself "dentist," however much his practice of dentisty had conformed to the standard of perfection which some now seek to maintain is alone worthy of recognition.

It seems therefore evident that chemists and druggists who at the time of the passing of the Dental Act were engaged either in the extraction of natural teeth or the provision of artificial ones were right in their apprehension that this part of their business might be interfered with by the provisions of the Act, if they did not obtain the registration that would admit of their continuing to call themselves dentists as they had previously done. The action taken with that object was merely a reasonable protection of rights that had been obtained by usage, and that were on that account entitled to respect, notwithstanding any reasons there might be for regarding the organization of the dental art as desirable so far as the future was concerned. Nor can we, apart from these considerations, conceive it possible to have any more thorough justification of the course taken in this matter by the Council of the Pharmaceutical Society on behalf of chemists and druggists than the above-mentioned opinion of counsel on the interpretation of the Act. In saying this much we do not at all desire it to be inferred that we sympathize with persons who may have obtained registration as dentists by improperly representing their connection with pharmacy in a manner that will not bear the test of *bona fides*; but it is the business of the Registrar under the Act to deal with such cases according to their merits.

INSPECTION OF APOTHECARIES' WEIGHTS AND MEASURES.

Our readers will probably have noticed that at the last meeting of the Council the President drew attention to a Government paper describing the denomination, shape and material of local standards of apothecaries' weights and measures. The fact that this paper has been issued will suffice to indicate that progress is being made towards carrying out the provisions of the new Act in regard to the inspection of apothecaries' weights and measures used in pharmacy, and that before long it may be expected the local inspectors will be at work subjecting chemists and druggists' weights and measures to examination. It is therefore advisable that attention should be at once given to this matter in order to avoid liability under the 25th section of the Act, which provides that every person who has in his possession for use for trade any weight, measure, scale, balance, steelyard or weighing machine which is false or unjust shall be liable to a fine of £5, and in the case of a second offence to a fine of £10.

In the paper now issued by the Government, directions are given by which local authorities will be enabled at once to obtain the standards requisite for testing and verifying weights and measures, and in our next issue we purpose giving a statement of the chief points of these directions, with wood cuts illustrating the several standards, and any other information that can be obtained on the subject. It is also intended that at the next Evening Meeting of the Society in December a set of standard weights and measures shall be placed upon the table to show the mode in which the verifications of weights and measures is to be carried out in practice.

We have reason to believe that in some instances the weights and graduated measures sold for pharmaceutical purposes are far from being so correct as they should be, even when new, and consequently it may readily happen that serious inconvenience and annoyance might arise if such weights and measures came under the examination of the inspectors under the Act. We cannot therefore too strongly urge upon chemists and druggists the necessity of protecting themselves in this respect by giving immediate attention to the verification of their weights and measures. The duty of providing means for such verification belongs to the local authorities of every county and borough, by whom also times and places are to be appointed when the inspectors are to attend for the purpose of verifying and stamping weights and measures sent to them for the purpose. In regard to this function of the local authorities, it is provided by section 29 of the Act that any person who uses, or has in his possession for use in trade, any measure or weight not stamped as required shall be liable to a fine of £5.

PETROLEUM TESTING.

We have received some inquiries respecting the new form of test and apparatus for testing the inflammability of petroleum, in accordance with the new Act that is to come into force on January 1, 1880, but are not yet able to give any information on the subject inasmuch as we find that the statement made in a note appended to the Act, that "a model apparatus is deposited at the Weights and Measures Department of the Board of Trade,"* does not yet represent the fact indicated, but we have been promised information that will enable us very soon to satisfy the requirements of our correspondents.

PROVISION FOR ORPHANS.

At the last meeting of the Council it was decided, on the recommendation of the Benevolent Fund Committee, to render assistance in securing the election of Hugh Peter Victor Wiggin for admission to the London Orphan Asylum, Watford, in January next. This child is one of five left unprovided for through the death of Mr. John Wiggin, Pharmaceutical Chemist, of Ipswich, who was more than thirty years a member of the Pharmaceutical Society. Another case is that of Edward William Hall, who seeks admission to the British Orphan Asylum, Slough. This child is one of four left unprovided for by Mr. Frederick George Hall, who was formerly in business as a Chemist and Druggist at Brompton. Subscribers and others willing to assist the Council in securing the election of these children are requested to send proxies to the Secretary, Mr. Elias Bremridge, 17, Bloomsbury Square, W.C.

MUNICIPAL HONOURS.

Among the gentlemen who have been elected to the honourable office of Mayor for the municipal year just commenced, we notice the names of Mr. William Ballard, Pharmaceutical Chemist, Abingdon, Mr. Charles W. Jones, Pharmaceutical Chemist, Carmarthen, and Mr. Herbert J. Orchard, Local Secretary of the Pharmaceutical Society, Newport, Isle of Wight.

THE MEETING OF THE SOCIETY OF ARTS.

The opening meeting of the session will be held on Wednesday next, November 19, when an address will be delivered by the Chairman of the Council, Lord Alfred S. Churchill. At the ensuing meeting, the unsavory, but important subject of London sewage will be dealt with by Major-General Scott. On December 3, "Scientific and Unscientific Apprenticeship" will be the subject of a paper by Mr. Thompson, Professor of Applied Physics at University College, Bristol. Among the subjects likely to be of interest to our readers that will be brought forward at the meetings after Christmas, we may mention "Domestic Poisons," "Gas Furnaces and Pottery Kilns," "Utilization of Slag" and "Explosive Agents." The first course of Cantor lectures is to be given by Dr. C. Graham, on the "Chemistry of Bread and Bread Making;" the second course by Mr. Bolas, on the "Manufacture of India Rubber and Gutta Percha."

* See *Pharm. Journ.*, *ante*, p. 199.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The third general meeting of the thirty-first session was held at the Royal Institution on November 6. The President, Mr. Charles Symes, Ph.D., in the chair. The minutes of the previous meeting were read and confirmed. The following donations were announced:—The current number of the *Pharmaceutical Journal*, from the Society, the *Analyst*, from the editor, and the 'Registers of Pharmaceutical Chemists and Chemists and Druggists' from the Pharmaceutical Society. The President announced the purchase of the following books for the library:—Roscoe and Schorlemmer's 'Inorganic Chemistry,' in 3 vols., Schorlemmer's 'Organic Chemistry,' in 1 vol. Mr. J. M. Carter was elected an Associate.

The President announced that arrangements were in progress for holding the associated *soirée* of the literary, scientific and art societies of Liverpool, in St. George's Hall, on Wednesday, December 10, next, and requested members to assist as much as possible in the collection of objects of interest for exhibition on the occasion.

The Vice-President, Mr. A. H. Mason, F.C.S., exhibited a specimen of vincetoxicum root (*Asclepias vincetoxicum*), which had been taken from a bale of senega root, and was used on the continent as an adulterant of senega, hellebore and valerian roots. He said that good western senega root as imported from America was not adulterated, but some roots which were shipped to London from Brussels last year were found to be adulterated with this substance. A most interesting paper had been written by Mr. E. M. Holmes, F.L.S., entitled, "An Adulteration of Senega," published in the *Pharmaceutical Journal*, November 9, 1878.

Mr. Edward Davies, F.C.S., F.I.C., made a most interesting communication on "A Proposed Popular Milk Test," to which attention had been called by Mr. J. Hallawell, at the previous meeting. The communication gave rise to a somewhat prolonged discussion, in which the President, Messrs. Abraham, Hallawell and Mason took part.

The President then called upon Mr. A. H. Mason, F.C.S., to read the paper for the evening, on—

Thymol and Menthol.

BY ALFRED HENRY MASON, F.C.S.

My interest in the subject of this paper has arisen from the following circumstance:—Menthol was required, and an order sent to two of the leading manufacturers of pharmaceutical chemicals in London for some; one supplied a liquid, the other a crystalline substance. Which was correct? To an abrupt question, What is menthol? I received the following reply: Menthol is the crystalline principle of oil of peppermint as thymol is of oil of thyme. And such is a natural reply, though not correct. Thymol is of interest to the members of this Association from the fact that a sample was first exhibited in this country at the meeting of the Pharmaceutical Conference in Liverpool, 1870, by one of our honorary members, Mr. H. Sugden Evans; and secondly, from the fact that the source of the thymol of commerce, which is the fruit of *Ptychotis Ajowan*, comes to our market.

A full description of this fruit is given in Flückiger and Hanbury's 'Pharmacographia' (page 269), but the following information supplied by the exporter to the broker here may be of present interest:—

"Ajowan seed comes principally from the Ahmebabad, but also from above the ghauts Khandish, etc. The ordinary crop amounts to about 2000 candies, that is, 6000 cwts., but last year's crop was deficient, amounting in all to not more than 2400 cwts. The seed arrives in the Bombay market in February and March; it possesses an aromatic smell, and rather a warm, pungent taste, and Burjorjee informs us that it is an excellent remedy for flatulent colic."

In confirmation of this statement, I refer you to a paragraph in the *Pharmaceutical Journal*, February 22, 1879, page 694.

"Some reports appear to have gained currency in Germany that the *rôle* of thymol is nearly played out. But these are met by Messrs. Metzner and Otto in their 'Bericht,' by the statements that during the months of September and October, 1878, their house alone sent out more than a ton of it, that the works are occupied day and night in its preparation, and that the demand for thymol and thymol wadding is greater than ever. This firm appears to use the seeds of *Ptychotis Ajowan* as the source of thymol, but they state that they have advices that not only has the price of these seeds advanced through a bad harvest, but also by the increased consumption of them in India by the natives during the very sickly season of last year."

According to Watts:—Thymol ($C_{10}H_{14}O$), thymylic hydrate, thymylic alcohol, thymylic acid, camphor or stearoptene of thyme oil, is the oxygenated constituent of thyme oil, isomeric with cymylic alcohol, and homologous with phenol. It was first obtained from thyme oil by Doveri, and afterwards examined more particularly by Lallemand; it appears to be identical with the stearoptene of the volatile oil of horse mint (*Monarda punctata*), which was examined by Arppe, and with that of the oil of *Ptychotis Ajowan*, an East Indian umbelliferous plant, examined by Stenhouse, also by Haines. Thymol is obtained from these sources by fractional distillation and recrystallization from alcohol.

From Oil of Thyme.—Thymol crystallizes in rhomboidal plates with angles 97° 30′, striated parallel to the lateral faces and often aggregated into irregular six-sided tables. From oil of *Ptychotis Ajowan* it crystallizes (according to Miller) in rhombohedral crystals, from alcoholic solution in thin plates, which appear monoclinic in consequence of the great development of rhomboidal faces.

Thymol has a mild odour, which (according to Lallemand), is quite distinct from that of thyme oil, and an aromatic peppery taste. In the solid state it is somewhat heavier than water; specific gravity, 1·0285; in the liquid state rather lighter. It does not act on polarized light. Its melting point is variously stated. According to Lallemand it melts at 44° to a colourless liquid, and remains fluid for a long time after cooling, but if pure it solidifies immediately when touched by a solid body. According to Arppe it melts at 48°, and does not solidify till cooled to 27°. Thymol from ajowan melts according to Haines at 53°; according to Stenhouse at 44°. Thymol from thyme boils at 230° (Doveri and Lallemand), from ajowan at 222° (Stenhouse). Thymol dissolves in about 300 parts of water, easily in alcohol, ether and strong acetic acid, and is not precipitated from the alcoholic solution by water. It is not altered by aqueous ammonia, but takes up a large quantity of gaseous ammonia, becoming liquid, but resolidifying after the ammonia has escaped. It dissolves in aqueous potash and soda, forming compounds which are soluble in water and in alcohol, but are very unstable, being decomposed by acids, even by carbonic acid of the air, with separation of thymol.

In the *Journal of the Chemical Society*, vol. xvii., there is published an elaborate paper by Dr. Gladstone, in which he reports his examination of the physical and chemical properties of different essential oils. Of thyme, he says, "This oil from *Thymus Serpyllum* is deep red in colour. The specimen examined was principally composed of a hydrocarbon, like that of turpentine. It contained little, if any, of the thymol, $C_{20}H_{14}O$, which has been described by Doveri and Lallemand as occurring in this essential oil. The hydrocarbon has been named thymene."

Of mint, he says, "*Mentha viridis* yields this oil, which was found to contain a hydrocarbon almost identical with oil of turpentine in odour and other physical properties, mixed with an oxidized oil, to which is due the peculiar smell of the plant. It boils at 225°; sp. gravity 9·575, [?0·9575]; and it was found to be isomeric with carvol; it should therefore by analogy be called menthol." He makes the following note:—"Dr. Oppenheim has suggested this as one of the new names of camphor of peppermint, but the other name, mentholic alcohol, is more consonant with his theory." In concluding this paper, Dr. Gladstone says, "that his observations on the oxidized oils are reserved for a future occasion." This communication was made eight years afterwards and is published in the *Journal of the Chemical Society*, vol. xxv. He states that he is indebted to Mr. Hanbury for some criticisms on his former paper, which relate to the plants from which the oils are derived; amongst others he states that the wild thyme of our heaths, *Thymus Serpillum*, gives an essential oil, but the oil of thyme of commerce is from *Thymus vulgaris*. Under the heading "Carvol and its Isomerides," he states, "in my previous paper it was stated that the oils of spearmint and nutmeg contain oxidized liquids which appear to isomerides of carvol, the principle which gives its peculiar flavour to the oil of caraway. They were named respectively menthol and myristicol. These had been submitted to a fuller investigation, and it was found that oil of dill also yields a substance isomeric, or perhaps identical with ordinary carvol."

There are two ways in which these oxidized oils may be separated; either by fractional distillation, which must always be an imperfect method, or by taking advantage of the fact that they form crystalline bodies with hydrosulphuric acid, which can be easily purified, and which yield the original oil when decomposed by an alkali. The oil from nutmeg, however, was found not to form such a compound.

The following are the physical properties of the substances above mentioned. Menthol 1 was prepared by fractional distillation. Menthol 2 was prepared from the hydrosulphuric compound.

Substance.	Boiling point.	Specific gravity at 20°C.	Refractive index A at 20° C.	Dispersion.	Sensitiveness.	Refraction equivalent-	Arcular polarization
Carvol	227°	0·9530	1·4886	0·0345	46	51·26	+145°
Dill Carvol	—	0·9562	1·4891	0·0333	45	51·15	+108°
Menthol 1	225°	0·9515	1·4839	0·0326	44	50·86	−103°
Menthol 2	252°	0·9394	1·4791	0·0311	42	51·60	−114°
Myristicol	224°	0·9466	1·4·48	0·0312	46	15·20	+31°

Menthol.—This compound has the very characteristic odour of spearmint, totally different from that of carvol, and it retains the same odour when it has been reproduced from the hydrosulphate.

A combustion was made, agreeing with the formula $C_{10}H_{14}O$, vapour density, 5·29. As the composition of the hydrosulphates seemed to be identical, yet yielding a different oil on treatment with alkali, their relative solubility in ether was examined.

At 23° one part of the hydrosulphate from the three sources required the following amount of ether to dissolve it—

From Caraway . . . . 226 parts.
,, Dill . . . . . . 279 ,,
,, Spearmint . . . 216 ,,

From the foregoing it will be evident that the physical properties are almost identical, and there can be little doubt they are isomeric.

It will be noted that the menthol referred to was obtained from spearmint and is a liquid; it is therefore assumed from a chemical point of view, that if a scientific chemist requires menthol, the liquid $C_{10}H_{14}O$ should be supplied.

Peppermint Camphor.—Gmelin does not mention the word menthol, he calls it stearoptene of peppermint oil—solid peppermint oil. Oil of peppermint obtained by distilling *Mentha piperita* with water deposits on standing, or when cooled to—20°, crystals of peppermint camphor. American peppermint oil solidifies at 0° (Dumas); when it is subjected to fractional distillation, the last third of the distillate, if collected apart, deposits crystals on standing. *Properties*—Transparent, colourless, shining prisms, melts at 36·5 Dumas; 27° Blanchet and Sell; 34° Walter. Volatilizes without decomposition; solidifies at 24°; boiling point, 208°, Blanchett and Sell; 213° Walter; vapour density equals 5·62 Walter; formula $C_{10}H_{20}O_2$.

Respecting menthol from peppermint, Hanbury writes, 'Pharmacographia' (page 270):—"When oil of peppermint is cooled to 4° C. it sometimes deposits colourless hexagonal crystals of peppermint camphor, $C_{10}H_{18}+H_2O$ called also menthol. This camphor (the deposit of which in the oil we have not observed) boils at 210° C. and possesses the odour of crude oil; it deviates the ray of polarized light to the left. The proportion of oils of different origin is very variable. Pure crystallized menthol is sometimes found in commerce under the name of Chinese oil of peppermint. It is distilled at Canton from a plant which appears to be *Mentha arvensis*." (Mr. Holmes, *Pharmaceutical Journal*, September 13, 1879, p. 201, disputes this statement.) "The oil was exported from Canton in 1872, to the extent of 800 pounds; it was valued at 80*s.* per pound." (A specimen of this was presented to our museum at that time by Messrs. Cyriax and Farries, of London.) With this substance was sent over a bottle of liquid oil, and a most exhaustive report was made upon these by Mr. John Moss, F.C.S. (*Pharmaceutical Journal*, 3rd series, vol v. p. 366; see also 'Year-Book of Pharmacy,' 1875, p. 198).

In 1862 Oppenheim made a communication to the Chemical Society on this substance, and specimens which came over from Japan about that time were found to be adulterated with 10 to 20 per cent. of sulphate of magnesia. I am indebted to Messrs. Morson and Son for the specimen exhibited, they having retained a portion of the original importation referred to.

Peppermint camphor is but slightly soluble in water, but imparts to that liquid a strong smell and taste. It is very soluble in alcohol, ether, sulphide of carbon and oils, both fixed and volatile, insoluble in aqueous alkalies.

Peppermint camphor is an alcohol containing the radicle $C_{10}H_{19}$ (menthy); it is homologenous with allylic alcohol C_3H_6O, and isologous with campholic alcohol, or camphol $C_{10}H_{18}O$ (*i.e.*, differs from the latter body by 2 at H); hence the names menthylic or mentholic alcohol and menthol applied to it.

Bearing in mind the reply I received to the question "What is menthol?" my conclusions from the foregoing are as follows:—

Menthol ($C_{10}H_{14}O$) is the oxidized oil of mint obtained from different varieties of the plant, each having a distinct flavour. Menthol camphor ($C_{10}H_{20}O$) is a crystalline principle obtained from Japanese and Chinese oil of peppermint, variety undetermined. Thymol ($C_{10}H_{14}O$) is a crystalline body obtained from the oil of *Ptychotis Ajowan*. I have tried to obtain a sample of thymol guaranteed to be obtained from oil of thyme, but without success. The fact is that true oil of thyme yields so little to potash that it does not pay to make it from that source commercially.

In naming the stearoptene of Japanese peppermint a camphor there is an obvious objection, because it forms compound ethers with acids, and must obviously be an alcohol or body more analogous to phenol than camphor.

As the notice of medical practitioners has been called to this substance from a paragraph published in the *Lancet*, June 7, 1879, page 822, its repetition will be of some interest, as follows:—"Menthol a new antiseptic. Menthol, or peppermint camphor, is a crystalline body deposited from Chinese oil of peppermint on exposure to cold. It is met with in the form of small colourless fragrant prismatic crystals, not unlike sulphate of magnesia. In fact, when first imported from Japan some twenty years ago, it was for some time suspected to be nothing but epsom salts flavoured with peppermint. It is now known to have a definite chemical composition, and to be the camphor or stearoptene of peppermint oil." After describing the physical properties I have previously stated, the writer proceeds:—"From a series of experiments recently undertaken by Mr. Archibald Duncan, a student in the University of Edinburgh, it would appear that it is possessed of antiseptic properties similar to those of its homologue, thymol. At present it can hardly be regarded as a commercial article; but it could be readily imported from Japan, and there is no reason to suppose that its price would be prohibited. (*Note.*—There are at the present time four cases for sale in the London market; probable price 10*s.* or 12*s.* per pound.) An impure sample sent over from Canton in 1872 was valued at 30*s.* per pound. (*Note.*—This is an obvious error, since Mr. Moss and all who reported upon this consignment testify to its purity.) We are not aware that it has been used in therapeutics; but strong oil of peppermint painted over the part has long been a favourite mode of treatment in China for gout and neuralgia, and it might prove useful in these complaints. The Japanese po-ho-yo, or neuralgic remedy, probably contains menthol."

A few years ago my brother-in-law brought with him from China some bottles of this po-ho-yo, which he said was used out there as a specific for headaches, and as he happened to call when I was prostrate with a severe nervous headache he insisted upon anointing my forehead with this magic liquid. I immediately experienced an agreeable burning sensation and perceived a powerful odour of peppermint, fell asleep and awoke minus the headache. When I smelt this liquid menthol I fancied I recognized my old restorative, and I should not hesitate to apply it (of course diluted) should occasion require.

I exhibit a bottle of liquid commonly sold in Paris and Vienna as Gouttes Japonaises, or po ho; it is put up in these little bottles especially for the Japanese market, Chinese oil being preferred by the Japanese to their own. The circulars, in character, which accompany each bottle, set forth its virtues. It is mentioned by Christison as po-ho-yo.

Whatever source they are from, Chinese and Japanese have a more decided effect than either the English or American oils; the latter do not relieve neuralgia to the same extent.

Menthol camphor has for some time been used by dentists for dental cases (see *Practitioner* for November, 1877, page 383). Mr. Macdonald recommends it for sciatica and neuralgia, intercostal neuralgia particularly (see *Lancet*, vol. ii., 1879, page 448). He used a solution 1 in 60, adding a little oil of cloves. This solution is being prescribed in London, and also of varying strength up to 1 in 10 spirit of wine, according to the requirements of the case.

A little menthol camphor was put into a carious tooth, from which the patient was suffering great pain; this it relieved at once, but for some time afterwards the patient was so elated that she appeared as though she had had a little of something else.

It appears to be a powerful diffusible stimulant.

Records of its internal administration are not published, but experiments have been made to test its efficacy in conjunction with thymol.

Thymol is acknowledged to be an antiseptic of value to the practitioner, and is employed in the form of ointment combined with vaseline, and also combined with rectified spirit and glycerine for nasal douches and gargles. It is intensely caustic, and unless freely diluted, say 1 part to 4000, it is irritating when administered internally.

The introduction of these substances into medical practice at the present time naturally gives the study of the composition of essential oils an additional interest. Whilst it is admitted that phenol is an invaluable antiseptic, its poisonous and irritating properties are such that the practitioner naturally looks for something more agreeable as a substitute, and since the recent investigations of scientific chemists have shown that nature's hygiene provides such substitutes, we may naturally look to some of these substances which are isomeric.

I desire to acknowlege my obligations to Mr. Martindale, of London (who has given considerable attention to the study of menthol), for his valuable information in connection with this substance, and to Mr. Williams and Mr. Taubman for assistance (without prejudice) in working out the conclusions I have arrived at in this paper.

An animated discussion followed, which proved the existence of different opinions concerning the nature and physical properties of menthol.

A hearty vote of thanks, proposed by Mr. Conroy and seconded by Mr. Davies, was accorded Mr. Mason for his valuable paper, and the meeting closed.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The second meeting of the session was held in the Pharmaceutical Society's rooms, 119A, George Street, on the evening of Wednesday, November 5, Mr. Robertson, Vice-President, in the chair. There were about forty members present.

The minutes of last meeting having been read and adopted, the chairman called upon Mr. Maben to read a paper on "French Pharmacy."

Mr. Maben first sketched the regulations existing in France as to the sale of drugs and poisons, dispensing of prescriptions, registration of pharmaciens, inspection of pharmacies, etc., and compared these with the laws of our country, the advantage not always being on the side of the latter. He gave a short account of the curriculum of study, and of the examinations required, before a candidate can receive a diploma. Referring to the metric system of weights and measures, the essayist thought that the government had made a mistake in again legalizing the apothecaries' weights, arguing that the time had come when the decimal weights and measures should be adopted. Mr. Maben then passed rapidly under review the French Codex, noticing briefly some of its more distinctive characteristics. Worthy of admiration as the Codex was, it would be much more appreciated, he thought, if it contained a half fewer formulæ, and if all the more ridiculously complex preparations, examples of which he cited, were omitted.

The paper was criticized by Messrs. Aitken, Henry and Fisher, and on the motion of the chairman a hearty vote of thanks was awarded to Mr. Maben.

The report of the "Shorter Hours" Committee was then read, and after an animated discussion thereon it was resolved to continue the Committee, with power to add to their number.

On the motion of Mr. Robertson, seconded by Mr. Fisher, it was resolved to offer to the apprentice members of the Association a prize, value 10*s.* 6*d.*, for the best essay on a given subject; the subject to be fixed by the Committee, and intimated at next meeting.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The opening meeting of the session was held in Anderson's College, on Wednesday, November 5, Mr. A. Kinninmont, F.C.S., presiding.

After the minutes of the previous meeting had been read and adopted, the President gave a short address on—

SOME POINTS OF PHARMACEUTICAL ETHICS.

He said that he did not intend to discuss the whole question of pharmaceutical ethics, as that had been so well done by Mr. Ince in the Journal many years ago, but he would say a few words on the relation that sometimes exists between the physician and chemist and druggist. He was of the opinion that there was nothing morally wrong in a physician sending his prescriptions to a particular dispenser if there was no monetary value passed between both, but the public and the trade sometimes thought that the physician reaped a golden harvest from every prescription sent to his favourite dispenser, apart from his professional fee, or he would not be so very eager to impress upon the patient the necessity to send the prescription to his particular shop. With reference to private formulæ to be had only at certain shops, he said the chemist was not entitled to give the formula when asked for unless he thought proper to do so, but he had always found the chemist willing to give to his brother in trade the made up material at wholesale rate, so that it allowed the dispenser of it his profit just the same as if he had made it up with the ingredients himself. The speaker then touched upon the retention of the prescription by the patient, and said that he always considered the prescription was by right the patient's and not the dispenser's, although the American druggists thought different, for they took possession of the prescription and pasted it into a book, and if the patient wished a copy of it they would give it to him. As to repeats of prescriptions he thought if any patient wished his prescription renewed again and again, the pharmacist had no right to refuse it, although it might prevent some fees from going to the physician. Mr. Kinninmont closed his remarks by saying that some of the points touched upon caused in Glasgow some time ago some amount of acrimonious feeling to exist among a great number of dispensing chemists in the city, but from the remarks of the various members he was glad to hear that a good amount of it had disappeared.

After his address, Messrs. Brodie, Clarke, Simpson, Hunter and others, discussed some of the remarks, but they agreed pretty well with the President's ideas respecting the subjects touched upon by him.

Mr. Maltman was then elected Treasurer in room of Mr. Hick, who was leaving Glasgow.

On the table were placed the new books that had been bought since last session, along with three volumes of *New Remedies*, presented by the President; and after the election of members, the usual vote of thanks to the President brought the meeting to a close.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, November 6, Mr. Warren De La Rue, F.R.S., President, in the chair.

The minutes of the last meeting was read and confirmed.

A list of presents to the library were read, and the thanks of the Society voted to the respective donors.

The following certificates were read for the first time:—G. S. Albright, W. J. F. Churchouse, M. Cochrane, W. R. Dunstan, J. J. Hummel, E. Hughes, T. S. Humpidge, F. Hatton, A. Leibius, R. Jones, H. F. Morley, H. Newton, J. Parette, G. Stallard, J. M. Wilson.

The President announced that the Council had expended about £300 in purchasing books for reference and circulation; he invited Fellows to offer suggestions as to the purchase of new books and the general improvement of the circulating library.

The Secretary then read a paper by C. O'SULLIVAN—

On the Transformation Products of Starch.—This paper was originally presented to the President of the Société Chimique de Paris, on June 18; extracts therefrom were read on July 4; but as the bye-laws of the Council exclude papers longer than eight printed pages, the author thought it desirable to bring the communication before the Society, especially as it appeared from papers published by MM. Musculus and Gruber that these chemists were, to a great extent, unacquainted with the previous work of the author. The author commences by re-asserting that the molecule of starch under the influence of malt extract splits up in one of four ways:—

$$\text{(C).}\quad C_{72}H_{120}O_{60} + H_2O = \underset{\text{Maltose.}}{C_{12}H_{22}O_{11}} + \underset{\alpha\text{—Dextrin.}}{C_{60}H_{100}O_{50}}.$$

$$\text{(B).}\quad C_{72}H_{120}O_{60} + 2H_2O = 2C_{12}H_{22}O_{11} + \underset{\beta\text{ Dextrin I.}}{C_{48}H_{80}O_{40}}.$$

$$\text{(B}'\text{).}\quad C_{72}H_{120}O_{60} + 3H_2O = 3C_{12}H_{22}O_{11} + \underset{\beta\text{ Dextrin II.}}{C_{36}H_{60}O_{30}}.$$

$$\text{(A).}\quad C_{72}H_{120}O_{60} + 4H_2O = 4C_{12}H_{22}O_{11} + \underset{\beta\text{ Dextrin III.}}{C_{24}H_{40}O_{20}}.$$

Other proportions of maltose and dextrin have been observed, but these are due to either the splitting up of the starch, partially according to one equation and partially according to one or more others, or to the further action of the active agents of malt extract on the dextrin first produced. The proportions of maltose and dextrin represented by the equation of MM. Musculus and Gruber belong to the latter class. These chemists confirm the author's work as far as it relates to maltose, but have made a serious error (about 2 per cent.) in calculating the specific rotatory power, as they have taken 220 mm. of a 1 per cent. solution of maltose to give a deviation of 13·5 divisions on the scale of the Soleil-Duboscq instrument; this number should be 13·75. MM. Musculus and Gruber point out at least three dextrins with different optical activities and cupric oxide reducing powers. The author declares the existence of four distinct dextrins to be highly probable; but states that all, when pure, have the same optical activity, but that none are reducing bodies. Soluble starch has the same optical activity as the dextrins, but like them does not reduce when pure. The author then gives details of the preparations and properties of soluble starch and the various dextrins, criticizing the statements and methods of MM. Musculus and Gruber, as well as the various products obtained by them. In the second part the author investigates the action of malt extract on the transformed products. At first sight it would seem probable that the starch molecule breaks down first into maltose and α dextrin. The latter is then converted into maltose and β dextrin I., which in its turn forms maltose and β dextrin II., etc. The author has made many experiments to elucidate this question, and finds that the above theory, viz., the breaking down of the starch molecule into dextrin molecules, which become smaller at each step, is not supported by all the facts. Continual work with these bodies has forced the author to the conclusion that they are not a series of polymers, but rather a series of bodies of the same molecular weight, in which the difference in their behaviour must be accounted for by a difference of relation in the arrangement of the molecules to one another, probably in solution alone. We may take it, continues the author, that the molecule of soluble starch, or the dextrin, giving a purple with iodine, is simply $C_{12}H_{20}O_{10}$, but that these molecules in solution are arranged in groups of six sixes, all the groups being in an intimate state of tension one with another, so that the motion affecting one under certain conditions affects all under the same condition. In conclusion, the author states that the theory of splitting up and breaking down of the starch molecule as represented by the equations, does not hold all the facts eliminated, and is not in accord with some of them. The theory, on the other hand, of the arrangement of the molecules in groups all dependent one on the other, and capable therefore of undergoing a simultaneous movement, and the re-arrangement of these groups attendant upon the hydration of a definite proportion of the molecules in each of them, holds all the facts at present known, and is in perfect accord with all of them. The author is still engaged on the chemistry of the subject, but points out that the physics ought now to be studied, and the heat absorbed or eliminated during the different transformations determined; thus some idea of the character of the apparent work done will be gained.

Dr. ARMSTRONG then read a note on—

The Formulæ of the Carbohydrates.—The simplest carbohydrates—dextroglucose and its isomerides—are closely related to mannite and dulcite, as shown by their conversion into one or other of these alcohols by the action of nascent hydrogen, and therefore they are derivatives of the paraffin, normal hexane. Of the three possible formulæ which may be assigned to a body formed from mannite or dulcite by the abstraction of two atoms of hydrogen, that which represents glucose as being both an aldehyde and a penthydric alcohol,

$CH_2(OH),CH(OH)CH(OH)CH(OH)CH(OH)COH$,

appears to be the most probable, as it is the only one which accounts for the formation of saccharic or mucic acids from it on oxidation. The carbohydrates of the cane sugar group are probably related to the glucoses in the same way that ordinary ether is related to ethyl alcohol; moreover, it appears most probable that the simplest carbohydrate of the empirical formula $C_6H_{10}O_5$, *i.e.*, dextrin, and if several exist, the lowest of them, bears a similar relation to the carbohydrates of the cane sugar group, and therefore has the formula $C_{24}H_{40}O_{20}$. Suppposing starch to be a body of highly complex formula, the author is inclined to prefer this hypothesis to that advanced by O'Sullivan. There is very little doubt that it bears an altogether different relation to the lower carbohydrates; most probably the relation is of the character of that which obtains between aldehyde and its polymerides; *i.e.*, the groups composing the starch molecule are partly held together by the COH groups, these groups being rendered capable of thus acting by their conversion into HC—O— groups. On this hypothesis a number of $C_6H_{10}O_5$ polymerides, of varying molecular weight, may be conceived to be capable of existing, and bodies such as inulin, glycogen, etc., are not improbable by intermediate terms in such a series. The fact that the dextrins obtained by the decomposition of starch under various conditions are very similar in their properties is not so difficult to reconcile with this hypothesis, if it be assumed, as appears probable, that the polymerization and formation of higher terms in the series are attended with the expenditure of only a small amount of energy: in this case the polymerides would not, probably, differ greatly from each other in properties. It may be argued that as cane sugar and the dextrins are not cupric oxide-reducing bodies, it cannot be assumed that they contain the group COH in their formulæ; probably, however, the power of reducing cupric salts is in no way connected with the presence of COH groups. In conclusion, the author considers that there is little doubt that our present theory of isomerism is insufficient and incapable of explaining the isomerism of mannite with dulcite and of the glucoses with one another. The Le Bel hypothesis appears at first sight to be applicable, but there is much evidence tending to show that this hypothesis does not furnish the entire solution of the problem.

The next paper was read by the Secretary—

On a New Method of Determining Sulphur in Coal. By TEIKICHI NAKAMURA, of the Engineering College, Tôkiô.—The author criticizes the methods generally used: the nitric acid and potassium chlorate method, the potassium hydrate method, and the method of fusion with alkaline carbonates and nitre, and he finds them all more or less inaccurate or inconvenient. He recommends the following procedure: 3 or 4 parts of the mixed alkali carbonates or of sodium carbonate are intimately mixed with 1 part of coal in very fine powder in a large platinum dish. The mixture is heated at first very gently, a spirit lamp being used, to prevent possible absorption of sulphur, instead of a Bunsen; the heat is then raised slowly without attaining that of visible redness until the surface becomes only faintly grey. No smoke or odorous gases should escape during the whole of the oxidation. The temperature is now raised to a faintly red heat for sixty minutes, at the end of which time the mass is perfectly white, or reddish if iron be present. The mass is not to be stirred during the ignition. The residue is treated with water, filtered and the sulphates determined in the ordinary way. The author quotes some results obtained by his process. To the paper is appended a note by Dr. Divers, stating that the above process was worked out some time before the *Chemical News* of January 17 was received, which contains a somewhat similar process by Mr. Pattinson, who estimates the sulphur by heating a mixture of coal and calcium hydrate in a muffle.

At the conclusion of this paper Dr. Gilbert took the chair.

The next paper was read by the Secretary on—

The Bromine Derivatives of β Naphthol. By A. J. SMITH.—The author prepared β monobromnaphthol by adding to a tolerably concentrated solution of β napthol in glacial acetic acid the theoretical amount of bromine mixed with an equal volume of glacial acetic acid; the bromine is added drop by drop and the mixture kept cool. On standing, colourless needles with an adamantine lustre crystallize out. These were purified and analysed. β monobromnaphthol is soluble in alcohol, ether, and benzene, melts at 84° C.; begins to decompose at 130°; when oxidized by alkaline permanganate it yields orthophthallic acid. The author prepared β tetrabromnaphthol in a similar way; on oxidation it yielded monobromophthallic acid. In conclusion the author discusses the bearing of his results on the constitution of these bodies.

The next paper was read by the Secretary—

Notes on the Dissociation of Ammonia Iron Alum. By J. S. THOMSON.—When a dilute neutral solution of a ferric salt is heated it dissociates, and a basic salt is precipitated. This basic salt is readily soluble in dilute sulphuric acid; if an acid of known strength be employed and the quantity necessary to bring about the desired solution be known, an insight into the nature of the decomposition can be arrived at. The author refers to the previous work of Krecke, Wiedemann, Tichborne, Naumann and others. Several series of experiments were made. Taking the mean of these, the quantity of sulphuric acid required to prevent dissociation, for each addition of 10 c.c. of water after 50 c.c., when ammonium iron alum equal to 0·1 grm. Fe_2O_3 is used was found to be 0·0186 grm.; if 0·15 grm. Fe_2O_3 be used, the quantity of H_2SO_4 was 0·02479 grm.; the addition of sulphate of ammonia equal to 0·05 ammonia necessitates an additional quantity of sulphuric acid equal to 0·05005 grm. Ammonia salts exert this influence when present as double salts, ammonia alumina alum and the double sulphates of ammonia and magnesia and of ammonia and zinc were used. Potash salts exert a still more powerful influence in promoting dissociation. A solution of ammonia iron alum containing more than 1 grm. in 14·37 c.c. does not dissociate on boiling; the dissociation begins in more dilute solutions and increases regularly, as the above results prove, with each addition of water

The next paper was read by the Secretary on—

a Methyl Oxysuccinic Acid, the product of the action of Anhydrous Hydrocyanic Acid upon Aceto-acetic Ether. By G. H. MORRIS—Demarçay (*Compt. Rend.*, 82, 337) has described an acid, obtained as above, under the name of oxypyrotartaric acid, as an unstable uncrystallizable syrup, whose barium salt is decomposed by boiling with excess of water. The author at the suggestion of Wislicenus has prepared the body according to the directions of Demarçay. The thick brown syrup thus obtained was purified by solution in water, precipitated with lead acetate, the lead salt treated with sulphuretted hydrogen, the solution filtered, evaporated, and treated with ether, until finally, the ethereal solution after standing a few days in the air-pump vacuum deposited the pure acid in star-like groups of needles, deliquescent and melting at 108°. The following salts were prepared and analysed:—the barium salt, which when pure did not decompose on boiling with water; the calcium, potassium, silver, lead and copper salts, most of which are deliquescent. The author has investigated the action of fuming hydriodic acid, and the products of the dry distillation of the acid. In conclusion, he discusses the constitution of some of the isomers of α methyloxysuccinic acid and assigns the following formulæ:—

$$\text{Citramalic acid} \left\{ \begin{array}{l} CH_3 \\ CHCOOH \\ CHOH \\ COOH \end{array} \right.$$

$$\text{Itamalic acid} \left\{ \begin{array}{l} CH_2OH \\ CHCOOH \\ CH_2 \\ COOH \end{array} \right.$$

and

$$\alpha\ \text{Methyloxysuccinic acid} \left\{ \begin{array}{l} CH_3 \\ COHCOOH \\ CH_2 \\ COOH \end{array} \right.$$

The next paper was read by the Secretary on—

The Action of Phosgene on Ammonia. By H. J. H. Fenton.—When these gases are mixed a white neutral amorphous substance is produced, which has been shown by Regnault and others to consist of ammonium chloride, a substance identical or isomorphous with urea, and in addition small quantities of guanidine, cyanuric acid, etc. (Bouchardat). The author prepared some quantity of this white substance and obtained a small quantity of guanidine, which he identified by its crystalline form, and some urea which was identical with ordinary urea in its behaviour with hypochlorites and hypobromites (*Journ. Chem. Soc.*, July, 1878), and in other respects. The author concludes that either carbamide and urea are identical, or that symmetrical carbamide has not been obtained by this method.

The next paper was read by the Secretary on—

The Rehydration of Dehydrated Metallic Oxides. By C. F. Cross.—The author has obtained various anhydrous basic metallic oxides by igniting the precipitated hydrates. These oxides he exposed at the ordinary temperature to an atmosphere saturated with aqueous vapour; rehydration occurs up to a definite limit of a molecular character, attended in most cases with a change of volume, He has investigated thus the oxides of aluminium, chromium, cobalt, iron and copper.

The following paper was taken as read—

On Alizarin Blue. By G. Auerbach.—About eighteen months since, a blue colouring matter was brought into the market as a substitute for indigo; it is now disused on account of its high price and its unstable nature when exposed to sunlight. The researches contained in this paper were finished in May, 1878. The author gives a *résumé* of previous work on the subject, and recommends the following method of preparation:—1 part of dry mononitroalizarin, 5 parts of concentrated sulphuric acid and 1½ parts of glycerin (specific gravity 1·262), are mixed and heated gently. Reaction commences at 107° C., becomes violent, the temperature rising to 200° C.; much frothing takes place, with evolution of sulphurous acid and acrolein. The whole mass, when frothing has subsided, is poured into water, boiled up and filtered, the residue being boiled out three or four times with dilute sulphuric acid. The mixed filtrates are allowed to cool, and the blue separates in brown crystals. These are purified by mixing with water and adding borax till the solution becomes brownish violet, the blue with the boric acid forming an insoluble compound. This residue is washed, decomposed with an acid, and the pure blue obtained as a violet silky paste. If required perfectly pure, it must be crystallized successively from its various solvents, high boiling naphtha, amylic alcohol and glacial acetic acid. When pure, it forms brown shining needles, melting at 268°-270°; it has the formula $C_{17}H_{11}NO_4$. Salts were prepared and analysed, but the results were not satisfactory, as it was difficult to obtain them quite pure. Bromine derivatives were also prepared and examined. The action of chlorine, zinc dust, acetic anhydride, etc., have also been studied. The author discusses the constitution of the blue and thinks it must be closely related to the aldehydines discovered by Ladenberg, which are formed when aromatic orthodiamides act upon aldehydes.

The Society then adjourned to November 20, when the following papers will be read:—A Chemical Study of Vegetable Albinism, Part II.: Respiration and Transpiration of Albino Foliage. by A. H. Church; Estimation of Manganic Oxide and Potassium Bichromate, by S. Pickering; Contributions to the History of Putrefaction, by C. T. Kingzett; Notes on Manganese Dioxide, by C. R. A. Wright and A. E. Menke.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the above Association was held on Wednesday evening, October 29, Mr. Branson in the chair, at which there was a large attendance. A paper was read by Mr. R. H. Parker on "The Products of the Coniferæ."

The author commenced by giving a brief sketch of the botanical and geographical positions of the natural order Coniferæ, its diagnostic characters and the numerical relation of its species among the Gymnospermia. The substances derived from this order were described individually, according to the genera yielding them, namely, those of Pinus and Abies, Juniperus, Callitris and Dammara; the relation of the various products to one another being demonstrated very clearly by a chart containing the whole of them systematically tabulated. The numerous crude turpentines (oleoresins) and their volatile oils were described physically and chemically. Especial mention was made of ol. pini sylvestris and ol. pini pumilionis, used for the inhalations of the Throat Hospital Pharmacopœia, and the necessity of care being taken to use those obtained from the leaves, since in the case of ol. pini sylvestris that produced from the oleoresin was occasionally supplied. Terebene and camphene received a passing notice, the former being obtained by converting oil of turpentine into two optically inactive hydrocarbons, viz:—terebene, $C_{10}H_{16}$ boiling at 160°C., and colophene $C_{20}H_{32}$, boiling at a much higher temperature, separated by fractional distillation. While dealing with the coniferous oleoresins, the author mentioned the curiously close relation, both chemically and physically, which exists between them and Chian turpentine, the botanical source of which is so remote from the pines. The various pine timbers were enumerated, together with the trees yielding them, and the study of this genus concluded with a reference to the importance of pine forests upon the sanitary condition of the atmosphere; the essential oil from the leaves is volatilized by solar heat and in the presence of oxygen and moisture produces peroxide of hydrogen and several camphoraceous substances, all having great antiseptic properties.

A study of the genus Juniperus was next submitted; the distinguishing specific characters of juniperus and savin branchlets were mentioned, and the chemical and other properties of the drugs obtained from these species. Huile de cade was mentioned, but no definite information could be given as to whether the article appearing in commerce at the present day is obtained from *J. oxy-*

cedrus. Juniperus bermudiana and *J. virginiana* were noticed as the sources of the wood known as "Cedar," largely used for pencils, etc., the essential oil distilled from the wood being the "oil of cedar" of commerce, used for perfumes. Sandarach or "gum juniper," from *Callitris quadrivalvis*, was described, also the means of distinguishing it from mastich. The sources of the fossil kaurie resin (*Dammara australis*) and of gum "dammar" (*D. orientalis*) were stated, together with their commercial applications. In conclusion, the various ornamental conifers of our gardens were refered to, viz.:—*Araucaria imbricata* (Monkey puzzle), *Cedrus Libani, Thuja orientalis* and *T. occidentalis.*

The paper was illustrated by specimens of nearly all the substances referred to, lent from the Museum of the Pharmaceutical Society, by the permission of the Council; by a collection of cones of different species of *Pinus* and *Abies* lent by Mr. E. M. Holmes; by microscopic specimens of sections of coniferous woods, the pollen of *Pinus pinaster*, crystallized derivatives of turpentine, etc.; and by the complete series of coloured plates of the Coniferæ from Bentley and Trimen's 'Medicinal Plants.' A discussion followed in which Messrs. Branson, Collinson, Hardwick, Piper, Sangster, Miller and Wallis took part; and at the conclusion a hearty vote of thanks was awarded to Mr. Parker, proposed by Mr. James, and seconded by Mr. Robinson.

Parliamentary and Law Proceedings.

Prosecution under the 17th Section of the Pharmacy Act.

At Aberdare Police Court, on Tuesday, November 11, Daniel Tudor Williams, whose name was in March last erased from the Register of Chemists and Druggists, by order of the Council of the Pharmaceutical Society, was fined 2*s.* 6*d.* and costs for an infringement of the 17th section of the Pharmacy Act. Last month a penalty was recovered from the same defendant for an offence against the 15th section, on the prosecution of the Council of the Pharmaceutical Society (see before, p. 267). The present summons was taken out by the Secretary of the Chemists and Druggists' Trade Association.

Poisoning by Chloral.

On Thursday, November 6, Dr. Elliott, the Carlisle city coroner, held an inquest concerning the death of Dr. W. Hay, who had been found dead in his bed on the previous afternoon.

Mary Jane Donaldson, six years servant with Dr. Hay, said Dr. Hay's rest was very much broken. She had frequently heard him say he had taken opium pills. She waited upon him at dinner at one o'clock on Wednesday, when he partook of it as he used to do at any other time. She heard him say that he had taken poison without mentioning what it was. When he used to say he had taken opium he did not mention the word poison. She took a bottle of potass water up into his room at half-past three o'clock, as he had signified a desire for it previously to the housekeeper. He was asleep and snoring, but she thought that she would not disturb him. She went about four o'clock, and saw that his face was of a bluish-black colour. She spoke to him twice and got no answer. She found that he did not stir, and put her hand to his forehead and found it covered with a cold perspiration. She then went for medical assistance.

Dr. Barnes said, when he saw Dr. Hay, he had evidently been dead only a short time. Dr. Sullivan and then Mr. Page came in. They went down into Dr. Hay's surgery and had some talk as to the cause of death, coming to the conclusion that it was the result of an overdose of some poison. On the surgery table they found a bottle, produced. It could contain six ounces, but it had now only an ounce in it. The stopper was wet, and led them to believe that it had been recently used. On the bottle was the label "Liq. chloral hydrate. 1 minim equal to ½ grain chloral hydrate." This was an exceptionally strong preparation of the drug and not commonly used. It was a dangerous strength to use—three times more than the usual. There was a measure glass on the table which they found had also been recently used. With a preparation of the drug of the strength stated a person might very easily take an overdose inadvertently. On the previous afternoon, in company with Dr. Sullivan, witness made an internal examination of the body, and found no appearances of disease sufficient to cause death. The appearances were quite consistent with the opinion that death had been due to an overdose of such a narcotic as chloral, and of no other poison that he and Dr. Sullivan were acquainted with.

Dr. Sullivan corroborated at some length the evidence of Dr. Barnes. He explained that on the label on the bottle produced and spoken to by Dr. Barnes, the figure ½ was written with ink and the word "one" which was printed was scored out. He and Dr. Barnes were particularly struck with the small size of the heart. Dr. Hay was a large man, and the heart was not at all in keeping with the size of the body. This explained what he heard the housekeeper say that in going upstairs Dr. Hay used to exhibit signs of shortness of breath. The muscular part of the heart was flabby, and the organ would not be able to undergo much exercise.

The jury returned an unanimous verdict to the effect that Dr. Hay came by his death from inadvertently taking an overdose of chloral. The foreman added that he believed it was quite possible that the deceased had taken a similar dose before, but the heart being perhaps weaker was not able to stand it.—*Carlisle Paper.*

A Boy Poisoned by Eating Yew Berries.

An inquest was held on Monday, October 4, at Chalfont House, Kingston Road, Oxford, before the city coroner (Mr. E. L. Hussey), touching the death of a boy, nine years old, named Charles Wood. Thomas Wood, stated that deceased was his son, and had generally good health. Witness had heard that he and his sisters and a cousin went on Sunday afternoon to Holywell Cemetery, to see their aunt's grave. In the evening about six o'clock as deceased was at tea two of the children (deceased and one of his sisters) said they had eaten a good many yew berries which they got off the trees in the cemetery. The girls had not been ill since. They all had dinner on Sunday at two o'clock, and went to the cemetery afterwards. Deceased went to bed about a quarter to nine and slept in the same room with witness. About three o'clock he heard deceased groaning, and got out of bed, and tried to wake him. Witness put on a mustard poultice to deceased's chest, and also gave him some mustard and water. He vomited very little. The boy afterwards had convulsions, and died about a quarter to four. Witness went to Mr. Symonds, but he did not arrive till deceased was dead. He (witness) had often eaten the pulp of the berries himself, but he never swallowed the stones.

Eliza S. Wood said that deceased was her brother, and he went with her and one of her sisters, and one of her cousins to the Holywell Cemetery on Sunday afternoon. All of them picked some of the red berries off the yew trees and ate them, and deceased put some into his pocket and ate them as they were walking home. Witness spat out the stones, and her sister and cousin also did so. As they were walking home deceased put a handful of berries into his mouth, and crunched them up and swallowed stones and all. She did not know how many berries deceased ate, but she thought more than a hundred. They got to the cemetery about half-past three.

The jury returned a verdict that deceased died from the effects of swallowing poisonous yew berry stones, administered by himself not knowing that they were poison.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[348]. It is not often I feel called upon to differ from the writer of the "Month" in his very able and welcome *résumé*, but I think, with respect to "ferri ammon. sulph." that he has fallen into an error. I think there can be do doubt that the *ferric* and not the *ferrous* salt is intended; both the ammonio-ferric and the potassio-ferric alums have long been used in chronic dysentery, leucorrhœa and diarrhœa. A notice of them will be found in the *Pharmaceutical Journal* for January, 1854. They have been found to be more astringent than common alum, whilst they are free from the stimulating effects of other salts of iron. "Ferri et ammonii sulphas" is officinal in the United States Pharmacopœia. For the benefit of your readers, I beg to be allowed to transcribe the process ordered for its preparation: "Take of solution of tersulphate of iron, 2 pints; sulphate of ammonium, 4½ troyounces. Heat the solution to the boiling point, add the ammonium, stirring until it is dissolved, and set aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper and dry in the open air."

It is of course to be borne in mind that the U. S. pint is the old wine pint of 16 fluid ounces.

J. Hart.

The formula has also been received from Mr. F. Stevens.

[365]. *Lavandula* is in error when he says that double the quantity of potass bicarb. ordered in the B.P. should be used.

The ung. potass. iodid. is prepared with pot. carbon. If the ointments are made strictly according to the B.P., and mixed, decomposition ensues at once, ammonia is evolved, and mercuric iodide is formed, therefore a creamy white ointment cannot be produced. Pot. Carbon.

[368]. There ought to be no question as to who was right in this instance. The B.P. tinct. zingib. should be dispensed, otherwise there would be a deviation from the prescription. It should have a milky appearance, owing to the volatile oil in the ginger and sp. ammon. aromat.

Lavandula.

[370]. Place about ℥v of distilled water in a bottle and add the sp. myristicæ and liq. strychniæ, then dilute the tinct. ferri perchlor. with the remainder of the distilled water, and add it to the other ingredients already in the bottle. The mixture will have a milky appearance owing to the volatile oil of nutmegs, and it should *not* be filtered.

Lavandula.

[370]. Would any of your readers kindly say the best way to dispense the following prescription so as to make a smooth ointment?

℞ Ext. Bellad. . . . . grs. vj.
Ext. Opii. . . . . ʒij.
Adipis Præp. . . . . ad ℥j.
Ft. unguent.

J. Y.

[371]. I should be glad if any reader can suggest an excipient for the following pills, so that they may be prepared expeditiously and without making them excessively large:—

℞ Acidi Carbolici . . . . gr j.
Ferri Arseniatis . . . . gr $\frac{1}{16}$
Pil. Assafœtidæ Co. . . . . gr. ij.
Pulv. Guaiaci Res. . . . . gr j.
M. Ft. pil. Mitte xvi.
To be silvered.

P. T. W.

[372]. I shall be glad to have some opinion how the following prescription should be dispensed:—

℞ Phosphorus . . . . gr. $\frac{1}{50}$.
Ferri Redacti . . . . gr. iij.
Quinæ Sulph. . . . . gr. ss.
Fiat pil. Mitte xxx.

Staff.

[373]. Will some one oblige me with the strength of the solution of daturin for hypodermic injection, with the quantity usually injected?

M. P. S.

[374]. Would some of your readers kindly inform me how to dispense the following so as not to separate?—

℞ Liq. Potassæ . . . . ʒiss.
Ol. Jecoris Aselli . . . . ℥ij.
Aquæ . . . . ad ℥viij.
M. Ft. mist.
Sumat cochl. j. amp. bis in die.

T. B. L.

P.S.—I have tried several ways in mixing, but after standing the oil floats.

Correspondence.

The Question of Policy.

Sir,—I read Mr. Wilson's letter in your last week's issue with the greatest satisfaction, and I feel sure that the question of policy which he has raised is one which should be seriously thought over by every chemist in England.

Surely there can never again be a time so pregnant as the present with questions of the deepest interest to us as a body, whilst, perhaps, of them all, the patent medicine so-called, has taken up the greatest amount of consideration. Many, from amidst our ranks, are, alas! already lost in the whirl of "reduced prices and still further reductions!!" whilst others stand hesitating upon the brink, knowing too well the slippery paths they will, perforce, have to tread when once they have plunged therein. A third section, and I will not believe it is an inconsiderable one, is prepared to look the matter full in the face, and to ask many curious questions concerning it; these will not so much relate to price or profit, but if I mistake not, are rather more likely to be resonant with ominous words, in which quackery, fiction, ignorance, gullibility and social degradation will take no meaningless part.

To speak more plainly, are we, the pharmacists of the future, individually or collectively prepared to give support or otherwise to a trade which cannot stand in the glare of this latter half of the nineteenth century?—a trade founded upon the credulity of the illiterate; at war with almost every intellectual instinct, and in many phases of it, to say the most, of only questionable morality. Long since has this traffic, the offspring of the dark middle ages, and the foster child of the misdirected knowledge of to-day, been checked in other countries. How much longer shall it prosper unchallenged in our own? Must not this be a question of the very first importance to the Parliamentary Committee of the Pharmaceutical Society?

Kilburn, N.W. Charles B. Allen.

The Evening Meetings: A Growl from the Gallery.

Sir,—Numerous correspondents have lately addressed you upon the subject of the unhealthiness of the drug trade, and various have been the theories put forth to account for the early decease of its members.

Will you permit me to swell the list of these hypotheses, by suggesting that a fruitful source of mortality amongst metropolitan pharmacists is to be found in the Evening Meetings.

To be entombed, sir, for a couple of hours on those occasions, in the subterranean cavern known at Bloomsbury as the "lecture theatre," is to drive twenty nails into one's coffin at a blow. Whether it pertains to the duties of either one of the multitudinous Committees of Council to occupy itself with so insignificant a matter as that of ventilation, I cannot tell. If it be so, the Committee in question has apparently quailed before the task of cleansing the air of the Augean chamber downstairs. Be this as it may, I am sure that I only express the opinion of every frequenter of our Evening Meetings, when I say that the suffocating atmosphere of the room in which we are asked to assemble is a disgrace to the Society.

Conceive the odoriferous remains of three chemical lectures, combined with the mingled emanations from as many hundred students, sedulously confined within four walls; add to this the products of combustion from a few thousand feet of gas, and the exhalations arising from the lungs of a dozen orators in the arena below, and a faint idea is presented of the atmospheric surroundings of an unfortunate pharmacist located in the gallery of the "lecture theatre" at Bloomsbury Square, at about 10 p.m. on a Wednesday evening.

When it comes to pass that twelve fellow-citizens are summoned to sit upon the asphyxiated remains of some eminent professor or distinguished member of Council, perhaps more attention will be given to the matter than will probably be awarded to this solitary howl from

One of the "Gods."

The Health of the Drug Trade.

Sir,—Of all the reasons which have been adduced in explanation of the early mortality of chemists none seems to have obtained greater prominence than that of long hours. In fact all the others have gradually disappeared and the subject of "Hours of Business" has insensibly taken the place of "Health of the Drug Trade" in your correspondence columns. Having regard to the high educational status and scientific knowledge which are now required for the satisfactory discharge of our professional duties, this anxiety to have our business hours shortened cannot be wondered at. It has been well said by one of your correspondents that instead of our hours being long they ought to be exceptionally short.

One strong reason for a shortening of hours is the continuous and intense mental application required in the practice of dispensing. This mental application extending over a period of ten or twelve hours is most exhausting and enervating, and is unquestionably prejudicial to both mental and physical health, and in other professions it is never kept up for more than a few hours at a time.

The strongest reason of all, however, is the high educational status and scientific knowledge to which I have referred. To pass from ten or twelve hours' application to the duties of a pharmacist to a period of even more intense application to the subjects of materia medica, theoretical botany and practical and theoretical chemistry, coupled with early rising for the pursuit of practical botany, is enough to shake the strongest constitution, and what shall we say of the very ordinary constitutions of the great majority of chemists? Can we wonder that many of them give way under the strain?

This subject of shorter hours is at present occupying the attention of the Chemists' Assistants' Association of this city, and it is most earnestly to be hoped that their efforts will be crowned with success. Their object is to have all the shops closed by 8 p.m. at latest. This would throw open to assistants and apprentices the splendid educational advantages of the School of Arts, the classes in connection with which are held at 8.30 p.m. The evening meetings of the North British Branch are also held at 8.30 p.m., and it would allow many to attend them who are now debarred from doing so by long hours.

It is most desirable that those occupying influential positions in the community of pharmacists should lend the weight of their influence in the furtherance of so good a cause.

Surely by a mutual understanding and rising superior to petty jealousy something can be done to remove this terrible incubus, which acts as a perpetual embargo to our launching out into the wide, and to too many of us unknown, fields of pharmaceutical knowledge.

Edinburgh. Excelsior.

The Promotion of Amateur Dispensing.

Sir,—It is bad enough when those in the trade do their personal friends a "good turn" (?) by translating into English the Latin prescriptions of their physician in order that a few pence may be economized thereby, but what are we to say when medical men themselves stoop to such paltry tricks? A lady presented me with the following prescription this morning, and asked what the price would be for dispensing it. On my informing her, she coolly took from a pocket book the appended English copy of it, telling me "she could make it up cheaper herself," and that full instructions had been given her by the *surgeon* who wrote the translation. Upon my explaining to her that extra care and precaution were necessary in the compounding of medicines containing strychnine, she replied that she knew all about that and that her friend (the surgeon) told her any druggist would measure that quantity of strychnine for her and mix it with the water.

℞ Mrs. ———

Acid. Phos. Dil.	ʒiij.
Liq. Strychniæ, B.P.	♏ 50.
Ferri Sulph.	gr. 3ß.
Magnes. Sulph.	℥vj.
Spir. Chloroform.	℥iij.
Syr. Simpl.	℥vj.
Aq. M. Pip.	ad ℥vj.

M. Take one teaspoonful 3 times a day (etc., etc.).

The Surgeon's copy of the above.

An ounce of Dilute Phosphoric Acid.—Three drams to be measured off to make the mixture.
Sulphate of Iron.—One pennyworth.
Epsom Salts.—Three parts of an ounce in each bottle.
Spirit of Chloroform.—An ounce, three drachms to each bottle.
Sugar as you like.
Peppermint Water.—Half a pint.

Comments on my part are unnecessary, you readers will readily form their own conclusions and join with myself in the strongest condemnation of this new phase of medical antagonism to the chemist.

Leominster. M. J. Ellwood.

Taraxacum.

Sir,—The importance and usefulness of such a paper as that read by Dr. Symes at the last Evening Meeting and reported in your Journal of November 8, as evidenced by the full and lengthly discussion which followed, must I think be apparent to all; that the subject of taraxacum, albeit an old one, is not yet exhausted, may be seen in the diversity of opinion expressed in said discussion. Although for some long time past, little has been said or written pharmaceutically on the subject, medical men have continued to prescribe and pharmacists to prepare it for use, and apparently its popularity as a remedy is as great as ever. Of course there will be differences of opinion as to its therapeutic virtues, but with this matter, I take it, the pharmacist has little concern. Whether either rabbits or taraxacum have a *raison de'tre* in the scheme of things pharmaceutical, I do not pretend to say, but so long as the medical profession demand a certain remedy, it is the duty of the pharmacist, and likewise to his interest, to supply a preparation which shall most ably represent the drug from which it is prepared and which shall be most eligible for use. Now it has always struck me that the succus taraxaci, even when carefully and honestly prepared, is a most weak and inefficient preparation, prone to change and deterioration, and possessing little to recommend it, from a pharmaceutical point of view; this opinion has been strengthened by the varying amounts of extract obtainable, by careful evaporation, from the succus taraxaci of my own and other makers; and I fully agree with Dr. Symes that the fluid extract of the U. S. Pharmacopœia is a concentrated, efficient, elegant and stable preparation, and representative of the root in a high degree. Some seven years ago, on the appearance of the last revision of the U. S. Pharmacopœia, I prepared a quantity of this fluid extract, by the formula there indicated and I found that both in flavour, colour and density it stood in very favourable contrast with the succus of the B.P. and was to all appearances a perfect representative of the root from which it was prepared. I remember being very favourably impressed with its eligibility and usefulness. A friend who is in possession of a portion of this identical sample, now over seven years old, informs me that it has kept perfectly and that in flavour and appearance it is to all intents and purposes as good as when it was made. I am not prepared to endorse the advantages of the menstruum ordered in the U. S. Pharmacopœia for the preparation of this fluid extract. Glycerine is a very useful solvent in its way, but I think we may have too much of a good thing. The menstruum I would suggest as best adapted for taraxacum is one composed of equal parts of rectified spirit and water, with a small proportion of glycerine; a fluid extract made with this menstruum from roots dug up in November, and carefully dried and powdered, will, so far as being representative of the drug, give every satisfaction; and will be one which every pharmacist can prepare for himself, with satisfaction and profit. We have the authority of Mr. Umney that the fluid extract of the U. S. Pharmacopœia is at least ten times the strength (in the weight of dry root that it represents) of the succus of the B.P., and has therefore a more bitter flavour, and as to the elegance of fluid extracts as a class, that gentleman was personally of opinion that they far surpassed those of British pharmacy. In the face of this opinion I was rather surprised that in the discussion which followed the reading of Dr. Symes's paper he (Mr. Umney) should feel it necessary to forget his former love, and stand up in defence of the succus of the B.P.

I trust that we shall see in the next edition of our Pharmacopœia a class of preparations more worthy the name of liquid extracts than those it at present contains, and that taraxacum will be one of them.

137a, Aldersgate Street, E.C. ALFRED E. TANNER.

Sir,—In some remarks which I made on Dr. Symes's paper, I find that my words convey a wrong impression, *i.e.*, I said that the Belgian and old Edinburgh Pharmacopœias got over the difficulty connected with the best time for gathering the roots by using the whole plant. What I meant to say was that the before mentioned authorities ordered the whole plant to be used.

The question of the time best suited for collecting the roots still remains.

35, Baker Street, W. A. W. POSTANS.

SODA WATER.

Sir,—In view of the recent vexatious prosecutions anent this article, it may be of use to point out an authority in the matter, and one which has apparently been overlooked, as I have not seen any reference to it in the published defence of any of the cases instituted up to the present.

On page 153 of the latest edition of Royle's 'Materia Medica,' under "Liq. Sodæ Efferves." the editor states—"The soda water of commerce, it must be remembered, is merely carbonic acid water, and the preparation of the Pharmacopœia may be extemporized by dissolving 15 grs. of bicarb. of soda in ½ ounce of water, and then adding a half-pint bottle of common soda water."

Such a statement in a standard work is surely entitled to some consideration even by such punctilious pioneers of utopian purity and such sticklers for pharmacopœial standards as our public analysts.

EDWARD HALL, PH.C.

ARSENICAL PASTE.

Sir,—I cordially endorse the caution mentioned by E. W. in a recent issue, as regards the use of arsenical paste as a nerve cautery. In two cases it played me ugly tricks, so much so that I resolved never to use it again, and nothing would induce me to do so. Not only that but as often as not it will set up a severe inflammation of the lining periosteum. In fact, I have no hesitation in writing, it is bad.

Now as to the paragraph to which E. W. draws attention. All I can say is I also saw it in *Lloyd's Newspaper* as copied from the *New York Times*. Still the sad event therein mentioned no more militates against the skill and aggregate talent of the matchless dental profession of America, than the failure in a chloroform case the other day militates against the talent of our medical faculty. The best of us may any hour be subject to a sad failure, the wonder is we do not fail more often. Now, sir, I much fear E. W. has not seen American skill, or instruments. The best part of filling and other instruments and tools used by the majority of British dentists are American. More American teeth are used in this country than *native* make. Only let E. W. just glance at the American dental engine, a matchless marvel of human ingenuity, and then confess that "in America there is a matchless dental profession independent of medical men and chemists." They educate not men there to be surgeons *first*, and then leave such to pick up mechanical dentistry as best they can. No! but educate them in every sense of the word to be surgeon *dentists*. Sever mechanical dentistry from the surgical, and it at once ceases to be the *dental* profession, as the man who cannot execute the first named ceases to be a surgeon *dentist* and becomes a surgeon of an extremely limited form of surgery. I am, sir, no Yankee but out-and-out British, yet love to give credit and honour where both are due and deserved.

185, Oxford Street. GEORGE WARD, L.D.

"*Subscriber* and *Student*," who should have complied with the rule respecting anonymous contributions, will find recipes for depilatories by referring to the indexes of back volumes.

"*Antiseptic*."—Dr. Symes has pointed out (vol. ix., 598) that a strong solution of thymol can be prepared with milk.

W. G.—In such a case a declaration sworn before a magistrate would be received.

T. Robinson.—A recipe for incense will be found in vol. viii., p. 519.

J. T. Greenwood.—See the paper on *Fucus vesiculosus* in the Journal of the 1st inst., p. 343.

"*Student*."—The principal products of combustion would be the same in both cases, and the relative innocuousness would depend rather upon the amount of impurity present in the original material.

"*Juvenis*."—There can be no doubt that the use of the title "Surgeon-Dentist" by a person not registered under the Dental Act is illegal.

M. B.—We have been unable to find a reference to any preparation bearing the name.

H. Boutell.—If you refer again to Mr. Langbeck's translation you will see that you have misread it.

H. J. Pearson.—A list of the subscribers to the Benevolent Fund, arranged under the heading of the towns in which they reside, is published in the Calendar of the Society.

M.P.S.—The opaque turbid appearance sometimes presented by distilled water when it has been kept is probably due to the growth of confervæ.

"*A Pharmaceutical Chemist*."—Before publishing your letter we should be glad to have particulars of the case you refer to, for our private information.

Mr. Modlen, Mr. Pollard and Mr. Evans are thanked for their communications.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Hall, Brown, Turner, Reynolds, Gordon, Robinson, Wershoven, Coleby, Miller, Masson, Stevens, Rogers, G. Faitpierre, X., A. P. S., T. H., J. L. B., The Encloser, Alex, Nu.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 383.)

IPOMŒA TURPETHUM, *R. Br.* CONVOLVULACEÆ. *The stem and root.* *Vernacular.*—NISOT, NAKPATAR, PITOHRI (Hind.), NISHOTAR (Bombay), SHIVADAI (Tam.), TEORI (Beng.).

History, Uses, etc.—Sanskrit writers mention two varieties of trivrit or triputa, viz., sveta, white; and krishna, black. The white kind only should be used, the black is said to be poisonous; it is not very clear what the black kind is. Nisot is one of the most common native cathartics, and has probably been in use all over India from a very early date. The usual method of administration is to rub down about a drachm of the root or stem with water and add to it some rock salt and ginger, or sugar and black pepper.

Under the name of turbud Mahometan writers also mention two kinds, white and black, and direct the black to be avoided on account of its poisonous properties, which are said to resemble those of hellebore. As regards the properties of the white kind, they say that it is a drastic purgative of phlegmatic humours and bile; its action is promoted by combination with ginger; it is particularly beneficial in rheumatic and paralytic affections. Combined with Chebulic myrobalans it is useful in melancholy and dropsies. Ainslie tells us that the *Convolvulus Indicus alatus maximus* had long a place in the British materia medica, but of late years has fallen into disuse. He says, "I find it mentioned by Avicenna under the name of turbud; but the first among the Arabs who prescribed it was Mesue (see 'Rei Herbariæ,' Spring., vol. i., p. 249), also Bhazes (c. 173). Alston in his 'Materia Medica' speaks of turbith as a strong and resinous cathartic, and recommended in his days in gout, dropsy, and leprosy. The plant is known to the modern Greeks by the name of τουρπεθ. It is a native of the Society and Friendly Isles, as well as of India, of the New Hebrides and of New Holland. Virey, in his 'Histoire Naturelle des Medicamens' (p. 184), speaks of the root of the *Convolvulus turpethum* as more drastic than the common jalap, which, however, does not seem to be found in India" ('Mat. Ind.,' ii., p. 384).

Wallich, Gordon, and Glass considered this drug to be of considerable value as a cathartic. Sir W. O'Shaughnessy ('Beng. Disp.,' p. 504) found it so uncertain in its operation that he pronounced it unworthy of a place in the Pharmacopœia, but he does not give any particulars as to the method of administration he employed. Further experiments with the drug are required, as there seems to be no doubt of its efficacy in native hands.

Description.—The turbith of commerce consists of the root and stem of the plant cut in short lengths, usually from ½ to 2 inches in diameter; the central woody portion is often removed by splitting the bark on one side. The exterior surface has a twisted rope-like or columnar appearance and is of dull grey colour. A transverse section shows a porous surface of a dirty white colour and loaded with pale yellowish white resin; through this substance pass numerous bundles composed of large vessels and woody fibre. The drug is free from smell, but has a nauseous taste which is only perceptible after it has been some time in the mouth. In some specimens all or a portion of the central wood remains. It resembles a piece of rotten cane. Black nisot presents a similar appearance, but is of smaller size and of a darker colour.

Microscopic structure.—The epidermis consists of tubular brown cells. The parenchyma is starchy; in it are thickly scattered very large resin cells and numerous rosette-like raphides. The many large vascular bundles are composed of large dotted vessels surrounded by wood-fibres; each of the prominent external ridges of the bark contains one of these bundles. The central cane-like woody column of the root or stem, when present, is seen to be divided into four parts by four bands of parenchyma (medullary rays); it consists of large dotted vessels connected together by narrow portions of woody fibre.

The black nisot has exactly the same structure as the white.

Chemical composition.—Turbith resin consists of a small quantity of soft resin soluble in ether, and of a substance insoluble in ether, benzine, sulphide of carbon and essential oils. This substance has been named turpethine and is present in the root to the extent of 4 per cent. It has been examined by Spirgatis, who describes it as a grey powder having a powerfully irritant action upon the mucous membranes of the mouth and nose, and being analogous in its reactions with jalapine and convolvuline. Under the action of alkaline bases it is transformed into turpethic acid and in the presence of hydrochloric acid it becomes converted into glucose and turpetholic acid (*Zeitschr. der Chemie und Pharmacie*, 1865).

BATATAS PANICULATA, *Chois.* CONVOLVULACEÆ. *The root.* *Vernacular.*—BIBAI-KAND (Hind.), BHUI-KUMRA (Beng.), BHUI-KOHALA (Bomb.), MATTA-PAL-TIGA (Tel.), PHAL-MODECCA (Mal.).

History, Uses, etc.—This plant is mentioned by the early Sanskrit writers on materia medica under the names of Vidari and Bhumiku shmánda.

The large tuberous root is considered tonic, alterative, aphrodisiac, demulcent and lactagogue. In the emaciation of children, with debility and want of digestive power, the following diet is recommended. Take of vidari, wheat flower and barley, equal parts, and make into a confection with milk, clarified butter, sugar and honey. Susruta gives several prescriptions for its use as an aphrodisiac. The simplest is as follows: Macerate the powder of the root in its own juice and administer with honey and clarified butter. Vidari enters into the composition of several diuretic and demulcent mixtures (Confer. Dutt 'Hindu Mat. Med.' p. 205). Rheede ('Hort. Malab', ii., pp. 101–102, t. 49) notices the use of the root dried in the sun, powdered and boiled with sugar and butter to promote obesity and moderate the menstrual discharge. In Bombay it is used medicinally for the above-mentioned purposes, and can always be obtained in the druggists' shops. The plant is commonly cultivated in gardens, on account of its handsome rose-coloured flowers, which appear in the rains.

Description.—The root is a forked tuber, sometimes as much as 10 to 12 lbs. in weight; externally it is of a grey colour and somewhat warty and scabrous. When a transverse section is made the cut surface is of a dirty white colour and marked by concentric rings which are formed by the vascular and laticiferous vessels; from the latter a viscid milky fluid exudes. The taste is astringent and somewhat acrid, not unlike raw potato.

Microscopic structure.—The bulk of the tuber consists of a starchy parenchyme. The vascular system is scalariform. The lacticiferous vessels are most numerous towards the cortical part; raphides abound.

Commerce.—The tubers are sold by the herbalists and are very extensively used in Bombay. The largest fetch about two annas.

CORDIA MYXA, *Linn.* C. LATIFOLIA, *Roxb.* BORAGINACEÆ. *The fruit. Vernacular.*—LASORA (Hind.), BAHUBÁRA (Beng.), BHOKAR, SAPISTÁN (Bomb.), NARUVILLI (Tam.)

History, Uses, etc.—The dried fruits of these trees are the Selu of Sanskrit writers, the Sapistan of the Mahometans, and the Sebestens of old European works on materia medica. Both trees are common in many parts of India. On the western coast *C. latifolia* is abundant in Guzerat, where it is called Burgoond, and *C. myxa* in the neighbourhood of Bombay. The natives pickle the fruit of both trees. Medicinally the dried fruit is valued on account of its mucilaginous nature and demulcent properties; it is much used in coughs and chest affections, also in irritation of the urinary passages; in larger quantities it is given in bilious affections as a laxative. Mahometan writers describe two kinds of Sapistan: the greater (*C. cordifolia*), the pulp of which is separable from the stone, and the lesser (*C. myxa*), the pulp of which is adherent. The word "Sapistán" is an abreviation of Sag-pistán which means in Persian "Dog's dugs." In Arabic they are called Dibk and Mukhitah. Both trees are minutely described by Roxburgh. According to Horsfield the bark of *C. myxa* is used by the Javanese as a tonic.

Description.—*C. latifolia.*—Drupe oblate, spheroidal, about an inch or inch and a quarter in diameter, smooth; when ripe, yellow. Pulp in large quantity, soft, clear and very clammy; one-celled. Nut nearly circular, laterally compressed, rugose on the outside, with a cavity at each end, the lower one deeper than the other; exceedingly hard, four-celled, though rarely all fertile. Seed solitary, ovate-oblong.

C. myxa.—Drupe globular, smooth, the size of a cherry, sitting in the enlarged calyx; when ripe, yellow; the pulp almost transparent, very tough, and viscid. Nut cordate, at both ends bidentate and perforated, rugose, somewhat four-sided, four-celled; but it rarely happens that all prove fertile. Seeds solitary (Roxb.). Both kinds of fruit when dry are shrivelled and of the colour of a dry prune. The pulp of *C. cordifolia* can be separated from the nut, that of *C. myxa* cannot. On sawing through the nut a heavy disagreeable smell is observable.

HERPESTIS MONNIERA, *H. B. et K.* SCROPHULARIACEÆ. *The Herb. Vernacular.*—BRAHMI (Hind., Beng.), NIR-BRAMI (Tam.).

History, Uses, etc.—Dutt informs us that this plant is the Brahmi of the native physicians of Calcutta, where it is considered to be a nervine tonic, useful in insanity, epilepsy, etc. Whether he is correct in taking it to be the Brahmi of Sanskrit writers is, I think, doubtful. In Bombay *Hydrocotyle Asiatica* is known by this name. Ainslie says that in Southern India the *Gratiola Monnieria* is considered diuretic and aperient, and useful in that sort of stoppage of urine which is accompanied with obstinate costiveness. Roxburgh mentions the use of the juice mixed with petroleum as an external remedy in rheumatism. These accounts hardly agree with the properties ascribed to Brahmi by Sanskrit writers. *H. Monniera* is a very common plant in moist places, such as the borders of tanks, etc., in the neighbourhood of Bombay, but I have not seen it made use of medicinally.

Description.—Stems several, annual, creeping, round, jointed, smooth, succulent; leaves opposite, sessile, obovate, wedge-shaped or oblong, smooth entire, obtuse, fleshy, dotted with minute spots; peduncles axillary, alternate, solitary, round, smooth, shorter than the leaves, one-flowered; flowers blue; bracts two-awled, pressing on the calyx laterally; calyx five-leaved, the exterior three leaflets large, oblong, the two interior small, linear, all are concave, smooth, pointed and permanent; corolla campanulate, border five-parted, nearly equal; anthers two-cleft at the base, blue; stigma large, somewhat two-lobed; capsule ovate, two-celled, two-valved; seeds very numerous (Roxburgh 'Flora Ind.,' i., p. 141).

BARLERIA PRIONITIS, *Linn.* ACANTHACEÆ KARUNTAKA (Sans.), KATSAREYA (Hind.), KANTAJUTI (Beng.), KALSUNDA (Bomb.), SHEMMÚLLI, VARAMÚLLI (Tam.)

This is a very common plant near the sea shore in Bombay and the neighbourhood. The natives apply the juice of the leaves to their feet in the rainy season to harden them, and thus prevent the maceration and cracking of the sole which would otherwise occur. Ainslie says that the juice of the leaves, which is slightly bitter and acid, is a favourite medicine of the Hindus of Lower India, in those catarrhal affections of children which are accompanied with fever and much phlegm. It is generally administered in a little honey or sugar and water, in the quantity of two tablespoonfuls twice daily ('Materia Ind.,' ii., p. 376). *B. prionitis* is the Coletta-veetla of Rheede ('Hort. Mat.,' ix., p. 77, t. 41), and the *Hystrix frutex* of Rumphius ('Amb.,' vii., t. 13).

Description.—Stem short, erect; branches numerous, opposite, erect, round, smooth; the whole plant two to three feet high; thorns axillary, generally about four, straight, slender, sharp; leaves opposite, decussate, short petioled, oblong, waved, a little mucronate, smooth; flowers axillary, generally solitary, sessile, large, yellow; bracts uncertain, when there are no thorns on the same axil there are two, opposite, linear daggered, besides an undetermined number of very small ones; stamens, the long pair projecting, their filaments compressed; stigma entire, cylindric, open, pitted; capsule conical, two-seeded, one seed in each cell (Roxb.).

JUSTICIA ECBOLIUM, *Linn.* ACANTHACEÆ.

Udwjati (Hind.), Rán-oboli (Bomb.), is a small shrub very common in the Concon. The roots are prescribed in jaundice and menorrhagia.

Description.—Roots tuberous, spindle-shaped, as thick as a quill, several inches in length and covered by a dark brown bark; stems several, straight-jointed and swelled above the joints, woody and round below, quadrangular and tender above; leaves elliptic oblong, attenuated at both ends, pubescent or glabrous; spikes terminal, tetragonal; bracts oval, quite entire, ciliated, mucronate, as long as the capsule; flowers azure-coloured, turning red as they fade; capsule half an inch long, two-seeded.

ACANTHODIUM SPICATUM, *Delile* (?). ACANTHACEÆ. *The seeds.* *Vernacular.*—UTANGAN (Hind.), UTINJAN (Bomb.).

History, Uses, etc.—Under the local name of utinjan, and the Persian name anjurah, an acanthaceous seed is sold in the Bombay shops. From an examination of the capsules which are sometimes found mixed with the seeds there would appear to be little doubt that they are those of the plant placed at the head of this article. Utinjan is a standard native remedy, and is universally kept in the druggists' shops. The author of the 'Makhzan-ul-adwiya' (article Anjurah) gives us the following account of it, from which it would appear that the true anjurah is the *Urtica prima* of Latin writers (*U. pilulifera*, Lin.), and that the seeds now in use in India have somehow come to take the place of the genuine article:—"Anjurah is a Persian word; it is the Kuriz of the Arabs, the Kurnah of Shiraz, the Kajeet of the Turks, the Utangan of the Indians, the Urtik-parim of Latin writers and the Hartikah of Gilan. The plant has numerous serrate leaves which are armed with prickles; the stem is still more prickly; when it comes in contact with the body it causes redness, burning and itching. The flowers are yellow. The seed smooth and shining, flattened, of a brownish colour, larger than those of sesamum and altogether not unlike linseed. They are the officinal part and if good should be heavy and of a brown colour." Medicinally they are considered to be attenuant, resolvent, diuretic, aphrodisiac, expectorant and deobstruent.

Description.—The utinjan of the Bombay shops consists of the seeds mixed with a large proportion of broken pieces of the capsule and a few entire fruits. The latter is mitre-shaped, about three-tenths of an inch long, and two-tenths broad, laterally compressed; sides furrowed; surface polished, of a chestnut colour; capsule two-celled, two-seeded; seeds heart-shaped, flat, covered with long coarse hairs; when soaked in water the hairs disintegrate and produce a large quantity of viscid mucilage.

Microscopic Structure.—Each hair is made up of several columnar cells, each of which contains a spiral fibre, which upon the solution of the cell wall uncoils and imparts an unusual stringiness to the mucilage.

Commerce.—Utinjan is imported into Bombay by way of the Red Sea. Value Re. 1¼ per pound.

LEONOTIS NEPETÆFOLIA, *Br.* LABIATÆ. HEJURCHEI (Beng.), MATIJER, MATISÚL (Bomb.).

This is a large and conspicuous annual, common in the neighbourhood of villages. It is easily recognized by its globular, spinous heads of orange-coloured flowers. Roxburgh gives the following description of the plant:—"Stem annual, straight, four-sided, simple, from 4—6 feet high. Leaves opposite, spreading, petioled, cordate, serrate, pointed, downy, from 4—8 inches long and 2—3 broad. Floral leaves lanceolate, depending. Petioles channelled, winged with the decurrent leaf; verticels globular, 2—3 or 4, towards the apex of the plant about 5 inches asunder. Involucres many, subulate. Flowers numerous, of a deep rich orange colour. Calyx 10-striated, 8-toothed; corolla under lip very short, 3-toothed, at all times of a dirty withered colour.

The ashes of the flower heads mixed with curds are applied in Bombay to ringworm and other itchy diseases of the skin.

(*To be continued.*)

ALEURONE.

Aleurone has recently become the object of a certain amount of interest, and was not long since the subject of a question at one of the University examinations. Nothing, however, has yet been published respecting it in this Journal, and very little in this country. The following notes, compiled from various works, have been supplied by Mr. Marshall Leigh:—

Aleurone grains were discovered by Hartig in 1855; their importance, however, was not generally acknowledged until Dr. Pfeffer published his researches in 1872 (*Jahrb. f. wiss. Bot.* 1872). These researches are still the standard work in Germany, and contain a larger amount of reliable information than any other.

The reservoirs of ripe seeds, the endosperm and cotyledons, always contain aleurone together with starch and oily matter. If the seeds contain much starch, as in the chestnut, the aleurone grains occupy the interstices and consist of minute granules; in oily seeds, however, the granules are found in the place of starch.

Their formation commences when the seeds have attained their last condition of ripeness and the funiculus become sapless; the seed loses water by evaporation, the mucilaginous mass in its interior gradually becoming firmer, and the grains of aleurone separate from the turbid matrix.

The origin of the grains is therefore simply a dissociation which arises from loss of water; on germination, the cells absorb moisture and the aleurone grain again unites with the matrix.

The matrix surrounding the grain may be considered as the protoplasmic mass of the cell, in which water is replaced, on drying, by oil or starch.

The use of aleurone is to act as a reservoir of protein, in the same way as starch and oil globules are reservoirs of hydrocarbons, the protein being the source from which the protoplasm of the young plant is formed upon germination.

Occasionally the grains are seen to have a crystalline appearance due to their enclosing crystals of oxalate of calcium, more frequently however they contain non-crystalline and clustered granules of a double phosphate of calcium and magnesium mechanically enveloped during the contraction of the proteine.

Aleurone grains are absolutely insoluble in alcohol, ether, benzol or chloroform; they are mostly soluble in water and can by that means be separated from the enclosed crystals or globoids.

Their chemical composition has recently been made the subject of observation by several chemists. In 1872,* Ritthausen exhausted the seeds by alkaline solutions and demonstrated the presence of vegetable caseins, such as legumin and conglutin.

In 1877,† Weyl published some observations which tended to show that the proteids existed as globulins and that the caseins extracted by Ritthausen were the products of alteration caused by his alkaline solutions.

Mr. Sidney Vines‡ has lately contributed an article to the Royal Society which in many respects confirms Weyl's observations.

An extract of the seeds of blue lupin (*Lupinus*

---

* 'Die Eiweiss Korper der Getreidearten,' 1872.

† 'Zeitschr. fur Physiol. Chemie,' 1877.

‡ 'Proc. Roy. Society,' December 19, 1878.

varius) in common salt was found to contain two proteids belonging to the group of globulins and hitherto known to occur only in animals: myosin, a constituent of dead muscle, and vitellin, a constituent of the yolk of egg; these two substances, vegetable myosin and vegetable vitellin, were found to have exactly similar reactions to the animal substances of the same name.

An aqueous extract of the seeds contained another proteid having all the properties of peptone and agreeing very nearly with the α peptone of Meissner, or hemialbumose of Kuhne,* an easily decomposable peptone formed by the action of gastric juice on proteids.

ALKALOIDS OF THE BERBERIDACEÆ.†

BY ALBERT B. PRESCOTT, M.D.,

Professor of Organic and Applied Chemistry and Pharmacy, University of Michigan.

The discovery of an alkaloid in any plant is undoubtedly a fact of the first importance, both as concerning the strictly chemical interest of the plant and as bearing upon its medical application. But, of course, the fact that a plant contains or does not contain one or more alkaloids, is not in itself a decisive fact in materia medica. Over a hundred alkaloids have been definitely distinguished in the vegetable kingdom, and it is probable that a greater number remain undiscovered. Possessing a class of substances in class character chemically distinct, and comprising articles of such intense power and diversified influence upon the human organism as strychnia, quinia, atropia, aconitina, morphia, etc., the medical world must look with the liveliest interest upon the finding of new alkaloids in well known medicinal plants. But the medical world would not, and should not, venture to trust upon the lines of analogy beyond the support of facts. Alkaloids, like all other agents, must be put directly to the proof, as to their physiological power and therapeutic value. Testimonies of trial—a fair trial in a fair field—are wanted. Certain alkaloids have but a third-rate medicinal consequence, as the narcotina of opium, the brucia of nux vomica and the ergotina of ergot. Alkaloids are not the only substances known to stand distinctly as the active principles of plants. The resins of podophyllum, for instance, are stable, easily separated, and represent almost the entire medicinal power of the crude drug in a very concentrated form. It has stood in the books since 1863, though now disproved, that the podophyllum root contained an alkaloid, berberina, but the question of the use of this alkaloid has been wholly overshadowed by the greater potency of the resins. Finally, it must not be forgotten that a larger number of medicinal plants contain a group of therapeutic agents, presented by nature in most useful proportions, so that if these several bodies could be separated and safely preserved by chemical skill we could do no better than to put them together again in the original proportions for administration. The greater number of vegetable drugs are best kept intact, with only such rejection of inert matters and concentration of medicinal virtues as the fluid extract, when skilfully and faithfully made, best provides. Nevertheless, an alkaloid of any decided mechanical power, capable of production in purity, is always an article of importance.

At this time four at least of the medicinal plants of the barberry family have been found to contain alkaloids, as follows:—

Berberis vulgaris. Common barberry; root, bark. Berberina (Buchner, 1835); oxycanthia (Polex, 1836).

Berberis aquifolium. Pacific coast. Root. Berberina (Neppach, 1878); mahonia* (Jungk, Detroit, 1879).

Berberis aristata; B. asiatica: B. lyceum. Indian barberry bark. Berberina (Solly, 1843; Stewart, 1866).

Jeffersonia diphylla. Twinleaf. Rhizome. Berberina and a white alkaloid (Mayer, 1865).

Berberina, the alkaloid named from the berberideæ, is probably more widely distributed than any other alkaloid known. It is found in five botanical families, or as Husemann classifies, in seven families, as follows:—

Of the Berberidaceæ, in *Berberis vulgaris*, *B. aquifolium*, the Indian species of *Berberis*, and *Jeffersonia diphylla.* Also, according to Husemann, in *Caulophyllum thalictroides*, or blue cohosh.

Of the Ranunculaceæ, in *Hydrastis Canadensis*, with two other alkaloids; in *Coptis trifoliata*, goldthread, with another alkaloid; in *Coptis teeta*, India, 8½ per cent. berberina; and in *Xanthorriza apifolia*, or yellow root.

Of the Menispermaceæ, in Calumba root, *Cocculus palmatus*, along with columbin and columbic acid; in *Menispermum Canadense*, Canadian moonseed; and in *Coscinium fenestratum*, or Ceylon calumba wood.

Of the Anonaceæ, in *Cœlocline polycarpa.*

Of the Rutaceæ, in *Xanthoxylum clava-Herculis*, the Hercules club, of West Indies.

Also, according to Perrins, in the St. John's root, of Rio Grande, and the pachinello tree, of New Grenada.

In many instances berberina is accompanied by a colourless alkaloid in the same plant. In calumba root the alkaloid is believed to be formed, along with the calumbic acid, from colombin, a neutral body.

The English chemist, Perrins, in 1862, after a full report upon the chemistry of berberina, a report which was the first and is still the fullest given in Europe, thus remarks upon the value of this alkaloid (*Journ. Chem. Soc.*, xv., 456): "Though it has long been used as a fine yellow dye, more especially for animal tissues, its chief claims to usefulness do not reside in its application to the economic arts. . . . The polished Greeks the semi-barbarous nations of Hindostan and China, the North American Indians and the natives of tropical Africa have been all impressed with the medicinal value of berberina."†

THE MIGRATION OF PLANTS FROM EUROPE TO AMERICA, WITH AN ATTEMPT TO EXPLAIN CERTAIN PHENOMENA CONNECTED THEREWITH.‡

BY PROF. E. W. CLAYPOLE, B.A., B.SC. (LONDON), OF ANTIOCH COLLEGE, OHIO.

Underneath the great wave of human emigration from the so-called Old to the so-called New World, underneath the noisy busy surface tide that has swept westward from the shores of Europe to these of America during the last two hundred years, there has existed another and a less conspicuous wave, another and a less prominent tide of

* 'Verhandl. d. Nat. Med. Vereins zu Heidelberg,' 1876.

† From *New Preparations* for September, 1879.

* Dr. Jungk and *New Preparations* are to be congratulated upon the identification of this alkaloid, with ultimate analysis, determination of formula and analytical reactions, as given in the August number of that Journal. Further report promised, with investigation of physiological effect, etc.

† It is unfortunate that the hydrochlorate of berberina, a beautiful bright yellow salt, should have so often gone under the name of *hydrastia*, the cognomen of the more abundant of the two colourless alkaloids in hydrastis. In an examination of "hydrastin," of commerce, Mr. Beach, in 1875, working under the observation of the writer, found in six samples, respectively, 1·7, 17·4, 6·7, 5·1, 6·8, and 0·0 per cent. of hydrastia alkaloid; and found, respectively, 35·1, 21·9, 6·9, 28·0, 36·0, and 100 per cent. of berberina hydrochlorate.

‡ Paper read before the Montreal Horticultural Society, 1877.

emigration. Westward in its direction, like the former, it has silently accomplished results that seldom strike the superficial eye, but yet are scarcely less in magnitude than those which have followed the advent of the white man to the shores of America.

I allude to that slow and noiseless immigration of European plants which has been going on for many years, and which probably commenced when the first European vessel touched our shores. Side by side with the displacement of the red man by the white man has gone on the displacement of the red man's vegetable companions by plants which accompanied the white man from his trans-Atlantic home. Not more completely have the children of the Pilgrim Fathers made themselves at home on the banks of the Charles and the Neponset, not more completely have the successors of Champlain and Jacques Cartier established themselves along the St. Lawrence, not more completely have the descendants of the aristocratic colonists of Maryland and Virginia appropriated the shores of the Chesapeake, than have the homely weeds of England and France made themselves at home in the New World; established themselves on its soil, appropriated its fields, its gardens and its waysides. Nor have the older States alone been seized by these European invaders. The stream has flowed beyond them, and as no village or hamlet in the West is without its population of European descent, so too it is never without its plant population of European weeds. To the American, born and reared among them, these things have none of the significance which they possess to him who comes across the Atlantic, conversant with the flora of Europe, and anticipating a complete change of plant life as well as of place and scene after voyaging 3000 miles. And yet I scarcely know which strikes the thoughtful stranger most, the resemblance or the difference between the Old which he has left or the New to which he has come. Differences of course, there are, many and great, but in the face of the fact that the new country with its millions of inhabitants is using the same language and laws and customs as the old country he has so lately left, they are less striking. The same is true of the American flora. The writer will never forget the impression made on his own mind when soon after landing in America he set to work upon the botany of his new home. The summer, with its floral treasures, had gone by and the brilliant New England foliage told that winter was rapidly approaching. In the woods and shrubberies the falling leaves revealed new types of tree-life mingled with old forms well known in England. But on the ground, in the fields, along the waysides and fences were many well-known plants. Old acquaintances, friends and foes both, which he had years before learned to know—sometimes to cherish and often to uproot—when a boy in the old country. So far was the flora from being totally new that sometimes he was puzzled to know whether, on a given space, there were more strange or familiar forms around him. This result was quite unexpected and opened before him a new and very interesting field of observation and investigation, which has continued ever since to occupy at intervals his attention. The fact here mentioned—this migration of European plants into America—became all the more striking when, after a longer residence in this country, and a further study of its flora, he looked back to his earlier botanical studies in Europe and observed that this vegetable migration is almost entirely in one direction. In the midst of this rich flora, aliens by origin, but naturalized by the letters patent of time, he looked back to his old home and tried, but almost in vain, to recall American forms of plant life naturalized there. Scarcely a solitary specimen could be found to which the Old World, always chary of conferring its citizenship upon foreigners, could be said to have given the rights to home. Whence comes this striking difference? Why is the Western World so hospitable and the Eastern so inhospitable to vegetable strangers? Is it that these Western strangers do not claim naturalization? Do they feel their inability to make way against the crowded life of the East, and therefore fail in the intenser struggle for existence which marks newer and more highly developed Europe? The full answer to this question is at present impossible, and the writer desires this paper to be considered merely suggestive. Facts must be gathered before conclusions can be drawn. The field is so vast and the need of patient and continuous observation so great that many years may pass ere a solution of the problem can be reached. "The harvest is plenteous but the labourers are few."

A few illustrations will show the kind of facts to which this paper is intended to call attention, and the writer's purpose will be fully served if its perusal should incite any who are familiar with European botany to note the occurrence of European species in different localities, and especially if it should lead any to inquire as to the cause which prevents the naturalization of others that can only be raised here under cultivation.

The careful observer will notice foreign plants in all stages of naturalization. Some are at present only cultivated in fields or gardens, others have escaped from the domain of the plough and the spade, and are maintaining a precarious existence among conditions not altogether congenial, and are liable to extermination at any time, by an unfavourable season. Others have a stronger hold and occupy the fence corner or the wayside, while a number, bolder and hardier, have emerged from these sheltering nooks, and have begun an independent career among the indigenous vegetation, hoping, often in vain, to hold their own against the aborigines of the land. Not a few, more hardy still, or more adaptable in their nature, have altogether cut themselves loose from the cultivated field and the domain of man, have ventured out into open conflict with the denizens of the soil, and emerged victorious from the struggle. By crowding upon them, by stifling them, by appropriating their food, they have succeeded in ousting their antagonists, the rightful heirs, as by similar practices the white man has ousted the red man from his ancestral land, and both now occupy the country often to the exclusion of all save the hardiest of the native tribes.

For example, the Scarlet Poppy (*Papaver dubium*), a weed so common in England that many a wheat field appears one sheet of glowing red when it is in full flower, must have come over to America many times in seed wheat, and is occasionally met with here in the fields, especially in Wisconsin and other North-Western States. Yet outside of these, it has never to our knowledge succeeded in propagating itself. It is quite scarce in America. The Giant Elecampane (*Inula helenium*), the Horseheal and Scabwort of the leech, so renowned among the old herbalists as a remedy in complaints of the chest, is but scantily diffused. The writer has met with it in the East near Boston and in the Island of Montreal, and it is abundant in the West in some parts of Ohio and Indiana.

The English Groundsel (*Senecio vulgaris*), a favourite with the keepers of canary birds, but by no means in equal liking of the English gardener, has failed to establish itself in America. A few specimens may occasionally be met with near gardens, but it shows here none of that reproductive power that makes it in England one of the earliest weeds in the spring, and the latest in the fall.

The Salsify, or Vegetable Oyster (*Tragopogon porrifolius*), a native of the Mediterranean region, but established in a few places in the south of England, whence it was probably imported, is most likely of late introduction, and still on trial, not having found a place in Professor Gray's 'Manual of the American Flora.' The writer has only found it once near St. Catharine's, in Ontario, in considerable quantities, flowering and apparently bringing its seed to perfection.

The Henbane, a dangerous narcotic (*Hyoscyamus niger*), is sparingly diffused in some places. It may be found in tolerable abundance on Fletcher's Field, near Montreal showing the same predilection as in England for dunghills and heaps of old bricks and mortar.

The Thorn Apple (*Datura stramonium*), a native of Asia and Europe, where it extends as far north as Sweden, is scantily met with in England, having escaped from gardens, where it prefers similar spots to those chosen by the Henbane. But it has been introduced into this country where, under a new name, "Jamestown (Jimson) Weed," it is only too well known. The American name seems to indicate that it was introduced or first noticed as a nuisance in the neighbourhood of Jamestown, Virginia.

The Common Hemp (*Cannabis sativa*), so valuable for its fibre, a native of the Caucasus and of the mountains of Northern India, only known in Western Europe in cultivation, and doubtless early brought here for economic purposes, has run completely wild, and may now be found in waste land near human dwellings, from the streets of Montreal and Boston to the west of Ohio, and probably farther still.

The Grape Hyacinth (*Muscari botryoides*), and the Star of Bethlehem (*Ornithogalum umbellatum*), both common English garden flowers, may be occasionally found in the vicinity of Montreal, as if longing, yet fearing, to strike for freedom from the control of man in their new country.

The Corn Cockle (*Lychnis githago*), so mischievous in English wheat fields, is tolerably common here in similar places, but has not succeeded in establishing itself outside of the protection of man. The same may, in the northern districts, be said of the common Red Clover (*Trifolium pratense*). In spite of its deep tap root and rank growth, it is unable to bear the cold, and an occasional severe winter will exterminate it if unprotected even in cultivated fields. Its near relative, however, the White Clover (*Trifolium repens*) was introduced in early days, and called by the Indians, "White Man's Foot." Longfellow sings in the story of Hiawatha:—

> "Wheresoe'er they tread, beneath them
> Springs a flower unknown among us—
> Springs the White Man's Foot in blossom."

This is much more hardy and seldom yields except to the severest frosts. It overruns field and wayside, fence-corner and common, holding its own against even the aborigines, and strangling them out by its tangled perennial roots. Early in the spring it secures such headway that larger and coarser plants are compelled to give way. Its flowers afford the honey bee so rich a harvest that its seeds are surely fertilized, and this double method of reproduction by root and by seed gives it such an advantage in the struggle for existence that it has spread rapidly over the country, and many an American common is as white with its flowers as is an English lawn with daisies. It is worthy of notice that similar results have attended the introduction of this plant into New Zealand. There also it has run wild, and is said to be pushing out some of the native species, among others the hard and stiff New Zealand flax (*Phormium tenax*), which is said to be unable to hold its ground against the strangling roots of the White Clover.

The English Buttercup (*Ranunculus acris*), beloved of English children and poets, especially of the school of Wordsworth, has overrun the north-east, and the writer has met with it even in the Canadian backwoods, where only a trail through the bush existed, carried doubtless in the hay taken thither to feed the horses and oxen of the lumbermen when driving logs in a Canadian winter.

The Barberry (*Berberis vulgaris*), with its graceful drooping stems and pendant racemes of bright yellow flowers and scarlet fruit, followed the pilgrims to Plymouth Rock, and like them has struck its roots deep in the bleak hills of New England, until now it is far more common in the neighbourhood of Boston than in any part of England with which the writer is acquainted.

Every one who has owned or worked a garden in America has made the acquaintance of the ubiquitous Purslane (*Portulaca oleracea*), so fondly mentioned by the author of 'My Summer in a Garden' as "pusley," one of his pets which stuck to him so closely that he could not get rid of it. This, the only *valuable* (start not, American gardener, it is even so) plant of its order, is cultivated as a salad and pot-herb; but, transplanted into our soil and under our skies, it has squatted on the land until nothing save constant watchfulness and hoe can prevent its complete monopoly of the garden. It occupies here the place of the sow-thistle in England. Both break off at the surface of the ground as soon as an attempt is made to pull them up, and when the gardener's back is turned both send out a new crop of leaves, flowers and seed, to punish him for his assault. The writer would like to suggest to the Horticultural Society of Montreal the desirability of offering a prize for the best illustrated essay on the means of turning this European immigrant to account in the Canadian and American kitchens. Possibly the surest way of getting rid of it would be to make it useful. Useful plants are seldom so abundant as to be a nuisance.

The Common Water Cress (*Nasturtium vulgare*)—when, how, and by whom introduced we know not—is now so abundant in some places that one is almost tempted to look upon it as a native. Many of the streams of New York and of South-Western Ohio are as thickly set with it as are any of the water-courses in old England.

The Common Parsnip (*Pastinaca sativa*) has run wild in America in fence-corners and along railway banks near Montreal and other places.

The Hemlock (*Conium maculatum*), of Socratic infamy, has taken possession of certain spots, as it does in Europe. The writer has seen acres of it along the banks of the White River at Richmond, in Indiana.

The Ox-Eye Daisy, or White Weed of New York (*Chrysanthemum leucanthemum*), has crossed the Atlantic with hay-seed and so completely monopolized many of the meadows in the Eastern States that they more resemble snowfields than hayfields when the plant is in blossom. It is slowly spreading west and south, and last summer the writer found it in Ohio close to the State line of Indiana, appearing in full vigour and of large size.

The Tansy (*Tanacetum vulgare*), valued by herbalists as a tonic, is not uncommon. The crimped variety (*crispum*) grows near Montreal.

The Chicory (*Cichorium intybus*), with its stiff stem and lovely but evanescent azure blue flowers, wild in England and well known to manufacturers of coffee (the genuine article!) is now one of the wild flowers of the Island of Montreal.

The Great Mullein, or Flannel plant (*Verbascum thapsus*), common in waste ground in Europe and Asia, is more common here than in England in similar situations, but never so far as the writer is aware on ground that is truly wild.

The Yellow Toadflax, or "butter and eggs" (*Linaria vulgaris*), has been introduced with crops, and now shows its two-tinted blossoms in gardens and on waysides, and once in is with difficulty eradicated.

The Catmint or Catnip (*Nepeta cataria*), a native of England and southern Europe, is now as common in America. The Burdock (*Arctium lappa*) is another importation from the Old World, "who left his country for his country's good," and has proved like many others who did the same no blessing to his adopted land. Moreover, he has left so many of his kith and kin behind him that his absence is not noticed. Every boy knows the hooked burs or seed vessels of this plant, which cling so closely to the clothes of men, the fleeces of sheep, and the manes of horses that its rapid extension is inevitable.

The Great Celandine (*Chelidonium majus*), with its bright yellow flowers and orange juice, may be found on the eastern seaboard and near dwellings in the inland States.

The Shepherd's Purse (*Capsella bursa-pastoris*), a common weed in England, is common in Canada and the States.

The Bladder Campion (*Silene inflata*) spreads its white petals by the roadside, while its little congener, the Mouse Ear (*Cerastium vulgatum*), grows ensconced, as in Europe, in gardens and in fields.

Our list is long enough, but a few remain too common to be completely omitted. Every street and road in many parts of the country is covered with a soft summer-green carpet of the little insignificant Knot-grass (*Polygonum aviculare*). It forms a substitute for grass where grass cannot find a foothold and keeps its ground in defiance of dust and traffic and heat.

Not a few of the European grasses, too, imported for meadows, have escaped from cultivation and succeeded in establishing themselves more or less firmly as occupants of the soil. The little Annual Meadow Grass (*Poa annua*), the Timothy (*Phleum pratense*), the Fox-tail (*Alopecurus pratensis*), the Redtop (*Agrostis vulgaris*), the White Bent (*Agrostis alba*) have become perfectly wild in different places. The Cocksfoot (*Dactylis glomerata*), the Couch or Quick grass (*Triticum repens*) have been less successful. The former apparently dislikes the hot sun of America, though it does well in the shade. The so-called Blue Grass, more properly the June Grass (*Poa pratensis*), of the famous Kentucky pastures, has almost monopolized the ground in many places, and the Chess or Cheat (*Bromus secalinus*) constantly cheats the American farmer into a more than Darwinian belief in the transformation of species, not, by the way, upward, but downward. The Purple Finger Grass (*Panicum sanguineum*), an immigrant from Southern Europe, found but not native in England, may be gathered by the wayside in the Eastern and Midland States. Finally, in some parts of the country the hay betrays to the European by its scent the presence of the Sweet Spring Grass (*Anthoxanthum odoratum*), so well known as giving much of the finest of the fragrance to an English hayfield.

In thus noting instances of vegetable immigration from Europe to America, another side of the question must not be overlooked. Many common English plants have totally failed to secure a foothold here. The seed of the English Daisy must have come over in almost every case of grass-seed that has been imported; yet it has not become naturalized in America. The only instance with which the writer is acquainted of its lasting for several years in a lawn, as in England, occurred in the immediate vicinity of Montreal, and was communicated to him by a friend in that city. It would therefore appear that the heat of summer rather than the cold of winter is the barrier to the establishment in the New World of the "wee modest crimson-tipped flower," so familiar to every British eye. Equally "conspicuous by their absence" are the Primrose and the Cowslip, the flowers of childhood in the old country. Many other instances of this kind might be adduced, but the converse side of the problem now claims attention.

(*To be continued.*)

FRAXINUS CULTIVATION AND MANNA PRODUCTION.*

BY J. JANSSEN, FLORENCE.

The planting of Fraxinus trees in Italy yields pecuniarily a good return without any great trouble or cost being incurred. The best trees for planting are *Fraxinus Ornus*, L., and *F. excelsior*, L. The former species has been artificially introduced into Sicily and Calabria, though both species occur there growing wild.

When the tree has attained an age of eight to ten years it is used in the production of manna. For this purpose a horizontal incision is made in the bark with a sharp garden knife, equal to about one-fifth of the entire breadth. In doing this the following points are observed. In the first year the incisions are made upon the side of the tree towards which it inclines (the Fraxinus scarcely ever grows straight) and they always progress from below upwards. The first incision is made at the base of the tree, and then one incision over another at intervals of one centimetre until the ramification of the branches is reached. The incisions are then made on the opposite side, commencing at the base of the tree as before. From the beginning of July to the end of September an incision is made daily in each tree.

The manna is collected during nine years, when the tree becomes exhausted and incapable of production. For this reason during the ninth year incisions are made simultaneously on both sides of the tree in order to use it up completely. The tree is now cut down, leaving only a single shoot, which at the end of four or five years is capable of production.

The juice which flows only from the incisions is at first brownish and has a bitterish taste; but after some hours in contact with air it becomes solid, whitish and sweet, forming long pipes or small stalactites. But frequently the juice is very fluid and it then runs down, forming a kind of long plaster that adheres to the bark, whilst a portion drops to the ground where it is collected upon leaves of *Ficus Indica*.

The manna is collected once in the week and only in fine weather; if rain falls the gathering is hastened. Rain and dew interfere with the profits. A man provided with two vessels goes round to the trees, collects the pipes and scrapes off the smooth mass lying on the surface, putting each sort into a different vessel, as in commerce they have a very different value. The first sort is the "manna canellata," the second "manna in sorta." After the collection both sorts are spread out in the sun to dry a little and then sent into commerce.

The gross returns from a hectare of land is on the average 830·35 Italian francs, viz., manna canellata 6 kilos at 22·10 = 132·60; manna in sorta, 94 kilos at 7·50 = 705; wood cut down, 12·75. Total 850·35 francs.

PREPARATION OF PERFECTLY PURE HYPOPHOSPHITE OF SODA.*

BY M. BOYMOND.

It has long been known that the preparation of hypophosphite of soda by the action of phosphorus on a solution of soda is not a practical process. This finds a ready explanation in the property possessed by the hypophosphites of oxidizing rapidly in alkaline solutions in proportion as the base is energetic and the solutions concentrated. It consequently happens that in heating phosphorus in a strong solution of potash or soda, much phosphite is formed, and in boiling hypophosphites in such solutions they are converted, with disengagement of hydrogen, into phosphites and phosphates. Besides the formation of considerable a quantity of phosphite, this process presents the inconvenience that the phosphite and phosphate formed, as well as the alkali in excess, are dissolved, and are very difficult to eliminate.

As to the preparation of the hypophosphites by means of a milk of lime, although that base presents important advantages over soda,—as the quantities of phosphite and phosphate formed are less considerable and the elimination of these salts and the lime in excess is more easy,—this process does not yield a perfectly pure product, the proportion of phosphite and phosphate present amount sometimes to as much as 5 per cent. Hypophosphite of soda prepared with such a salt of lime could not be pure. Besides, even when the hypophosphite of lime is perfectly pure, the evaporation in a water-bath of an alcoholic solution of pure sodic hypophosphite is sufficient to give rise to an appreciable quantity of phosphite.

* *Répertoire de Pharmacie*, vol. vii., p. 328, from the *Schweizerische Wochenschrift f. Pharmacie*, vol. xvii., p. 92.

The author has obtained this salt entirely pure by employing, in the place of hypophosphite of lime, a clear solution of hypophosphite of baryta, in the following manner:—

25 grams of commercial hypophosphite of soda, containing phosphite, and 1 gram of hypophosphite of baryta (sufficient to precipitate all the phosphorous and phosphoric acid contaminating the product) were mixed and water added so that the volume of the whole solution did not exceed 50 c.c. Some time afterwards, without filtration, nearly 200 c.c. of absolute alcohol were added, the mixture was allowed to stand, and then filtered. In this way all the phosphoric acid was precipitated, as well as nearly all the excess of baryta in the state of hypophosphite. To the clear filtered liquid was added, in small quantities, sufficient solution of sulphate of soda to precipitate the baryta still dissolved; then about 100 c.c. of absolute alcohol was added and the liquid allowed to stand. The clear liquid obtained by filtration and decantation was afterwards mixed in a larger vessel with about 500 c.c. of absolute alcohol, and as much absolute ether as was required to agitate the mixture strongly, when all the hypophosphite separated. The salt was collected and deprived of the last traces of alcohol and ether by passing over it a current of dry air.

The ethereo-alcoholic liquid, after the separation of the salt, was completely neutral. The hypophosphite, crystallized in small needles, dissolved perfectly in water and in alcohol, and the solution was not rendered turbid by the addition of baryta or sulphate of soda. Once only it contained a trace of sulphuric acid, consequent upon the employment of a slight excess of sulphate of soda.

ERYTHROXYLON COCA.*

BY D. F. SHULL, PH.G.

The leaves of this plant, which grows wild in South America, and belongs to the natural order Erythroxylaceæ, possess peculiar stimulating properties, which properties have been of late the subject of considerable investigation.

Specimens of the leaves which I obtained were of an oval-oblong pointed shape, resembling the leaves of tea, about one inch in breadth and from one and a half to two inches in length; with an entire margin, short, delicate footstalks, with a small vein in each side of the mid-rib, running from the base to the apex. The leaves when of good quality are of a light green colour, with an aromatic odour similar to tea.

The leaves when chewed have a slightly astringent and aromatic taste, producing smarting and a feeling of numbness to the tongue. The smarting and feeling of numbness produced are due to the alkaloid cocaina. The alkaloid, when taken in small doses, produces the same effect, except in a more marked degree. I also found that those specimens of the leaves which did not possess this property were entirely devoid of any medicinal effect, which goes to prove that the alkaloid must be the active principle.

There is much variance in the quality of the leaves. Some specimens obtained, which were of a light brown colour, I found to be entirely worthless. A good quality of leaves can be readily recognized by their taste and colour.

The alkaloid cocaina I obtained by exhausting the leaves with alcohol, precipitating the colouring matter with lime, filtering, evaporating to a small bulk, adding water and evaporating until all the alcohol was driven off, adding carbonate of potassa, filtering, saturating with carbonate of potassa, and dissolving out the alkaloid with ether, then decolorizing with charcoal, and allowing the menstruum to evaporate and the alkaloid to crystallize. Cocaina forms small, colourless prismatic crystals, inodorous, with bitter taste, producing smarting and a sensation of numbness to the tongue. In small doses it has strong stimulating properties; it produces a feeling of intoxication. I also obtained the alkaloid from a decoction by treating with lime, evaporating to small bulk, saturating with carbonate of potassa and dissolving out with ether.

Cocaina is soluble in alcohol, ether, chloroform and water. I found the active principle not to be a glucoside by boiling it with dilute sulphuric acid and applying Trommer's test for glucose.

I obtained, associated with cocaina, an uncrystallizable principle of a light brown colour, strong odour, sharp burning taste, with an alkaline reaction, soluble in alcohol, ether, chloroform and water.

The other constituents which I found were gum, tannin, wax and resin.

I prepared an extract by exhausting the powdered leaves with alcohol and evaporating at a temperature of 160° F. to the proper consistency. The preparation was of a green colour and of a resinous appearance, with the characteristic odour and taste of the leaves. When exposed to the air it does not harden, but absorbs moisture and becomes quite liquid. This makes it inconvenient for forming into pills, as they become quite soft in a few days. From one hundred parts of the leaves I obtained fourteen of extract.

A fluid extract was prepared by exhausting two ounces of the powdered leaves with alcohol, reserving the first ounce and a half and evaporating the remainder to half an ounce, and mixing this with the first. This preparation was of a light green colour, with the odour and taste of the leaves, and seems to be permanent.

An infusion was made by macerating two ounces of the powdered leaves in a pint of boiling water for four hours and straining with pressure. This preparation was of a light brown colour, with an aromatic and astringent taste similar to green tea.

Experiments were made with these three preparations by taking doses of a known quantity of leaves and doses of the preparations representing the same amount of the drug and noting the effect of each on the pulse. I found that all three produced the full stimulating effect of the leaves on the heart's action. Of these three preparations I think the fluid extract would be preferable, as it is not so liable to be affected by age as the others.

In a few experiments made as to the therapeutic effects of coca, I found that in doses of from 30 to 60 grains it produces a gently excitant effect, with an indisposition to sleep, in this respect resembling tea and coffee, but having a more decided action on the heart, increasing its contractions and giving elasticity to its action. It also possesses a peculiar stimulating power over the digestive organs, giving almost immediate relief to that feeling of depression after eating caused by indigestion. Taken in larger doses of from two to three drachms it excites the whole system, causing the face to flush and imparting increased vigour to the muscles as well as to the intellect, with an indescribable feeling of satisfaction.

I took note of the stimulating power on the heart's action of a good quality of coca in doses of thirty grains each, on four young men at the same time, by noting the pulse of each before taking and again twenty minutes after taking, with the result of an increase of the pulse in the first from 90 to 110, in the second from 76 to 86, in the third from 66 to 82, and in the fourth from 92 to 125, making the average increase of the pulse $19\frac{3}{4}$.

Many contradictory statements have been made by those who have studied coca as to its stimulating properties. I think this is largely due to the difference in the quality of the leaves used. Some extraordinary stories are told by travellers in South America of the endurance of hard labour, famine and loss of sleep, afforded to the natives by the use of coca. They are probably in most cases exaggerated, although there can be no doubt that the fresh leaves used by them are more active than those we obtain.

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 22, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ADULTERATION OF CREAM OF TARTAR.

THE adulteration of "cream of tartar" still continues to be a source of vexation, and from inquiries we have made, there seems to be good reason for apprehending that many persons who use this article for various purposes, as well as those who supply them with it, may find themselves unexpectedly involved in difficulty, arising from the presence of sulphate of baryta in the "cream of tartar" they are using or selling. For this reason, we think it will not be out of place to again warn members of the trade against the danger attending the sale of "cream of tartar," unless they satisfy themselves that the article is free from adulteration or impurity.

Some two years ago, the presence of sulphate of baryta in "cream of tartar" was noticed by Mr. KINNINMONT and other of our correspondents, and the examination of a number of samples all purporting to be obtained from the same source showed that those samples all contained sulphate of baryta. But notwithstanding the circumstance that the samples represented the same original bulk of ground "cream of tartar," the percentage amount of sulphate of baryta was, strange to say, very different in the several samples; in some it exceeded 3 per cent., and in others it did not exceed ½ per cent.

This strange variation in the amount of impurity seemed at first sight unaccountable, and it was only by the examination of the crystals from which the powder had been obtained that a clue was found to the explanation of the fact. When a quantity of these crystals were placed in a large bottle and shaken about, so as to detach any dust adhering to the lumps of crystals, and then this dust was separated from the crystals by sifting, the analysis of the dust showed that the percentage of sulphate of baryta in it was six times as great as in the powder obtained by grinding the original crystals.

Moreover, upon microscopic examination of that portion of the separated dust which could not be dissolved by boiling water, it turned out that it consisted of small particles of "heavy spar," the form in which sulphate of baryta occurs naturally as a mineral. Hence it became evident that the presence of baryta in the "cream of tartar" was not due to any introduction of impurity in the course of its manufacture. The sulphate of baryta was not, in fact, an ingredient of the "cream of tartar" crystals, but was merely mixed mechanically with them.

From a chemical point of view it seems highly improbable that sulphate of baryta should be introduced into "cream of tartar" as a consequence of the presence of some baryta compound in the material called yeso, or Spanish earth, which is used for plastering wine, for the insoluble nature of the sulphate of baryta is alone sufficient to justify the opposite conclusion. We do not therefore, on these grounds, share the opinion expressed by Professor REDWOOD and Mr. FLETCHER, and in the case we have above referred to there was no inducement to regard the presence of sulphate of baryta as being thus explicable, for in addition to the fact that the substance was only an admixture, it was in the state of coarsely ground "heavy spar."

Further examination of other samples of "cream of tartar" within the last few weeks has shown that sulphate of baryta is frequently present in this article and invariably in the state of "heavy spar," and it has been possible to account for the circumstance that in the ground "cream of tartar" the percentage amount is so variable even when the powder represents the same parcel of crystals. Bearing in mind that in a cask of "cream of tartar" the crystals of bitartrate of potash are mixed with the particles of "heavy spar," and having regard also to the great difference in density of these two substances, it is obviously natural that the heavy particles should shake down towards the bottom of the cask and thus become unevenly distributed. A sample of the crystals taken from such a cask with every intention of fairness might give results on analysis indicating the entire absence of baryta, and yet analysis of the powdered "cream of tartar" obtained by grinding the contents of the cask would show that sulphate of baryta was present in it, and the question, How did it get there? would arise, possibly to the inconvenience of the grinder or of the retailer, as in the late case of Mr. BOYCE.

Moreover, the amount of sulphate of baryta in the powder obtained from different parts of the contents of a cask of "cream of tartar" crystals may vary in consequence of the unequal distribution of the "heavy spar," so much that in one part it may be so small as to appear inconsistent with the probability of adulteration having been practised, and in this way further difficulties may be created, leading to the conclusion that sulphate of baryta, even in the form of "heavy spar," may be derived from the stones used in grinding, as suggested by Mr. TANNER some weeks ago. Very little consideration of the matter, however, will suffice to show that there is no real foundation for the idea that this can be the source of the contamination. The weight of "cream of tartar," ground by one pair of stones will sometimes amount to fifteen or twenty tons in a month, and if only 1 per cent. of sulphate of baryta was introduced into the powder by the abrasion of the stones, they would very soon cease to exist as stones, since they do not weigh more than five or six hundredweight each. On the contrary, the fact is that these stones wear down very little and last a very long time.

But there is another point of evidence, especially conclusive in regard to the origin of the sulphate of baryta in "cream of tartar" and explanatory of the varying proportion, and this is the fact that by shaking a cask of "cream of tartar" crystals in such a manner as to make all the dust settle down to the bottom, almost all the sulphate of baryta will be found in this dust—in one instance that lately came within our knowledge the amount was no less than 45 per cent.

There is, therefore, reason to believe that the adulteration of "cream of tartar" with "heavy spar" is systematically practised and that it is probably carried out by throwing a handful of the coarse powder here and there into the casks while they are being packed. By the base ingenuity thus exercised it becomes possible for the seller at some stage of the commercial history of the article, either to sell below the market rate, and thus to put honest dealers at a disadvantage, or to obtain an extra profit when selling at the market rate. In the manufacture of tartaric acid the presence of such an adulterating material as "heavy spar" may well escape detection, and in the use of "cream of tartar" for various other purposes it may happen that the presence of 2 to 6 per cent. of sulphate of baryta may pass unnoticed until some one of the commodities into which "cream of tartar" enters falls into the hands of a public analyst, and either the seller or the manufacturer comes to grief on a change of adulterating his wares.

Considering the possible damage that may arise from this vicious practice, as well as the actual fraud that is perpetrated, we have thought it desirable to place the facts of the case before our readers and by thus making them known we trust that an end may be put to this instance of adulteration.

THE PROPERTY IN A PRESCRIPTION.

Referring to the remarks made recently upon this subject by Mr. Kinninmont, President of the Glasgow Chemists' Association (see before, p. 394), the *Medical Press and Circular* has this week some outspoken words not quite in accord with opinions that have been uttered by some medical men. Admitting that occasionally the repetition of prescriptions works disadvantageously, and that in some cases a high-class pharmacist might very properly refuse to continue an endless repetition of doses, the editor declines to "encourage for a moment the "theory that the right to that repetition is possessed "by anyone but the patient." The writer concludes by saying, "We fail to understand upon what prin-"ciple a patient who has paid his fee for advice and "a recipe for medicine should be obliged to seek "leave from either doctor or dispenser to make "unlimited use of the recipe which he has thus "purchased, and however justifiable it might be for "the dispenser to retain the original prescription for "his own safety, we certainly think he is bound in "equity to send to his patient, with the medicine, a "true copy, so that the patient may please himself "as to when and where he will have a repetition of "it compounded."

THE OOTACAMUND QUINOLOGIST.

In a recent number of the *Madras Mail* it is stated that Mr. Broughton, who formerly held the post of quinologist in connection with the Government plantations of cinchona in the Neilgherries, is at the present time in Colombo. It may be in the recollection of some of our readers that about four years since Mr. Broughton left his place of residence in India somewhat unexpectedly, and that, with the exception of some mysterious rumours, nothing was known as to where he had gone. A correspondent of the *Daily News*, referring to the statement in the *Madras Mail*, remarks that "it is "little to the credit of the Madras Government that "the fate of an officer high in their service should "be involved in such mystery."

BRITISH MEDICAL ASSOCIATION GRANTS.

We understand that the sum of £282 5*s*. has been voted by the British Medical Association in the shape of grants in aid of scientific investigation connected with physiology and other subjects bearing upon the practice of medicine. Amongst these subjects we may mention "Anæsthetics" as having been entrusted to Dr. McKendrick, of Glasgow University, the "Relation between Bacteria and Surgical Diseases" to be investigated by Dr. Ogston, and the "Physiological Action of Alcohol with Especial Reference to the Mode of its Elimination," which is to be continued by Dr. Crocker.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held on Thursday next, the 27th inst., at 17, Bloomsbury Square, when Mr. E. M. Holmes, F.L.S., will read a paper on "Study."

CHEMISTS' ASSISTANTS' ASSOCIATION.

On Wednesday next, November 26, at the rooms of the above Association, 32a, George Street, Hanover Square, a paper will be read by Mr. A. P. Luff, F.C.S., on "Water Analysis." Chair to be taken at 9 p.m.

In addition to the pharmacists mentioned last week as having received municipal honours, Mr. John Babtie, Pharmaceutical Chemist, has been elected Provost of Dumbarton.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

The opening meeting of the twenty-sixth session took place on Tuesday, November 11, Mr. J. B. Stephenson, President of the Branch, in the chair.

The minutes of former meeting were read and confirmed.

The Honorary Secretary announced the following donations:—

To the Library:—'Manual of Materia Medica,' Craig, 4th ed., from Dr. Wm. Craig; *Canadian Pharmaceutical Journal*, 5 numbers, from the Ontario College of Pharmacy; *The Pharmacist and Chemist*, 5 numbers, from the Chicago College of Pharmacy; *Journal of the Chemical Society*, 6 numbers, Redwood on Electricity as a Source of Light; Programme of the City and Guilds of London Institute; Technological Examinations for 1880, from Mr. Mackay.

To the Museum:—Collection of dried specimens of indigenous Medical Plants, from the Society in London, *per* Mr. Holmes.

The President's Address.

Gentlemen,—On several occasions during my protracted tenure of office, I have been led to offer a few remarks on some considerations arising from a view of the complex character of our business as being at once a *profession* and a *trade*, and I have thought the subject one of such interest to us all, and so suitable for an address on the opening of our scientific session, that I have ventured to reproduce it this evening. My previous remarks were of a fragmentary nature, and had reference to varying occasions, and I have therefore endeavoured now to treat the subject more as a whole, and to enlarge somewhat both its scope and comprehensiveness. Still, I fear, I shall be open to the charge of reiteration, and I must just ask the indulgence of those brethren who have already listened to the expression of the same ideas, and probably even the same words.

I shall assume that our business may be legitimately classed as a *profession*—that at least to some extent, and in some of its details, it partakes of that character. I think the day is gone past when we are to be regarded as mere hewers of wood and drawers of water, and that now, pharmacy constitutes one of the recognized provinces of the medical field, which not only can be cultivated better, but cannot be efficiently cultivated at all, except by those whose exclusive business it is. We have, indeed, occasionally complaints, and quite recently in high quarters, of the non-recognition of the true position and character of pharmacy and the pharmacist by the medical profession and the public. I am bound to say that as far as my experience goes these complaints are groundless. I have almost invariably found a ready recognition of our claims by both the one and the other, or at least a readiness to admit them when the state of the case was explained. But my object this evening is not at all affected by the recognition or non-recognition of our professional claims by any outside our own body. It has to do exclusively with the realizing and carrying out the idea by ourselves, which it is much to be desired were done more consistently and thoroughly; but of this more by-and-by. Well, but on the other hand, there can be no doubt ours is a *trade* as well as a profession,—subject to commercial conditions like any other trade. We have indeed high authorities remarking on this as an anomalous state of things, and recording their aspirations for the time when pharmacy shall be freed from commercial associations entirely, and assume its proper position as a pure profession. I have no such views to advocate to-night. Whether such a state of matters is attainable or probable, it is not for me to say. As matters stand at present, I cannot see that such a consummation is either practicable or desirable, and my own inclination is to accept the present situation loyally. I wish to magnify our *profession* as much as I can, but am by no means disposed to minimize the *trade*. It is as honourable in itself as any other trade, and in sooth, I think very few of us could afford to let it go. And there is, to my mind, nothing to hinder the prosecution of it honestly and efficiently, while maintaining the professional idea in its integrity. But then if the higher character is realized and the principle of it cherished, it ought to have an effect on all our business actings, and it is the gist of my address this evening to try to show how legitimately and inevitably such an effect will follow—for it has long been my firm persuasion that the surest means of advancing true pharmacy is to cultivate this higher view of our business.

The pharmacist must be a man possessed of a good general, as well as of a special technical knowledge, both of which are tested by examinations of fair comprehensiveness and stringency. He is a man on terms of confidence with his clients, of the same kind, and only less in degree, with the medical practitioner, and in the details of his calling he is constantly invested with a responsibility, which although often ignored, it is not easy to over-estimate. These and like considerations, duly pondered, are fitted to evoke, in every properly constituted mind, a legitimate pride in belonging to his guild —an "*esprit de corps*," in fact—which will not remain inoperative, but will prompt the possessor to a careful and jealous guarding against anything compromising either it or himself. And, as in other cases, a high sense of honour and the aspirations after a lofty ideal will dignify any course of action, however humble, so here a sense of what our profession requires of us will lighten the drudgeries and ennoble the commonplaces of our business. Nor is the effect of this professional idea which I am commending, restricted by any mean. to the region of sentiment. On the contrary, as I have hinted, it is capable of being applied constantly in the active duties of our calling, and I believe, it will be found a most practical and operative principle. It will suggest the solution of many a difficulty —it will adjust our relations to one another and to the public generally, and it will keep us right with regard to many practices, where there is considerable temptation to go wrong. Let me endeavour to illustrate this in a few instances.

Consider first, for a few moments, the pecuniary remuneration of our business, and the first thing that occurs is this—if our transactions are of a professional character the payment of them ought to be on the basis of a professional fee. No doubt this is recognized in our tariff of charges for prescriptions; but is the idea properly realized? Is there a distinct estimation made of the knowledge, skill and responsibility which come into play with reference to the purity and the potency of every drug we handle? or are these not all thrown in as a mere makeweight to the cost of the ingredients, just exactly reversing what ought to be done? At any rate, I do not believe that dispensing is a paying business. I do not doubt that this statement will meet with an incredulous reception; but I would suggest a ready method of putting it to the proof. Our dispensing operations are so mixed up with other business, such as patents, perfumery, aerated waters, etc., that the returns of the former are overlaid and lost sight of; but let them be carefully eliminated, and see how matters stand; or, let anyone arrange for himself, say half a day's work of pure dispensing—let there be a fair assortment—mixtures, pills, powders, ointments, suppositories to make, a plaster to spread, an infusion to prepare, and let him have to prepare, copy prescription, finish off, and send out, and then see how much he gets for his half-day's work by the tariff of our own price list, and estimate from that if he could make his living as a simple dispenser. I am confident the conclusion will be that he could not. Well only think of a member of another profession—say a doctor or a lawyer—who had as many clients as occupied all his time, and yet could not make a living out of it. It is not my object in what I am saying to advocate raising prices. I think my brethren on the Price Committee will bear me out when I say that my action has been (somewhat illogically) in the other direction; but I venture to predict that if my proposition be true, viz., that dispensing *per se* is not remunerative, then, in the event of the public insisting on depriving us of our profits on such articles as they can get at stores, etc., this will inevitably happen—they will have to pay for their medicine at a very different rate from what they have been accustomed to. We must all have met with cases of complaint by parties who have become accidentally aware of the inexpensive composition of some preparation they have had, and for which they have been charged, as they call it, an exorbitant, or extortionate, price, and I have known medical men, who surely should have known better, indulge in the same tone. And there is another class of cases where parties want, say one dozen powders in bulk, for themselves to divide, or the solid ingredients of a mixture that they may add the water themselves. These are very unpleasant cases, and I am afraid I cannot suggest any consideration that will suffice to get the better of such knowing ones; but the only course open to us in such circumstances, is the firm maintenance and the respectful assertion of our professional standing, both as a rule of action to ourselves and a vindication of it to others.

Again, there is the old question, but one of the last importance, our relation to the medical profession, with the grievance of *medical dispensing* on the one side, and *counter prescribing* on the other. As to the former, we in Edinburgh have no experience of it, but we know how in many places in Scotland, and still more in England, it is still maintained with the greatest tenacity, and it presents to the mind one of the dreariest prospects of pharmacy. One peculiarly objectionable form of it is the case where open shop is kept with the doctor's name over the door. Surely our Pharmacy Bill might be adapted to meet such a case as this. But it is the other grievance that falls within the scope of my subject. Now, there is a certain *counter prescribing* which I hold to be indispensable in the carrying on of our business, and which I would rather describe as *recommending our goods*, and to be able to do so implies a knowledge of their nature and uses, and is of the essence of a pharmacist's qualifications. So that, if this were the extent of the grievance, I should feel it unnecessary to say anything on the subject. But I am bound to admit that I believe prescribing of a most objectionable character prevails to a great extent, and it is therefore necessary to apply the professional standard to it. Now, as a general rule, the higher view a man takes of his own profession the less likely will he be to encroach on that of another. The pharmacist feels that he has his own field, worthy of, and demanding all his exertions, and that he has neither the right nor the qualification to occupy the field of the practitioner. His professional instincts will impel him to take up this position at once. He would rather be a good pharmacist than an unqualified medical man—a quack in fact—and various considerations will confirm him in the conclusion. Respect for his clients will influence him, and respect for the medical practitioner will come into play, as well as respect for his own profession and himself, and the result will be that in maintaining his self-respect, he will acquire that of the others. I do not say that medical dispensing will cease all at once on this happening; but surely there is more likelihood of it ceasing when the doctor comes to look on the pharmacist not as an antagonist, but as a co-operator, and to be entirely freed from all suspicion of him as a rival—and just as surely will this result never be attained by the assertion of rights and qualifications on our part, which do not belong to us, and which can only embitter and exasperate the whole question.

There is another department of our business upon which I should much like to see the influence of this professional spirit, which I am commending, brought to bear. I allude to patent and proprietary medicines, and with them I include specialities and novelties of various kinds—preparations sometimes of articles of the Pharmacopœia, but purporting to have an excellence peculiar to themselves—a daily increasing tribe, and I bracket them all together "Quackery." I shall be sorry to give offence or to do injustice to any article of real merit—and some such do unquestionably exist in this class; but my apology is just that I find them in bad company, and I cannot draw any distinction. These productions are all characterized by their wonderful properties in curing disease—diseases of the most formidable character, and generally indeed of the most widely differing character—in proof of which we have the *ipse dixit* of the authors, given for the most part in such high-flown and bombastical language that the wonder is it does not defeat the object in view, accompanied by testimonials of the most wonderful kind, from all classes, but chiefly clergymen; and both mixed up with a jargon of a quasi-scientific or offensively pious—I should rather say profane—description. And all this is poured forth on the world by means of advertisements in newspapers and magazines, bills, pamphlets, almanacs, etc., etc., constituting in fact a literature *sui generis*. The other characteristic of the whole tribe is the secret of their composition or mode of preparation—which is known only to the author—a fact, the importance of which the public is carefully instructed in and warned as to the fatal consequences of neglecting. Surely, gentlemen, it might be thought that a different standard from the professional might suffice for passing condemnation on this whole system, and that all these pretensions and secrecies are not more incompatible with true science than with the simplest dictates of morality or even decency. And indeed before saying anything of the *professional*, I have one or two remarks on some other aspects of the case. And *first* I would require the authors of every one of these articles to declare on oath the composition of it. This appears a simple provision, but I would anticipate much good from the working of it. From what I have seen in the case of several much vaunted preparations, I am sure that the wonderful secret would turn out to be of such a common-place character as to necessitate the calling in some other agency to account for the effects. We would be shut up to find this in Faith, and the inference would at once follow if Faith can work such wonders with such rubbishy materials, what will it not perform if allied with a rational treatment. This consideration applies to the public interest, but there is another strictly related to our own. It appears to me that this class of business is so much on the increase as to threaten to effect a change in the character of our business, so that from being compounders of medicines we shall become in great measure merely the salesmen of the preparations of others. This may appear from a simple commercial point of view no great evil, because—as we all know—the public—strangely enough—will give without grudging *shillings* for these articles, when they grudge *pence* for our own preparations, or for medical prescriptions. I am not at all sure, however, that our pecuniary interests will not suffer, and that disastrously, in the long run; but apart from that, I must protest for myself and for my brethren upon whose qualifications as compounders of medicine our Boards of Examiners have set their *imprimatur* against the degradation which is inflicted on us, and the slur cast upon us in the eyes of the world, by any body of persons and for any reasons whatever. Let we take a leaf out of these gentlemen's books. Well do they know the prestige of our profession in the estimation of the public, and how necessary our agency is for the introduction of their productions, although, when once established, general merchants or stores may safely be trusted to sell them; let us utilize this prestige in the opposite direction, for the purpose of discouraging and discrediting the whole system. Then lastly, on this head—I feel it almost unnecessary to make any remark on the professional attitude we ought to assume towards this question. Only one word. We see the credulity of the public—even of the educated part of it—on this matter, and we recognize a reason for it in their ignorance on the special subject, and often perhaps in the unsettledness of mind that goes along with illness, and we even see medical men often lend their sanction to this system, and especially to that section of it which I have alluded to as *specialities*. But then, *doctors* are not *pharmacists*. We claim that part of the field as ours, and to us therefore falls the duty of forming an opinion on the subject, and if we find the system opposed to the whole scope and genius of true pharmacy, which I think there can be no intelligent doubt that we shall, then is there not a call upon us as the accredited exponents of pharmacy to denounce this as a counterfeit system, and, in as far as we can, to stand between the public and the medical practitioners on the one hand, and these helots of our own profession on the other?

In conclusion, you ask me whether these are not fancy pictures I have been drawing, and whether this professional spirit, or at least the practical carrying of it into business, is not entirely a myth; whether in fact the end of our business is not after all to make money. I admit in sober sadness that there is not much evidence around us of the prevalence of the professional element, while there is abundance of that of the money making. Herein indeed, lie the occasion and the apology for my enlarging on the subject. Mammon, gentlemen, is an exacting master. According to the sacred dictum, no man can serve two masters when Mammon is one of them, so that if a man allows it to master him, there can be no scope for the higher and nobler allegiance. Yet there may be much more of the professional spirit in full and active operation than what meets the eye, for like other noble principles it often leads a hidden life, and it never courts publicity. I said "*may be*," but I confidently cherish, and we must all cherish, the hope and belief that there *really is*, for on it depends the future of pharmacy. Without this it were but the body without the soul; and who of us can be so distrustful and so disloyal as to doubt that there is a bright and a glorious future for our as yet infant organization? And, gentlemen, if I have awakened or strengthened in any of you the conviction or the faith that this principle may and ought thoroughly to pervade our profession, my object has been abundantly accomplished, for I shall feel assured that thereby I have done something towards helping on this better state of things which is yet in store for us.

Mr. Wm. Gilmour then read communications on (1) Gregory's Powder, (2) Proof Spirit, and (3) Physic Balls and Mass.

Note on Gregory's Powder.

BY W. GILMOUR.

Some time ago my attention was called to the fact that complaints were frequent regarding Gregory's Powder, these complaints generally being to the effect that it was next to impossible to get it to mix with water. Shortly before this there had been some change, I was aware, in the density of the magnesia used in making the Gregory (Pattison's), and the blame was therefore at once connected with this. Further investigation, however, proved this not to be the case, but directly attached the cause of complaint with the use of one of Baker's sieves, which had about this time been introduced to the trade. Baker's sieve, as probably everyone knows, is constructed with a metal agitator working backwards and forwards above but in close contact with a concave sieve. Sieve No. 5, recommended for Gregory and similar powders, has 2500 holes to the square inch, and this is as near as possible of a fineness with the muslin sieve which we had been in the habit of passing the powder through. It was, therefore, I was convinced, nothing connected with the fineness or coarseness of sieve used which accounted for the peculiar change which had taken place in the powder. I should state here that the plan pursued in making the Gregory was the same in both cases. Operating on a pound of material the ingredients were first mixed in a large mortar, then transferred to the sieves, in the one case a Baker and in the other a fine muslin through which the powder was pressed by means of a brush, and afterwards again transferred to the mortar and lightly mixed and finally bottled. Prepared in this way, the powder in the one case mixed readily with water, in the other it was, as already stated, next to impossible to mix it. Even when it was placed in a bottle and thoroughly shaken with water the mass of the powder floated to the surface in the froth, and only by repeated shaking and after the lapse of considerable time did it assume the dark brown, homogeneous appearance produced in the other powder by a single shake under the same conditions. The peculiar way in which the powder floated in little balls on the surface of the water and resisted its penetrating action, together with its general behaviour, forced the impression on my mind at an early stage of the investigation that some electric action had been set up in the powder in passing through the sieve. I soon, however, set aside this idea, principally because I felt persuaded that any electric action which might have been set up in the powder had ample time to exhaust itself in the exposure of the second mixing which the powder received in the mortar after having passed through the sieve. To make quite certain, however, I attached a delicate electroscope both to the sieve and the powder whilst in operation, but as I quite expected with entirely negative results, and I therefore had to cast about for another and more probable explanation of the phenomenon. In thinking the matter over two theories presented themselves for consideration. First, that the powders were not sufficiently mixed with the Baker sieve, and in consequence the rhubarb floating about in little masses, prevented the powder being taken up by the water. To favour this theory there was the well-known fact that rhubarb, especially when in little granulated masses, is much more difficult to mix with water than magnesia, and the further fact that on mixing the powder with water the little of the powder that was taken up did not colour to the dark brown which rhubarb always assumes when acted upon by water. The other theory was that the powder passing through the Baker sieve was less acted upon by the atmosphere, there being a much smaller surface of the powder exposed to its action and the process also being more quickly finished. We all know how quickly Gregory is acted upon by the air, and the natural inference was that the density of a powder thus acted upon would be greater, and that consequently it would be much more easily mixed with water. In support of this theory of the miscibility of the one and not of the other, there was the fact that the powder passing through the Baker sieve was undoubtedly the lighter in colour of the two, showing apparently that it had been less acted upon than the other by the atmosphere. I may state at once that both of these theories were most thoroughly knocked upon the head when upon further experiment I discovered that *the powder which had passed through a Baker sieve did not afterwards regain its property of miscibility by passing it through the muslin sieve also.* It could not, therefore, be from want of exposure to the atmosphere or from want of the powders being thoroughly mixed that it exhibited this peculiar property, for here we had the Gregory, so to speak, doubly exposed and doubly sifted, and still it had not regained the power of mixing with water to any extent.

Examined with an ordinary pocket lens no difference could be detected between the powders, and even with a low power the microscope revealed little to account for the change. It was only under a higher power and after sundry experiments I concluded I had arrived at a probable solution of the problem. Baker's sieve, it will be kept in mind, consists of a brass sieve and a metal mixer. Both of these present hard, unyielding surfaces to the powder passing through. The mixer, it will further be noticed, is simply an arrangement of wires (four or five), separated from each other by intervals, and passing closely over the face of the sieve. These wires are, comparatively speaking, small, and therefore they pass through the powders without, to any extent, mixing them. At the same time, they pass so close to the surface of the sieve as to force through whatever they come into contact with, and there is in consequence more a process of granulation than of mixing set up and continually going on, which, to a great extent, might account for the phenomenon in Gregory's Powder under consideration. Along with this, however, and to my mind a more important element in its production, is the heat generated by friction from the mixer passing so closely and quickly over the surface of the sieve. I am not prepared to say how far this heat consolidates the little granulated masses, but that it has some very decided effect may be proved by a very simple experiment. If a small quantity of the powder, for example, be exposed to a gentle heat, its repellant action to water is encreased, but if on the other hand, it be exposed for a short time to the action of the atmosphere it loses it entirely. Either the heat dries the powder, or it consolidates the particles, the result in either case being the same.

Since writing the foregoing, the subject has grown somewhat on my hands. I did not expect to find, as I now do, that the phenomenon described had been for the last two years the subject of such general observation and complaint, far less was I prepared to find such a diversity of opinion as to its cause. It appears that this non-miscibility of Gregory with water may exist, although no Baker's sieve has been used in its preparation; and, on the other hand, it has been known not to exist where the Baker's sieve has alone been used. Having investigated the subject entirely in connection with the Baker's sieve, to the use of which this peculiar property of Gregory was in my own case undoubtedly traced, and on abandoning the use of which it as undoubtedly ceased to exist, I might well be content to leave it there without endeavouring also to reconcile conflicting opinions. It seems to me, however, that the subject is of sufficient importance to justify better treatment than this would indicate, and moreover I cannot but think that many of the opinions expressed are perfectly reconcilable, not only with the solution of the question given in the preceding paper, but reconcilable also to a great extent with each other. Some, for example, blame the magnesia and change the kind which they have been using, and find the evil complained of ceases. Others again blame the rhubarb and change if for another, and likewise some also blame the ginger, and so on. I am thoroughly convinced the true explanation of the phenomenon is to be found in the magnesia being more or less hydrated. If the magnesia as well as the other powders be (comparatively speaking) in a dry condition, circumstances will then be favourable to produce a Gregory non-miscible. On the other hand should the same magnesia be used with a rhubarb or a ginger (comparatively speaking) in a moist condition, the magnesia would absorb the moisture, and the Gregory would be converted into a miscible. In proof of this, if the magnesia from which a non-miscible Gregory has been made be exposed for a time to the atmosphere, it will be found to have changed into a miscible on being made into Gregory. In the same way if a non-miscible Gregory be exposed for a time to the atmosphere it changes into a miscible, and on the other hand one perfectly miscible may to a certain extent be changed to a non-miscible by exposure for a time to a gentle heat, but in this case its non-miscibility will neither be so aggravated nor so aggravating as a powder which has passed through a Baker sieve.

The note on Gregory's Powder gave rise to considerable discussion, in which Messrs. Heron, Noble, Young, Symington, Napier and the President took part. Several of them had experienced the same difficulty as Mr. Gilmour, and had overcome it by different means. In connection with this preparation a very interesting document was submitted to the meeting, by Mr. Mackay, containing some prescriptions in the handwriting of the late Dr. Gregory, and among these was the recipe for Gregory's Powder, in the same proportions as it now stands in the British Pharmacopœia. The date on the prescription is December 22, 1816, and it is signed J. G.

Note on Physic Balls and Mass.

BY W. GILMOUR.

I do not know if my experience as an apprentice was a common one, but I can well recall after the lapse of all these years (not a few now) the feeling of aversion which I soon entertained to all veterinary medicines and to horse balls in particular. One of my earliest experiences was gained from an endeavour to make a good mass with olive oil. I was directed to melt the aloes in a large iron crucible over the fire, next to add a certain quantity of oil, and then stir till cold. If any of my young friends have a forenoon to spare, and want a little diversion, and do not mind wasting a little aloes, they may try this formula. The plan generally followed, however, was powdered aloes and soft soap a sufficiency. This at least made a mass, and what did it matter, although, to use the expression of an ancient farrier who patronized the establishment, they became through course of time "as hard as *chucky stones*." They were made to sell, and sell they did. Times have changed, and doubtless we change with them, and what suited the taste and fancy and wants of twenty of thirty years ago will not suit those, I need scarcely say, of the present day. Thoughts such as these were called up recently, when on turning over the pages of an old number of the *Pharmaceutical Journal* (December 22, 1877), I came upon an article on "Physic Balls and Mass." The paper was certainly in the direction of elegant veterinary pharmacy, but, unfortunately, what was new in the paper was not of much use to the general reader, and what might have been of use was not new. The somewhat elaborate, not to say expensive, paraphernalia therein referred to, placed it, I think, entirely beyond the scope of the great majority of its readers, whose aim, I take it, is not so much to supply so many gross on the shortest possible notice, as to meet the limited, but daily, wants of their own immediate sphere. For more than ten years I have used nothing but glycerine in the making of physic mass, and while in my earlier experiments I endeavoured to formulate the amount of glycerine necessary to make a proper mass, I soon gave up the hope of doing so, being persuaded that it was next to impossible. A change in the quantity of aloes operated upon, even although a corresponding proportion of glycerine was employed, a change in the temperature, a more or less lengthened exposure of the mass to heat in preparation, and probably many other causes also, modified the results obtained.

The plan I now adopt is to break up the aloes into small pieces, pour over it a little glycerine (about an ounce to each pound of aloes) to make it work freely, and when the aloes is melted, pour it on to a slab well smeared with glycerine, with which the aloes is worked up into a proper consistence. A good mass may in this way be obtained at any time, under any circumstances, with the use of a minimum of glycerine. The pan which I use for melting the aloes is one of my own devising, made of ordinary tin ware, and fitted up on the glue-pot principle—one pan fitting into another. When the balls are weighed they are first wrapped into waxed paper and then into ordinary counter paper, after which they are placed in their proper divisions *end up*. In this way I have a ball, I think, as near perfection as possible, and I never have any trouble from their falling or getting soft.

Mr. Gilmour afterward brought before the meeting the following—

Memorandum with Reference to the Weights and Measures Act, 1878 (41 & 42 Vict., c. 49).

It will be remembered that by a recent Order in Council the various weights, such for example as the 4 grain, the ½ drachm, the 2 scruple, etc., which were excluded in the original Act, have been legalized, together with the symbols ℈j, ʒj, and the only point now necessary to be observed is that these weights, together with every other, must be properly stamped.

I am not aware, however, of ever having seen a proper explanation of the order relating to apothecaries' measures, and therefore the following short account may not be uninteresting. It need only be further premised that the various points noted are now law, although it is not at all probable that the inspector will enforce it for some time to come. The first point to be noted is that every measure must be graduated into its own denomination—that is to say a measure glass graduated into ounces must not contain drachms, or one graduated into drachms must not contain minims and *vice versâ*. Each glass must either be all ounces, or drachms, or minims.

The second point is that each graduation must be distinctly marked on each measure glass. In the case of ounces each graduation must be distinctly marked with the number of ounces, but an intermediate half-ounce is also allowed to be graduated, although not marked half-ounce; the same applies to the drachms, but in the case of the minim measure each tenth minim only requires to be marked, and the law apparently admits of any number of intermediate graduations unmarked.

The next point is that no symbols are allowed, and all measure glasses must therefore be marked fl. oz., fl. dram., min., and each glass must also have marked upon it, t = 62° Fah.

The largest measure glass provided for is 40 ozs., but any smaller number may be legal, such for example as a 20 ozs., 10 ozs., 5 ozs., 4 ozs., down to ½ oz. In the same way the drachms and minims, I presume, may be legal up to or down to any reasonable number, but the exact limits I for the moment forget.

The last point to be observed is that the same rule applies as with the weights, viz., that wherever a measure glass is stamped or engraved it is legal in every other place if the stamp be the Government stamp of a crown, and V.R. The Order in Council provides for no distinctive mark in the case of the measure glass, and therefore the presumption is that it will be the same with the weights, but it expressly provides for or allows the engraving of the mark. It will be kept in mind that it is as much illegal to have a measure glass not engraved or stamped, as it is to have one incorrect in measure, or not conforming to the other requirements of the Act.

Some discussion ensued with regard to the glass measures and considerable difference of opinion was expressed as to the precise scope of the different provisions.

Mr. Mackay mentioned that last month when he was in London, this subject had been fully discussed and it had not then been definitely arranged, although a specimen of the proposed marked measure had been submitted, but not officially. From the remark made by the President of the Society in Bloomsbury Square, at the last meeting, it was evident that the Government was now about to take action in the matter, and he thought it probable, that, without much further delay, specific instructions would be issued and ample time given to chemists to get a series of the new measures for general use. In the meantime Mr. Mackay suggested that further inquiry might be made of the inspector of the Edinburgh district, and the meeting thereafter appointed the President, Messrs. Gilmour and Mackay for that purpose.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

Wednesday, November 5, 1879.

Present — Charles R. C. Tichborne, LL.D., Ph.D., President; Dr. A. Smith, Vice-President; Sir George Owens, M.D., Messrs. Brunker, Goodwin, Hayes, Hodgson, Oldham, Payne (Belfast), Pring (Belfast), Simpson.

The minutes of the meeting held on October 1 were read and signed.

The letter from Mr. Robert Barklie, F.C.S., read at last meeting, was now considered.

Proposed by Mr. Payne, seconded by Mr. Pring, and resolved—

"That the School of Chemistry in connection with the Working Men's Institute, Belfast, be one of the schools from which this Society will accept certificates of Practical Chemistry, provided Mr. Barklie conforms to the regulations of this Council."

Read letter from Messrs. T. Devlin, Sons and Co., Belfast, respecting the loss, by fire, of Mr. Frederick Devlin's certificate as pharmaceutical chemist.

Proposed by Mr. Hodgson, seconded by Mr. Pring, and resolved—

"To acknowledge the letter from Messrs. T. Devlin, Sons and Co., and to state that Mr. Frederick Devlin has passed his examination as a pharmaceutical chemist, and that a certificate was issued to that effect on 4th April, 1877."

Read a letter from Mr. James Acheson, Pharmaceutical Chemist, of Ballymena, making inquiries relative to the certificate for compounding presented by one of the candidates at the last pharmaceutical examination.

The Registrar to inform him that the Council are of opinion that Mr. Fennell is not authorized to answer private inquiries.

The letters from Mr. William Dowling, of Killarney, and Mr. William Prott, of Belfast, which were read at last meeting, were now considered in connection with the the notice of motion given by Mr. Holmes.

Mr. Holmes being absent, his motion by his request was proposed by Mr. Payne as follows:—

"That the Preliminary, Entrance, or Matriculation examinations of the following bodies be accepted by the Pharmaceutical Society of Ireland, in lieu of the Preliminary examination as at present required, viz.: Trinity College, the Queen's Colleges, the College of Surgeons, and the Apothecaries' Hall of Ireland. Candidate to pay entrance fee as heretofore."

The motion was not seconded, and was, by permission withdrawn.

Proposed by Mr. Brunker, and seconded by Dr. A. Smith—

"That the Preliminary or Matriculation examination of the College of Surgeons, or such other examination as is accepted by the General Medical Council as equivalent to it, and the Preliminary examination of the Pharmaceutical Society of Great Britain, be accepted instead of the Preliminary examination of this Society; such examination to be passed at least two years before the candidate presents himself for the licence of this Society. The usual fee of two guineas to be paid."

The following amendment was proposed by Mr. Payne, and seconded by Mr. Pring:—

"That the Preliminary examination of the Pharmaceutical Society of Great Britain be omitted, until the Council of that Society be asked if they will accept the certificates of candidates who have passed the Preliminary examination of the Irish Pharmaceutical Society, in lieu of their own Preliminary."

This amendment was lost, on a division, and the original motion (Mr. Brunker's) was then put and carried.

Mr. Dowling and Mr. Prott to be informed that the Preliminary examination passed by them shall be accepted in accordance with the foregoing resolution.

The Reports of the Examinations held in October were laid on the table.

At the Pharmaceutical examination held on October 1st, five candidates presented themselves, of whom the following three passed:—

David Baxter ....Ballymoney.
Patrick John Joseph English ...Mullingar.
Andrew McIlwaine ...33, High Street, Belfast.

At the Preliminary examinations held on October 6th and 7th, twenty candidates presented themselves, of whom eighteen passed.

Proposed by Mr. Brunker, seconded by Mr. Hayes, and resolved—

"That Regulation III. FINANCE (page 61 of Calendar), relating to members, read as follows:—'The annual subscription of elected members of the Society shall be one guinea, payable in advance on 1st October in each year, or a life composition of ten guineas.'"

Proposed by Mr. Brunker, seconded by Mr. Payne, and resolved—

"That the Chief Secretary for Ireland be requested to receive a deputation, who shall be empowered to explain the views of the Council with reference to the proposed amendments in the Pharmacy Act, and the working of the Poisons Act generally in Ireland."

The following to form the deputation, viz., the President, the Vice-President, Mr. Payne, Mr. W. Hayes, Mr. Brunker, Dr. Collins and Mr. Oldham.

Proposed by Mr. Oldham, and seconded by Mr. Hayes—

"That a circular be addressed to all licentiates who are not members, inviting them to join the Society."

Mr. Oldham read the draft of a circular prepared by him, setting forth the advantages to licentiates of becoming members of the Society. Some slight alterations were made in it, and it was then resolved—

"That the circular as thus amended be adopted and printed, and that a copy be sent to each licentiate of the Society."

Some bills were ordered for payment, and the Council then rose.

Provincial Transactions.

LEEDS CHEMISTS' ASSOCIATION.

The second meeting of the session was held in the library, Church Institute, on Wednesday, November 12, the President, Mr. Councillor Stead, in the chair.

The minutes of the former meeting having been read and confirmed, Mr. J. Slater was elected a member and Messrs. G. F. Bacon, F. Cooper, F. A. Graham, William Wallace and Henry Thorpe were elected associates.

Mr. James Abbott gave a lecture on Ergot, in which he illustrated upon the black board the various stages of the development of this fungus, and explained its action upon the involuntary muscles of the capillaries whereby hæmorrhage was checked. He was of opinion that the oil present in the ergotized grain was inert and that a fresh aqueous infusion answered all the purposes required. In order to keep the ergot free from parasites, it was best to powder it as soon as received, add a little water and then dry at a temperature not exceeding 212° F., constantly stirring so as to granulate the powder, in which condition it would keep well for two or three years though it was advisable to replenish the stock with new annually.

Mr. S. Taylor proposed a vote of thanks to Mr. Abbott for the very interesting and instructive lecture, regretting that there was not a better attendance of associates, for whose especial interest these monthly meetings were held.

Mr. E. Yewdall seconded the motion and thought it was very necessary there should be experiments instituted with various solvents in order to obtain a preparation which would give uniform results; although the subject had received a fair share of attention there was yet a difference of opinion, shown by the various preparations in the market, in some of which the oil was retained, giving a very unsightly preparation, whilst others prepared with water gave unsatisfactory results.

The President supported the motion and stated that a freshly prepared decoction in which the smallest possible quantity of water was used had been found to give the best results in a large obstetrical practice extending over a period of more than twenty-five years.

The motion was carried.

GRIMSBY CHEMISTS' ASSOCIATION.

A meeting of this newly-formed Association was held on November 12, at Druig's Hotel. There was a very fair attendance of chemists belonging to Grimsby and district. The business transacted was mostly of a preliminary or introductory character. The chief objects of the institution are to establish a uniform scale of prices in retail business as well as charges for prescriptions, etc., and to protect trade interests generally. An inaugural dinner was spoken of, to come off about the middle of January next, so as to supplement Christmas festivities. This proposition was heartily supported by all present, and the meeting then broke up. Good wholesome kindly feelings was manifest throughout.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of this Association was held on Thursday, November 13, 1879, when the President, Professor Attfield, occupied the chair.

The Secretary reported that during the last session the number of members had been ninety-one, and that the number of meetings had been seventeen.

A list of seventeen papers read at these meetings was read.

A Committee had been appointed to report on recent advances in pharmacy and allied branches to the Association, and reports had been presented on subjects in Chemical Physics, Inorganic Chemistry, Organic Chemistry, Analytical Chemistry, Botany, Materia Medica and Pharmacy.

The subjects of these papers and reports have already appeared in this Journal.

The Secretary then read the report of the Committee appointed at the Annual Meeting, for the obtaining of pharmaceutical papers of a practical character, which was adopted unanimously.

The election of officers was then proceeded with, Messrs. Drew and Jackson having been appointed as a Committee to examine the voting papers. For Vice-Presidents, Mr. H. Allen, Mr. R. H. Parker; for Committee, Mr. W. Elborne, Mr. A. F. Dimmock, Mr. J. Thomas, Mr. J. B. Taylor; for Secretary and Treasurer, Mr. W. R. Dunstan, 17, Bloomsbury Square, W.C.

The President then delivered his annual address as follows:—

THE PRESIDENT'S ADDRESS.

After addressing some words of welcome to old members, new members and prospective members, Professor Attfield reminded those who had recently joined the Association, that their aim should be threefold, namely, to get knowledge because they desired to pass the examinations; to get knowledge irrespective of that desire; and to become useful, active members of the Students' Association. To the extent to which they attained those objects would they afterwards become successful pharmacists and possibly leaders in pharmacy. Pharmaceutical education was technical and general. That which related to dispensing and the preparation of galenicals was technical; that which related to chemistry, physics and botany, was, for them, general. Materia medica was partly general, partly technical. The man who wished to become solely a chemist, or botanist, or physicist, must not only acquaint himself with the fundamental truths and principles, and analogies of chemistry, botany or physics, but must have a technical knowledge of the respective subjects. The pharmaceutical student, however, studying those sciences because they formed the basis of the practice of pharmacy, only went so far into them as to learn the general working of their laws, went far enough to enable him to take a broader view of his calling than he would otherwise possess, went far enough to enable him to anticipate as well as supply the demands of the public, went far enough to enable him to extend as well as occupy the area of his avocation. When properly taught and properly learned, they enlarged and improved the powers of the student's mind, not only as a man, but very specially as a pharmacist. The Pharmaceutical Society had for nearly forty years been directly and indirectly maintaining and encouraging courses of general education in these subjects at Bloomsbury and in connection with the provincial pharmaceutical associations, and had instituted examinations with the same objects. In the legal profession the subjects which occupied a similar position in general legal education as distinguished from technical legal education were, he was assured, Roman law, jurisprudence, and international law. In the medical profession the subjects of *general* medical education were much the same as their own. The efforts of the Pharmaceutical Society in promoting general pharmaceutical education were thwarted to the extent that students through too rapidly learning these subjects very rapidly forget them, possessing them indeed only long enough to enable them to pass an examination. There was, he feared, in pharmacy just now a tendency to depend too much on rapid teaching and too little on deliberate learning. He implored students to get knowledge not only on account of, but irrespective of their desire to pass the examinations. Their technical pharmaceutical knowledge would be kept bright by daily use in business, it was their general pharmaceutical knowledge which was liable to rust, and which therefore needed their utmost care as to its being of the right kind and of a lasting kind. He trusted too that those whom he addressed would also have the honourable ambition to some day become leaders in pharmacy and leaders in local efforts to promote the good of those around them. To that end he commended to their notice the machinery of the Students' Association and of similar associations. There was no better way of fitting themselves for such public, pharmaceutical, or other work than by compiling papers on chemical, physical, botanical, mechanical, or more specially pharmaceutical or galenical subjects, and reading them before their assembled fellow-students of the current or past sessions.

Mr. Branson proposed, and Mr. Gutheridge seconded, a vote of thanks to the President for his able address and for the interest which he takes in the welfare of the Association, which was carried unanimously.

A vote of thanks was then proposed by Mr. Taylor to the retiring officers, which was carried *nem. con.*

Mr. Hutchinson and Mr. Dunstan having responded to this vote, the meeting adjourned.

Parliamentary and Law Proceedings.

Is Nitrate of Potash a Poison?

At the Liskeard County Court, on Monday, before the judge (Mr. Montague Bere, Q.C.), an action was brought by Richard Young, chemist and druggist, of Liskeard, against Daniel Bray, farmer, of Alternun, to recover the sum of £2 2*s*., the cost of an analysis supplied defendant. Mr. Borlase Childs appeared for plaintiff, and Mr. Collings, of Bodmin, defended. According to Mr. Childs' statement, the defendant went to his client in September, last year, and complained that certain of his cattle had died, and he was unable to account for their death. Defendant said that he had been giving the cattle some "drenches," and the plaintiff said that they must have contained poisonous matter. Mr. Young told the defendant to send him one of the drenches, and he would have it analysed. This defendant did, and he expressed his intention of bringing an action against the person who supplied the drenches if they were found to contain poison. The plaintiff forwarded a sample to Messrs. Allen and Hanburys, Lombard Street, London, and on September 27, he received the following from them:—"The sample consists of nitrate of potash with a small admixture of some species of starch. It is entirely free from the poisonous matter, and from prussic acid, and carbolic acid. The poisons, if any are present, must therefore be sought by a complete poison analysis. The starch could only be identified by an expensive, and perhaps useless, search." Mr. Young then informed the defendant that the drenches contained nitrate of potash, and that if he wanted the analysis he would have to pay £2 2*s*. He agreed to take it upon the terms named, and defendant was entered as a debtor to plaintiff, but for some reason or other defendant thought fit not to pay the sum. The action was accordingly brought to recover the sum paid for the analysis.

Plaintiff was called, and said he was led to believe that there was poison in the drenches from the description of the death of the animals given by defendant. Witness told him that if the analysis did not prove there was poison he would pay for the analysis himself. He had paid the fees for the analysis, which stated that there was nitrate of potash in the drenches.

His Honour: What did you pay for the analysis?

Witness: The charge was £2 2*s*., but I got a discount of 20 per cent. allowed.

His Honour: So you paid £1 14*s*. for it?

Witness: Yes.

His Honour: The analysis produced is no analysis at all. It does not state the quantity of poisonous matter in it, and to say that a certain mixture contained two items without mentioning the quantities was not a complete analysis, and if you paid £2 2*s*. for that you are a very unwise man.

Witness: But it proves that there was poison in the sample.

His Honour: But nitrate of potash used in certain quantities is not poison, and you told the defendant that you would take the risk of the analysis as to its containing poisonous matter.

Witness: There was a large quantity of nitrate of potash contained in the drenches. I understood this to be the case from the analyst.

His Honour: Well, he does not state in the document what the amount was.

Witness: I understood that it contained more than 80 per cent. of poison.

Mr. Collings contended that the analysis spoke for itself. They did not require to go any further into the case.

His Honour reminded Mr. Young that the analysis did not even state that nitrate of potash was a poison.

Mr. Childs: But it is a fact that it is a poison.

His Honour: The document does not show that the poisonous matter was there in such a quantity as to cause death.

Mr. Childs reminded his honour that the only question was whether his client was entitled to the sum he paid for the analysis.

His Honour gave a verdict for defendant.—*Western Daily Mercury.*

Action for Protection of Trade Mark.

In the Supreme Court of Judicature, before Lords Justices James, Baggallay and Thesiger, on Monday, November 17, an appeal from the decision of Vice-Chancellor Malins in the case of Dence *v.* Mason, was heard.

The action was brought by Thomas Dence and John James Mason, carrying on business as provision dealers in Little Stanhope Street, Mayfair, under the title of Brand and Co., to restrain the defendant, Frank Mason, from selling any essence of beef, concentrated beef-tea, meat lozenges, or other meat essences in tins, or otherwise having thereon labels or wrappers in imitation of the labels or wrappers used by the plaintiffs, and from using the name of Brand, either alone or in combination with Mason or any other name, in the manufacture of these articles in such manner as to represent or lead to the belief that the articles made by the defendant had been manufactured by the plaintiffs. The plaintiffs' firm was established about forty-five years ago, when the business was conducted by Mr. Henderson William Brand, and was, about the year 1835, acquired by Mr. Withall, who, on September 29, 1875, sold the same to the plaintiff, Thomas Dence, for the sum of £5000. The business had always been carried on under the name of Brand and Co. The plaintiff, John Mason, was for fifteen years employed as the manager of the business; and the defendant, who is his brother, was for about fourteen years prior to March, 1874, when he left the plaintiffs' service, employed as an assistant in the business. After leaving the firm he entered into partnership with a grocer in Sloane Street, named Brand, and commenced the sale of essence of beef and other articles of a similar nature under the style of Brand and Mason. This he was constrained by a consent order from doing, and he then called the firm Mason and Brand till the partnership was dissolved at the end of 1874. After that he continued the use of the word Brand in one form or another upon his labels, and this action was commenced in December, 1876. In February, 1878, the Vice-Chancellor granted a perpetual injunction against the defendant, with costs. Afterwards the defendant became a bankrupt. He appealed from the judgment, but the trustee in his bankruptcy was not made a party.

Mr. Solomon was for the appellant; Mr. Glasse, Q.C., Mr. Bristowe, Q.C., and Mr. Freeman were for the plaintiff.

Their Lordships had at first some doubt whether the defendant was entitled to appeal, but they ultimately decided that he could appeal from the injunction, which was a personal order against him, notwithstanding the bankruptcy, though he had no interest in the order as to costs, his estate being now vested in the trustee. But on the merits their Lordships agreed with the Vice-Chancellor and affirmed his order with this exception, that they thought it went too far in restraining the defendant from using the names of Mason and Brand, and that it ought to be qualified by inserting a proviso that the injunction was not to restrain the defendant from using the names of Mason and Brand *bonâ fide*, if and when there should be a real partnership properly designated by that name. But this alteration was not to affect the costs of the appeal, which must be paid by the defendant.—*Times.*

Obituary.

Notice has been received of the death of the following:—

On the 26th of October, 1879, Mr. James Barnes, Pharmaceutical Chemist, Fishergate, Preston. Mr. Barnes was a Local Secretary of the Pharmaceutical Society, of which he was also one of the Founders, having joined it in 1841.

On the 1st of November, 1879, Mr. James Pasmore, Pharmaceutical Chemist, King's Road, Chelsea. Aged 65 years. Mr. Pasmore had been a Member of the Pharmaceutical Society since 1842.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[345]. In reply to Mr. Fox, with regard to the proper mode of dispensing this injection, I may say that the presence or absence of a precipitate in certain patent medicines of comparable composition does not justify us in assuming that it is right to imitate the plan there adopted. I very much question whether "Injectio Brou" and similar remedial preparations have their efficacy increased by the insoluble lead salt; but if Mr. Fox can point out any book on therapeutics that recommends sulphate of lead for its "soothing properties," or, indeed, for any medicinal purpose, I shall be glad to see it. He will consult the standard works of Pereira, Christison, Neligan, Royle, Waring, or Adolphe Wahltuch, without avail. It is not even included in the 'Pharmacopée Universelle.'

I may repeat that I have known prescribers ordering such a lotion who were quite unaware of the chemical incompatibility, and others who meant the precipitate to be filtered out. Such a mixture is often used as a collyrium, and a muddy sediment diffused through the liquid would not be very nice for such a delicate and sensitive organ as the eye.

The writer of "The Month," while allowing that it is unusual to filter, directs that a "Shake the bottle" label should not be put on, and further adds "the deposit is not considered an essential part of the remedy or one that possesses any value. The dispenser, therefore, has nothing to justify him in ordering the bottle to be shaken." The last quotation is sound sense, but coupled with the first allusion seems to indicate a degree of uncertainty if not an evasive reply. If lead sulphate be useless, why retain it, especially when many patients have acquired the habit of shaking up the sedimentary deposits in their medicaments before administration? Thus all the precautions of the dispenser would be rendered useless.

J. B. L. Mackay.

---

[365]. It was no doubt a slip of *Lavandula's* to mention "Potass. Bicarb." as a constituent of this ointment—but his suggestion to use double quantity of the potash salt is not a good one.

I differ from *Pot. Carbon.* in the opinion that a creamy ointment cannot be produced with fresh official ingredients. Doubtless, however, much depends on manipulation and the amount of exposure to air. Omitting the water in the iodide of potassium ointment, and using lard free from moisture, would retard the decomposition, but sooner or later the chemical change is inevitable—hence the prescriber should be informed of the results and questioned as to his intentions.

J. B. L. Mackay.

*** *Lavandula* writes to say that "Potass. Bicarb." was a mistake for "Potass. Carb."

---

[370]. Rub the two extracts with a few drops of boiling water to a smooth paste, then mix them thoroughly with the lard and a smooth ointment will be the result. This is similar to No. 359.

Lavandula.

[370]. J. Y. should rub the extracts in a mortar with a little hot water, warming the mortar at the same time will diminish the labour. When smooth and soft add the adeps and thus a good ointment may be turned out.

J. M.

[370b]. Rub down both the extracts to a smooth paste with a little hot water, then mix thoroughly with the prepared lard.

J. B. L. Mackay.

---

[371]. P. T. W. will find by using the proper acid. carbolic. crystal., that no excipient is necessary, as a good enough mass can be had from the ingredients in the prescription, mixing first the powders, adding the acid last.

J. M.

[371]. In reply to P. T. W., I beg to state that if P. T. W. will try spts. rect. as an excipient for his pill mass, he will (I think) find it answer admirably. By virtue of its solvent power, it will to an extent operate on the guaiacum resin, so that a large quantity of ferri arsen. or other dry powder may be added at leisure.

H. R. L.

---

[372]. This might be dispensed in the following manner. Weigh the proper quantity of phosphorus, say gr. j. Melt with, say gr. x. each, bals. tolu. and cera flav. under water, using a small dish half full of warm water, mix well under water. When cold take $\frac{3}{5}$ part for 30 pills and mix with the quinine and iron, making it into a mass with s. v. r. These pills should also be coated.

J. M.

---

[374]. Dilute the liq. potassæ with a fluid ounce of water, pour into the right sized bottle and add all at once the cod-liver oil, shake vigorously, and gradually add the remainder of the water, shaking well on each addition.

J. B. L. Mackay.

[374.] The quantity of liq. potassæ ordered in this prescription is insufficient to saponify the oil, therefore a little more must be used, and the water to be added gradually, shaking after each addition.

Lavandula.

---

[375]. I had the enclosed sent me to dispense to-day, it was neatly printed on pink paper. Can any correspondent inform me how to do it?—

Dermaline.

℞	Acidi Malachiti	♏v.
	Acidi Acetici.	♏x.
	Tinct. Amyrru.,	
	Balsam. Nervini	āā ♏xx.

According to the directions it is intended for removing corns, etc.

Is the third intended for tr. myrrhæ, and is not nervine balsam a solid ointment?

L. J. Latham.

---

[376]. I enclose copy of recipe that came into my hands yesterday, can any of your readers kindly tell me what should be given?—

℞	Ol. Origani	5 drops.
	Ol. Apii.	½ ounce.
	Ol. Carui.	5 drops.
	Com. Ex. Valeriat.	30 drops.
	Com. Ex. Sesquianha Rad.	j dram.

Sp. Rect. to make an ounce.

Robert Rogers.

Notes and Queries.

[634]. COLOURING FOR WAX.—*Epsilon* will find that colouring the turpentine with anchusa is a very good plan, viz:—

℞	Rad. Anchusæ	ℨij.
	Spt. Terebinth.	℥xvj.

Macerate two or three days with occasional agitation and filter through tow.

Then melt your wax in the coloured turpentine.

C. H. Bradshaw.

[634]. Digest in a warm place a small quantity of alkanet root, with the turpentine and wax, until sufficiently coloured. I have no doubt but that this will answer *Epsilon's* purpose.

Lavandula.

[634]. Immersion of fragments of alkanet root (enclosed in a muslin bag) into the melted wax will impart beautiful red more or less deep according to requirements.

J. B. L. Mackay.

---

[635]. SALICYLIC MOUTH WASH.—Would any reader oblige with a good formula for "Salicylic tooth and mouth wash"?

Jacque.

[636]. DR. STARTIN'S POMADE.—Will one of your readers oblige me with the formula of "Dr. Startin's Pomade?" It is used for scurf, etc.

W. Richards.

[637]. CROTON CHLORAL.—Will some correspondent kindly oblige by giving a method of determining the purity or otherwise of croton chloral.

Quidnunc.

---

[638]. CLEANING OF PAINTINGS.—Will any of your readers kindly furnish me with the method of cleaning oil paintings with peroxide of hydrogen, its application, and the manner in which it acts?

H. W.

---

[639]. PRINCE'S BALSAM.—Can any of your readers inform me, if there is any authority for a preparation called "Prince's Balsam?"

H. A. Howe..

Correspondence.

Sale of Drugs in Doctors' Shops in Glasgow.

Sir,—Being in Glasgow for a few days lately, I was surprised at the comparatively small number of qualified chemists carrying on business in that greatest of Scotland's commercial cities. I was told by an authority that there were nearly one hundred "doctors' shops" on the south side of the river. Curious to know how they conducted business in those shops I called at one in Crown Street and demanded 15 grains of Dover's powder. I was served by a girl apparently about sixteen years of age, and who appeared to have charge of the dispensing department. She did not appear very familiar with the apothecaries' weights, but at last succeeded in getting 13 grains into the scale pan. The powder appeared dark in colour and not like the genuine article, but as the girl did not appear to possess much pharmaceutical knowledge, I paid the moderate charge of 1½d. and departed. On arriving at my lodgings and examining the powder, I found that it had little taste and no smell, and although I did not get it analysed, I am sure that it did not contain the proper proportion of either opium or potass. sulph. On going back to the shop, and asking the doctor if the article was the pulv. ipecac. co., B.P., he very coolly told me that no druggist could sell me Dover's powder without a prescription, at the same time refusing to give me back what I had purchased of the girl. I observed that some of his other medicines appeared to be much of the same character as the pulv. Doveri, but of course unless analysed according to Act 38 and 39 Vict., cap. 63, no penalty could be imposed. What, with your kind permission, I want to ask your correspondents, is—

1. Is it lawful for a doctor to keep a girl not qualified, for the purpose of dispensing medicines?

2. Is it lawful for a doctor, such as the above, to keep an open shop for the purpose of retailing and dispensing medicines?

3. As I see a great many grocers selling citrate of magnesia; and ironmongers and others selling poisonous sheep dips. Is this lawful?

If some of your numerous correspondents will kindly supply the information required, they will greatly oblige.

GEO. CORMACK.

DRUGGISTS' SUNDAY WORK.

Sir,—I was very pleased to see in a recent Journal the letter of Mr. Long on the above subject, and I, as an advocate for early closing, fully endorse his remarks, and I really do think that the late hours and constant confinement of many of our brethren are most undoubtedly the sole cause of them "departing this life" much earlier than they otherwise would if they would only give themselves more liberty for recreation, etc. It is indeed very painful to see in the obituary of our Journal the comparatively young ages at which chemists succumb. I have now closed (in conjunction with my neighbour) at 8 p.m. for over three years, and I find that it does not interfere with business in the least, it works very well, and may, I think, be extended to other chemists in the neighbourhood if they would only unite. I am sorry to say that my brethren within ten or fifteen minutes' walk of me keep their shops wide open every night until 10.30 or 11 p.m. and I feel certain that the amount of business they do as a rule after 8 or 9 o'clock cannot pay for gas. Besides they are daily injuring their bodily health and I should not be surprised to find their names down in the obituary at any time. They are not even content with the late hours on week days, but must open on Sundays from 5 or 6 in the evening till 10.30 or 11, which to my mind is very bad taste, and it takes the respectability of the establishment off at once. I do not deny for one minute but that it is necessary to be on the premises at certain hours to supply the "needful," but to invite a Sunday trade by the lighting of the lamp and opening the shop is altogether quite uncalled for. I never show a light in the evening of Sunday (or any Bank-holiday), excepting I should be engaged in dispensing, but the gas is turned out directly.

FREDERICK D. HEATH.

30, *Highbury Park, N.*

Sir,—Now that Mr. Nicol's health question has been duly discussed in the Journal, would you kindly allow me to ask what a chemist's shop is open on Sunday for? Whether is it for the sale of medicines and medicines only, or perfumes, confectioneries, soda water, tobacco, cigars, etc.? I always had an impression it was for the former, but have met with several, who say, that you cannot well refuse to supply anything that may be asked for, while the shop is open. Is this right? Perhaps some of your readers will oblige with their opinion of druggists' Sunday duties.

JEK.

EXTRACT OF MALT.

Sir,—As an illustration of adage "There is nothing new under the sun," I send the formula copied from an old book, viz., 'Pharmacopœia Bateana,' date 1693. At the present time when ext. of malt, either alone or in combination, seems so popular, it is interesting to find that it was prescribed for the same class of diseases at that remote period as it is now.

Extm. Maltæ Compositum.

℞ Leaves of Coltsfoot,	
Spotted Lungwort . . . . . . :	℥vj.
Liquorice	℥viij.
Raisins, stoned	℔ij.
Strongest Ale, not hopt, of a due age .	Gall. vj.

Boyl to the consumption of gall. iv., then express strongly and evaporate to the consistency of honey. Dose: ʒij twice or thrice a day, against the phthisick or consumption of the lungs, etc.

C. S. MILLER.

R. H. L.—Recipes for materials for stopping teeth will be found in vol. vii., p. 706.

G. D. R.—The *Chemical News* is published weekly, and the office is in Boy Court, Ludgate Hill. The *Analyst* is a monthly journal, and is published by Baillière, Tindall and Cox, King William Street, W.C. Application as to terms of subscription should be made at the respective publishing offices.

R. Modlen.—The botanical origin of Damiana was first determined by Mr. E. M. Holmes, and published in this Journal, vol. vi. (1876), p. 581. See also other notices of the drug in the same volume, pp. 24 and 423 (figure).

"*Surrey.*"—(1) The pod has been received and will receive attention. (2) The fee, which is for registration, must be paid, if a certificate of another examining body be accepted, and the person, after registration, stands in exactly the same position as to the Bell Scholarship, and in every other respect, as if he had passed the Society's examination.

"*Pil. Rhei Co.*"—It would be against the rules of this Journal to invite an expression of opinion upon the merits of a particular apparatus. The recipe you require would probably be supplied by the manufacturer.

Hampton.—A good transparent cement may be made by warming best transparent gelatine, cut small, with a little acetic acid until liquefied. Other recipes have been given in back numbers of this Journal.

H. Eeles.—We can only refer you to the numerous advertisements in another part of this Journal.

"*Pickering.*"—The definition is to be found in most modern works on English grammar.

K. K.—(1) See the note on "Green Extract Suppositories," vol. ix., p. 949. (2) See the remarks on ext. taraxaci liq., Dispensing Memorandum No. 10, vol. viii., 145.

"*Inquirer.*"—See remarks on Dispensing Memorandum No. 259, vol. ix., p. 797.

C. Swinn and *Chemist and Dentist.*—We are obliged for your letters, and think that the use of the alternative terms in the Act was intended to indicate, as the words of the section purport, that the exemption provided by the sixth section had reference to all persons who were at the passing of the Act *bonâ fide* engaged in the practice of performing operations upon the teeth. We think the most ordinary common-sense view of the case, as well as the terms of the Act itself, are alike sufficient to justify this view should the position of pharmaceutical dentists ever be disputed.

A. Billington.—Your inquiry should be addressed to a rabbit fancier, or to the editor of the *Field* or of *Land and Water*.

D. K. Whitlock.—The communication of which you speak as having been forwarded has not been received.

Scrutator.—The precipitate is probably hydrobromate. A paper upon an analogous case is to be found in the *Pharm. Journal* for July 30, 1870, p. 96.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Stocks, Haydon, Toomey, Sumner, Harrington, Stott, Thompson, Liebig and Co., Inquirer, One who would try to be even with them, Noris, H. R. L., A. P. S.

"THE MONTH."

The sudden accession of severe weather has stripped the gardens and hedges of the last lingering traces of flowers. Mulberry trees that on the 13th instant were covered with leaves, at 10 o'clock the next morning had shed every leaf, and from the fine bracing weather of autumn we are suddenly landed, as it were, in the middle of December or January. The Gardens at Kew, except in the hothouse, hardly show a flower anywhere. A solitary hellebore in blossom and a single Boraginaceous plant were the only ones that were noticed in the Herbaceous Ground on a recent visit.

In the Economic House at Kew there are at present in blossom the Assam tea plant, the staminate plant of the papaw tree, the ground nut (*Arachis hypogœa*), *Petiveria alliacea*, and the sour varieties of the tobacco plant. The boldo tree is in bud, and will probably be in flower in another week.

At Mr. Bull's nursery at Chelsea, during the early part of this month, *Gentiana Kurroo*, an Indian medicinal plant, was in blossom. The root of this plant appears to have been frequently confounded with that of *Picrorrhiza Kurroa*, a Scrophulariaceous plant, which is also intensely bitter.

In *Flora*, Dr. Otto Kuntze has a long paper on "The Relationship of Seaweeds and Flowering Plants." He would trace the derivation of the Angiosperms from the Carposporous algæ, and the Gymnosperms from the Oosporeæ.

At a recent meeting of the Royal Horticultural Society, Professor Henslow exhibited a curious specimen of *Begonia*, in which the connectives of the anther were developed as stigmas. Dr. Berggren has stated his opinion that the further plants are found from the centre where they are most abundant and luxuriant, the greater is their tendency to produce male plants, or male inflorescence, while, in their native home, the tendency is rather to produce the female plant. It would be interesting to know whether an improvement in the circumstances of the plant led to this curious phenomenon noticed in the Begonia.

At a recent meeting of the Linnean Society, Professor Henslow read a paper on the origin of the scorpioid cyme, which he considers to belong to the indefinite or centripetal system. He points out that the flower sometimes found in the fork of the two branches of the inflorescence in *Myosotis* is not the terminal bud of the primary axis, but belongs to one or other branch of the inflorescence, and owes its position to the adhesion between the terminal and the highest axillary raceme. He considers that this form of inflorescence owes its origin to a new principle of phyllotaxis, by which opposite decussate leaves are resolved into alternate, the ordinary spiral line *oscillating* through three-fourths of a circle, so that if a line be drawn from flower to bract it will represent the scorpioid cyme (or rather raceme) of the *Boraginaceæ*.

The well-known fungologist, the Rev. M. J. Berkeley, has recently met with a specimen of *Polyporus varius*, bearing asci, containing spores, on the pores beneath the pileus. A similar occurrence on the hymenium of *Agaricus melleus* was described by De Barry some years ago. If this be not a parasitical growth, but a natural, though rarely seen development in the hymenomycetous fungi, it will open a new field of observation, and probably modify to a certain extent the views held concerning the reproductive organs of this group of fungi. A drawing of asci and spores may be seen in the *Gardeners' Chronicle* for Nov. 15.

A writer in the same journal makes some curious remarks with regard to cowbane, *Cicuta virosa*, which are worthy of attention. He states that it is certainly eaten by cattle wherever they can get at it. He has frequently examined the sides of those pits where it grows abundantly and where it is regularly cropped as far as a cow can reach, and he can find no sign of its being dropped after it is bitten. He has never been able on inquiry to hear of any suspicious death or illness of cattle in the neighbourhood where it grows. He has also seen *Œnanthe crocata* quite cropped down, while *Œnanthe Phellandrium* is never touched by the cows. Unfortunately the address of the writer is not given, but even supposing it to be in the North of England or Scotland, it is interesting to know that *Cicuta virosa* and *Œnanthe crocata* do not prove poisonous to cattle in some localities, since the latter is known to be remarkably fatal to human beings. The effect of eating the plants upon the milk of the cow is one that needs inquiry.

Those who have visited the hothouse containing succulent plants at Kew must have noticed a peculiar feature in the spines of many of the cacti, viz. that the tips are frequently dark coloured. In that very valuable work, 'Notes of a Naturalist on the "Challenger,"' the use of this discoloration is pointed out in a very interesting manner. The author believes it to be intended to protect the plants from being devoured by animals, for he has observed that on attempting to touch the end of one of the spines it is almost impossible to do so without getting pricked, owing to the illusion produced by the dark tips of the spines causing a miscalculation of distance. Animals in this way probably get severely pricked and learn to avoid the plant. The black tips being almost invisible as viewed at many angles, the spines look as if they terminated where the white portions of the spines end and consequently the hand is advanced as if the prickles began there and is pricked suddenly by the unseen black tips. This feature, however, is not present in several species of *Opuntia*.

Some time ago attention was called in these columns to the discovery of the largest aroid known, *Conophallus titanum*, by Dr. Beccari, and now there is announced the discovery of the smallest in the world. It is called *Microcasia pygmæa* and inhabits moist rocks, etc., in Borneo. The whole plant is not more than one inch high and has fleshy lanceolate obovate leaves, with rose coloured spathes just appearing above them. The spathe is deciduous, separating above the base, and has a cup-like appearance.

Most of those who use the microscope are familiar with the beautiful little object called *Volvox globator*, one of the fresh water algæ, and know how difficult it is to keep in a healthy state. Mr. N. E. Brown, of Kew, has found that if it be kept out of doors in a bottle or vessel exposed to the drip from a roof, it keeps in good health and multiplies freely. Mr. Bolton, of Birmingham, has recently sent out specimens of this beautiful little plant in a very rare state, namely with antheridia, which are readily distinguished by their orange colour.

Several changes have recently been made in colonial botanical gardens. Dr. Trimen, senior assistant in the Botanical Department of the British Museum, and well known, not only for his disinterested labours as one of the editors of the *Journal* *of Botany*, but also in connection with Professor Bentley as one of the editors of the very valuable and well known work on 'Medicinal Plants,' has been appointed director of the Botanical Gardens of Ceylon. Fortunately he has been able to complete 'Medicinal Plants' before leaving. It would have been a matter of regret had it been necessary to leave this work unfinished, as it will undoubtedly be the standard work on the subject for many years to come. The Government may be congratulated on their choice of one who is not only an able botanist but who is peculiarly fitted by his special knowledge of and interest in medicinal plants for the duties which will be incumbent on him in an island where cinchona, cinnamon and other plantations of great value and extent form important branches of industry. The invariable kindness and courtesy experienced at his hands by all inquirers, and the readiness with which he at all times frequently spends both considerable trouble and time in helping amateur botanists to determine knotty botanical points, indicate that his Directorate will be a highly gratifying one to all who are concerned in it.

Mr. H. Marshall Ward, scholar of Christ's College, Cambridge, who read a valuable paper on the development of the Embryo in Phanerogams at the Linnean Society last week, goes out with Dr. Trimen as cryptogamist, for two years, to investigate the coffee leaf disease in Ceylon.

Mr. D. Morris, B.A., former assistant director of the Botanical Garden at Ceylon, is appointed to be director of the Botanical Department, Jamaica, and other changes in the superintendence of the botanical gardens at Jamaica, Demerara and Trinidad have also taken place.

The *Gardeners' Chronicle* states that the fruit of the *Ptelea trifoliata*, or wafer ash (so-called from the resemblance of its fruits to a wafer in shape and thinness), has been tried in France as a substitute for hops in beer. The quality and flavour are reported equal to the best Strassburg beer. The tree is called the hop tree in the United States, on account of the fruit having the odour of the hop. The bark of the tree is used in medicine in the United States in cases where a soothing tonic is required to relieve debility after fevers or gastro-intestinal irritation, and can be taken where other tonics are rejected. As the fruits probably contain the same alkaloid, berberine, which is found in the bark, beer made from the *Ptelea* fruits may be expected to prove quite a semi-medicinal drink, and will possibly be free from the slightly narcotic influence of the hop. Without going to America, there is an extremely common plant in this country having not merely the odour of the hop in a powerful degree, but also its bitterness, viz., *Teucrium Scorodonia*, which would prove an excellent substitute for hops when such is required. It also possesses the advantage of having been proved to be very useful in the relief of pyrosis, or water-brash, and as a stomachic tonic.

According to a paragraph quoted in the *Pharm. Zeitung f. Russland* (Oct. 1, p. 591) the juice of a South American species of *Ocimum—O. basilicum*—known in Brazil under the name of "albahaca," is a valuable anthelmintic. It is said to rapidly cause the removal of the worm in any stage of its development, whilst if no worm be present it simply exercises an aperient and antiseptic action. Fifty grams of the juice are administered, followed about two hours afterwards by a dose of castor oil.

In a St. Petersburg weekly medical journal (quoted *Pharm. Zeit. f. Russl.*, Oct. 15, p. 623), P. Filatow reports that in the provincial hospital of Ssaransk, during the last three years, an infusion of sunflower (*Helianthus annuus*) has been used in numerous cases of intermittent fever and in most of them with results as certain and satisfactory as those following the use of quinine. The "infusion" used was prepared by digesting sunflower stalks, cut into small pieces, during three or four days in eight parts of ordinary brandy; it is described as being then of the colour of sherry and tasting of sunflower. The dose for adults was a tablespoonful three times a day, and the action is said to have been equally favourable whether administered before or during the paroxysm of fever. In fresh cases of fever the cure was completed in from one to three days, but in more confirmed ones the use of the infusion required to be continued during a week or longer.

In the *Deutsch. med. Woch.*, No. 34, Dr. Auerbach, of Berlin, recommends the use of balsam of Peru for pruritus as well as for itch, having found its use attended with the greatest success.

Dr. E. U. Kerr, in the *British Medical Journal* of November 1, reports a new and important use for nitrite of amyl. He has found its inhalation in doses of 5 minims to cause even severe *post partum* hæmorrhage to cease.

A specimen of "saffron" is described M. Boutet in the *Répertoire de Pharmacie* (vii., 469), which requires almost a stretch of courtesy to accord to it the term adulterated. It was found to contain only 25 per cent. of true saffron, the other 75 per cent. being made up of sulphate of lime (25 per cent.), glucose (20 per cent.), colouring matter, water, and the stalks and radicles of a dicotyledonous plant. Another commercial specimen of saffron, which recently came into the hands of Herr Martenson, of Dorpat, for examination, was found by him (*Pharm. Zeit. f. Russl.*, Oct. 15), to contain 39 per cent. of calcium carbonate (the total ash in a genuine specimen being about 6 per cent.), some foreign colouring matter, and saccharine matter, probably honey. Although similar adulteration of saffron has been long ago recognized and pointed out, the practice appears still to possess considerable vitality.

The same Russian journal also mentions (*Pharm. Zeit. f. Russl.*, Oct. 1) a spurious "essential oil of bitter almonds" which has occurred in the market for some years, but the origin of which is not known, it not being the volatile oil of cherry-laurel, peach kernels or apricot kernels. It differs from the true essential oil of almonds in its specific gravity being only 1·029 to 1·030; that of the true oil, according to 'Pharmacographia,' varying between 1·061 and 1·065, or when purified, according to Umney, 1·049. The spurious oil has also a less agreeable and more acrid smell. Boyveau indicates as a means of distinguishing between these oils their behaviour towards concentrated sulphuric acid. With an equal volume of the true oil the mixture acquires a beautiful red colour that becomes gradually darker, but the liquid remains thin and clear. The essential oils from peach and apricot kernels also turn red at first, but become dark red more rapidly; the mixtures also become thick, but remain clear. Cherry-laurel oil behaves similarly, but becomes immediately very dark red. The mixture of the spurious oil with sulphuric acid also becomes red, but afterwards brown, and then thick and turbid, and after one day forms a stiff brownish mass.

At the drug sales in London this month, an unusually large quantity of Siam benzoin in the tear was offered, also a small quantity of Sumatra benzoin in the tear, a form in which it rarely occurs. In this state it differs from the Siam in having a paler colour and more dusty surface, and has not the peculiar vanilla odour of the Siam benzoin. Balsam of tolu also appeared in quantity. Among those of less common occurrence were noticed kamala, condurango bark, myrtle wax, German chamomile, Para tonquin beans, Ceylon cardamoms and araroba. Among spurious drugs offered were jaborandi, consisting of leaves of a species of pepper, false buchu (*Empleurum serrulatum*) and horse-cassia pods (*Cassia grandis*).

In Messrs. Gehe's 'September Report,' it is stated that owing to the Zulu war the supply of Cape aloes had stopped during the preceeding six months.

Calabar beans are stated also to have been scarce. Several packages of these beans have, however, been offered for sale during the last few drug sales in London, and some of them of good quality.

In South Italy the olive trees have suffered much from drought and not even a moderate supply of oil is reported, so that an advance in the price of olive oil also may be expected.

Owing to the great demand for artificial benzoic acid its value has increased 10 per cent. in spite of the establishment of new factories. It is now prepared both in France and Germany, not only, as formerly, from the urine of herbivorous animals, but also from the toluol of coal tar. This has a much less penetrating peculiar odour than that made from urine, but does not yield such fine crystals.

Messrs. Gehe's agent in Shanghai reports concerning rhubarb that the Shansi root is scarce, since from its low price the natives of the Shansi mountains have found it unprofitable to collect it. This is probably due to some extent to the fact that it is mostly of inferior quality and dried with less care, apparently in ovens, in which case it soon rots in the centre or is attacked by insects.

The district of Tanyue in the province of Sze-chuen yields a good and cheap rhubarb. "This variety is in much demand in London where it is called high dried Shanghai rhubarb." It is easily distinguished from the more woody and fibrous Emow-Wo brand, which is collected in the Kwanyue district of Sze-chuen, by the wartlike points on the upper surface, and by its hard bony exterior. The stock of the Shansi rhubarb in Shanghai is said to be about two hundred chests, and that of Sze-chuen rhubarb from six hundred to seven hundred chests.

According to Dr. Septimus Piesse, in a letter to the *Times*, the produce of the lavender and peppermint farms at Mitcham, Merton and Carshalton, in Surrey, and at Hitchin, in Hertfordshire, has fallen this year 40 per cent. below a seven years' average, and since August, 1876, the crops have suffered from want of sunlight and temperature. A rise in the price of the oils of these plants may therefore be expected.

It is interesting to notice that after a general acceptance during several years of Mantegazzi's theory as to the beneficial influence of odoriferous plants upon the atmosphere, because of the formation of ozone induced by the oxidation of their essential oils, a continental chemist has just been publishing his reasons for believing that the hitherto belauded ozone may exercise an injurious and even poisonous effect when breathed. Whilst doctors are thus disagreeing, Mr. Rimmel steps forward with Christmas novelties in the shape of "ozonized" lavender water, eau de cologne and florida water, the special merits of which, it is claimed, lie in their power to evolve ozone. How the ozonization is accomplished does not appear, but his "aromatic ozonizer," another device by which the same effect is produced, was shown in the Paris exhibition, and was understood to be a fine sawdust saturated with oil of eucalyptus.

Attention is being called by our contemporary, *Iron*, to the value of the gum euphorbium for coating iron exposed to the action of sea water. It not only, by its poisonous properties, prevents the adhesion of marine animals, but it also keeps the iron from rusting.

The possibility of utilizing the banana fruit in the production of alcohol has been under the consideration of the Academy of Sciences more than once recently. M. Buignet has found, that during the whole growth of this fruit the saccharine matter is constituted entirely of cane sugar, but the proportion varies considerably. From some results of analysis published by M. Correnwinder it appears that a sound ripe banana fruit contains as much as 22 per cent. of its weight of sugar, 16 per cent. being crystallizable and the remainder uncrystallizable. In the mature sugar cane the proportion of cane sugar present is, according to Payen, 18 per cent. After the banana has become quite ripe there is a rapid diminution in the proportion of crystallizable sugar and an increase in the proportion of inverted sugar, but not to the same extent. An over ripe fruit, the flesh of which had become very mellow, contained only 2·84 per cent. of crystallizable and 11·84 per cent. of uncrystallizable sugar, being a total of 14·68 per cent. or two thirds of the original quantity.

In a communication to the Berlin Chemical Society (*Berichte*, Nov. 10, p. 2059), G. Bruylants describes a method of preparing hydriodic and hydrobromic acids, based upon the property possessed by the halogens of combining at ordinary temperatures with certain organic substances, and under the influence of heat separating again in the form of hydriodic or hydrobromic acid. The organic body preferred by Bruylants belongs to the class of terpenes, it being the essential oil obtained by the distillation of balsam of copaiba and dried over chloride of calcium. This is said to be capable of converting three times its weight of iodine or bromine into the corresponding hydrogen acid. About 60 grams of oil are put into a tubulated retort of 500 c.c. capacity, combined with an inverted condenser, which on the opposite side is connected by a bent tube with a gas drying tower, having a loose plug of asbestos in its lower part and a delivery tube above. The oil is slightly warmed and 20 grams of iodine are gradually dissolved in it; the temperature is then allowed to rise. An abundant and regular evolution of gas soon takes place, and when this ceases the retort is allowed to cool a little and then more iodine is added, the operation being repeated with increasing quantities of iodine until about 150 grams have been used. The acid obtained about equals in weight the iodine used. In preparing hydrobromic acid by this method the quantities of bromine added are about the same, but the bromine is allowed to fall upon the oil slowly, drop by drop, and the gas is passed through two or three drying towers. The greater part of the oil becomes solid during the operation, and a smaller portion is converted into cymol and perhaps dicymol.

The solubility of morphia in chloroform has been variously stated by different authors. Professor v. d. Burg (*Pharm. Zeitung*, Nov. 8, p. 696) has tried to settle the doubt by operating with freshly precipitated morphia and chloroform washed four times with its own volume of water and then distilled over calcium chloride. The morphia was finely powdered, submitted for several hours to an increasing temperature and then repeatedly shaken up with the chloroform, the liquid being afterwards rapidly filtered and 10 c.c. of it evaporated in a porcelain capsule. In pure chloroform morphia was found to be nearly insoluble, only one milligram of residue being left from the 10 c.c. But the solubility rapidly increases with the presence of alcohol; chloroform containing 1 per cent. of alcohol leaving a residue of 5 milligrams from 10 c.c.; with 5 per cent. of alcohol, 45 milligrams; and with 10 per cent., 90 milligrams. Morphia containing narcotine, which is soluble in chloroform, would give a larger residue when pure chloroform is used, and its presence might be detected in this way

The intrusion of sensationalism into that part of the domain of scientific investigation which has reference specially to the nature of the elements appears to be very persistent. Dr. Endemann, wishing to bring before the American Chemical Society the subject of the alleged dissociation of the elements at high temperatures, applied to Professor Victor Meyer as to the nature of some results recently alleged to have been obtained by him, the report of which has raised considerable expectation in the scientific world. In his reply the professor declares that the communications in the English journals concerning his investigations which report the separation of oxygen from chlorine have been published without his knowledge and against his wishes, and that they are entirely incorrect in essential particulars. It will not be unreasonable to expect that by the time the next "Month" is due there will be some explanation to report.

The onerous task undertaken by the New York College of Pharmacy in order to ward off from the pharmacists of the State of New York the inconveniences of an Act for the compulsory verification of weights and measures (see before, p. 168) has hardly yet received the recognition it deserves. Eight weeks after the sending out of the circular recently quoted in this Journal only eight pharmacists had (according to *New Remedies*) sent in their weights for verification, and only forty-nine new sets of correct weights had been sold to twenty-seven buyers, three of whom resided outside the State. Yet it appears to be acknowledged that such an Act would have had some *raison d'être* in the "bad character of the weights used in some establishments." A gentle fillip has been administered to the sluggards by the Medical Society of New York, which has passed a resolution advising its members to patronize, so far as may be consistent, only those apothecaries who use weights certified by the College of Pharmacy to be correct.

November is the month in which even the most laggard societies show signs of getting to work, and as a result of the meetings which are now getting into full swing there will no doubt be soon an abundance of more or less scientific papers on topics in every department of science. Next Monday the annual distribution of medals by the Royal Society takes place. The Copley medal goes to Professor Clausius, of Bonn, for his researches on Heat; the Davy medal to M. Boisbaudran, for his discovery of Gallium; a Royal medal to Mr. W. H. Perkin, for his researches in organic chemistry; and another Royal medal to Professor A. C. Ramsay, for his work in geology and physicial geography. At the Royal Institution the Christmas lectures to juvenile audiences are this year to be delivered by Professor Tyndall, the subject being Air and Water.

Pharmacopœia literature is just now assuming considerable prominence in various parts of world. In the United States, many eminent pharmacists are working hard to secure all possible perfection in the next edition of their text-book. In Germany, a committee appointed by the Deutsche Apotheker-Verein, and presided over by Dr. C. Brunnengraber, of Rostock, has just issued a long and elaborate report upon the form it is advisable that the next pharmacopœia of that country should take. In Norway a new edition of the Pharmacopœia has just been published, and in Russia a new edition is to be put into the hands of the printer this month and is expected to come into force in March or April of next year.

In the presence of a difficulty with regard to a prescription, whether that difficulty arises from an "unusual dose," incompatibility of ingredients, or any one of many other causes, the dispenser would often gladly avail himself of a communication with the writer, and in justice to the persons involved, the writer, the dispenser, and the patient, such an opportunity should be afforded him.

In every dispensing establishment, instances of this kind must occasionally occur, and it will have been observed how frequently in these columns the remark has been made, that the "the writer of the prescription should be referred to." This wholesome advice is very easily given, but in practice, having in view the present method of writing prescriptions, very difficult for the dispenser to follow; the prescription is usually written on a sheet of note paper which may have been picked up at the house of the patient, and it may or may not have even the patient's address on it; sometimes an old envelope does this duty. But the sole clue to the prescriber are the initials, generally illegibly written at the bottom of the prescription, and from long continued use this signature may have assumed the form of a hieroglyphic, the mystical characters of which it is composed having no relation to the combined letters of their prototype.

As a result of this, the dispenser, unless he is familiar with the writing, tries in vain to decipher the writer, and the only alternatives which present themselves to him are, to use his own judgment, or to apply to the patient for the writer's address. The former of these, in the case of an unusual dose, throws on the dispenser a grave responsibility; the latter involves a modified explanation, which very rarely satisfies the patient.

The remedy for this state of things is very simple; it is for those who write prescriptions to make a practice of writing them on paper bearing their address, not only when being consulted at home, but also when visiting their patients. It is true that this would involve the carrying of a small case of their own paper to the houses of their patients, but simply one adapted to a side pocket, and such as are now commonly made use of for letters.

It may be said that this course would not be considered professional, that it would savour of advertisement; but the necessity for some such course is apparent, and it is only necessary that the subject should receive the attention of those in the profession above suspicion, to be followed by others and to become a general and accepted practice. A directory could then be referred to, and the writer, if necessary, communicated with. This common sense course of procedure, if generally adopted by the medical profession, would prove a boon to dispensers, and relieve them of responsibilities which form no part of their legitimate business, and to which, with their consequences, they should not be subjected.

The ointment, No. 365, directly on being mixed evolves ammonia with the formation of mercuric iodide; this gives it a reddish-yellow colour. The decomposition has been fully explained by "Pot. Carb.," p. 398. "Unguentum" does not state whether the "creamy" applies to colour or consistence, or both.

No. 366. The acid. carbolic. should be dissolved in the ol. olivæ, and the extract of opium made smooth by the addition of a little water and with the aid of heat; sufficient water should be added, so that when the bottle is shaken the ext. opii may be diffused through the oil, but not more than is necessary for that purpose. The remarks of "Lavandula" on this prescription, p. 377, may be referred to.

Mr. Thursfield has already replied to "Sub Umbra Floresco," No. 367, with regard to the pitch pill. The pitch selected should be firm enough, so that the pills made of it retain their shape; then the manipulation referred to by Mr. Thursfield may be adopted with advantage.

The prescription No. 368 should be dispensed with tr. zingib, B.P.; its strength does not usually vary materially in any two establishments. The result must necessarily be a milky mixture, and the milkiness would to some extent depend on the strength of the sp. am. arom. and sp. æth. nit. used, but more so on the variety of ginger employed in making the tincture. The Pharmacopœia directs the tincture to be made from the "dried rhizome of *Zingiber officinalis*, from plants cultivated in the West Indies, India and other countries." So long as ginger is the product of *Zingiber officinalis*, there is considerable latitude allowed as to the country from which it is obtained. From a paper by Mr. Thresh, read at the British Pharmaceutical Conference in Sheffield, and the discussion to which it gave rise, it will be seen that the African ginger, with more resin and less starch, must yield a tincture differing in its milky character when mixed with water from that yielded by Jamaica ginger. As a commentary on this, "Leo" is referred to some remarks on tinct. sumbul. obtained from various sources, and the discussion which followed the reading of the paper, showing the different results obtained when such a tincture was combined with the other ingredients of which the mixture was composed (*Pharm. Journ.*, Nov. 8, p. 373).

In No. 369, Mr. Bessant has met with a mixture containing a larger amount of camphor than is usually prescribed, but, nevertheless, quite within the B.P. indicated dose—1 to 10 grs. In accordance with "faithful dispensing" this difficulty may be easily and satisfactorily overcome, and the "reins of conscience" by no means relaxed. The camphor should be put into a mortar with the spirit of nitre, and a small addition of rectified spirit, but only sufficient to dissolve the camphor, and then ℥ss mucilage gradually added, and with trituration till smooth. The camphor, on the gradual addition of the other ingredients, remains suspended, so that each measured dose of ℥j shall contain 5 grs. camphor. Mr. Bessant's attention is directed to remarks in "The Month," January 28, 1879, p. 1058, No. 308, and previously, on the method of suspending camphor when prescribed in mixtures.

In mixtures like that of No. 370, each ingredient should be mixed with separate proportions of the vehicle. The remarks of "Lavandula," p. 378, convey all that need be said on the subject, and his observation that the mixture should not be filtered may be emphasized.

The manipulation of ointments containing extracts, as No. 370, has been on several occasions explained. J. Y. is therefore referred to the remarks in the last "Month," p. 326, No. 359. Several correspondents also have in last week's Journal replied to this question, suggesting the same manipulation.

The pills, No. 371, do not require an excipient; they should be made with the carbolic acid in crystals. If the mass become too soft for pills, more especially as these pills are to be silvered, $\frac{1}{2}$ grain of pulv. tragacanth. added to each pill will give them the requisite firmness, and if allowed to stand a short time they may be satisfactorily silvered.

The phosphorus pills, No. 372, may be made in the following manner:—The ferri redact. and quinæ sulph. should be combined with glycerine and tragacanth into a firm and suitable pill mass. The phosphorus then should be dissolved in a few drops of bisulphide of carbon, to which a drop or two of chloroform should be added, the vapour of the chloroform preventing the oxidation of the phosphorus during the manipulation. As soon as the phosphorus is dissolved, the pill mass of ferri redact. and quinæ, previously prepared, should be added, the whole combined and divided into thirty pills.

The manipulation of phosphorus in a pill mass has on several occasions previously been referred to, and bisulphide of carbon recommended as a solvent.

M. P. S., in No. 373, requires the strength and also the quantity usually injected, of solution of daturin. Daturin is generally considered as being chemically identical with atropin, and may be administered hypodermically in the same dose. The strength of a solution of sulphate of atropia for hypodermic injection is 1 to 2 per cent., and the dose from two to five minims, equivalent to from one-fiftieth to one-twentieth grain.

The emulsion, No. 374, should be made by adding the liq. potassæ to the water previously to the addition of the cod liver oil. Little need be added to the method given by J. B. L. Mackay, p. 419. It may, however, be stated that a successful result must necessarily in great measure depend upon the liq. potass. being of full strength; a deficiency in this respect may account for the separation mentioned by T. B. L. as having occurred in every sample that he had experimented on. The B.P. says that the fluid ounce of liq. potassæ should contain 27 grs. of hydrate of potash.

The prescriptions Nos. 375 and 376 resemble those obscure combinations which can be prepared satisfactorily only under the directions of the writers; they seem typical of those valuable recipes sent in return for a certain amount in postage stamps.

GLYCERITUM FERRI SUBSULPHATIS.*

BY I. E. SAYRE, PH.G.

A liquid preparation of Monsel's salt, free from acid or irritating properties, bearing a definite and easily recollected ratio of strength to the salt in question, with a basis of glycerin or some other liquid as capable of permeating tissue, is one of the pharmaceutical wants of the present time. These combinations have grown greatly in favour of late years in the treatment of various kinds of mucous discharges and chronic ulcerated surfaces where a powerful astringent effect is required; they are highly commended by some in the treatment of diphtheria. In vaginal, rectal and local hemorrhages they are believed to have advantages over the officinal solution in forming less hard and irritating clots when applied to such delicate parts. Such preparations cannot be compounded extemporaneously from the subsulphate of iron, in a form which is desirable for the physician or creditable to the pharmacist. The argument then is greatly in favour of the adoption of a standard preparation which would do with justice.

The commercial persulphate (so called) is found in the shops in a yellow pulverulent mass, or in powder. It is very slowly and imperfectly soluble in water or glycerin —it probably contains oxysulphate. Several samples of the salt have been tried, and they all proved incompletely soluble in water or glycerin, either cold or boiling. The perfectly soluble and deliquescent Monsel's salt can be produced by evaporating the officinal solution at a moderate temperature upon porcelain or glass plates; but this is an unstable salt and very inconvenient to handle, its proneness to change suggests the idea of making it at once into a glycerite of definite strength, so that it may be at once ready for use, or can be made so by simple dilution.

A glycerite containing fifty per cent., by weight, of the salt furnishes perhaps the most convenient form, and, furthermore, one which possesses qualities which render such a standard of strength most desirable.

The process adopted for its manufacture consists in first preparing a solution of the subsulphate, following the directions of the U. S. Pharmacopœia for the solution; this is evaporated in a tared capsule at a moderate temperature until a thick viscid liquid is obtained; this is then diluted with a sufficient quantity of glycerin to produce a solution of the above percentage. In order to use this process the quantity of dry subsulphate of iron in the officinal solution must be known. By careful experiment it has been found to contain 47 per cent. The use of weight instead of measure, in the formula, is suggested by the writer as being easier and apt to secure more accurate manipulation.

The following process is recommended, the finished glycerite measuring about twelve fluidounces, the quantity directed by the U. S. Pharmacopœia for the solution:—

Take of liquor ferri subsulphatis 6·127 grains, evaporate to 3·963 grains, continue the heat and add glycerin sufficient to make the weight 5·760 grains.

This furnishes the easily recollected percentage of dry salt, half its weight being Monsel's salt, each fluid drachm representing about 50 grains of subsulphate of iron—in exact figures 51·08 grains.

It can readily be diluted to any extent without destroying its transparency, either by water or glycerin, and in this respect furnishes a much superior article for compounding than the dry salt of commerce. Its viscidity renders it of that plastic character so very advantageous where the application is intended to remain upon the surface of the affected part and in addition to the styptic effect of the iron salt, the glycerin exercises its emollient properties in many ways and particularly in preventing the formation of the irritating clots and crusts peculiar to the salt itself or its solution.

* From the *American Journal of Pharmacy*, November, 1879.

ELIXIR GLYCYRRHIZÆ COMPOSITUM.*

The following formula has been calculated on the basis of various formulæ heretofore proposed, substituting parts by weights for definite weight and measure. A convenient quantity of the elixir, on a small scale, will be obtained by substituting for part the quantity "10 grains." The resulting product will then measure about 1 pint.

Take of

Licorice root, cut and bruised, ninety parts.	90
Sugar, two hundred parts	200
Water, a sufficient quantity	q.s.

Digest the licorice root with

Water, six hundred parts	600

for an hour on a water-bath, then heat to boiling, boil for about fifteen minutes, and then strain with strong expression. Pass through the strainer enough water to make the decoction weigh seven hundred parts . . 700

Then take of

Star-anise, in No. 40 powder, six parts . .	6
Cinnamon, in No. 40 powder, five parts . .	5
Coriander, in No. 40 powder, four parts . .	4
Caraway, in No. 40 powder, two parts . .	2
Nutmeg, in No. 40 powder, one part . . .	1
Alcohol, 93 per cent., a sufficient quantity	q.s.
Water, a sufficient quantity	q.s.

Mix the powders, pack them firmly in a conical percolator, then pour upon them about one-half of a mixture of

Alcohol, seventy parts	70
Water, forty parts	40

When the percolate begins to drop, close the orifice with a cork, and set the percolator aside in a warm place for four days. Then allow the percolation to proceed, pouring gradually more of the menstruum on top, until the percolate weighs one hundred parts 100

Add this percolate to the strained decoction of the licorice, let the mixture stand twenty-four hours, filter and add the sugar. Dissolve the latter by agitation, then filter again, and wash the filter with enough of a mixture of alcohol, seven parts, and water, four parts, until the whole filtrate weighs one thousand parts . . 1000

SOME OF THE CONSTITUENTS OF PHYTOLACCA DECANDRA.†

BY A. C. EHRHARD.

Powdered poke-root was percolated with three successive portions of ether, and the percolate evaporated spontaneously to dryness. The greater portion of this ethereal extract was dissolved in alcohol and had an *acid* reaction. From a part of this, by means of alcoholic and aqueous reagents, the following results were obtained. With alcoholic solution of potassa, a precipitate soluble in excess; with solution of lime, a precipitate insoluble in excess; with aqueous solution of platinic chloride, a whitish crystalline precipitate. No precipitates were

* From *New Remedies*, October, 1879.

† From *New Remedies*, September, 1879. Abstract of a thesis presented to the College of Pharmacy of the City of New York, in 1875.

Poke-root was partially analysed in 1843 by E. Donelly (*Amer. Journ. Pharm.*, Oct., 1843, p. 165). Nothing of special interest, besides the usual constituents of plants, was found in it. No chemical examination has since been published on any part of the plant, unless we may reckon here Reichel's (1836) analysis of another species of *Phytolacca*, which established the presence in the root of *Ph. drastica*, Poppig, of about 6·6 per cent. of calcium malate. Baillon (*Compt. Rend.*, 80 (1875), p. 426) has published some interesting observations on the behaviour of the colouring matter.—ED. N. R.

obtained with silver nitrates, potassium iodide, or other reagents. A portion of the alcoholic solution was then treated with acetate of lead, a precipitate obtained and filtered. The excess of lead in the filtrate was removed in the usual manner by hydrosulphuric acid, and on evaporating the final filtrate, the residue was dissolved with the aid of a drop of dilute hydrochloric acid. Platinic chloride produced with this a precipitate, which turned out to contain *potassa*. The lead precipitate was freed from lead by hydrosulphuric acid, and the final filtrate was found to contain *calcium* and *sulphuric acid*.

The remainder of the alcoholic solution was evaporated to dryness on the water-bath, the residue dissolved in ether and shaken with a mixture of acetic acid and water (1:10), which produced a flocculent precipitate, which dissolved in concentrated sulphuric acid with an olive-green colour changing to purple on applying heat. The acid aqueous, separated from the ethereal solution, was evaporated to dryness to expel the acetic acid, and the residue examined for alkaloids, with a negative result. Although iodine with potassium iodide produced a light-coloured precipitate, and ammonia a flocculent precipitate, solution of nutgalls only caused a slight turbidity, and platinic chloride gave no precipitate.

The ethereal solution, after a partial precipitation by acidulated water, was evaporated spontaneously to dryness, yielding a light-brown *fat* or *wax*, part of which was saponified with potassa, leaving a slight residue soluble in dilute nitric acid, but too small for further examination. The soap solution was a clear light-brown liquid.

After treating the original ethereal extract with alcohol, the greater portion of the residue left after the evaporation of the latter was redissolved in ether, when a white crystalline substance was left, which was apparently very difficultly soluble in this menstruum. This was dissolved in boiling alcohol and found to be a *crystallizable acid resin*, insoluble in water, and soluble in ammonia; on evaporating the ammoniacal solution, ammonia was lost, and the acid resin separated. Sulphuric acid dissolves this with an olive-green colour, changing to purple on heating, and to red on adding nitric acid. Reducing agents turn the sulphuric acid solution a dirty purplish colour.

The same lot of poke-root, which had thus been exhausted with ether, was then percolated with alcohol, the percolate concentrated (*a*) and set aside. A crop of crystals was thus produced, which were dissolved in water, decolorized with bone-black, and the solution evaporated, when colourless crystals were obtained. They dissolved slowly in strong sulphuric acid, yielding a colourless solution. The aqueous solution of the crystals was found to yield no precipitate with potassium iodo-hydrargyrate, potassium iodo-iodide, picric acid, barium chloride, ammonium carbonate, lime-water, and acetate of lead. Heated in a dry test-tube, they frothed, emitting a peculiar odour, then charred, and by increase of heat became colourless. The crystals were found to be potassa combined with a *peculiar organic acid*. By further concentration (*b*) of the alcoholic percolate, another crop of crystals was obtained, different from the preceding, and neutral. Some of these were dissolved in water, decolorized by animal charcoal, and the solution concentrated. An uncrystallizable substance of a sweet taste remained behind, which gave, with Fehling's test, a brick-red precipitate. The pure crystals, when boiled about ten minutes with a little dilute sulphuric acid, gave the same reaction. The remaining crystals were dissolved in water, the impurities precipitated by acetate of lead, and the solution, after removal of the lead, concentrated, when almost pure *cane sugar* was obtained. The whole remaining alcoholic percolate was then concentrated (*c*) on the sand-bath, until all the alcohol was expelled, water added, and the mixture filtered to separate *the resin*. Part of the filtrate was tested with the following reagents with the results stated: phosphomolybdic acid, a light gelatinous precipitate; tannic acid, light flocculent precipitate; potassium iodo-iodide, light-coloured precipitate; potassium iodo-hydrargyrate, a very light-coloured precipitate; sodium tungstate and mercuric chloride, a white precipitate. The remainder of the filtrate was precipitated by acetate of lead, and after removal of the excess of lead by hydrosulphuric acid and evaporating, the residue was dissolved in water. This aqueous solution gave no precipitate with ammonia, but gave light-coloured precipitates with picric acid, potassium iodo-iodide, tannic acid, sodium tungstate and phosphomolybdic acid. The larger bulk of the solution was precipitated with potassium iodo-hydrargyrate, producing a flocculent precipitate, which on the addition of an excess changed to a tough resinous mass. This was dissolved by moderately dilute hydrochloric acid, water added, and decomposed by sulphuretted hydrogen. The solution was freed from the excess of hydrochloric and sulphydric acids by evaporation to dryness, and the residue again dissolved in water. Potassium iodo-hydrargyrate produced in the solution a precipitate, which dissolved on the application of heat and separated again on cooling.*

THE CONSTITUTION AND PROPERTIES OF DIALYSED IRON.†

BY M. PERSONNE.

The ferruginous liquor designated under the name of dialysed iron is not a true aqueous solution of sesquioxide of iron; it is nothing but a pseudo solution of modified sesquioxide of iron, which differs from the ordinary oxide in being insoluble in acids and its specific heat being less.

This particular state of sesquioxide of iron has been long known; it was discovered in the chemical laboratory of Pelouze more than twenty-five year since by Pean de Saint-Gilles, who obtained it by the action of heat upon the acetate of sesquioxide of iron. M. Béchamp obtained it afterwards by the action of heat upon nitrate of iron. From that time all the physical and chemical properties of modified sesquioxide of iron have been perfectly known, and in consequence of its weak taste it has been recommended as a ferruginous medicine.

Subsequently, Graham demonstrated in his work upon dialysis that the modified sesquioxide of iron was a colloid body, that is to say could not form a true solution, its apparent or pseudo solution not possessing the property of traversing an organic membrane. The preparation of this oxide of iron was then effected by submitting to dialysis a solution of perchloride of iron in which a great excess of sesquioxide of iron had been dissolved. The hydrochloric acid and the salts of the solution diffuse through the membrane of the dialyser and there remains upon this membrane or septum a more or less concentrated liquor, which is nothing but the pseudo solution of sesquioxide of iron containing some perchloride of iron which constitutes the dialysed iron of commerce.

This very process of preparation proves that dialysed iron cannot pass through the membranes in the same manner as crystalloids. It contains perchloride of iron and even sulphate of sesquioxide in variable quantities. If, for example, the commercial product announced as the purest be taken, analysis indicates that it contains—

Perchloride of Iron	6·75
Persulphate of Iron	0·76
	7·51

Or $7\frac{1}{2}$ per cent. of foreign bodies. It is therefore very far from being of the purity announced.

* The author's manuscript omits to state what conclusion he arrives at from the facts stated. The behaviour of the substance contained in the watery solution obtained by adding water to the concentrated alcoholic percolate appears to point to the existence of an alkaloid soluble in water.—Ed. N. R.

† Communicated to the French Academy of Medicine (*Journal de Pharmacie et de Chimie* for October, p. 332).

As to the properties of this dialysed iron, they are the following: it is precipitated by the more powerful acids, whether employed concentrated or diluted with water. Saline solutions, such as marine salt, for instance, also precipitate it. Its insolubility in the gastric juice is complete; this I have verified with gastric juice obtained by Dr. Bochefontaine. Some was injected into the stomach of a dog in full digestion; the stomach having been opened two hours afterwards the oxide of iron was found adhering in flocculent condition to portions of undigested food and it was impossible to detect a trace in solution in the acid liquids of the stomach or upon the whole surface of the digestive canal.

These experiments are completely in accord with the chemical properties of this modified oxide and go to confirm its insolubility. Being insoluble it cannot be absorbed, in virtue of the old and universally true principle *corpora non agunt nisi soluta*. Insolubility therefore implies inactivity.

This inactivity has long been recognized. In fact at time of the discovery of the modified oxide of iron it was recommended as a therapeutic agent, the more convenient from its being devoid of the inky taste of salt of iron. But notwithstanding this it was quickly abandoned. Why did it not succeed at that time and succeed now, the compound being the same? Misleading advertisement everywhere and under every form can alone explain it.

DENOMINATION, SHAPE, AND MATERIAL OF LOCAL STANDARDS OF APOTHECARIES' WEIGHTS AND MEASURES.*

APOTHECARIES' WEIGHTS.

1. *Denomination.*

1. Local standards of apothecaries' weights should have their denominations, or abbreviations thereof, engraved or stamped on them as follows:—

Denomination.	Abbreviation.	Denomination.	Abbreviation.
10 ounces, apothecaries' weight.	10 oz. tr.	2 scruples, apothecaries' weight.	℈ij
8 ounces, apothecaries' weight.	8 „	1½ scruples, apothecaries' weight.	ʒss
6 ounces, apothecaries' weight.	6 „	or half a drachm, apothecaries' weight.	ʒss
4 ounces, apothecaries' weight.	4 „	1 scruple, apothecaries' weight.	℈j
2 ounces, apothecaries' weight.	2 „	½ scruple, apothecaries' weight.	℈ss
1 ounce, apothecaries' weight.	1 „	6 grains, apothecaries' weight.	6 gr.
		5 grains, apothecaries' weight.	5 „
4 drachms, apothecaries' weight. or half an ounce, apothecaries' weight.	ʒiv ½ oz. tr.	4 grains, apothecaries' weight.	4 „
		3 grains, apothecaries' weight.	3 „
2 drachms, apothecaries' weight.	ʒij	2 grains, apothecaries' weight.	2 „
1 drachm, apothecaries' weight.	ʒj	1 grain, apothecaries' weight.	1 „
		½ grain, apothecaries' weight.	½ „

As it may not be practicable to engrave or stamp the denomination on small weights below the scruple, the abbreviation of the legal denomination of each small weight should be marked inside the box in which the weights are placed.

2. The actual weights in grains (of which the imperial pound contains 7000 grains) of apothecaries' weights are as follows:—the apothecaries' ounce and the troy ounce being of the same weight.

Denomination.	Weight in Grains.	Denomination.	Weight in Grains.
Ounces:—		Scruples:—	
10 oz. tr.	4800 gr.	2	40 gr.
8 „	3840 „	1½ or ʒss	30 „
6 „	2880 „	1	20 „
4 „	1920 „	½	10 „
2 „	960 „		
1 „	480 „	Grains:—	
		6	6 „
		5	5 „
Drachms:—		4	4 „
ʒiv or ½ oz. tr.	240 „	3	3 „
		2	2 „
ʒij	120 „	1	1 „
ʒj	60 „	½	0·5 gr.

3. It has been suggested that the amounts of errors to be allowed on local standards of apothecaries' weight should be as follows:—

Denomination.	Amount of error to be tolerated in excess. No error in deficiency allowed.	Denomination.	Amount of error to be tolerated in excess. No error in deficiency allowed.
Ounces:—		Scruples:—	
10, 8, 6, 4	0·1 grain.	2, 1½, 1, ½	0·03 gr.
2			
Drachms:—		6 grs., 5 „, 4 „, 3 „, 2 „, 1 gr.	0·02 „
1, 4, 2, 1	0·05 „		
		½ „	0·01 „

4. The form of these local standard weights from 8 ounces to 1 ounce should be cylindrical with a small knob as in fig. 16. From 4 drachms to ½ scruple either cylindrical (fig. 16) or flat shape (fig. 17). From 6 grains to ½ grain either wire shape (fig. 18) or flat shape (fig 17).

Fig 16. 8 oz. . 1 oz. tr.
4 dr. . ½ sc.

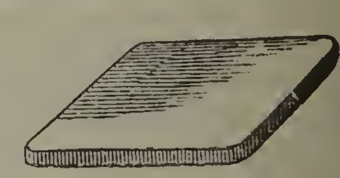

Fig. 17. 4 dr. . ½ sc.

Fig. 18. 6 gr. . . ½ gr.

* Reprint of copy of Instructions issued from the Standards Office of the Board of Trade.

5. These local standards weights are to be made of bronze, gun metal, or hard brass. Below ½ scruple they should be made of platinum or aluminium.

APOTHECARIES' MEASURES, OR MEASURES TO BE USED IN THE SALE OF DRUGS.

6. The denomination of every measure, or an abbreviation thereof, should be engraved on the measure.

Denomination.	Abbreviation.
40 fluid ounces to half a fluid ounce	40 fl. oz. to ½ fl. oz.
16 fluid drachms to half a fluid drachm	16 fl. dr. to ½ fl. dr.
60 minims to 1 minim	60 min. to 1 min.

Each measure is also to have engraved on it "$t=62°$ Faht.'

7. At the temperature of 62° F. (the barometer being at 30 inches) the weights of the contents in distilled water of the several apothecaries' measures are as follows.

8. It has been suggested to allow on local standards the several amounts of error or remedy defined in the third column of the table.

Denominations.	Weight of water contained in the Measure. $t=62°$ F. $b=30$ in.	Amount of error to be tolerated in excess or in deficiency.
	Grains.	Grains Weight of Water.

9. The following are the Board of Trade standards:—

Thirteen standards made of gun metal, cylindrical shape (see Fig. 20), each containing one quantity or measure as follows:—

40 fluid ounces (or a quart).
20 „ (or a pint).
10 „ (or half-a-pint).
5 „ (or a gill).
4 „
3 „
2 „
1 „
½ „
4 fluid drachms.
3 „
2 „
1 fluid drachm or 60 minims.

Five standards made of glass, pipette form graduated (see Figs. 21, 22) each standard containing several measures, as follows:—

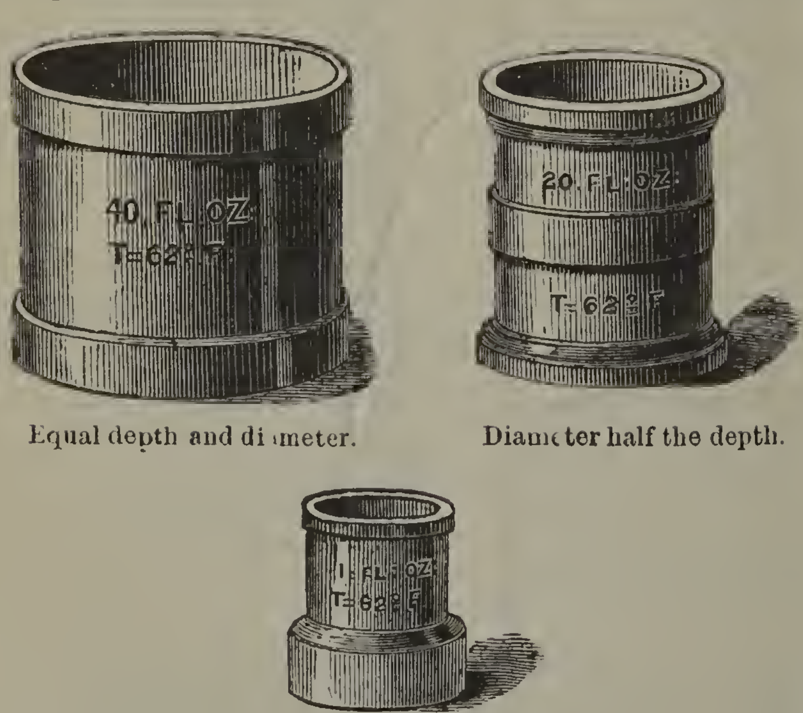
1 pipette, 40 to 10 fluid ounces. Each ounce being numbered.

1 pipette, 10 to 1 fluid ounce. Each ounce being numbered.

1 pipette, 16 to 8 drachms. Each drachm being numbered.

1 pipette, 8 drachms to ½ drachm. Each drachm being numbered.

1 pipette, 60 minims to 1 minim. Each tenth minim being numbered.



Equal depth and diameter. Diameter half the depth.

On ivory stand.

Fig. 19. Gun-metal measures.

10. Apothecaries' measures, as already explained, may be made of gun-metal or of glass. If made of gun-metal they are to be of the usual cylindrical shapes of measures of capacity. See paragraph 9.

If made of glass local standards are either to be pipette, flask or beaker shape, marked as explained in paragraph 9. See Figs. 20, 21, and 22.

Fig. 20.

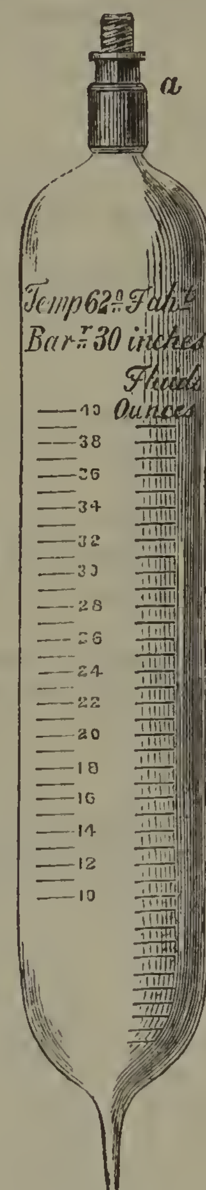


Fig. 21.

Fig. 22.

[*In the original drawing of Fig. 21 each graduation is numbered, but in the above reduced engraving the alternate figures have been omitted.*]

With these pipettes the inspectors may find it necessary to use a filling apparatus similar to that used at the Standards Office. When this apparatus is used the brass fittings shown at *a*, Figs. 21 and 22 are required.

11. Apothecaries' weights or measures should be placed in a mahogany box having a lock and key. On the outside of the box there should be a brass plate bearing the following inscription:—Apothecaries' Weights. Local Standards. Of [*Insert name of County or Town*].

12. It is for the local authorities to decide whether they require any standards of apothecaries' weights and measures.

Many inspectors of weights and measures are already provided with some of the principal apothecaries' measures; as 40 fluid ounces (or a quart), 20 fluid ounces (or a pint), 10 fluid ounces (or half a pint), 5 fluid ounces (or a gill). Local standards of the several apothecaries' measures, or measures to be used in the sale of drugs, as set forth in the second schedule of the Weights and Measures Act, 1878, have also been already verified for local authorities, viz.:—

Fluid ounces	4, 3, 2, 1.
Fluid drachms	4, 3, 2, 1.
Minims . . .	30, 20, 10, 5, 4, 3, 2, 1.

APOTHECARIES' WEIGHTS AND MEASURES.

ON the previous pages will be found the text of the memorandum relating to the standards of apothecaries' weights and measures mentioned by the President at the last meeting of Council.* It enumerates the several denominations of standards authorized by the Board of Trade for the purpose of being used by inspectors of weights and measures under the new Act as local standards for the verification or inspection of the apothecaries' weights and measures used in trade. It further indicates the corresponding abbreviations which are to be stamped or engraved on the respective standards, as well as the actual weight in grains of each weight and the number of grains of water at 62° F. contained in each of the measures. The shape of the local standards and the materials of which they are to be made are specified, and the amounts of error to be allowed in the several local standards of apothecaries' weights and measures are also stated.

From the concluding paragraph of this document it will be seen that in some instances there is nothing to prevent the work of inspection being commenced at once, or as soon as the local authorities may direct, and as this is a point of some importance to bear in mind, we think it desirable again to urge our readers to take every means of learning what is being done in regard to inspection of apothecaries' weights and measures by the local authorities in their respective districts. In speaking upon this subject at the evening meeting of the North British Branch of the Society, Mr. GILMOUR suggested that it was improbable the inspectors would proceed to carry the new law into force "for some time to come;" but we are disposed to think that in taking this view he was misled, and should rather advise chemists and druggists throughout the country to communicate at once with the local authorities of their district, with the object of obtaining information as to the steps to be taken in the inspection of apothecaries' weights and measures and the facilities to be afforded for their verification when the Act comes into operation on the 1st of January next. This could be done either through the medium of the local secretaries of the Society or by the secretaries of provincial associations, and it would, at least, remove any ground for commencing the work of inspection in such a way as to cause inconvenience.

* See also *Pharm. Journ., ante*, p. 390.

In some other particulars Mr. GILMOUR's statements as to the provisions of the new Act respecting apothecaries' weights and measures were not altogether correct and their inaccuracy appears to have arisen from the want of due distinction between the provisions as to local standards and those applying to the actual weights and measures used in trade. Thus for instance, the point that every measure must be graduated into its own denomination—that each glass must be either all ounces, drachms or minims—does not apply to trade measures, but only to the local standards by which such measures are to be verified. It would indeed, be a most arbitrary requirement to compel dispensers to use a special drachm measure for measuring 3 or 6 drachms when an ounce measure graduated into drachms would answer the purpose perfectly well.

We are quite at a loss to imagine on what authority it is stated by Mr. GILMOUR that no symbols are to be used on graduated glass measures and that each glass measure is to have marked upon it "t=62° F." These again are provisions that relate only to the local standards and not at all to the measures actually in use. As to the stamping or engraving of weights and measures with the Government stamp of a crown and the letters V.R., which Mr. GILMOUR describes as being requisite, we equally fail to discover any authority for this statement, either in the memorandum lately issued by the Standards Office, or in the Act itself. On the contrary, section 43 of the Act distinctly states that the stamp of verification with which lawful weights and measures are to be stamped by the inspector of a particular district is to be "some name, number, or mark" that will distinguish that district. It is for the local authorities to decide also what they will stamp and what they will not stamp, and they will have to exercise their discretion as to where the impracticability of stamping with the abbreviated denomination, or the mark of verification, obtains on account of the small size of the weight or measure. In fact, all the proceedings to be taken under the new Act for the local verification and inspection of weights and measures are to be taken by the local authorities of counties and boroughs, independently of the Government, and it is only in regard to verification and custody of standards that the Act confers any powers or duties upon the Board of Trade.

Again, therefore, we would remind our readers that it will be unwise to wait until the time when it may be supposed the Government will take action in the matter and issue specific instructions that will enable chemists and druggists to provide themselves with proper weights and measures. So far as the trade is concerned, the action of the Government was at an end when the Order in Council authorizing the apothecaries' standards was issued, and it now remains for the local authorities to act. It is, therefore, in this direction that application should be made to know how the provisions of the Act are to be carried out in different localities.

Before leaving this subject we venture to suggest an alteration in the mode of using the pipette-shaped vessel, fig. 21, as a standard, which would, in our opinion, be an improvement upon the arrangement which that figure represents. For convenience of manipulation there is perhaps no form of instrument better than the delivery pipette, especially when fitted with a filling apparatus and air taps. In regard to accuracy, also, this form of apparatus leaves little to be desired when the surface of the liquid at the point of reading off the volume is not too extended. Certainly in gauging a number of measures a pipette would be much more convenient to use than a vessel having the form of those represented by fig. 19, or even a flask like fig. 20; but in the way that the graduation of the large pipette, fig. 21, is applied there would be considerable liability to error, owing to the large surface of the liquid at any one of the points of graduation. Considering that the capacity of the graduated portion of the pipette is 40 fluid ounces, the diameter of the vessel must be too great for accurate reading, and the arrangement indicated appears, therefore, unsuited for the purpose in view when such large volumes have to be read off. In the smaller pipette, fig. 22, the objection would not apply with equal force, but in either case we should be disposed to give the preference to a pipette made of such a size as, when filled to a point in the narrow neck, *a*, to hold the particular measure it is intended for. The adoption of this plan would, however, entail the use of a separate pipette for each measure, but much greater accuracy of measurement would thus be ensured and also the possibility of more rapid manipulation.

PAREGORIC WITHOUT OPIUM.

In reference to the case reported in this Journal some weeks ago, and to the comments we felt compelled to make upon the impropriety of the practice disclosed before the Chesterfield police magistrates, we have received a letter from Mr. Greaves in which he seeks to justify the sale of the preparation then called in question. We should have been glad if there had been any possibility of recognizing the sufficiency of the arguments he brings forward for this purpose, but unfortunately we cannot do this. The signification of the term "paregoric" and its application to a compound containing opium is too familiar to admit of the name being applied to a preparation that does not contain opium.

The statement that such a preparation has been for a long time sold as a specialty does not to our apprehension constitute any justification of the use of the term "paregoric" to describe it, nor can we admit that regard for trade interests involves the adoption of such a palpable misnomer.

Another argument put forward by Mr. Greaves is based upon the large area of country round Chesterfield in which there is no registered chemist and druggist and no immediate local provision for the supply of medicine or drugs, but we are equally unable to regard that circumstance as a reason for supplying the population of that district with articles under names that do not belong to them.

As regards the fitness of the repressive action which the Pharmacy Act and the Sale of Food and Drugs Act are intended to exercise, the Legislature has deemed it good for the public welfare that poisons should not be indiscriminately sold by persons unqualified by education and experience to deal in such articles, and we believe it is for the good of pharmacy that this restriction should be enforced. Public feeling is also decidedly opposed to the sale of articles which are not of the nature, substance and quality they purport to be, and though we believe that the state of public opinion as to the extent of such practices is exaggerated we do not think there would be any good done to legitimate trade interests by seeking to excuse any instances in which they have been shown to exist.

Of course we do not intend to suggest that the preparation which Mr. Greaves has sold under the name of "paregoric," may not be, as he states, better adapted for certain purposes than the preparation with opium to which that name properly belongs. All we object to is the misuse of this term, and we would suggest that the popularity of Mr. Greaves's special preparation would be in no way damaged by giving it an appropriate name instead of one which represents a preparation that he contends is not so good.

POISONING OF HORSES.

We learn from the *Lincolnshire Gazette* that a meeting has been held in the Corn Exchange of Lincoln for the purpose of forming an association for preventing the administration of poisonous drugs to horses. It appears that a farmer in the district has recently suffered very serious loss in this way, and several of the speakers at the meeting mentioned cases in which horses had been killed by the administration of arsenic by grooms and waggoners. One of the number expressed the opinion that many chemists and druggists sold poisons recklessly, and thought there should be some more stringent law with regard to them, but in most instances it was considered that the mischief was done by hawkers going into the stables and selling poisonous drugs to the persons who had charge of horses. It would appear that the most fitting remedy for this would be to make known to these persons the penalty imposed by the Drugging of Animals Act, 1876, and to warn them against the consequences of their ignorant use of drugs of which they do not know the effects.

We regret to learn that on Tuesday last a fire broke out on the premises of Messrs. Smeeton and Pick, wholesale druggists, Bond Street, Leeds, which, before it could be extinguished, consumed property to the value of several thousands of pounds. The basement was saved by flooding it with water, but the upper stories, partly occupied as a woollen warehouse and by the Globe Parcels Company, were completely destroyed.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourth general meeting of the thirty-first session was held at the Royal Institution on Thursday evening, November 20, the President, Dr. Charles Symes, in the chair.

The minutes of the previous meeting were read and confirmed.

The following donations were announced:—The two last numbers of the *Pharmaceutical Journal*, from the Society; and the *Canadian Pharmaceutical Journal*, from the Editor.

The President called attention to the progress which is being made in the preparation of the new United States Pharmacopœia. He said that at a recent meeting of the American Pharmaceutical Association the Pharmacopœia Revision Committee brought up their report, and it was agreed that one thousand copies of the proposed new work should be printed in pamphlet form and distributed amongst the eminent pharmacists of America, thus enabling them to test the merits of the proposed formulæ, processes, etc., and to judge of the merits of each before they became law. This he considered was a broad and liberal spirit, which contrasted favourably with that displayed under similar circumstances in this country.

The President also called attention to some remarks by Heintz, published in the *Pharm. Zeitung*, respecting the influence of tannin in preventing the colour reaction between iodine and starch, and experimentally showed that a few drops of a moderately strong solution of tannin, added to a weak solution of starch, entirely prevented the formation of the usual blue colour on the addition of a solution of iodine.

Mr. Edward Davies, F.C.S., said that this was not a new discovery, for it was mentioned in 'Gmelin's Chemistry.'

The President then exhibited a new form of microphone transmitter which is coming into general use, for the transmission of articulate sounds, possessing the advantage over the telephone, when used in the same capacity, that the speaker might be some feet distant from it and need not raise his voice above an ordinary tone to be distinctly heard. This was practically shown by means of a wire laid between the lecture hall and the library. The instrument was also taken to pieces and its construction explained.

The Honorary Secretary, Mr. M. Conroy, called attention to the immense sensation caused in Birkenhead and elsewhere by that great queen of quackery, Madame Enault; and to show the immense sale which she had for her "Indian Malachite" he read an extract from the *British Medical Journal*, which stated that the manufacturers of the bottles in which it was put up had supplied her with upwards of fifty thousand during the past few weeks. The "Malachite" was a green coloured, aromatic liquid, put up in bottles of $1\frac{1}{2}$ or 2 fluid ounce capacity, and sold at 2*s.* each. He found, however, that it was not at all uniform in composition, three samples which were lately examined by him giving the following respective specific gravities: 1·047, 0·972 and 1·000. The samples also varied in colour and smell. He had made a proximate analysis of one sample, as far as it was possible to do so with such a complex organic mixture, and found it to consist as under. A sample made by this formula was exhibited at the meeting, and the general opinion was that it represented the original in every way:—

"*Indian Malachite.*"

Glycerine	$12\frac{1}{2}$ fluid ounces.
Rectified Spirit . . .	$12\frac{1}{2}$,, ,,
Oil of Cajuput	4 fluid drachms.
,, Cloves	1 ,, ,,
,, Cassia	1 ,, ,,
,, Peppermint . .	20 minims.
Aniline Green	1 grain.

Aniline greens frequently possess a blue tint, but this could be rectified by the addition of a very small amount of aniline yellow.

A brief discussion followed this communication, in which several of those present joined.

The President then called upon the Hon. Secretary to read the paper for the evening, on—

Fucus Vesiculosus.

BY MICHAEL CONROY, F.C.S.

Fucus vesiculosus, commonly known as bladder-wrack, sea-ware, sea-wrack, black-tang and kelp-ware, belongs to the great natural order of marine plants known as *Algæ*, and, as indicated by its name, to the genus *Fucus*. Greville applies to it the following special botanical characters:—*Frond* plane, linear, dichotomous, entire at the margin. *Air vessels* roundish-oval; in pairs. *Receptacles* mostly elliptical, terminating the branches."

The species is very variable; but the varieties pass so insensibly into each other that it is very difficult to strictly define them. Harvey says*: "The first and most obvious distinction is in size; some fully developed specimens in fruit being found under an inch in length, while others reach several feet. Other varieties possess elongated air-vessels, or are entirely destitute of any; while others vary in the shape of the fructification, the receptacles being sometimes globose, sometimes ellipsoidal, and occasionally spindle-shaped. Lastly, the frond is frequently spirally twisted.

It is a perennial plant and a native of the British shores, bearing the fructification in the spring. The root is an expanded, black, woody, callous disk. The frond is smooth and glossy, and in colour is a dark olivaceous green, furnished through its whole length with a darker coloured midrib, as thick as a goose-quill at the root, but gradually growing pale and thin. The vesicles, varying in size from a pea to a hazel nut, of thin substance, and their cavities filled with air, are found imbedded in the membranous part of the frond, near the midrib. The fructification consists of compressed, turgid, solitary or twin receptacles, perforated and filled with a pellucid mucus.

Fucus vesiculosus is the commonest and one of the most widely diffused species of the genus. It abounds on the coasts of our own islands, and along the shores of the Northern Atlantic, extending to the tropics, and is said to have been found in the southern part of the ocean.

The uses made of this weed are manifold. In Northern Europe it is used as thatch and fuel, and when vegetation is scarce, or the land is covered with snow, it furnishes an abundant fodder for cattle, which regularly visit the shore, at the retreat of the tide, in search of it. The Norwegian and Lapland peasants collect and boil it, and when mixed with a coarse meal, feed their pigs, horses and cattle with it. In Ireland and Scotland it is largely used for similar purposes, and it is said to be both grateful and nourishing to the animals, which become very partial to it. Formerly it was largely used in the manufacture of kelp, which is now used for the manufacture of iodine.

Some of its medical properties have been known from early times; the burnt plant, under the name of vegetable ethiops, having long enjoyed considerable celebrity in the treatment of bronchocele and scrofulous diseases, the dose being from 10 grs. to 2 drachms. Dr. Russel found the mucus of the vesicles an excellent resolvent, when externally applied to glandular enlargements and other scrofulous tumours. He also gave the expressed juice of the vesicles in glandular affections.

Since the discovery of iodine it has fallen into disuse for the treatment of these diseases, its place having been more effectually supplied by that agent and its salts.

According to Pereira, its organic constituents are cellulose, mucilage or carrageen, mannite, odorous oil, with colouring and bitter matters. The mineral constitu-

* 'Phycologia Britannica.'

ents, which amount to 16·6 per cent. of the dry fucus, are according to the mean of the analyses by Gödechens, James, Schweitzer and Forchhammer, as under:—

Potash	11·96
Soda	12·25
Lime	10·92
Magnesia	9·53
Sodium Chloride	19·82
Sodium Iodide	0·25
Iron and Lime Phosphates	5·64
Iron Peroxide	0·95
Sulphuric Acid	24·62
Silica	4·06
	100·00

According to Gualtier de Glaubry, the iodine exists as potassium iodide, but I am unable to see how he has determined this point.

It will be seen from the above table that this plant contains little iodine, 0·21 per cent., but even this percentage is greater than what has been found by other chemists. M. Eugène Marchaud states that it is one of the poorest species in this respect, and he mentions that *Fucus digitatus* contains seven times as much.

Recently we have heard a great deal respecting the use of *Fucus vesiculosus* in the treatment of morbid obesity, and if it possesses a tithe of the virtues ascribed to it, it is truly a marvellous remedy, and one well worth the attention of both the medical and pharmaceutical professions. Its fat-reducing properties seem to have been first observed by M. Duchesne Duparc, who, while using it in a case of inveterate psoriasis, in which it had considerable reputation as a remedy, noticed its unexpected effect of reducing corpulency, without in any way causing injury to health. He was thus induced to try it as a remedy in this disease, and prescribed it in the form of powder, decoction and extract (hydroalcoholic). Better results, he states, were obtained from the extract than the powder, but the best results were observed by the combined use of the extract, in pilular form, and the decoction. He recommends the remedy to be taken in the morning, fasting; and observes that no change is needed in the habitual diet. No special action of the remedy is noticed for two or three weeks and the earliest effect observed is generally the more abundant flow of urine, which on standing, becomes covered with a dark coloured film. M. Duchesne states that from this moment the reducing action of the remedy begins, and he ascribes its action to the property it possesses of stimulating the absorbents, concentrating its action principally on the fatty cells. (*Journ. de Pharm. et de Chimie*, Juillet, 1862.) Following the above article in the same journal there is a communication by Dr. Godefroy, wherein he gives an account of the effects of the remedy upon himself. He gives full particulars respecting his age, height and weight, and goes on to say that he commenced the treatment on March 6, by taking, at regular intervals, three pills daily, each pill containing 30 centigrams of the hydroalcoholic extract. One pill was taken before each meal and no alteration whatever was made in his manner of living. He observed that his urine became more abundant, darker in colour, and of a more offensive odour. The treatment was continued until April 10, during which time he took ninety pills and lost in weight 1½ kilos. From the 10th to the 20th April he took two pills a day, and from the latter date until May 18 he returned to the three pills a day, and by this time he had taken ninety more pills, and found that he had lost another kilo in weight, so that from March 6 till May 11 he lost 2½ kilos. The weighings, he states, were carefully taken under the same conditions.

I may here call your attention to Dr. Fairbank's letter, which appeared in the *British Medical Journal* of June 7 last, in answer to a query contained in the previous week's journal respecting the nature of the much advertised nostrum, "anti-fat." He writes:—

"I beg to state that 'anti-fat' is most probably an extract of the *Fucus vesiculosus*, or "popping seaweed." More than fifteen years ago, I gave some of this extract in pill (four grains three times a-day) to a very corpulent lady, who in three months lost three stones in weight without any change of diet. Since then I have frequently given it for reducing weight, depending on the accumulation of adipose tissue, and have never found it fail. The solid extract can be easily made into four-grain pills, which must, however, be kept in a stoppered bottle, as they readily absorb moisture from the air. I may state that a patient who has been lately taking it as an anti-fat, and who always suffered very much from rheumatic pains about the body, has been entirely free from such trouble while she has been taking the extract, a fact which she quite independently noted."

Since the appearance of this above letter there has been a somewhat brisk demand for both the liquid and solid extracts, and no doubt some of you, as well as myself, have been at a loss to find suitable working formulæ for their manufacture. The following formula, by M. Dannecy, is published in the *Journal de Pharmacie*, November, 1862:—In the first place, he insists upon the plant being gathered during the period of fructification, and rapidly dried in the sun until it becomes sufficiently crisp to powder. It is then reduced to coarse powder, and macerated for three days in four times its weight of 86° alcohol. It is then expressed, and the marc again treated in a similar manner with 54° alcohol. The tinctures are then mixed and filtered, the spirit recovered by distillation, and the extract evaporated to a suitable consistence. Of this hydroalcoholic extract, which is one-fifteenth the weight of the dry plant, he makes pills according to the following formula:—

Ext. Fuci Vesic.	30 grams.
Pulv. Fuci Vesic.	5 ,,

Mix and divide into pills of 25 centigrams each (3·75 grains). Three of these pills, he says, may be taken daily in the beginning, and gradually increased to twenty-four pills daily, a quantity which has often been attained without the slightest derangement of the stomach.

I have lately had some experience in the manufacture of both the liquid and solid extracts, and not being aware at the time of the existence of the above formula, I tried a few experiments with the object of finding a suitable menstruum. Without going into details, I may say that I have not tried any spirit stronger than proof, simply because I saw no necessity for so doing, judging by the composition of the *fucus*, as above given. I found even a weaker spirit to give good results; water is unsuitable, as it dissolves the carrageen, thus producing a gelatinous liquid, which is not only difficult to work, but which produces a bulky and almost inert extract, owing to the very large amount of this mucilage which it extracts, and it is on this account that a spirituous menstruum is rendered necessary.

M. Dannecy, in the article above mentioned, lays great stress upon the necessity of rapidly drying the fucus in the sun, until it becomes crisp; and other authorities state that the mode of drying employed greatly influences the therapeutic value of the remedy. Judging by parcels which I have met with, there seems to be good ground for this caution, for it is a common thing to find the plant half rotten by careless drying. As, however, there is no benefit to be derived by drying, I have thought it advisable to work on the fresh plant, and thus avoid any risk on that score. Several experiments made with the object of arriving at the relative values of the fresh and dried plant, gave me the following average results:—

100 parts of fresh fucus dried under ordinary atmospheric influences, in summer weather, yielded 33 parts, nearly equal to one-third.

100 parts dried at 212° F., until it ceased to lose weight, produced 26 parts, or a little over one-fourth;

therefore, for all practical purposes, we may say that 1 part of air-dried fucus is equivalent to 3 parts of the fresh plant and that 1 part thoroughly dried at 212° F., is equivalent to 4 parts of the fresh plant. Using freshly gathered fucus, the following formula will produce a very fine fluid extract:—

Fresh Fucus Vesiculosus . . .	$7\frac{1}{2}$ lbs.
Proof Spirit	1 gallon.

Thoroughly cut and crush the fucus, and macerate it for a couple of days in half a gallon of the spirit, then press, and repeat the process with the remainder of the spirit. Reserve 35 fluid ounces of the first liquor, distil the spirit from the remainder of both liquors and evaporate to a soft extract. Dissolve this in the reserved 35 fluid ounces, make the measurement up to 40 fluid ounces with proof spirit and filter after a few hours; 1 fluid ounce of this extract is equal to 1 ounce of the air-dried plant or to 3 ounces of the fresh.

For the solid extract use the same menstruum and exhaust as above, but evaporate the whole of the liquors to a suitable pilular extract. 1 part of this hydro-alcoholic extract is equal to 7·33 parts of the air-dried plant, or to 22 parts of the fresh.

To make these extracts from the air-dried fucus it would be necessary to use a menstruum consisting of 2 parts of proof spirit and 1 part of water, which would be equivalent to using proof spirit on the fresh plant, for it will be seen from the above formula that 1 gallon of proof spirit is used for $7\frac{1}{2}$ pounds of the fresh plant, and, as this weight only represents $2\frac{1}{2}$ pounds, or one-third of the dry plant, it is evident that the 5 pounds lost by drying should be added to the gallon of proof spirit, if it be thought desirable to keep to the above mentioned alcoholic strength, which, in my opinion, is well suited, as it thoroughly exhausts the fucus without taking up the troublesome and inert carrageen.

Since writing this paper, which was intended to have been read a couple of weeks ago, an article has appeared in the *Lancet*, respecting this remedy, and it is evident that the writer of that article and myself have been fishing in the same waters. There are, however, a couple of points to which I must take exception, namely, that *Fucus vesiculosus* contains "large quantities of iodine," and that in Ireland it is found "invaluable for fattening pigs." Now, it is well known that this fucus contains very little iodine, some varieties containing only the merest trace, in fact, as stated before, it is the poorest species of the genus in this respect. Regarding its invaluable fattening properties, I think the writer must have been drawing upon his imagination, for although it is used as pig food by the poor peasantry, when nothing better is obtainable, it is certainly not a fattening food, and anyone who has travelled in the west of Ireland, where it is largely used for this purpose, will have formed a very high opinion of its non-fattening properties by the appearance and the agility of the pigs themselves. The remark in the *Lancet* that most of our fucus comes from Billingsgate market, where it had been used for packing fish, will account for the horrid fishy taste and smell noticed in some samples of the fluid extract made in London.

In conclusion, I wish to remind you of a remark that we often hear respecting this plant, namely, that any active medicinal properties which it may possess *must* be due to the iodine, which it contains. That the beneficial effects obtained by the use of this and other species of fuci in scrofulous diseases depend upon this agent, there can be no doubt whatever, since the same results are obtained by the use of this element or its salts; but it has not yet been found that either iodine or any of its salts will produce such results, in the treatment of morbid obesity, as those ascribed to the galenical preparations of this plant. Moreover, it is not an easily ascertained point, as to what particular principle the therapeutic value of a remedy of this complex nature is due; and, as an example, I will take the somewhat analogous case of lime-fruit juice, the antiscorbutic properties of which have been attributed to the contained citric acid, still we find that this acid has utterly failed either as a remedy or a preventive of scurvy. It is also very improbable that if iodine or the iodides possessed the fat-reducing properties credited to *Fucus vesiculosus*, that it could have escaped the attention of the medical profession for so long.

The paper, which was illustrated with specimens of *Fucus vesiculosus*, and other species of *Fuci*, together with samples of the fluid and solid extracts, powder and pearl coated pills, gave rise to the following discussion:—

The President said he had listened with pleasure to Mr. Conroy's paper; he had no idea there was so much to be said on the subject, without introducing much that was of medical rather than of pharmaceutical interest. The author had, however, kept the question of the medicinal properties of the fucus within very reasonable limits, and had given a considerable amount of information, and some good working formulæ for the excellent pharmaceutical preparations with which he had illustrated his paper. It was a recognized fact, that this particular fucus contained, on an average, much less iodine than *Fucus digitatus*; but the amount of iodine in seaweeds was known to be influenced by the Gulf Stream. He considered there was no right to assume that the medicinal properties (such as they were) were due alone to iodine. It was a matter of common experience that the so-called active principle of a drug did not always possess the whole of its medicinal properties.

Mr. Edward Davies, F.C.S., considered that, even granting that this fucus constituted a fattening food for pigs, it did not follow that it would have the same effect on man, for it was a known fact that the physiological effects of many drugs on man and the lower animals were very different.

Mr. A. H. Mason, F.C.S., said it afforded him much pleasure, in the name of those present, to express their obligations to the gentlemen who had contributed to the success of the meeting. Firstly, to the President, for his able exposition of the principle and demonstration of the action of Hughes's microphone transmitter; such communications, which kept the members conversant with some of the recent advances in physical science, were of immense value and caused wholesome variety in the proceedings. They are also indebted to Mr. Conroy, their Honorary Secretary, for contributing such a valuable *résumé* of the history and properties of *Fucus vesiculosus*. He congratulated Mr. Conroy upon his having avoided the sensationalism which surrounded this substance in the present time and strongly deprecated the use of "Anti-fat" as empirical and simply a destroyer of vitality, and thought it too bad that foreign adventurers with large capitals should be able to so successfully hoodwink the British people. Without wishing to detract from the value of Mr. Conroy's communication on "Malachite," he considered it would have been much more valuable if it had been contributed a few weeks earlier, when its publication might have put a stop to some of the nefarious practices which had been carried on in Birkenhead. At the time he felt that the excitement produced had received far more attention from the press and the public than it was worthy of. Mr. Mason concluded by moving a vote of thanks to the President and Mr. Conroy for their communications.

Mr. R. M. Sumner, in seconding the vote of thanks, said he fully endorsed all that Mr. Mason had said, but he would like to add, what appeared to him an omission, namely, to congratulate Mr. Conroy upon the great excellence of the preparations of *Fucus vesiculosus* which he had exhibited, which were most perfect.

The President and Mr. Conroy returned thanks, after which the meeting closed.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The first meeting of the session of this Association was held at Britannia Chambers on Tuesday evening, the 4th inst., the chair being occupied by the President Mr. R. Fitzhugh, F.C.S. After the transaction of some preliminary business, the President, with a few appropriate remarks, presented the prizes to the successful associates in last session's classes, the recipients being Messrs. W. W. Talbot, W. Gill, G. E. Hare and H. Granger. He then delivered his inaugural address, in which, after alluding to the apathy shown by many of the members, he reviewed briefly the work of last session, and announced the arrangements already made for the coming one. He then went on to speak of the advantage of study to the chemist and druggist and the relationship existing between masters and apprentices, both of which subjects were treated in an eminently practical manner.

The address was listened to with much attention, and at the close Mr. R. Jackson proposed a hearty vote of thanks to the President, which was seconded by Mr. Warriner and carried unanimously and suitably responded to.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on November 20, 1879, Dr. Gilbert, Vice-President, in the chair.

The minutes of the preceding meeting were read and confirmed.

The Chairman announced that a ballot for the election of Fellows would take place at the next meeting of the Society (December 4).

The following certificates were read for the first time:—J. Howard, J. Knowles, J. Snodgrass, A. Scott, E. J. Day, J. Steiner.

The Chairman then called on Mr. CHURCH to read a paper—

On a Chemical Study of Vegetable Albinism. Part II. Respiration and Transpiration of Albino Foliage.—The author has proved that white foliage does not possess the power even in sunshine of decomposing the carbon dioxide of the air, but adds largely to the normal amount of that gas in the air, thus resembling the petals of flowers and the action of green leaves during darkness. The best results were obtained with the maple (*Acer negundo*), the holly, the ivy and the *Alocasia macrorhiza.* Every care was taken to choose white and green foliage comparable in every respect, age, etc. The leaf stalks were placed in boiled distilled water and covered by a bell-jar inverted over mercury; to the mouth of this bell-jar is fitted a cork through which pass two tubes, one long and the other short. Air is sucked from the long tube through a Pettenkofer tube containing baryta water. At the end of the experiment the Pettenkofer tube is washed out without exposure to the atmosphere, and the carbonate determined after the method of Dupré and Hake (*Chem. Soc. Jour.*, March, 1879). The CO_2 in the atmosphere was found to be 3·21 parts in 10,000. The author embodies his results in a table; 1000 sq. centims of the white foliage of the maple evolved in two hours 16·69 parts of CO_2 per 10,000 of air; 1000 sq. centims of green foliage evolved 0·44 parts CO_2; similarly 1000 sq. centims of white holly leaves evolved 18·82 parts CO_2 per 10,000; of green 4·49; 1000 sq. centims of white alocasia leaves in two experiments evolved 15·06 and 38·96 parts of CO_2 per 10,000; of green 1·14 parts. The author has also studied the comparative loss and gain of albino and green foliage. White holly sprays placed in water gained in two hours 0·29 per cent., green holly under similar conditions gained 1·55 per cent.; when no water was supplied the white holly lost 0·54 per cent., the green 10·26 per cent. The author promises further work on this interesting subject. He exhibited some dried specimens of albino and ordinary leaves, the albino leaves being thinner and altogether much less substantial in their structure.

Dr. Gilbert said that the results obtained by the author seemed to be of considerable importance. In a former paper the composition of the green and white leaves had been investigated, the white leaves containing less lime, but more non-albumenoid nitrogen than the green, indicating a capability for development without actual growth. In the present paper the author shows that these white leaves do not perform leaf functions.

Mr. Warington remarked that in the white leaves respiration seemed to take place in an exalted state. He would like to know whether much starch had been found in the white leaves.

Mr. Groves asked if there was any difference in the number of stomata in the white and green leaves.

Dr. Voelcker inquired where the large amount of carbonic acid given off by the white leaves came from; the researches seemed to indicate that the white leaves seemed to be partially if not quite dead, or at least gradually decomposing; this would account for the evolution of CO_2.

Mr. Church in reply said there was more starch in the green than in the white leaves, and that the leaves used in the experiments were all in active growth and not in the least decaying. In his opinion the CO_2 given off by the white leaves came from substances elaborated by the green leaves; in the same way the flowers of the white lily and green leaves in the dark evolved CO_2, without any actual decay. The green leaves gave off CO_2 as well as the white, but in sunshine they decomposed more than they excreted. As far as he knew, white and green leaves had the same number of stomata.

Mr. KINGZETT then read a paper entitled—

Contributions to the History of Putrefaction. Part I.—The author discusses to a certain extent the process of putrefaction, and concludes that it would naturally be expected that a substance allowed to undergo putrid fermentation without oxidation would more readily undergo chemical oxidation than the original integral mass, and therefore that the oxygen-absorbing capacity of a substance would progress increasingly with such putrefactive decomposition. He therefore endeavoured to determine the oxygen-absorbing capacities of organic solutions from time to time as they passed into putrefaction, and to compare these numbers with the oxygen capacities of similar solutions protected during the same periods by so-called antiseptics. Various difficulties were met with, and the author does not offer all the results obtained. Some of the experiments, however, have an important bearing on Tidy's oxygen process, which, in the words of its author, "undoubtedly furnishes us with exact information as to the relative quantities of putrescent and easily oxidizable matter and of non-putrescent or less easily oxidizable matters present in the water." The author of the present paper thinks that the oxygen process is liable to mislead chemists in interpreting their results if the most pernicious organic matters are those which are in a putrescent state, for from the results obtained by Kingzett, it appears that the oxygen absorbed by a water containing organic matter in a non-putrescent condition is more than that required by the same organic matter in a putrescent state. Thus 5 c.c. of a dilute solution of albumen, which began to stink after 150 hours, requires, when fresh, permanganate equal to 0·008004 grm. oxygen; after keeping 24 hours, 0·008671; after 120 hours, 0·0076038; after 1104 hours, 0·00667; after 1176 hours, 0·0062031; after 1440 hours, 0·0058696; after 1534, 0·0054694; showing after a slight rise (8 per cent.) a decrease of over 30 per cent. in the oxygen absorbed. Similar results were obtained with extracts of beef, fish, etc. Thus the author concludes that the oxygen process might pass a water containing pernicious products, since it is possible to obtain an organic solution in an active state of putrefaction which requires less permanganate than the same solution in a fresh state.

Professor Tidy said that the results obtained by Mr. Kingzett required thinking about. No doubt different materials had different oxygen-absorbing powers. As a practical man he was satisfied with the third place of decimals. He was pleased to see Mr. Kingzett found it necessary to go to the seventh.

Mr. Otto Hehner thought that the results rather proved than disproved the accuracy of the oxygen process, because the oxygen-absorbing power did at first increase. Afterwards, of course, substances nitrified, and in other ways the organic matter disappeared. This rise and subsequent decrease he had himself pointed out, using the albumenoid ammonia process.

Mr. Church suggested that some inaccuracy might arise from the deposit which fell as the solution putrified, the successive quantities of 5 c.c. containing less and less organic matter as the deposit increased.

After some remarks by Dr. Voelcker, and a brief reply by Mr. Kingzett to the various points raised in the discussion,

The next paper was read by Dr. Wright; it was entitled—

Notes on Manganese Dioxide. By C. R. A. Wright and A. E. Menke.—The authors have repeated many of the experiments of former observers, with, in some cases, very different results. They have made many careful gravimetric analyses of the substances precipitated under various conditions, the experiments being more particularly directed to the examination of substances formed in presence of potassium compounds, so as to determine how far potash is carried down in combination with the manganese. Substances were prepared by the action of nitric acid or sulphuric acid on potassium permanganate. By solution in hydrochloric acid, and re-precipitation by water in presence, or absence, of potassium salts; by acting on potassium permanganate with sulphurous acid, alcohol and glycerin; by precipitating manganese salts with potassium permanganate under various conditions; by acting with air and caustic potash on manganese salts (Weldonizing); by precipitating from solution by bromine, etc., under various conditions, and by heating manganese nitrate to 160° alone and in the presence of potassium nitrate. In every case, except the last, potassium was present in the ultimate product in considerable quantity, even though the precipitate was formed in presence of very large quantities of free hydrochloric, sulphuric, nitric or acetic acids. Other metals if present are often carried down in preference to potassium, *e.g.*, calcium; unless the circumstances of the experiments are such as to allow of the precipitation of a large percentage of potassium or other equivalent metal the precipitate never contains as much oxygen as corresponds to MnO_2, the deficiency being greater or less as the quantity of potash present is less or more. The only exception to this rule occurs when hot solutions of manganese salt and excess of permanganate act on one another; with cold solutions the precipitate is deficient in oxygen unless zinc sulphate be added. Manganese dioxide containing potash can be completely converted into MnO, retaining but traces of potash, by long continued ignition in a current of hydrogen; the free oxide thus formed does not spontaneously oxidize in the air. When freshly thrown down and just dry to the sight and touch, the dioxide is a hydrate $4MnO_2+H_2O$; on standing over sulphuric acid this hydrate loses water indefinitely and continuously. MnO_2H_2O is the lowest hydrate stable in dry air. Up to 108° no appreciable loss of oxygen accompanies the expulsion of water; at 210° all the precipitated oxides, etc., dried, lose oxygen slowly and regularly; the nearly anhydrous MnO_2, prepared by heating manganese nitrate to 160°, does not evolve oxygen at 210°. In all cases perceptible amounts of water from a few tenths to 2 per cent. are retained after many hours' drying in a current of dry pure air at 210°. The volumetric processes of Kessler and Pattinson have been examined; they give good results. The authors suggest a convenient modification of Pattinson's method. The diluted solution slightly acid is heated to nearly 100°, a considerable excess of bromine water added and then freshly precipitated zinc carbonate, all free bromine being expelled by boiling. Ferric chloride usually forms permanganate, and thus complicates the manipulation. A more convenient and quite as accurate a method as any of those requiring bromine, etc., was found to be the addition of the diluted and not too acid solution of manganese in the cold, to a small excess of dilute permanganate solution containing zinc sulphate; the precipitate is collected on a glass wool funnel, dissolved in excess of acid ferrous sulphate, and titrated as usual. Three-fifths of the manganese in the precipitate represent the manganese in the original solution. The authors have verified the statement of Gorgeu that actual MnO_2 is obtained by heating manganese nitrate to 160°. The statements of Guyard as to the effect of heat on the precipitate formed by adding manganese salts to permanganate are also corroborated. The recent statements of Pickering as to the deficiency of oxygen in the substances thrown down by acting with water on the superchlorides of manganese are also substantially correct. The accuracy of the results of Volhard, as to obtaining pure MnO_2 free from potash by precipitating manganese sulphate with permanganate in the presence of nitric acid, etc., is questioned by the authors. The experiments of Morawski and Stingl have not been confirmed as far as they have been repeated, viz., hydrated manganese dioxide containing potash does not (as stated by these chemists) lose all its water by ignition, the substance thrown down by the action of manganese sulphate on potassium permanganate is not $3MnO_2 2H_2O$, but an indefinite hydrate containing much potash; on boiling with caustic potash it does not form (after washing and drying at 100°) $Mn_4KH_3O_{10}$ or $8MnO_2K_2O,_3H_2O$ as stated, but a substance much richer in potash $5MnO_2K_2O$; $Mn_4KH_3O_{10}$ does not uniformly result by the action of alcohol, glycerin, etc., on potassium permanganate, but instead, substances of very variable composition. The authors also notice incidentally that manganese chloride is sensibly volatile at a red heat in a current of HCl, and that perceptible errors in alkali determinations may be introduced if solutions containing ammonium sulphide are evaporated down in glass or porcelain. Identical results were obtained when titrating the available oxygen in a substance, whether the material was dissolved in acid ferrous sulphate checked by dichromate, or was distilled with HCl into KI and the liberated iodine estimated by adding excess of thiosulphate, and titrating back with iodine solution.

The next paper was read by the Secretary, on—

The Reaction between Sodium Thiosulphate and Iodine—Estimation of Manganese Oxides and Potassium Bichromate. By S. Pickering.—In a former paper the author suggested a modification of Bunsen's volumetric method, viz., transferring the sample to be analysed to a beaker containing a large excess of potassium iodide, adding a small quantity of acid and determining the iodine liberated by running in sodium thiosulphate solution. This method gives results slightly higher than the original method of Bunsen, viz., boiling the oxides with hydrochloric acid and collecting the evolved chlorine in a solution of potassium iodide. The author has in the present paper exhaustively examined the effects produced by varying the several conditions of the reaction. When iodine and sodium thiosulphate react in warm solution, a decomposition, $4I_2+Na_2S_2O_3+5H_2O=2NaHSO_4+8HI$, attended with the formation of sulphate, occurs, as well as the ordinary reaction $I_2+2Na_2S_2O_3=Na_2S_4O_6+2NaI$. Thus at 52° 3·9 per cent. of iodine reacted to form sulphate, at 0° 1·84 to 2 per cent. reacted in a similar manner. Dilution increases very slightly the amount of sulphate formed. An excess of potassium iodide is without effect. Dilute solutions of iodine do not vary in four days as regards the amount of iodine they contain, whether kept in the dark or in diffused daylight. Within certain limits the amount of iodine liberated at once is proportional to the amount of hydrochloric acid added, but the acid has no influence on the relative proportions in which the two above-mentioned reactions take place. No difference occurs whether the reaction is made by adding iodine solution to an excess of thiosulphate or thiosulphate to the iodine; if, however, hydrochloric acid be present the amount of sulphate is increased. The author discusses the various forms of apparatus for estimating the oxides of manganese by Bunsen's plan. He prefers boiling the oxide in a small flask fitted with a thistle funnel, the chlorine being absorbed in three other flasks containing potassium iodide. Traces of chlorine were retained by the acid liquid, even after prolonged boiling. If undiluted acid be used the Bunsen method gives results almost identical with those obtained by using the plan suggested by the author; if the acid be diluted, the amount of chlorine evolved is diminished in the Bunsen method. If potassium bichromate be estimated by the Bunsen method, a notable deficiency of chlorine is observed, even if the acid be undiluted. If chlorine water be diluted and boiled, considerable loss of chlorine takes place, from the formation of hydrochloric acid; this loss begins at lower temperatures. This probably is sufficient to explain the low results obtained with the Bunsen method. The author's modification is, of course, not applicable to manganese ores, owing to the presence of ferric oxide. Bunsen's method must, therefore, be used with the precautions above indicated.

The Society then adjourned to December 4, when a ballot for the election of Fellows will take place, and the following papers be read:—On the Theory of Fractional Distillation, Part II.; by F. D. Brown; On the Influences exerted upon Certain Chemical Changes by Variations in the Amount of Water of Dilution, by M. M. P. Muir and C. Slater; On α and β Phenanthrene Carbonic Acid, by F. R. Japp; On Some Derivations of Phenylacetic Acid, by P. Phillips Bedson.

Parliamentary and Law Proceedings.

ADULTERATION OF BAKING POWDER.

At the Cambridge Borough Police Court, on Thursday, November 20, before the Mayor, the Master of Christ's, Professor G. D. Livering, Dr. Fawcett, J. Deighton and S. Peed, Esqrs., Messrs. Warren, of Cambridge, wholesale grocers, were charged with selling baking powder containing ingredients injurious to health, viz., 15 per cent. of alum. These were the nominal defendants, the case being really defended in the interests of the manufacturers, Messrs. J. B. Smith and Sons, of Norwich, wholesale druggists, and manufacturers of the "Norfolk Baking Powder." Mr. Cockerell, instructed by the Town Clerk, prosecuted; Mr. Blofeld, instructed by Mr. G. B. Kennett, appeared for the defence. The case lasted upwards of four hours. For the defence it was contended that the powder was not an article of food, and further, that the alum in the powder was neutralized in its effect by the addition of bicarbonate of soda. In the result, the Bench inflicted a penalty of 40*s.* and costs.—Notice of appeal was given.—*East Anglian Daily Times.*

THE SOCIETY OF ARTS ARTISAN REPORTS ON THE PARIS UNIVERSAL EXHIBITION OF 1878. London: Sampson Low and Co. 1879.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

[345]. Mr. Mackay having failed finding any authority upon this, I beg to refer him to Parrish's 'Pharmacy,' page 856, where he will find a formula for an injection containing zinc sulphate and lead acetate, combined with other ingredients, also the following:—"This is an instance in which chemical incompatibles are mixed advisably so as to produce a very fine precipitate, which, being diffused in the liquid and deposited on the mucous membrane favours the therapeutic effect intended." The value of such an authority needs no comment of mine.

FELIX STEVENS.

[345]. A few days ago I dispensed an old prescription of Henry Lee's, containing lead and zinc for an injection, and notwithstanding the opinion of J. B. L. Mackay, with his long list of standard works, I did not filter, but directed the bottle to be shaken.

I have frequently made a similar injection from the late W. Acton's prescriptions, and I venture to think these two eminent surgeons knew as much about injections as all Mr. Mackay's authorities put together.

Some years ago, when living at Cheltenham, a doctor wrote a similar prescription in the shop, and when I pointed out to him the decomposition that would take place he told me he was quite aware of it, that he always prescribed it and it always had the desired effect.

For once, I do not agree with the editor of "The Month;" I would sooner filter it out than leave the precipitate for the last syringeful.

WM. GEO. STRONGITHARM.

[347]. THE COLOUR OF EUONYMIN.—It is doubtless correct that to some extent this varies with the manipulation (see page 325), but to a much greater extent the variation is due to the age of the bark when used. The recent extended demand for euonymin has led to the utilization of whatever bark could be obtained, with perhaps but little reference to its age or the time of collection. The green euonymin is prepared from young green bark, and the brown kind without any shade of green (which is not so acceptable or so powerful) is prepared from bark which is so old that chlorophyll has disappeared from it; the intermediate tints are procured by working bark of which the age varies between these extremes. It may be useful to state here that liquorice powder should not be dispensed with euonymin or other resinoids; in several cases it has been found to have the effect of rendering them all but inert. For instance, when in New York, a few weeks ago, I was informed by a manufacturer that a sufficiently active pill composed of euonymin, ½ grain, podophyllin, ⅛ grain, and leptandrin,

$\frac{3}{8}$ grain, had hardly any purgative power when made up with liquorice powder. JOHN MOSS.

[377]. Would any reader of the Journal kindly inform me the best mode of dispensing the following?

℞ Sodæ Salicylic.	. . . .	ʒij.
Ammonii Bromid.	. . . .	ʒiss.
Sp. Chloroform.	. . . .	ʒij.
Ext. Cinchon. Liq.	. . . .	ʒiij.
Aq. Destil.	. . . . ad	℥viij.

M. Take one tablespoonful every four hours.

NOVIS.

[378]. Would any reader kindly inform me how to proceed with the following prescription? I have been told by the prescriber that it has been dispensed in London to his entire satisfaction.

℞ Zinci Oxidi	. . . .	ʒij.
Calaminæ Pulv.	. . . .	ʒj.
Vaseline	. . . .	℥ss.
Aq. Calcis	. . . . ad	℥iv.

M. ADOLESCENS.

Notes and Queries.

[636]. DR. STARTIN'S POMADE.—In answer to W. Richards's query, I believe that the following is the formula for "Dr. Startin's pomade:"—

℞ Hydrarg. Oxid. Rub.,		
Hydrarg. Ammoniat.	. . . . . āā	℈ss.
Ol. Amygdal. Dulc.,		
Adipis	. . . . āā	ʒj.

M. Ft. pomade. T. ROBERTS.

[640]. SANTONIN WORM CAKES.—Will any correspondent oblige me with a form for "Worm Cakes" containing santonine; also the dose? NU.

[641]. GINGER ALE.—Can any of your readers give a good formula for making ginger ale? J. S. C.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

THE BOTANICAL ORIGIN OF DAMIANA.

Sir,—In your last issue I observe in the "Answers to Correspondents," on p. 420, that you have attributed to me the determination of the botanical origin of Damiana. This is not strictly correct, for although I identified the true Damiana as a species of *Turnera*, probably hitherto undescribed, but near to *T. microphylla*, D.C., my identification was made from a few isolated flowers found mixed with the Damiana leaves of commerce. Some months after the publication of my paper I accidentally came across a statement that the plant had been identified and described in the United States, and after considerable difficulty traced the article alluded to and obtained a copy of the journal containing it, when I found that it had been published earlier than my paper. It is to be found in the *Virginia Medical Monthly*, vol. iii., No. 1, April, 1876, p. 47. As the description of the plant has not yet been published, so far as I am aware, in this country, I send it herewith:—

"*Turnera aphrodisaica*, L. Ward.—*Calyx* tubular, funnel-shaped, the lobes shorter than the tube; *styles* three, distinct; *stigma* flabellate; *stems* woody, the branches reddish, densely canescent or lanulose, as well as the petioles and lower portion of the midrib; *leaves*, obovate to oblanceolate, 6 to 9 lines long, 2 to 3 lines wide, on short petioles, strongly crenate-dentate, the teeth with revolute margins, prominently veined beneath, nearly glabrous above, glandular below, bearing fascicles of smaller leaves in their axils, together with the flowers; *flowers* shortly pedicelled or nearly sessile, axillary or petiolary, *i.e.*, developed either from the centre of axillary fascicles of minute leaves or from between them and the base of the petioles, or in some cases from the petiole itself above the base, bibracteolate, the bracts ovate, long, acuminate, ciliate; *anthers* somewhat sagittate, introrse, the cells thin, ovaries dehiscent from the apex to near the base; seeds, large, long, kidney-shaped or curved, grooved lengthwise and pitted, only a few maturing, the rest abortive and persistent."

The above is the description given in January, 1876, by Mr. Lester F. Ward, a comparison of which with my description in *Pharm. Journ.* [3], vol. vi., p. 531, will show that the two determinations were made independently, since points omitted in the one are mentioned in the other and *vice versâ*.

The Editor of the *Virginia Medical Monthly* remarks concerning the plant that it differs from *T. carpinifolia* in the shape and serration of the leaves, and that the latter plant, which he thinks is the one most likely to be confounded with Damiana, is a native of damp river bottoms in South America, while the former is found only on dry rocky places in Western Mexico. E. M. HOLMES.

THE EVENING MEETINGS.

Sir,—The voice from the gallery is, I am sure, no less discordant to most of your readers (who know the true state of things) than to me, and the "growler" is but turning into ridicule a subject of vital importance by such a communication.

I fully intended writing upon the death rate among *pharmaciens* myself, but have not had time to give the matter the amount of consideration it deserves. Yet this ridiculous and delusive letter from "One of the Gods" calls for some reply.

He need not liken the house of the Society, so remarkable for its orderliness to the Augean chamber of Grecian mythology.

Comparisons are very odious in this case!

There are not 300 students attending the lectures of the school, but about one-tenth part of that number; while, from personal experience, I can state that the students do not suffer from a tendency to asphyxia during class hours, but rather feel the draughts very much in winter. If, therefore, currents of air are freely established, how can we be suffocated by the emanations from students or exhalations from the lungs of the orators he speaks of? Or how could the products of burning "a few thousand feet of gas" (as if the writer in question daily regulated the metre registration), or the odoriferous remains of three lectures, accumulate against the Wednesday meetings? To carry out the hyperbole why not say six-and-twenty lectures, since the evening meetings are only held once a month?

There are good ventilators in the theatre, for the products of gas combustion are carried off directly into the open air—a thing which seldom obtains in our churches or dwellings or theatres of a lower order.

It should be remembered that it is quite possible to suffocate a crowd of people with the open canopy of heaven overhead, if only confined by four walls, but here more provision is made than simple diffusion of gases.

Again, there are no less than six walls to the lecture theatre at "the Square," and as to the gallery—though such exists—it is not open to the public (save a few ladies of a reserved nature on the occasion of the inaugural meeting), because, unfortunately, the evening meetings are not sufficiently patronized ordinarily to demand the extra accommodation.

But even were the "atmospheric surroundings" so dreadful as he makes out, your correspondent could not sustain much injury if he only inhales the noxious air for the few minutes after ten o'clock once a month.

What must your readers think of our head-quarters from this description of a "subterranean cavern?"

Such a singular collection of inaccuracies one does not often meet with—but the whole story of the perpetrator of the "solitary howl" seems as much a myth as the very fable of Augeas itself.

Evidently he has only visited the building once in his life, and as to his recollections thereof, we might safely say, as Elijah said of Baal to the false prophets, "Peradventure he dreameth," especially when he acknowledges himself to be "One of the Gods." J. B. L. MACKAY.

THE QUESTION OF POLICY.

Sir,—I was very much pleased in reading the remarks of Mr. C. B. Allen, in a recent issue, and to me as an old established pharmacist, it seems to be the best suggestion that has been put forth to counteract the sale of patent and other preparations by unqualified shopkeepers.

I think we as pharmacists should take the initiative to protect ourselves, and have a clause in the proposed new amended Pharmacy Act whereby all preparations, so called patents or any other secret preparations, containing poisons, should not be sold except by registered chemists.

Lodge Lane, Liverpool. J. THOMPSON.

THE PROMOTION OF AMATEUR DISPENSING.

Sir,—If I were Mr. Ellwood I should not think of measuring the strychnine and mixing it with the water unless I were called upon to dispense the whole of the prescription, and I would take care that if the customer purchased the ingredients separately from me, with a view to dispense them herself, that the cost of them should be quite equal to that of my dispensing the prescription.

The method of Anglicizing prescriptions is most objectionable, and I wonder that any surgeon should condescend to lower himself to it. No doubt he took as full a fee as he thought he could get, and then grudged the chemist a fair charge for dispensing his prescription. If he take my advice, next time, instead of Anglicizing the prescription he had better prepare it free of charge, and then it will not involve the patient in any cost whatever, and it will also save her all trouble, which of course would be a great consideration with such a man.

"ONE WHO WOULD TRY TO BE EVEN WITH THEM."

SUNDAY TRADING.

Sir,—In answer to your correspondent "Jek," who wishes for the opinion of others regarding Sunday duty, I would say let us all abide by the rules of that Book of Books given for the guidance of all men; rules for every day, and Sunday too, are copiously given.

"Jek" has heard some say they "cannot refuse to sell other things besides medicine whilst the shop is open."

Would it not be nearer the truth to say "will not" instead of "cannot?" If they are Christians, let them show the light before all men, not hide it on an emergency, or when they think it keeps a 6*d*. or 1*s*. out of their till.

Thinking of "Jek" on Sunday evening, I made a note of my customers' wants, about thirty in number, from 7 to 10 p.m. All but two were medicine, in the truest sense of the word; the two refused were Pears' soap and sachet powder.

I have drawn the line between necessary and unnecessary articles for six years and find it works well, and I believe a good impression is produced by a kind refusal of what can be as well bought on Monday. It is true every rule has its exception. Sometimes, a bottle of eau de Cologne or perfume is required for the "sick room," I then sell it readily. If the customer tells an untruth in order to obtain it, it rests with him; I sell it in ignorance thereof, and on good intent.

I think I am asked prices of hair brushes and combs more on Sundays than any other day, my reply is "I sell nothing but medicines."

Once only, did I break through this rule. A poor woman came one Sunday morning, begging me to let her have a 6*d*. comb; hers had got lost, she wanted to get her little ones ready for church; this was, I thought, a case of necessity.

Let us all strive to elevate our position; by doing what we can to benefit our fellows and drop a good word in season, when opportunity offers itself. VOLO.

THE HEALTH OF THE DRUG TRADE.

Sir,—It will be a cause for regret if the correspondence upon this important subject is allowed to drop without producing any practical effect.

In reply to my challenge I received a large bundle of letters inquiring how a chemist may be as healthy and live as long as his next door tradesmen do.

These letters showed that the writers were in grievous want of the knowledge of self-preservation; I spent a fortnight in answering each in the fullest possible way. I do not pretend to have done any good, for I fear that only a few will make the attempt to do what is required of them, and that the majority will go down to their graves as negligent suicides.

Now, with respect to our vital statistics, taking the thing in the abstract, the early death of a simpleton is not a thing to be deplored; for should he live, there is a danger that, owing to a great compensatory law of nature he will breed a good many more simpletons; should he have already some children, we find that the children of simpletons generally fare better as orphans than otherwise, because they often fall under the care of the wise and the prudent, whereas the children of simpletons under the care of simpletons make a pitiful picture indeed. In this way we may console ourselves while we see the survival of the fittest.

But the point which strikes me is that while this wretched process is going on, that the poor "drugerist" is half dead so long before he dies. If I take a walk round a large town and ask a question of the grocers, I get a smart answer from most of them, but if I venture to call upon the druggists, the result will be just the reverse.

The poor white faced man does not recollect if "he has had any voting papers sent him, he is not sure, he has a great many papers sent him, he does not know where they are now, there is no one that he wishes to vote for, he does not know anything about it, he could not give him an answer to-morrow, no, he would consider the matter." If that will get me out of his shop, this done, he relapses into helplessness and the daily newspaper, wonders when business will improve, thinks that the Council ought to do something!

This is a picture drawn from life, and one which proves that our politics and our health are not disconnected.

Moses of old found that a race of slaves could not be made into a nation, and I find that a race of men like this cannot be raised above their degradation.

The letters which have appeared indicate a consciousness that more outdoor exercise should be taken Well for once we are agreed.

Now, let each reader of the above, who feels that he is a better man than is here described, determine at once to call upon a fellow-sufferer and see if the hours of business can be curtailed. Not that the shutters should be put up and a victim kept to listen to the bell; this is rank hypocrisy. When a companion is found, let them both go round the town and neighbourhood and urge the importance of health *versus* money. Do not be discouraged by refusals; call again and again, and be sure to hunt in couples. The moral effect of two to one is very great. Much more can be done, but begin with this.

Rochester. H. BARNABY.

Ichthyoc.—See an article on the Solidification of Balsam of Copaiba, by M. Thiery, in the first series of the *Pharm. Journ.*, vol. i., p. 655, and another by Roussin in the second series, vol. vii., p. 326.

Apprentice.—Recipes for lavender water may be found in any work on perfumery.

J. W. H.—Full information will be found in the "Students' Number" of any of the medical journals, published in September.

"*Galangal.*"—Recipes for glycerine jelly were given in the Journal Nov. 30, 1878, p. 463.

"*Lapides*" does not say what kind of "stones" he wishes to dissolve. We know of no book treating specially of the subject.

E. Hall.—You are advised to apply for information to the local authority. The law applies to all measures used for the purposes of trade.

Statim.—The recipe has not been published and we must leave to our correspondent the opportunity of making an application to the maker for it. Probably it resembles closely in composition other well known preparations.

R. E.—A simple test is the evaporation of a quantity of the water and noticing whether the residue becomes browned when moderately heated. Positive indications in this case may be relied upon, though a negative result would be less trustworthy.

COMMUNICATIONS, LETTERS, etc., have been received from Warneford, Stevens, Gostling, Brown, Billing, Roberts, Jackson, Osbourn, Young, Culverwell, Beta, Sub Umbra Floresco, Syrupus, Nemo, G. A. F., J. B. O., A. C., A. P. S., J. W. H., J. A.

A METHOD FOR THE VOLUMETRIC ESTIMATION OF ARSENIC ACID.*

BY W. A. H. NAYLOR, F.C.S.

While conducting some experiments upon the action of certain reducing agents upon arsenic compounds, my attention was directed to a peculiar reaction which takes place between arseniate of sodium and the iodine halogen acid. It was found that upon adding a solution of hydriodic acid to an alkaline arseniate, iodine was slowly and continuously set free. As this observation was new to me, the literature on arsenicum was diligently searched with the general result that no mention of this decomposition could be found in any of the well known text-books, or even in Watts's 'Dictionary.' English and French journals were likewise consulted, but with no better result. From a desire to understand more thoroughly the nature of this reaction, and not knowing from whence to obtain the necessary information, recourse was had to experiment. As these experiments progressed they grew in interest and widened in their range, inducing me at last to make a careful and systematic study of the action of the halogen acids upon arsenic compounds. The results embodied in this paper have reference mainly to the reaction above cited, and are intended first to explain the nature of that reaction and then to show how it may be advantageously applied to the volumetric estimation of arsenic acid.

My earliest inquiries led to the establishment of the following, that when iodine acts upon a boiling aqueous solution of arsenious acid no iodo-arsenic acid is produced, but that the acid is partially oxidized with the simultaneous formation of hydriodic acid, and that when this solution becomes concentrated a portion of the arsenic acid suffers reduction, while a proportionate quantity of iodine is set free. It was not until a few days ago that I had the gratification of discovering that these facts formed a substantial epitome of a paper published by M. Wegner† on the action of iodine on arsenious acid. Confirmation in this instance has a certain value quite apart from its independent character, inasmuch as Zinno had previously concluded from his experiments that iodo-arsenic acid was produced under these conditions.

Passing from this preliminary work, it next became a matter of interest to ascertain whether an alkaline arseniate would be completely reduced to the condition of arsenite, and if so, would the amount of iodine set free be constant in its quantitative expression of the reduction. On the supposition that this reduction would be complete it was thought that one of the two following equations would represent the final decomposition.

$$Na_2HAsO_4 + 2HI = Na_2HAsO_3 + I_2 + H_2O$$

or

$$Na_2HAsO_4 + 3HI = NaH_2AsO_3 + NaI + I_2 + H_2O.$$

It will be seen that in each case one molecule of the anhydrous salt would be equivalent to two atoms of iodine. Inasmuch, however, as one equation represents a combination of iodine with sodium, it was not difficult to decide which of the two is the more correct. This was done in the following way. To a 20 per cent. solution of hydriodic acid a little arseniate of sodium was added and allowed to stand for three hours. It was then intimately mixed with recently precipitated well washed mercurous oxide, and evaporated to dryness in presence of metallic mercury. The residue was digested in warm water, filtered, and the filtrate tested for iodine. There was no indication of an iodide. The second equation cannot therefore represent this decomposition. In order to determine the completeness or otherwise of the reduction, the following methods were employed. The hydriodic acid, prepared by the action of sulphuric acid upon iodide of barium and subsequent distillation, was allowed to act for stated and different periods upon the arseniate in an atmosphere of carbonic acid gas. At the end of the allotted time—varying from three to six hours—the free iodine was removed by hyposulphite of sodium, ammonia added in excess, followed by a little ammonium chloride and magnesium mixture. Of a number of experiments made in this way there was not one which showed the reduction to have been complete, although in many cases the solution after standing twenty-four hours gave only a small precipitate.

A second method was to remove the free iodine and hydriodic acid by moist mercurous oxide and metallic mercury; here also a distinct precipitate was observable after long standing. A third method was to add to the neutral solution from which iodine and hydriodic acid had been removed a solution of nitrate of silver drop by drop. No reddish or chocolate-coloured precipitate fell, the deposit was uniformly yellow.

The extent of the most complete reduction hitherto obtained was next determined by titrating, with decinormal solution of hyposulphite of sodium the iodine liberated by a known weight of anhydrous arseniate of sodium. A 20 per cent. solution of hydriodic acid was used and allowed to remain in contact with the arseniate for four hours. The result of this determination showed a deficiency of 3 per cent. of the salt taken. It now became important to ascertain whether the extent of reduction was dependent upon the strength of the hydriodic acid; also, whether by repeated removals of the iodine by mercurous oxide and successive digestions with hydriodic acid solution complete reduction would be effected. To the first query, there was no difficulty in furnishing a reply. A few experiments conclusively proved that the greatest reduction was obtainable by solutions containing not less than 20 per cent. of hydriodic acid, while with 10 per cent. solutions the reduction was relatively small. With reference to the second query the reply must be negative. Complete reduction was not effected by removing the iodine at comparatively long intervals and adding more hydriodic acid. The facts of this experiment taken in conjunction with subsequent ones appear to be capable of explanation only on the ground that reduction proceeds until it arrives at its point of completion and then the free iodine begins a gradual work of oxidation. To decide this point it was necessary to devise some means of removing the iodine as it was liberated from a known weight of anhydrous arseniate of sodium and at the same time determine its quantity. This was done by inclosing the hydriodic acid and a known weight of arseniate of sodium in a tube the air of which was replaced by carbonic acid gas. As the iodine was set free a standard solution of hyposulphite of sodium was run in from a burette in such quantities as to leave a trace of free iodine. When no more iodine

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 3, 1879.

† *Annal. Chem.*, clxxiv., 129—133.

was liberated the decomposition was considered complete. This method was found to give accurate results when calculated on the assumption that every 186 parts of anhydrous arseniate of sodium gave 254 parts of iodine. The length of time, however, consumed in working the process, together with the precautions to be observed in the preparation of the hydriodic acid, proved a fatal objection to its employment. After further experiment, it was found possible to overcome these difficulties, partly by the addition of a little hydrochloric acid to the solution of the alkaline arseniate, thereby substituting free arsenic acid for the alkaline salt, and partly by resorting to the use of iodide of potassium as the source of the hydriodic acid. The operation may be briefly described thus:—Weigh out a quantity of the substance to be examined equivalent to from ·05 to ·03 gram of arsenic acid, and, having dissolved it in just sufficient water or dilute hydrochloric acid, pour in 5 c.c. of a 20 per cent. solution of hydriodic acid. The iodine, as it is liberated, is titrated with a decinormal solution of hyposulphite of sodium. This part of the operation must be conducted in an atmosphere of carbonic acid gas to guard against any decomposition of the hydriodic acid by the surrounding atmosphere. Towards the end of the process the iodine will appear at increased intervals, so that if it is desired to attain the degree of accuracy of which the test is capable, fifteen minutes should be allowed after the decoloration of the solution before taking the final reading on the burette.

The hydriodic acid solution may be conveniently prepared by dissolving 25 grains of iodide of potassium in 80 minims of water, and adding thereto 20 minims of hydrochloric acid 1·16.

Operating in this way upon arseniate of sodium of known purity, the following results were obtained:—

	Na_2HAsO_4 taken.	Na_2HAsO_4 found.
No. 1 . . .	·0615 gram.	·0610 gram.
„ 2 . . .	·0625 „	·0622 „
„ 3 . . .	·1300 „	·1298 „
„ 4 . . .	·0560 „	·0556 „
„ 5 . . .	·0500 „	·0510 „
„ 6 . . .	·0500 „	·0510 „
„ 7 . . .	·0500 „	·0500 „
„ 8 . . .	·0500 „	·0500 „

These figures show a maximum error of 2 per cent., while the minimum is less than ·25 per cent. of the salt taken. They further indicate an almost complete reduction of the arsenic acid. Additional confirmation of this fact was obtained by neutralizing the free acid of the solution with soda, then adding a little ammonia and magnesium mixture; after twenty-four hours a white crystalline film was found coating the side of the tube. By carefully noting the time required to produce turbidity, and imitating the conditions under which it was formed, the amount of arseniate present could be approximately ascertained from experiments made upon solutions containing known weights of the acid. This method usually represented a deficiency in the reduction of ·75 per cent.

There is still one other point which demands attention. Upon a closer examination of the general process it will be seen that the conditions favourable for the formation of iodide of arsenicum are in part fulfilled, since the reduced arsenic acid is in contact with excess of hydriodic acid. The mode of search for iodide of arsenicum was extremely simple. After allowing the mixed solutions of arsenic and hydriodic acids to stand for half an hour the free iodine was removed by ether; the aqueous portion was then carefully neutralized, or rendered feebly alkaline by soda, and evaporated rapidly to dryness; the residue was digested in bisulphide of carbon, which by spontaneous vaporization would deposit any iodide of arsenicum the solution originally contained.

This process was many times repeated, but always with negative results, except when small quantities of the salt were added; its detection then affording corroborative evidence. It now became a matter of interest to ascertain whether after having deoxidized the arseniate concordant results would be obtained by reconverting it into arsenic acid on the addition of iodine to its alkaline solution. For this purpose a definite quantity of arseniate of sodium was treated in the usual manner with hydriodic acid, and the iodine removed by decinormal solution of hyposulphite of sodium; the solution was then rendered alkaline by bicarbonate of sodium, and a decinormal solution of iodine run in until its colour no longer disappeared. The following are some of the results obtained:—

	Na_2HAsO_4. taken.	Na_2HAsO_4 found by de-oxidation.	Na_2HAsO_4 found by re-oxidation.
No. 1 .	·095 gram.	·0945 gram.	·0948 gram.
„ 2 .	·047 „	·0470 „	·0480 „
„ 3 .	·066 „	·0660 „	·0665 „
„ 5 .	·075 „	·0760 „	·0760 „
„ 4 .	·070 „	·0710 „	·0706 „
„ 6 .	·073 „	·0740 „	·0740 „

Here the maximum error is 2·12 per cent. of the salt taken.

It will be observed that these results corroborate those other experiments which represent the reduction as being practically complete.

The facts now acquired present us with a simple explanation of the manner in which arsenic acid and hydriodic acid react upon each other under certain conditions, and may be expressed thus:—

$$\underbrace{H_3AsO_4}_{142} + 2HI = H_3AsO_3 + H_2O + \underbrace{I_2}_{254}.$$

The difficulty of estimating arsenic acid when mixed with relatively large quantities of alkaline arsenites and phosphates suggested the following experiments. Results obtained with arseniate of sodium in presence of alkaline arsenites:—

	Na_2HAsO_4 taken.	$+Na_2HAsO_3$?	Na_2HAsO_4 found.
No. 1 .	·053 gram.	·100 gram.	·0531 gram.
„ 2 .	·067 „	·300 „	·0671 „
„ 3 .	·063 „	·400 „	·0628 „
„ 4 .	·082 „	·800 „	·0817 „
„ 5 .	·062 „	·500 „	·0630 „
„ 6 .	·052 „	1·000 „	·051 „

These numbers show a maximum error of 2 per cent. with a minimum error of ·14 per cent.

From these results it is evident that much arsenious acid does not exert so material an influence as to render the determinations untrustworthy. It must, however, be admitted that some little inconvenience attends this operation; this is caused by the comparative insolubility and consequent separation of arsenious acid. It is important that the iodine be removed as rapidly as it is liberated, otherwise it is apt to form a mechanical admixture with the arsenious acid, a condition in which it cannot readily be attacked.

The following results were obtained when arseniate of sodium was mixed with phosphate of sodium:—

	Na_2HAsO_4 taken.	$+ Na_2HPO_4$.	Na_2HAsO_4 found.
No. 1 .	·050 gram.	·500 gram.	·0493 gram.
„ 2 .	·050 „	·800 „	·0500 „
„ 3 .	·050 „	1·000 „	·0500 „
„ 4 .	·044 „	1·200 „	·0441 „
„ 5 .	·082 „	1·500 „	·0822 „
„ 6 .	·034 „	2·000 „	·0340 „

In connection with these results one remark need only be made, that is, phosphates appear to retard somewhat the rapid progress of the reduction; in such cases all that is necessary is the addition of a little hydrochloric acid.

This method of estimating arsenic acid has been extended to the compounds of metals other than sodium, with this general result: that it is advisable to obtain the acid in the form of an alkaline arseniate before attempting to determine its quantity. In this way those sources of error are obviated which would arise from the action of certain metallic salts upon hydriodic acid. As the one most generally met with may be mentioned perchloride of iron. The two following equations represent its action upon hydriodic acid and hyposulphite of sodium respectively.—

(*a*). $Fe_2Cl_6 + 6HI = 2FeI_2 + 6HCl + I_2$.

(*b*). $Fe_2Cl_6 + 2Na_2S_2O_3 = 2FeCl_2 + 2NaCl + Na_2S_4O_6$.

These last observations are in nowise intended to convey the impression that the method now described for the volumetric estimation of arsenic acid will prove the most serviceable under all circumstances. That it is accurate is clearly shown by the results obtained, and like all other volumetric processes, it requires to be used with intelligence and discretion.

In respect of its capabilities as a qualitative test it may be affirmed that it will detect with ease the one-tenth milligram of arsenic acid when mixed with one gram of arsenious acid.

Remarks upon its comparative merits as a quantitative method form no part of the object of this paper, and are therefore omitted. In conclusion, it may be stated that experiments on the reversal of this method are now in progress, but are not yet sufficiently advanced to warrant its applicability for the estimation of iodine compounds. There only remains for me the pleasurable duty of acknowledging the kind services of Messrs. Corbyn, Stacey and Co., for having placed at my disposal the resources of their laboratory.

TOOTH-WASH.

Take of

Quillaya Saponaria (soapbark) in coarse powder	16 grams
add	
Alcohol	100 c.c.
Aqua Destillata	150 c.c.
macerate for ten days and filter. Then add	
Cochineal	0·5 grams
dissolved in	
Aqua Menthæ Piperitæ	125 c.c.
also:	
Ol. Gaultheriæ	2 c.c.
rubbed up with	
Glycerin	50 cc.

finally sufficient distilled water to make the whole measure ¾ litre.

A few drops on a tooth-brush previously dipped in water will, when rubbed on the teeth, produce a rich lather; it cleanses thoroughly and is also an excellent remedy for soft gums, which it hardens in a short time. It is fragrant and agreeable to use.—W. Myers, M.D., in *New Remedies.*

POISON VENDING.

Under the above heading the *Medical Press and Circular* has in its last issue a leading article referring to the popular misuse of poisonous drugs and medicinal agents, and insisting upon the urgent necessity for "demanding a speedy and sweeping "reform in the system by which the chemist and "druggist is empowered, to a great extent, to deal "wholesale destruction in the vicinity of his shop."

One of the reasons assigned for making this demand is the sacrifice of life that has been caused by the improper or ignorant use of chloral, and coupled with the reference to this it is alleged that "in almost every case of death by overdoses of "chloral, the hypnotic has been obtained directly "through the agency of an incompetent adviser, "usually a chemist." It is further stated that there is "constantly accumulating proof that the entire "list of poisonous drugs must be carefully considered "in its relation to the mortality of any given district "and more particularly the larger towns and vil-"lages."

The writer of the article referred to considers that, in the face of the evidence furnished by police courts and coroners' inquests, indicating the immense evil of indiscriminate sales of poisons, it is imperative to raise a protest against the continuance of a system that permits such facilities as are now enjoyed by the incautious and the rash. We are further informed that this is not a singular opinion but one that is "assured of the support of an influential body," on which ground the writer does not hesitate to insist that the right to "sell poisons "irresponsibly be withdrawn from counter prescribers "and every other unqualified dispenser or vendor of "medicines and drugs."

In support of this demand it is further stated that the evil wrought by chemists in the present is not calculable from the evident results, large though they are; but that the cases of severe and even fatal injury brought about by the chemist are much more numerous than those made public.

In reading these very startling remarks our first impression was that the editorial columns of our contemporary had been by some mischance placed at the disposal of a person who from some cause or other was not himself at all, but on reading them over again the phraseology called to mind the diatribes which used to appear in the same journal directed against chemists and druggists from the point of view of the Medical Defence Association. It is true that the writer disclaims any intention to impugn the capacity or the integrity of chemists and druggists as a body; as useful and essential assistants to the medical profession he says the greatest respect is to be entertained for them. But it is contended that the chemist, being only a salesman, can exert only so much control over the use of poisonous materials as the Sale of Poisons Act empowers him to exercise. Besides this, it is held that the Act is framed in a manner so inefficient as to leave great room for improvement; that its provisions are inadequate to prevent the determined suicide from fulfilling his intention; and that even those provisions are not rigorously or invariably enforced.

Hence it is thought that the corporation to which chemists and druggists are subject will be the first to recognize the importance and the justice of the measure advocated by our contemporary, and with this belief, apparently, the Pharmaceutical Society is recommended to perform, in a dignified manner, the happy dispatch, and hand over its powers and privileges respecting the sale of poisons to "one of the three great corporations whose duty "it naturally seems to be, viz., the College of "Physicians or Surgeons, or the General Medical "Council."

Though these suggestions and remarks appear to be put forward seriously, we will not attempt to waste argument upon them, and even in bringing them under the notice of our readers, as having appeared in the editorial columns of a medical journal, we must express the opinion that they are so far eminently suggestive of the "silly season." But there is a further characteristic of this article which cannot be regarded so lightly, and that is the insinuation that since chemists and druggists are sellers of poison, the body representing them cannot be trusted to regulate with propriety the trade in such articles, without a danger that the claims of society and of humanity will be "subordinated to the sordid desire of gain entertained by the vendor." On this we refrain to comment and we leave it to the consideration of our readers whether it is a suggestion that is in any way justified by facts or at all worthy a place in the columns of a journal that professes to represent an honourable profession with which chemists and druggists have intimate relations.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association will be held on Thursday next, 11th inst., at 8.30 p.m., when a paper will be read on "The Manufacture of Sodium Carbonate," by Dr. J. Elliott.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next meeting of the above Association will be held on Wednesday, December 10, when Mr. C. B. Miller will read a paper on "Sugar."

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, December 3, 1879.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Frazer, Gostling, Greenish, Hampson, Hills, Mackay, Richardson, Rimmington, Robbins, Savage, Shaw, Symes, Williams and Woolley.

The minutes of the previous meeting were read and confirmed.

The President said it would be remembered that at the last meeting he requested his colleagues to provide for a successor to the presidential chair at this meeting. At that time he felt completely overdone by the very heavy and prolonged work of the day before, and he felt he must resign; but his announcement was received with so many kind remonstrances at that table, which had since been supported by similar expressions from other members of the Society not connected with the Council, that under the circumstances he felt if he were to retire it would be attributed to failing health, from which he was glad to be able to say he did not suffer, or to failing interest in the welfare of the Society; this was certainly not the case; or it might be supposed that his proverbial firmness was drifting into obstinacy. He would, therefore, with the permission of the Council, withdraw his resignation.

Appeal from the Registrar's Decision.

The Secretary placed before the Council a further memorial from Mr. Hardcastle, of Hunslet, accompanied by a certificate from a medical practitioner, who, in reply to a letter from the Secretary, said he fully understood the nature of the declaration, and from inquiries he had made was fully satisfied of the truth of Mr. Hardcastle's representations.

The President thought under these circumstances the Council was bound to instruct the Registrar to put Mr. Hardcastle's name on the register.

Mr. Rimmington said he looked with great suspicion on these applications, and thought they ought to be thoroughly tested. The medical gentleman only said he "believed" Mr. Hardcastle was in business.

Mr. Greenish said he had noticed the word "believed;" it seemed only a matter of opinion.

After some further discussion, Mr. Williams moved, Mr. Woolley seconded, and it was carried by a considerable majority, that Mr. Hardcastle's name be placed on the register.

The Council then went into Committee to consider the circumstances of another case in which an application had been made for registration. In this case the Registrar was advised not to put the name on the register.

Additions to Register.

The Secretary reported that the following persons having satisfied him by proper evidence that they were duly qualified, by being in business before July 31, 1868, he had placed their names on the Register of Chemists and Druggists:—

John Charles Young, Bishop's Waltham.
Charles Stevens Budgett, Pevensey Road, Eastbourne.

Appointment of Examiners for 1880.

England and Wales.

No alteration having been suggested in the constitution of the Boards of Examiners, it was resolved on the motion of Mr. Hills, seconded by Mr. Mackay, that the following pharmaceutical chemists should constitute the Board of Examiners for England and Wales for the ensuing year, subject to the approval of the Privy Council:—Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman, Southall and Taylor.

Scotland.

Mr. Shaw moved and Mr. Atkins seconded and it was carried unanimously that the Examiners for Scotland be also re-appointed, subject to the approval of the Privy Council. The names are as follows:—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Noble, Stephenson and Young.

The months for holding the examinations were directed to be the same as during the present year.

Elections.

The following, having passed their respective examinations, and tendered (or paid as Apprentices or Students) their subscriptions for the current year, were elected "Associates" of the Society:—

Cole, Edwin Henry ....Dorking.
Hewlett, James ....Northwich.

Reports of Committees.

Finance.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid. It was also resolved to purchase £2000 New three per cents.

House.

The report of this Committee recommended that certain repairs to the staircase, skylights, etc., be carried out as per estimate obtained. Also, that the house porter be allowed an addition to his salary to provide sleeping accommodation out of the house, his present bedroom in the basement being considered unhealthy. The Secretary had also been instructed to draw up a memorial to the District Board of Works, asking that wood pavement should be placed in front of the Society's premises in Great Russell Street.

The Council went into committee to consider the report.

On resuming, the report and recommendations were received and adopted.

The Hanbury Memorial Fund.

A letter was read from the Solicitor enclosing the deed of trust of the Hanbury Memorial Fund, duly executed, for deposit in the hands of the Society, and a resolution was unanimously passed thanking Mr. Flux for preparing the said deed free of expense.

Reports of Council Meetings.

Mr. Symes moved according to notice—

"That reporters, other than the one officially employed by the Society, be admitted to the Council room during the ordinary business of the monthly Council meetings."

He said this subject was by no means a new one, and it would probably have been better if it had been in the hands of an old member of Council, but perhaps he had one advantage in bringing it forward, for being a junior member he was able to refer to it from the point of view which he had taken when he had not the honour of being on the Council, and could therefore better represent the views of outside members. He did not wish any of his remarks to be of a vituperative nature, or to blame those who voted against this motion before, because his experience was that all members of the Council were desirous of serving the interests of the trade and of pharmacy to the best of their ability. It was simply a question of what means would be best for that purpose. These opinions had been strengthened the more he had become acquainted with members of Council, and therefore, if there was anything which made him anxious to carry this motion, it was, that others who were outside the Council should participate in a more close acquaintance with their doings and with the feeling he had gained by his membership there. He thought that if the feeling, wishes and views of the Council were better known to the trade generally, there would be much less complaint, because the trade would be better acquainted with the Council, and he believed the Council would be better acquainted with the trade. If this motion were passed to-day, there would not probably be ten members out of the 4000 constituting the Society, or even out of the 10,000 constituting the trade, who would blame the Council for so doing; and, as it legislated for the whole trade, he considered the whole trade had a right to have the fullest information on matters with which it dealt. When this motion was proposed two or three years ago, a large majority felt the proper time had not arrived for carrying it; but opinion had now matured and last year it was only lost by the casting vote of the President. This showed the time was arriving when the Council, in common with all other public bodies, should be fairly and fully reported. In saying this he was not in any way wishing to blame the work of the present reporter. The members of Council could all bear testimony that he did his work well, and if his were a verbatim report, which would perhaps be undesirable, half-a-dozen reporters, if present, could not differently report the proceedings if their accounts were faithful; but as it was necessarily an epitome, several reporters might report the speakers each in a different way, and thus the trade would have a more fair and full representation of what took place. They spoke of the reporter as the "official reporter," which implied to the trade outside that he was acting for the Council, and he could not see why the trade or the body outside should not also be represented. He would not trespass on the time of the Council longer, because the arguments had been very largely thrashed out. He must say, as a member of the Society, he was much disappointed, and he had met with many leading members of the trade who were also much disappointed, in fact there was a general disappointment amongst all who took an interest in the trade throughout the country, when this motion was negatived on the former occasion. It was known that a large number of the trade took, practically, no interest in the Society, but it should be, and was, he believed, the object of the Council to create that interest. The Council desired that the Society should be as comprehensive and broad as possible, and would be only too pleased if every member of the trade could be registered as a member of the Society. One step in that direction would be the passing of this motion, because it would show that the Council was holding out the hand of fellowship to them, that it desired them all to come in and give their numerical strength and assistance to the Society, by doing which they would also elevate the trade. When this subject was first introduced, a considerable anxiety was felt by some as to whether the Council would not be committing itself to something very serious; but the custom of reporting was extending, the reports had grown and become more extensive, and he would ask any gentleman if he would willingly return to the old state of things or if any of the evils had been seen which it was supposed would ensue. His acquaintance with reporters was not extensive, but he had always been treated with the utmost courtesy by them, and he did not anticipate that anyone but gentlemen would be sent there. He had learned to respect the profession and to regard its members as gentlemen, and he was quite sure that if reporters were introduced they might be treated with every confidence, and the reporters being free would give confidence to the whole body. He hoped there would not be a division to-day, but that the Council would be unanimous in deciding that the time had arrived when it would have other reporters than the one employed by itself.

Mr. Hampson had much pleasure in seconding the motion. He said it would be difficult for him to add anything to the remarks made by Mr. Symes. It appeared to him that the time had arrived when the Council probably might vote unanimously in favour of this motion. It was easy to understand that people are disposed to remain on the old lines which they had been accustomed to, but the Council could not ignore the social force outside on such a question as that. The Society surely ought to be above suspicion, and whilst the Council reported itself that could not be the case. The fact of having an independent reporter, who had no interest to serve except to give a faithful report to some journal or journals, would remove all feelings of that kind, and he was quite sure it would also benefit the whole body of the Council in the mode in which the work was done, and it would probably get through the work in a more convenient form. There would probably be less desultory conversation, and members would come prepared with their views on the questions to be discussed.

Mr. FRAZER doubted if Mr. Symes and Mr. Hampson's anticipations could be realized with the motion in its present form, and he would suggest that an intermediate course be taken, and that one additional reporter, namely, one representing the *Chemist and Druggist*, should be invited to co-operate with the present reporter. The reason he named that paper was simply that it undoubtedly represented the trade and the trade interests, and in doing so, it represented the interests of the members of Council, for they were all traders, although the *Chemist and Druggist* had occasionally criticized their proceedings in a manner they did not approve. But there was no question that this had been done entirely in good faith, and he did not expect that even if the *Chemist and Druggist* reporter was to appear there, that the reports would in any sense, differ materially from what they now were; but it would remove any ground of suspicion that the reports did not fully represent the Council. He thought the reports hitherto given were eminently satisfactory, and that an additional one given by another journal would not modify that materially. He did not think it was absolutely necessary as a question of principle that this motion should be carried, but as a matter of the highest expediency he thought the proceedings of the Council should be thoroughly open, and that would be sufficiently insured by having one additional reporter.

The PRESIDENT asked if this was an amendment.

Mr. SYMES said he could not accept Mr. Frazer's suggestion. He had well considered that matter.

Mr. FRAZER said in that case he would move as an amendment—

"That in addition to our present reporter, a reporter from the *Chemist and Druggist* be invited to attend the Council Meetings."

Mr. ROBBINS asked if Mr. Symes meant that any reporter who chose to come in, or that any reporter coming in would have to ask permission?

Mr. SYMES said the reporters would have to send in their application. His motion would cover the whole ground, and the Council having passed this resolution would not be able frivolously or lightly to refuse admission, but only on some special grounds. Still, it would have power on special grounds to refuse admission to anyone.

Mr. WILLIAMS thought taking the words of the motion there was no such power. It simply said that reporters other than the one officially employed be admitted.

Mr. HAMPSON asked if the members of Council thought they were likely to have an avalanche.

Mr. HILLS said he would second the amendment.

The VICE-PRESIDENT said it would be easy to limit the resolution if it were passed. He was not quite so sanguine about it being so unanimously voted, for there might be in the minds of some an opinion that no other reporters should be introduced, and it would be almost better that that point should be decided first. He did not see, therefore, that Mr. Frazer's amendment was quite in order.

The PRESIDENT thought it would be more regular to ut Mr. Frazer's amendment in the ordinary way.

Mr. GOSTLING said he had another suggestion to make, which perhaps would meet the case. He was in favour of the meetings being fully reported. He quite felt, as Mr. Symes had said, that the reports had been most excellent, most faithful, and most true; but it was very disagreeable to hear the remarks which were sometimes heard in the country,—persons calling attention to infringements of the Pharmacy Act, and expressing surprise that the Council was so indifferent to the interests of the trade upon this matter. It was also disagreeable to see in print the ungenerous and unjust remarks which were sometimes seen, and it appeared to him that if the public were in possession of the facts with regard to the attention given by the members of the Council to the work devolving upon the Committees, and also round that table, and the care and anxiety which were given to the proper fulfillment of their duties, they would hear less of those complaints. He therefore would propose that the Council should resolve that it was prepared favourably to consider any application for the admission of independent reporters.

The PRESIDENT said the Council must take one amendment at a time.

Mr. SAVAGE said his object in rising was to support in a large measure, as he had hitherto, that there should be a reporter or reporters; but he was going to suggest that the present motion should only extend to one year, so that there should be no difficulty in the event of its being found inconvenient, or anything arising to justify the Council in changing its opinion at the expiration of a year, in returning to the old system, as it would be then known that the period for which the extra reporters had been elected had then terminated, and there would be no offence committed by not re-electing them. At the same time he had no fear of its being permanent when once adopted; still some gentlemen did object to it, and feared something serious would occur. There was also a feeling outside the Council that the reports of its proceedings were garbled by reason of having only its own reporter. The members of Council knew that such was not the case, and if there were half-a-dozen reporters they could scarcely report better than was already done, except perhaps a little more fully, but it would remove a suspicion which at present existed in the minds of those who did not know the facts. If there were any matter of importance to be brought forward any gentleman who came there, seeing the notice of Committee stuck up, would respect it in the same way as now, and any proceedings which it was not desirable to be brought forward in public might be discussed in Committee, and the Council would not have, as it did frequently, to go over the ground again which had been already gone over by the Committee.

Mr. MACKAY did not agree with Mr. Symes that the time had arrived when other reporters should be admitted, nor even that the amendment should be carried. He certainly, of the two, looked upon the motion of Mr. Symes as being by far the more objectionable, because to put it as he had done, as he said, after full consideration, that reporters of any kind or description and in any number should be admitted would be a thing he thought the Council could scarcely agree to. On the other hand the proposal of Mr. Frazer was not so objectionable, because the members of Council knew the *Chemist and Druggist* found its way into the hands of an immense number of the trade. At the same time, he failed to see the necessity of even a reporter from that journal coming in, and for this reason—the Council meetings took place early in the month, and what to his mind was a fair report of the proceedings was given, although as he had always argued not quite so full a report as might be given, in the Society's own Journal. The *Chemist and Druggist* was published about the middle of the month, and he could not see that it was placed at any great disadvantage, inasmuch, as it had in its hands, ten days or so before hand, the proceedings of the Council. But he rose more to argue that the Council had been hitherto a little remiss in not giving effect to what he had more than once suggested, and which he held more strongly than ever, that it should admit the Editor of the Journal. He should be very much pleased to see some such plan as that tried, that the Editor of the Journal be admitted to the Council room during the ordinary business of the Council meetings. He knew that outside many remarks had been made regarding the reporting of the proceedings; sometimes brevity had been named as a fault, and sometimes it had been stated that they had not been as correctly reported as they might have been. When the Editor had been applied to, his reply had been that he had nothing to do with what went on in the Council room, that he only printed the report furnished to him. Now if he were present in the room the report might be more extended, or he would be in a position to answer some of these complaints. He did not know what effect these two motions might have, but he was exceedingly anxious that the Council should admit the Editor to a seat at the reporter's table.

Mr. Richardson had great pleasure, as a young member of the Council, in supporting Mr. Symes's motion. He might say in the first place how astonished he was at his friend Mr. Mackay, coming from liberal Scotland, not supporting it also.

Mr. Symes here said that he was desirous of adding a rider to his motion, namely—

"That the Council retain power to consider each application for admission on its merits."

Mr. Richardson said he entirely concurred in that condition. The members of Council ought in justice to themselves to have some discretionary power as to the expulsion of reporters if they in any way exceeded their legitimate duty, for they were not now an exclusive body as they were before the passing of the Pharmacy Act, but were legislators for the whole trade. As had been said, the Journal only circulated to 4000 members and associates of the Society; but there were 10,000 chemists and druggists, 6000 of whom, therefore, were not supposed to have a proper knowledge of the actions of the Council, and they ought to be considered. The only way to do that was by the introduction of independent reporters. Having watched the proceedings at the Council, he was much disposed to think that it would facilitate the progress of business if independent reporters were admitted. He might be thought, perhaps, impertinent in saying so, but he did seriously think that a great deal of time was wasted in the Council by work which was really Committee work, and which there was no necessity for dealing with there at all. He maintained that if there were some method of independent reporting those desultory conversations would not occur, and the Council would have a much more progressive mode of conducting business. There was a very great deal of complaint, and those who, like himself, lived in the country, were constantly hearing it. He did not wish to say one word against the Council's reporter, for he had sufficient knowledge of him to see that his sagacity was irreproachable, but if there were a method of open reporting it would take the sting out of a great deal which was now said about the Council, not only by the *Chemist and Druggist*, which was a very excellent journal, but also by those constituents whom the Council was supposed to represent. The *Chemist and Druggist* had been mentioned, but he should not confine himself to that journal. If the *Times* wished to send a reporter there the Council had no right to refuse him admission. It must be remembered that the Council was legislating for the public as well as in the interests of chemists and druggists. It was not an executive body, which was supposed to be legislating for the benefit of chemists and druggists solely, but it also represented the public, and he should be the first to send in his resignation if he thought he did not fulfil his duty to the public as well as to chemists and druggists. He should therefore support Mr. Symes's motion rather than the amendment. He remembered a letter written by Mr. Joseph Ince, who some years ago prognosticated that if the *Chemist and Druggist* did not follow a certain line it would become a matter of history and would be used for lining boxes; but he had watched the progress of that paper, and it had become a very great power in the pharmacy of the country. It had a large circulation and was read very extensively. Mr. Mackay complained that it was only published monthly.

Mr. Mackay said he did not complain at all; he only stated it as a fact.

Mr. Richardson said a very few years ago the *Pharmaceutical Journal* was only published monthly, and possibly when the *Chemist and Druggist* was admitted to report the meetings of the Council it also would become a weekly publication. One other reason why he wished independent reporters to be admitted was that the members of Council might be able to answer the continuous complaints addressed to them by private letters. Since he made a little speech at the last meeting, complaining that the Registrar did not exercise sufficient vigilance in testing applicants to be placed on the register, he had had no less than twenty letters making similar complaints. If the meetings of Council were open the sting might at once be taken out of all these complaints. It was impossible for him to answer twenty letters to twenty gentlemen every month, but if the reporting were thrown open to any papers representing the pharmaceutical body, and to the public prints if they liked to come, it would give very great satisfaction to the trade and especially to those whom he represented.

Mr. Mackay asked if Mr. Richardson meant to convey that if the *Chemist and Druggist* reporter were admitted that publication would change from a monthly to a weekly one?

Mr. Richardson replied that he did not say that at all. He said that perhaps it might be the case.

The Secretary asked Mr. Richardson if he would give him the letters of the gentlemen who had complained, and he would guarantee to satisfy both the Council and those gentlemen that there had been no want of vigilance on his part.

Mr. Williams said if there were twenty reporters present, he did not see how it would affect such a question as this.

Mr. Richardson said he did not come there to be catechized by the Secretary. In no other deliberative assembly did he ever hear of one of the staff being permitted to speak, unless he were asked a question. Those letters were written to him in confidence, and he should certainly not give them up to the Secretary.

Mr. Woolley had much pleasure in supporting the motion with the addition which had been made to it. He had not intended to say anything, thinking it would probably be carried more unanimously than now seemed likely, but for one or two expressions which had fallen from Mr. Gostling and Mr. Mackay. Mr. Gostling had said that the reports were most faithful, most true and most correct, and Mr. Mackay said they were generally very fair. Now he knew one instance where he thought he had very good grounds for complaint and he gave this as an instance to show why it would be better to have other reporters present. He was not complaining of the reporter, who he believed did his work most properly; but at the August meeting, if he recollected rightly, the Council agreed to raise the salary of the Editor and Sub-Editor, the Editor's by £100 and the Sub-Editor's by £50. That piece of business was not reported, and in September he drew attention to it and was most careful in giving the figures, which he had given again now in the hope that they might get into the Journal. He had very good reason to believe that the reporter took due note of those figures both in August and September, but by some mysterious process which he did not understand, and he did not know who was to blame for it, notwithstanding his efforts to get the figures published in the Journal they were left out. He thought ordinary constitutional procedure ought to have dictated to whoever had these reports before him the propriety of making such an expenditure of money as that public to the body which found these funds. That was an illustration of the advantage which would accrue from having an independent reporter present.

Mr. Hills had only one word to say on the subject. Mr. Symes said that other institutions had reporters; but he (Mr. Hills) believed that neither the College of Physicians, nor the College of Surgeons, nor the Society of Apothecaries, ever published reports. All these were qualified gentlemen, and chemists and druggists also were qualified, their qualifications being decided by examination. It was not as if theirs was an open trade. At any trade meeting of the members of these institutions, or at a vestry, reporters might be desirable With regard to the *Chemist and Druggist*, it was a well known paper, which represented chemists and druggists, and therefore stood on a different footing, but he was not prepared to say that this should be the only exception. He should be quite ready to admit any other reporter when he made good his claim.

Mr. Shaw said that on several former occasions when this matter had been before the Council he had voted for additional reporters, and he might remind Mr. Symes that the matter was first brought forward about ten years ago, when it was said to be utterly inpracticable. If his memory served him correctly, at the second meeting he had the honour of attending as a member of Council, the subject was brought forward by Mr. Reynolds, his motion being to the effect that other reporters be admitted, and remain at the continued pleasure of the Council. So far it coincided with Mr. Symes's motion as now amended. Last year, the matter was brought forward by Mr. Hampson, when he moved that an invitation be given to the editor of the *Chemist and Druggist* to send a reporter, and it struck him that it would be very desirable that this should be done. This was what Mr. Frazer's amendment amounted to. There were only two journals which represented pharmaceutical interests, the Society's own Journal, and the *Chemist and Druggist*, and therefore he should like to see an invitation given to the latter to send a reporter. He was quite certain the editor of that paper would not use the information he gained there to the disadvantage of the trade, or members of the Council, for whatever was detrimental to them would certainly be detrimental to that paper. There could be no objection to the present reporter being supplemented by another. For his own part he was thoroughly satisfied with the manner in which the reports were given; in fact, he was astonished at the marvellous accuracy with which they were rendered. At the same time, mistakes occasionally would occur, and he remembered on one occasion, Mr. Woolley making restitution of some speech attributed to him, which had been delivered by someone else. He thought it would be a relief to the present reporter to have another one present, and it would do away with a large amount of feeling throughout the country.

Mr. Atkins said last year he had the pleasure of seconding the motion of Mr. Hampson that a reporter from the *Chemist and Druggist* be permitted to attend the meetings, and he would not detain the Council with the reasons he then gave, but he believed it would be better to pass the wider resolution, because of necessity the greater included the lesser, but the converse did not hold good. There was no doubt that in all these debates what the members of Council had present in their minds was the fact of the reporter of the *Chemist and Druggist* being admitted; they did not anticipate there would be any applications from any other sources whatever, although he should not be at all alarmed at an application from the *Times* if there were any matter coming forward of public interest. He had no complaints to make with respect to the reports in the Journal. He would not stop to repeat the well-earned compliments that had passed round the table on this matter, but, he believed, as a matter of expediency it was very desirable that this motion should be carried. It was deeply to be regretted that there was a considerable amount of estrangement, most undeserved, on the part of some of their constituents towards the Council, and, he believed, the wider the representation was made, and the more broadly the debates were printed and circulated, the healthier it would be, and the more united they would be as a body. With regard to the *Chemist and Druggist* he could speak most impartially, and he believed if the tone of that journal were altered, as he thought it might be and hoped it would be, towards the deliberations of the Council it would very largely affect their constituents outside. A large section of them read that paper, and did not read their own Journal, and if the tone of the *Chemist and Druggist* towards the deliberations of the Council were a little more considerate and impartial it would have a very good effect, not so much on that paper itself as on their constituents at large, and it would be a splendid day for them as a body when they had not, as they now had, a divided camp. He longed for the day when there should be a more thorough appreciation of the work done at the Council Board, and he knew no better means of accomplishing this than that the organ which confessedly took a somewhat antagonistic position towards the members of Council should be brought more thoroughly into accord with them. He would remind Mr. Hills that the nearest analogy he knew of to that Council was the town councils, which were representative bodies, and also to a certain extent executive bodies, and in many respects were parallel in their action to that Council. In their case it was the right of every newspaper to send a representative. Of course they had the power in the case of any private matter coming forward to ask them either not to notice it, or to leave the room, and at present he was not conscious of any reason why the same could not be done in that room.

Mr. Frazer asked if he might be allowed to dissent from the statement made by Mr. Atkins that the *Chemist and Druggist* was antagonistic to that Council? Had he thought so he certainly would not have proposed the amendment. He believed it was thoroughly in accord with the Council, although it sometimes criticized it.

Mr. Atkins said that Mr. Frazer had somewhat misconceived him. He simply referred to the general tone of the *Chemist and Druggist*, a paper which he regularly read himself, and he would ask them, was its general tone one of cordial appreciation or not? He believed it might be brought thoroughly into accord with the Council.

Mr. Greenish did not wish to give a silent vote on this occasion, though he had nothing to add to that which he stated two years ago. He then thought the time had arrived when the Council might admit reporters other than its own to that room. He could not help stating, however, that the present reports were marvellously accurate. In fact, very frequently when the proof was sent to him he had not to make the slightest verbal alteration in anything he had said. If this motion passed, however, he hoped that it would not merely be passed for the editor or reporter of the *Chemist and Druggist* to be admitted, but on the broad principle that, on application being made, any reporter would be admitted. Mr. Richardson had stated that he believed a great deal of time was wasted at the Council. It was possible he had been somewhat unfortunate in the meetings other than those of this Council which he had attended and taken part in, but it seemed to him that time was always more or less wasted, and he did hope that at that Council the time was far distant when members would cease to take an interest in and criticize the reports of the various committees which were brought before them. It would be a most unfortunate thing if when a few gentlemen, forming a committee out of twenty-one, presented a report, the others should simply receive it without any criticism whatever. He was not at all an advocate for the reports of committees being pulled to pieces systematically, but he did hope that members would not cease to take an interest in these matters which were brought before them.

Mr. Bottle said he proposed to give his vote differently to the way he did last year. He then voted in great measure on personal grounds, and that question had again been mooted as to whether the *Chemist and Druggist* commented fairly on the proceedings of the Council. At any rate, he had noted during the past year that there was a manifest improvement in the tone of that paper towards the Council and the Society, and, as showing his appreciation of that, he intended to vote in favour of admitting the reporter of the *Chemist and Druggist*. On the other hand, he should oppose the wider scheme of Mr. Symes's motion, more especially so as it would open the way for what Mr. Richardson said he should like to see, the reporter of the *Times* being there.

Mr. Richardson said he did not say that. He said that if that reporter applied they had no right to refuse him admission.

Mr. Bottle said that to pass such a general resolution was a serious matter, especially considering the limited space at command. If the reporter of the *Times* had a right to admission the Council could not refuse the reporter of any other morning papers or of even the *Figaro* or *Funny Folks*. The accommodation was not sufficient to allow of asking all, and it could not admit one and refuse another; but the *Chemist and Druggist* was a publication which was known to be increasing in circulation among the members and the trade generally, and he would ask the Council, certainly as a first step, to restrict admission to one other reporter, rather than to open the door wide and have to admit any gentleman who might make application.

Mr. Williams said he had hitherto felt it his duty to oppose this motion, and he was sorry to say that notwithstanding all he had heard, he must still hold that opinion. It was not that he in any way wished to restrict reporting; on the contrary he should be very glad to see, if possible, the meetings more fully reported than they were now. But he thought that should be done by an arrangement quite different to that of having extra reporters. He did not see how extra reporters could give the result they were all desiring, viz., increased reports; on the contrary there was no doubt when other reporters were present the Council would have to arrange that a great deal of business should be done not in the presence of reporters at all, and it would be going in the opposite direction to that which was desired. He believed great practical inconvenience would result. As he had said before, he should like to see the reporting done on the principle of taking down all that took place in committee or otherwise, and that then the report should, before publication, be submitted to a committee or some one who should have the power of striking out only portions which would be obviously improper for publication. In that way there would be obtained a full and nearly perfect report of the proceedings of the Council. He need not say that the introduction of a second or non-official reporter to the Council room would stand in the way of any such process as that, and also that it would be very difficult indeed at any future time for the Council to go back from the step it was now proposed to take. If it once passed this resolution it would entail a great deal of odium to attempt to go back from it. He really thought if the Council looked at the question from the proper point of view it would be seen that to accomplish the end the members all desired, namely, fuller and more consistent reports of their own proceedings, so that members in the country and elsewhere might really have a knowledge of all that was doing, as far as practicable, there might be devised a better mode of arriving at it than by having an independent reporter who would be merely present when a debate like the present was going forward, but who would not be able to give the constituents any account of the more private or more important business which might often be of the greatest interest, and might be published without detriment. Under these circumstances he should vote against both the amendment and the motion.

The Vice-President wished to point out a very essential difference in the wording of the motion as it stood, and in the style of language adopted by the mover of the amendment. In the one case something like a broad principle was asserted, in support of which broad principles could be urged; in the other case the attendance of a reporter of a particular journal was invited. He scarcely thought the amendment could be carried, inasmuch as by a strange coincidence, due to the introduction of such an amendment on such a motion, both those who opposed Mr. Symes's motion and many who approved of it would vote against this amendment. On the other hand, if the Council adopted the amendment it would do away with the motion, whilst at the same time it would alter the present arrangements with regard to reporting. He did not see, therefore, any chance of the amendment being carried. With regard to the original motion he should like to say that, for his own part, he thought it should be carried upon the broad principle that the members of the Council were the administrators of an Act of Parliament, in which the whole public were interested equally with themselves, and that all such proceedings ought to be conducted in such a way that the outside public could, if it liked, approach and see what they were doing. If it were carried the chances were there would be no other applications than from the one journal named in Mr. Frazer's amendment, so that practically, in all probability, the result of carrying the resolution would be merely to admit the reporter of the *Chemist and Druggist*, if the editor chose to apply. But the principle should be either that the proceedings should be private or that they should be public and open to any inspection from the outside public which the public chose to require, and this was the view he took, seeing that they were administrators of an Act of Parliament. One more argument he should like to use was, that the Council would better consult its own dignity in adopting this abstract motion than by sending an invitation to the editor of any particular paper. He was not quite certain of the relation in which the members of the Council stood to their present reporter, but he believed they had no asked the Editor of the *Pharmaceutical Journal* to send a reporter, and if so it would be a strange thing to invite the editor of the *Chemist and Druggist* to do so. Be that as it may, he thought the Council would be best consulting its own dignity, and at the same time better consulting the public interests committed to its charge if it left the matter perfectly open, reserving only the right of imposing such limitations on the action of the reporters as it was supposed to do at present. There were certain simple regulations which they would be required to adhere to, and if forty were present, supposing there were room for them, he did not think any harm would be done, while at the same time the Council would be disabusing the public mind of any notion that it was acting unfairly.

Mr. Symes said he would not reply at any length to the observations which had been made, several of which had been ably answered by Mr. Schacht. The editor of the *Chemist and Druggist* was exactly in this position at the present moment. His journal was very largely read by a number of persons who never read the *Pharmaceutical Journal*, and whether it were published at the beginning of the month, or in the middle, was of little importance. It was read by a large number of persons, and the editor was in this invidious position that he had either to copy the report of the *Pharmaceutical Journal*, or to make an epitome of it. He might say that he thought some of the remarks made were rather unjust to that editor, inasmuch as he was placed in this very awkward position. The

Council did not allow him to know anything of the proceedings, except what he gained from the official report. It was not likely that an editor placed in that position would simply copy the report; he made certain inferences and deductions of his own which seemed to some of them ridiculous and perverted, but which were really the natural deductions of any person outside the Council. Anyone else drawing deductions would probably draw deductions quite as full of error as any in the *Chemist and Druggist*. He did not wish to say a word against their own Journal or the *Chemist and Druggist*, but some gentlemen had complained that other reporters being there would merely furnish the editor of the *Chemist and Druggist* with further means of enlarging his reports, but the fact was if his reporter were present the Council could pin him to his own report, and there would be no necessity for deductions. In answer to Mr. Hills, he would say that the Medical Council admitted reporters, and that was the body which practically corresponded to the Pharmaceutical Council, as representing the medical profession. The Colleges of Physicians and Surgeons were private bodies, but the legislative body was the Medical Council. Mr. Bottle had some anxiety as to the room, and he could quite understand his anxiety that the room should not be over-crowded, but the Council could refuse admission to any reporter on any plausible ground, and if ever so eligible a man applied for admission and there was not room, he could be told so, and there was nothing in the motion to prevent that. As had been said, the broader motion was far more dignified, and as the greater included the less, it would be perfectly eligible to anyone to oppose any other reporter being present except the one from the *Chemist and Druggist*, but the question of broad principle was most important. Mr. Williams, he thought, had been a little inconsistent, because he proposed that a committee should be formed which should have the power, not of adding anything, but only of striking out anything which it might think objectionable. Yet the first thing Mr. Williams did that morning was to ask to have something added to the minutes, whereas such a committee as he proposed would be utterly powerless to put in anything that was omitted or to set anything right. He was quite convinced that no ill result would follow from the adoption of his motion, and that if he had the honour of being on the Council three or four years hence when it had been tried he should be able to stand forward and ask if the adoption had not served both the interests of the Council and those of the outside public, in whom it was interested.

The amendment was then put with the following result:—

For—Messrs. Bottle, Frazer, Hills and Shaw.

Against—Messrs. Atkins, Gostling, Greenish, Hampson, Richardson, Rimmington, Robbins, Savage, Schacht, Symes, Williams and Woolley.

The amendment was therefore lost.

The President and Mr. Mackay did not vote.

The motion with the words subsequently added by Mr. Symes was then put with the following result:—

For—Messrs. Atkins, Frazer, Gostling, Greenish, Hampson, Richardson, Rimmington, Robbins, Savage, Schacht, Shaw, Symes and Woolley.

Against—Mr. Williams.

The motion was therefore carried.

The President, Messrs. Bottle, Hills and Mackay did not vote.

Reports of Committees.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a registered chemist and druggist, aged 68, who had a similar grant in January last.

£15 to a registered chemist and druggist, aged 73, formerly in business, who has had three previous grants.

£10 to the widow of a registered chemist and druggist, who has had one former grant.

£5 to a registered chemist and druggist, aged 70, who had a grant of £10 in May last.

One or two other cases were deferred for further inquiries, and one application was refused.

The report and recommendations were received and adopted.

Mr. Shaw asked if there would be any objection to publishing the balance sheet of the Benevolent Fund in the calendar.

The Secretary explained why he did not think it advisable to do so, his explanation being given in committee.

Personal Explanation.

Mr. Richardson said he understood that some remarks he had made earlier in the day were understood to cast some reflection on the Secretary and Registrar and he wished in the most complete manner to withdraw anything he might have said which was offensive to his friend Mr. Bremridge, or in any way personal to him. He knew that the Secretary exercised the greatest caution with regard to any applications made to him, and what he wished to convey was that if the reports were more open it would remove misapprehensions which existed and tend to lessen the labour of the Registrar.

LIBRARY, MUSEUM AND LABORATORY.

This report included the Librarian's usual report as to attendance in the Library during October as follows:—Total: day, 489; evening 298; average per day, 18; evening 13. Circulation of books town, 213; country 79; carriage paid £1 6*s*. 8*d*.

The following donations to the Library had been received and the Committee had recommended that the usual letter of thanks be sent to the respective donors:—

Dentists Register, 1879.
From the General Medical Council.

Dragendorff (G.), Über die Beziehungen zwischen chemischen Bestandtheilen und botanischen Eigenthumlichkeiten der Pflanzen, 1879.

Kühn (P.), Ein Beitrag zur Biologie der Bacterien, 1879. From Professor Dragendorff.

Royal College of Surgeons of England, Calendar, 1879. From the College.

Royal Medical and Chirurgical Society of London, Catalogue of the Library, 1879, 3 v.
From the Society.

St. Thomas's Hospital, Reports, 1879, n.s., v. 9.
From the Hospital.

Thibaut (P.), Art of Chymistry, 1668.
From Mr. W. Herbert Hyatt.

Tommasi (Dr. Donato).
Sur la Non-existence de l'Hydrogène naissant, 5e partie, Réduction du Perchlorate de Potasse, 1879.
Ricerche sulle Formole di Costituzione dei Composti Ferrici, parte 1, Idrati Ferrici, 1879.
From the Author.

Valentin (W. G.), Twenty Lessons in Inorganic Chemistry, 1879.
From Messrs. W. Collins, Sons and Co.

The Committee had recommended the purchase of the following books for the Library:—

Foster (M.), Text-book of Physiology, 8th ed., 1879.
Godman (F. D.) and O. Salvin, Biologia Centrali-Americana: Botanical portion by W. B. Hemsley; about 20 parts, with 120 pl.
Guy (W. A.) and D. Ferrier, Forensic Medicine, 4th ed., 1875.
Lunan (J.), Hortus Jamaicensis, 1814.
Masters (M. T.), Vegetable Teratology, 1861.
Noad (H. M.), Student's Text-book of Electricity, new ed. by W. H. Preece, 1879.
Pharmaceutisches Repertorium, half-yearly.
Practitioner, monthly.

Physicians of Myddvai, translated by J. Pughe and J. Williams ab Ithel, 1861, (Welsh Mss. Society).

Quain (J), Anatomy, by W. Sharpey, A. Thomson and E. A. Schäfer, 8th ed., 1878.

Spon (E.), Workshop Receipts.

The Committee had ordered that a reward of £5 be offered for information leading to the conviction of any person stealing books from the Library, several being missing.

The Curator had reported that the attendance in the Museum had been:—Morning: average, 15. Evening: average, 3.

The Curator had reported that the following donations to the Museum had been received:—

Specimens of fresh Indian Bael, preserved by sugar. From Messrs. Young and Postans.

Specimens of Quebracho Bark and astringent gum from the same tree.

Specimens of the leaves, flowers, and two sections (one of the stem and the other of the branch of the tree) from which Goa Powder is obtained (*Andira Araroba*, Ag.). From Mr. T. Christy.

The third and final series of plates of Bentley and Trimen's Medical Plants.' From the artist, Mr. D. Blair.

Fourteen specimens of rare and valuable minerals including:—

Two specimens of Vivianite, one in foliated bands, and the other a very transparent crystal.

Ludlamite.

Two specimens of Cronstedtite, one having the new green variety upon it.

Liskeardite.

Tetrahedite.

Tallingite.

Childrenite.

Anabergite.

Limonite.

Blende containing Gallium, Brown Mica, and Lithia Mica.

All the minerals were obtained from Cornish Mines except the Gallium Blende, which came from Cologne.

From Mr. Richard Tallgin of Lostwithiel.

The Committee recommended certain arrangements to be made in the Museum cases to prevent the injury of specimens by dust.

The Professors had attended the Committee and reported on their respective classes.

The report and recommendations of the Committee were received and adopted.

The Council then went into committee to consider some estimates for paper for the Journal which had been submitted to the Committee, and a resolution thereon was agreed to.

GENERAL PURPOSES.

This report included the usual report from the Solicitor with regard to various matters of business in progress.

The Solicitor had reported that—

E. Speight, Doncaster,

had paid £5, as penalty for breach of the Pharmacy Act, without going to trial.

Daniel Tudor Williams, Aberdare,

had also remitted £5 as penalty.

The Committee also recommended that—

Mr. Greaves, Chesterfield,

be requested to resign his appointment as local secretary, a letter from him with reference to the supply of paregoric without opium for sale by unregistered persons, being, in the opinion of the Committee, entirely at variance with the provisions of the Pharmacy Act.

Several cases of alleged infringement of the Pharmacy Act had been considered, and in some it was recommended that proceedings be commenced.

It had been arranged that the appeal in the case of the Society *v.* London and Provincial Supply Association, should not come on for hearing until Hilary Term, in order that the services of the Attorney-General might be secured.

The Council, as usual, went into committee to consider the various cases referred to. After a long discussion, the report and recommendations were received and adopted.

LOCAL SECRETARY AT PRESTON.

Owing to the decease of Mr. Barnes, the late local secretary at Preston, the Council proceeded to appoint as his successor, Mr. J. L. Barnes.

REPORTING THE COUNCIL PROCEEDINGS.

Mr. ATKINS then moved the following resolution of which he had given notice:—

"That the fact of the Council having resolved itself into committee be reported in the record of the proceedings of Council, and that it be left to the discretion of the President and the Secretary in what manner the announcement be made as to the subject matter discussed in Committee."

He thought very little need be said in support of this motion, as the principle had been already ventilated and generally accepted, the only question being as to the form in which the announcement should be made in the publication of the proceedings. At the previous meeting, Mr. Symes proposed a motion, which was afterwards withdrawn, with the spirit of which he was in entire accord though not in the detail, because, as he understood it, Mr. Symes wished the President at the time to formulate the express manner in which the report should be made, which he thought would be throwing a degree of responsibility on the President, which the Council had scarcely a right to do. He believed Mr. Symes would agree with him in what he now proposed, which was, to simply go on as at present. It might be asked why should he move in the matter, but he thought it would be wise to put on the record of the proceedings a law of this kind for the guidance of officials.

Mr. SYMES seconded the motion. A slight alteration, which Mr. Atkins had made in it since he had first given notice, had been brought about by the altered position in consequence of the resolution passed that morning.

Mr. MACKAY asked if it was understood that the new reporters were to remain and hear what passed when any matter was under consideration in committee, or were they to leave the room.

Mr. GREENISH said he should be prepared to move that the reporters leave the room while the Council was in committee.

Mr. MACKAY asked if that were so, was this proposed summary to be made out by the President and Secretary, and a copy handed to each reporter.

Mr. SYMES said it was to be handed to the reporters.

Mr. MACKAY said he understood that reporters, other than their own, should leave the room; that their own report should be noted by their own reporter and handed to the President and Secretary, who should make a condensed report of it, and hand it to the reporters of other journals.

Mr. ATKINS said that was not in his motion at all. If he were asked his opinion with regard to reporters he should differ from Mr. Greenish. He thought it would be impracticable to ask gentlemen to leave the room whenever the Council went into committee, or else they would be trotting in and out all the time.

Mr. WILLIAMS said he should decline to discuss matters of serious importance before strangers.

Mr. ATKINS did not see how the Council could draw any invidious distinctions between its own reporter and others. This was a very important question, but it was not part of the motion at all. It would no doubt require serious consideration how reporting should be dealt with in future, but it was no part of his motion.

Mr. Mackay did not see how the Council could pass this motion until it had cleared the ground by settling the point he had raised. This was one of the most important things that had to be dealt with, and if, as Mr. Atkins suggested, the new reporters were to be allowed to sit and listen to all that took place in committee the tongues of many members would be tied. He looked upon it as an unsafe thing to let other parties listen to a discussion connected with names and other matters which occasionally cropped up. It was quite true that if the Council found an improper use was made of what passed in committee it could pass a vote of censure afterwards, but that would involve great unpleasantness.

Mr. Richardson approved of what Mr. Mackay said, and thought before the Council accepted a motion like this a committee should be appointed to go into the whole matter, and present a report to the Council. He thought a great deal of time might be saved, and a good deal of information given by the Committees' reports being presented in such a form that they could be printed in the Journal, and that that report should be presented by the Chairman of the Committee and explained. If the system were followed it would never be required to go into committee of the whole Council, all the private work might be done in committee, and the Council would be able openly to discuss all that came before it.

Mr. Savage moved that the further consideration of this matter be postponed, because the very essence of the thing was the mode in which it was to be used.

Mr. Shaw seconded the amendment. He thought it would give rise to very great difficulty if reporters were to leave the room whenever the Council went into committee, but if that were not done there would be a great difficulty in carrying out the arrangements.

Mr. Atkins said it was not the custom in council rooms for reporters to be called upon to withdraw. He could give an instance in which a gentlemen who recently served the office of mayor made a statement affecting the character of another person which he asked the reporters not to take notice of. A question was afterwards referred to counsel whether any action could be taken upon it, and his opinion was it could not. He fully agreed that this was an important matter, and if it was felt that the whole question of reporting deserved consideration, he had no objection to letting it go back to the proper Committee, and he would therefore withdraw his motion.

The British Pharmacopœia.

Mr. Hampson then moved the following motion, of which he had given notice:—

> "That the General Medical Council be asked to receive a deputation to respectfully urge upon them the desirability of the Pharmaceutical Council being legally empowered to nominate pharmacists to cooperate with the General Medical Council in framing and amending future editions of the British Pharmacopœia; and also to endeavour to obtain their concurrence and friendly interest in this object."

He said that in July, 1874, the Council passed a resolution to the effect that it respectfully urged upon the General Medical Council the desirability of associating more practical pharmacists with any committee which might be appointed for the purpose of preparing any future editions of the British Pharmacopœia. A copy of that resolution was sent to the Medical Council at the time, and no doubt it was received, but he believed there had been no acknowledgment of it. Pharmacopœias were originally framed by the Colleges of Physicians of England and of Scotland and Ireland, the first English Pharmacopœia being in 1618 and the last in 1851, there being ten in all. Afterwards the responsibility of framing the Pharmacopœia was conferred upon the General Medical Council in 1858 and re-affirmed in 1862, and there were two editions of the British Pharmacopœia, in 1864 and 1867, and the appendix of 1874. He should like here to bear testimony to the great services rendered to the Society by Professor Redwood. The Pharmacopœia of 1874 was no doubt a great improvement on all preceding ones, and it was a great boon that there was only one, the British. But he would call attention to the great authority which this Pharmacopœia proceeding from the Medical Council possessed. The first edition contained a warning to all apothecaries and chemists that on its publication it was necessary to destroy all preparations not made according to its provisions, which of course was a very proper warning; but it was a serious thing that the Medical Council had this unlimited power entirely in its hands. It might alter or expunge a formula, and pharmacists generally had no voice at all in the matter. No doubt the Medical Council had called to its aid Professor Redwood and another practical pharmacist, for it was impossible for its members to give the special attention to that important work which it required. But the position of Professor Redwood and the other gentleman was simply that of assistants to some sub-committee. They had no recognized status. This acknowledged necessity of getting extraneous aid showed that it was really the function of pharmacists to frame the national Pharmacopœia. The book thus framed was accepted as a standard in courts of law and by public analysts, and there was sufficient experience to show that pharmacists were absolutely at the mercy of those standards and were compelled to conform to them, notwithstanding they were not consulted as to their accuracy or suitability, and by their own Act of Parliament also they were subject to penalties if they did not conform to it. Therefore, however impossible the formulæ might be, or imperfect the standards, they were liable to a penalty if they did not conform thereto He did not object to fair restrictions, but he did object to the Pharmaceutical Society being so utterly ignored in the fixing of these standards. There was an old axiom in politics that taxation without representation was tyranny, and he should say that being subject to penalties without representation was injustice. The Pharmaceutical Society was entitled to an equal legal status in framing the national Pharmacopœia with the Medical Council; it had fairly earned that position and recognition on the part of their medical friends. As a voluntary society, it had done much for the furtherance of pharmacy; it had educated many good men who had shone in their ranks of pharmacy and in higher ranks still. It possessed a school and library which was more like the fountain head of pharmacy than any other centre could be, and it had the privilege of examining men who wished to enter the trade. In the culinary art, professed cooks were supposed to be the best authority in preparing a cookery book, and in like manner it was not unnatural to claim the professional services of those whose education and daily occupation fitted them to frame, conjointly with the physician, such an important national work as the national Pharmacopœia. In no other civilized country did pharmacists occupy such an unenviable and undignified position. They were, as it were, ignored, not in an offensive way, but simply because their position was unrecognized. Years ago the Apothecaries' Society and the College of Physicians had the professional knowledge to frame the national Pharmacopœia; but circumstances had now altered, and the Pharmaceutical Society was really now the faculty of pharmacy. It was necessary, he thought, to assert its equitable claim in such a manner as not to give offence to the medical profession in order to receive that fair recognition which was its due. There was no desire to trench in any way on medical grounds. Pharmacists did not want to interfere with doses or therapeutics, but simply to have an equal share in framing that portion of the Pharmacopœia which referred to chemistry, materia medica and pharmacy proper; to be able to do that particular class of work which fell legitimately to their hands.

And he hoped when the Medical Council received the intimation of their desire to confer with them in a friendly manner upon this important subject it would meet them in the same spirit.

The VICE-PRESIDENT had much pleasure in seconding the motion. He was glad Mr. Hampson had framed his arguments mainly on the idea that pharmacy constituted an essential portion of the medical art, because it enabled him with complete cordiality to endorse the views that had been expressed. He had so fully expressed himself upon that subject lately that it was not necessary to trouble the Council with any further remarks upon it, for he thought it was the great argument with which this representative body, the Medical Council, should be approached. He felt sure that all those who in the least degree felt, as he did, that an injustice was done them by the general body of medical practitioners in the non-recognition of the great advance which they had made in the cultivation of their own body and also in the furtherance of the great cause of scientific pharmacy, would hesitate to find a way out of the difficulty, unless it were by some such process as this, which would gain a recognition of themselves at the hands of the Medical Council. If this were once done it would be a recognition of their work in connection with the medical art so clear and plain that all the rest would follow easily enough. Every argument Mr. Hampson had used on the score of justice to pharmacists, who had to obey certain instructions given to them, without the power to say a word as to what was right or wrong in the matter, was unassailable, and he should further like to say that he thought the terms in which he had worded the motion were singularly fortunate. They approached the Medical Council with great respect, and asked to have a hearing, and until he knew the result of such an application he should not like to say a word as to any ulterior course of action. But it would be well for the Council to keep in mind that what it was asking for was a right thing, and if this corporation did not feel inclined to regard the application with full consideration there was a Sovereign on the throne who had the power of appointing a large portion of the Medical Council, to whom an appeal might most properly and fairly be made.

Mr. WILLIAMS sympathized entirely with the position taken up by Mr. Hampson with regard to the necessity and policy of pharmacists generally being permitted to take a part in the formation of the new Pharmacopœia; but he would suggest that he should alter the wording of the motion, and leave out the last clause. Before arguing the question the members of Council should bear in mind their true position. Mr. Hampson had already spoken of the services rendered by Professor Redwood to the Society, but that idea was just what they should guard themselves against. His services were not rendered to the Society, but to the Medical Council. The Act of Parliament under which the Pharmacopœia was framed entrusted to the Medical Council the office and responsibility of framing it, and it had done so, employing certain gentlemen of eminence to assist. What was really wanted was to ask the Medical Council to permit a committee or deputation of pharmacists to be engaged, and employed in assisting it in producing this work. Mr. Hampson might have strengthened his case by pointing out some discrepancies and inconsistencies in the Pharmacopœia as it at present stood. He was in error in supposing that they were responsible for any mistakes that appear in it. At the same time it was a matter of some delicacy to approach the Medical Council, because when the Council did so on a former occasion its request to be permitted to take a part in this matter did not even receive an answer. He feared it must be considered that the medical authorities who had the ordering of this matter did not look with great favour on the legitimate wish of pharmacists to be taken into consultation. It was a pity it should be so, and if by deputation that feeling could be removed it would be most desirable; but it must be still remembered that in approaching the medical body pharmacists must not do so with loss of dignity to themselves, and it would require great care in moving in the matter.

Mr. MACKAY thought there was but one feeling amongst true pharmacists, namely, that they should take a part in framing any future Pharmacopœia. But, having that feeling strongly himself, he felt he could not vote for the motion now brought forward. Going back to the publication in 1864, when the different pharmacopœias were all united in one, there were two pharmacists appointed in Edinburgh to confer with the Committee appointed there, and it must have been a source of satisfaction to them all to know that Professor Redwood did such eminent service with regard to the various formulæ which appear in the present Pharmacopœia. As Mr. Williams said it was a matter of great delicacy to approach the General Medical Council with any such request. The motion suggested the desirability of the Pharmaceutical Council being legally empowered to nominate pharmacists to co-operate; but he did not know how that legal empowerment could be obtained. Did it point to a special Act of Parliament? His great fear was that if the Council went forward with any such request it would be pooh-poohed. It was quite true it might take ulterior measures, but he would suggest a pause for a time. It might be that a new Pharmacopœia would be proposed in a year or two, and then it might be possible to approach the Medical Council, or at all events to take some such steps as would be the means of attaining their object in a much better way than the one pointed out in this motion.

Mr. GREENISH said he should very cordially vote for the motion. It seemed a remarkable thing that in 1879 the pharmacists of Great Britain should be asking to be allowed to take part in the formation of a national Pharmacopœia. When he was on the Continent, attending the International Congress, and mentioned that pharmacists in Great Britain had no voice whatever in the preparation of the Pharmacopœia, his statement was received with the greatest astonishment, that men who were considered by their brethren abroad, to occupy so high a position had really no voice in such a matter. It seemed only right when medical men attended to therapeutics that pharmacists should have a voice in pharmacy. It was only reason and common sense. He had spoken to some members of the Medical Council on the subject, who said the request was quite reasonable and they should be prepared to support it, but there were others who were opposed to it. He, therefore, thought the Council should press the matter on. In Holland, Belgium, Germany, Austria and Russia pharmacists took part in the preparation of the Pharmacopœia, and he hoped the Council would not hesitate to take the necessary and proper steps to advance their claims in this matter.

Mr. HILLS thought it premature to move in the matter at the present time. He had not heard that there was to be a new edition of the Pharmacopœia or another appendix, and he would much rather wait until something had been decided, and then respectfully write and place their services at the disposal of the Medical Council.

The VICE-PRESIDENT, referring to the Act of Parliament under which the Medical Council was constituted, pointed out that it consisted of one person chosen from time to time from various medical bodies and universities, and six persons nominated by Her Majesty with the advice of the Privy Council. They were not all necessarily therefore medical men.

Mr. SYMES said in October last he had brought forward the subject of a new Pharmacopœia, and made it pretty clear that if there was not to be a new one soon there ought to be. According to his idea the Pharmacopœia was a work on pharmacy, but it included therapeutics; in other words the ideas to be carried out were those of medical men, but the men to carry them out were essentially pharmacists. If any evidence was wanted as to who were capable of preparing the Pharmacopœia, he had only to refer to the two which had appeared since it had been in the hands of the Medical Council. They all knew the Pharmacopœia of 1864 was a perfect failure. There were no doubt extenuating circumstances, owing to three having to be brought together into one, but the chief cause of failure was that it was almost entirely a medical production. That of 1867 was probably one of the best which had ever appeared, and the improvement could be attributed no doubt to the fact that an eminent pharmacist was engaged. He, however, had no authority of his own, but was simply the servant of the Medical Council. When the Pharmacopœia appeared it was binding upon pharmacists, and they were obliged to make things in a certain way, although when made they would not sometimes answer to the tests there given. Under such circumstances he could not understand any pharmacist doing anything but most strongly supporting the idea that the Pharmaceutical Council, so far as the law would allow, should be represented fully in the framing of a new Pharmacopœia, and, if necessary, he should have much pleasure in aiding the deputation in endeavouring to impress upon the Medical Council the desirability of a new Pharmacopœia very soon appearing.

Mr. Mackay said there was but one feeling as to the desirability of pharmacists aiding in a new Pharmacopœia, but the question before them was whether this form of motion and the present time were the most suitable.

The President said there was but one feeling as to the abstract view being right, but it was a question of policy. He must correct Mr. Symes in one particular. The Pharmacopœia Committee of 1864 was more fully supplied with men who were supposed to have a knowledge of pharmacy than that of 1867. That Council was requested to send a deputation to the Committee, and it nominated certain persons to act upon it, and those persons set all their hands to work to prepare the edition of 1864. So much fault was found with that work that in 1867 the Committee was very much reduced, and it simply consisted of Professor Redwood and Mr. Warington, of Apothecaries' Hall, under the direction of a Committee of the Medical Council, consisting of Dr. Burrows, Dr. Apjohn, Dr. Sharpy and Dr. Quain. Therefore, pharmacy was very fully represented on that occasion. It was a very difficult thing to go to the Medical Council, to whom was given by Act of Parliament the power and duty of issuing the Pharmacopœia, and say, "Take us in." Of course pharmacists could offer their services with a good grace, but if they went in the way proposed by Mr. Hampson they would probably get a rebuff. He could also remember the time when the College of Physicians were about to issue a Pharmacopœia, though it never came to maturity. That body asked this Council to appoint a committee to work with it and to send the result of its labours. It therefore acknowledged, and he had no doubt the Medical Council acknowleged also, that pharmacists were in possession of much experience and information which would be extremely useful. But although the medical bodies would be glad to take it in the ordinary course, they would not like to have it forced on them by legal measures, and he did think it would be extremely unwise to convert the General Medical Council and the members of it into antagonists of the Pharmaceutical Society, because he happened to know that some of the best friends of the Pharmaceutical Society sat on that Council, and in all things considered and deferred to the interests of that Society. In fact they had done as much to advance the interests of the Pharmaceutical Society as anybody, not being a member of it, could do. He therefore hoped the motion would not be passed, but that the Council would trust rather to assisting the Medical Council by offering it what assistance it required.

Mr. Frazer said he should use the same arguments he used when this matter was before the Council five years ago against insisting on pharmacists having a legal position in the matter. There was one reason why pharmacists should not have it. It was medical men who were responsible for the medicines prescribed, and he did not think pharmacists had any right to arrogate themselves that position. They did not prescribe and it was those who prescribed who had the full responsibility of making the various formulæ. Besides that, although not legally on the Council, they were practically aiding it, as had already been shown. He himself was consulted on many points and he believed the same thing was done in many other instances.

Mr. Williams suggested the word "legal" should be omitted from the motion.

Mr. Hampson said he could not do so. He regretted to find that he lacked the support of several respected members of the Council, as he had five years ago. He expected a hearty support and almost unanimous on that occasion, for he felt that in five years the subject had so ripened, and the position of the Society had been so acknowledged, that the claim he made of a conference with their medical friends would be most readily received. Mr. Mackay seemed to think it was all sufficient that Professor Redwood had been called in to assist, but they could not always have the services of Professor Redwood. He altogether demurred to the position taken by those who opposed him. It was not for them simply to assist in the narrow sense, but to do the work along with the Medical Council; to take the proper position, not as members of the Medical Council, of course. That body had had to go to Parliament to get fresh powers, and certainly in its bill, or in an amended Pharmacy Bill, pharmacists' proper claim should be recognized. He did not attempt to describe the method of this recognition. He simply said it was their natural position as pharmacists to have a fair legal share in the preparation of the Pharmacopœia, so that they might occupy the same status as pharmacists in all other countries. It seemed to him a mistake to wait until a new Pharmacopœia was about to be published. The Committee should sit a considerable time before that, for it was a scientific work which would take two or three years to be put into shape, and all kinds of experiments would be required to be made. He was sorry to find that Mr. Sandford and Mr. Mackay held the opinion they did regarding the feeling of the Medical Council, namely, that this course would put this Council in opposition to it. He had a higher opinion of those gentlemen than to think they would pooh-pooh this proposition. They would surely respect pharmacists more for knowing that they did not undervalue their qualification as pharmacists.

Mr. Williams asked Mr. Hampson to define the word "legal."

Mr. Hampson said this word seemed somewhat misunderstood. At the present time pharmacists could not step into the room with the Medical Council and take any part in its deliberations; but he believed it to be absolutely essential that when the Medical Council, if it agreed with the proposal, went to Parliament for a new medical bill, it should ask for such provisions, that the Pharmacopœia should be framed by a Committee, consisting of so many medical men and so many pharmacists, the latter being nominated by the Pharmaceutical Council.

Mr. Mackay said any remarks he had made with regard to the Medical Council pooh-poohing this proposal simply had reference to the word "legally" in the resolution.

Mr. Williams moved an amendment that the word "legally" be omitted and also the last sentence.

Mr. Robbins seconded the amendment.

The Vice-President opposed the amendment. He thought it would be better to do nothing at all if they did not claim a legal status.

The amendment being put was lost by 8 votes to 3.

The motion was then put with the following result:—

For—Messrs. Greenish, Hampson, Schacht and Symes

Against—Messrs. Bottle, Fraser, Hills, Mackay, Rimmington and Robbins.

The motion was therefore lost.

The President and Mr. Williams did not vote.

Reports of Council Meetings.

Mr. Symes moved and Mr. Greenish seconded,

"That a Committee consisting of Messrs. Hampson, Atkins, Mackay, Bottle, Symes and Greenish, be appointed to make proper arrangements for the admission of reporters to the meetings of this Council and consider if any, and if any, what regulations are necessary to be made in reference to their presence in the room. The Committee to report to this Council at its next meeting."

The motion was carried unanimously.

Loan of Specimens from the Museum.

A letter was read from Mr. Davidson, asking for the loan of some mineral specimens from the Museum, to illustrate a paper on Coal, which he was about to read before the Chemists' Assistants' Association.

The request was granted.

PHARMACEUTICAL MEETING.

Wednesday, December 3, 1879.

MR. GEORGE WEBB SANDFORD, PRESIDENT, IN THE CHAIR.

An Evening Meeting of the Society was held on Wednesday the 3rd inst. The chair was taken at half-past eight o'clock.

The minutes of the last previous meeting having been read and approved,

The Curator called attention to the specimens which were on the table. He said that one was of rather unusual interest, namely, the stem of the araroba tree, presented by Mr. T. Christy, which was the first specimen that had been seen in this country. There was also a specimen of the leaf and a few of the flowers. The leaflets had been put together as nearly as possible to represent the habit of the plant, but the flowers were so broken up that he could not represent them as he should like to have done. In the specimen of the stem they would see that the araroba or Goa powder occurred in the porous vessels of the plant, and the porous vessels seemed to be corroded and run together, so that the small masses of the substance which was now known in commerce as araroba could be seen under a lens. There was also a specimen of bark of the white quebracho tree (*Aspidosperma Quebracho*), which had been sent over by Dr. Lorentz, from Cordoba. This plant was interesting for one or two reasons. Mr. Fielding, who had been staying for some time in the Argentine Republic, told him that it formed a common feature of the landscape, and had somewhat the appearance of that form of English ash tree which was sometimes seen with slightly drooping branches. The bark was remarkably smooth; but became exceedingly corky when once the thin covering became cracked, in which respect it very much resembled the bark of the birch tree. He imagined that the thinner bark of the quebracho was by far the most active portion of the plant, and as it would probably come into use in this country, as it had already done on the Continent, it was well to know that the corky bark was less valuable. It derived its name of "aspidosperma" partly from the very curious circular membranous seed which was attached to the fruit by a very slender thread, so that it resembled somewhat a shield. The name "quebracho," was Spanish, and meant "break axe," because the wood was so exceedingly hard, and could not be cut by ordinary tools without injury to them. There was also one specimen of yellow pareira brava, brought over by Mr. Moss, from New York, it having been presented by Professor Bedford. It had recently come into American commerce, and he believed Mr. Moss was engaged in examining it.

Mr. Greenish asked whether the araroba was a deposition or decomposition, and, if so, in what tissue the araroba was found.

Mr. Holmes said that the araroba could be seen in small patches in the porous vessels of the specimen now exhibited. Whether it was a decomposition or a deposition he had no means of ascertaining.

Mr. Symes said that quebracho wood was being used in large quantities on the Continent. He should like to know whether the bark contained special medicinal activity. The wood was astringent, and used for tanning, and was said to contain double as much tannin as ordinary crushed oak bark. Large quantities were imported into this country, but chiefly on the Continent. He had sent samples of the wood to one large firm of chemists, and they appeared to be satisfied that that was the article they wanted.

Mr. Holmes said that it was the bark of the white quebracho which was used in medicine. The quebracho wood was obtained from a different tree, known as the red quebracho, belonging to a different natural order. He was not aware that that wood was used medicinally. The specimen on the table was white quebracho.

Mr. Greenish thought that it was unusual to find tannin in wood. It had been usually found in the bark.

Mr. Holmes said that tannin was often found in the wood. With regard to the white quebracho, it was curious that the leaves contained more tannin than the bark, namely 27·5 per cent.

Dr. Paul said that the tannin principle of the red quebracho tree was contained in the wood, and that this wood was now being imported largely into France for the purpose of tanning leather. Some months ago some samples had been sent to him for the purpose of ascertaining its value, and he found that the active principle was contained in the wood brought over for the purpose of being used in tanning.

Apothecaries' Weights and Measures.

The President said that there was on the table a set of the new local standards of apothecaries' weights and measures which are to come into use under the new Act. They had been lent for exhibition by the head of the Standards Department, and were placed on the table for inspection. He would call on Dr. Paul to make some remarks in respect to them.

Dr. Paul said that the task which he proposed to undertake that evening was one justified mainly by the special practical importance of the subject. It was not necessary to address pharmaceutical chemists in a descriptive manner on the nature of the weights and measures that they were accustomed to use daily; but hitherto the weights and measures used in pharmacy had been things outside the law, not altogether unlawful to use, but used without any legislative sanction or recognition. In the introduction of new legislation on the subject of weights and measures it had been thought desirable, as in other respects, to bring pharmacy within the protection and control of legislative enactment, and to make the weights and measures used in British pharmacy no exception to weights and measures used for other purposes of trade in the country. The result of this had been that in future the weights and measures used in dispensing would be subject to inspection and verification in the same way as all other weights and measures used in the country; and, as a further result, they saw there some of the standards that had been constructed for the purpose of controlling the accuracy of the weights and measures used by chemists and druggists throughout the country. In the first place he would refer to the weight standards, of which there was a case on the table. These weights were made after the manner of the weights used in chemical analysis and for general chemical work—round blocks of metal with a knob at the top that could be easily grasped. They ranged from 10 ounces down to 10 grains, and then there was a further set of small weights, running from 6 grains to $\frac{5}{10}$ of a grain. The set was exactly a counterpart of the set of standards that would be used by the inspectors in controlling and verifying the weights that were used in pharmacy. With regard to the measures there were, first of all, a set of bronze vessels of certain capacities one made to contain 4 fluid ounces, and others ranging down to one containing a fluid drachm. These vessels were constructed to hold, when filled exactly to the brim, the quantity to which they corresponded. They were struck with a glass disk, used in the same way as striking a measure of corn, so as to remove any superfluous liquid, and leave the exact volume of water weighing, at the specified temperature, the corresponding weight. This was a form of measure which he imagined would be exceedingly difficult to use for the purpose of verification or for any practical purpose which required a number of measurements to be made rapidly and within a short space of time. Another of the measures indicated as competent to be used was the ordinary flask, like a litre flask, with a line in the neck, indicating the level to which it was to be filled for holding a certain volume and weight of water at 62° C. It was a convenient form of vessel, and there was a set ranging down to half an ounce. In vessels of that arrangement there was no provision for anything below the half ounce. In another set there was a pipette which was graduated into minims and containing in all 30 minims. Another form of measure that had been proposed for use for the verification of the ordinary graduated measures in use was made after the manner of an ordinary discharge pipette. By opening the air tap the water was allowed to run in until just above a certain level, when it was shut off and the air tap closed. The liquid then remained suspended. This was exactly the same sort of apparatus that was used in very many forms of volumetric analysis for measuring definite volumes. The one then in position was gauged to contain exactly a pound of water, or 7000 grains. The standard measures were graduated in a different way, not upon the neck, but upon the body of the bulb. The 2 ounce measure was graduated from 8 drachms to 16. There was another one which was graduated to hold 40 ounces, which was the largest volume, and another to hold 10 ounces which was the smallest. The connection of these vessels with the filling apparatus and system of air cocks was made by means of screws. One pipette could be taken off and another put on. It occurred to him, and it had been mentioned in the Journal, that the use of a measure of this kind for the purpose of verification was most objectionable, on account of the very large diameter of the surface of the liquid. The accuracy of such a measure depended upon having the surface of the liquid where the reading was taken reduced to the smallest possible diameter. When in comparison with the bulk of the liquid the diameter was very small, the amount of error made in reading off the level of the liquid was very much less than it would be in reading off from the other level, where the surface of the liquid was large. In point of convenience for use nothing could be preferred to that form of apparatus, and if these vessels were used it would be best, he thought, to have one pipette for each capacity of measure to be tested, and have a fresh one attached on every occasion. This would involve a larger number of vessels, but for facility and accuracy of work the advantage would be very considerable. With regard to the use of these it would be superfluous to say more than had already been stated in the Journal. In future, chemists and druggists throughout the country would be subject to inspection of their dispensing weights and measures, and if those weights and measures were incorrect in any respect, either in excess or deficiency, the owners of them would be liable to a penalty for each one which was so incorrect. Moreover, if they were correct, and were not also stamped with the stamp of verification they would also be liable to a penalty, and therefore it became the business of all who were engaged in pharmaceutical matters to take precautions to ascertain how their weights and measures were to be verified and stamped, so as to leave them safe under the operation of the Act. The provision to be made for carrying out the work of inspection and verification of weights and measures was to be made by the local authorities, that is to say the corporations, town councils, and bodies of that kind in different parts of the country, and it would be extremely desirable, for the sake of preventing inconvenience to individuals, if the local secretaries of the Society or the secretaries of local associations were to inquire of the corporations of their district, or the magistrates at quarter sessions, as to what arrangements were to be made for inspecting weights and measures, and what facilities were to be given for enabling them to be verified. Such a step would remove any possibility of harsh action at a future time and probably do away with a good deal of inconvenience. The Society was indebted to Mr. Chaney, of the Standards Department of the Board of Trade, who at the request of the President had placed these measures at the disposal of the Society for the purpose of this explanation. Dr. Paul said he had omitted to mention the cathetometer, which was the sort of apparatus used in the measurement of gases for reading off the exact level of mercury, and there was a very finely adjusted telescope by which one was enabled to read exactly where the level of the liquid cut the line of graduation. For gas analysis, and in dealing with gases, such an apparatus was exceedingly appropriate and did very good service; but when they had to read a level in the instruments shown such an apparatus as this seemed to be too delicate, and though altogether admirable in its way, quite inappropriate for the purpose specified.

Mr. Mackay said that the meeting was very much indebted to Dr. Paul for the trouble he had taken in this matter, and also for his lucid explanation. There appeared to have been a great deal of work about a very little matter; but, be that as it might, the whole country, and especially the people in the north, had been in very considerable alarm about the subject of weights and measures. He specially wished that, now they had the standards before them, the minds of pharmacists might be set at rest on one point, namely, that although the smaller weights were far better than those in ordinary use, both as to form and material, yet so long as those now in use corresponded with the new standards, the owners would come under no penalty. As to the more intricate set of glass measures he could not understand the wisdom of producing these wonderful gun metal or metallic looking things with ivory bases and very correctly fitted glass tops, with a view to measure from 1 ounce up to 4 or 5 ounces. Perhaps Dr. Paul could explain why they were produced in that particular form. These glass measures, as standards, seemed to be very beautifully made. He did not doubt their correctness, but he should think that the huge 40 ounce pipette was a thing which, in the hands of the inspector, would not be easily managed, and would be likely to lead to error, notwithstanding the aid of that wonderfully constructed telescope. Where the pipette was surmounted, as in this case, with the short tube, and where the indication was made by a small line, any man of ordinary eyesight would be able to verify correctly without the aid of such a curious looking instrument as that which they had before them. He was rather pleased than otherwise to find that there was a complete regiment of pipettes, ranging from 2 pints to ½ an oz. The smaller pipettes for drachms were quite proper. Curious ideas had been taken up by some inspectors. It would be invidious to name the inspector of a particular district, seeing that the business of verification was yet in its infancy; but in Edinburgh they had an inspector who, no doubt, would like to be the prince of all inspectors and to do his work with great skill and accuracy. He seemed to be possessed with the idea that dispensing chemists were to follow the particular form of these verifying measures. In confirmation of this, he might mention that Mr. Gilmour, who had taken a great deal of interest in the subject, and who had been misled once or twice on the subject, had written to him (Mr. Mackay), a note in which he said, "The point principally to be noticed is that there seems to be some important divergence of opinion regarding the interpretation of the Act." "The inspector for this district is prepared to accept and enforce the provisions of the Act in the lines put forward by me at our meeting here." The writer was referring to the last scientific meeting of their Society in Edinburgh in connection with this subject. As he (Mr. Mackay) remarked at that meeting, the inspector was undoubtedly wrong, though Mr. Gilmour thought that he was right. This inspector might be the type of others. It had been promulgated that, even if they departed from the pipette form of measure, still they must have a measure which would represent only ounces, drachms or minims, as the case might be. He apprehended that, in addition to all these new appliances for verification, a compound measure, could still be allowed, so that, if A. B. should take to an inspector a measure graduated from 5 minims up to an ounce, the inspector would verify that measure even though it contained marks for minims, drachms and ounces. Without such compound measures, the difficulty in dispensing would be beyond expression. If they had a measure larger than one ounce, the mode of graduation would be left to the option of the party wishing to have the measure verified. It would give great satisfaction if they could assure their friends in the country that when such a graduated measure came into the hands of the inspector there would be no difficulty in getting it verified. Then there were many wholesale houses which had a great many measures in stock. It seemed a peculiarly hard case that, in the event of these existing measures being found to be a few drops above the standard, there would be no remedy but throwing them into the cullet cask to be used as broken glass. But he supposed that that was a hardship to which they must submit. There was a certain scale of charges for verification, fixed by the Act. Could Dr. Paul tell them whether the charges fixed in the fifth schedule of the Act could be set aside altogether by the local authorities, and higher fees charged in their place? He believed that the fifth schedule apportioned 2*d.* to a local inspector for verifying a set of weights from 1 pound downwards, and one halfpenny for verifying a single measure. Three or four times these charges had been made for verifying solid weights and measures.

Mr. Bottle, referring to the liquid measures, said it would probably become his duty, in the borough of Dover, to instruct the ordinary inspector of weights and measures in the use of the new standards. He confessed that he felt a great deal of apprehension in instructing a non-professional man to use such apparatus. Dr. Paul had told them that it would be much more advantageous to have a series of pipettes graduated on the neck. To a certain extent that would be an advantage. Then one had to set against that the disadvantage of the liability to knock off the extremely fine nipple, and then when they had made sure of fastening the screw connection of the pipette apparatus, he very much doubted whether a series of pipettes ranging from a quart to half an ounce or half a drachm would, in the hands of a non-professional man, be of very much advantage. The old-fashioned flask would be, in the hands of non-professional men, a much more efficient way of getting at a standard, whether quarts or ounces, than the pretty piece of pipette apparatus on the table.

Mr. Greenish said that the inspector of weights and measures had called on him about his measures, and he (Mr. Greenish) had sent down to him four dozen and ten measures, and only two out of that number had been found to be incorrect. On the others the inspector had engraved or scratched a crown, a "V.R.," and the number 21, and for each he had charged one halfpenny. Usually Government officers received a great deal of pay for a very little work; but in this case there was an immense amount of work for very little pay.

Mr. Postans said that he knew there had been considerable activity amongst inspectors in connection with avoirdupois weights, and that, of course, bore on the matter of apothecaries' weights. In future it would become the duty of inspectors to see that chemists properly fulfilled the standard requirements by their weights. But great discretion should be exercised in the summoning and fining of chemists. The fine was in itself small, but there would be a great reflection cast upon its recipient, especially in country places where each person was well known. In most instances, chemists in the country did very little dispensing, and consequently the apothecaries' weights were liable to get into very bad order; and whereas previously a man might get only a few prescriptions per week, he would, after being fined, probably get none at all. They knew how the public took up such matters. He felt sure that the Board of Trade, in suggesting to local authorities their duty in the matter, would be most anxious that great discretion should be exercised as to inflicting fines.

Mr. Williams said that he would like to remind the meeting that the apparatus before them consisted of *standard* pieces of apparatus, not *patterns.* It did not follow that these forms of measures would be sent down to the inspectors for use. These, he imagined, would be kept to be used by scientific and expert men in London, for verifying those measures which would be sent down for use in the country by inspectors and others; and it was not intended that chemists were to use these exact patterns for practical purposes in dispensing. They were simply the standards by which other measures would be made for the guidance of those who had to measure and verify throughout the country. Therefore it was necessary that such apparatus should be very accurate, and they would no doubt be found to be so, or the Government would not have adopted them.

Mr. Robinson asked whether the Act applied not only to the measures used in dispensing, but also to those glass measures which they sold in the course of business.

The President asked if Mr. Robinson meant the glasses graduated for spoonfuls; those would not be interfered with by the Act, but the possession of incorrect ounce or drachm measures which might be used for selling as well as dispensing would he thought be liable.

Mr. Frazer said that his experience differed from that of Mr. Mackay. The inspector, in Glasgow, had told them to be quite easy in their minds as he had got the standards and was able to verify the larger weights at once, and this he had done. There had been no difficulty with him, and the charge was not unreasonable. He (Mr. Frazer) thought it would be well, if pharmacists at once invited the inspectors to come and inspect their weights, or send them to him to be verified.

The President said, that having had several opportunities of attending at the head offices respecting these weights and measures, he could say there was not the slightest inclination at the central office to interfere in any way, hardly or unfairly, with chemists and druggists. Very much would depend on local inspectors, who were very different from each other in their nature and character. Some would be particularly officious, rather more so than they would have occasion to be. Mr. Greenish had told them that he had had his glass measures stamped by a local inspector. When was that done?

Mr. Greenish said that they were stamped about two months ago.

The President said that in the month of August he was at the head office and was then told that the inspectors could not take any steps with regard to the measures for three months to come as the standards were not in their possession. Therefore, he very much doubted whether Mr. Greenish's four dozen measures had been properly verified. He (the President) received his information from the head office, as far back, he believed, as July. As to the weights, he had repeatedly called in at Young's, the scale maker's, in Bear Street, to ask whether they had any weights marked under the new Act, and the scale maker said that he was in constant communication with the local inspector at Westminster, but that officer was not yet in a position to mark his weights, as he had not got the standards. On the day previous to the meeting, he (the President) called at De Grave's, whose house was, perhaps, as high an authority as any in London, and he was told that they had no means of getting the weights stamped, and that the inspector had no authority to stamp them. They were preparing glass measures for standards, but they were not yet in a position to supply any. That seemed to settle the matter for the present; but he had been advised by the head of the Standards Office that it would be well for chemists living in the great centres to make application to the inspectors to have their weights verified the moment that the standards were in their possession. If chemists did that, it would show that they were not trying to evade the Act, but were ready to submit their measures to the inspector. He also advised that chemists should be on their guard, according to the recommendation in the paper last week. He thought that Dr. Paul had been led into a little error with respect to the weights used in dispensing. Those weights would, it was true, be under supervision, inasmuch as they were the weights by which drugs might be sold; but they were told by the Board of Trade, when the Act was coming forward, that the provisions of the Act would have nothing to do with dispensing, and would apply simply to buying and selling; that if they were dispensing a mixture their weights and measures would not be interfered with in so doing. As to the question of the shape and material of the weights, they must remember that the weights now exhibited were simply the standards for the inspectors, and it was not to be supposed that chemists were to have weights of the same shape and material, if the weights were exactly of the same value. They might be the flat grain weights such as they had now, marked as to their denomination, so that there would be no difference in that respect. With regard to the bronze measures of capacity which Mr. Mackay had thought would be very useless, they were simply to be used as standards. He (the President) thought that they were part of the series carried down from the much larger measures which were necessarily in bronze, so as to make a complete set. These others would be used, no doubt, in verifying measures. Then, as to the inspectors, they would have very great power, because it would be for them to say what measure they would stamp as verified, and what they would not. They would put the mark of a certain district on a measure; but it was yet a question whether they would verify from 20 ounces down to the bottom. Chemists had been told that, if the inspectors verified in the latter fashion, the charge would be about 2*d.* for verifying the 20 ounce measure, and about 1*d.* for the rest, but not 1*d.* each. They could only act according to the provisions of the Weights and Measures Act, and their charges could only be according to that statute. Some time ago an inspector led chemists to suppose that they could only use the weights bearing the stamp of the particular district in which they lived. That was altogether a mistake. A weight which was stamped in one district was good in all districts; but on the other hand, a person living in a particular district and wishing to have his weights verified, must take them to the inspector of the district in which he resided. Mr. Mackay said that the Edinburgh inspector led people to suppose that measures of the same shape as the standards must be used; but that was altogether an error. The pipettes were simply standards for the inspectors. He must correct Mr. Williams in the matter of the pipettes. That gentleman had expressed his belief that the district inspectors throughout the country would not have standards similar to these; but he (the President) had been told that they would, and on being told so, he had remarked, "Well, you will find that very few inspectors will be able to use them." These were not absolutely the set of standards which had been used in the Standards Office, but they were copies. He took it that the standards would be verified and prepared before being sent out. Then as to the measures of different denominations, he had been confirmed at the Standards Office in the idea that an 8 ounce measure might be graduated in ounces and half ounces and drachms. And, more than that, he might say that when the Act was framed, a resolution had been carried in the Council, which was published in the Journal, recommending that a 6 ounce measure should have graduations from ½ drachm up to the full measure. This had been laid before the Standards Department of the Board of Trade, and it was fully provided for in the Act, so they were perfectly safe on that point. Mr. Mackay had asked whether the incorrect measures which many possessed should be put into the cullet cask. He (the President) was afraid that if they were incorrect they must go somewhere. If they belonged to him he should be glad to get rid of them. With regard to Mr. Robinson's question, any incorrect measure found in their possession would render them liable to a penalty. He did not mean the measured spoons but any ounce measures must be correct.

Mr. Robinson: I misunderstood you then, sir. I thought that the Act did not apply to compounding, but only to selling.

The President said that it was not a question of selling at all; it was a matter of possession. He could assure them that there was every possible desire on the part of the superior officials of the Standards Department to deal fairly with chemists.

Mr. Cleaver said that he had seen a set of weights that were sold to a chemist, which bore the stamp of verification. He did not know where they were sold, but he had seen them in a chemist's in Chelsea a week ago. He believed that they were procured at one of the wholesale houses in the City. The stamp was a crown.

Mr. Atkins said that he had recently had some grain weights ready stamped from Maw's, but he could not remember what the stamp was.

The President said that they might perhaps remember that grain weights were stamped some years ago with the Westminster mark. Certain chemists were brought up before the magistrate for not having their weights so marked. He did not know whether they were fined or dismissed, but it was then proved that chemists in Westminster must have their weights stamped with the Westminster portcullis.

Mr. Greenish said that this was not the case at the present time.

The President said that he believed not, but no doubt many such weights were still extant.

Mr. Schacht said that there were inspectors still in existence who required people to send their weights and measures down to their office to be rectified and stamped every year. This was so in his own neighbourhood of Clifton, where pharmacists had to send their own weights and measures every year for rectification, so that the fact of the stamp did not involve verification according to the new special standards. The statements of Mr. Greenish and Mr. Atkins were not inconsistent with the President's statement that the authorities who had recently regulated all these fresh standards had not yet issued those standards to the inspectors. There was the old standard and the new standard. He did not know that glass measures had to be stamped, but he saw no reason why the same rule should not be applied to glass as to metal.

Mr. Mackay said that the inspector in his district had for months been stamping, under the new Act, weights up to a pound, but he had declined to mark any kind of glass measure. The chairman had misapprehended his point as to the incorrect measures. He thought that the rule was a severe one that there should be only a margin of so many drops allowed for possible error. Within the the last ten days, he had written to one of the largest glass measure makers, who had confessed their entire ignorance of any law by which they were bound to have any measure verified which they manufactured.

The PRESIDENT remarked that the grain weights were already subject to verification as avoirdupois weights, and could be verified without waiting for the new Act.

Mr. GREENISH said that he had been called upon by the local inspector three or four times, and urged to send his weights and measures down to the Court House for verification. The weights and measures had been sent and each measure verified and stamped. Each glass measure had a "V.R." and a crown, with a special number, 21, for Marylebone, and a definite charge was made of one halfpenny for each measure. Two measures had been rejected as being incorrect, and therefore they had been verified in some way, although he did not know by what means.

Professor REDWOOD wished to remind the meeting that there were three authorities who took cognizance of the subject of weights and measures. In the first place there was the central authority at the Board of Trade, who had all the necessary appliances for submitting weights and measures to strict and severe test. Then below that authority there were the district authorities to whom weights and measures might be sent from time to time to be tested and stamped if found to be correct, and in those cases any weights or measures found to be incorrect would simply be returned to those who sent them, with an indication of their incorrectness, and it would be optional to the owners of those weights and measures to get them corrected. This was frequently done in regard to weights. The weight might become incorrect from wear, and it was then optional to the owner of the weight to have it made correct. And so if a measure was found to have been incorrectly graduated, some correction, if practicable, might be made in it. The third authority was the inspectors, who were distributed over the country. The meeting had before it the standards which were used by the authorities at the Board of Trade. He apprehended that such standards would probably never come into possession of the second and lower authority. These were simply measures which, in accordance with the statute, were constructed upon the same principle as the bushel and the gallon, and so forth. This was simply an extension downwards without any intention of their being used in any other way than that they might possibly be required to be used by the higher authority at the Board of Trade. More practicable means of testing would be supplied to the subordinate authority—probably a set of flasks such as they had been in the habit of using, and which were now pointed out in the Pharmacopœia as affording the most accurate method of determining volumes where it was required to determine them with any great degree of accuracy. He had reason to believe that the Board of Trade had not yet fully decided as to what would be the form of verifying measures. Then there was a third authority upon whom the duty devolved of going round from shop to shop and making a personal examination of the weights and measures, and he (Professor Redwood) was constantly brought into communication with those inspectors, who had other duties to perform besides those of examining the weights and measures, and they were men who, if these pipettes were put into their hands, would be utterly at fault as to using them. Moreover, how could all those apparatus be carried round from shop to shop? There would be provided verifying measures of different kinds. There would be measures of the description now in use, but accurate measures, that had been subjected to examination by the second authority which he had indicated, and measures of that description, once known to be correct, would be used by the inspectors in the same way as at present. He agreed in the main with what Mr. Williams had stated, that there was no probability that the complicated apparatus, which had been put before them that evening, would be used by the ordinary inspectors.

Dr. PAUL, in replying to the discussion said that several points had been raised to which he should not have ventured otherwise to refer; but as they were of some importance he would, in replying, ask their attention to them for a few moments. In regard to the inspectors, who were the persons with whom chemists and druggists would come into contact, it was to be apprehended that some considerable difficulty would arise in many cases. Mr. Mackay had referred to one of those inspectors—the one which they were blest with in Edinburgh, and they had heard of performances of that particular inspector on a former occasion, when he took upon himself to interpret the Act as amounting either to the actual prohibition of the use of apothecaries' weights and measures altogether, or else to establish the other alternative, that the Act itself was null and void. That was early in the present year, and he took that ground with considerable tenacity and excited no little alarm amongst chemists and druggists in Edinburgh and in other parts of the country. It had been necessary to point out to him, somewhat plainly in order to reach his powers of apprehension, that he was totally wrong, and they had heard nothing more of this extraordinary interpretation of the law by the Edinburgh inspector. He (Dr. Paul) inferred that the inspiration of Mr. Gilmour's information given on a recent occasion was derived from the same source, and he had no hesitation in saying that it was equally untrustworthy. It seemed, in fact, that so far as this particular inspector illustrated the state of the case in the north, they might expect a considerable amount of difficulty arising from the blind attempting to lead the blind, and they would have to provide a very considerable ditch to accommodate those who were misled.

Mr. FRAZER: North-east, not north-west, if you please.

Dr. PAUL said that he was referring particularly to Edinburgh. He was glad that Mr. Frazer was more happy in his possession of a sensible inspector. The measure makers appeared to know nothing at all, and to take very little interest as to the provisions of the Act, and as to any necessity for providing accurate measures. He might mention that, as he understood, the owners of apothecaries' graduated measures and weights were to be liable only for the accuracy of the weights and measures which were in use. But however that might be, it surely would not be looked upon by pharmacists as a hardship that they should be expected to have correct weights and measures for use in dispensing. The President had thrown out a suggestion that dispensing was excluded from the operation of the Act, but he (Dr. Paul) could not agree with that view. Probably a medical man in dispensing medicine would not be subject to the visit of the inspector, nor would a private individual be subject to the visit of the inspector to test the accuracy of his graduated ounce measure, or the accuracy of his drachm weights, but a chemist and druggist engaged in trade and dispensing medicines for the purpose of selling them, was undoubtedly using those weights and measures for the purpose of trade, and in doing so he would come within the provisions of the Act. Therefore, he was bound to take care that the weights should be verified and stamped in accordance with those provisions. With regard to the matter of charges, he might mention that the provisions of the Act were very specific. It was stated in section 47, "an inspector under this Act may take in respect to the verification and stamping of weights and measures, such fees, not exceeding those specified in the fifth schedule to the Act, as the authority appointing him may from time to time fix." That was to say, the fees he was to charge for verifying weights and measures were to be those stated in the schedule or something less, but they were not to be anything in excess of that. Those fees were stated in the fifth schedule as follows:—"Each weight under 1 pound, ½*d.*, each set of weights of 1 pound and under, 2*d.*," and so on. Then there was another provision to which Professor Redwood had called his attention, which was that an alteration in those fees could be made on the recommendation of the local authority, but it was only to be done provided it was sanctioned by the Board of Trade, and provided that the representations of the local authority were such as to demand the recognition of the Board of Trade. Therefore there was no shadow of a ground for arbitrary charges, such as were referred to by Mr. Mackay, being made by any inspector. Moreover, with regard to charges for stamping the apothecaries' weights and measures all together, it would be an illegal proceeding on the part of any inspector to receive or to insist upon receiving any charge until this Act came fully into operation. It might be that certain measures used by chemists and druggists, and corresponding with the old apothecaries' weights and measures, might be stamped as provided under the old system, and those might be charged for as hitherto. Those, he apprehended, were the weights and measures referred to in the paper that was published in the Journal of the 29th of November, the last paragraph of which stated that many inspectors of weights and measures were already provided with some of the principal apothecaries' measures. Mr. Bottle had referred to the competence of the inspectors to deal with apparatus of the kind now before the meeting, and he (Dr. Paul) was quite at one with him in thinking that it was very likely indeed that the existing inspectors of weights and measures would be found very unequal to the work which they would have to carry out, and no doubt this would be a fact which would soon call for the attention of the municipal authorities, among whom many gentlemen connected with the Society had a place, to advise measures for supplying more competent persons to carry out the duties that would have to be performed under their control, for it was those local authorities, and they alone, who had any power to take any action in the matter. The inspector had no power at all, except that which was delegated to him and conferred upon him by the local authority which appointed him. With regard to that point, he (Dr. Paul) must differ from what was said by Professor Redwood as to the relative duties of the several authorities. The central authority had no power at all to deal with anything beyond the verification of the standards that were to be used by the local authorities. It might be said that practically it was their sole duty to verify from time to time the standards which were used in, say Manchester, Edinburgh, Glasgow and other towns, and to see that those standards were kept up to the mark and in a proper state to be used. Beyond that they had no power to interfere at all, either as to stamping, or as to the imposition of fees, or anything of the kind. Then, again, with regard to the use of the apparatus then before the meeting which had been referred to by Professor Redwood and other speakers, he must repeat that these several forms of apparatus were not those to be used by the central authority, but were the precise duplicates of the instruments to be sent down to be used by the inspectors as the standards of apothecaries' weights and measures in provincial localities. The Act specifically stated that the inspector was the person who was to use the standards, and to test weights and measures by comparison with the standards. The local authority had no power but to appoint and instruct the local inspector in the nature of the duties that he had to carry out. That was specifically set forth in the sections of the Act which dealt with the verification and local inspection of weights and measures, and was beyond the shadow of a doubt. How the inspectors would carry out their duties of testing druggists' weights and measures by these instruments was a matter which he did not pretend to be acquainted with. That was not disclosed. It might be that chemists and druggists would best anticipate and prevent any vexatious interference of inspectors by sending, as he suggested, their weights and measures to be verified, and then the result would be this—the inspector would come to the shop, and if the weights bore the stamp of verification of the district there would be an end of the matter, but if they did not they would have to go and be tested.

After some further discussion,

Professor Redwood said that he quite conceded the point to Dr. Paul.

Dr. Paul said with regard to the stamp that had been spoken of, one of the points mentioned by Mr. Gilmour, under the inspiration, no doubt, of the Edinburgh inspector, was that the stamp was to be a crown with a "V.R." underneath. Now in the Act it was stated that some "name, number or mark" should be used, and the only stipulation was that there should be a mark distinctive of the district. Some difficulty had arisen in reference to the use of those marks. It appeared that there were no less than 1355 separate districts, and these had all their own particular stamp or mark, so that there was great difficulty in telling whether any mark on a set of weights and measures was a mark of verification or some spurious mark, and in order to prevent the use of fraudulent stamps, and other misleading "practices of itinerant and unauthorized adjusters of weights and measures," a circular had been issued by the Standards Department suggesting the propriety of adopting a uniform mark of verification. It was not competent for the Board of Trade to compel the use of a uniform mark, and it was not necessary that there should be a uniform mark on weights and measures, as stated by Mr. Gilmour, but it was merely suggested that the stamp of verification might well be of the following design—an oval band containing a crown, and underneath that a "V.R." in a sort of cipher, together with a number distinctive of the particular district. With regard to pipettes and measures, there certainly might still be some little question remaining as to which particular form should be adopted for the standards, whether pipettes of the kind which he had recommended, guaged on the neck and delivering a certain volume, or the ordinary narrow necked flasks.

The President said that they were all much obliged to Dr. Paul for the lucid manner in which he had brought the question before them. It was a matter of great interest to pharmacists. He would still advise them to be on their guard. He (the President) happened to know that there still existed a very bad arrangement in some districts between the local authorities and the inspectors. Certain inducements were offered to the inspectors to bring forward cases of false weights and measures, and in some cases the authorities went so far as to give the inspectors half the penalties. This was considered a very objectionable arrangement. He hoped that the country magistrates would bear this in mind.

Mr. Bottle said that there was no such practice prevailing in Dover.

The President said that he was not at liberty to state the district in which it was done.

In consequences of the lateness of the hour when this discussion closed, it was agreed that a paper by Mr. Naylor, on "A Method for the Volumetric Estimation of Arsenic Acid," should be taken as read and published in the Transactions, and it will be found on p. 441, and that a paper by Mr. Collyer, on "Tincture of Senega as an Emulsifying Agent," should be read at the next meeting.

The President announced that the next meeting would take place on February 4.

Communications, Letters, etc., have been received from Messrs. Reynolds, Dewson, Casseebeer, Burt, Woodward, Carr, Maggs, Parker, Golding, Robert, Hurn, Sumner, Wilford, Swenden, Modlen, Ward, Southall, J. A., M.P.S., J. A. H., A. C., G. W., W. R. H., Over twenty years in the trade, London Dispenser, Delta, Quæro, Galangal, Nos, Hoc Age, Labor omnia vincit, Theta, One of the Gods, NH_4.

The length of the reports of the meetings of the Pharmeceutical Society this week necessitates the postponement of several communications.

NOTES ON INDIAN DRUGS.

BY W. DYMOCK.

(*Continued from page* 403.)

VITEX Sp. (?) VERBENACEÆ, HAB-UL-FAKAD (Arab.), TUKM-I-PANJANGUSHT (Pers.), SAMBHALOO-KA-BIJ (Hind. and Bomb.).

This small fruit is considered by native physicians to be astringent, resolvent and deobstruent, and useful for removing obstructions of the brain and liver. It is also given in enlargement of the spleen and dropsy.

Description.—A small dull-grey ovoid fruit the size of a duck-shot, half enclosed in the calyx, to which a portion of the peduncle remains attached. Upon section it is found to be extremely hard, and if perfect to consist of four cells, each containing a small flat seed. Generally one or more of the cells are abortive. The drug is imported from Persia. Value Re. ¼ per pound.

PLUMBAGO ZEYLANICA, *Linn.* PLUMBAGINEÆ. *The root. Vernacular*: CHITRAK (Hind.), CHITA (Beng.), CHITRA (Bomb.), CHITTIRA (Tam.).

History, Uses, etc.—Dutt gives us the following summary extracted from Sanskrit works of the uses to which Chitraka is put. The root is said to increase the digestive power, to promote the appetite and to be useful in dyspepsia, piles, anasarca, diarrhœa and skin diseases. It is much used as a stimulant adjunct to other preparations; in the form of a combination called "trimada," consisting of plumbago root, báberang (fruit of *Embelia ribes*), and the tubers of *Cyperus rotundus*, it enters into the composition of numerous medicines for dyspepsia. The following is an illustration:—Take of plumbago root, rock salt, chebulic myrobalans and long pepper, equal parts; powder and mix. Dose about 40 grains (Chakradatta). A favourite medicine for flatulence is an old prescription of Susruta's called "shaddharanayoga." It is a powder composed of equal parts of the following substances: plumbago root, seeds of *Holarrhena antidysenterica*, roots of *Stephania hernandifolia*, of *Picrorrhiza Kurroa* and *Aconitum heterophyllum*, and chebulic myrobalans. Dose about 1 drachm. The root of *P. zeylanica* is said to exercise a beneficial effect on piles, in which disease it is given in various combinations. One mode of administering it is as follows: An earthen jar or pot is lined in its interior with a paste of the root and curdled milk (dadhi), or kanjika (rice vinegar), is prepared in this pot. Plumbago root reduced to a paste is applied to abscesses with the object of opening them. It enters also into the composition of several preparations used as caustics ('Hindu Materia Med.,' p. 185). Mahometan writers treat of the drug under the name of "sheetaraj," a corruption of the Hindustani "chitrak;" they describe it as caustic and vesicant, an expellant of phlegmatic humours; useful in rheumatism and spleen, digestive. It also causes abortion. For administration it is made into a paste with milk, vinegar or salt and water. Such a paste may be applied externally in leprosy and other skin diseases of an obstinate character, and be allowed to remain until a blister has formed. In rheumatism it should be removed after fifteen to twenty minutes. When administered internally the dose is one drachm. Meer Muhammad Husain speaks of several kinds of "sheetaraj," and says one of them is the "leebadiyun" or "leefadiyun" of the Greeks. Rhazes describes two kinds, Indian and Syrian.

The Sheetaraj of Mahometan writers must, therefore, be considered to refer to the genus plumbago, and not to any particular species. *P. zeylanica* is mentioned by several European writers upon Indian drugs, but has not attracted the same amount of attention as *P. rosea*, which is said to be more active. However this may be, the former is the "chitrak" of the native physicians and very possibly may have been used by some under the supposition that it was the root of *P. rosea*. In the 'Phar. of India' Dr. Oswald is said to have employed *P. zeylanica* in the treatment of intermittents with good effect. It acts as a powerful odorific. In the neighbourhood of Bombay this root is one of the most important drugs of the itinerant herbalist; it is also sold in the shops. Cases frequently occur in which it has been used to procure abortion, a piece being inserted in the os uteri.

Description.—The roots are from ¼—½ an inch in diameter, seldom branched. When dry the external surface of the bark is of a dark reddish-brown colour, longitudinally striated and marked here and there by small warty projections; internally it is also brown and striated; the fracture short, the taste acrid and biting. Wood hard, reddish, close grained.

Microscopic Structure.—A moist section of the bark is of a greenish-yellow colour. The cells of the parenchyma are large and filled with starch. There are numerous large bundles of bright yellow stony cells forming an irregular zone towards the inner part of the middle layer of the bark.

Chemical Composition.—The activity of the drug is stated in the 'Phar. of India' to depend upon the presence of plumbagin. This acrid principle has been separated from the root of *Plumbago Europæa*. It is obtained by repeatedly boiling the ethereal extract of the root with water, whence it is deposited on cooling and may be purified by crystallization from alcohol or ether-alcohol. It crystallizes in delicate needles or prisms often grouped in tufts; has a styptic saccharine taste, with acrid biting after-taste; melts very easily, and partly volatilizes; unaltered when heated. It is neutral, nearly insoluble in cold, more soluble in boiling water, very soluble in alcohol and ether. It dissolves with yellow colour in strong sulphuric and in fuming nitric acid, and is precipitated by water in yellow flocks. Alkalies change the colour of the solution to a fine cherry-red; acids restore the yellow colour. Basic acetate of lead also colours it red, and forms a crimson precipitate (Dulong in Watts' 'Dict. of Chem.,' vol. iv. p. 685).

Commerce.—The shops are supplied by the herbalists, who collect the roots in this neighbourhood, where it is very common.

DATURA ALBA, *Rumph.*, D. FASTUOSA, *Linn.* SOLANACEÆ. *The root, leaves and seeds. Vernacular*: SAFED-DHATURA (Hind., Bomb., Beng.), URNATTAI (Tam.).

History, Uses, etc.—These two species of datura, as well as several varieties which have resulted from cultivation, are all included under the Sanskrit names "dhustura" and "unmatta." Sanskrit writers describe the plant as beneficial in mental derangements, fever with catarrhal and cerebral complications, diarrhœa, skin diseases depending upon the presence of animal parasites, painful tumours, inflammation of the breast, etc. A pill made of the pounded seeds is placed in decayed teeth to relieve toothache, and the leaves are smoked along with tobacco in asthma. According to Dutt no mention of the latter use of the plant is to be found in old Hindu books. Mahometan writers also are silent upon this point. Ainslie found upon inquiry that the physicians of Southern India were unacquainted with the value of datura in spasmodic asthma, but he tells us that his friend Dr. Sherwood, of Chittore, noticed the smoking of *D. fastuosa* as a remedy in that disease. The several species of datura are described by Mahometan writers under the Arabic name of "jouz-ul-máthil." The Persian name is "tátúlah." The author of the 'Makhzan' recommends preference to be given to the purple kind, he says that all parts of the plant are powerfully intoxicating and narcotic; as a local application they relieve the pain of tumours, piles, etc. The roasted leaves applied to the eyes give relief in ophthalmia; similarly they are useful in headache, enlarged testicles, boils, etc. The following description of datura intoxication is by the same author. "Everything he (the patient) looks at appears dark; he fancies that he really sees all the absurd impressions of his brain, his senses are deranged, he talks in a wild disconnected manner, tries to walk but is unable, cannot sit straight, insects and reptiles float before his eyes, he tries to seize them and laughs inordinately at his failure. His eyes are bloodshot, he sees with difficulty and catches at his clothes and the furniture and walls of the room. In short, he has the appearance of a madman" ('Makhzan,' article "Jouz-ul-máthil"). On account of their intoxicating and stupefying effects, dhatura seeds are frequently used in India for criminal purposes. An interesting account of Dhatureeás, or professional dhatura poisoners, will be found in Chever's 'Jurisprudence.' In Bombay country liquor is made more intoxicating by placing some of the seeds upon red hot charcoal and inverting an earthern vessel over them, when this is full of the smoke it is removed, filled with liquor and tied down. The leaves and seeds of *D. alba* have been made official in the 'Pharmacopœia of India;' of these a tincture, extract, plaster and poultice are directed to be made. The tincture of the seeds is highly recommended by the editor of that work as a substitute for opium. An extract of the leaves has been used successfully at the General Hospital, Madras, as a substitute for extract of belladonna, and it appears to me that the alkaloid might well be used instead of atropia in ophthalmic practice. The value of the leaves as an application to painful nodes, tumours, etc., is well known to many European physicians in India.

Description.—The fruit is about the size of a walnut, and nearly globular, covered with sharp tubercles or short spines, the capsule does not dehisce but splits in an irregular manner into numerous fragments. The seeds are ear-shaped, of a light yellowish-brown colour. The testa is rugose and spongy. The ends of the cotyledons in the embryo are turned outwards, which enables it to be distinguished from that of other solanaceous seeds. The tincture of the seeds is not fluorescent. The leaves are from 6—10 inches in length, ovate, acuminate, unequal at the base, very coarsely dentate; they have a fœtid odour.

Microscopic Structure.—The outer envelope of the seed is formed of a layer of thick-walled, sinuous cells with numerous secondary deposits; the second of tangentially extended cells. The albumen consists of polyhedral cells containing granular matter and fatty oil. The structure of the embryo is similar, but the cells are much smaller.

Chemical Composition.—The Indian daturas do not appear to have been examined, but there can be little doubt that the plant contains the alkaloid daturine, which has been separated from *D. stramonium.*

Commerce.—No part of the plant can be called an article of commerce, but the seeds are collected and sold by herbalists. Value nominal.

SOLANUM JACQUINII, *Linn.*, SOLANACEÆ. *The plant.*

Vernacular: BHATKATYA, KATÁI, RINGNI (Hind.), BHU-RINGNI (Bomb.), KANDAN-KATTIRI (Tam.), KANTAKÁRI (Beng.).

History, Uses, etc.—This plant is an article of considerable importance in the Hindu materia medica, as it is one of the dasamula, or ten plants, so much used in preparing a compound decoction by the Hindus. It is considered to have expectorant and diuretic properties and is prescribed in asthma, cough, certain urinary affections, catarrhal fever, costiveness, etc. In Hindu practice the drug is generally combined with other expectorants, demulcents and aromatics. The following prescription from the 'Bhavaprakasha' is extracted from Dutt's Hindu 'Materia Medica.' "Kantakáryavaleha, or electuary of *S. jacquinii.* Take of kantakari 12½ seers, water 64 seers, boil till reduced to one-fourth and strain. Boil the strained decoction till reduced to the consistence of a fluid extract and add to it the following substances in fine powder, namely, *Tinospora cordifolia*, *Piper chaba*, *Plumbago zeylanica*, *Cyperus rotundus*, *Rhus succedanea*, long pepper, black pepper, ginger, *Alhagi maurorum*, *Clerodendron Siphonanthes*, *Vanda Roxburghii*, and zedoary root, each 8 tolas, sugar 2½ seers, sesamum oil and clarified butter each one seer. Boil together until reduced to the proper consistence. Lastly, add honey one seer, bamboo manna and long pepper in fine powder each half a seer." Mahometan writers, under the Arabic name of "hadak," or the Persian "badinjan-i-barree" (wild egg plant), mention three kinds of solanum having somewhat similar properties. Their small kind, or "hejazee," appears to be the *Solanum jacquinii*, which they recommend in asthma, cough, dysuria, catarrhal fever, leprosy, costiveness and stone in the bladder. Under the Tamil name of "cundunghatrievayr," Ainslie notices the use of this drug in Southern India as an expectorant. The stems, flowers and fruit, according to Dr. Wilson (*Calcutta Med. Phys. Trans.*, vol. ii., p. 406), are bitter and carminative, and are prescribed in those forms of ignipeditis which are attended with a vesicular, watery eruption. Fumigations with the vapour of the burning seeds of this plant are in high repute in the cure of toothache. The mode of application followed by the natives is given in detail by Morehead (*ibid.*, vol. vii., p. ii., p. 489). It acts as a powerful sialogogue and thus affords relief (Confer. 'Phar. of India,' p. 181).

Description.—Root at least biennial. Stem none, but several flexuose, ramous branches, spreading close on the ground, for an extent of some feet, often striking root at the insertion of the leaves; angular, nearly void of pubescence. Leaves frequently in pairs, oblong, pinnatifid or laciniate, smooth, but armed on both sides with long, strong, straight spines. Racemes between the leaves, and almost as long, bearing 4—6 alternate, pedicelled, large, bright blue flowers. Calyx armed with straight spines. Berries spherical, size of a large gooseberry, very smooth, drooping, while immature variegated with green and white, when ripe with different shades of yellow only (Roxb.). No chemical examination of the plant appears to have been made.

Commerce.—The dried plant is kept in every druggist's shop in India. It is not an article of commerce, but is supplied by the herbalists as required.

SOLANUM INDICUM, *Linn.* SOLANACEÆ. BIRHATTA (Hind.), MOTIRINGNI (Bomb.), MULLI (Tam.), BYÁKURA (Beng.).

This owes its importance to being one of the plants used for the preparation of the Dasamala Kvatha. It is called "vrihati" and "bhantáki" in Sanskrit and does not appear to be used except in combination with more important drugs. According to the author of the 'Makhzan,' it is cardiacal, aphrodisiacal, astringent and resolvent; useful in asthma, cough, chronic febrile affections, colic, flatulence, worms, etc. (Confer. 'Makhzan,' article "Birhatta.")

Description.—Trunk trifling, but the branches are numerous, ligneous and perennial, forming a large, very ramous shrub of several feet in height, armed with numerous, very acute, somewhat recurved spines; the young parts are downy. Leaves solitary, or in pairs, petioled, ovate, lobate, downy and armed with a few straight spines on both sides from 2—4 inches long. Racemes between or opposite to the leaves, supporting several long pedicelled, middle sized, pale blue flowers. Calyx deeply 5-cleft, armed. Berries erect, round, smooth, size of a marrowfat pea; while immature variegated with deeper and lighter green, when ripe with deep orange yellow (Roxb.).

(*To be continued.*)

ACONITUM HETEROPHYLLUM, WALL.*

BY DR. M. DUNIN V. WASOWICZ.

(*Concluded from page* 343.)

(c). *The filtrate from the lead precipitate.*—After removing the excess of lead the purified liquid always appeared to be coloured darker by ferric chloride, and it also reduced Fehling's solution after long boiling and especially when a small quantity of oxalic acid had been added. It was again treated with acetate of lead and then again purified as before. After this treatment it was pale yellow or brownish-red according to the degree of concentration, had a strong persistent bitter taste, an acid reaction, and in reflected light had a strong green fluorescence; it was no longer coloured by ferric chloride, and did not reduce Fehling's solution in the cold, but only after addition of dilute acid and warming. Mixed with tannic acid solution it gave a very voluminous brownish precipitate, and with double iodide of mercury and potassium a copious white precipitate.

In order to remove the saccharine substance indicated to be present by the reduction of an alkaline solution of cupric oxide, a portion of the liquid was evaporated to the thickness of syrup, and mixed with alcohol and with some water and ether, until there was a perfect separation of the liquid into two layers. In the lower watery layer there would be the principal part of the sugar and the extractive; in the upper alcoholic and ethereal layer the bitter substance or alkaloid was to be sought for.

(1). The watery liquid was still somewhat bitter, readily reduced Fehling's solution, and still gave a precipitate with double iodide of potassium and mercury. It was mixed with animal charcoal and evaporated, with repeated addition of water, and ultimately the extract remaining was dissolved out with warm water, the animal charcoal being afterwards several times digested with small portions of alcohol. The watery extract was no longer bitter but had a dark brown colour. It was evaporated to a small bulk, but after several days it had not deposited any crystals. It was then boiled with albumen, again treated with animal charcoal, boiled with a little dilute acid and left to crystallize. A small quantity of a warty crystalline mass was thus obtained, which was only partially to be freed from adhering extractive by means of absolute alcohol, since the alcohol dissolved a portion of the extractive, but in this way sufficient quantity of the crystalline substance was obtained to establish the fact that it was grape sugar. The extractive substance presented no characteristic reaction except that of reducing Fehling's solution. The alcoholic extract, obtained by digesting the animal charcoal was but little coloured, became turbid upon the addition of the double iodide of potassium and mercury and reduced Fehling's solution. On evaporating it left a very small quantity of extract, which proved to consist of the several substances existing in the original liquid, and accordingly was further treated.

(2). The upper alcoholic and ethereal liquid was first digested for some days with animal charcoal to remove the colour, but this was only partially effected. After distilling off the alcohol there remained a yellow resinous mass with a neutral reaction, readily soluble in absolute alcohol and ether, but only partially soluble in water and dilute spirit. It was then treated with a large quantity of water and some ether added, so as to effect almost complete solution, and the separation of the liquid into two layers. The watery liquid left on evaporation a brown resinous substance, of a bitter taste, only partially soluble in water and not altered by alkalies. In the watery solution tannic acid gave no precipitate; double iodide of potassium and mercury an inconsiderable white precipitate. The portion insoluble in water dissolved readily in absolute alcohol and gave a considerable precipitate with tannic acid. The ethereal liquid deposited on evaporation a tough yellow mass, readily soluble in alcohol and ether and having a strong persistent bitter taste. The solutions gave both with tannic acid and double iodide of potassium and mercury considerable precipitates. This substance was found to contain nitrogen and consequently it consisted of impure atisine. The mass was digested for some time with animal charcoal, extracted with ether, and left to crystallize. After the evaporation of the ether no crystals were left, but a yellowish-white mass that could be readily powdered. The powder, when exposed for some time to light and air aggregated to a tough doughy mass of a dark brown colour, and in experiments with benzol, chloroform

---

* *Archiv. der Pharmacie,* vol. xi., p. 19.

bisulphide of carbon, dilute and absolute alcohol as solvents no crystals could be obtained. By repeated solution and treatment with animal charcoal this mass was ultimately obtained quite white, and in that state a combustion was made. 0·3231 of the dry substance (constant under the air-pump) gave—

0·91 CO_2 = 0·248 C = 76·756 per cent. C.
0·3101 H_2O = 0·03445 H = 10·622 per cent. H.

These figures approximate closely to those calculated from the formula assigned to atisine by Broughton; $C_{46}H_{74}N_2O_4$ which requires—

		Found.
C	76·88	76·756
H	10·306	10·662
N	3·899	
O	8·903	

The alkaloid thus purified was white and uncrystallizable, and when dried under the air pump could be readily powdered. By exposure to the air the powder readily became yellowish or yellowish brown and resinous. Heated in a water-bath it also ran into a yellowish brown mass. It was very little soluble in water, rather more soluble in dilute alcohol, but readily and completely soluble in ether, absolute alcohol, benzol, etc. The solutions had a strong clean bitter taste, without any acrid or burning after-taste. The alcoholic solution, strongly diluted with water, was distinctly opalescent and frothed very much when shaken, like saponin; but atisine is distinguished from this latter substance by the slight solubility in water, as on diluting the alcoholic solution the greater part of the alkaloid is separated in white flocks. Alkalies do not produce any colour; concentrated sulphuric acid produces at first a faint violet, which becomes reddish, then dark red, and after about an hour, dirty brown. Sulphuric acid and bichromate of potash produce a green colour, with a distinct reddish violet zone. Nitric acid produces a brown colour. The nitrate, sulphate and acetate of the alkaloid do not admit of being crystallized. As obtained by evaporating the solutions, these salts are readily soluble in water, have a yellowish colour and taste very bitter.

Ammonia precipitates the alkaloid from solutions in white flocks. Tannic acid gives a yellowish brown precipitate, and the iodide of potassium and mercury a white precipitate that is perfectly soluble in alcohol. On evaporating the alcohol a distinctly crystalline mass remains. I did not succeed in obtaining a well crystallized platinum salt.

Only the hydrochlorate, hydrobromate and hydriodate of the alkaloid are crystallizable and sparingly soluble salts, among which the hydriodate is most manageable. This circumstance, and the tedious nature of the previously described method of obtaining the pure alkaloid, induced me to operate upon the second part of the liquid* in a different way, and I added to it iodide of potassium and mercury until no further precipitate was produced. After complete deposition the precipitate was collected upon a suitable filter, carefully washed with distilled water, and while still moist suspended in water and treated with sulphuretted hydrogen. Together with the mercuric sulphide there was formed a quantity of shining pearly scales, which could be dissolved in a sufficiency of boiling water, and separated again on partial cooling. They were separated from the mercuric sulphide by repeatedly boiling with water and filtering the hot solution. The yellowish filtrate upon cooling separated an abundant quantity of the above-mentioned pearly crystals, which proved to be hydriodate of the alkaloid.

* See previous page.

The mother-liquor was concentrated as long as crystals were deposited upon cooling. At a certain point, when crystals were no longer formed and the presence of iodine could no longer be detected, there was still alkaloid in solution, since considerable turbidity was produced by iodide of potassium and mercury and by phosphotungstic acid. On the addition of hydriodic acid to this liquid, however, no further crystals could be obtained. This would apparently lead to the conclusion that the roots examined contained a second alkaloid, the hydriodate of which is not crystallizable, and this is further supported by the circumstance that the precipitate produced by iodide of potassium and mercury, when dissolved in alcohol, gives on evaporation a residue that is not crystalline. This question, however, must for the present remain undecided, as the material at my disposal is too small for the purpose.

The substance considered to be hydriodate of atisine was re-crystallized from water several times and dried under the air pump. It was in the form of scaly crystals having a pearly lustre, soluble in 318 parts of water at 20° C., 420 parts of 96 per cent. alcohol, and very slightly soluble in alcohol. Analyses led to the formula $C_{46}H_{74}N_2O_4\ IH + H_2O$.

The hydrobromate and hydrochlorate have a similar constitution. The hydrochlorate is a white crystalline powder, more soluble in water than the hydriodate, and having a strong bitter taste, but not the disagreeable after-taste that the hydriodate has.

The general results of this investigation are that I have found the root of *Aconitum heterophyllum* to contain (1) a fat of soft consistence, probably a mixture of oleic, palmitic, and stearic glycerides; (2) aconitic acid; (3) an acid related to ordinary tannic acid; (4) cane sugar; (5) vegetable mucilage; (6) pectous substances; (7) atisine, the alkaloid already observed by Broughton, and probably another uncrystallizable alkaloid; (8) starch. The root contained 2·331 per cent. of ash that dissolved partly in water and partially in dilute hydrochloric acid.

It may be remarked that the experiments I have made in administering the alkaloid to rabbits show that it is not poisonous. It was, however, impossible to ascertain whether the alkaloid could be used as a febrifuge, as the quantity in the root was exceedingly small and the entire amount at my disposal was not quite 3 grams.

THE MIGRATION OF PLANTS FROM EUROPE TO AMERICA, WITH AN ATTEMPT TO EXPLAIN CERTAIN PHENOMENA CONNECTED THEREWITH.*

BY PROF. E. W. CLAYPOLE, B.A., B.SC. (LONDON), OF ANTIOCH COLLEGE, OHIO.

(*Concluded from page* 407.)

It is singular that while so many European species have forced their way into possession of the American soil, the cases of counter-migration are exceedingly few—so few that they may be counted on the fingers. It

* Paper read before the Montreal Horticultural Society, 1877.

appears as if some invisible barrier existed preventing passage eastward, though allowing it westward. One or two species may be named which, as exceptions, bring the general truth of this statement into stronger light. The Canadian Fleabane (*Erigeron Canadensis*), a native of North America, "is now established in nearly all temperate and hot countries, and occasionally appears so in England."* The Annual Fleabane (*Erigeron annuus*), though not in England, has become wild in some parts of Europe. Add to these two the so-called "Water Thyme" (*Elodea Canadensis*), and we have all the conspicuous examples with which the writer is acquainted of the eastward migration of American plants to Europe and their naturalization there. The last named plant was first observed about 1847 in the northern and midland counties of England and the south of Scotland, in Yorkshire, Leicestershire and near Berwick and Edinburgh.† How it was introduced is not known. Thence it spread until in about ten years many of the slower streams were almost clogged with it, and the writer well recollects that it was then difficult to row on the upper and middle Thames in consequence of the accumulation of this weed. Fears were even entertained that it would form a serious impediment to inland navigation. But in a short time the evil diminished, and after a few years, though still present, the quantity in the rivers became insignificant, and no inconvenience is now caused by its presence.

Such facts naturally suggest the question: Why are these things so? What invisible door bars the passage of the American flora to Europe, but admits the free passage of the European flora to America? One reply will naturally occur. Seed is mainly brought from Europe to America, and thereby a favourable chance is afforded for introducing the seeds of European weeds. This is so; and to this cause, doubtless, is due the immense number of introduced plants. But, if European seed is largely brought to America, American crops go much more largely to Europe; and it would be absurd to suppose that any crop gathered from the half cleared and weedy fields of this country could be sent thither without, at the same time, sending in abundance the seeds of our native weeds. All the ill weeds that grow in Canada or the States must, ere now, have been many times exported to the mother country. Yet they do not appear. It may be replied that the greater part of the corn crops are destined for the mill and not for the land, and that in this way their chances of propagation are largely diminished. Making all due allowance for this, should we not look for a rank crop of American weeds springing up around the mills from the cleanings and the waste? Yet such is not the case. With all the millions of bushels, moreover, that go to England for feeding purposes, and are never ground, there is the same result. The weeds no more take root and run wild than do the wheat and maize among which they cross the Atlantic. And when, in addition to this, we consider that there has been for two centuries an organized and regular introduction of American wild plants into European botanic and flower gardens, might we not reasonably expect to see at least a few of them, or of others which must have accidentally accompanied them, spreading outside of the limits of these gardens, and becoming naturalized in Europe? Yet nothing of the kind has occurred. Neither the rank and abundant Ragweed (*Ambrosia*), nor the widely diffused Golden Rods (*Solidago*), nor the Protean Asters (*Aster*), nor the wayside Pepper Grasses (*Lepidium*), nor the prolific Sumachs (*Rhus*), nor the clinging Burr-marigolds (*Bidens*), nor the ubiquitous and striking Milkweeds (*Asclepias*), have succeeded in naturalizing themselves in England. Even where a genus contains species on both sides of the Atlantic, as is the case with the Houndstongue (*Cynoglossum*), we find that the English species—the common Houndstongue (*C. vulgare*)—has migrated westward, and become so common near Montreal and almost everywhere in the eastern and midland States that Professor Gray can term it "a familiar and troublesome weed;" while at the same time, the common American species, or Beggar-lice Houndstongue (*C. Morisoni*), which the same writer brands as "a common and vile weed," is completely unknown in England.

Some may be inclined to urge that the comparatively cool English summer may not afford sufficient heat to perfect and ripen the seed, which the fiercer sun and continental climate of Eastern America can easily mature. This may account for the inability of some American species to sustain themselves in England, but it is evidently far from sufficient to solve the whole problem. Many of these plants can perpetuate themselves in the short, cool summer of New England and Lower Canada, and we might therefore reasonably expect, even if want of summer heat excluded them from England, that they would find a congenial climate somewhere in the warmer countries of Southern Europe. But not in England only, but throughout Europe, the absence of American species is remarkable. Difference of climate seems insufficient as the only or the chief factor in the solution of the problem, and we are compelled to look farther.

Nor, can it be urged as an objection that European weeds alone have come in. Without at present defining a weed, the reply is obvious that American weeds have not gained a foothold in Europe. It is not to be anticipated that large, conspicuous and slow-growing plants, such as forest trees, or highly developed and cultivated forms, such as garden-flowers, will often run wild. The former require too long a time to grow and propagate themselves, and are subject to too many dangers, while the latter are only maintained at their high standing by constant and careful cultivation. It is only, therefore, among the smaller and more insignificant plants that the facts here detailed can be looked for, and accordingly of such our list altogether consists. It may be that the forest trees of Europe, or some of them, will one day grow wild here. But the life of a tree is so long, and its growth so slow, that the experiment cannot be said to have been yet made. So far from planting and propagating European trees, men are bent in most parts of the country upon destroying their own. The present generation has not outgrown that insane hatred of trees which possessed the past, and was perhaps an almost unavoidable result of the severity of their struggle with the primeval forest. Timber is still contemptuously termed "lumber." No respect is felt for it, and consequently no European tree, if trying to run wild, would stand much chance of life during the attempt. A high authority on forest trees in this country has informed the writer that in his experience some European species have grown better than the American species of the same genus—that the English beech and larch, for example, surpassed the native beech and the tamarack. Time alone can prove this point.

The comparison, therefore, must be made, and can only be made justly, between the weeds of the two continents, or plants which come very near them and may be called almost weeds. By the term "weed" we mean those plants to which the surroundings are so suitable that they increase and multiply, year after year, more rapidly than others by which they are surrounded. Entering into details, the soil affords them the nourishment they need; the spring frosts do not kill them, or they bud and grow only when this danger has passed; they ripen their seed in quantity sufficient before the winter sets in; the heat of summer does not scorch them, nor the cold of winter destroy their roots or seeds; they are not so much injured by insects as to preclude their coming to maturity; while their flowers are sufficiently visited by insects to ensure the fertilization of their seeds, or else they spread so rapidly by underground stems as to render seed unnecessary. Granted all these conditions, and we have weeds of the first order, while the failure of any one of

* Bentham's 'Handbook of the British Flora.'
† *Ibid.*

more of them may reduce such a weed to the position of a very harmless and comparatively rare plant. In fact, the great abundance of a weed or wild flower in one year and its scarcity in another, is often due to its lacking one or more of these requisites. Weeds are the *homely* plants of a country, using the word in its true and original sense. A plant that is perfectly comfortable in its surroundings, if possessing considerable power of reproduction, becomes master of the situation, and is a *weed*.

The weeds of different countries must therefore differ because their conditions differ. For the same reason the weeds of different ages must also differ. Climate changes as geological time passes by, and all plants are not able to adapt themselves to these changes. It is frequently the case that a man placed in new circumstances is quite unable to adjust himself to them. His nature is not sufficiently plastic. So with plants. A wide range in time or space, with changing conditions can only be enjoyed by a plant whose nature is plastic or capable of change. Place a weed of stiff or unyielding nature in less favourable conditions and it cannot adapt itself to them. It becomes unhealthy and lingers on, as it were, by sufferance among stronger neighbours—no longer a weed —or it speedily dies out. But a weed possessing a plastic nature—one capable of being moulded by and to its new surroundings ere long adapts itself, if the change is not too great or sudden, to its new situation, takes out a new lease of life, and continues in the strictest sense *a weed*.

Is it not possible that some such cause as this may lie underneath the facts we detailed in the earlier part of this paper? The true and full explanation of the transfer of European species to America should at the same time explain the absence of American species from Europe. But the partial causes already alluded to fail to do this. There is a residual effect for which they do not account. May it not be true that the plants of the European flora possess more of this plasticity, are less unyielding in their constitution, can adapt themselves more readily to their surroundings, and thus secure their continuance in the New World? And may it not be the lack of this plasticity in the American flora which incapacitates it for securing a foothold and obtaining a living in the different conditions of the Old World? Under the care of the gardener they grow and embellish the gardens and conservatories of Europe, but without this care they speedily fail and die.

To point out the physiological basis of this property of plasticity is at present and will probably long remain impossible. But that such a property exists in both the animal and vegetable kingdoms is beyond a question. It is the secret of that variation which so strongly marks some species, while its absence is the cause of that fixedness which characterizes others. It is the secret of that quick response which some plants make to a change of conditions, and whereby they gain fresh vitality at the cost, it may be, of some slight modification of structure. Its absence, on the contrary, causes that indifference or resistance which characterizes others, and which is almost always followed sooner or later by the extinction of the resisting species.

Though, however, the indication of the exact physiological basis of this plasticity of constitution is as yet beyond our reach, it seems possible to point out one fact which not improbably has had some share in reducing the plasticity of the American flora. To approach a single short step nearer to the object of our quest, when that object is at present unattainable, is so much ground gained. We are all familiar with the effects of habit upon ourselves. We all know how easy habitual actions become; how strong is the tendency to perform them when the conditions recur under which they are usually performed, and how unwillingly we deviate from our daily course after following it for years. To this one fact—the power of habit—is due the uncomfortable, unsettled state of most men who make some great change in their outward surroundings late in life. Few who emigrate in old age ever become quite reconciled to their new home. The habits of many years have so moulded them in body and mind, and set them so firmly in their mould, that the plasticity they may have once possessed is gone, as bricks dried and burnt have lost the pliancy they possessed when in the form of clay. Of the physiological cause of this fact we know nothing, but the fact no one can doubt. Experience shows us that habit is no less powerful in plants than in animals. What a plant has been in the habit of doing that it will incline to do again. The physical organization of the plant, acted upon by the conditions that surround it, produces its habit. The longer these remain unchanged the longer do its habits continue, and the longer its habits continue the more firmly, we must infer, do they become engrained in its physiological structure. Thus do habit and organization act and react on each other. Each may be changed, but all such changes are slow, and we may easily, in view of these facts, believe that after many years or ages of unchanged conditions a plant may become (as many an old man becomes) so firmly set in its habits, so rigid in its nature, as to resist modifying influences with all the energy it possesses, and rather die than change. This is what we mean by losing its plasticity. A plant accustomed in the climate of England to occupy two months in perfecting its seed may, if suddenly removed to another country, continue its former practice or it may not. In the former case if the new climate does not afford the time required, the seed is not ripened and the species fails. If, however, the plant can adapt itself to the shorter season, and ripen its seed earlier, it may survive. But for this result a high degree of plasticity is needed. On the other hand if the change of climate be made more slowly, the habits and organization of the plant may keep pace with it, and with even less plasticity than in the former case, the species may survive.

We may advance at least one step farther. If these views on the relation of habit and organization to time be correct, have we not a possible, though at present a rude, gauge for both? If the strength of habit increases with time, may we not roughly measure that strength by the length of time during which the habit has prevailed? And further, if the plasticity of plant nature diminishes and its rigidity increases with the duration of a habit, may not this duration in like manner be employed to some extent as a gauge of rigidity; that is of want of plasticity? We stand here on new and difficult ground, and any deduction must be tested severely before reliance can be placed upon it. The confines of geology and botany, the place where the two sciences march together, is almost unknown territory over which science is just beginning to extend its conquests. The tracing of earth's existing flowers into her past, the genealogy of plants, is a subject closely connected with that other subject—the descent of species—which now so sorely divides the leaders in natural science. Nevertheless, we propose in the concluding portion of this paper to grope out into this unknown land where the light is so dim, and try to feel our way along the clue indicated above, in the hope of finding some link that may connect the apparently inconsistent facts we are attempting to reconcile—the abundant westward migration of plants from Europe, and their scanty eastward migration from America.

Have we then, at the outset, any reason to believe that the North American flora possesses less plasticity than the European? Let us apply the gauge just mentioned and see the result—the gauge of time. We are in the habit of calling America "The New World." Botanically and also, we may add, zoologically speaking, America is the older and Europe the younger. Europe passed ages ago through the stages of plant life which America exhibits to-day. The trees and plants of America, like most of her native animals, belong to old-fashioned, antiquated types—types that have passed away from European life, and now lie entombed beneath its surface in the records of geology. If we turn for a moment and consult these buried registers of births and deaths, we find that in ages past the existing families of America were living in Europe. Name after name may be turned up, long unknown and long forgotten where once it lived in the Eastern World, but faithfully recorded in these volumes and yet surviving through American relatives in the West. The woods of Europe, once contained trees identical with those now growing in the forests of North America. The miocene formations of Switzerland have yielded to the labour of Professor Heer, of Zurich, a rich harvest of fossil plants amounting to at least nine hundred species. The descriptions and illustrations of these may be found in his great work on the 'Tertiary Flora of Switzerland' (1855–59). These tertiary beds lie in the great valley between the Jura Mountains and the Alps, and bear the name of the Molasse. From other parts of Europe also, and from high northern regions, similar fossil remains have been brought to light, and our knowledge of the European tertiary flora, though still very fragmentary, is in a condition to admit of fair comparison with the existing floras of the world.

Space will not allow a minute enumeration of examples. Nor is it necessary for the purpose of establishing the assertion made above concerning the relationship of the living plants of America to the fossil tertiary plants of Europe. A few illustrations of the better known forms will suffice. Among the relics obtained from the beds at Oeningen are the leaves of a maple tree with flowers and seed. Europe possesses several maples, but these fossils resemble none of them, while they can scarcely be distinguished from the common Red Maple (*Acer rubrum*) of North America. Europe also possesses her Plane-tree (*Platanus orientalis*), but the fossil plane of Oeningen is not identical with this. It much more closely resembles the Western Plane or Button-wood (*P. occidentalis*) of America. The Miocene Vine of Oeningen is of an American type, and very closely allied to the Muscadine or Southern Fox Grape of Maryland and Kentucky. A Fan Palm (*Sabal major*) has been found in the Swiss Miocene. It belongs to a genus now known only in America, and found in the Southern States. The genus Taxodium, to which belongs the beautiful Bald Cypress (*T. distichum*) of the Southern cedar swamps, was once represented in Europe by a species so like the American that its remains can be with difficulty distinguished. The Tulip Tree (*Liriodendron tulipiferum*) is the queen of the forest in the Middle States. In Europe it has passed away, but its remains are entombed in the Swiss Miocene. Another of these tertiary fossils—an elm-like tree—was at first only distinguished from the American Planer Tree (*Planera aquatica*) by Professor Heer on account of the size of its fruit; but on seeing the specimens at Kew he admitted that no distinction could be drawn between them. The Giant Redwood (*Sequoia gigantea*) lingers in California, dependent upon the protection of man to save it from extinction. Though now replanted and flourishing in European shrubberies, it passed away from that continent, ages before the woodman's axe or the more murderous forest fire had begun to destroy. Of somewhat more recent date, but yet fossil, is the European Sweet Gum Tree (*Liquidambar Europœum*), a species closely allied to the Sweet Gum of the Eastern and Middle States of America (*L. styraciflum*), but the genus is now totally unknown in Europe. Again, the Black Walnut of America (*Juglans nigra*) lies buried in the Miocene beds at Oeningen, and Europe has imported the far superior walnut from Persia to supply its place. The writer has been informed that the late Professor Agassiz, on his arrival in this country, applied to a gentleman well known for his study of the American forest trees, and asked for a introduction to the Hickory family of America, remarking that all the members with which he was acquainted in Europe were fossil in the tertiary beds of his native land. Lastly, no fewer than eight species of Smilax, a genus scarcely known in Europe, but abundant in America, have been found in the Miocene of Switzerland.

We may here remark in passing that anyone desiring to see for himself the close resemblance between the European fossils and their living American representatives can do so by paying a visit to the Agassiz Museum at Cambridge where, in one of the upper galleries, may be seen a collection which has no equal or second on this side of the Atlantic.

It is just necessary here, in order to avoid leaving a flaw in the argument, to state that many of these species have been discovered in beds of equal or greater age in this country. It is therefore impossible to urge that they may have passed from Europe to America so lately that changes have not yet had time to develop themselves. On the contrary, some geologists are inclined to maintain that they existed in America before they appeared in Europe. At all events, we are warranted in asserting that during the Miocene age trees of the kinds named grew in Europe and America, as well as in Greenland and Spitzbergen and other points in the far north.

We do not propose here to investigate the causes of these changes. It is sufficient for our purpose to maintain the fact that during tertiary geological time the European flora has changed, and largely changed, while the American flora has remained stationary or nearly so. Plants which have changed in this interval thereby show an ability to change—a plasticity—which may be shown again should occasion arise. Plants which have not changed during the same interval show no proof of possessing the same plasticity. Moreover, if the principle is true that long existence without change strengthens the habits or increases the rigidity of the species, it is a necessary inference that the American flora, or so much of it as has existed during this long interval unchanged, must be less plastic than the present European flora which has during the same interval been so largely modified. So many ages of persistence in type cannot well be without effect. Little as we yet know of geological time, we cannot estimate the age of the Swiss fossil plants at less than 500,000 years, and it may well be twice as much. This would place the European flora just as far later or newer in age and in development than the American—would give it the advantage of so many years of slow change—and may be supposed in some degree to have maintained or developed that plasticity, to the possession of which we incline to attribute its ascendency over the native American flora. On the other hand, the native American flora, living unchanged through all these 500,000 years, may well have lost some of the plasticity it perhaps once possessed, and have become comparatively rigid, so that it is to that extent unable to adapt itself suddenly to the changed condition of Europe at present. It cannot therefore compete with the more plastic and more highly developed forms which it meets in the Eastern World; nor can it, in all cases, even hold its own against them on a soil and in a climate where it has dwelt for so many ages unmolested. The younger plant life of Europe, like the white man, is more than a match for the old fashioned life of this so-called New World of America, and the weaker fails in the struggle. Our country swarms with the weeds of Europe, while our own weeds shrink from the conflict both in Europe and at home.

Summing up the argument, in conclusion, we have pointed out:—

1. That many of the weeds of Europe have migrated to America.

2. That many of these have become so thoroughly naturalized here that they prevail over some of the plants native to the soil.

3. That only two or three American weeds hav crossed the Atlantic and become naturalized in England.

4. That the difference of climate and the conditions of mutual commerce do not fully account for this marked difference in the migrative power of the two floras.

5. That in the Miocene era the European and American floras were very much alike.

6. That since that era the European flora has been vastly altered, while the American flora still retains a Miocene aspect, and is therefore the older of the two.

7. That this long persistence of type in the American flora may have induced, by habit, a rigidity or indisposition to change in the American flora.

8. That the changes in the European flora since the Miocene age betray a plasticity of nature or power of adapting itself to circumstances of which the American flora gives no sign.

9. That in this view the European flora is better able to adapt itself to the strange climate and conditions—that is, to emigrate—than the American flora.

10. That being thus more plastic or adaptable it succeeds in the New World, while the less adaptable American flora fails in the Old World.

The writer wishes to add that in the above paper he has brought forward chiefly the instances of migration from England to America and *vice versâ*. A few other American plants might be found naturalized in other parts of Europe on closer examination, but the list, at best, would be exceedingly scanty.

PODOPHYLLUM.*

BY C. J. BIDDLE, PH.G.

Collections of the root were made in the months named below; it was washed, weighed and carefully dried.

March 3. 1000 grs. when dry weighed 220 grs. Loss, 780 grs.

April 3. 1000 grs. when dry weighed 233 grs. Loss, 767 grs.

May 7. 1000 grs. when dry weighed 245 grs. Loss, 755 grs.

July 16. 1000 grs. when dry weighed 340 grs. Loss 660 grs.

Oct. 12. 1000 grs. when dry weighed 317 grs. Loss, 683 grs.

It will be noticed by the above table that the weight of the dried root increases as the season advances until July is reached, when it is highest; it then begins to decrease, and in October it is much lighter.

A short description of the appearance of the plant at times of the different collections may not be out of place here. In March, when I made the first collection, it had not made its appearance above ground, but the bud was waiting for the heat of the spring sun. In April the plant was just coming above ground; in May it was in bloom; in July the fruit was mature, with the next year's portion of the rhizome near its full growth, and in October the stem of the plant had died away and the next year's rhizome, fully developed, including the rootlets and the bud, was seemingly waiting for spring to come.

The following table will show the yield of resin, etc. The root was treated as directed in U.S. Pharmacopœia for resina podophylli.

It will be noticed that the washings for March and April showed different and more marked results with reagents than those of the three months that follow. All were treated in the same manner and subjected to the same influences. I was unable to get a precipitate with Mayer's test with the mixed washings when they were dilute, so each washing was concentrated to about 6 fluid ounces, when a slight precipitate would show in the liquid near the top; in that of the three later months it could scarcely be seen.

	Yield of resin, in grs., from 1000 grs. of dried rhizome.	Colour of washings of resin.	Per cent. soluble in ether	Washings react with							
				Mayer's test.	Phosphomolybdic acid.	Ferric chloride.	Ferrous sulphate.	Chlorine water.	Argentic nitrate.	Alkalies	Lead acetate.
March	49·30	Reddish brown.	89	Precip.	Precip.	Dark green	No change	Slight coloration.	Heavy white precip.	Dark brown.	Yellow precip.
April .	52·40	"	84	"	"	"	"	"	"	"	"
May .	37·90	Light straw colour.	87	Very slight precip.	No precip.	"	"	Scarcely perceptible.	"	"	Scarcely any precip.
July .	28·30	"	90	"	"	"	"	"	"	"	"
Oct. .	32·40	"	78	"	"	"	"	"	"	"	"

The resins obtained show scarcely any difference in colour, all being light coloured with the exception of that from the April root, which is a little darker than the others, probably due to the chlorophyll of the young buds.

In evaporating the alcoholic tincture of the rhizome, when it had been reduced sufficient to pour in the acidulated water, every lot had small globules of oil floating on the surface.

The washings of March and April were dark coloured, and on evaporating deposited a precipitate; those of May, July and October were very light straw coloured, and also deposited a precipitate. This precipitate is probably a portion of the resin dissolved when it is washed, as I believe, with Professor Maisch, that a portion of the resin is soluble in water, and that which is dissolved is purgative.

I know of a case where a lady purchased five cents' worth of the rhizome, made a tea of it, and drank a portion (the exact amount is not known), and it had a decided cathartic effect, so much so that she returned to the store to ask if she had not been given the wrong article.

One thousand grains of the dried rhizome were boiled with three portions of water and expressed, and the resulting decoction was evaporated to the consistence of an extract, which weighed 540 grains, over 50 per cent. soluble in water. The portion remaining after making the decoctions was exhausted with alcohol and treated for resin; but the yield was scarcely perceptible, not more than two or three grains.

* From a paper read at the Pharmaceutical Meeting of the Philadelphia College of Pharmacy, October 21.

PHOSPHORIC ACID.*

BY W. F. HORN.

The acknowledged value of the compounds of phosphorus as remedial and nutritive agents has of late years rendered them particularly interesting to physicians

* From the 'Proceedings of the Pennsylvania Pharmaceutical Association, 1878—9.'

and pharmacists. The numerous papers that have been written, and the discussions which have occurred, abundantly testify to the fact.

Among these compounds, phosphoric acid has received no small share of attention—the modes of manufacture in particular—and the subject has not yet lost its interest. The object of this paper is to bring to your notice a new process, which in the experience of the writer has proved especially satisfactory, and to propound a theory which, in his judgment, best explains the facts. The process is as follows:—Pour 3 fluid ounces of water into a pint or larger flask, beaker glass, or evaporating dish. Put into it 6 drachms of phosphorus (deprived of its coating), observing that it lies in such a position as to be covered by the water. Drop into it 2 grains of iodine, and move the flask gently so that the iodine and phosphorus may come into contact, and lastly, add all at once, 4 troy ounces of nitric acid, U.S.P.

The action begins at once, and the vessel is set aside, the mouth being left open; and no further attention is required until the oxidation is completed, which requires from twenty-four to thirty-six hours.

Under ordinary conditions of temperature and pressure, the rapidity of the oxidation depends upon the amount of iodine used, and should the necessity arise, the process can be proportionately shortened by taking four, six, or more grains, but in that case the vessel must be set in water at the temperature at which it runs from the hydrant. On the other hand, if there is no urgency, one grain, or a fraction of a grain, will accomplish the same purpose in a longer time. After the oxidation is completed, the product is evaporated and finished, as the Pharmacopœia directs.

The advantages of this process are economy of time, attention and material, and absolute safety from explosions. The process may be continued indefinitely, and indefinitely large quantities of phosphorus may be oxidized to phosphoric acid by the addition of new portions of phosphorus and nitric acid as fast as they are consumed, no further addition of iodine being necessary. A much less quantity of nitric acid will accomplish the work, under favourable conditions, owing to the peculiar property which nitric oxide possesses of absorbing oxygen spontaneously from the air, thereby being converted into hyponitric acid, in which condition it is ready to act again on the phosphorus, somewhat similarly to its action in the leaden chamber process for sulphuric acid.

So much for the facts; now for the theory. Brodie, in 1852 (*Chem. Soc. Journ.*, p. 289), discovered that "a small quantity of iodine can convert an almost indefinitely large quantity of phosphorus into the amorphous modification." He supposes the reactions to proceed as follows:—The first stage "is the formation of an iodide of phosphorus, probably the di-iodide, in which the phosphorus exists in the amorphous modification." "This compound is then decomposed with the separation of amorphous phosphorus and formation of a more volatile iodine product, which reacts upon the second portion of phosphorus, reproducing the first decomposable iodide, and so on continually." Again, amorphous phosphorus is acted on directly and rapidly at a comparatively low temperature by nitric acid.

The writer's theory then is, that as the iodine combines successively with the different portions of the phosphorus and liberates them in the amorphous condition at a high temperature, the nitric acid acts rapidly on this phosphorus in the nascent state and oxidizes it to phosphoric acid.

The writer has not failed to consider the experiments of Pettenkoffer, but the cases are dissimilar. Pettenkoffer produced hydriodic acid, by the action of iodine on phosphorus, and then by the double chemical decomposition of the phosphoric iodide with water. The products of the reaction were hydriodic acid, phosphoric acid and phosphorous acid. The first was distilled off, and the latter completely oxidized by the use of nitric acid, so that hydriodic acid and phosphoric acid were the ultimate products. But he used the iodine in saturating quantity, combining the whole of the phosphorus at once, and again the mutual decompositions and recompositions were effected in the absence of nitric acid. It is improbable that the phosphorus, in the presence of a powerful oxidizing agent like nitric acid, would draw on the water for its oxygen: more so, in view of the fact that hydriodic acid is so very unstable, especially in contact with nitric acid. It matters very little, however, on what theory the facts may be explained, in view of the practical results obtained.

ROSE-FARMING AS A COLONIAL INDUSTRY.*

Rose-growing for perfumery is a branch of industry which appears to deserve the attention of some of our colonial friends in localities where the agricultural conditions are favourable and labour cheap. The pursuit would be an attractive one, and tried on a suitable scale, large enough to pay, but not so large as to disturb the market, it might, we consider, be made a very remunerative affair. The pure "attar" or "otto" of roses—never very abundant at the best of times—has risen enormously in price since the despoliation of the Turkish and Bulgarian rose-farms during the war of 1877–78; indeed, we are informed, it is now rarely to be found in the European market, and for this article, even more than the rose-water, a ready sale could doubtless be commanded.

A short account of the methods of growing and manufacturing attar and rose-water followed in Bulgaria and in India may supply some useful hints and suggestions to those disposed to give the subject consideration.

Colonel Baker—not Valentine Baker, by the way—in his recent work on Turkey, gives the following account of the method pursued at Kezanlik, a small district south of the Balkans and about 1500 feet above the sea level, which is or was the centre of the industry:—

"The flowers have the appearance of our common dog-rose, and are of the varieties *R. damascena*, *R. sempervirens*, and *R. moschata*. The last affords the chief ingredient of the attar. The natives know very little of varieties, and are concerned only with the profits they can make out of the oil. The rose is grown by the farmers in every village in the district, and requires a sandy soil on sloping ground exposed to the rays of the sun. The greatest care is bestowed on the cultivation and on the harvesting of the crop. A rose-garden may be laid down in spring or autumn, in ground that has been well cleared and ploughed. The young rose-shoots are torn off larger plants, so as to carry with them a portion of the roots, and these are laid, almost horizontally, in trenches about 1 foot deep and 5 feet apart, so as to form a future hedge; they are then covered with earth and manure and carefully trodden down. Under favourable circumstances the shoots will appear at the end of six months, when they should be earthed up, and the plants will be over a foot high by the end of the year. In the second year they yield a few flowers; but they are not a source of profit till the third year. They are in full bearing in five years, at a height of about 6 feet, and last for about fifteen years, when the trees cease to flower. They require earthing-up four times a year, and should be manured every second year; but, although the manure increases the quantity, it interferes with the quality of the attar. No pruning is required except cutting off dead branches. Very severe cold kills the trees, and those of the whole district were thus destroyed in 1870. Hoar-frost and foggy misty weather are also injurious to the crop, and hot weather during distillation interferes with the yield of oil. The harvest begins in May, and lasts about twenty days. The farmer counts the buds upon his trees, which he makes a

* From *The Colonies and India*, November 15, 1879.

divisor for the whole, and so counts the number of buds which will blossom daily, and the number of days his harvest will last. The flowers must be gathered before the morning dew is off them, and be distilled at once. Herein lies the difficulty, because it is impossible to judge, even approximately, of the rapidity with which the buds will open; consequently, unless a very large staff is kept, so as to pick off all the blossoms of a heavy crop in the short space available, and unless a number of alembics are ready to distil them, a great part of the crop may be wasted in the case of rapid blowing. When the temperature during harvest is cold and damp, the blowing is gradual; when hot and sunny it is rapid.

"The yield of attar varies, but, on an average, it takes 4000 rose-blossoms to make 1 lb. of oil. Best quality attar varies in price from 17 to 18 Turkish piastres the miscal, or 15*s.* 4*d.* to 16*s.* 10*d.* the ounce; inferior qualities, 14 to 15 piastres the miscal. The mode adopted for testing the purity of different qualities of oil is to put the essence into flasks, which are immersed in water of 63 to 68 degrees Fahr., when, if good, it congeals. This is considered the purest oil. A stony, sandy ground, impregnated with iron, produces the best oil, while a hard, badly cultivated land will only yield an inferior quality, which will not congeal at temperatures above 52 degrees Fahr. . . . . An English acre produces 4000 lbs. to 6,000 lbs. of blossom in fair years, and 34½ lbs. of blossom produce 1½ drachms of oil, which may be said to be worth in this market 4*s.*"

The roses, it may be added, are put in the stills without detaching the calices, the charge being 25 lbs. to 50 lbs. of roses per still. The above description was written previous to the war, it should be said. The last really good year in Bulgaria, 1873, produced a rose-crop valued at 70,000*l.*

At the recent Agricultural Exhibition at Kilburn, Messrs. Piesse and Lubin exhibited a vase of attar distilled by MM. Pappazouglou Brothers, of Constantinople, from roses grown in the Kezanlik district, the price of which was marked 35*s.* per oz.

Turning next to India, we find roses grown for attar and rose-water at Lahore, Umritzur, and elsewhere, but the chief site of the industry is Ghazepore, on the Ganges, where about 150 English acres in the suburbs are grown with *Rosea damascena* for that purpose.

According to information quoted by Dr. W. W. Hunter, in his 'Statistics of Bengal,' the ground is divided into small fields carefully protected on all sides by high mud walls and prickly pear fences to keep out the cattle. These fields, which belong to the zemindar, are planted with rose-trees and let by the year, at so much per *biggah* for the ground, and so much extra for the trees on it. The rent is generally 5 rupees per *biggah* for the ground, and 25 rupees extra for the rose-trees, of which there are 1000 on each *biggah.* If the season be good, these 1000 trees should yield 1 lac of roses, the value of which will vary with the year from 40 to 70 rupees, *i.e.*, 4*l.* to 7*l.* The purchases are always made at so much per lac. The rose-trees come into flower in March and continue so throughout April. The flowers are plucked in the early morning by men, women and children, and are conveyed in bags to the contracting parties for distillation into rose-water. The growers themselves rarely distill. The stills are of the most primitive make. There is a great variety of rose-water manufactured in the bazaar, and much that bears the name is nothing more than a mixture of sandal-oil. The best rose-water procurable may be computed as requiring 1000 roses to a seer of water, which yields 1½ seer of rose-water. The boiler of the still holds from 8000 to 12,000 or 16,000 rose-blooms. On each 8000 roses 10 to 11 seers of water are placed, and 8 seers of rose-water distilled. This is placed in a glass carboy, and exposed to the sun for a few days to become *pucka*, or ripe; it is then stopped with cotton and luted with wet clay to prevent the scent escaping. The 8 seers of rose-water will fetch 12 to 16 rupees. The value of the roses sold at Ghazepore is estimated at 15,000 to 20,000 rupees per annum, and the profit thereon, at the prices asked and given, 40,000 rupees (£4000).

To procure the attar or otto the roses are put into the still and the water passed over gradually, as in the rose-water process; after the whole has come over, the rose-water is placed in a large metal basin, which is covered with wetted muslin to prevent insects or dust getting in. The basin is then let into the ground about two feet, the ground having previously been watered, and allowed to remain quiet all night. This is always done at the beginning of the season, when the nights are cool; in the morning the little film of attar or oil which has collected on the surface during the night is removed with a feather and placed in a small phial, and day by day, after the collection has been made, it is placed for a short period in the sun, and after a sufficient quantity has been procured, is poured off clear into fresh phials.

From one lac of roses it is estimated that 180 grains or one *tolah* of attar can be obtained, or more if the roses are full-sized and the nights at the same time cool enough to admit of perfect congelation. The attar sells in India at 50 to 90 rupees the *tolah.* None has hitherto been exported.

In both cases it will be seen the processes of culture and manufacture are of the most primitive kind. In skilled hands they might, no doubt, be materially improved at comparatively small cost, and the profits, already considerable, increased proportionately.

LIQUID EXTRACT OF ERGOT FOR SUBCUTANEOUS INJECTION.*

BY P. YVON.

Subcutaneous injections of ergotine are very difficult to make with the aqueous extract of ergot generally known as ergotine. In fact this extract when dissolved is muddy, thick and requires to be filtered; the solution then gives only feeble results, as the best part of the extract remains upon the filter. I therefore prefer the following formula:—

The ergot is coarsely powdered and deprived of its fixed oil by treatment with carbon bisulphide; afterwards it is dried in the open air, sheltered from light, until the odour of the solvent has totally disappeared. The powder is then introduced into a displacement apparatus and exhausted in the cold with distilled water containing four parts in a thousand of tartaric acid. This liquid is heated so as to coagulate albuminoid matters and then reduced in a water-bath to about one-third of its volume, allowed to cool and filtered. It is then treated with a slight excess of freshly prepared carbonate of lime, so as to saturate the excess of tartaric acid, filtered, evaporated to a syrupy consistence and precipitated with 90° alcohol. After another filtration it is decolourized with washed animal charcoal, again filtered and evaporated so as to drive off all the alcohol. It is then taken up a second time with distilled water and to this solution is added 0·15 gram of salicylic acid for each 100 grams of ergot, and it is completed with water or cherry-laurel water so as to make a liquid equal in weight to that of the ergot employed. The extract is allowed to deposit some days in a cool quiet place and then divided into small bottles.

The liquid thus obtained is of a fine amber colour and keeps perfectly. It gives an abundant precipitate with all the reagents for alkaloids and represents the active principle of an equal weight of ergot. As an injection one gram of the liquid gives excellent results.

---

* *Revue Médicale* for November 15.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 13, 1879.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

PATENT MEDICINES.

THE great and growing increase in the demand for secret nostrums is a circumstance that must almost necessarily be highly prejudicial to the legitimate practice of medicine, no less than to that of pharmacy. Though there seems to be little prospect of preventing the public from being influenced by stories of wonderful cures and thus led to seek relief by the use of some of the secret preparations that are now so persistently recommended to them by advertisement rather than have recourse to the advice of a legally qualified medical practitioner, it does seem feasible that the trade in secret preparations or patent medicines might be subjected to some kind of regulation. We cannot pretend to have any opinion as to the merits of these preparations, since the secrecy thrown over their nature and composition renders that impossible except by the aid of analysis, which would at best only give uncertain results. We cannot, therefore, say that in some cases these preparations may not be possessed of all the virtues that are claimed for them, and it would not be a matter of much importance if we could do so, since it is to faith or credulity, and not to reason or common sense, that the recommendation of these secret preparations is addressed.

But without raising any question as to the intrinsic merits of secret preparations, or as to the propriety of recommending them for the relief of disease, the way in which the trade in these articles has lately been developed is a matter that it is impossible for the recognized vendors of medicine to disregard. The effect of the trade in these preparations is no longer merely one which limits the practice of pharmacy as well as medicine, but it is of such a nature as to tend towards entirely superseding the pharmacist, as well as the physician. There is no longer the fatal attraction of a good trade profit to induce the chemist and druggist to engage in the sale of patent medicines, and to contribute as far as he can to the promotion of a system that would eventually make him a superfluity, for under the conditions that now prevail the trade in patent medicines is carried on so as to do away with the possibility of the former profit to the chemist and druggist and put him out of the field altogether.

Under these circumstances it is natural to find correspondents in this Journal inveighing against the competition set up amongst them by the sale of patent medicines and similar articles at rates consistent only with such business as is carried on by the grocer or oilman. No pharmaceutical skill is required in selling a patent medicine; no experienced knowledge of the materia medica is necessary, nor any acquaintance with the characters and doses of potent drugs; a grocer's apprentice can hand over the package and take the price of it as well as the most scientifically trained pharmacist. Consequently, it is not at all unfrequent that chemists and druggists find themselves suddenly cut off from what was formerly no inconsiderable portion of their business and see this transferred to establishments with which they are wholly unable to compete.

How this state of things is to be remedied in the interest of chemists and druggists is a question to which many of our correspondents have addressed themselves, but notwithstanding the various suggestions that have been offered we appear to be as far as ever from combating the evil. Some have advised the entire abandonment of the patent medicine trade, others have recommended carrying on the trade so as to compete with the co-operative stores and other dealers who sell them at reduced rates; but we do not think that either course would be productive of much benefit to the chemist and druggist regarded simply as a trader. The former plan would have the advantage of being sound in principle from a pharmaceutical point of view; but there is reason to question its expediency, since patent medicines have so much popularity with the public, and they are so much in demand, that a refusal to sell them might be productive of damage to the pharmacist's more legitimate business. This has actually been found the case in some parts of Germany where there are numerous English residents, and although it is in that country generally considered to be unpharmaceutical to deal in secret remedies, the necessity of meeting the demand for them on the part of customers has been found imperative, or as an alternative result, business has been lost.

The plan of meeting the competition in patent medicines by selling them at what are termed "store" rates is one that may be said at first sight to be compatible only with a low class of business, and it would not in any case be a remedy conducive to the general interests of pharmacy. A recent correspondent has suggested the adoption of this course in a somewhat heroic fashion which, he thinks, would be quite effectual. He proposes that the chemists and druggists of a particular locality should unite and form a Patent Medicine Defence Association, each member subscribing a small sum annually, so that whenever patent medicines are sold by anyone in the neighbourhood for less than the advertized prices a shop should be opened by the association where patent medicines should be given away or sold at a mere nominal price until the competition was suppressed. Our correspondent is of the opinion that in a brief period this procedure would suffice to bring the short-sighted under-sellers to their senses, and impress upon them that business cannot be carried on without a fair remuneration. We confess that we do not share this opinion, and are far from being so sanguine as our correspondent as to the probable consequences of the plan he suggests.

Another correspondent suggests that the best way of stopping or, at any rate, curtailing the sale of patent medicines by others than registered chemists and druggists would be to increase the payment for the licence to deal in patent medicines to as much as twenty or thirty pounds a-year. Doubtless, such a step would put a stop to the sale of patent medicines by many small shopkeepers, and if it could be carried out, some good might be done in the interest of chemists and druggists. We have always thought that the reduction of the charge for the selling licence was a great mistake in this respect. Now that the licence can be obtained for the trifling sum of 5*s*., it is within the power of a large number of small dealers to qualify legally for the sale of patent medicines, and thus to take away from chemists and druggists a considerable share of the trade that ought to be restricted to them.

But if an attempt were made to increase the charge for licences there is reason to expect objection would be offered by the proprietors of patent medicines and the wholesale dealers in them. From their point of view the small shopkeepers and the "stores" serve as well, for the retail sale of their articles, as the educated pharmacist, and it might be difficult to convince them that they would not be prejudiced to some extent by transferring the trade from a large number of grocers, drapers, booksellers and general stores to the hands of a much less numerous class of tradesmen.

As regards those preparations which contain poisons or drugs of dangerous potency, another consideration, viz., that of public safely, is involved. In regard to patent medicines of this class at least there is a more reasonable prospect of restricting the trade to registered chemists and druggists by means of the provisions of the Pharmacy Act.

WEIGHTS AND MEASURES.

As it may be useful to some members of the trade to know what is being done in regard to the inspection and verification of apothecaries' weights and measures, we take this opportunity of stating that we have received a letter from Mr. T. Fell Abraham, of Liverpool, in which he informs us that, as Local Secretary for that town, he has called upon the inspector of weights and measures, as suggested in the Journal of 29th ult. Mr. Abraham finds that this inspector has been supplied with local standards for 1, 2, and 4 fluid ounces, and for 1, 2, and 4 fluid drachms, also with a 30 minim graduated tube of the kind represented at page 430. None of the other appliances there described have, as yet, been received by the Liverpool inspector, nor has he received any instructions from the corporation to put the provisions of the new Act into force. We shall be glad to learn from the Local Secretaries in other places what progress is being made.

PROPRIETARY ARTICLES AND THE PATENT MEDICINE STAMP ACT.

It appears from the letters of some correspondents that in Sheffield a somewhat unexpected activity has been manifested by the Excise authorities in regard to certain articles sold by chemists and druggists with labels that are held to render the use of patent medicine stamps necessary. Upwards of forty chemists, we are informed, have been fined in sums varying from five shillings to five pounds. In one or two instances the Excise officers have bought a gross of "penny pills" and the sellers have received notice from the Somerset House authorities that they are liable to a penalty of ten pounds for each box sold. The action thus taken is most probably due to the use of labels in which the pills or other preparations are described as being prepared solely by the seller, and as being useful as remedies for certain forms of bodily ailment. We are informed that many of the condemned labels had been in use for a number of years and were considered to be quite safe.

Unfortunately, we have not been able to obtain any particulars of these cases, and cannot, therefore, do more than speak of them in general terms, but this reference to the subject will suffice to point out the desirability of inquiring whether the labels used for such articles may not be of a nature to involve the stamp or liability to a penalty for infringement of the Act. In some instances it is difficult to decide this question, and it is always best to send the labels to Somerset House, and ask whether they require a stamp or not.

HONOURS TO PHARMACISTS.

Another addition to the number of pharmacists who hold the position of magistrates has lately been made by the appointment of Captain J. G. F. Richardson, of Leicester, now a Member of the Council of the Pharmaceutical Society, as one of the magistrates of that borough.

The election of Mr. C. J. Blelock, Chemist and Druggist, as Mayor of Chester, also, has been the occasion of a very graceful compliment from his *confrères* in the city, an address congratulating him upon his attainment to the dignity, signed by twenty-five members of the trade, having been presented to him by Mr. T. Shepheard, on behalf of the chemists and druggists of Chester.

Provincial Transactions.

LEICESTER CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Tuesday evening, Nov. 18th, a lecture was delivered by Mr. J. Young, on "The Ethylic Alcohols of the B.P." Mr. Thirlby in the chair.

The lecturer commenced by referring to the etymology of the word alcohol, and proceeded to define an alcohol as "a compound of a hydrocarbon radical with hydroxyl." Some time was spent in discussing the chemistry of the alcohols in general, and coming more particularly to the consideration of ethylic alcohol, the lecturer treated of its derivation, the process employed in its manufacture and rectification. The researches of Fownes, by which he obtained an absolute alcohol of the specific gravity 0·79380 and their bearing on the absolute alcohol of the B.P. specific gravity 0·795, were noticed, and also the loose way in which, until lately, alcohol was defined to be proof, or over, or under proof. The lecturer showed by experiment that alcohol considerably stronger than proof spirit does not ignite gunpowder when inflamed. Proof spirit was defined to be "an alcohol containing 49·24 per cent. of absolute alcohol." Some interesting experiments on the contraction of mixtures of alcohol and water, were also performed.

A vote of thanks to the lecturer was proposed by Mr. Thirlby, seconded by Mr. Edwards, and carried unanimously.

DOVER CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held on Friday, November 7.

Mr. Cotterell and Mr. Wilford were re-appointed to the respective offices of President and Secretary for the ensuing year.

After the transaction of business, the members adjourned to the supper table and a pleasant evening was passed.

In replying to the toast "Success to the Dover Chemists' Association," the President expressed his gratification at the continued success and usefulness of the Association, which had now entered upon its fourth year, and hoped that in the future these would be increased.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual meeting was held in the Great Western Hotel, on Tuesday, the President, Mr. W. Southall, F.L.S., in the chair. In spite of the unfavourable weather there was a very fair attendance.

The annual report, which was read, spoke with satisfaction of the financial condition of the Association, there being a balance of £57 6*s.* 5*d.* remaining in the Treasurer's hands after payment of all expenses. After referring to the settlement of the action of the Apothecaries' Company *v.* Shepperley, and the death of Mr. Alfred Bird, for many years a valued member and supporter of the Association, the report stated that during the past winter a series of highly interesting and instructing lectures had been delivered, at which the attendance had been very encouraging. The annual *soirée* also, which had been held in the Town Hall, had proved very successful. With regard to the grant which was voted at the last annual meeting to the Chemists and Druggists' Trade Association of Great Britain, the committee said that the hope then expressed had been fully realized, and that many other local Associations had followed the example of the Midland Counties Chemists' Association in voting a grant of money to the above society. The librarian had reported an increased circulation of books, especially among assistants and students, and it is hoped that the new catalogue which is about to be issued will cause a further increase of circulation. Some time ago, on the application of the secretary, the Pharmaceutical Society presented to the Association a parcel of materia medica and dried botanical specimens, and the committee expressed a hope that this example may be followed by pharmacists, and the nucleus of a valuable museum of materia medica may be thus formed. The educational work has proceeded satisfactorily during the past year, but no student has claimed the grant of money in part payment of lecture fees. Finally it was reported that the prices at which patent medicines are sold have had the serious consideration of the committee, but notwithstanding much deliberation it was not yet prepared to recommend any distinct course of action.

The Chairman, in a speech of some length, commented on the report and eventually moved the adoption of it. This was carried.

The Treasurer, Mr. Lucas, proposed that £5 be voted for the purpose of affording temporary relief to any well authenticated case of distress among chemists, and this was agreed to, the treasurer to administer the fund. A sum of money was next voted for the purchase of a bookcase for the library, and £5 was voted for the purchase of new books, the secretary being instructed to draw up a new catalogue of the library and send a copy to each member and asssociate.

On the motion of the Chairman, Mr. J. Green was elected President; Messrs. Holdsworth and Wilcox Vice-Presidents; Messrs. Gibson and Morris Auditors, and Mr. Lucas Treasurer. The following gentlemen form the committee for the year:—Messrs. Arblaster, Bellamy, Barclay, R. Brown, A. Bird, Gibson, Stirling, Grieves, Haydon, Jones, Morris, Partridge, W. Southall, A. Southall, Wilcox, jun.

The committee appointed the following sub-committee to carry out the *soirée* arrangements:—Messrs. Price, Careless, Howes, Bellamy, Arblaster, Thouger, Walker, Haydon, Mantell, Bate, Morris, Grieves, Gould, A. Bird, Barclay, Brown, McCredie, Partridge, Gibson, W. Southall, A. Southall.

A lengthened discussion took place upon the subject of the prices of patent medicines, but no resolution was proposed. There was no other business of importance.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The second meeting of the session was held in Anderson's College, 204, George Street, on Wednesday, December 3, at 9 p.m. Mr. Alexander Kinninmont, F.C.S., President, in the chair.

After the minutes of the previous meeting had been read and adopted, the President called upon Dr. J. S. Whittaker to give a lecture on the "Chemistry of Digestion."

Dr. Whittaker commenced his lecture by a general survey of the various parts of the alimentary canal directly employed in the process of digestion, and with the aid of a large diagram he showed the way in which food introduced into the mouth, after being torn by the teeth and mixed with the saliva, was carried into the stomach to be acted upon by the gastric juice, etc. As the food of mankind consists of various elements, starch, albuminoids and fats, the various juices of the alimentary canal act differently on them; thus the saliva converts starch into glucose but does not act on albuminoids; pepsin of the gastric juice acts on albuminoids but not on starch or fat. Dr. Whittaker, after describing the digestion of food in the stomach, as carried on by the pepsin of the gastric juice in presence of hydrochloric acid, passed on to notice the functions of the liver and pancreas. Although it is known that the bile from the liver aids digestion in the large intestines, yet its real function is not known, and it cannot be said with certainty what is the true part played by the bilious secretion in the human body. After stating the large amount of bile secreted, Dr. Whittaker directed attention to the pancreas, an organ that has occupied the attention of physiologists somewhat largely of late as to its true function in the economy of digestion. From late observations it has been shown that the secretion of the pancreas acts on the various classes of food, viz., starch, albuminoids, and fats; it acts like the saliva and gastric juice together. One of the active principles of the pancreas is called tripsine; it acts on albuminoids. The action of the pancreatic juice in the duodenum was then described by Dr. Whittaker, and its power in changing starch into glucose, dissolving albuminoids, and emulsifying fats and causing them to be absorbed into the system. All the foregoing results could be obtained artificially by using the various medicinal preparations, *e.g.*, pepsine for albuminoids, malt extract for starch, and pancreatic juice either for starch, albuminoids or fats. But the lecturer remarked that the medicinal value of these articles depended greatly on careful preparation, for that from overheating in preparation the majority of commercial specimens of malt extract are inert ; in preparing therefore the fluid from the pancreas artificially great care must be taken not to destroy its activity by too much heat. In continuation the lecturer said that the aqueous extract of the pancreas of the cow or hog contained tripsine, etc., it was therefore useful in some cases of deranged digestion. The extract is best given, if to aid intestinal digestion and the absorption of fats, about two hours after food along with 15 grains of bicarbonate of soda dissolved in water, the soda being to prevent its action being impaired by the gastric juice in passing through the stomach. Dr. Whittaker concluded his lecture by stating that food, artificially digested by the aid of ferments, diastase, pepsine and pancreatine, develops a nauseous disagreeable taste; hence in order to digest milk, wheaten gruel, etc., artificially by the aid of aqueous pancreatic extract and keep it palatable, the process must be arrested before it is completed by raising the temperature to the boiling point.

The Secretary, Mr. John C. Hunter, showed a specimen of the aqueous extract of the pancreas made by Dr. Whittaker's directions, also a specimen of pancreatized cod liver oil prepared with pancreatic liquor made according to Mattison's process, *vide* 'Year-Book of Pharmacy, 1874.' He found that the cod liver oil emulsified very well with the fluid, and it required no gum tragacanth.

After a few remarks from the President, Dr. Whittaker was awarded a very hearty vote of thanks for his instructive and interesting lecture. The meeting then separated.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The third meeting of the second session of the above Association was held in the rooms of the Pharmaceutical Society (North British Branch), 19A, George Street, on Thursday, December 4. The President, Mr. D. McLaren, occupied the chair.

The minutes of the preceding meeting having been read and confirmed, the Secretary, Mr. J. H. Fisher, read a paper on "Superstition."

In introducing the subject, he remarked that to a large extent superstition had been, and still was, mixed up with the trade of a pharmacist, and pointed out that its agency was very often the cause of remarkable cures. The very fact that the public gazed with awe and wonder on the mysterious operations, quaint symbols and unintelligible writings of the dealer in drugs, was largely taken advantage of, and innumerable preparations bearing the name of medicine—some of them utterly worthless and often pernicious—were palmed off upon the unsuspecting and credulous. Passing from pharmacy proper, the essayist gave a short sketch of witchcraft, and the means employed by its devotees to obtain their desired ends, and showed that their success rested wholly on the superstition of the common herd. The struggles of the alchemists to obtain the "elixir vitæ" and the "philosopher's stone" were noted, as well as the complex calculations of the astrologers in order that they might open up a future closed to all mortal eyes save their own. Mr. Fisher then referred to the mythologies of several countries, and noticed in conclusion the spiritualism of the present day, remarking that superstition could not be said to have disappeared, so long as Dr. Slade and his no less popular transatlantic compatriots could so easily batten on the purses of our gullible countrymen.

The paper was criticized at some length by Mr. Mahen, who concluded by moving a hearty vote of thanks to Mr Fisher, which was seconded by the President, and carried by acclamation.

The President intimated that the committee had fixed upon "Rhubarb" as the subject of the essay for apprentices' prize, and having read over the regulations to be observed by intending competitors, he invited all apprentices who were members of the Association to become competitors.

The President then gave a detailed account of the steps he had taken in the subject of shorter hours, and intimated that for the present the committee had no hope of attaining the object in view. After considerable discussion, it was resolved to discontinue the committee, and defer all further consideration of the subject until the annual meeting in April.

The next meeting would take place early in January, when there will be a debate on the admission of women as members of the Pharmaceutical Society.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on December 4, Mr. Warren De La Rue, President, in the chair.

The following certificates were read for the first time:— J. C. Evans, W. H. Glazier, K. W. Hedges, R. Howell, J. Hogarth, J. McCarthy, A. K. Miller, W. O. Prosser. An election of Fellows was to have been held, but as less than forty Fellows were present, the ballot could not be taken. The President expressed a hope that all members would endeavour to be present at the next meeting (December 18), when, if possible, the ballot would take place.

The following papers were read:—

The Comparative Value of different Methods of Fractional Distillation. By F. D. Brown.—When fractional distillation is carried out on a large scale, either or both of two well defined processes can be used. In the first, "washing," the mixed vapours are passed through several layers of liquid obtained by their own partial condensation; in the second, "cooling," the mixed vapours are partially condensed by allowing radiation to take place or by passing them through a coil kept at a given temperature. In both processes the liquids of highest boiling point are kept back and a better distillate is accordingly obtained. A possible explanation of the success of the first process is that by obstructing the passage of the vapour, the successive layers of liquid give it more time to cool; from this point of view the two processes are identical. In the present paper the author has endeavoured to determine whether there is any essential difference between "washing" and "cooling" or not. The mixture employed throughout the experiments was the one used by the author in his previous research and consisted of carbon disulphide and benzene. The dephlegmator advocated by Linnemann, Bel and Henninger, etc., was first compared with a glass tube, 600 mm. long, inclining gently upwards, exposed freely to the cooling influence of the atmosphere, etc. As a result of several experiments it was found that the distillation with the long cooling tube yielded slightly better results than that in which the vapour was washed by passing through the dephlegmator, and that both the dephlegmator and the cooling tube produced better distillates than the retort or the flask with T piece usually employed. These results were to some extent, however, vitiated by the fact that the distillations were not carried out in equal times, and in order to render the results more strictly comparable, the author constructed a long glass tube and fitted it up with a movable series of disks of wire gauze (each disk containing a short brass tube, trapped at the bottom to prevent the vapour passing up the tube instead of through the layer of liquid condensed on the wire gauze), so that this tube could be used either as a simple cooling tube or by inserting the disks could be converted into a dephlegmator. Great care was taken to make the times of the distillation as equal as possible. As a result of these experiments the author concludes that "washing" and "cooling" are not identical processes and that the dephlegmator has a special value and gives better results, other things being equal, than the simple cooling tube. The author then contrived a more exact and delicate process of cooling by means of which the still-head could be kept at the lowest possible temperature compatible with the passage of vapour into the condenser. This was effected by passing the worm of the still through a strong copper box which is partly filled with a liquid boiling about the temperature desired; the vapour from this boiling liquid is condensed in a worm which returns the liquid to the box, the box, worm, etc., being air-tight and constructed of stout copper. The final adjustment of temperature was obtained by connecting this air-tight system with a pump, so that the pressure under which the liquid boiled in the box could be varied at will; by this means the vapour round the still-head could be kept at a constant temperature for an indefinite period, or could be varied without much trouble by alteration of the pressure. By using this apparatus and charging the box with carbon disulphide and the still with a mixture containing 42·69 per cent. of CS_2, a distillate was obtained containing in two experiments 97 to 99 per cent. of CS_2. The author also tested the apparatus by distilling commercial benzene and separating almost pure benzene. Thus, 1100 c.c. of a very impure sample gave (the still-head being kept at 81°) at 80°·4, 155 c.c.; at 80°·8, 176 c.c; 81°, 180 c.c.; 82°, 191 c.c.; after 500 c.c. had distilled over the experiment was stopped, a sample of the residue distilled as follows:—At 95°, 80 c.c.; at 100°, 130 c.c.; at 105°, 158 c.c.; at 110°, 186 c.c. The paper contains tables of the details of the experiments, curves showing the compositions of the distillates and drawings of the apparatus.

Dr. Armstrong said that as far as he knew no one had previously compared the values of these two processes of washing and cooling from a scientific point of view. He could confirm Mr. Brown's statements as to the importance of the rate of distillation and the extent of cooling surface; he did not think that fractional distillations of homologous bodies, the vapours of which seemed, so to speak, to hang together, were of much value, unless large quantities were employed.

Mr. Neison thought that a separation could be effected by fractionally distilling small quantities. He had used a very simple apparatus with good results; it consisted of a flask, the neck being closed with a cork, through which passed a tube ending inside the flask in a bulb with a drawn out and turned up beak.

The Chairman remarked that he had worked on the same principle as that carried out so completely by the author; but instead of surrounding the still-head with a vapour of constant temperature a thermometer was inserted in the still-head and the temperature carefully watched.

Mr. Brown did not think that any hanging together of vapours took place; in his opinion small quantities could be successfully manipulated by using an apparatus of small size.

The next paper was read by Mr. Muir—

On the Influence Exerted upon the Course of Certain Chemical Changes by Variations in the Amount of Water of Dilution. By M. M. P. Muir and C. Slater.—The authors have studied the influence of the addition of water on the reactions which ensue when solutions of (1) calcium chloride and sodium carbonate, (2) strontium chloride and sulphuric acid, (3) barium chloride and potassium oxalate are respectively mixed at various temperatures and for various times. The two solutions under experiment were mixed, allowed to stand for the required time and the precipitate formed estimated by filtering off or pipetting some of the clear supernatant liquid. In the first reaction, the amount of chemical change decreases regularly as the dilution increases; in the second and third various irregularities occur which the authors have investigated in detail. The paper is lengthy, and contains numerous and elaborate tables and curves, without which the results cannot be given intelligibly. The authors continue:—Every chemical system appears to tend towards that condition of equilibrium which is marked by the greatest loss of energy. This tendency may be arrested in various ways, *e.g.*, by impressing upon the system what may perhaps be described as an artificial state of equilibrium. Thus, the condition of most stable equilibrium for a system originally consisting of barium chloride and potassium oxalate would be that in which barium oxalate and potassium chloride are produced; but by adding much water a portion of the reacting molecules is, according to the hypothesis of the authors, loaded with water of hydration. In this loading energy is lost, but the loss is less than that which would occur were molecules of barium oxalate and potassium chloride formed; the system is therefore unstable, but a certain degree of stability is impressed upon it by the presence of a large mass of one of the products of the dissociation of the complex and unstable hydrated molecules. Thus a system in a state of strain is produced; a small force may be sufficient to relieve the strain and the relief may be attended with a rapid rearrangement of the parts of the system. Accordingly the authors found that small physical differences, such as the roughness or smoothness of a beaker, filtering instead of pipetting, etc., had a large influence in dilute solutions. The authors conclude with the hypothesis that the amount of chemical change which occurs when barium chloride and potassium oxalate are mixed in the proportion of 1 : 1 molecules is irregularly affected by the mass of water of dilution present, because the entire system is brought into a state of strain due to the stress between its parts, and that the principal forces of which this stress is compounded are the force tending to produce cryohydrates and other hydrated molecules, the force tending to split up these molecules and the force tending to separate, and so to impart greater mobility to the chemically active molecules of the system.

Mr. Muir then read a paper—

On the Influence of Temperature upon the Decomposition of Barium Chloride by Potassium Oxalate in Aqueous Solutions.—In concentrated solutions temperature has but little influence; with more dilute solutions, the first increase of about 20° causes a marked increase of action, after this the influence of temperature is more regular. With still more dilute solutions increase of temperature causes at first a slight increase, then a rapid increase of action until a point is reached, after which further increase of temperature but slightly affects the amount of chemical change; with very dilute solutions the influence of temperature again becomes nearly regular.

Mr. Neison showed by the aid of some mathematical formulæ that for the lower temperatures a larger period of time should be given, otherwise the results obtained would not be comparable with those obtained at the higher temperatures.

The next paper was read by Dr. F. R. Japp—

On α and β Phenanthrene Carbonic Acids.—The author has already described with Dr. Schultz (*B. Chem. Gesell.*

x., 1661) the alpha acid, he has since prepared it in a purer state and finds its melting point to be 266° instead of 260°. This acid was prepared from crystallized calcic phenanthrene sulphonate by converting the latter into the sodium salt, distributing the dry sodium salt with potassic ferrocyanide and saponifying the nitrite thus obtained. In the preparation of the calcic phenanthrene sulphonate much dark-coloured syrupy mother liquor was left. This mother liquor was subjected to the same processes which had yielded α phenanthrene carbonic acid from the crystallized salt, in the hope that the corresponding phenanthrene carbonic acid might be more easily purified than the syrupy sulphonate. 80 grams of crude acid were thus obtained from 2 kilos of commercial phenanthrene; after considerable difficulty the acid was purified by recrystallizing it as a sodium salt. By distillation with soda lime phenanthrene was obtained, being identified by its melting point, picric acid double compound, and the quinone obtained by oxidation. By oxidation with chromic anhydride in acetic acid phenanthrene quinone was formed. The author has tabulated a comparison of the salts of the α and β acids. The α acid crystallizes from hot glacial acetic acid in colourless curved blades, melting at 266°; the β acid crystallizes in stellate groups melting at 250°—252°. The α sodium salt crystallizes with 4 mols. of water in colourless pointed blades; the β salt with 5 mols. of water in rhomboidal laminæ. The α barium salt crystallizes with 7 mols. of water in long flexible needles, the β barium salt with 6 mols. of water in long brittle rectangular laminæ. In conclusion the author enters at some length into a theoretical consideration as to the constitutional formula of phenanthrene, which in his opinion consists of three benzene nuclei, one of which shares four adjacent carbon atoms with the two others, one ortho pair with each. Phenanthrene may thus be derived from naphthalene by a repetition of the process by which the latter hydrocarbon is derived from benzene.

After some remarks by Dr. Armstrong, to which Dr. Japp briefly replied, the Secretary read a paper—

On some Derivatives of Phenylacetic Acid. By P. PHILIPPS BEDSON.—This paper contains an account of the separation of para and ortho nitrophenylacetic acids, both of which are crystalline substances; the former melts at 150°—151°, the latter at 137°—138°. Also of para and ortho bromo derivatives which crystallize from water in white needles; the former melts at 114°—115°, the latter at 103°—104°. A dibromophenylacetic acid has also been prepared by the long-continued action of bromine on monobromophenylacetic acid in sunlight; it crystallizes in white needles, melting at 114°—115°. A more detailed account is given of the bromonitrophenylacetic acids and the corresponding bromamido acids, short notices of which have appeared in the *Ber. Deut. Chem. Gesell.*, x., 530 and 1065. A third isomeride has been obtained with these substances by nitrating crude bromophenylacetic acid. This β bromonitrophenylacetic acid crystallizes from glacial acetic acid in small transparent prismatic needles, melting at 162°, yielding by reduction β bromamidophenylacetic acid, melting at 186°.

The Society then adjourned to December 18, when the following papers will be read:—On the Specific Volume and Density of Water of Crystallization. By T. E. Thorpe. On the Analysis of Organic Bodies containing Nitrogen. By W. H. Perkin. A ballot for the election of Fellows will also be held.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of the above Association was held on Thursday evening, November 27, when the President, Professor Attfield occupied the chair. A paper on "Study" was read by Mr. E. M. Holmes, F.L.S. Mr. Holmes divided pharmaceutical students into two classes—those who wish to acquire just sufficient knowledge to enable them to pass the examinations and no more, and those who from love of knowlege desire to acquire all the information that they possibly can on matters scientific or otherwise connected with their business. The object that a student ought to have in view when studying at the School of Pharmacy is to obtain such information as cannot under ordinary circumstances be acquired in retail business, but which nevertheless is necessary for the safety of the public and for the proper carrying on of business. Business habits and a sound knowledge of the physical characters of the various galenical and other preparations should have been learnt during apprenticeship, but as long as apprentices are taken merely with a view to get work done cheaply and but little trouble is taken to impart information to them, or to inculcate business habits, so long will the evil recoil upon the masters in the form of incompetent assistants and ignorant members of the trade. If these facts were rightly understood the complaint which is sometimes querulously but most unreasonably made that men who have passed the examinations of the Society are less useful in business than those who have not, and that they are conceited with the knowledge which they have obtained, would never occur. The best reply to such a complaint is the undeniable fact that the most successful students are almost invariably employed in the leading houses of business in London, and that a large number of the best businesses in the country are in the possession of men who formerly took prizes in the School of Pharmacy. Mr. Holmes then gave his advice as to the best time for study, which he considered was the morning, and showed the important influences of rest, diet, and pure air upon the student. The different methods of memorizing by sight, place, sound etc., were then noticed, and the importance of close observation, and the taking of mental notes, as well as the maintenance of a concise and clearly-written note-book, in which the matter can be referred to with ease, were impressed upon the student. In reading books the student was warned against skipping difficult passages or delaying the comprehension of them until a future time, and was advised to thoroughly master the meaning of every sentence at the time of reading. The advantages of recreation by means of physical exercise was noticed and recommended to the student. Mr. Holmes urged all to strive to obtain prizes, arguing that although it was possible only for a few to get them yet the competition served as a stimulus for strenuous study. He considered that those who endeavour to shorten their course of study at the expense of efficiency, are guilty of an attempt not merely to deceive the examiners, but to falsely represent to the public the amount of knowledge they possess. The passing of an examination ought to be an honest guarantee to the public that the examinee possesses the knowledge which the government of the country stipulates he shall have acquired.

After the reading of this paper a lengthy discussion took place, and a hearty vote of thanks was accorded to Mr. Holmes.

The Secretary then announced that at a meeting of the Executive Committee, held on November 21, the following gentlemen were appointed reporters on science for the ensuing session:—

Pharmacy ....H. R. Arnold.
Botany......................F. W. Branson.
Materia Medica ....R. H. Parker.
Physical Chemistry......A. Senier, M.D., F.I.C., F.C.S
Inorganic Chemistry.....C. H. Hutchinson, F.C.S.
Organic Chemistry ......W. R. Dunstan.
Analytical Chemistry....A. F. Dimmock.

The meeting then adjourned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting was held at 32A George Street, Hanover Square, on Wednesday evening, November 26, Mr. F. W. Branson in the chair, when a paper was read by Mr. A. P. Luff on "Water Analysis." The paper commenced with a description of the substances liable to be present in potable water, the sources of those substances, and the influence that their presence or absence would exercise in deciding as to the quality of a "water." A *résumé* and criticism of the various processes employed in water analysis then followed, the subject being illustrated by several experiments and an exhibition of some of the apparatus used.

A discussion followed in which Messrs. Branson, Nayson, Parker and Wallis took part.

A vote of thanks was proposed by Mr. Wallis, seconded by Mr. Parker, and carried unanimously, by a very large meeting, who evidently fully appreciated Mr Luff's interesting paper.

Parliamentary and Law Proceedings.

Poisoning by Arsenic.—Omission to obtain Signature in Poison Book.

An inquest on Mary Elizabeth Perry has been held by Dr. Thompson, borough coroner, at the Dispensary, Bideford.

Annie Greenoff, a fellow-servant of the deceased, stated deceased asked witness to go on an errand for her, which she consented to do, and she gave her a small bottle, and asked her to go to Mr. Cadd, chemist, and obtain the smallest quantity of arsenic. She went, and Mr. Cadd said three pennyworth was the smallest quantity he could sell, and that if she would leave the bottle he would supply it on the morrow. She left the bottle, and on the following evening she went accordingly, and Mr. Codd gave her the bottle, and told her not to poison herself. The bottle was wrapped up, and deceased seemed pleased on her giving it to her. When going up to bed deceased took the bottle up with her, and placed it on a box. It was labelled "poison," and the contents were of a white colour. Her fellow-servant caught up the bottle, and the deceased ran after her to secure it, saying, "Don't, don't be foolish. Let me have it. It is used for killing blackbeetles." The bottle was given up, and deceased put it in a drawer. On Wednesday deceased got the breakfast as usual, and sat down and partook of it, and then shortly after she became sick, and Mrs. Gottwaltz, her mistress, sent in some brandy and water, and deceased was put to bed. She had heard deceased say something about taking arsenic for spots in the face. Deceased was generally of a quiet disposition. About three weeks ago she remarked, in consequence of her not getting the dinner properly, that she had a "good mind to destroy herself;" but on Tuesday last she said that "life was sweet."

Mr. E. Rouse, medical practitioner, said he was called to see the deceased shortly after ten o'clock on Wednesday morning, and found her quiet and not suffering any pain. On asking her what she had taken deceased replied, "Arsenic," that she had taken more than a teaspoonful, and that she had thrown the bottle with the remainder in the fire. He applied the usual remedies, but without avail, and she died the same evening. When he first saw her she was not suffering from any aberration of mind. He made a *post mortem* examination of the body, and the contents of the stomach indicated strong symptoms of arsenical poisoning. Deceased was not pregnant.

Mr. William Cadd, chemist and druggist, said that he supplied half an ounce of grey arsenic to Annie Greenoff on Tuesday last. It was not much coloured, but the bottle was properly labelled "poison." He made an entry in the book of the sale, but he did not get the young woman to sign it according to the Act; but he knew the young woman very well as he had supplied similar poison to her father for killing rats. He thought it was for a similar purpose. The book was put in.

Mrs. Gottwaltz deposed that the deceased was generally of a quiet and even disposition, and, so far as she was concerned, there had been no unpleasantness with the deceased. On Wednesday morning, when she was taken so ill, the deceased said that she had taken more than a teaspoonful of arsenic. Witness said, "You have taken poison," and the deceased did not reply; but afterwards said that she had taken the poison for the spots in her face, and added, "I have been very silly." Witness replied, "You have been more than silly." This same statement she repeated to her mother in the afternoon. She was perfectly responsible for her acts, and seemed to know perfectly well what she was doing.

The jury, after a brief deliberation, returned a verdict "That deceased died by an overdose of arsenic." The coroner remarked that it did not lay with the jury to take any action against Mr. Cadd, the chemist, who supplied the poison, and who admitted having sold the arsenic without getting the girl to sign the book, and without colouring the poison. The matter of colouring was not important in this case, but had the girl taken the white powder in mistake for starch, or anything uninjurious, it would have been very serious. The jury could scarcely, he thought, let the matter pass without some cognizance.—The jury, however, declined to express an opinion on the subject.—*Western Morning News.*

Obituary.

Notice has been received of the death of the following:—

On the 13th of November, 1879, Mr. Robert Griffith, Chemist and Druggist, Llanbedr. Aged 66 years.

On the 18th of November, 1879, Mr. Edward Preston Hornby, Pharmaceutical Chemist, Lower Hillgate, Stockport. Aged 53 years. Mr. Hornby had been a Member of the Pharmaceutical Society since 1853.

On the 22nd of November, 1879, Mr. Charles Samuel Dale Steward, Great Yarmouth. Aged 78 years. Mr. Steward was one of the earliest Members of the Pharmaceutical Society, but had retired from business several years previous to his death. Mr. Steward was universally respected by all classes and held the office of churchwarden of the parish for thirty years. After the funeral a meeting of the mayor and principal inhabitants of the town was held and £50 were subscribed towards a memorial window to be put into the parish church in respect to his memory.

On the 23rd of November, 1879, Mr. William Smith Lingard, Chemist and Druggist, Stockport. Aged 63 years.

On the 23rd of November, 1879, Mr. William Judson, Pharmaceutical Chemist, High Wycombe. Aged 46 years. Mr. Judson had been a Member of the Pharmaceutical Society since 1869.

On the 25th of November, 1879, at Manchester, Mr. Thomas Simcock, for forty years in business in Manchester and Liverpool. Aged 79 years.

On the 29th of November, 1879, Mr. Ebenezer Vaughan Williams, Chemist and Druggist, St. Thomas Street, Weymouth. Aged 46 years.

On the 3rd of December, 1879, Mr. John Sidney Bowes, Chemist and Druggist, Camp Road, Leeds. Aged 32 years.

On the 6th of December, 1879, Mr. Edward Snape, Pharmaceutical Chemist, Great Hampton Street, Birmingham. Aged 71 years. Mr. Snape had been a Member of the Pharmaceutical Society since 1842.

Notes and Queries.

[632]. CHLORAL HYDRATE.—*Delta* will find that if he keeps his solution of chloral hydrate more concentrated, one minim to represent a grain, no change of importance will take place.

LAVANDULA.

[636]. DR. STARTIN'S POMADE.—I have used the following formula :—

℞ Hydrarg. Subchlor.,
Pulv. Hyd. Ox. Rub. . . . . . . āā ʒss.
Ung. Simplicis. . . . . ℥j
M. bene.

A. T. OSBOURNE.

[642]. PRESERVATION OF JELLIES.—Can any reader inform me of the process adopted in preserving jellies in a large way? A safe way is to immerse the bottles in water up to 140°, cork and then boil. The jelly thus prepared will keep; but it never sets firmly while in the bottle and therefore is of no use in preparing for the trade. ALEX.

[643]. CURING BACON.—Can any reader kindly inform me how the Irish cure bacon in so short a time?

T. H.

[644]. EXTRACT OF SALT.—Does any reader of the *Pharmaceutical Journal* know what it is that confectioners designate by the above? The person who applied for it stated that it was a white crystalline powder used by bakers with carb. soda and hop liquor for making a kind of yeast.

A. P. S.

A NEW MARKING INK.—The use of chloride of lime in washing being now so general, the old nitrate of silver ink is of very little use. I send the recipe of one I have tried and which cannot be removed by any chemical means and does not require heating.

One ounce of phosphate of manganese to 2 ounces of hydrochloric acid; then add ½ ounce of anthracene in ¼ ounce of water with a ¼ ounce of potassic chromate; add gum and well shake. Write with any pen.

R. ROBERT.

GREGORY'S POWDER.—As a note to Mr Gilmour's excellent paper on Gregory's Powder, I may say with others that I have had the same complaint about its non-miscibility with water.

This I believe I have overcome by first wetting the sieve all round, an inch or so from the sides, and drying it to a certain degree of dryness before a quick fire, then sifting the magnesia through in this condition of damp warmth; lastly, making the Gregory and sifting the whole. The resulting powder should be the colour of chamois leather and should be kept air-tight in a cold dry place.

C. BILLING.

THYMIC ACID (THYMOL) AND THYMATE OF SODIUM.—Dr. Alvin gives the following formula for using thymol in place of carbolic acid in caustic, alterative, or astringent applications to the mucous membrane of the throat. He has found these preparations much better tolerated, more agreeable, and quite as active as those of carbolic acid :—

Caustic.

℞	Thymol Cryst.	pt. 1.
	Glycerinæ Puræ	pts. 2–4.
℞	Thymol Cryst.	pt. 1.
	Iodinii	pt. 1.
	Potassii Iodidi.	pt. 1.
	Glycerinæ Puræ	pts. 5–15.

Alterative.

℞	Thymol Cryst.	pt. 1.
	Glycerinæ Puræ	pts. 50.
℞	Thymol Cryst.	pt. 1.
	Iodinii	pt. 1.
	Potassii Iodidi	pts. 1-2
	Glycerinæ Puræ	pts. 12·0.
℞	Thymol Cryst.	pt. 1.
	Tannin	pt. 1.
	Glycerinæ Puræ	pts. 100.

Astringent.

℞	Thymol Cryst.	pt. 1.
	Glycerinæ Puræ	pts. 500.

Pastils.

(Useful in superficial stomatitis, irritation of the upper air passages, and erosion of the mucous membrane in smokers, and they are very useful in quieting spasmodic cough. They should be made trial of in whooping-cough.)

℞ Thymate of Sodium . . . 1 milligr. (gr. $\frac{1}{65}$).
Chlorate of Potassium . . 10 centigr. (gr 1½).

In severer forms of stomatitis, amygdalitis, pharyngo-laryngitis :—

℞ Thymate of Sodium . . 1 milligr. (gr. $\frac{1}{65}$).
Borax . . . . 10 centigr. (gr. 1½).

These pastils may be taken to the number of six to ten daily.

THYMOL-VASELINE OINTMENT is made by dissolving twenty grains of thymol in an ounce of vaseline. It is useful in eczema and as a parasiticide.

GLYCEROLE OF THYMOL.—The formula is: thymol, 20 grains; glycerin, rectified spirit, of each, an ounce; distilled water to 16 ounces. Useful in pityriasis, and, when diluted, as an effective antiseptic mouth-wash

It is said that thymol has the property of immediately removing the smell of tobacco.—*New Remedies.*

INDELIBLE INK WITHOUT SILVER SALTS. —Triturate 1·75 gram of aniline black with 60 drops of strong hydrochloric acid and 42–43 grams of strong alcohol. The mixture is diluted with a hot solution of 2·5 grams gum arabic in 170 grams of water.

This ink does not attack steel-pens, and is neither destroyed by mineral acids nor by caustic alkalies.—*Pharm. Centralh.*

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Replies.

[345]. To the opinions already expressed on this prescription allow me to add mine.

I am of opinion with Mr. Mackay that chemists are certainly not justified in retaining a precipitate in a preparation, because a certain physician so orders his, or because a similar proprietary preparation contains one, but at the same time I hold that a dispenser is not entitled to filter or otherwise tamper with a prescription unless he has distinct injunctions to do so.

C. BILLING.

[377]. *Novis* will probably find the source of his difficulty (which should have been stated) in an impure specimen of sodæ salicylas. The pure salt, such as is obtained from the natural acid existing as methyl salicylate in oil of wintergreen, should always be used in dispensing, for reasons recorded in *Pharm. Journ.* [3], viii., p. 785.

If the ext. cinch. liq. be added to the other ingredients in solution, a copious precipitate is produced, readily diffusible by agitation, and not at all inelegant. If, however, the sodæ salicylas used has been obtained by the action of carbonic anhydride on sodium carbolate, the precipitate will assume a more or less flocculent and disagreeable appearance according to the amount and character of the impurity present.

R. H. PARKER.

[378]. *Adolescens* will find the following method of dispensing the prescription satisfactory:—

Place 3 ozs. of the lime water in a 4 oz. bottle and pour in the vaseline, previously melted, shaking vigorously immediately, when a nice creamy emulsion will result, now rub down in a mortar the oxide of zinc and calamine, with the emulsion added gradually making up the bulk to 4 oz. with aq. calcis.

THE LONDON DISPENSER.

Query.

[379]. I had the following prescription to dispense, would you kindly publish it in the Journal, so that I may learn which would be the correct way to dispense it?—

℞ Pepsina Porci . . . . gr. 4
Ol. Absinth. . . . . q. s. ft.
Pil. i. Mitte xii.

THETA.

Correspondence.

*** *No notice can be taken of anonymous communications. Whatever is intended for insertion must be authenticated by the name and address of the writer; not necessarily for publication, but as a guarantee of good faith.*

ELECTION OF THREE ANNUITANTS.

Sir,—I think that I may venture to assume that in recording our votes, we shall all wish to act on the principle of "*Detur digniori;*" but, speaking for myself, I find it impossible to persuade myself that we have sufficient data given us in the voting papers, from which to form a satisfactory judgment, and thus confer our votes on "the most worthy." To a very great extent, I submit, that for present purposes (though *cæteris paribus* or *pæne paribus*, I do not forget other considerations) need is worth, the most needy the most worthy. But how to divine which of the nine are most needy, I find not.

B has about £23 per annum; H (with a child dependent on her) has £32. These are the only two who make at all a definite statement of their resources, for I cannot understand in what sense, D, who has £12 from her son, says, that she "with the assistance of her daughter is keeping a school, the proceeds of which do not cover the expenses." It surely cannot mean that her daughter is helping her to do something which makes her poorer than if it were left undone; to continue in such a course as this were absurd, and suicidal indeed. But I think one may, on consideration, reasonably infer that she does not mean this, and that this school keeping is of some advantage to her, although we are quite in the dark as to its amount, and so can form no definite estimate of D's income. C's children cannot afford "much" pecuniary assistance; F depends on "two daughters in situations;" G, on "two sons, clerks." Now, really, considering C, F and G, we must perforce indulge in such flights of imagination in trying to fix that very elastic quantity "not much," and the multiform capabilities of "daughters in situations" and of "clerks," that I am afraid there would be no reasonable probability of our returning in time to give our votes on the 19th. A "has no means, no children, no friends:" D, "no relations;" T (with a wife subject to epileptic fits), "no relatives, no friends in a position to assist him." Now, are we really intended to suppose from this, that A, D and T, have been, and are, and will be till the time of the election (and, if unelected, after), living on nothing? If we are to take A's account *au pied de la lettre*, we have no alternative, that I can see, about him. About D we might fancy that though he has no relations, he may have means or friends; and that T, though he has no relations and no friends able to assist, may have means.

You see, Mr. Editor, in groping about in a vain endeavour to do my duty, how bewildered I have become for want of more light; shed some of your beneficent rays on my darkness (I will not dare for a moment to hint that it is not as clear as noonday to every other voter), and then I shall see that great desideratum—how to live on nothing! But not like the horse, please, who did without eating, and died as soon as he had learned! Seriously, sir, I do think that we ought to have the exact income of each candidate given to us, and not to be left to the tender mercies of our own unguided imaginations; we are men of business, and should act as such. If we are not in a position to do this, would it not be better to give up the responsibility and the farce of voting, and leave, once for all, the matter to be settled by the Council? But, if this may not be, if we must retain our responsibility, at least, raise your powerful voice, sir, and do your best to make our voting a reality, and the Benevolent Fund the greatest benefit to "the most worthy."

HOC AGE.

41, *Church Road, Tranmere, Birkenhead.*

THE EVENING MEETINGS.

Sir,—I infinitely regret that my modest "growl from the gallery" should have constrained your correspondent Mr. J. B. L. Mackay to dance forth in war-paint and feathers as the champion of "our head quarters."

I am sure my "ridiculous and delusive letter" did not merit such exertions on his part. Nevertheless, your readers, in common with myself, will owe a lasting debt of gratitude to Mr. Mackay for his affecting description of the beautiful arrangements which have made the house of the Society so remarkable.

What more convincing proof is needed of the perfect ventilation of the "lecture theatre" than is to be found in your correspondent's assurance that during class hours the students sit and shiver from the draughts? Besides, who would venture to complain of being nearly choked with foul air, when it is possible, as Mr. Mackay says, to be "suffocated with the open canopy of heaven?"

I would fain hope that Mr. Mackay will not long delay his promised contributions touching the "death-rate among *pharmaciens;*" and if in the meantime he has to submit himself to the surgical operation, of which tradition tell us most of his countrymen stand in need, he may find comfort in the reflection that he will be thereby enabled to more fully appreciate the value of what Horace once said about *ridentem dicere verum.*

Your correspondent has concluded his letter by comparing me to Baal. I must gently disavow any connection with so exalted a personage. Rather than Baal, I would liken myself to the humbler Baalam, inasmuch as I have met with rebuke from an unexpected quarter.

Notwithstanding this, as long as I survive the effects of the Evening Meetings, I shall take my place in the gallery as

ONE OF THE "GODS."

[*** There is much in this letter, as well as that to which it is put forward as an answer, which is quite beside the subject of the ventilation of the Society's lecture theatre. If the discussion is to continue we must request our correspondents to avoid personalities and confine their remarks to that question.—ED. PH. J.]

HEALTH AND LATE HOURS.

Sir,—Another side of this question as affected by late closing is the moral health of chemists' assistants.

Whether justly or unjustly, they are sometimes blamed with being faster than assistants in other lines of business. After all, they are subject to human wants, as much as more favoured mortals. They require the relaxation of company after a long day's work, and into what society can they enter after 9 or 10 o'clock at night? It is too late to visit friendly circles, and there seems only one chance for them. Either they must sink into the creature described by your correspondent in a recent issue, or take the company that is found easiest at such hours. If it is not always of the best class, their employers are largely to blame, and must stand the consequences of not endeavouring to create a steady and trustworthy race of assistants.

True, it is possible to withstand temptation, and it is to their credit that numbers prefer no company to the other alternative, but they belong to two classes. They either swell the ranks of these "poor, white faced men," who, lacking all energy, are not competent assistants; or, they refuse to accept a situation with such unreasonable hours, and failing to find "anything suitable," they leave the business. This may perhaps cast a contradictory light over Mr. Barnaby's source of consolation, "the survival of the fittest."

When an assistant, some years ago, in Edinburgh, where chemists close much earlier than in London, I called upon all those north of George Street, and obtained the signature or assent of all but one to close at 8 o'clock. To this one hung another, and to these more, and the attempt fell through. But there is little reason to think that chemists would suffer from the opposition of an extra hour at night. Did they determine to act reasonably, and in this matter, independently, they might surpass, by additional energy diffused into eleven hours, the business dragged out over thirteen or fourteen.

Menton. G. W.

Sunday Trading.

Sir,—I read with great interest the weekly correspondence on the above subject. I quite agree with the remarks of "Volo" on the unnecessary articles applied for on Sundays. A few Sundays ago I too took notice of a few things applied for at our shop; amongst a host of others were soft soap, turpentine, baking powder, lemon kali, hair oil and vinegar. On inquiring what the vinegar was required for, the customer told me that she had some fish for supper, and wanted some vinegar to it. Could she not just as well have bought her vinegar on Saturday? When the public know that a chemist's shop is open on Sundays (especially if it is a shop where the trade is mixed) they make a "convenience" of it, and think we are compelled to be open as a matter of course. Even the poorest working man has his day of rest on Sunday. Why then should a chemist's assistant have to stand behind a counter for two or three hours on Sunday evenings. Again, if medicines are required they can be supplied at the side-door equally as well as through the shop. Why should the door be thrown open and the place lit up like a public house?

Is a halfpennyworth of laudanum or paregoric to be called medicine specially on Sundays? for such is the nature of a few of the "medicines" applied for at our shop. I think that if some association were formed it might tend to mitigate the evil.

With respect to late closing, which is extremely bad in this town,—indeed I should think it is the worst in England for that,—is not twelve hours long enough for anyone to stand behind a counter? Is it likely that an assistant after working for thirteen or fourteen hours will commence to study at ten o'clock at night? No. If he means to keep in good health he must get a little fresh air then, if he cannot get it at any other time, or else go to bed and prepare for another day's drudgery: for so it is in some shops. I have seen a chemist's shop open here at 11·15 p.m. on an ordinary night (not Saturday) in order that the proprietor might scrape together a few more pence than his brethren who closed earlier. H. Woodward.

44, *Great Alfred Street, Central, Nottingham.*

Wood Sage as a Substitute for Hops.

Sir,—Perhaps it will not be amiss to point out to those of your readers who may be tempted to try the substitution of wood sage for hops in the operations of "home-brewed," that it will not do for pale ales; for upon the authority of Gray it will darken the product.

I had hoped that your suggestion in the "Month," for September 27, as to a new edition of Gray, would have been responded to. Is it too much to ask for one more favour at the hands of Professor Redwood?

Worthing. J. Burt.

Is Nitrate of Potash a Poison?

Sir,—In the report headed "Is Nitrate of Potash a Poison?" (before, p. 417) it should have been stated that the cattle drench weighed over 8 ozs. Your readers will probably differ in opinion from the County Court Judge as to whether containing only a "small admixture" of other substance it was a poison or not.

Richard Young.

How can a New Name be Protected?

Sir,—I should be obliged if some of your readers could inform me how to proceed in order to secure the sole right of using a newly coined word to be applied to a newly devised preparation.

I understand that entry at Stationers' Hall gives no sole right to any word that may be used on a label, and that registration under the "Trade Marks Act" requires something more than a mere name or word in the shape of a "device,' but that the same name or word may be used by any other person in connection with any other device. Am I correct in this?

Σιγμα.

R. Modlen.—As such weights and measures could hardly be said to be used for purposes of trade it is at least doubtful whether their verification would be compulsory under the new Act. But there can be no doubt as to the advisability of having them verified.

W. R. H.—For a recipe for liquid dentifrice, see before, p. 79.

J. Sumner.—The fact that you imply that the preparation is an occult one, prepared only by yourself, would most probably be held to constitute it a patent medicine. But you are recommended to send a copy of the label to the Inland Revenue authorities, as they alone can answer your question with authority.

A. C.—'Historical Sketch of the Progress of Pharmacy,' by Jacob Bell, a copy of which is in the Society's library.

"*Galangal.*"—Back numbers of this Journal may be obtained from the publishers, Messrs. Churchill, 11, New Burlington Street.

J. F. Golding.—We cannot say. You are recommended to make an analysis of it.

Delta.—For a recipe for cherry tooth paste, see before, p. 79.

K.—Pulvis glycyrrhizæ co. of the Prussian Pharmacopœia is the same as the pulvis liquiritiæ co. of the German Pharmacopœia, the formula of which has been already given in this Journal on several occasions:—

℞ Foliorum Sennæ	2
Radicis Liquiritiæ, singulorum pulveratorum partes duas	2
Fructum Fœniculi pulveratorum	1
Sulfuris depurati, singulorum partem unam	1
Sacchari optimi pulverati partes sex	6

Misceantur.

J. L. Wilkes.—Numerous recipes for ink have been already given in the present series Among others see vol. v., p. 704, for coloured inks, and, for black, vol. vi., p. 1004; vol. vii., p. 95; vol. viii., p. 702, and vol. ix., p. 713.

W. Ruthven.—See before, p. 340.

J. H. McIntyre.—(1) Apply to the local authority for the district in which you reside. (2) It must be a matter of arrangement between the buyer and seller, but probably some of the wholesale houses will undertake the work when proper arrangements are made for carrying out the Act.

A. Greaves (Chesterfield).—We regret the discrepancy between your opinion and our own, and can furnish no further explanation of our reasons for not publishing your letter in defence of the sale of paregoric without opium than we have already given in this Journal on pp. 331 and 432.

NH_4.—The formation of a deposit in the B.P. spirit. ammon. aromat. in seasons when the temperature is very low is not of uncommon occurrence. It consists, probably, nearly entirely of bicarbonate of ammonia and is much more likely to occur when the distillate does not contain the full percentage of alcohol. If you take the specific gravity of the preparations in question at 60° F., you will probably have an indication of 0·875 to 0·880, instead of 0·870.

J. D. M.—You are recommended to submit your label to the Inland Revenue authorities, who alone can decide whether it will necessitate the use of a stamp.

Communications, Letters, etc., have been received from Messrs. McNaughten, Reynolds, Cranwell, Mitchell, Goss, Southall, Fair Remuneration, Devon, St. Rule, J. D. M., T. W. L.

NOTE ON ERVUM ERVILIA, THE BITTER VETCH.

BY WILLIAM SOUTHALL, F.L.S.

In the Journal for April, 1873, was given the result of a trial at the Birmingham County Court, as follows:—

"An action has recently been brought to recover damages alleged to have been sustained by the death of fifteen pigs, caused by eating adulterated meal, supplied by the defendant. Evidence was given that the stomachs of the dead pigs presented symptoms of irritant poisoning. Dr. Hill, the borough analyst, said that he had analysed a portion of the meal, and had been unable to detect any trace of poison; but that there was some sand present, to which, perhaps, the inflammation was due. For the defence chemical evidence was given by experts that the meal contained no poison. The judge decided in favour of the defendant, expressing an opinion that the deaths resulted from the improper manner in which the food was given."—*Birmingham Gazette.*

This trial occupied two days, and twenty-four witnesses were called. My firm was employed by one of the several parties interested to analyse the meal but, the result being negative as regarded the ordinary poisons, was not called upon to give evidence. The hypothesis relating to the proper cooking of the meal was raised by my ingenious friend, the late Alfred Bird, who suggested that the meal being mixed with cold water lumps of starchy coagulate were formed which were totally indigestible and so caused death, whereas had the meal been properly cooked with hot water it would have been soluble, and no harm would have resulted. In this view he was followed by a professor of materia medica and by a professional chemist. The manifest effect of the food was severe vomiting, followed by speedy death. The judge delivered an elaborate judgment, in which he said he laid no claim to practical knowledge in feeding pigs, but he adopted the view, and gave a verdict for the defendant. It will presently be seen that this view was in the direction of the truth, but was quite erroneous.

Being interested in the subject, and desirous of solving the obscurity in which it was left by the trial, I procured some of the seeds of which the so-called pea meal was made and found that they had been called Egyptian peas, but that they were really very much smaller than peas, and that the correct name was Rovi seed, a cargo of which had been imported from Turkey. These I sowed in my garden; they sprang up, flowered and bore fruit, and proved to be the *Ervum Ervilia*, or bitter vetch. I sent a specimen to Professor Oliver, at Kew, who confirmed the name. The mystery was now made clear, as these seeds are known to be poisonous.

Since that period I have heard of several cases of pigs being poisoned, but could not obtain the seeds of which the meal they were fed upon was made. During the last summer, however, a number of pigs were poisoned at Stratford-on-Avon, and on examining the seed, I found it to be about half Rovi seed, and the remainder a black tare, or vetch, a much larger seed. It therefore seemed to me desirable that a statement of these facts should be published, for the sake of the pigs and possibly for that of men.

The seed of *Ervum Ervilia* is about the same size and almost exactly the same rufous-brown colour as that of the Egyptian lentils (*Ervum Lens*), and when the testa is removed they are both of an orange-pinkish colour, but the former is not so bright as the latter. The seeds of *E. Ervilia* are not, however, lenticular, but are obtusely triangular, and this serves to distinguish them from lentils, for which popular food they might be an unpleasant substitute.

Modern writers do not take much notice of *E. Ervilia*; it is by several simply mentioned as poisonous. Lindley, in his 'Vegetable Kingdom,'* says that the seeds mixed with flour produce weakness of the extremities and render horses almost paralytic. J. C. Loudon† attributes these same qualities to *Lathyrus sativus*, but his figure of *L. sativus* is that of *L. Aphaca*, so there may be some confusion with both writers. Sir John Hill, whose 'Herbal' is dated 1756, dismisses it as a plant having no properties worthy of notice; but if we gob ack another hundred years we find it to be an article of the materia medica, and that it had the credit of curing the Emperor Augustus, "whose griefe it is probable was a toughe flegme condensate in the lungs, and hard to be avoyded and spit forth."

In those well-known books, Gerarde's 'Herball'‡ and Parkinson's 'Theater of Plantes,'§ the bitter vetch and its virtues are fully described, and the same engraving does service in both. The name given is "*Orobus receptus herbariorum*;" and it is curious to observe how the properties attributed to it by Galen and the older writers are quoted in every book of this and of anterior date, except Celsus, that I have consulted. After the old fashion it is said to be hot in the first degree and dry in the second. Gerarde says that "men do altogether abstain from the bitter vetch, for it hath a very unpleasant taste and naughty juice; but kine in Asia and in most other countries do eat thereof, being made sweet by steeping in water." It is directed to be given as a medicine with honey as an electuary.

In the Commentaries of Matthiolus upon Dioscorides,‖ a book of about the same date, we find that there was then considerable controversy as to the true identity of Orobus, Ervum, and Ervilia, and which of the plants known to the ancients were meant by those names. He quotes Galen, "*Boves apud nos ut apud alios plerasque gentes Ervo in aqua edulcato pascuntur; hominum cibis prorsus hoc semen damnatur, est enim insuavissimum, et pravi succi.*" In Bauhinus' great work, 'Historia Plantarum,'¶ the difficulty is still further worked out, one suggestion being that Ervilia must be the same as *Phaseolus*, the kidney bean, because that is the only legume of which men eat the pods and seeds together. It is even suggested that it may be Dolichos. He says that Brasevolus believes Ervilia to be the legitimate Ervum, but the more general testimony appears to be that it was a different plant, known to the Greeks as *Ochros*. One species of Orobus is spoken of as *Orobus semine obtuso triangulo*," and this answers well to our bitter vetch.

An interesting clue to the name Ervum is given. "*Quòd verò Erbum Avicennæ* (*Orobon Græci appellant, nos Ervum*)." I may say that it appears to me that the name Rovi is also clearly derived and descended from Orobus, it being probably grown on some

shores of the Greek Archipelago. Whilst this note has been passing through the press my attention has been called to the *Gardeners' Chronicle* of December 13, where it is mentioned that Dr. Whittmack recently exhibited some carbonized leguminous seeds disinterred in the ruins of Troy by Dr. Schliemann, which on careful examination proved to be the seeds of *Ervum Ervilia.*

A hundred years further back than Bauhinus, we meet with a mention of Ervum in the works of our first English botanist of repute,* William Turner, 1551, printed in black letter, with beautiful plates. He says, "Bitter fiche burdeneth the hede mych, the same eaten troubleth the belly. It draweth out bloude by the water. This pulse well sodden maketh oxen fatt. Ervum helpeth a mā to pis well. The same maketh a man haue a good colour." He is exercised as to the identity of the plant; scolds Fuchsius for misleading him, and gives for his engraving a species of *Lathyrus*, which he calls *Orobus Sylvestre.*

We now get back to the ancients. I have not Galen to refer to. Celsus† mentions both Lenticula and Ervum, and his editor, Dr. Milligan, notes the first to be, "*Ervi Lentis*, L., *varietas major*," the second, "*Ervum Lens*, L.;" but if the Latin "Ervum" be the same as the Greek "Orobus," this would be incorrect. Pliny,‡ writing soon after, mentions the twenty virtues ascribed to it, including its curing the bite of serpents—and of men—and also adds that if sown in March, it is injurious to oxen, if in autumn, it produces headache, but if sown in early spring, it produces no bad results; but Pliny does not discriminate his facts. Dr. Bostock, his editor (Bohn's edition), says in a note that the blade is said to be poisonous to pigs, and that the farina of *E. Ervilia*, is much advertized as a food—but Revalenta is now supposed to be the farina of *Ervum Lens.*

Having now traced the history of the Rovi seed of the Archipelago up to the Orobus of the ancient Greeks, let me return to its poisonous properties. The ancients and those accustomed to use it knew that these could be eliminated or destroyed, by soaking in water, as is the case with other vegetable products which are poisonous in their natural condition, but which are made wholesome by water, by heat, or by both combined. This property may reside in the testa, which is the most bitter part, so that when decorticated, the seeds would be wholesome, but I am not aware if this be the case or not.

It has been stated that sheep may feed on the Rovi seed. On the other hand, pigs, notwithstanding they are such gross feeders, have delicate stomachs; it is said they cannot eat even haricot beans with impunity. They are probably modified by the artificial life they lead. Darwin§ says that white sheep and pigs are injured by certain plants, whilst dark coloured individuals escape. In Florida, the squatter selects the black members of a litter, as they only have a good chance of living—as the pigs eat the paint root (*Lachnanthes*), which colours their bones pink, and causes the hoofs of all but the black varieties to drop off.

At the trial it was stated that one of the witnesses offered the meal to some pigs who declined to partake of it; he kept them without food all day, and offered it again, but they still declined. Whether these pigs were black or not was not stated, but it would appear that their original aptitude for discernment in the selection of proper food had not been destroyed by their artificial mode of living—whatever their original physical capacity might have been. Light coloured pigs certainly have a much more objectionable appearance than black; their skin is too much the colour of the noble biped to look correct. One witness stated that she had given the meal to her pigs without harm, but then she had only given a small proportion with other food and had first well steeped it in accordance with the ancient custom.

I fear this subject has been treated too much at length, but it is certainly one of importance to the porcine world, and if an occasional cargo of Rovi seed is imported we do not know where it may find its way.

THE BOTANY OF THE KURAM AND HARIAB DISTRICTS.

The following report, dated 22nd June, 1879, from Surgeon-Major J. E. T. Aitchison, botanist, Kuram Field Force, upon the Kuram and Hariab Districts has been communicated to the *Indian Daily News* by the Press Commissioner, and will be read with considerable interest:—

I have the honour to forward, for the information of Major-General F. S. Roberts, C.B., V.C., commanding the Kuram Field Force, the accompanying report upon our present knowledge of the Kuram and Hariab districts. I have only touched upon the more salient points, and those with which I have been able to make myself familiar during the short period I have been investigating the flora. I consider it a matter of great importance to science if Government would consider the subject, and permit me to remain employed for some time at these investigations, and hope the Major-General will take the matter under his favourable consideration.

Thull.—Thull is a village on the Kuram river, at an altitude of 2500 feet, surrounded closely by low hills, the highest peak in its vicinity being that of Kadimuk, 4900 feet. In the small basin of Thull the flora is peculiarly that of the salt range of the Punjab, consisting of a few stunted shrubs, with occasional trees near water. The hills are, with the exception of grass, nearly barren of anything like vegetation, and when it does exist it is in hollows where shade and moisture can be obtained. Kadimuk would, from its altitude, if it were in the Punjab salt range, be much better clothed. Here, already the crushing-out effects of a winter cold enough to deposit snow, and want of moisture in the atmosphere, point out why, between this and the base of the Safed Koh range, there exists little or no natural vegetation. In summer, for several months the climate is that of the Punjab—a dry tropical heat. There are few plants that can withstand these extremes of temperature. The result is that, as we proceed towards the town of Kuram (4800 feet), we find, except such parts of the country as are cultivated by irrigation, that it is treeless and almost a barren waste. In the basin of Thull, where the Punjab forms are nearly all present, the first characteristic one to be absent is *Capparis aphylla*. The olive is rare; from this to the village of Shaluzan I have only seen it near houses and holy places, as ziarats, its place being taken taken by *Reptonia buxifolia*, which bears a remarkable resemblance to the olive. A little distance out of Thull, in the more open country, *Daphne mucronata*, Royle, *Sophora mollis*, Wall., and *Cotoneaster nummularia*, Fisch, are the plants that make up most of the scrub jungles, and range from this right through the Kuram Valley up to the Hariab, all reaching to nearly 10,000 feet, and from that little scrub there occasionally is amongst the pines at this high altitude. In gradually ascending the Kuram Valley, we soon lose our chief Punjab forms. At Ahmad-de-Shama, eight miles from Thull, *Acacia modesta* and *Dalbergia sissoo* are last seen. *Periploca aphylla*, however, accompanies us to nearly opposite Kuram, and in some quantity, being largely cut and collected as fodder for camels. The only occasional tree, except in the immediate vicinity of water, is *Pistacia integerrima* and a small *Rhus*. Wherever water is employed for irrigation there the crops are good, and trees of various sorts rapidly spring up. At Hazir Pir Ziarat fine trees of *Platanus orientalis* and *Salix* are to be seen. These increase in number and size as we reach Kuram. Up to this *Chamærops Ritchieana* has been more or less frequent, but from this it gradually disappears, along the left bank, at least, of the Kuram Valley, but is found forming a thick, dense, aloe-like scrub on the plateaux that lead west up to the Darwaza Gai Pass. When this palm is not injured or cut, it forms a branching tree of from 15 to 25 feet in height, as may be seen at many of the shrines between Kohat and this, or even within the walls of Peshawur, near one of the gateways. It extends largely into the Khost country. In the Kuram Valley the fibre of the leaves is the usual, and ordinarily the only, source of rope, all imported as leaves from Khost.

Kuram.—Kuram is a large village and fortress situated on the left bank of the river of that name, at an altitude of nearly 4800 feet, in an open valley. The nearest hills to the north being over nine miles off, to the south some low hills descend close into the river; but, speaking generally, it is situated in an extensive open plain, the broad bed of the river lying to its south. At a distance of about fifteen miles running from east to west (slightly south) is the Safed Koh range of hills. The two highest points are at the extreme ends. The one at the east called Karaira is about 15,200 feet, the one at the west called Sika Ram (but by the local natives Spin Ghar) is 15,400. From Kuram, 4800 feet to the base of the hills to its south, up to 6000 feet except for irrigation, which has been most laboriously carried out, the plain country would be an arid, shrubless tract, perfectly treeless; grasses and a few small herbs alone give the little green that occasionally meets the eye. When irrigation is employed then the crops are in profusion and rich, the soil yielding two crops in the year—the first, barley, wheat, and clover; the second, maize, rice, millets, tobacco, peas, cucurbitaceæ, a little opium, and some cotton in the more southern parts of the district, with numerous orchards of large trees. The greatest extent and finest cultivation occurs at the exit of the various streams from the mountains on to the plains, under the protection of the hills; as, for instance, at Shaluzan, where the trees grow to as great a size of their kind as any in Cashmere, and much more healthy, owing to the dryness of the climate preventing the numerous lichens and fungi affecting the trees. There are *Chunars Platanus orientalis* with a girth of 14, 16, 18, 25, and one 33 feet. The walnuts are finer than I have ever seen. Many trees of 9, 11, 12, 13, and one of 17 feet. With rare exceptions, are the trunks ever hollow or unsound. They have neither lichens nor mistletoes infesting them as in Kashmir. The amlok, *Diospyrus Lotus*, is very numerous and a good tree; its fruit is considered next in value to that of the walnut. Apricots, plums, apples, pears, grapes, *Elæagnus*, a few peaches, quinces, pomegranates, and almonds, form the mass of the orchards. There are no cherries.* Mulberries are grown for feeding silkworms with, and, as trees, are not extremely numerous, but are fine trees. In actual gardening the natives do little. Onions, and a large white radish, with numerous cucurbitaceæ, are all they go in for. Cultivated flowers in gardens, and near holy places, are the red Damascene rose, a white one, and the double yellow Persian rose, an iris, a mallow, *Melia Azedarach*, as also an *Elæagnus* cultivated both for its scented flowers as well as its fruit.

The other cultivated trees are *Populus alba*, *Salix babylonica*, and *Celtis australis*, L., besides another poplar, new to me. There is one cypress in the valley of great age: it is on the side of a hill close to Shaluzan, and noticeable at a great distance. On the plains between the Kuram river and Shaluzan, the little scrub that is there consists of *Daphne*, *Sophora Cotoneaster*, some barberries, a *Buddleia*, numerous *Astragali*, *Labiatæ*, *Compositæ*, of which species of *Artemisia* are very numerous; but any or all of them are chiefly found in the more sheltered hollows rather than on the open plain. *Convolvulus lanuginosus* is profuse in small hummocks from the Salt Range to Kuram and Ali Khel. Many species of the numerous *Astragali* found here will prove to be Tibetan in their type. These plains consist of *débris* of all shapes and sizes with mould poured down from the adjacent hills by the force of snow and water deposited in great fan-shaped masses, with a stream belonging to each fan, cutting its way down through its centre and making its way towards the river, usually reaching it with a much diminished supply of water, whether taken from it for irrigation purposes, or absorbed in passing over the lower beds or shingle. In some instances the whole of the water of a stream, especially in summer, is expended long before it has any opportunity of getting to its proper outlet—the River Kuram.

The general outline of the country, and the above peculiar fan-shaped *débris* deposits are best noticed at some distance from the south, as in crossing over the Darwaza Gai Pass towards Kuram, from which the view very much resembles that seen of the Ladakh valley on looking southwards from Leh, as long as one can imagine the distant forests to be mere shading of the hills. In looking over the Kuram Valley and the hills beyond from the Darwaza Gai Pass, we see lying before us (usually) the great mass of the snow-clad peaks of the Safed Koh range, extending from north-east to south-west. The lower hills, or rather high peaks of the spurs of the main range, seem to form two or three lower ranges; these are all covered with forest from the top down to 7000 feet, after which they are seen to be bare as they gradually lose themselves in the plain that extends from nine to fifteen miles before it reaches the river. The first vegetation to be traced on these hills on their southern exposure is *Quercus Ilex* commencing at about 7000 feet, as a good large dense bush; this as it ascends gets more tree-like and begins to be mixed with Deodar, *Pinus excelsa*, *Abies Smithiana*, gradually forming a dense forest when *Abies Webbiana* appears in it, chiefly near the ridges, and continues up to 11,000 feet, when the forests thin off, and gradually cease. At 9000 feet, commonly *Quercus semicarpifolia* appears and takes the place of *Quercus Ilex*, if it has come up as far, or often drives out the pines and forms a forest of its own. East of Shaluzan with a south exposure there is no *Juniperus excelsa* or *Pinus Gerardiana*, and as far as I can hear, and of what I myself have seen, there is no *Pinus longifolia* from Thull to this. *Pinus excelsa* abounds in this district taking to itself the Pashtu term "Nakhtar." Except the bushes being larger of the already specified *Daphne*, *Sophora*, *Cotoneaster*, barberries with an occasional *Viburnum* and honeysuckle, there is no undergrowth or bush vegetation. In this locality these forests of Deodar are very fine, and the timber superb. It forms fully three-fourths of the forests usually. Except of *Quercus semicarpifolia* in certain localities, the timber of the other trees is in too small a quantity to be alluded to when so much deodar is forthcoming.

It is curious to note how the forest of pines is directly got at through the *Quercus Ilex* scrub, there being no intervening forest as in the Himalayan ranges. As already stated these forests reach up to 11,000 feet; here they

* This statement is, I think, incorrect.—H. C.

become less dense, and a few shrubs of *Rhododendron Anthopopon*, the gooseberry and currant with bush juniper (*not excelsa*) and some willows and loniceras fill up the vacant spaces in the ending forest, until the bush juniper along with *Betula Lhojpattra* (in one locality) remain to be superseded by rhubarb, *Eremuri*, *Fritillaria*, some grasses, Carexes and Cruciferæ. Vegetation here is not stopped by perpetual snow, as on the southern exposure of this range there was no snow during the winter of 1878-79. But it is kept down, I should say in its altitude, by want of moisture in the soil as well as air. If snow existed all the year round vegetation would naturally ascend, I believe, higher than it now does. From Thull to Shaluzan and up the southern face of these hills I have seen but one fern, *Adiantum Capillus Veneris*. Heretofore I have gone over the vegetation as presented to us upon the southern aspect of these hills. Let us go along a water-course, or stream-bed, and examine any other exposures of these hills than the south. We find in the first place the pines descending to form a natural forest much lower down, a Deodar and *Pinus excelsa* may be seen at 6500 feet. The forests thin with a great deal of shrub and underwood, and shrubs gradually being removed by other trees than pines. At first it is enlarged bushes of the original *Daphne*, *Sophora*, *Cotoneaster*, barberries, then *Fothergilla involucrata* (a Kashmir type), *Cotoneaster bacillaris*, several roses, *Buddleia* in profusion, several large astragaloid Leguminosœ, another large barberry, two jasmines, several loniceras, pomegranate (wild), all mixing with *Quercus Ilex* as a dense bush, sometimes a tree, and a profusion of grasses. In the "Shud Tor" ravine, with entirely precipitous sides and narrow, we come upon the walnut as a forest tree quite wild, proved by the fruit, and perfectly natural, two species of *Euonymus*, *Viburnum Carpinus*, *Prunus Padus*, *Sterculia*, various *Lonicera*, *Rhamnus*, and in the moisture of this valley *Taxus baccata*, this being its western limit! it occurs in all the valleys to the east in similar positions. At from 8000 to 9000 feet a *Rhododendron*, near *lepidotum* of Wallich, with green flowers. Besides a *Lycopodium*, eleven species of ferns, *Podophyllum*, and quantities of *Hedera Helix*. Neither *Juniperus excelsa* nor *Pinus Gerardiana* exist here.

The Peiwar Kotal range is a spur from Sika Ram (Spin Ghar) extending south-west until it gradually loses itself in numerous small spurs at the Kuram river, round which the Kuram river bends from a southerly to a south-east direction. The range of hills at the Peiwar Kotal has an altitude of from 8400 to over 9000 feet, with a precipitous descent of nearly 1000 feet to the east.

At the base of the Kotal, in the valley leading up to it by the village of Turai, except when cultivated, the ground is covered with a more or less dense jungle of *Quercus Ilex* (covered with two species of mistletoe), but mixed here as we notice for the first time as a shrub soon becoming a tree, *Juniperus excelsa*, and our old friends the *Daphne*, *Cotoneaster* and *Sophora*, besides more numerously the small yellow rose, and *Buddleia*. As the ascent up the precipitous face of the Kotal takes place, Deodar becomes numerous with the oak as a tree, and *Abies Smithiana* and *Pinus excelsa* now forming a tolerable forest. Here an ash, *Fraxinus Moorcroftiana*, Wall., is not uncommon, and *Juniperus excelsa* as a tree numerous.

But not until we get fairly on and into the woods of the Kotal do we come upon *Abies Webbiana*.

Except the two oaks, *Quercus Ilex* and *Semicarpifolia*, there is no undergrowth whatsoever.

Taxus baccata does not exist in the forest, nor do we come upon Gerard's pine until we pass through the forests of Kotal and come upon their north exposure, where, on the lower edge of the forest, it is common.

The Deodar forest from the Spin Ghar Kotal to the Peiwar Kotal, and for miles to the south upon this spur of hills is simply superb, and almost unlimited in extent, and capable of being easily worked.

The other pines are proportionately few, but help to form a very dense forest.

The Hariab district is the basin of the Hariab river, that is formed by the south-western base of Sika Ram (Spin Ghar), and its two spurs, the Peiwar Kotal range running southwards, and the range that ends in Mount Matunge running nearly west. The Hariab falls into the Hazar Darakht river at Ali Khel.

The Hazar Darakht river forms the base of the triangle, with the two ranges of hills already spoken of, and thus completes the boundaries of the Hariab district.

The Hariab river takes its rise from the several streams that rise from the south-west face of Mount Sika Ram (Spin Ghar); it is supplied by tributaries from the hills to its north and south until it reaches Ali Khel, where only the streams from the south and east of Mount Matunge fall into it as it itself joins the Hazar Darakht, a much larger stream. This united stream subsequently flows into the Kuram.

At Zabr-Dast Killa the river may be called Hariab, as here at about 8200 feet the river is joined by several streams of one size.

On its southern or left bank until the river reaches Ali Khel, there is little or no cultivation, as the hills come down to the banks of the river. On the right bank there is a great deal of cultivation, as there is a large amount of good land on this side in plateaux, all of which is fairly cultivated from the base of Sika Ram to Ali Khel.

The land produces but one crop during the year—wheat, barley, maize, rice, millets, pulses, and clover.

Tobacco is occasionally grown and several of the cucurbitaceæ; no vegetables, opium, or oil-seeds.

The climate is much colder and drier than that of Kuram, with a more rigorous winter.

The plane tree, *Diospyros*, and vine do not grow here. The walnut, as a good sized tree bearing fruit, is rare; small trees are not uncommon. In the stream bed, *Salix babylonica* is a large tree, which, with a naturally wild *Salix*, are both cultivated to protect embankments for irrigation purposes.

Hippophae is cultivated as a hedge, and along with it an *Elæagnus* is common. The chief sources of fruit are apricots, plums, and apples, and a few pears.

The jungle scrub of the hills is chiefly *Juniperus excelsa*, with a very characteristic small stiff spinous grey *Prunus*, very handsome when in full bloom, with its peach-like blossom. *Daphne Sophora*, two species of *Cotoneaster*, honeysuckle, *Viburnum*, the single yellow rose, and another, with *Cratægus*. In addition to these, as we get somewhat into the forest, currants, gooseberry, a species of *Colutea*, and a very handsome laburnum-like *Astragalus*, called "jirrel:" the bark of this, cut off in rings, is employed in lieu of brass rings to the sheaths of Afghan knives, and not the bark of *Betula Bhojpattra*, the paper birch; also a most superb, great scandent honeysuckle, rose-red colour, very fine, and I think, a new plant. These forests would grow down to the stream, but they have been driven back by cultivation and search for firewood.

On the southern exposure of the Peiwar Kotal range, from two miles to the east of Zabr-Dast Killa, and in all forests lying to the west of Sergul, is *Pinus Gerardiana*. The Deodar and *Juniperus excelsa* form the forest from this to Ali Khel.

Pinus excelsa, *Abies Smithiana*, and *Webbiana*, are driven out into the higher forests and ridges.

Abies Smithiana and *Pinus excelsa* one can always detect, by their cones in the streams, as occurring somewhere above. *Abies Webbiana* has to be gone and looked for.

No *Taxus baccata*, Rhododendron, or *Betula Bhojpattra*, exist to the west of Sika Ram, at least in the Hariab district.

The fern that is occasionally to be met with is *Asplenium Ruta muraria*, but I have found five others: *Adiantum Capillus Veneris* and *Ceterach officinarum*—both only near Ali Khel; *Asplenium trichomanes*, *Asplenium sep-*

tentrionale, and another *Asplenium*—only in one locality each.

The forests here extend up to 11,000 feet, but higher on the northern side: the hills are not so precipitous and there is more moisture.

In a practical point of view, the great value to be attached to a botanical examination of the Kuram and Hariab valleys is its vegetable products, and the value they may possess for any export trade.

The first of these is timber. The Deodar, our finest Indian Himalayan timber tree, forms dense forests, many of which it will be found can be easily worked. There is at present no limit to the amount and quality of this timber that can be obtained: means of exportation and forest conservancy are the subjects that now require to be studied.

Deodar timber used to be exported from near the Kuram river in Mongul territory by floating down the Kuram *viâ* Thull to near Banu, but this has for some years been given up.

In grain these valleys have heretofore had no export trade, producing no more grain than was absolutely required for local consumption. I may say the same of their fruits, except perhaps walnuts and amlok (*Diospyros*).

The cause of this is simply *oppression*. There is land enough to double or treble the produce.

With a very little more than ordinary care of the water as it is expended, one-third more ground could be brought into cultivation; by appliances of a cheap nature, as wooden troughs, one-third more; and more expensive plant would enable it to be doubled.

The very first effects of our rule in this valley will show itself even this season in there being grain enough for our troops locally produced, and next year exportation will begin to take place towards the Punjab for exchange for cotton goods, which are at present expensive.

I cannot come to any opinion as to whether the nuts of Gerard's pine were exported as a real trade article from the Hariab. I know that it is so from Khost.

The natives use no oil, splinters of the roots of Gerard's pine, or of the stems of *Pinus excelsa*, being used in place of lights.

A crude tar is made from the roots of the above pines for local use. This is their nearest approach to oil. It is employed for local application to wounds and sores.

A little silk is produced at Shaluzan and some other villages; but in this there is no trade.

Probably the substance in which most trade is done, both on a large scale and barter, is honey. This is extensively exported by through-carriers to Kabul and the Khost country. Nearly every house in a village has its bees from Kuram to Ali Khel.

In a scientific point of view, the great value of a thorough and careful research in the vegetation of this altogether new to science district is the material assistance it will give to the better knowledge of the geographical distribution of plants, and the meeting of the several floras of Europe, Persia, Afghanistan, Tibetan, Himalayan, and Punjab tropical, which I already see radiate round the Safed Koh range as a focus, besides enabling one to obtain a more detailed and extensive knowledge of the peculiarities in the distribution of plants dependent on climatic zones, more or less influenced by a moist or dry atmosphere.

From the 600 species I have already collected, I can see already the immense value likely to accrue to scientific botanists by the collections I am now making, and consider that the Government should permit of the subject being thoroughly worked out.

Submitted and recommended.

FRED. ROBERTS, Major-General,
Commanding Kuram Field Force.

Camp Peiwar Kotal, the 5th July, 1879.

PREPARATIONS OF WHITE QUEBRACHO BARK.

(*Aspidosperma Quebracho.*)

BY DR. BURGOS.

The following extract from a thesis by the author appears in the *Revista Farmacéutica* (Buenos Ayres), for November:—

Powder of Quebracho Blancho.—Possesses all the physical and organoleptic properties of cinchona powder; in colour it is intermediate between the red and yellow barks. It is prepared in the same manner and can be used for the same purposes pharmaceutically, as an antiseptic alone or mixed with wood charcoal, or as an ingredient in dentifrice powders, electuaries, etc.

Infusion.—The infusion is similar to sherry in colour, clear and transparent. It has a bitter taste, analogous in every respect to that of an infusion of cinchona, but more pronounced. It is prepared with the same proportions as the decoction.

Decoction.—Quebracho Bark, bruised, 1 part; Water, 20 parts. Dr. Mantegazza prepares it in the proportions of 1 to 12 or 18. The decoction is more intense in colour than the infusion, and if it be concentrated so as to reduce it to one-third it acquires a colour as deep as that of port wine. It remains clear whilst kept at an elevated temperature, but as it cools it deposits an abundant precipitate. A few drops of sulphuric acid restore partially its transparency by dissolving the alkaloid it contains. If added to a solution of sulphate of iron a very large quantity of greenish grey precipitate is produced. With ammonia it undergoes no alteration.

The decoction is used as a tonic and febrifuge and it is the form in which quebracho is administered in the provinces where paludal fevers prevail.

Digestion.—Made with sulphuric or acetic acid in the proportions indicated for the preparation of the alkaloid according to Fraude's method. At the end of four to six days it is as intense in colour as the concentrated decoction and has a much more bitter taste, as it contains much alkaloid in solution.

It can also be prepared for internal use with a smaller quantity of sulphuric acid.

Tincture.—Quebracho Bark, bruised, 1 part; Alcohol, 56°, 5 parts. Macerate during eight days and filter. (This formula corresponds to the tincture of cinchona of the Codex.)

Compound Tincture.—Quebracho Bark, bruised, 2 parts; Orange Peel, 1 part; Alcohol, 56°, 15 parts.

Wine.—Quebracho Bark, bruised, 1 part; Alcohol, 56°, 2 parts; White Wine, San Juan or Mendoza, 16 parts.—Leave the alcohol in contact with the bark during twenty-four hours, then add the wine, macerate for eight days and filter. The use of one or other of these wines is recommended because they contain little tannin and possess a special aroma that communicates an agreeable flavour to the preparation.

An *Elixir*, very pleasant to the palate, is made by adding sugar to this preparation.

Extracts.—Both the aqueous and alcoholic extracts may be prepared by the ordinary processes.

Syrup.—Quebracho Bark, 3 parts; Water, 32 parts; Sugar, 16 parts.—Boil the bark with the water, filter and evaporate down to the fourth part, add the sugar and make the syrup *secundum artem*.

Preparations with the Alkaloid.—Aspidospermine or quebrachine is insoluble in glycerine. It dissolves readily in fats and fixed oils, and may be incorporated with cod liver oil in larger proportion than quinine. The following is a suitable formula:—

Cod Liver Oil, 100 parts; Aspidospermine 6 to 8 parts: Dissolve with the aid of heat. It is easy to conceive the usefulness of such a preparation as this, in which the special properties of the oil are joined with those of the alkaloid, and which in small doses acts as an eupeptic.

THE HECTOGRAPH.*

Some time ago, a new method for rapidly producing copies of letters, or any kind of written matter, was made the basis of a patent in Austria. The simplicity and facility of working the apparatus immediately attracted universal attention, but the high price of the first apparatus was not at all in proportion to the cheap materials, even allowing for a very respectable profit. It was soon ascertained that the process, or rather the composition of the printing material, was not capable of being patented, being nothing else than gelatin (or glue) and glycerin. Since then, in Europe as well as in the U. S., a number of such apparatus, under various names, have made their appearance, some of which may be seen at present at the Exhibition of the American Institute in New York. The price of any of these copying apparatuses is not at all unreasonable, and many will prefer to buy them ready made with all the necessary appliances. But for those who wish to make an apparatus for themselves, we append several methods:—

1. Ten parts of gelatin are softened in water, and then dissolved in 100 parts of concentrated glycerin, on the water-bath. When melted, the mass is slowly and carefully poured into a tin tray, about 1—2 cm. ($\frac{3}{8}$—$\frac{3}{4}$ inch) deep, and of any desired size. Any rising air-bubbles must be removed, and the mass is then allowed to become cold, when it will form an elastic mass, a little firmer than printers' rollers. Such is the process, as it has been published in some foreign journals. We have, however, ascertained that various other ingredients enter into its composition, among which sulphate of barium, sugar, glucose, and chrome preparations are mentioned. The latter, in the form of bichromate of potassium or ammonium, or of chrome-alum, would render the gelatin insoluble in water, after being exposed to light. As soon as we have further information on this subject, we shall take occasion to communicate it to our readers.

This mass has the property of absorbing to the depth of perhaps $\frac{1}{64}$ inch writing or tracings made with certain kinds of ink, particularly aniline inks. Any aqueous ink would answer, but it is necessary to use one which is made of very persistent colour. The writing desired to be multiplied is written upon a sheet of paper with the special ink below to be described; after the ink is completely dry, the sheet is laid on the moistened gelatin-surface (writing down), and gently rubbed over with the hand. After a short time (about 1—2 minutes), the paper is removed, and laid aside. Fresh paper being ready, a sheet is laid upon the writing, and the hand gently rubbed over the back, when a clear and complete copy of the writing will be found on the paper. This may be repeated from sixty to a hundred times, according to the quality of the ink, and the experience of the operator. When no more copies are wanted, or when the ink is exhausted, the surface is washed off with a sponge and cold water. Any traces of the ink left in the mass, after thoroughly washing, will not interfere with the next copy. When necessary, the mass in the tray may be remelted.

The ink may be prepared as follows:—

Violet: methyl-violet, 2; dilute acetic acid, 2; water, 4 parts.

Or, *red:* fuchsine, 2; alcohol, 1; water, 8 parts.

Or: Mix 5 parts of any desirable aniline colour, 5 of alcohol, 5 of mucilage, and 35 of water in a flask, heat until dissolved, and after twenty-four hours strain through flannel or wool. The selection of aniline colours is difficult, as many of them are largely composed of *dextrin*, which dries up or makes the solution thick. The best aniline colour, according to E. Störmer, is the Violet de Paris de Poirrier.

---

* Other names of this copying apparatus are: Copygraph, Copygram, Lithogram, Cheirograph, Autograph, etc. Reprinted from *New Remedies*, November, 1879.

IODATED AND CYANATED CAMPHOR.*

Although the iodine and cyanogen substitution products of camphor have not as yet found employment in medicine, like the corresponding bromine compound, yet it seems quite probable that they will be experimented with. Both bodies have been obtained by Haller. His primary object was the preparation of cyanated camphor. For this purpose he dissolved a mixture of iodide of camphor (improperly so called; being equal parts of iodine and camphor) and of sodium-borneol (or natrium-borneol)† in benzine, and treated this, under the application of heat, with a solution of iodide of cyanogen in benzine. He obtained crystals having the composition $C_{10}H_{15}IO$. When pure, they are white, insoluble in water, soluble in alcohol, ether, benzine, etc., melt at 43°—44° C., but do not again solidify until cooled to 28°—29° C. Heated to 100° C. it volatilizes without decomposition, but at 150° C. decomposition takes place. This body is mono-iodated camphor.

Cyanated camphor was prepared by very gradually adding to a solution of 100 grams of camphor in 100 grams boiling benzol (temperature between 100° and 110° C.) 8 grams of sodium, and then passing a stream of well-dried gaseous cyanogen through the liquid, until the latter commenced to assume a red colour. The liquid is then transferred to a separating funnel, where it is washed with water, which removes sodium cyanide; the remaining hydrocarbon compound is then treated with caustic soda and allowed to remain at rest, so as to separate the latter. This is several times repeated, the alkaline solutions united, acetic acid is added to faint acid reaction, the resulting white precipitate dried and then dissolved in ether. On evaporating this solution, cyanated camphor, $C_{10}H_{15}CNO$, is obtained in white prismatic crystals, soluble in alcohol, ether, chloroform, glacial acetic acid, and fixed alkalies. It melts at 127—128° C. and boils at 250° C.

Cyanobromated comphor is obtained by treating, at a gentle heat, a solution of cyanated camphor in carbon disulphide with bromine:

$$C_{10}H_{15}.CN.O + Br_2 = C_{10}H_{14}.Br.CN.O + H\,Br.$$

As soon as no more hydrobromic acid escapes, the carbon disulphide is distilled off, the residue is dissolved in alcohol and crystallized. It forms handsome crystals, soluble in the same solvents as the cyanated camphor, but with greater facility.

INK FOR WRITING ON SHEET-TIN.

1. Sulphate of copper (1 gram) is dissolved in 20 grams of water, 2 drops of hydrochloric acid are added, and sufficient solution of gum-arabic to make the ink adhesive. This ink writes intensely black, and is very durable. It must be written with copper pens. The addition of a little pyrogallic acid is advantageous, because the writing appears at once, which is not the case with the simple copper-solution.—C. Bernbeck, in *Pharm. Zeit.*

2. A jet-black, lustreless ink, or rather varnish, for writing on sheet-tin, which is absolutely insoluble in water, and dries instantly, may be prepared by dissolving shellac in alcohol (2 oz. in 1 pint), filtering with the aid of chalk, and mixing with finest lamp-black.

Incidentally, it may be remarked that a turpentine solution of shellac with lamp-black produces, on drying, a *glossy* black. On the other hand, an alcoholic solution produces a perfect *dead* black, without a trace of lustre. —Ed. *New Remedies*.

---

* *Journ. de Ph. et Chim.*, and *Arch. Ph.*, August, 1879. Reprinted from *New Remedies*, November, 1879.

† According to Baubigny, sodium (or natrium) borneol is obtained by carefully adding to a saturated solution of camphor in a pure hydrocarbon, f. i. toluol, heated to 80° C., small pieces of sodium. On cooling the compound, $C_{10}H_{15}NaO$ crystallizes out.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 20, 1879.

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

ACCIDENTAL POISONING BY MEDICINE.

Three weeks ago in mentioning an article in the *Medical Press and Circular* propounding opinions which, to say the least, seemed to us as eccentric as they were uncalled for, we suggested that the writer of the article might have been under the influence which in the dead season of the year brings back to our notice fresh accounts of prodigious gooseberries, of interviews with the sea serpent, and of other occult phenomena which seem conveniently to present themselves at that period. At any rate we gave him the benefit of the doubt, and, abstaining from any serious comment on the statements and suggestions made, we thought, a free quotation of the writer's own words would amply suffice to demonstrate their absurdity.

We have reason for saying that this has been the result in some cases, if not generally, and therefore the unfounded statements and insinuations contained in the article referred to might well have been consigned to oblivion, without further notice, if it had not been that in the following number of the journal in question we were charged in an editorial note with having "been unwise enough to make a virulent attack" upon that journal "for bringing to light the great evils that are the natural consequence of the existing law relating to sales of poison."

This editorial endorsement of the views against which we had entered a mild protest, together with some other circumstances to be mentioned presently, induce us to refer again to the subject, and in the first place we take exception to the assertion that the *Medical Press and Circular* has "brought to light great evils that are the natural consequence of the existing law relating to sales of poison." That journal denounced chemists and druggists as being irresponsible purveyors of poison and has brought against them the charge of carrying on their business so that the claims of society and of humanity are subordinated to the sordid desire of gain; but it has done so without furnishing any evidence to justify the charge. It claims, however, to have so forcibly exposed the evil which it assumes the existence of, that it is asserted the quotations we took from its article on "Poison Vending" must be destructive to ourselves. But we fail to recognize in those quotations anything of such a nature. On the contrary, as regards both the statements and the imputations conveyed by them, we consider that so far from their exposing any evil for which chemists and druggists are to blame, they are in reality either silly or malignant, besides being at variance with well-known facts and with the opinion of the medical profession as a body.

Our contemporary affects to be glad we did not attempt to justify the retention by the Pharmaceutical Society of the authority it possesses, and with patronizing presumption cautions us against weakening the cause we "must defend," by what it pleases to call "silly ebullitions of splenetic virulence."

When the power held by the Pharmaceutical Society is objected to upon grounds more valid than the lucubrations of the *Medical Press and Circular* upon "poison vending," it will be time enough to attempt its defence, and whenever our obligations constrain us to take up the defence of chemists and druggists it shall not be with such "men in buckram" as our contemporary has led out against them with true Falstaffian rant.

But is there really, as the *Medical Press and Circular* assumes, any question to discuss? and if so, what is the question? We take it for granted that so long as poisonous medicinal agents are used as remedies they will continue to be misapplied by the general public, and that consequently accidental poisoning will occur. We also assume that it is impossible to restrict the use of such poisonous medicines so exclusively that they can only be obtained on the order of a medical man. It would be as reasonable to expect the use of razors to be restricted to the order of barbers. The business of selling poisonous medicinal agents as carried on by the chemist and druggist is by law subject to restrictions that are directed towards limiting the facilities of obtaining dangerous articles. There can be no doubt the provisions of the Pharmacy Act do operate in that way and not, as the *Medical Press and Circular* alleges, by empowering the chemist and druggist to deal wholesale destruction in the vicinity of his shop.

Who then is responsible for that misuse of poisonous drugs and medicinal agents which impels our contemporary to insist upon the urgent necessity of reform? Taking, for example, the case of chloral. Is it not to the laudation of this article by medical men when it was a novelty, that we must ascribe much of its popularity? Is it not to the direct recommendation of it by the physician that we must ascribe much of the improper or ignorant use of this dangerous article? Have not those who used it to alleviate the consequences of intemperance helped to subject many of the public to the danger of accidental poisoning, and thus while endeavouring to drive out one devil opened the door to others worse than the first?

But while stating this which we believe to be the true view of the case it must not be inferred that we charge medical men individually or as a body with having acted regardless of the claims of society and of humanity, however much the consequences of their action may have proved pernicious. It is only because we are driven by false accusations of chemists and druggists to show where the source of accidental poisoning is really to be found, that we comply with this necessity of the obligation to defend them. We will for the present leave out of consideration the wholesome interference by which the chemist and druggist often prevents accidental poisoning, and still more often seeks to deter persons from the misuse of dangerous medicines. The service thus rendered is sufficiently well known to medical practitioners not to need more particular mention here. But as our correspondent, "A Village Chemist," shows in his letter at page 500, the tender of this service is not unfrequently productive of disadvantage to the chemist and druggist. If he is not told that his business is simply to supply the demands of his customers, he is left to find out from the withdrawal of their custom that this was the idea they entertained.

It so happens that a case just reported in the *Medical Times and Gazette* throws a strikingly illustrative light upon the subject of accidental poisoning and upon the question who is responsible for such occurrences. An American lady, resident in London, consulted a well-known West-End physician, who gave her two prescriptions—one for six pills containing one grain of opium each, the other for a mixture containing six moderate doses of chloral. By the aid of these prescriptions she appears to have obtained large quantities of these potent and dangerous medicines, and one day last October she was found in a dying condition, after having apparently swallowed in the night the whole six doses of mixture and a dozen of the pills. Perhaps the *Medical Press and Circular* would regard this case as illustrating the way in which it alleges the chemist and druggist deals wholesale destruction in the vicinity of his shop; but the *Medical Times and Gazette* puts another construction upon it and in these plain words: "Once, apparently, procure a prescription "for any noxious or poisonous drug, for whatever "purpose, and ever after this same drug is at the "command of anyone who may be able to lay "hands on the prescription!" If this means anything, it means that it is the physician's prescription, and not the facility of purchase offered by the chemist and druggist, which is the master key by which the public obtains possession of poison and of dangerous medicines; that document is the *passe-partout* which enables the holder to override the provisions of the law and to defy the caution of the pharmacist.

But, says our contemporary, the *Medical Times and Gazette*, in reference to the possible consequences of such power being placed in the hands of incautious or rash persons, "it is grossly unfair to hold a physician answerable for what may happen." And why is this held to be so surely the case? Why, because prescriptions that have been found serviceable are circulated from one to another and among the members of a family, or friends in the neighbourhood, and because being once out of the physician's hands they are at the will of the world. True these are the facts, and it appears to us that while they constitute an effectual stultification of the poison regulations of the Pharmacy Act, the logic which offers them as the exculpation of the prescriber is very remarkable. Might not the giving of prescriptions ordering poisonous drugs be more justly held to excuse the chemist and druggist for supplying these articles and simply complying with the demands of his customers? That is in fact his business and, as the successor of the apothecary he is, by tradition, if not by law, under obligation to supply what the physician orders.

There is a candour in the acknowledgment of the *Medical Times and Gazette* of the real source of the evil to which much accidental poisoning is due, and having recognized this we should have expected some suggestion of a remedy; but there is none offered, and, beyond the remark that if certain conditions existed which do not exist such things could not occur, the subject is left in *statu quo ante* with merely an expression of opinion that "the "mischief arises solely from the *hiatus* which now "exists between physicians and chemists, whose in"terests, taking this case for example, do not seem "to be identical. The physician would prefer to "give a fresh prescription, and receive a fresh fee; "the chemist undertakes so save the physician's "guinea to the patient by constantly dispensing the "same prescription."

This is, to say the least, disingenuous: inasmuch as it represents the chemist as voluntarily frustrating the desire and aim of the physician it is not true, and if the physician, knowing the way prescriptions are dealt with, knowing also their power to override the provisions of the Pharmacy Act as to the sale of poison, considers it desirable to prevent his prescription from becoming a facility for accidental poisoning, it is, we think, with him that the *onus* lies of adopting precautionary measures, either by giving his prescription conditionally and simply as an instruction to the dispenser for use on one occasion only, or in some other way. There may be difficulties in the adoption of such a plan; but it is not the business of the pharmacist to deal with or remove them, nor is he to be blamed for accidents which occur under the existing system. As to the *hiatus* supposed to exist between physicians and chemists, we are disbelievers; and if we are in this respect wrong, we would ask why should there be a *hiatus* between two classes so closely related in their avocations, and why should their interests if not identical be discordant or opposed when they are constantly called upon to act in concert and in reciprocal capacities as servants of the public?

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

December 10, 1879.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

MAJOR EXAMINATION.

Seven candidates were examined. *Two* failed. The following *five* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bown, John Quinton ....Nottingham.
Carter, Francis ....London.
Crook, Herbert ....Gravesend.
Eaton, Edward Jarrett ....Diss.
Greig, James.........................Glasgow.

MINOR EXAMINATION.

Seventeen candidates were examined. *Twelve* failed. The following *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Allison, William Bellyard ......Retford.
Bancroft, James ....Halifax.
Banks, James ....York.
Bell, Robert ....Lancaster.
Browne, Frank Styant ....Norwich.

MODIFIED EXAMINATION.

Four candidates were examined. *Two* failed. The following *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Althorp, George ....Henley-on-Thames.
Rich, George B. O. ....Islington.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of the Society's examination:—

Certificate of the College of Preceptors.

Gelsthorpe, James ....London.

December 11, 1879.

Present—Mr. Sandford, President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

MAJOR EXAMINATION.

Six candidates were examined. *Three* failed. The following *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Gulliver, William Inchle.........London.
Harburn, Alfred ....London.
Williams, Thomas Henry ......Plymouth.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Six* failed. The following *fifteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Chadwick, John ....Accrington.
Cock, James ....South Molton.
Cox, Frederick John ....Newark.
Crowther, William Fearne ......Beverley.
Davies, John.........................Haverfordwest.
Garrett, John Henry ....Notting Hill.
Gelsthorpe, James..................London.
George, John Irving...............Tunstall.
Grover, Frank ....Folkestone.
Henson, William John...........Maldon.
Hobbs, John Kingdon...........London.
Holdcroft, Francis Joseph ......Coventry.
Hooper, David ....Southwark.
Jackson, John Edward ....Maidstone.
Jones, Jonah.........................Aberdare.

December 17, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Professor Greenhow was also present on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Two* failed. The following *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Hugill, Arthur Major ....Leeds.
Kirk, William Peele ....Retford.
Powell, William ....Swansea.
Richardson, William Henry ...Boston Spa.

MINOR EXAMINATION.

Twenty-one candidates were examined. *Thirteen* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jacks, David Russell ....London.
Jones, Charles ....Ashton-under-Lyne.
Littlefield, James Clarence......Ventnor.
Lonnon, Frederick ....Plymouth.
Milne, Andrew .... London.
Newman, Alfred Pointon ......Crewe.
Parkes, Harry Charles............Fareham.
Playford, Frederick William ...Holt.

December 18, 1879.

Present—Mr. Schacht, Vice-President; Messrs. Allchin, Barnes, Benger, Brady, Carteighe, Corder, Gale, Greenish, Linford, Martindale, Moss, Plowman and Taylor.

Professor Greenhow was also present on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Fifteen* failed. The following *ten* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jones, William Harris............Abergavenny.
Protheroe, John Godwin.........Christchurch.
Rees, Harding ....South Norwood.
Richards, Thomas ....St. Clears.
Richardson, William Clarke ...Nottingham.
Smith, John Ord ....Scarborough.
Tod, John ....Coventry.
Wale, George ....New Malden.
Wilkins, Robert Elliott ....Surbiton.
Winfrey, Richard ....Long Sutton.

PRELIMINARY EXAMINATION.

The undermentioned certificate was received in lieu of the Society's Examination:—

Certificate of the University of Cambridge.

Beringer, Heinrich Roland......Redruth.

MEETING OF THE NORTH BRITISH BRANCH.

The second meeting of the session was held in the Society's Rooms, 119A, George Street, on Thursday evening, December 11, 1879. Mr. J. B. Stephenson, President of the Branch, in the chair.

The minutes of former meeting having been read and confirmed, the following paper was read:—

Thoughts on Botany (*continued*).

BY H. B. BAILDON, B.A. CANTAB.

When I had the honour of addressing this Society last session the concluding portion of the paper which I then read was occupied with the consideration of the wonderful and interesting phenomena exhibited by climbing plants: and the reason that the subject was treated of at that time was that, according to the order of progress I have endeavoured to observe, we had come to speak of the ascending axis or stem of the plant. No doubt a great deal more might be said on this plant-spine, which appears in so great a variety of forms, from the crown of the daisy to the column of the pine. One thing may be remarked, as being an obvious generalization, viz., the symmetric manner in which plants of all kinds tend to grow about this axis. It is by no means hard to discern ample natural cause for this symmetric tendency, but still the immense effect of this simple fact on the appearance of the world, must not be ignored, and cannot, indeed, be overrated. At the same time, every plant might have been symmetrical, and yet not exhibited a tithe of the grace and charm which we behold in nature. The marvellous subtlety, complexity and (what one can only call) air of unconcern with which natural forms are wrought into subjection or rather coincidence with this law of symmetry, give rise to that æsthetic power whose operation we so often feel. Take any way-side plant and make an accurate drawing of it in its natural posture, and, if the drawing only be accurate, you will find in it a charm which is best defined by saying that there is a certain symmetry in the distribution of the mass, in the modelling of the form into response and counterpoise of curve and angle, which is, at the same time, secret and subtle in the mode of its execution. Or look in winter at a line of leafless trees, as seen inlaid on the horizon, and you will perceive that, although no two are alike, they have all a certain poise, an air of being delicately balanced, which forms no small part of the æsthetic pleasure they produce. (There are, of course, cases in which they are maimed or warped by injuries beyond complete repair or elemental forces too potent to be successfully resisted.) Plants have been well symbolized—I think by Mr. Ruskin —as vegetative fountains. They do, indeed, rise from the earth with a certain impulse like a spring of water; some like a little bubbling well, some with the aerial grace of a Roman fountain, some as with the strong rush of a geyser. And, as a matter of fact, branch-division, apparently so hap-hazard a proceeding, is governed by the same simple law as rules the division of a water-jet or pipe; viz., that the two branches at a fork have the sum of their transverse sections equal to that of the branch below the fork. But their symmetric development is not the only element in plant-form which goes to feed the spring of that beauty with which so many are endowed. While this symmetry with its air of unconsciousness produces an intense satisfaction in our beauty-perceiving faculties, there is also a pleasure even more subtile and moving created by that aspect of dumb volition and dim but delicate consciousness which so many of the higher plants possess. This is a more recondite charm than the other, and there may be many who hardly notice or realize it, but it is, none the less, actually existent, even as those rays of light, to which our faculty of sight gives no response, and which are only made perceptible by passing through a certain medium, are as really existent as those which the least sharp-sighted can perceive and distinguish. Every plant, over and above that structure which science describes with such laboured detail, has an individuality, a certain mien and air of purpose about it, which is a more prompt and intuitive and yet no less reliable test than the items of a botanical description. And when this individuality is perceived by a man of poetic faculty and power of literary expression, he can hit off in a line that which seems ever eluding the most painstaking scientist. Burns's "Wee, modest, crimson-tippèd flower" is a more clear and readily recognized description, one as sharply individual and incapable of confusion as the most elaborate statement and catalogic definition of Babington or Hooker. It is a description, too, not only general but special, for the three adjectives would not apply to the daisy of the meadow and the wayside, which is rather frank and fearless than "modest," but yet exactly depict the "mountain daisy," found only where it has had some "scanty bield," and therefore with a look of shyness and reserve, such as its congener of the fields never affects. And of this description the immense power arises from the poet's being able, unlike the scientist, to leave the plane of mere physical fact and travel into the moral and emotional; the reason that this is a power being, that there is in the plant just that individualism which we associate with character, and therefore with moral qualities. Nor is such the mere fancy of poetic and imaginative minds, because while such characterization can only be made originally by an imaginative mind, it is, when made, recognizable to many, if not to all. No one, of course, believes that a plant is consciously "modest" in the sense that a human being is, but it is none the less a true symbol of that quality—an unbreathed word formed on the silent, beautiful lips of Nature. And without these symbols how poor and bare language and literature would be! The loss of half-a dozen plants and their symbolism would, in Yankee parlance, "bankrupt" every ancient poet and many moderns. Deprive, for instance, Hebrew poetry of but four—the rose, the lily, the cedar, and the vine—and what is left? Literature so bereft would be like some glorious illuminated missal deprived of its gold, and azure, and scarlet.

Evolution, as I have here accepted it, is a doctrine of progress and of hope, and it would almost seem as though the intellectual current,—which is to the world of life what the electric is to the electro-magnet—grew stronger as the ages ripen. The phenomena, for example, of twining stems, which we lately considered, are more fraught, it would seem, with accurate calculation and foresight than any we have before encountered. But this class of plants must have been of late development, seeing their powers would only be required among a highly developed vegetation. And we shall see further on that a tribe of plants, the orchids—obviously also late-comers —show the most delicate system of adaptation that nature presents. It would thus seem as though external nature, as we know of it in this planet, were becoming more highly charged intellectually as we approach the period of man. Nor can there be any reasonable doubt that whatever were the strange splendours of primæval jungles and forests, the world of to-day is richer and more refined in its beauty. So that, although we have to abandon the conceited conviction, so long prevalent, that the earth, if not the world, was created solely for the delectation or edification of mankind, we may console ourselves with the knowledge that we dwell in so ripe an age of the planet, and are so beset with beauty and instruction.

But we must cease marking time at our very starting point, and make an advance, which advance brings us to what is perhaps most significant of all plant organs, the leaf. One cannot congratulate the botanist on the felicity of his definition of a leaf as "an expansion of the bark," a phrase conveying just as little information on the subject of the nature of a leaf as is well possible without its being an absolute contradiction of fact. It is, indeed, incorrect—as incorrect as to say that the hand is an expansion of the skin. A leaf is rather a sub-division and expansion of the stem, over which the bark is stretched—even as the skin over the human hand or over the webbed foot of a bird. The midrib, veins, and nerves of a leaf correspond to the bone, cartilage, and muscle of an animal's limb. This alteration renders the definition much more consistent with the other doctrine of modern botany, that a plant consists of an axis, stem, and leaves —its primary divisions. For, as soon as we get beyond the very simplest organisms, where the organs are undifferentiated, and the functions—afterwards performed by the various plant-organs—only exercised by the general surface of the vegetable mass, we come to the differentiation of leaf and stem, the one the central, the other the radial, the one representing generally the vertical impulse, the other the centrifugal. Structurally considered, then, the leaf might quite well be defined as an expansion of the stem—an expansion existing long before any bark, even in its broadest sense, is discoverable—but, functionally, it is better described as an aerial rootlet; for the stem itself, like the rootstock, the more distinctly it becomes a stem, the more completely discontinues any direct nutritive action, while the leaves always remain operative in that respect, although their function again becomes clearly differentiated from that of the rootlets. And, even in this reference, our analogy of a leaf to the hand is singularly appropriate. What are leaves but so many searching, suppliant palms, held out for the alms of the physical heaven, whereon its largess of rain, and dew, and sunshine is outpoured? But more instructively and accurately may we take the hand and arm as analogous to the leaf and its petiole—it is a vegetable limb in which we have all varieties of proportions between hand and arm—some all hand and no arm, some all arm and no hand.

There is certainly no theme in connection with our subject more embarrassing, by reason of its extreme fertility, than this of the leaf. Whether we regard it in view of its function in plant economy, in respect of its utility to the plant itself, or consider its variety and beauty as a source of refined and ennobling pleasure to man, the theme is alike capable of indefinite expansion. Though, with regard to the former, it may justly be said that any signal failure in utility in a plant-organ would mean the certain and speedy extinction of the plant; for, while nature often exhibits the dignity of repose, she has obviously no faith in the nobility of idleness, and adopts certain methods of exterminating the idler. Even when we find that portion of a plant, which we would botanically designate the leaf, failing to fulfil its usual offices, we will still find it told off to a specific duty, while its function is assumed by some other organ; for nature's inevitable condition of ultimate continuance is utility—is the discharge of some essential office. No doubt, in the course of evolutionary progress, certain organs may become unnecessary and rudimentary without being obliterated, but they bear in themselves the sentence of death, and must eventually disappear unless they can make themselves useful and necessary in some new manner. Nothing can be more thoroughly just than such a law—one pervading creation, not excepting the moral and spiritual nature of mankind. Activity tends to strength and development, inaction to weakness and loss. The principle is so universal, and apparently self-demonstrative and automatic, that we give nature no credit for this exact equity of hers, although the supposition that a world might have existed, in which a different law was operative, is by no means so wild a conception as is often seriously entertained by scientific men. But it is the fashion now to discount the virtues of nature, as though they were something inevitable, while it is considered quite allowable to stigmatize her as cruel, merciless, and so on, because the earth will not get out of the way of a falling body, which happens to be human, or water declines to support an organism heavier than itself, because that organism has a wife and family to mourn his loss. Nature is sublimely impartial, and therefore intensely just. Any confusion between moral and physical condition, any deviation from the rectitude of law in the direction of that spurious form of justice which we call poetical, and which is merely sentimental, would involve an unreason, a chaos, and a complete loss of those characteristics which convince us of the sanity and stability of the cosmos. We can, in this case at least, claim for nature a justice which, if often terrible, is always majestic.

What most compels our astonishment and admiration, in regard to the utile aspect of leaves, is the infinite variety of form, and even method, they exhibit, along with a perfect equality in point of fitness. It would be, I think, impossible to make corrections on nature, and say in any case that, from the plant's own point of view, its present form of leaf could be advantageously replaced by any other. This is doubtless accounted for by such a doctrine as the survival of the fittest, but it is certainly fortunate for us that the fittest should have included so great, so useful, and so delightful a variety. But the question is, how came the fitness? Whence this accommodating power of organisms? A hap-hazard variation it can hardly be, for the advantages of many forms can only have come into play when the change has been carried out to a pitch approaching perfection. Take such a case as the floating apparatus of the Urticularia.

"Small *ascidia* or sacs are connected with the leaves, which, about the time of flowering, are filled with air, and buoy the plant to the surface. The opening of each sac is surrounded by forked hairs composed of four cells, and is closed by a transverse cellular membrane, like the valve of a pump, capable of opening from without inwards, and which resists when it is pressed from within outwards. The physiological action of these ascidia is full of interest. At first they are filled with a somewhat gelatinous liquid, which by its weight assists in retaining the plant at the bottom of the water. Very soon the branching hairs already described, which project into the interior, secrete a gas, which accumulates as the gelatinous substance diminishes. By and by, when the vessels are full, the plant gets light and buoyant, and, disengaging its roots from the soil, rises to the surface of the water and flowers. The flowering over and the fruit mature, the air disappears from the ascidia, the valve allows the water to enter, and again the plant sinks to the bottom, to remain there until spring stimulates its ascidia again into activity." (Brown's 'Manual of Botany,' page 158.)

Unnecessary and almost irreverent does it seem to offer any comment or commendation of a system of contrivances so ingenious and so adequate. Had such a system been suspected to be of human origin, we could not praise too highly the inventive genius and scientific acquirements therein displayed. But being only a piece of nature's handicraft, we are now taught that there can be no ingenuity or wisdom or foresight involved in its construction, but that it has somehow been blindly sculptured into its present form, through the influence of its varying environment. That this interaction of organism and environment is and has been a most important creative factor, operative and potent to an extent which at one time would not have appeared credible, it is not my wish to deny. None the less distinctly do I maintain, that, so far as my imagination and reason can carry me, I quite fail to see how this agent could, apart from some pervasive intelligence in nature, give rise to an organism whose structure, seems to involve, not only an accurate knowledge of hydrostatic and mechanical science, but the inventive and executive powers to bring that knowledge to practical effect. For this is what I fail to see, how a slight accidental variation in the direction of this system could be of the least use to the plant. Anything short of a perfect adjustment of the apparatus would be useless or worse. Of what use, for example, would the ascidia be, if the gas were not evolved in the necessary amount to buoy up the plant?—they would be mere ballast to keep it down. Or if, on the other hand, the ascidia began as mere air-bags, the plant must be continuously at the surface and could not in this way acquire its extraordinary habit for leaving go with its roots. The only explanation, then, that we pretend to give of such an elaborate phenomenon is, that it is apparently the work of intelligence of a very high order, and that apart from such intelligence we fail to understand its origin. In employing this argument, we certainly rely somewhat on the analogy between the works of man and those of nature. We know that the construction of a machine and the creation of a work of art involve certain pre-existent powers and qualities in the man who produces them. So in like manner we argue that we can infer the existence of an intelligent Power from the existence of intelligence-involving structures in nature. There is only one method of escaping this conclusion, and this method is adopted by Professor Clifford and others antitheistic writers, and is to deny point-blank the validity of the analogue, and to maintain that although there may appear to be the same or greater amount of thought involved in the construction of some natural objects as there is in some human work, still the former is not necessarily the work of intelligence although the latter is. But there is no attempt, so far as I know, to disprove the validity of the analogue; it is simply and brusquely denied. Yet it appears to me, being one at once so obvious and so conclusive to the majority of human minds, that it cannot be thus peremptorily dismissed, without some reason given. For to deny it, is entirely to block the way of any progress in the philosophy of nature, unless we are to dignify a purely materialist science, quite devoid of any intellectual, moral or spiritual significance, with that name. It is to land us in a complete ignorance of nature, except from the strictly physical side; it is to abolish at once the religion, the philosophy and the poetry of nature. That such denial hamstrings at once the argument in favour of the action of intelligence or any moral quality in nature is no more proof, however, that there is truth in the denial, than the fact that it is open to any one to deny the postulates on which the whole of a science, such as Euclid's geometry, depends, disproves the truth of the postulate and the dependent science. One necessary geometric postulate is that two straight lines cannot enclose a space. Anyone who choses to deny this at once deprives you of the power of convincing him of the truth of the first book of Euclid. Or to take a still simpler instance, a man might say he did not see why two and two always make four; and he would put it out of your power to prove to him the simplest proposition in arithmetic. Similarly to assert that the nice adaptation and ingenious contrivance observable in nature, is no sign of intellectual design, renders it impossible to prove to the assertor anything whatever as to any moral or intellectual qualities otherwise deducible from the facts of the cosmos.

In the decoration of this our beauty-abounding planet, the leaf is certainly nature's most effective instrument. Whether it be the pleasant verdure of field and lane, the soft reposeful masses of blending woods, or the solemn majesty of pathless forest that we regard, we cannot but attribute much of their beauty to the foliage in which they are clad. And if natural landscape owe so much to the leaf yet much more does each individual plant.

The green colour prevailing in leavage is an oft-acknowledged and a real source of satisfaction to the eye, and that although this same colour is the most difficult for a painter to reproduce successfully—that is to say, in such a manner as to cause a repetition of the same satisfaction. The older masters, whose colour is the wonder and despair of modern artists, banished it from their landscape-distances, and the daring Turner constantly evaded its use. Nature seems to possess some still undiscovered art, some secret principle which enables her to use that colour with an effect the ablest artist has not yet acquired. No one ever saw a complexion spoiled by the proximity of a green leaf, however many have fallen victims to a green ribbon.

Then in texture how various, coarse and homely in the dock and nettle, harsh though handsome in the elm, silken in the beech, lacquered in the oak, and burnished in the laurel; like leather, like paper, like velvet, like wax, like metal, like cloth, and unlike all these things: and in form still more diverse, and nearly all beautiful either by reason of individual design, or by virtue of combined effect, and through the union of these. In beauty of individual form we must, as before, accord the first place to some of the more elaborate and lovely fern fronds, but of charm of combined effect almost any branch or plant will afford us illustration. No matter how simple the original form, nature can elicit from it shapes of grandeur and of grace, as the pine and the larch may witness. Many a wayside weed, too, as we call them, displays when we study its form an elegance, a daintiness of outline, produced from leaves of humble and simple form. The sources of this charm are obedience—firstly, to the well-known law of phyllotaxis or leaf-order; and, secondly, to the less known of leaf-proportion; the former governing the position of leaves on the stem, the latter the variation in size and shape that they exhibit in their upward course. As to the former, not only is the general mode of growth spiral but each plant, and frequently whole orders, adopt one particular pattern of leaf-order. If we liken a plant to an ascending jet of water, giving off drops from the central column, we must, to complete the resemblance, suppose this column to have had a rotatory motion about its axis, so that the drops, instead of being given off in rings, would be given off in a continuous spiral. In a pine-cone the scales come off in close succession, just as drops would from a revolving fountain, but in other plants a rhythmic pause is observed, so that the leaves stand at distinct and definite intervals along the stem. Some are like rhymed couplets, two and two at measured intervals, some as the notes in a chime of bells or the endings in a stanza respond after a longer space and in a more complex order. And through this suggested simile we can understand how a plant-form may give an ever fresh pleasure to the eyes, even as a familiar verse or well-remembered cadence may give unpalling pleasure to the ear

What I have called the law of leaf-proportion is more clearly exemplified in the subtle, gradual diminution in size, accompanied often by even more subtly managed modification in shape, which leaves show in their ascent of the stem; that delicate fining off of the foliage preparatory for the final transition into flower. It is not difficult to understand that this is perfectly natural, that is in perfect accord with other mechanical forces and phenomena in nature, but this only argues toward the praise and admiration of natural law, not toward a contempt for its fruit. The mechanical laws of nature are never contravened, the apparent contravention being always obtained by a real obedience. Man, for instance, can produce the apparent contradiction of making water pump itself to a height greater than its original source, and that on the simple fact that two pounds of water falling one foot will raise one pound two feet. So can nature make the lower mechanic force available in support of the higher vital action without any violation of the laws of the former. And the wonder is not how, being constructed as they are, plants ascend into the air and take such a course, but where did they learn the art of so accommodating themselves to surrounding forces—forces which gave no promise or prophecy of such a development of nature?

There must, doubtless, have been a time in the history of the planet, when foliage was even a more prevailing element in nature's adornment than it is now; for we shall see, when we come to treat of the flower, that the more conspicuous and brightly-coloured blossoms have been evolved through the instrumentality of insect fertilization. Time was ere nature seems to have dreamed of the violet or the primrose, still less of the rose, the lily or the orchid, when vast green-waving savannahs rolled for leagues without a star of blossom, and sombre, pathless forests stretched their stately aisles and solemn verdant vistas unlit by the sweet face of any floret—ere snowdrop, on her pensive bells, rang in the spring-tide, or rose blushed in the summer, or the faint autumn crocus lent its timid beauty to the fading autumn fields. Fair enough, then, doubtless—too fair for the rude sense of the behemoth and his huge companions, but not yet fair enough for that strange prodigy of the ages, man—nature had yet to deck herself as with bridal raiment for the coming of her first mate and conqueror and monarch.

"The flower," say the men of science, "is a modification of the leaves;" and this truth, though it be partial, is instructive. If it be held merely to mean that the original elements of the two are similar—that, in point of fact, in the earliest stages of their formation they are identical and indistinguishable, so that the embryos, as we may call them, have a possibility of becoming either the one or the other, it is true. But if it means, as it seems sometimes to be put, that the flower is made up of unsuccessful leaves, of leaves that have failed to become leaves, it is a misleading doctrine. Morphologically considered, as throwing light on the structure of the flower, it is valuable and illuminative, even as the anatomical doctrine that the skull is a mere folding-in and modification of the spinal cord, is a convenient and instructive hypothesis for the anatomist. But looked at from a more central and philosophic stand-point it is far more correct to say that the flower is the culmination of the plant, the apotheosis of the leaf, and the brain the culmination, the crown and capital of the animal organism. That the flower is not simply the result of the failing of the growth-current, as the foam is the produce of the breaking wave, is proved by the fact of flowering frequently preceding foliation, and is corroborated by the certain knowledge we have that flowering is a more exhaustive process—a process requiring greater energy than leafing. The assertion, then, that petals are degraded leaves is absolutely false—as false as to say a man is a degraded boy. The petal is rather a refined and sublimated leaf than one that is fallen from a higher estate. One might as well call a perfect lady a degraded peasant; what is persistently left out of sight being that what is lost in vigour and force is gained in delicacy and refinement. Even if we accept as flowers all that are scientifically so called from their functions, it may safely be asserted that they display a yet finer and more finished workmanship—a material more dainty, and pure, and rare than that of the foliage. Though it must be admitted that the decorative importance of the flower varies, so far as we estimate it by ordinary powers of vision, from a position of complete supremacy to one of comparative insignificance—from the splendid atonement of the bizarre cactus to the unobtrusive florets of the majestic oak. Yet many quite inconspicuous flowers contribute greatly, if not permanently, to the beauty of plant-form. The airy and tremulous catkins of the birch, that seem to shake with the same conscious charm as the trembling pendants in the ear of a beauty at her bath; the green rosettes of the elm, that render rich the broidery of its branches against the soft cloud or tender twilight of May; or the carmine tufts that gem the greening branches of the larch, may be brief in the cycle of their beauty, yet make no small part of nature's spring-tide witchery.

Of the means through which flowers have been evolved from the less conspicuous and attractive forms to those of the highest beauty and splendour, a flood of light has of late years been thrown by the original and interesting researches of Darwin, Wallace, and others. These have laid bare to us, at least in many places, what we may call the industrial system of nature. We see, for the first time as it were, the very movement of those shuttles and spindles that are continuously weaving the web on nature's unresting, unhastening loom. There is displayed to us that complex and efficient machinery, that blessed conspiracy of minute and obscure causes, that elaborate and delicately-adjusted correlation of divers agencies, through which all that is delightsome or wondrous, strong, strange, or potent in nature has been evolved, is sustained, cherished, and perfected.

The aim of nature is progress, and her method competition—every organism is on its mettle to sustain itself and its successors against foes and rivals. But it is a competition, not blind and mechanical, but organized, complex, and intelligent. The function of every organism is dual—to sustain, improve, and increase itself, and to provide for its successor. In the first it is purely self-seeking, in the second it is rather self-sacrificing; and it is instructive to note that it is to this latter and renunciative act that the energy, effort, and contrivance of plants are the most intensely directed. No doubt many plants survive the act of reproduction, though by no means all; at the same time, the flowering and fruiting of a plant is the most exhaustive and perilous of its actions. To many the act is necessarily and invariably fatal. Through these two forms of activity, the productive and the reproductive, the energy of the organism is directed towards the development of its species. The power of advance in each individual is very limited, but the power of a long successive series is indefinitely great. Each organism has a certain latitude of change—a certain range of variation, through which it is at liberty to move; its successor has a latitude no greater, but measured from a new point, and that this new point may not tend to coincide with the old, and so the organism relapses again to its old condition, the edict of inter-marriage or cross-fertilization has been pronounced, and in the execution of this law no pains and no means are spared, from those comparatively primitive and simple to those most elaborate and exact.

At first sight the proximity in which the organs of sex are usually found to each other seems to point to self-fertilization as the object of this arrangement; but a closer and more intelligent examination has led to the establishment of the dogma that nature abhors self-fertilization, or, if that be too strong a manner of expressing the fact, that nature aims at and prefers cross-fertilization. It has further been established, through the unwearying and sagacious investigations of Dr. Charles Darwin, that cross-fertilization contributes, not only to introduce variety, but also tends to the invigoration and what we may call improvement of the species by which it is practised. As a rule self-fertilization is but a last resort in the event of the stigma failing to receive or come in contact with pollen from another plant.

To enumerate and describe even the most striking instances of the means which nature takes of carrying this her edict of intermarriage into execution would itself be work enough for one evening, so that I must be content with a few illustrations. There are, as most of you know, three agencies through which this process is accomplished, viz. the wind, insects and birds. A very large class of plants, such as the grasses and many forest-trees, depend on the wind for the distribution of their pollen, and it might seem that with so comparatively rude an agent it would be difficult to secure crossing with any certitude. By several very simple expedients the desired end is aimed at and accomplished. In all the grasses, for example, the stamens when ripe dangle outside the floret, so that, when their light dry pollen is carried away by the breeze, little or none can reach its own stigma which is sheltered by the glumes; and in many cases a yet more certain provision is made in the ripening of the stigma before the stamens, so that by the time its own pollen is mature the stigma is already pre-occupied and fertilized by other pollen or is effete and no longer capable of being affected by its own. Again in many plants, notably in the willow and other trees, crossing is rendered imperative by the individual plant producing flowers of one sex. But this method of wind-distribution is rude and clumsy compared with the subtler and more refined methods that occur in nature. In the first place it is extravagant, involving the production of an immense amount of pollen, the majority of which necessarily misses its mark; and secondly, while it obviously tends to produce and encourage that elegance and refinement of form which gives their charm to so many of the grasses, and the grace and shapeliness of catkin and cone, it does not tend to elicit and foster those so delightsome qualities which we all associate with the popular idea of what a flower is, viz. colour and odour. There may have been, and probably has been, a period of the earth's history in which the wind was the only go-between in the vegetable world, and if we can conceive of a human intelligence existing at that epoch and entering into the spirit of the creative method, and at the same time having discovered that the means of developing colour and odour lay latent in the plant-world, we can believe that such an intelligence with such data could have prognosticated that nature would develop some new method by which these latent qualities would be elicited. What such method and agency was to be it might have been beyond his power to predict, but this much might have been foretold, that the new agency must be of a more discriminative character than the old. To fulfil this office, or at least with the capacity for fulfilling this office, a great number of the insect world have come into existence.

Now, while it is easy to understand the action of this system of insect-crossing and to note its necessary effects on the colour, odour and shape of flowers, *now that it is in full working order*, it is by no means easy to understand or imagine how it took its rise. How did the first dawnings of colour-sense in the insect operate to produce the faint beginnings of coloration in the flower? They seem to have grown up side by side. Whence came the initial impulse that started them on their mutually involved orbits of progress? That same onward and upward tendency which characterizes nature, and without which its progress is not to be accounted for. But, before we grapple with such a problem, let us see the working of the system in some few instances.

It is surmised, not without strong probability of truth, that the first method adopted by plants to encourage the visits of insects was merely the production of an abundant supply of pollen upon which many insects—especially the Diptera—feed; but this comparatively rude and extravagant plan has been superseded in the more highly developed flowers by that of honey-secretion. That honey was ever a "waste product" of the vegetable world, I am certainly inclined to doubt, as being a fact inconsistent with the economic reasonableness of nature. Certain it is that in nearly, if not in all instances, in which this delicious product is found, it clearly performs a service to the plant that secrets it; and in most cases the nectaries and honey-hollows are so accurately and wisely placed that they seem absolutely to ensure the execution of that service for which it is meant, to attract and to reward its insect visitors. But that a plant should offer a *douceur* to its visitants is not enough, it must also make its presence notable to them at some distance; and this is effected by two means, colour and odour. Brightness and purity of hue are, no doubt, the most advantageous qualities for a flower to possess; but diversity is also necessary that insects may recognize those plants to which they are specially adapted. That some insects, at least, have a decided sense of colour has been proved by Sir John Lubbock. This being so, there is no difficulty in seeing that the development of bright and pure colour is encouraged by this relation, and that certain flowers would have an advantage through being distinctive, in which reference it is worthy of remark that the orchids and other highly specialized flowers have a tendency to extreme individuality of form and marking. Even those delicate pencillings of colour such as we find so markedly in the pelargoniums are not without their utility, and are believed to act as honey-guides in pointing the way to the nectaries; and perhaps nowhere is the union of utility and beauty more wonderfully instanced than here. But nature is too industrious to strike work with failing light, when colours are no longer easily perceived or distinguished, and in order to utilize the dusk and even the dark, she has gifted flowers with the power of manufacturing perfumes by which to communicate with and attract night-flying moths, which are absolutely necessary to the fertilization of some flowers. The following description by Sir John Lubbock of the behaviour of *Silene nutans*, is an excellent example of the manner in which a flower utilizes the visits of moths:—

"The upper part of its flowering stem is viscid, from which it has derived its local name, the Nottingham Catchfly. This prevents the access of ants and other small creeping insects. Each flower lasts three days or rather three nights. The stamens are ten in number, arranged in two sets, the one set standing in front of the sepals, the other in front of the petals. Like other night flowers, it is white and open towards evening, when it also becomes extremely fragrant. The first evening, towards dusk, the stamens in front of the sepals grow very rapidly for about two hours, so that they emerge from the flower; the pollen ripens and is exposed by the bursting of the anthers, so the flower remains through the night, very attractive to and much visited by moths. Towards three in the morning the scent ceases, the anthers begin to shrivel up and drop off, the filaments turn themselves outwards so as to be out of the way, while the petals, on the contrary, begin to roll themselves up, so that by daylight they close the aperture of the flower, and present only their brownish green outsides to view, which, moreover, are thrown into numerous wrinkles. Thus, by the morning's light the flower has all the appearance of being faded. It has no smell, and the honey is covered over by the petals. So it remains all day. Towards evening, however, everything is changed. The petals unfold themselves, by eight o'clock the flower is as fragrant as before, the second set of stamens have rapidly grown, their anthers are open and the pollen again exposed. By morning the plant is again asleep, the anthers are shrivelled, the scent has ceased and the petals roll up as before. The third evening again the same process, but this time it is the pistil which grows, and the long spiral stigma on the third evening takes the position which on the previous two has been occupied by the anthers, and can hardly fail to be dusted by the moths with pollen brought from another flower."

This one instance exemplifies, in addition to its beautiful correlation of plant and insect life exhibited in the arrangements for moth-fertilization, the defensive contrivances of nature and the rationale of plant-sleep. While there are certain insects which it is beneficial for the plant to attract, there are others whose visits would, if not injurious, be at least unprofitable, and against these plants are protected in a variety of ways by hairs, hooks, prickles, viscidity, and other defences. This fact is very significant and extremely difficult to account for without assuming consciousness in the plant or an intelligent power directing its development. There is something, too, touching and poetic, while eminently reasonable and in harmony with cosmic custom, that the plant, like the animal, should take its diurnal or nocturnal period of repose; nor is there any doubt that the plant opens at the time most advantageous for itself, and closes when it would be unnecessary or injurious to remain open. Then the whole arrangement is so complex, as well as complete, that any series of tentative variations, however numerous and extended over how-long-soever a period, does not seem capable of accounting for the perfect adjustment of the action and structure of the plant to an agency so diverse and independent. But I must be allowed to give an instance, if possible more startling in its ingenuity of contrivance. It refers to the fertilization of a tropical orchid, one of the Coryanthes, as observed by Dr. Crüger. He found that the labellum of this orchid is hollowed into a great bucket, in which drops of almost pure water continually fall from two secreting horns which stand above it, and when the bucket is half full the water overflows by a spout on one side. The bare part of the labellum stands in the bucket, and is itself hollowed out into a sort of chamber with two lateral entrances; within this chamber are curious fleshy ridges. The most ingenious man, if he had not witnessed what takes place, could never have imagined what purpose all these parts serve. But Crüger saw crowds of large humble bees visiting the gigantic flowers of this orchid, not in order to suck nectar, but to gnaw off the ridges within the chamber above the bucket. In doing this they frequently pushed each other into the bucket, and, their wings being thus wetted, they could not fly away, but were compelled to crawl through the passage formed by the spout or overflow. Dr. Crüger saw a "continual procession" of bees thus crawling out of their involuntary bath. The passage is narrow, and is roofed in by the column; so that a bee, in forcing its way out, first rubs its back against the viscid stigma, then against the viscid glands of the pollen masses. The pollen masses are thus glued to the back of the bees which first happen to crawl out through the passage of a lately-expanded flower, and are thus carried away. When the bee, thus provided, flies to another flower, or to the same flower a second time, and is pushed by his comrades into the bucket and then crawls out by the passage, the pollen-masses necessarily come first in contact with the viscid stigma and adhere to it, and so the flower is fertilized. Had any human being invented such an arrangement we could not fail to credit him, not only with an exquisite inventive faculty and power of precise adaptation of *means* to an end, but also that form of practical imagination that could foresee the "crush at the door," and the consequence of the ducking on the conduct of the bee. Almost a sense of humour seems to be involved in the structure, since the whole proceeding is just an excellent and innocent practical joke at the expense, without the injury, of the insects, who seem in no wise deterred or offended, but ever ready to renew the fun. Now, the case of this orchid, if very striking, is by no means exceptional; it is rather the general rule, in such genera as the orchids, to possess some equally ingenious contrivance. But one more illustration on this topic, and I must desist. In Mr. Belt's 'Naturalist in Nicaragua' he gives this account of the manner in which small birds, such as humming-birds, are employed in fertilization. "A climbing plant (*Marcgravia nepenthoides*) expands its flowers in a circle, and these hang down like an inverted candelabrum. From the centre of the floral circle and underneath the flowers there is suspended a number of pitchers, which are full of nectar when the flowers are ripe. The honey attracts insects and the latter attract birds, especially humming-birds. Before the latter can get at the honey-bearing pitchers, their backs must brush the open flowers out of which the pollen is ready to be shed, and in this manner they convey it from plant to plant and cross the flowers." Such a proceeding on the part of an animal would cause us to assign to it a rational mind, with the power of correct inference; for the secrction of honey is not for the prior purpose of attracting insects, in themselves not useful, but for the ulterior purpose of securing the visits of the birds which are necessary to the crossing of the flowers.

If such things can be produced by the mere incessant jostling of atoms as in a lucky-bag, if the work of consciousness can be more perfectly accomplished by that which is unconscious, and the part of intelligence better played by the unintelligent, then must we admit that consciousness is but a cloud, and intelligence a thick veil, and thought a diseased and mistaken evolute of divine imperturbable matter! Not that I mean in any way to gainsay the fact that the creative process is not historically graduated, or, as it is named, evolutionary. That, I think, no enlightened and well-informed person can seriously doubt. What I do deny is, that this process is to be accounted for on any hypothesis which undertakes to dispense with the necessity for previsive and controlling intellect. To deny the existence of such intellect is like denying the fact of atmospheric pressure, because we do not feel it; for the reason that the working of creative intellect does not obtrude itself upon us, is just the same as that which makes us unconscious of the miles of atmosphere piled on us, viz., that it acts equally in all directions and at every point successfully combats itself. Thus in nature ingenuity of attack is met by ingenuity of defence, elaborate needs are responded to by equally elaborate machinery and contrivance. The impartial thoughtfulness of nature puzzles us. We are offended to find the existence of a noxious weed, insect and parasite cared for as tenderly as man's. But everything in nature, man not excepted, is to be put on its mettle, the great meaning and moral of nature is activity and progress, and one of her greatest functions is to stimulate man even by what seem hardships and cruelties to yet intenser and more divine activity. Where nature is lavish and indulgent, man becomes indolent and often degraded. Nature pronounces thus for industry, but not for industry alone. She endorses, yea, rather anticipates the dictum of Mr. Ruskin, "Life without industry is crime; industry without art is brutality." While no organism can survive without the full exertion of its powers, and even the effort after advancement, neither is there any that does not tend to some beauty, that does not obey, in measure, however humble, the laws of grace as well as that of gain. The coarse and vagrant Colt's-foot that bastes together with straggling rootlets the loose soil of the embankment or the fallow, the slovenly and trampish Dock and its shrewish consort the Nettle, have their aspects and moments of fitness, and seem often, like Wordsworth's gypsy, "Weeds of glorious feature." Yet these are the mere idlers and runagates of the plant-world, outlawed from the civility of the park and lawn, where the Buttercup, and Daisy, and Cowslip are as invited guests.

But time presses, and however unfinished be my theme, it must now be left as it stands, and I must rather leave you to expand the line of thought for yourselves, and to draw from the significant facts I have mentioned their inevitable deductions. The researches and results of modern science, instead of in any wise detracting, to my mind, from the wonder and beauty of the cosmos, and the reverence we feel for its imposing and still, in a great measure, mysterious order, rather increase the wonder, emphasize and illuminate the beauty, and deepen into awe that reverence. So let science go on unafraid to the darkest and furthest recesses of nature, strong in the assurance, fearless in the faith, that nowhere can she miss the footprints of a supreme pervasive intelligence, nowhere find herself in a region alien and unresponsive to reason, nowhere fail, though she alight on the furthest star, brood over the strife of primæval atoms, or read the riddle of life's beginning, to perceive and devoutly acknowledge, "Thou art there also!"

Apothecaries' Weights and Measures.

Mr. Mackay then made a statement regarding the new weights and measures. After referring to the discussion which had recently occupied an entire evening in Bloomsbury Square, he proceeded to describe the standards, which by the kindness of Mr. Chaney had been sent along for the purpose of being exhibited and explained by Dr. Paul. He specially referred to the mistaken idea which many seemed to have regarding the standards, and explained very fully that the standards as devised and prepared at the Standards Office were meant to be really, as the name implied, standards proper, and not standards to be carried round by the various inspectors when they made their visitations with a view to examine and verify glass measures. He also stated that he had seen the inspector of weights and measures for the city of Edinburgh, who up to the present had not received the standards from London. The authorities had, however, adopted the mark proposed, and instead of the "City Arms" being now used in Edinburgh as the verifying mark, the local authority had given instructions to have prepared what the Standards Office had already suggested for general use—namely, the outline of a crown with V.R. underneath surrounded by an oval line and with a number immediately below. The number allotted to, and adopted by, Edinburgh was 3, each figure having a direct reference to the district using it. The verifying mark may probably, therefore, in future be alike in all places, the difference being in the numbers only. The fees in this locality will be exactly as prescribed in the schedule of the Act, the inspector having no interest whatever either in the fines for erroneous measures, or the charges made for comparing and verifying. This he thought a much better plan than to allow officials to supplement their salaries in what appeared to him (Mr. Mackay) a most objectionable manner. It would appear that while local authorities are the parties to work out details under the Act, and appoint their own inspectors, they have no power to alter the specified charges unless by a distinct resolution brought under the notice of the

Board of Trade and agreed to by it. Mr. Mackay further mentioned that since the meeting in London he had ascertained that even in Guildhall there were no standards yet ready for use, and saw a considerable number of graduated measures sent there to be marked returned with a message that they were not yet prepared to verify dispensing measures. He also had seen an extensive maker and dealer in glass measures who had just come from the Standards Office with the information that it would be some time before the inspectors would be in a position to verify, and probably a year or two before every district would be able to do what was required. From the same source he received undoubted information that while a compound measure, that is a 16 drachm graduated glass, verified as such, and marked on the opposite side with ounces and half-ounces, might not necessarily be considered in the terms of the Act a *legal* measure, it would certainly in all cases be *allowed* wherever the graduation was found to be correct and marked as such by the inspector of the district. He further intimated that he had received a promise from the inspector of the City of Edinburgh, that whenever he had received his standards from London, and was in a position to verify the weights and measures under the new Act, he would communicate with him as Local Secretary of the Society, and on receiving such information Mr. Mackay promised that he would, without delay, make the same known to the chemists and druggists in the city.

Mr. Gilmour rose for the purpose of complimenting Mr. Mackay on his lucid and exhaustive exposition, and took occasion to vindicate the inspector in Edinburgh and himself from the remarks made in the leader of the Journal, November 29, and also at the Evening Meeting in Bloomsbury Square. He still thought there might be an uncertainty about the legalizing of the different denominations on one measure, but still as Mr. Mackay put it he hoped that the present style of measure would be at least allowed. He felt assured that in a short time the question would assume a definite form, but meantime every view of the subject should be tolerated and examined, considering how much uncertainty still prevailed as to the exact scope and requirements of the enactment in its relation to the business.

Some discussion then took place, in which Mr. Stephenson and Mr. Young took part, at the close of which the meeting seemed satisfied that nothing could be done for the present, and that existing apothecaries' weights and measures, might be safely used until the arrival of the standards.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifth general meeting of the thirty-first session was held at St. George's Hall, on Wednesday evening, December 10, together with the Literary, Scientific and Art Societies of Liverpool, as an associated *soirée*, under the presidency of Mr. A. B. Forward, who occupied the chair, in the unavoidable absence of the Mayor. This was the third annual *soirée* of the learned societies of Liverpool, and nothing could have exceeded the brilliancy of the scene when the handsome and spacious suite of halls was thronged with between three and four thousand people. The proceedings were somewhat similar in character to those of the two preceding *soirées;* consisting of concerts, lectures on scientific and other subjects, and the exhibition of microscopical objects, antiquities, curiosities and works of art.

On behalf of the Liverpool Chemists' Association, the President, Dr. Symes, delivered a popular lecture in the Sheriff's Court, entitled "The Philosophy of a Tea-kettle;" and the Vice-President, Mr. A. H. Mason, F.C.S., delivered one in the Crown Court, entitled "The Chemistry of a Candle." The lectures were liberally illustrated with experiments and diagrams, and were highly appreciated by the respective audiences.

The Association exhibited a fine collection of alkaloids and rare inorganic salts, from its own museum, and the following firms kindly lent collections for the occasion, which were also exhibited:—

Mr. Thomas Whiffen, London: A very fine collection of the various cinchona barks; and a series of alkaloids and salts, representing the chemical principles of the bark.

Messrs. Hopkin and Williams, London: A selection of rare chemicals, etc.

Messrs. Coghill and Son, Liverpool: Specimens of boracic acid and gigantic borax crystals.

Messrs. Howard and Son, Stratford: A large album, containing a drawing of Count Lardarel's famous boracic acid springs and works, in Tuscany.

Messrs. Symes and Co., Liverpool: Pure metallic bismuth in fine crystals, and a variety of bismuth compounds; chemical and physical apparatus; the latest kinds of blast furnaces, blow-pipes, etc.

Messrs. Hallawell and Co., Liverpool: A variety of coal tar colours, arranged so as to illustrate the marked difference between the dry colours and their solutions.

Messrs. May and Baker, London: A series of mercurial products, illustrating the chemical combinations of mercury.

Messrs. Johnson, Matthey and Co., London: A very valuable selection of rare metals; platinum vessels; and extra fine metallic wires 0·001 inch diameter, showing weight of each per mile.

Messrs. P. Harris and Co., Birmingham: Hughes's audiometer; electric induction balance; cycloscope; and fine models of crystals in glass.

Messrs. J. C. and J. Field, London: Specimens of the various crude materials used in the manufacture of candles.

The gathering broke up at about 11 o'clock, evidently well pleased with the evening's entertainment.

LEEDS CHEMISTS' ASSOCIATION.

The second lecture of the session was given on Wednesday night to the members and associates of the Leeds Chemists' Association (the President, Mr. Councillor Stead, in the chair) by Mr. T. Fairley, F.R.S.E., on "Glass: Its Manufacture and Mode of Working."

The lecturer gave a short history of the manufacture of glass, showing that it was well known in ancient times. He explained its formation by the action of sand or any kind of silica on bases, such as soda, lime, potash, etc., at high temperatures, forming silicates, but that at least two bases of different kinds are required to form a true glass. Thus silicate of soda is soluble in water and in common with other simple silicates is easily decomposed. He stated that there were four well-known varieties of glass, viz.:—Bohemian glass—a silicate of potash and lime, crown or plate glass—a silicate of soda and lime, crystal glass—a silicate of potash and oxide of lead, made only from pure materials; and one other, ordinary bottle glass, resembling crown glass but made from the commonest materials. He referred to the sources of the materials, and the influence of the development of modern chemical manufactures on that of glass. The lecturer then passed to the relations between the composition of glass and the properties possessed by it, especially as regards fusibility, brilliancy, and the durability of the glass obtained, and showed how the latter is also affected by various substances and reagents, and illustrated his remarks with specimens showing the action of water, of alkaline solutions, and of hydrofluoric acid (as in the process of etching) on glass. The irridescence shown on certain glass was due to a surface decomposition either by long continued action of moisture, as in glass buried in the earth, or of moisture and ammonia, as in some old windows; or irridescent glass might be made artificially, as was now done, by the action of a hot atmosphere of hydrochloric acid gas. The lecturer also described the changes produced in glass by heat at various temperatures and the application of these in the manufacture and working of glass. He explained the tendency shown by glass to become in some degree crystalline when kept long at the softening point. The same change took place very slowly at ordinary temperatures, so that old glass could not be worked with the same facility as that recently manufactured. He also described the process of annealing, and showed that it was required to remove the state of strain due to unequal contraction and was therefore more necessary in proportion to the thickness of the glass and the complexity of the form into which it was made. He described and illustrated the manufacture of De la Bastie's toughened glass by heating glass to redness and suddenly plunging it into a mixture of hot oil and wax. Mr. Fairley explained the structure of this toughened glass, and said its remarkable strength resided only in the outer layers, which by quick cooling contract and compress the whole mass. He showed specimens of toughened glass from which the outer layer had been removed by hydrofluoric acid, and which then behaved like ordinary glass. He also stated that a bath of mercury or fusible metal could be used in the process, though with less perfect results than the oleaginous mixture. In conclusion the lecturer explained and demonstrated the details to be observed in the working of glass for laboratory purposes.

A cordial vote of thanks was accorded to Mr. Fairley on the motion of Mr. R. Reynolds.

ABERDEEN SOCIETY OF CHEMISTS AND DRUGGISTS.

The inaugural address in connection with the Aberdeen School of Pharmacy was delivered on the 9th inst. in the hall, St. Nicholas Street, by Mr. John Gordon (Messrs. J. and J. Urquhart), teacher of the chemistry class.

Mr. R. D. Presslie presided, and there was a large attendance. The subject of the lecture was "Chemical Force." The lecturer discussed the forms of matter of which the universe is composed, and proceeded to show, by a series of beautiful and instructive experiments, the manner in which all matter is affected by the natural forces which surround it, dwelling particularly on chemical force.

The experiments were eminently successful and the lecturer closed with an eloquent appeal to the students to devote their energy and industry to the work of the coming session. The usual votes of thanks were accorded at the close. The school now enters upon its second session, having hitherto been conducted successfully and gratuitously by Messrs. Gordon and Strachan.

The class for instruction in materia medica will be resumed on Thursday, 11th inst., and will be conducted by Mr. Strachan.

A class for the study of botany will be formed early in the ensuing summer under the charge of Mr. Presslie.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

Assistants' Section.

A meeting of this society was held in Anderson's College, on Wednesday evening, 10th inst., at which the office bearers were elected and general arrangements made for the session.

The gentlemen chosen to take office were:—Mr. Lees, President; Mr. William Simpson, Vice-President; Mr. John Adams, Secretary; Mr. James Finlay, Librarian; and four others as members of Committee.

The coming session promises to be a very successful one, papers being promised for all the evenings. The next meeting will be held about the beginning of January, 1880, when a paper will be read by Mr. Lees, President. Members will receive due notice of the exact date of meeting.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting was held at 32a, George Street, Hanover Square, on Wednesday evening, December 10, Mr. F. W. Branson in the chair, when a paper on "Sugar" was read by Mr. C. B. Miller, who gave a short account of the history, culture and manufacture of both cane and beet, together with their chemistry, including also that of dextrose, levulose and lactose. The paper was illustrated by specimens (kindly lent by Mr. Wigner), consisting of raw sugars from different parts of the world, as well as some samples of crystallized refined, made by various manufacturers.

In the discussion which followed, Mr. Robinson took the opportunity of asking the opinion of the meeting with regard to the manner in which mel boracis should be made and dispensed. Unanimous approval, however, was given to the method yielding a clear and bright result.

A vote of thanks having been proposed by Mr. Bull, seconded by Mr. Hardwick, and carried, the meeting terminated.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, December 11, Mr. R. H. Parker, Vice-President, in the chair, when a paper on "The Manufacture of Sodium Carbonate," was read by Dr. J. F. Elliott. The author, who had had considerable practical experience of the working of Leblanc's process, gave a detailed account of it, including the different kinds of plants used both in this country and in Germany. In describing the second part of the process where the salt cake is treated with coal and limestone, the author stated the evidence in favour of the assumption that carbonic anhydride is produced and not carbonic oxide; that is, that it takes place according to the following equations:—

$$(1)\ Na_2SO_4 + 2C = Na_2S + 2CO_2$$

$$(2)\ Na_2S + CaCO_3 = CaS + Na_2CO_3$$

The principal evidence being that the blue flame characteristic of carbonic oxide is not observed until the decomposition is complete; in fact the workmen know when the reaction has completely taken place by the occurrence of the blue flame, due to a further decomposition of the limestone. The different kinds of plant used in the lixiviation of the black ash and in the evaporation of the solution of sodium carbonate were then described.

After the reading of this paper a discussion took place, and a hearty vote of thanks was passed by the meeting to Dr. Elliott.

After the transaction of some miscellaneous business the meeting adjourned.

Parliamentary and Law Proceedings.

Poisoning by a Liniment.

An inquest was held at the White Horse Inn, Leiston, on Monday last, before Mr. A. F. Vulliamy, county coroner, on the body of William Moore, aged 59, lately a goods porter, in the employment of the Great Eastern Railway Company, who met with his death on Saturday under singular circumstances. He had been suffering from sciatica, and was attended by Mr. M. E. Ling, surgeon, of Saxmundham, as professional attendant of the Railway Provident Society, of which body the deceased was a member. On Friday last his wife administered to him a dose of medicine, which she supposed was a draught, but which turned out to be a liniment. Everything was done to assist his recovery, but he died early on Saturday morning. The first witness called was—

Naomi Moore, widow of the deceased, who said that her husband had been unwell since last Friday week. He suffered from sciatica, and was attended by Mr. Morris Ling, of Saxmundham, who sent him some medicine, which he took. The same bottle was filled twice with a draught which was to be taken the first thing in the morning. He took the first dose on Tuesday morning last. Witness gave it to him. There was printed on the bottle, "This aperient draught to be taken first thing in the morning." Witness sent the bottle back to Mr. Ling, and he returned it filled and with the same label on on Thursday night. The bottle was sent to Mr. Ling by the train, and was carried to the Leiston station by witness's daughter Elizabeth. When it was returned it was brought from the station to witness's house by Burrell, a railway clerk. Her daughter Elizabeth took it from him. There was another bottle with it. It was a large one, which had on it a label with the words, "Two tablespoonfuls to be taken every four hours to one of water." She gave her husband on the Friday morning the contents of the smaller bottle and none from the larger one. After he had taken the contents of the smaller bottle he said he thought it was poison, for it burnt his throat. She gave him some hot water, and then she sent her daughter with the bottle to Mr. Gooch's, the chemist. Her daughter came home and was followed in about half an hour by Mr. Cullen. When she came home witness gave her husband salt and water. It made him a little sick, but not enough to do him good. She got some mustard and water, but he could not swallow it. When Mr. Cullen came he ordered a mustard plaster to be put on the back of deceased's neck, and witness telegraphed for Mr. Ling to go over. Mr. Morris Ling reached there about 11 o'clock, her husband having taken the dose about 8.30. Mr. Cullen and Mr. Ling remained with him all day until six or seven at night, when the latter left. Deceased died about 4 o'clock on Saturday morning.

By the Foreman: He said as soon as he took it that he thought it was poison. He did not speak after the daughter came back, which was about 9 o'clock.

By a Juror: He did not speak until after Mr. Ling came and used the stomach pump.

By the Coroner: He never spoke to her.

By a Juror: Mr. Ling sent two bottles of medicine on the first occasion, and they were the same bottles as came the second time.

In answer to questions by Mr. Pollard, the witness said that her husband had suffered from sciatica before, but his general health was good, and he was a temperate man. On Saturday week her husband commenced to suffer from sciatica, and she sent for Mr. Ling, who attended on Monday morning, and in the afternoon sent her some medicine. When the medicine bottles were returned on Thursday she did not notice what the colour of the physic was. She did not notice the smell, but it seemed darker. Mr. Ling had said he would send some embrocation for her husband to be rubbed with, but she could not recollect if he said he would send some embrocation, and the mixture "as before." She expected some embrocation to be sent, and returned the bottles for that purpose. The bottles came to her on Thursday night by train, and were delivered at the house, when her daughter took them in. She thought it was the embrocation in the small bottle until she read the label, and when she smelt it she remarked that she thought it had hartshorn in it. She expected that the small bottle might have contained the embrocation, but it did not occur to her when she saw the label that it was the embrocation. She did not send for Mr. Morris Ling the first thing after she found she had given the embrocation to her husband, because she thought it would take too long for him to get there. He did all that he could for her husband after he came.

Elizabeth Moore, daughter of the deceased, stated that she remembered some medicine coming for her father last Tuesday afternoon. There were two bottles. She took the bottles to the station on Thursday morning, and gave them to William Burrell, the clerk, for him to send to Saxmundham. She took them in on Thursday night, from William Burrell, who brought them up from the station. She did not open the basket, but saw the bottles taken out. There were two, which were left standing downstairs on the table in the sitting-room. On the Friday morning, December 12, about 8.30 a.m., her mother brought the smaller bottle to her and asked her to read the label, which had on it "The aperient draught, to be taken in the morning." The bottle was full, and her mother took it away. About half an hour or so afterwards her mother sent her to Mr. Gooch's, and she took with her the bottle with a little of the medicine remaining in it. In consequence of what Mr. Gooch said to her she went for Mr. Cullen, who arrived at her father's soon after. She went up to her father when she got back, and he looked at her and said "I am poisoned." She saw him again in the evening, when he seemed better.

By Mr. Pollard: She did not know what the first medicine was like. She did not notice that the little bottle had differently coloured medicine in it to what it had at first. When her mother went to her in her bedroom on Friday morning, asking her to read the label on the bottle, she (Mrs. Moore) said it smelt very funny. Witness saw deceased after Mr. Ling left, and he then seemed like a madman. That was some time after, but she saw him just before Mr. Ling left, and he seemed much better.

Peter William Cullen, surgeon, Leiston, said that on Friday morning, about 9.20, he was summoned to visit the deceased. Witness was dressing at the time, and a bottle was sent up to him to look at. It smelt to him of camphorated liniment. He went to the deceased, who was half sitting up in bed, with a red and swollen face and widely dilated pupils. His extremities were cold, and the pulse scarcely perceptible, with a tumultous action of the heart. He ordered mustard and water, and deceased swallowed a little of it, and then sank back in bed in a sort of comatose condition, and commenced to breathe very heavily. In consequence of what Mrs. Thorne told him he advised that Mr. Ling should be telegraphed for. He administered nothing to deceased besides the mustard and water in the meantime. When Mr. Morris Ling came they applied the stomach pump, but scarcely anything was obtained from it. After that they galvanized deceased, and he appeared to revive for a time, but he sank back again. Witness remained with him until 4 o'clock, and saw him again at 9 the same evening, when he was delirious. Witness did nothing for him, but said he should be watched. From the symptoms it appeared to witness that he was suffering from belladonnic poisoning. Witness asked Mr. Ling what there was in the liniment, and he told him that it was belladonna and aconite.

By the Coroner: To make a liniment of the kind supplied there would be a couple of drachms of each ingredient. A quarter to half a drachm of belladonna would be sufficient to kill a man.

By Mr. Pollard: Witness thought that anyone smelling at the bottle would know that it was for outward application. Directly Mr. Ling got to deceased's house, he asked witness to help him apply the stomach pump. They then used the battery, and gave him ammonia, and he appeared to revive. Every time subsequently that the battery was used he got better, and his pulse increased. In the evening deceased took some brandy and water and egg and brandy, and then aromatic ammonia, which appeared to further revive him. Witness left at 4, and at that time thought there might be a little hope. About 5 o'clock witness saw Mr. Ling again, and he said he thought deceased was much better. At 9 o'clock witness went again, and was surprised to see deceased in the state he was. He had a full pulse, and was in the state of a man with *delirium tremens*, which he attributed to the belladonna. He agreed to the advice of Mr. Ling as to the subsequent treatment. He had, at 9 o'clock, some hope of his recovery. Belladonna got into the system immediately it was taken into the stomach, but it did not always act for some hours afterwards. That depended on the constitution of the patient and the state of the stomach at the time. If the stomach pump had been applied immediately after the liniment was taken it would not have made any difference to the man's state. Even if the belladonna had got immediately into the system he should say that the deceased would have survived as long as he did. Witness could not have applied the stomach pump first thing in the morning, because stertorous breathing and coma came on, and when witness saw deceased again with Mr. Ling, those symptoms had gone off. He could not say if galvanism would have been of use if immediately applied.

Edward West, engineer, of Leiston, said he was sent for just before 10 o'clock on Friday morning, and telegraphed for Mr. Ling at once. He then went to the house of the deceased and remained with him till he died. Deceased began to be delirious between 5 or 6 o'clock, and it continued till about 3 next morning, when he had a little sleep. Witness went downstairs, but had not been gone ten minutes when he was called back and told that deceased was dying. Directly after witness got upstairs deceased died.

By Mr. Pollard: Witness was the first to see Mr. Morris Ling, and told him that "They had given him poison." Mr. Ling replied, "Why did they not apply the stomach pump?" When the pump was applied by Mr. Ling it brought up a large quantity of matter of a brownish colour, and deceased revived very much towards 4 o'clock. Witness asked Mr. Ling several times if there was any hope, and he replied, "While there's life in his body I have hope." When Mr. Ling left he instructed witness what food to give him, and said that when he came round he would be like a drunken man. Witness was of opinion that Mr. Ling did all he could for the deceased.

William Burrell, booking clerk at the station, gave evidence as to the delivery of the basket containing the medicine at Mr. Moore's house.

Several more witnesses remained to be examined, and the Coroner adjourned the inquiry until Monday next. He gave instructions to Mr. E. D. Wallis, surgeon, of Leiston, to make a *post mortem* examination of the body in the meantime.—*East Anglian Daily Times.*

Prosecution for the Sale of "Unfermented Wine."

At the Salford Borough Police Court, on Friday, December 12, before Mr. Makinson (stipendiary), William Pilling, chemist, New Bailey Street, Salford, appeared in answer to a summons taken out against him under the Food and Drugs Act, 1875, for selling to Mr. C. H. Thompstone, inspector appointed under the Act, two bottles of what purported to be "unfermented port and sherry wine, manufactured from the juice of the grape, and used for family and sacramental purposes," which wine, on being submitted to the borough analyst, was found to be not of the substance, nature, and quality demanded by the purchaser. Mr. Walker (assistant town clerk) appeared in support of the summons, and Mr. W. S. Sebright Green appeared on behalf of the manufacturers of the wine, Messrs. Bell and Co., Upper Milk Street, Liverpool.

In opening, Mr. Walker said the case was one of considerably importance to the public. On the 22nd ult., Mr. Thompstone went to the defendant's shop and purchased two bottles of wine—one of port and one of sherry—which was said to be "unfermented, and manufactured from the juice of the grape." He divided the samples in the usual way, and submitted half of the quantities purchased to the public analyst, Mr. Carter Bell. The result of the analysis was that Mr. Bell found absent all the constituent parts which constituted the pure juice of the grape, and the liquid contained in the bottles was practically nothing more than coloured water. The so-called "unfermented wine" was sold in considerable quantities among total abstainers, and was said to be used largely for sacramental purposes. What the defence would be he could not conceive, unless the defendant confined himself to contending that he sold the liquid as he purchased it from the manufacturer. He reminded the bench, however, that the 25th section of the Food and Drugs Act provided that a person selling any adulterated article was liable to be fined unless he produced a written guarantee to prove that it had not been tampered with since the purchase took place. If the stipendiary, after hearing the evidence, should think it desirable he (Mr. Walker) would submit the samples obtained for analysis at Somerset House, and ask for the case to be adjourned, but if he were satisfied with the evidence of the borough analyst such a penalty would be asked for as would be commensurate with the importance of the case as it affected the public.

Charles E. Thompstone, inspector under the Food and Drugs Act, was the first witness. He deposed to purchasing a bottle of port and a bottle of sherry from the defendant's shop on November 22. The label on each bottle set forth that they were "unfermented wine, manufactured from the juice of the grape." The price was 2*s.* 6*d.* per bottle, and having paid for them witness submitted half the quantities to the borough analyst and left the remainder with the defendant in sealed bottles.

Cross-examined: witness said he did not actually ask the defendant to supply him with "the juice of the grape," but he expected when he made the purchase to get what was stated on the bottle, namely, "unfermented wine, manufactured from the juice of the grape."

Mr. Carter Bell, public analyst for the borough of Salford, said he received the two samples referred to by the last witness on the 22nd November. He analysed them, and found that they were not composed of the pure juice of the grape. He would not swear that there was not an infinitesimal quantity of the juice of the grape, but the proportion was certainly not equal to 10 per cent.

In cross-examination, witness admitted that several of the constituents which went to form the liquid purchased might have been contained in the juice of the grape.

Mr. Green submitted, in defence, that the liquid purchased by the inspector was really what it purported to be, namely, "unfermented wine," manufactured from the juice of the grape. It was not sold, or intended to be sold as pure juice of the vine, and therefore, the prosecution, he held, must fall to the ground.

Mr. G. B. Bell, one of the firm of manufacturers in Liverpool, said the wine was manufactured principally from grapes, and had a very large sale, there being no fewer than 3284 wholesale customers for it. Fifteen Nonconformist churches in Bradford were supplied with the wine, and there was one chapel where a dozen bottles were drunk every Sunday.

Mr. Hewson, manager of Messrs. Bell's works, said he manufactured the wine and it contained one-sixth part of pure grape juice, and five parts of sugar and water, with a small quantity of burnt sugar for colouring purposes.

Mr. L. Siebold, analytical chemist, deposed to analysing specimens of the wine purchased by the inspector. He found that the predominant constituents of the wine were such as were contained in the juice of the grape.

The Stipendiary, after hearing the evidence, said he was of opinion that the summons must be dismissed, inasmuch as it was not proved that the wine did not contain some portion of pure grape juice, and no standard was fixed by the law by which he could decide whether the proportion was sufficiently large or not to justify the sale.—The defendant was allowed costs.—*Manchester Courier.*

Patent Medicines.

Sir,—To those of your readers who have for a long time past been giving considerable attention to the various phases of the patent medicine question, the editorial, which appears in your last issue, affords another opportunity for further discussion. It is obvious that the intention implied therein is merely to give a summary of various communications which have appeared in your columns from time to time, without in any way attempting to suggest a course for further and more decided action.

That a certain amount of ambiguity should be very plainly perceptible in this article is therefore not to be wondered at, nor are you to be held responsible for it, seeing that many of the proposed schemes are of a widely opposite nature, and most of them relate entirely to what may be termed the trade aspect alone.

Whether, in the fulness of time, the chemist is to be either the proprietor or retailer of patent medicines, in conjunction with surgeons, drapers, storekeepers, grocers, stationers, working cobblers, or oilmen, or whether he is to get 10*d.*, 10½*d.*, 1*s.* or that *acme* of commercial joy and prospective fortune known as full price, for his thirteen pence halfpennyworth of stock, I am not prepared to say, as it is altogether outside my argument, but whether he is to sell them—even under the latter happy condition—without protest, and a strong determination to give challenge to the existing state of affairs is quite another thing.

To suppose that it will ever be possible to purge our pharmacies of these nostrums would be folly indeed; to refuse to sell them—absolute mania; but, at the same time, I should hope that it is no symptom of incipient insanity to suppose that the nostrums themselves can be purged to such an extent as to render their sale, by a man with an ordinary amount of intelligence, a matter of satisfaction, rather than humiliation, whether he be pharmacist or grocer.

Why this scandal in modern medical science has not long ago been an object for the combative instinct of higher bodies than ours, it is impossible to imagine, but, for the sake of our honour, as a society, let us no longer tarry.

If we have not yet arrived at that socially scientific degree of importance which will admit of our being legally represented in the compilation of our national pharmacopœia, let us, at least, show that we have no desire to patch up a system of charlatanism which aims at nothing less than its entire annihilation; it will scarcely be denied that we have qualifications sufficient for this.

I have neither experience nor ability enough to sketch out a way of doing it, but my mind is full of an earnest aspiration to see it done, and to give a helping hand in the struggle. Surely there must be many more who are just as eagerly awaiting the heralding of the campaign, and the time cannot be far distant when the literature of quackery, the wonderful panacea for the miraculous cure of every ill that flesh is heir to, will be made to feel the march of progressive civilization, and the patent violation of our poison schedule be in itself so dangerous an absurdity as to seal its own death warrant.

Kilburn, N.W. CHARLES B. ALLEN.

Poison Vending.

Sir,—The remarks under the above heading quoted by you from the *Medical Press and Circular* are most surprising. I should have thought the evidence would nearly all tend the other way, viz., that it is through the medical profession that the public generally become acquainted with the property of hypnotics, etc. I believe the habitual use of opiates has its origin more often than not in the doctor's prescription. I know many cases in which it has done so. Only lately I made up a prescription for a draught containing chloral. It was several times repeated, then two at a time were had, afterwards four, then six; at last I was asked to make up a large bottle instead of separate draughts. There having a short time since been a case of fatal poisoning in this neighbourhood by chloral supplied in a 6 oz. bottle by a surgeon to a patient suffering from delirium tremens, I demurred and advised the draughts not to be continued without further consulting the doctor who prescribed them. Whether the advice was acted on, or whether it gave offence, I do not know, but I have not since been favoured with a prescription from the family, who were previously frequent customers in that way. While not agreeing with those who go so far as to think that a prescription should never be repeated unless with the authority of the prescriber, I do think it cannot be right to entrust patients with prescriptions for medicines of a dangerous character without any limitation as to the time the medicine is to be continued.

A VILLAGE CHEMIST.

Sunday Trading and Earlier Closing.

Sir,—The above two subjects have been discussed for a few weeks in the Journal and as I have much more leisure than I like, through ill health, perhaps if I state my personal experience on both of these matters some of our members may be helped to a right decision, or at any rate to an improvement in the state of things as described by Mr. Woodward in last week's Journal. It is nearly fifty years since I was apprenticed in Norwich, and at that time, 1831, most chemists' shops in that good old city were open on Sunday till 10.30 a.m., this being the only part of the day of rest encroached upon, and before I left in 1837 to come to London I believe nearly all were entirely closed on Sunday, with very little if any inconvenience to the public and with great advantage and much comfort both to principals and employees. On coming to this great metropolis I found there was much more Sunday trading of all kinds than I had been accustomed to.

Public houses were open till 11 a.m., and as I occupied a situation not far from a large gin palace, and had to attend in an open shop all day, I saw enough to make me rejoice with many others when a regulation was introduced preventing their opening till after 1 p.m. On commencing business on my own account in 1841, I closed on Sundays from 11 a.m. till 6 p.m. and on week days was at business till 11 p.m. and on Saturday till 12, and at that time I was not singular in doing so. Some few years since there was much agitation both about late hours and Sunday opening and by slow degrees the present plan has been reached by me, of entirely closing on Sunday, and on other days, except Saturday, closing at 9 p.m. I sincerely believe that this has been accomplished without any loss of business, and my experience has convinced me that if the sales are confined to medicines the returns are very small indeed on Sundays. If I could persuade any doubting one to take the leap, I feel sure his loss will be scarcely perceptible, and the extra comfort and rest would fully compensate him, helping him to improve health and enabling him to rejoice in the feeling that the Sabbath was made for man and being a free man he intends to make a good use of it.

JAMES SLIPPER.

W. Hickman.—There is, perhaps, nothing in the Act to prevent a grocer whose name is not on the Register of Chemists and Druggists from charging for the making up of a prescription, but any such person selling or keeping an open shop for the dispensing or compounding of poisons, or exhibiting the name or title of chemist and druggist, or chemist or druggist, would be liable to a penalty under the 15th section of the Pharmacy Act, 1868.

T. Robinson.—A recipe for incense will be found in vol. viii., p. 519.

W. Murray should consult a work on veterinary medicine.

"*Devon.*"—(1) The preparation is, we believe, a proprietary one, of which the formula has not been published; but a few experiments would probably furnish you with what you want. (2) Dr. Dobell's formula for tincture of podophyllin will be found in the *Pharmaceutical Journal* for June 28 last, p. 1056. (3) No authoritative formula has been published; you would therefore be justified in using such a preparation as is usually kept in pharmacies.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Robinson, Reynolds, Key, Storey, Gostling, C. E. W., Spes, Wiltshire.

"THE MONTH."

Ordinarily, December is not a very promising month for a botanical gossip, and more especially is this the case in this unusually severe close to a most inclement year. Except in a few favoured localities there are but few flowers to be seen, the Christmas rose (*Helleborus niger*) being almost the only medicinal plant in blossom. *Petasites fragrans* and *Matricaria inodora* may be found here and there on hedgebanks in the south in blossom to illustrate the Compositæ. In hothouses the pretty poinsettia, with its brilliant scarlet bracts and insignificant flowers, represents the Euphorbiaceæ, while the lily of the valley and the hyacinth worthily represent the Liliaceæ. There are spots, however, in England where flowers still survive, even after Paris has been rendered impassable by snow, and, still further south, Algeria has been covered in several places with a carpet of white six inches thick. For, according to a letter in the *Western Morning News*, of the 16th inst., there were then in full bloom in the gardens of Ilfracombe, geraniums, heliotropes, mignonette, convolvulus minor, roses (various), fuchsias, red salvias, carnations, calceolarias, stocks, myrtles, magnolias, and many others.

During the last few days the metropolis has been visited by one of those fogs for which it is famous, and if there be any relief in a scientific explanation of a disagreeable infliction, it may be found in one by Professor Frankland. Noting that the persistent and irritating fogs which affect large towns frequently occur in comparatively dry air, he explains this persistency in a dry medium as due to the formation of a coating of coal oil, derived from coal smoke, upon the surface of the minute particles of water which compose fog, and which coating effectually prevents the evaporation of water. The remedy would therefore appear to lie in the use of a smokeless coal or of gas for heating purposes.

The season of mistletoe and holly is now approaching with rapid strides, and it is so familiar to see the mistletoe bough hung up, that the idea of having mistletoe "all a-growing" takes one rather by surprise. Nevertheless, Mr. R. Smith, of Worcester, has hit upon the novel plan of selling apple trees with mistletoe upon them. Such trees, although possibly admirable for ornamental purposes, even if dwarfed as the Japanese dwarf their trees, would scarcely do for the usual purpose to which mistletoe is applied at this festive season of the year. The mistletoe grows remarkably well, however, on a much more ornamental tree—the mountain ash. It is merely necessary to rub the berries on the bark of a young tree, and the germinating seed soon attaches itself.

Just now, when there is scarcely a green leaf to be seen, it seems somewhat anomalous to consider the subject of chlorophyll. This substance has, however, attracted considerable attention recently. M. Gautier, in *Comptes Rendus*, p. 862, describes the preparation of the crystalline form of chlorophyll, which is obtained by pounding spinach, or other leaves, in a mortar, neutralizing the pulp with carbonate of soda, expressing strongly, diluting the marc with 55° alcohol, and again expressing. The matter thus exhausted in the cold is treated with 83° alcohol. The liquor is filtered, and allowed to digest for four or five days with animal charcoal, which absorbs the chlorophyll, leaving a yellowish-green or brownish solution

that contains the impurities, wax, fat, colouring matters, etc. The animal charcoal, separated by cotton wool in a funnel, is washed with 65° alcohol, which removes a yellow crystallizable substance, that generally accompanies the chlorophyll, and seems to bear a close relation to it in composition. The charcoal is then treated with ether or light petroleum oil, which does not dissolve the yellow matter, but only the chlorophyll, and this crystallizes out in flattened needles when the petroleum solution is allowed to evaporate.

M. Gautier, who made the discovery of the crystalline state of chlorophyll first in 1877, was apparently anticipated by M. Trécul, who observed, in 1865, natural crystals in the cortical portion of *Lactuca altissima*; but his discovery was at that date received with incredulity. M. Gautier, in his remarks in *Comptes Rendus*, p. 863, states that he considers chlorophyll to be nearly allied to bilirubine in its reactions and elementary composition. It dissolves in the same solvents, like it plays the part of a feeble acid, gives unstable soluble salts with alkalies, and insoluble salts with all other bases, and agrees with it in the alkaline solutions being very easily altered and oxidized under the stimulus of light. Like bilirubine it can pass successively from green to yellow, red, or brown, by the subtraction or addition of oxygen. The preliminary analysis indicates the formula $C_{19}H_{22}N_2O_3$; that of bilirubine being $C_{16}H_{18}N_2O_3$. The paper is too long to give here further details; but sufficient has been said to show that M. Gautier is on a most interesting and important track. It may be hoped that he will continue his valuable researches and that they may lead to the solution of the mystery as to the means by which the change from the green colouring matter of leaves to the bright colours of petals is effected in nature, a discovery which would be of exceeding value to the horticulturist. The study of this subject is further of interest on account of the relation of chlorophyll to bilirubine, and consequently with the hæmatine derived from blood.

According to a notice in the *Journal of Botany*, Pringsheim has also recently published the results of his researches on the function of chlorophyll (*Monatsber. der Konig. Akad. der Wiss. zu Berlin*, July, 1879). He considers that chlorophyll, so long as it exists in the cell, protects the protoplasm from the injurious effects of sunlight, and suggests that it may serve as a regulator of respiration by reason of its strong absorption of light, especially of the chemical rays.

The author has also discovered in the ground substance of all chlorophyll grains, and of all amorphous chlorophyll, a new body very sensitive to light and easily destroyed by it. This substance he calls hypochlorin or hypochromyl. It may be obtained by placing any green tissue in weak hydrochloric acid for from twelve to twenty-four hours. This body he considers to be the true primary product of assimilation of green plants, from which are derived by oxidation under the influence of light the starchy and oily contents of chlorophyll grains. Accumulation and growth of the starchy contents of the chlorophyll grains proceed in proportion with a decrease of the hypochlorin in it. In darkness starch is less stable than hypochlorin, showing that the conversion of the latter into more highly organized bodies in the cell is favoured by the increased respiration occurring in light.

Some interesting experiments by Professor Hoffmann, of Giessen, have been reported in the *Berlin Monatsschrift* on the influence of thick sowing on the sex of diœcious plants. In his view sex does not reside in the seed, but is the result of the conditions of germination. In spinach he found that one hundred seeds crowded in a pot yielded two males to every female plant, but an equal number of each sex when seeds from the same sample were planted in the open ground. Unripe seeds also in the case of *Lychnis vespertina* gave more males than females, and the seed of *Mercurialis annua*, artificially impregnated in early summer, gave a larger proportion of males than seed ripened at the usual time. Similar results are said by Professor Prantl, of Aschaffenburg, to obtain in the prothallia of ferns, when crowded, and Professor Pfeffer, of Tubingen, has observed the same hold good with equisetum, in which more antheridia than archegonia are produced. In the case of hemp, the nutmeg tree and some other plants, this fact, if generally applicable, is of considerable importance.

Another interesting botanical fact has been discovered by M. Lemoine, of Nancy, who finds that the stigmas of double flowers are capable of fertilization by the pollen of single flowers, with the result of yielding seeds of which the majority produce double flowers.

Another important chapter in the history of nitrification has been contributed by Messrs. Schloesing and Muntz (*Comptes Rendus*, vol. lxxxix., p. 891). These experimenters claim to have identified the organized ferment by which nitrification is effected as consisting of small rounded or slightly elongated corpuscles, already noticed by Pasteur under the name of "*corpuscles brillants*," and looked upon by him as germs of bacteria. This organism, which has many analogies with the acetic ferment, multiplies by gemmation, but very slowly, which accounts for the progressive rate at which nitrification goes on. A temperature of 100° C. is fatal to it, and its activity is arrested by one of 90°; neither can it resist prolonged deprivation of oxygen, at least in liquids. Desiccation, even at ordinary temperatures, is also unfavourable. The ferment is widely diffused, the most favourable place for its development being earth containing vegetable *dêbris;* but drainage waters and waters containing organic matters are also rich in this organism. In the soil its greatest enemy is mucor, the development of which arrests the formation of saltpetre; but after the death of the mould it generally resumes its activity. The nitrification ferment does not appear to occur suspended in the atmosphere, possibly from its inability to resist desiccation.

In the *Gardeners' Chronicle* it is authoritatively stated that during the ensuing summer a students' garden will be thrown open in the Royal Gardens, Kew, where students will be permitted under certain regulations, which will be drawn up hereafter, to procure botanical specimens for scientific study and observation. This will be good news for botanical students and will, it may be hoped, lead to the greater development of a practical instead of a theoretical knowledge of botany, which it is to be feared is too often the result of a course of "botanical study."

In *Science Gossip*, for this month, under the title of "Friends in Council," is published a list of names of gentlemen willing to assist gratuitously amateurs in botany and other branches of natural history, in various localities. The list is to be further extended and it is hoped may prove very useful to those who in country districts are often somewhat hindered in their botanical studies for want of a little practical information.

M. Ed. Morren's 'Correspondance Botanique' or 'Botanical Directory,' giving a lists of botanists and botanical societies, etc., all over the world, has just reached a seventh edition, which contains numerous additions and improvements. This list is understood to be kept in stock by Mr. Quarritch, of Piccadilly.

Some confusion still seems to exist as to the kind of quebracho used medicinally. In the *Berichte d. Deutsch. Chem. Ges.*, 1879, p. 1560, G. Fraude states that his aspidospermine was obtained from *Aspidosperma Quebracho blanco*, Schl., according to Pedro Ardata's report in the 'Anales de la Sociedad Cientifica Argentina," and that explains why it has a different composition and properties from the "aspidospermine isolated from *Quebracho colorado*." Any alkaloid obtained from *Quebracho colorado* (*Loxopterygium Lorentzii*) should no longer be called aspidospermine, but loxopterygine, since it would be obtained from a totally different tree belonging to a different natural order. For a similar reason the name quebrachine, which is used in the 'Revista Farmaceutica' as an equivalent for aspidospermine, should not be used, lest it lead to a similar confusion. It is the bark of the white quebracho (*Aspidosperma Quebracho*) which has been used in medicine, and the alkaloid obtained from this bark should alone be called aspidospermine.

In *New Remedies* for this month an account of the barks of *Alstonia constricta* and *A. scholaris* is given, but by a curious oversight, while the characters of the flowers, etc., are described, there is no mention of the characters by which the barks may be distinguished. Woodcuts of sections of the two barks are, however, given, but that of *Alstonia constricta* can scarcely be looked upon as typical, being figured from a piece of old bark. Much of that which arrives in this country is only half or one-third the thickness represented, and is of course more powerful than the older and corky bark.

In the *Journal de Pharmacie* for November, Professor Planchon describes a bark, called "palomabi," which has been found mixed with pale cinchona supplied to the hospitals. It came into commerce apparently under the name of "ecorce de Porto Rico," and is said to be used in the Antilles in the manufacture of beer. He refers it to *Colubrina reclinata*, Rich., a rhamnaceous plant. It contains no alkaloid, but resin, a free acid of undetermined composition, tannin, extractive matter and salts of lime.

The *Medical Times and Gazette* for December 6, calls attention to the researches of Nikitin on the physiological action of sclerotic acid, and remarks that sclerotic acid "seems likely before long to partially replace ergot as a drug." Nikitin states as the results of his experiments that both sclerotic acid and its sodium salt possess the physiological and therapeutical properties of ergot itself, but the salt is a weaker drug than the acid. The acid remains indefinitely without loss of strength if kept in a dry place and undissolved. He considers, however, the sodium salt to be the best preparation for internal use. Whether from the mode of preparation, or from whatever cause, sclerotic acid does not seem to have been received with much favour in this country as yet, its use having, it is believed, decreased rather than increased of late.

In *Le Moniteur Thérap.* for October, M. H. Bergeron is stated to have obtained very favourable results in diphtheria from the inhalation of an atmosphere containing a definite small proportion of hydrofluoric acid gas. This is somewhat interesting, since the action of hydrofluoric acid or fluorides is believed to have an influence in producing another disease (goître) in the same part of the body.

The *American Journal of Pharmacy* for December gives an account of experiments on the action of artificial vanilla by Mr. L. Wolff, who has found that in one grain doses taken for three weeks it produces no bad results whatever. The vanillin experimented with was Dr. J. M. Haarmann's. He therefore concludes that it is not to artificial vanillin that the reported poisonous effects of vanilla ice cream must be attributed, but rather to the other ingredients. He recommends vanillin for disguising the taste of chlorate of potash in lozenges and recommends it to be used in the following proportions:—Pot. chlor., lb. iv.; powdered sugar, lb. xvi; vanillin, gr. xv.; mucilage of gum acacia, q.s.; made into lozenges weighing twenty-five grains each.

In the *Berliner Klinische Woch.* for November 3, Dr. Koehler, of Kösten, recommends a salt prepared by dissolving boracite (borate of magnesium) in citric acid, as a remedy in cases of gravel, or probable uric acid calculus. The boracite used is that from Stassfurt, known as stassfurtite. The salt, which is known as boro-citrate of magnesium, is in the form of a white powder of a sour taste, and is given mixed with sugar in the proportion of one to two. The dose is a large teaspoonful in half a tumbler of water three times a day.

At this season of the year colds are of such common occurrence that any mode of preventing or curing them will doubtless be welcomed. The *Lancet*, Nov. 29, p. 808, makes the following remarks:—"The truth would seem to be that what we call cold-taking is the result of a sufficient impression of cold to reduce the vital energy of nerve centres presiding over the functions in special organs." After alluding to sneezing and shivering as efforts of nature "to rouse the dormant centres and enable them at once to resume work and avoid evil consequences," it goes on to say—"It follows from what we have said that the natural indication to ward off the effects of a chill is to restore the vital energy of the nerve centres, and there is no more potent influence by which to attain this object than a strong and sustained effort of the will. The man who resolves not to take cold seldom does." After this excellent advice, it is to be hoped that readers will all resolve not to take cold and will succeed.

Dr. Woodward, in the *British Medical Journal* (Nov. 29, p. 882), calls attention to the value of a cold water pillow in cases where headache, heat of head, and similar symptoms have prevailed. He says that anyone who has experienced the vain attempt to find any permanently cool place in a feather pillow will appreciate its value.

A note in Reimann's *Farber Zeitung* (No. 43) states that the cochineal harvest in the Canary Islands has suffered greatly from unseasonable rains. In Mogador the almond crop, notwithstanding the droughts, has been up to the average; but the almond crop is said to have been devoured by the starving population before it reached maturity owing to the severity of the famine.

In the neighbourhood of Naples the cultivation of madder, which for some time past had been decreasing, has at last been completely abandoned, owing to the extended use of the aniline dyes in Europe. It is estimated that 3000 bales, of 8 cwt. each, are still to be had, the growth of former crops.

The distress which is always more or less associated with the present season of the year, even in the most prosperous times, has during the month again given rise to many suggestions as to the provision of cheap and nutritious food, and among others have been brought forward once more the claims of lentils, which the British poor so persistently ignore. But the overcoming of prejudices with respect to new articles of diet is not of more importance than the diffusion of correct information respecting the articles of food already in common use. In this direction such lectures as those on the "Chemistry of Bread and Bread Making," delivered during the present month as a Cantor course before the Society of Arts, by Dr. Charles Graham, cannot fail to have a beneficial influence. The teaching of such subjects in schools, too, as now practised, is a great gain, and for this and similar purposes a series of collections of specimens illustrating the composition of articles of food and drink, which have been prepared for the use of lecturers and schoolmasters by Messrs. Southall Brothers and Barclay, of Birmingham, promise to be of utility. These illustrate the chemical composition of the various classes of food by means of typical specimens. In the collection illustrating the alcoholic drinks the various amounts of water, alcohol, flesh-forming and heat-giving matters are shown.

A short paragraph in *The Month* for October (before, p. 324) relative to the appointment of "quiz-masters" in connection with the New York College of Pharmacy has provoked results strangely disproportionate to its superficial appearance. In the first place, it has excited the wonder of the editor of *New Remedies*; and next, it has drawn from Mr. Cassebeer, the Secretary of the college, a letter of sorrowful explanation as to the nature of this office which he describes as a "peculiar institution connected with most colleges in this country." Mr. Cassebeer says: "Experience has shown that students do not profit so much from didactic lectures alone, but that a more practical method is required to make them fully understand the subjects taught in the former. This may be done either by practical instruction, for instance, in a pharmaceutical or chemical laboratory (in chemical schools), or by clinical lectures at the bedside (in medical schools), or by oral recitations in form of questions and answers. This latter system is known in this country as 'quiz.' In some medical colleges the professors conduct this quizzing class themselves, in other colleges special instructors are appointed to conduct them." Such a practice, it may be remarked, is not unknown in this country, but so far as the name under which it is known in the United States is concerned Mr. Cassebeer speaks with authority from his official position, and is entitled to the thanks of the English readers of this Journal for his courtesy in affording this information, which will probably be new to most of them. It is evident that a mistake has been made, though why the suggestion that quiz is associated with banter should raise so much ire is not quite evident, since "*ridentem dicere verum*" has the respectability of antiquity at least. But when he proceeds to rebuke the levity of the paragraph, and to state that "we are charitable enough to believe that the author of the remark was unaware of the *true* meaning of the term," which is further defined by him as an Americanism, the tribunal becomes changed and others are as competent as himself to express an opinion upon this part of the subject. In fact, the "levity" that disturbs Mr. Cassebeer and his colleagues consists, in the eyes of the editor of *New Remedies*, of "grave remarks;" further, the writer was not unaware of the true meaning of the term "quiz," and it is not an Americanism. Few words have a better-known history, and in its definition lexicographers are all in accord. It would perhaps be looked upon as begging the question to quote an Englishman's definition, but that of Webster will suffice, namely: "Quiz, *v.t.* To puzzle; to run on; to make a fool of. A popular, but not an elegant word." Neither is any other meaning suggested under the other forms of the word. It would appear, therefore, that the mistake which has so excited our New York contemporary and the staff of the New York College was due primarily to the peculiar misapplication of a well-known term to a not very peculiar institution. Similar mistakes continually occur on both sides of the Atlantic, originating in mutual ignorance of local customs, an ignorance which it is hoped may gradually be dispelled by the very work that is marred by such errors.

The opinion expressed last month that some explanation would be forthcoming as to Professor Meyer's disclaimer to Dr. Endemann with respect to the notices of his researches on chlorine that have appeared in the English journals, has been justified by a letter to Mr. Watson Smith published in the *Chemical News* (Nov. 28, p. 263). In this letter, Professor Meyer states that he was not referring to the communication of Mr. Watson Smith to the *Chemical News* (quoted before p. 164), which has his entire approval, but to an article in the *Chemical News*, August 15, on "The Decomposition of Chlorine," and the paper of Sir B. C. Brodie in the *Journal of the Chemical Society* for September.

In a paper recently read before the Royal Society (*Nature*, Nov. 27, p. 82), Messrs. Hannay and Hogarth record some interesting results obtained while pursuing an investigation into the conditions of liquid matter up to the "critical" point with a view to determine under what conditions liquids are dynamically comparable. It was thought that some clue might be obtained by dissolving in a liquid some solid substance the fusing point of which was much above the critical point of the liquid, and noticing whether, on the latter assuming the gaseous condition, the solid was precipitated or remained in solution. It was found that the solid was not deposited, but remained in solution, or rather in diffusion, in the atmosphere of vapour, even when the temperature was raised 130° above the critical point, and the gas was considerably expanded. But when a local disturbance in temperature was caused, as by bringing a red hot iron near a tube containing a strong gaseous solution of a solid, the side of the tube nearest the source of heat became coated with a crystalline deposit, which slowly disappeared on the disturbing influence being removed. When the pressure of the gas was suddenly reduced, also, the solid was deposited in a crystalline form, but was easily redissolved by the gas on increasing the pressure. The experiments were made with such solvents as methyl and ethyl alcohols, ether, carbon bisulphide and tetrachloride, paraffins and olefines, and such solids as sulphur, the chlorides, bromides and iodides of the metals, chlorophyll and the aniline dyes.

Once more the news comes from the United States that Mr. Edison has solved the problem of a cheap burner for the electric light, and this time, although only in the form of a telegram to the *Daily News* (December 22), some slight information is given as to the ground for the assertion. This burner is said to consist of a coil, or horseshoe, of charred paper, enclosed in an exhausted glass globe, where it can be rendered incandescent without being consumed. It is claimed that carbonized paper is not open to the objections which have rendered former experiments with other substances *in vacuo* unsatisfactory. The new burner is to be tested on a large scale in Mr. Edison's village of Menlo Park on New Year's Eve. It is also stated that Mr. Edison has invented a means of measuring the electricity delivered to consumers.

In the closing days of the year France has lost another of her most eminent pharmaciens in Jean Baptiste Alphonse Chevallier, who died on the first instant, in his eighty-seventh year. Born in Lorraine he commenced business as a pharmacien in Paris, where he soon attracted attention by his ability. In 1825, when the *Journal de Chimie Médicale* was started, M. Chevallier was appointed principal editor, and contributed to the first number an article on the detection of the adulteration of iodine by means of alcohol, and in this work he was supported by such well-known men as Guibourt, Fée, Orfila, Payen, Vauquelin, Thénard, Péligot, Pélouze and Serullas. He was the author and joint author of a large number of treatises on subjects more or less closely associated with pharmacy and hygiene, whilst of his larger works may be mentioned as one of the most important his 'Dictionnaire des Altérations et Falsifications des Substances alimentaires, médicamenteuses et commerciales,' first published in 1850, and a new edition of which —we believe the fourth—has not long been issued. In 1823 he was elected to the Académie de Médecine, of which he lived to be the oldest member, and a few years afterwards he relinquished his business as a pharmacien, upon his appointment by the Government to the chair of chemistry in the Paris School of Pharmacy, an appointment he still retained at the time of his death.

On a previous occasion the necessity of fully and clearly labelling the bottles in which medicines are dispensed was fully commented on, and the use of the coloured and fluted bottles strongly recommended for all external applications; the labels also for these should be different in colour and distinct in character, so that the eye of the public may, in due course, be educated to recognize at once an external application before even the specific directions on the label are read.

A circumstance recorded in the last issue of this Journal should bring this subject before dispensers with greater force, and tend to impress on them a due sense of their responsibilities as dispensers of medicine for the public, some of whom are extremely careless in the administration of the same in the sick room.

The mixture, No. 377, may be dispensed by dissolving the salicylate of soda and the bromide of ammonium in 4 ounces of the water, to which the sp. chlorof. should be added; then having diluted the ext. cinch. liq. with the remaining water, mix them together. A copious flocculent separation takes place, which will gradually subside. The mixture is not inelegant, the precipitate being readily diffusible on agitation. Of course the patient should be directed to shakes the bottle before each dose.

No. 378 contains vaseline in a lotion, for which vaseline is not adapted. Probably the writer may not be aware of this, and the sooner he is made aware of it the better for the dispenser. It has been stated in these columns before that the pharmacy of vaseline is little understood, and many members of the medical profession seem to consider that in its properties it resembles glycerine, and that like glycerine it is miscible with either spirit or water or a mixture of the two. It is otherwise difficult to understand why a substitute for, and a representative of lard, without its tendency to oxidation, should form an ingredient in a lotion, and take the place which has hitherto been occupied by glycerine. Vaseline is not adapted for use in lotions, it is not miscible with any aqueous vehicle, and is only suited as a substitute for lard. A "London Dispenser" has given a theoretical method of making an emulsion by melting the vaseline and pouring it into 3 ounces of lime water. "Adolescens" would, there is no doubt, be very glad to see a specimen of the emulsion thus made; it would solve a difficulty and advance a step the pharmacy of the subject. If it has been dispensed to the "entire satisfaction" of the prescriber, "Adolescens" is recommended to procure a sample of the emulsion, neutralize the lime water with a little dilute acid, and thus ascertain how much vaseline the mixture contains. In a paper read at an Evening Meeting by Mr. J. Moss (*Pharm. Journ.* [3], vol. vi., p. 624), it is stated, as the result of experiment, that "vaseline does not saponify with alkalies."

The pills, No. 379, contain ol. absinth. q. s. An essential oil is not a suitable excipient to make a pill mass of pepsine. Mucilage is well adapted for the purpose, and a few drops of ol. absinth. may be added to the mass; or the glycerine of tragacanth may be used, and would probably be better adapted for the admixture of ol. absinth. or any other essential oil.

REMACERATION.*

BY R. ROTHER.

Since the process of percolation has become so generalized, even to the extent of its authorized application where there is a positive disadvantage in its use, it sounds rather surprising, if not altogether doubtful, to speak of the superiority of the nearly antiquated method of extracting drugs by maceration. There is in all things a tendency to extremes, but the observation had not escaped even the remote past that a middle course is best in everything. The process of percolation, when practically viewed, has an entirely different aspect than when looked at from its theoretical side. In theory, percolation consists in the displacement of one layer of liquid by another, on the assumption that there is no intermingling, but on the principle that the successive layers displace one another like so many solid disks. In practice, however, this result is by no means realized; in fact, the theory of its operation in practice is founded on quite a different principle. Percolation signifies that an interposed solid is being permeated by a liquid. The definition here alone already bars the principle of displacement as above stated. A layer of liquid whilst penetrating a mass of solid particles, as any ordinary powdered drug not of a compact, resinous or gummy nature, is at the very outset of its descent broken up into numerous distinct and independent currents of different velocities, varied according to the width of the interstices passed through. This action, therefore, results in a retardation of portions of the layer, and thus, in the very incipiency of the process, vitiating the principle of displacement. But, superadded to this, now comes the effect of capillarity, a force of remarkable power, whose obstructive action, varied according to the nature of the drug and the menstruum employed, causes a further disarrangement of the liquid, by its absorption within the solid as well as by adhesion to the surfaces of the particles. Whilst thus a large proportion of the liquid is greatly retarded by capillary action, the freer portions escape more rapidly. To this effect is now added the result of diffusion, which is even of a retrogressive character, although closely allied to capillarity. Finally, the chemical nature of the drug, in conjunction with the power of the solvent, exerts the most momentous influence over the ultimate result of the operation. In substances containing a large proportion of soluble material, especially of a viscid kind, the greatest amount of retardation, and consequent interference, occurs in many cases, so much so that a perfect bar is set to all further progress in that direction. Such an obstruction naturally throws the course of the currents towards those places offering the least resistance. The higher the column to be permeated is, the more defective becomes the process, in many cases even to the extent of entirely vitiating the final result. From this it will be seen that the process of percolation can in no sense be harmonized with the theory of displacement. In practice it is a maze of intermingling currents of the greatest complexity in volume, direction, velocity, etc., dependent upon the struggling forces of gravity, capillarity, diffusion, solution, chemism, etc. Therefore, the theoretical process of displacement compares with percolation in practice as the regular descent of the ideal solid disk compares with its shattered fragments projected down pell-mell.

There are numerous substances which, although readily permeated by certain menstrua, still contain their active matters in such a condition and possessed of such other properties that the extraction is but slowly and difficultly effected. Such drugs, whilst having the disturbing features but moderately intensified, yet, for the reason just stated, require a relatively large volume of menstruum for their complete exhaustion. There is, however, a very small class of substances in which the deranging tendency is at a minimum and the extractability of the active parts at a maximum. Of these, ginger and capsicum are the best known. Ginger, with a properly low column and the use of $\frac{7}{8}$ alcohol, will yield, by the exercise of moderate care, its total activity from 16 troy ounces, in the ordinary powdered form, to 16 fluid ounces of the menstruum. Common powdered capsicum, somewhat more carefully treated and in low column, with a properly regulated flow, can be satisfactorily extracted with strong alcohol, so that 16 fluid ounces of percolate represent 16 troy ounces. Opposed to these are others, again, that permit but a small measure of success by percolation. These are cantharides, Calabar bean, calumba, seneka, squill, taraxacum, vanilla, and a host of others. If, in the treatment of these, moderately alcoholic or preponderatingly aqueous menstrua are used obstructions and erratic currents will certainly form, which then require comparatively large volumes of liquid to wash down the impeded portions. But if a pretty strongly alcoholic

* From the *Pharmacist* for October, 1879.

mixture is employed, then the extraction is defective, from lack of solvent power upon the enveloping tissues of the active matters. Then, finally, there is another class that cannot be treated by percolation at all. These are the resins, gum resins and gums.

In the method of extraction of these various drugs the United States Pharmacopœia makes no distinction, however, but submits them all to percolation. Some slight discrimination is made in the use of menstrua, and considerable regard given to the degree of comminution, both of which latter are considerations of great importance bearing upon the success of the operation. But no manner of preliminaries will render the process available in the exceptions above cited. In the manner of preparing fluid extracts the Pharmacopœia has made a new departure, by partially abandoning the idea of displacement and adopting coarser powders in connection with a modified method of maceration combined with percolation. The results of this process are believed to be very satisfactory in affording a higher degree of concentration in the percolate, and thus requiring less liquid to be subsequently evaporated. With the exception of the large, and in most cases superfluous, use of glycerin, the process is evidently an improvement.

The method of repercolation, owing to its very plausible appearance, seemed to recommend itself especially for the preparation of fluid extracts. But this method also has of late undergone considerable revolution, or rather evolution, in borrowing the improved features of the officinal method, namely, the coarser powders in connection with maceration. Repercolation, however, is too intricate to become generally popular, and particularly in its original form, in conjunction with fine powders, it was altogether too precarious and tedious for general use. With the latest improvements, as above noted, and by reducing the repetitions to two percolations, and then applying it only to adaptable cases, it will certainly find more frequent use. However, no amount of skill in manipulation or ingenious accessories will ever make percolation an art. The inherent uncertainties are beyond the control of mechanical means.

Among the strong points of percolation, its great convenience is often cited, when compared with the method of extracting drugs by maceration and expression. It is true, for the multifarious small operations in the pharmacal laboratory the press is a decidedly objectionable apparatus, for more reasons than one. But when all the necessary preparatory operations attaching to percolation are considered, there remains but little choice. Now, the method of remaceration which the writer here proposes for the preparation of certain tinctures, syrups, etc., but not fluid extracts, dispenses with the press as a necessary adjunct, although its application in connection with it is not by any means precluded.

When a root, bark, wood or other pervious drug in small fragments is immersed in the menstruum by which it is to be extracted, a certain volume of the latter is absorbed, the amount depending upon the affinity of the solid for the liquid employed. This pretty definite quantity peculiar to each drug, and a corresponding menstruum, the writer will designate as the normal of absorption of that particular drug. For instance, if one troy ounce of a certain root, bark, etc., should saturate itself with one, two, two and a half, or any number of fluid ounces of menstruum, then its normal of absorption would be indicated by the respective number. Now, if in any formula, for a certain tincture for example, a definite number of ounces of the drug are to yield a specified measure of the finished preparation, the given volume must be increased by the amount of liquid that is finally retained in the drug after decantation. The portion of menstruum lost in the marc will of course contain a relative proportion of the original drug, and with but one maceration this loss would be altogether too great unless partly recovered by the press. Now, in order to avoid the use of the press, the writer divides the menstruum into three parts and macerates the material in these separate portions successively. The prescribed measure of the final product is assumed to be divided into three equal parts, since a division into equal parts extracts in greater ratio than when in any other proportion. The whole menstruum used is, therefore, made up of the three equal parts as just stated, plus the matter absorbed by the material, which latter is the product of the normal of absorption into the quantity of drug employed. The first portion of the menstruum to be applied consequently represents one-third of the final measure, plus the absorbed volume. For instance, if 6 troy ounces of a drug is to be extracted with a specified menstruum whose final volume after three macerations shall be 48 fluid ounces, the normal of absorption being ·75, then the absorbed volume will be 4·5 fluid ounces and the measure of the first macerate consequently will be $16+4·5=20·5$ fluid ounces. Now, after due maceration and decantation of 16 fluid ounces, the residual menstruum must retain 4·5 parts of the 20·5 into which the activity of the drug is assumed to be divided. This ratio, when reduced to a vulgar fraction whose numerator is 1 and denominator 4·55+, shows that in the first maceration one part out of every 4·55+ of the whole material is lost. The denominator of this fraction the writer terms the subnormal of absorption. But in the second maceration 16 fluid ounces of fresh menstruum is poured upon the first residue, thereby restoring the original measure of 20·5 A second decantation now again leaves 4·5 parts of the first loss unextracted, and the third or final maceration sustains again a permanent loss of 4·5 parts of the second. The ratio of the total loss in the whole operation will therefore be represented by the product of the fraction whose denominator is termed the subnormal of absorption multiplied into itself three times. The denominator 94·5 of this new fraction, which, as will be seen, is the cube of the subnormal of absorption, the writer styles the subnormal of loss. Hence it becomes evident that if the normal of absorption is small the subnormal of absorption must be correspondingly great, and the cube of this, or the subnormal of loss, must be great in proportion, and so inversely small will be the actual loss. This calculation shows that in this formula 1 part out of every 94·5 of the drug remains unextracted, and hence, in order to prepare an extraction representing a given quantity of any substance, this must be used in such increased proportion as to cover the anticipated waste. To ascertain this required addition the above calculation becomes necessary; but in such cases where the normal of absorption is large the extra addition of absorptive matter decreases the subnormals to such an extent that several trial estimates will have to be made in order to adjust the formula to these conditions. Now, if we assume a case in which the subnormal of loss is 8, for instance, that is, one-eighth of the drug as above explained, then it is not sufficient to add simply one-eighth as much more as a correction for loss, because, as will be easily seen, one eighth of this addition will also be lost; and if, again, one-eighth of this is added, still there remains a deficiency of one-eighth of each amount added. This process is naturally endless in extent, and the finding of the true correction involves the summation of an infinite decreasing geometrical series in which both the first term and the ratio is one-eighth. The result is found by dividing the first term by the difference between unity and ratio, and is therefore in this instance one-seventh. The writer designates the denominator of this fraction the subnormal of correction, and which is in every instance one less than the subnormal of loss. If the latter is eight, the former becomes seven. Hence the true correction is eight divided by seven, or one and one-seventh, that is, the subnormal of loss divided by the subnormal of correction. Yet, in cases where the normal is large and the subnormals small, the addition of the true correction augments the solid material to such an extent that the consequent decrease of the subnormal of absorption becomes very perceptible and necessitates the increase of the correction beyond the indication of the calculated subnormals. Several trial estimates, as above already noted, will readily point out the proper amount of the required increase. Since, however, remaceration is not intended for universal application, the case can always be selected to meet the process. In several instances, where it is desirable to employ this method, but where the material is inexpensive, a large proportionate direct loss of crude drug is not to be considered when indirect disadvantages are incurred by the employment of other methods. Such is the case in calumba and squill, whose normals of absorption are very high. A modification of the method which the writer designates as double remaceration can also be advantageously applied in similar cases, as, for instance, in the preparation of syrup of rhubarb, as will be seen farther on. It is not, however, necessary to sustain any great amount of loss in any formula by remaceration, as by means of the press or a further maceration the most part may be saved for the next batch.

In the following formulæ the expressions $\frac{1}{2}$, $\frac{1}{3}$, $\frac{2}{3}$, $\frac{3}{4}$, etc., alcohol, mean mixtures of strong alcohol and water containing the strong alcohol in the proportion thus indicated. This renders the preparations one-eighth more alcoholic than officinally directed. The antiquated term "alcohol," as employed by the Pharmacopœia, is long since obsolete and decidedly cumbersome, in fact, almost entirely disregarded by the great majority of pharmacists, who, having become accustomed to modern usage, make no discrimination, but use only the one article which the market affords. Hence, in this instance, the officinal authority is properly ignored in favour of that which long established custom has sanctioned.

Cantharides.—Cantharides often contains its activity in a form not easily extracted by ordinary menstrua. Alkalies, however, by generating very soluble cantharidates, become excellent means for this purpose, especially since they also recover that portion that is usually retained in combination with a peculiar fixed oil. In using an alkaline menstruum, percolation of the powder is nearly impossible; but for the purpose of remaceration, even in conjunction with a weaker alcohol than the officinal, the whole flies are most effectively treated. The normal of absorption for cantharides is rather high, but since the proportion in the tincture is but small, the subnormals are correspondingly great, being 5· and 125· respectively, so that the loss in 3 troy ounces is only about 12 grains. Six pints of the tincture is prepared by macerating with occasional agitation 3 troy ounces and 15 grains of whole cantharides, and 90 grains of potassium hydrate, in 40 fluid ounces of $\frac{1}{3}$ alcohol, for four days, decanting 32 fluid ounces and pouring on the residue 32 fluid ounces more of the menstruum; macerating again as before for three days, decanting 32 fluid ounces a second time; and again macerating the residue with 32 fluid ounces of menstruum for three days, then decanting 32 fluid ounces as before, mixing the three decantates thus obtained and filtering. Should the filtration not proceed with sufficient rapidity the addition of a little powdered chalk will greatly hasten it.

Capsicum.—For similar reasons as those obtaining in the case of cantharides, capsicum cannot be exhausted with the officinal menstruum; but since alkalies form very soluble capsicates, and also free the capsicin from its combination with fixed oil, they are excellent adjuvants to the process. The normal of absorption of capsicum in the pod is 1·25; its subnormals, 9·53 + and 865·5 +. This shows that, as the loss is so small, even one maceration with equal subnormals of 26·5 would suffice for its extraction, since to prepare one gallon of the tincture in that manner requires but an extra addition of 1·22 drachms to compensate the loss. With so large a volume as one gallon it is, however, more convenient to perform two macerations in which the subnormals are 13·8 and 150·44. Hence the formula. Take of capsicum in pod 4 troy ounces and 15 grains; potassium hydrate, 2 drachms; $\frac{1}{2}$ alcohol, 133 fluid ounces. Upon the capsicum pods and potassium hydrate pour 69 fluid ounces of the menstruum, and after four days' maceration, the mixture being occasionally stirred or shaken, decant 64 fluid ounces; upon the residue pour the remaining 64 fluid ounces of menstruum, and after three days of maceration, as before, decant 64 fluid ounces. Mix the two decantates and filter. The tincture filters very rapidly and remains permanently bright. It is much deeper tinted than the officinal tincture, and can be mixed with water in all proportions, remaining perfectly clear.

Catechu.—Catechu is one of that class of substances that cannot be extracted by percolation. Remaceration, however, effects its total exhaustion without loss. Tincture of catechu, however, contains cinnamon, whose normal of absorption is 1. Four pints of the tincture is prepared as follows:—Take of catechu, dry and coarsely powdered, 6 troy ounces and 1 drachm; cinnamon, coarsely bruised, 4 troy ounces and 1 drachm; $\frac{1}{2}$ alcohol, 71 fluid ounces. Upon the mixed solids pour 29 fluid ounces of the menstruum. After macerating the mixture with frequent agitation for three days, decant 22 fluid ounces; on the residue pour 21 fluid ounces of menstruum, and after two or three days decant 21 fluid ounces. Finally, macerate the residue once more for two or three days with 21 fluid ounces of menstruum, decant 21 fluid ounces, mix the several decantates and filter. The tincture can, however, be more conveniently made by two macerations, using $6\frac{1}{4}$ troy ounces of catechu and $4\frac{1}{4}$ troy ounces of cinnamon, macerating these with 39 fluid ounces of menstruum, decanting 32 fluid ounces, macerating the residue again with 32 fluid ounces of menstruum, decanting, mixing and filtering.

Cinchona.—The normal (n) of cinchona is ·75, and its subnormal of absorption ($s\ a$) in the simple tincture 3·37, and the subnormal of loss ($s\ l$) 38·28. One gallon of the tincture is prepared by macerating $24\frac{3}{4}$ troy ounces of cinchona, coarsely bruised and freed from dust by sifting, in 62 fluid ounces of $\frac{3}{4}$ alcohol for four or five days, decanting 43 fluid ounces, pouring on the residue 42 fluid ounces of the alcohol, decanting after three days, macerating the residue again with 42 fluid ounces of the menstruum, decanting after three days, mixing and filtering.

The compound tincture of cinchona contains, in addition to the bark, orange peel and serpentaria. The n of orange peel is 1·2, which of course increases the n of the mixed drugs. Ten pints of this tincture is prepared as follows:—$16\frac{3}{4}$ troy ounces of red cinchona, coarsely bruised, 13 troy ounces of orange peel, coarsely bruised or cut in slices, 3 troy ounces of serpentaria, in coarse powder, are mixed and macerated for four or five days in 84 fluid ounces of $\frac{3}{4}$ alcohol; 54 fluid ounces of the liquid is then decanted. On the residue 53 fluid ounces of the alcohol is now poured, and after three days the same measure is again decanted. Lastly, 53 fluid ounces more of the menstruum is poured on the residue, and after three days again decanted. The three decantates are then mixed and filtered.

Cinnamon.—One gallon of tincture of cinnamon is prepared by macerating, for three days, 12 troy ounces and 1 drachm of cinnamon, coarsely bruised, with 55 fluid ounces of $\frac{2}{3}$ alcohol, then decanting 43 fluid ounces, again macerating the residue, as before, with 43 fluid ounces of menstruum, decanting 43 fluid ounces, macerating the residue once more with 42 fluid ounces of the alcohol, decanting, mixing and filtering.

Calumba.—This root cannot be properly treated by percolation. Remaceration, however, extracts it admirably. To prepare four pints of the tincture $8\frac{1}{2}$ troy ounces of the root, in small fragments free from dust, is macerated for three or four days with 35 fluid ounces of $\frac{1}{2}$ alcohol; 22 fluid ounces are then decanted, and on the residue 21 fluid ounces more of the alcohol is poured; after three days 21 fluid ounces are decanted, and the residue once more macerated for three days with 21 fluid ounces of the alcohol; this is then decanted, the decantates mixed, set away to clear by deposition, and the tincture decanted from the dregs.

Gentian.—The *n* of gentian in 1·75; but since the compound tincture of gentian contains also orange peel and cardamom these additions reduce it for the mixture to 1·43. The *s a* then becomes 3, and the *s l* 27. One gallon of the tincture is prepared by macerating for three days a mixture of 8 troy ounces and 3 drachms of gentian, cut in small fragments, 4 troy ounces and 1½ drachms of orange peel, cut in thin slices, 2 troy ounces and ¾ drachm of cardamom, in coarse powder, in 64 fluid ounces of ½ alcohol; then decanting 43 fluid ounces, pouring on the residue 43 fluid ounces of the menstruum, macerating for three days, again decanting 43 fluid ounces; macerating the residue once more for three days with 42 fluid ounces of the menstruum, decanting, mixing the decantates, setting the mixture aside for repose and pouring the clear tincture from the dregs.

Ipecac.—The officinal syrup of ipecac is prepared from the fluid extract and becomes cloudy from deposition of resinous matter. In an earlier volume of the *Pharmacist* the writer proposed a process for preparing a clear syrup, by first diluting the fluid extract with water, after repose filtering, and then converting the clear filtrate into syrup by adding the required amount of sugar. Remaceration is, however, a much more satisfactory method for obtaining a clear and permanent syrup. The writer had on previous occasions recommended the addition of alcohol to fermentable syrups, to insure their permanency. The new formula contains one fluid ounce of this in the pint of syrup. The *n* of ipecac with ⅛ alcohol is 1·125, the *s a* 3·32, and the *s l* 36·6. One gallon of syrup of ipecac is made by taking 8¼ troy ounces of ipecac, coarsely bruised, acetic acid, ½ fluid ounce, and ⅙ alcohol, 20½ fluid ounces, mixing these and macerating with occasional stirring for three or four days, then decanting 21 fluid ounces; macerating the residue again with 21 fluid ounces of ⅛ alcohol, decanting after three days; pouring 20½ fluid ounces more of the menstruum upon the residue, decanting after three days, mixing the several decantates and filtering, through starch if necessary. Upon 98 troy ounces of granulated sugar then pour 56 fluid ounces of the filtrate, shake the mixture frequently during three or four hours and decant the syrup from the undissolved sugar. On the residue pour the remainder of the filtrate, shake until all the sugar has dissolved, mix the solution with the first decantate and strain through muslin.

Rhubarb.—Rhubarb cannot always be practically treated by percolation. By remaceration, however, it is most easily extracted. The normal of rhubarb in ½ alcohol is very high, being 2·083, its *s a* is 2·7 and *s l* 19·68. One gallon of the tincture is prepared by macerating 12¾ troy ounces of rhubarb, in small fragments, free from dust, and 2 troy ounces and 1 drachm of cardamom, in coarse powder, in 70 fluid ounces of ½ alcohol for three or four days, decanting 43 fluid ounces; macerating the residue again with 43 fluid ounces of the menstruum for three days, decanting 43 fluid ounces; pouring 42 fluid ounces more of menstruum on the residue, decanting 42 fluid ounces after three days, mixing and filtering. The accuracy of this method of extraction was verified in the case of rhubarb, more than twenty experiments having shown that the yield of extract on evaporation accords closely with the calculation.

Owing to the high *n* of rhubarb with ⅛ alcohol, this being 2·57, it is impossible to obtain a sufficient concentration in the decantates by the ordinary method to answer for the preparation of the simple syrup of rhubarb. But by a modification which the writer terms double remaceration it is very convenient, by a slight augmentation of loss, to obtain an extraction of the requisite strength.

The following is the formula for two gallons of syrup of rhubarb made without heat:—On 14 troy ounces of rhubarb, in small pieces free from dust, pour 91 fluid ounces of ⅛ alcohol and macerate for four days, then decant 55 fluid ounces, and on the residue pour 55 fluid ounces more of the mixture; after three days again decant 55 fluid ounces, and on the residue pour 54 fluid ounces of the menstruum, decanting this after three days. Then on 13 troy ounces more of rhubarb pour 77 fluid ounces of the first two decantates and macerate for four days; then decant 44 fluid ounces, and on the residue pour 43 fluid ounces of the second and third decantates; after three days' maceration decant 43 fluid ounces, and on the residue pour the remaining 43 fluid ounces of the third decantate, decanting this after three days. Mix all the last decantates, amounting to 130 fluid ounces, and set the mixture aside for repose, and then decant the clear liquid from the dregs and filter the remainder. On 192 troy ounces of granulated sugar pour 114 fluid ounces of the liquid, and shake the mixture frequently during five or six hours, then pour the syrup from the undissolved sugar and dissolve this in the remaining liquid; mix the two solutions, strain through muslin, add half a fluid ounce of ammonia water and mix.

Aromatic syrup of rhubarb is prepared as follows:—Take of rhubarb in small pieces 2¾ troy ounces, cloves in coarse powder, ½ troy ounce, cinnamon in coarse powder, ½ troy ounce, nutmeg in coarse powder, 2 drachms, ⅛ alcohol, 38 fluid ounces. Macerate the solids in the alcohol for three days and then decant 30 fluid ounces. On the residue pour 30 fluid ounces more of the alcohol, and after three days decant it again. Mix the two decantates, and after a sufficient repose pour 3 pints of the cleared liquid upon 78 troy ounces of granulated sugar; decant after five or six hours and on the sugar residue pour the remainder of the liquid. When all the sugar has been dissolved, mix the solutions, strain through muslin and add 1 fluid drachm of ammonia water.

This syrup may also be prepared by making an extraction of the unexhausted marc remaining after the preparation of the simple syrup. By using the press more than a sufficiency of liquid may be obtained for the purpose. But it is far more convenient to pour 61 fluid ounces of ⅛ alcohol upon the first residue, and decanting after three days, then pouring 31 fluid ounces of this decantate upon the second residue, decanting after three days, continuing the maceration with the remaining 30 fluid ounces, decanting again after three days, mixing, macerating the aromatics in this for several days, decanting and completing as above.

Squill.—Squill is another of those substances that cannot be properly treated by percolation. Ordinary maceration, in conjunction with the press, is also comparatively inefficient and very inconvenient. The *n* of squill is exceedingly high, being 2·53, and the subnormals low in proportion; but since squill is a very cheap drug, a larger proportionate waste is of no consequence, if the ratio of exhaustion can be accurately determined. One gallon of vinegar of squill is prepared as follows:—On 19 troy ounces of squill pour 19 fluid ounces of acetic acid and 72 fluid ounces of water; after a maceration of four or five days decant 43 fluid ounces, and on the residue pour 43 fluid ounces of water; after three days decant 43 fluid ounces, and on the residue pour 42 fluid ounces of water; decant this, mix the several decantates and filter.

In making the syrup from a fresh vinegar of squill a voluminous, unsightly precipitate of pectous matter is always thrown out by the sugar. This precipitate does not occur when using a vinegar less recent, owing to action of the acetic acid in transforming the pectin. This syrup is readily prepared by using granulated sugar without heat, as described in the processes for the syrups of rhubarb, noted above.

The method of remaceration will probably also apply to the preparation of compound syrup of squill, by using the menstruum in such increased volume as to admit of a concentration requiring the least amount of evaporation consistent with the smallest possible waste of drug.

Vanilla.—Vanilla cannot be properly extracted by percolation. Remaceration, however, effects this most admirably and conveniently. With ½ alcohol the *n* of vanilla is about ·75, and in a tincture containing 1 troy ounce in 8 fluid ounces the *s a* is 4·55 and *s l* 94·5. To prepare one half gallon of this tincture 8 troy ounces and 40 grains of vanilla cut very obliquely into thin slices is macerated with 28 fluid ounces of ½ alcohol for four days. Twenty-two fluid ounces is then decanted and 21 fluid ounces of the alcohol is again poured on the residue; after three days this is decanted and 21 fluid ounces of the menstruum is once more poured on the residue; after three days this is decanted. The three decantates are then mixed and filtered after a sufficient repose.

There are numerous other cases in which the method of remaceration can be very advantageously employed, but it is thought that the above enumerated are among the most important.

ANALYSIS OF ERIODICTYON CALIFORNICUM.*

BY CHARLES MOHR.

Eriodictyon Californicum is receiving attention for its action in lung diseases and bronchial affections. What is its therapeutical value, and to what is its activity due? Make a chemical examination of it.

In reply to this query it was found necessary to subject the plant to the regular course of analysis followed in the separation of the organic constituents of plants.

Ten grams of the air-dried herb, of good quality, successively exhausted by pure ether, alcohol of 95 per cent., and distilled water, yielded the following results:—

1. The ethereal percolate, evaporated spontaneously and finally by application of gentle heat, was mixed with water. A copious precipitate of resinous matter occurred; the supernatant aqueous liquid, after having been freed from suspended resin, was of a very pale straw colour, slight taste and faint acid reaction.

A. *Examination of Resinous Precipitate.*—By treating with boiling alcohol of 70 per cent. for an hour, and subsequent maceration at a low temperature for twenty-four hours, filtering and washing the undissolved portion with alcohol of 70 per cent., and digesting the concentrated filtrates with animal charcoal, evaporating and exsiccating over sulphuric acid, a brittle resin was separated having a yellow-greenish colour, slight acid reaction, aromatic, acrid slightly bitter taste, faint odour, and fusing at about the temperature of boiling water. The portion left undissolved by alcohol of 70 per cent. was treated with hot alcohol of 95 per cent., as long as this dissolved any of the material.

A greyish soft and tenacious substance was left, not volatile, on stronger heating fusing and burning with a smoky flame, destitute of taste and odour, insoluble in alcohol, partially soluble in petroleum naphtha, ether and benzole, readily soluble in chloroform and in a mixture of carbon disulphide and absolute alcohol, which facts prove its identity with caoutchouc. From the hot alcoholic solution, on cooling, a soft waxy substance separated, forming a pellicle; this substance, freed from adhering resin by continued washing with cold alcohol, possesses a greenish-white colour proven to be a vegetable wax. The quantity obtained was too small to permit a closer study of its properties. The remaining alcoholic liquid was of a dark green colour, possessing no peculiar taste or odour, and was completely decolorized by animal charcoal, and could not be regarded as a resin proper but as inert colouring matter.

B. *Examination of the Aqueous Liquid.*—No crystallizable substance was obtained, and on application of the proper tests no indication of an alkaloid or nitrogenous compound was obtained. The acid found present in small quantity proved to be a tannic acid precipitated by ferric chloride, almost black in colour.

2. The alcoholic percolate was evaporated to a small bulk and mixed with water.

The insoluble resinous portion obtained consisted entirely of colouring matter, its alcoholic solution being without taste or odour, was entirely decolorized by animal charcoal.

A portion of the aqueous liquid, after being entirely freed from resinous colouring matter, was concentrated by slow evaporation and left on ice for several days. It yielded no crystals, and the application of alkaloid tests led to no results. To be firmly convinced on this point a portion of the liquid was digested with oxide of lead to remove tannic acid, the filtrate evaporated to dryness and extracted with hot alcohol of 95 per cent.; the solution on spontaneous evaporation left no residue. Another part of the same liquid was examined for organic acids; a tannic acid was found, which precipitated ferric salts green.

To separate the organic acids lead acetate in solution was added until further addition produced no precipitate; filtered; the filtrate was treated with ammonium hydrate to a still feeble acid reaction, and on addition of acetate of lead no turbidity was produced, thus showing all organic acids present were obtained in the lead precipitate, which is absolutely insoluble in boiling water.

The lead precipitate was dissolved in acetic acid, reprecipitated by ammonia, carefully washed and, whilst still moist, mixed with absolute alcohol and decomposed by means of sulphuretted hydrogen, filtered, and the filtrate evaporated to dryness, at a low temperature; the tannic acid was obtained as an amorphous brittle substance, of a clear yellowish-brown colour, having an astringent acidulous taste. It was perfectly soluble in alcohol, yielding a turbid solution in water, which on addition of solution of the alkalies turned to deep reddish-brown colour, and became perfectly clear.

Ferric chloride gives a green precipitate, turning to a dirty grey on standing; it is dissolved by ammonia, yielding a solution of a dingy purple colour, and is decolorized by oxalic acid.

Sulphate of cinchonia gives a copious white precipitate.

Plumbic acetate yields a golden yellow precipitate, not dissolved by potassic hydrate.

Plumbic subacetate yields a dingy-yellow precipitate, soluble in potassic hydrate.

Tartar emetic, no precipitate.

Glue, no precipitate.

Hydric sulphate dissolves it with a deep crimson, somewhat purplish colour.

Argentic nitrate—on heating the metal is partly reduced in the specular form.

Diluted hydric sulphate, when added to either alcoholic or aqueous solutions, shows a peculiar behaviour by rendering the solution at first milky white, and on short standing, a viscous brownish mass separates. Fehling's solution then added, copper is reduced.

This decomposition, effected by diluted sulphuric acid, takes place very rapidly at ordinary temperature, and this fact and the general behaviour to other reagents proves it to be a glucoside of the tannic acid series, of decided peculiarities, closely allied if not identical with that found by the writer existing in *Pycnanthemum linifolium* and perhaps to exist in *Ballota vulgaris* and *Leonurus cardiaca* (Rochleder).

To obtain the acid in sufficient quantity, so as to be able to study its properties more closely, and particularly to satisfy myself that it is not associated with any other solid organic or volatile acids, such as benzoic or cinnamic acid, a fresh quantity of dried herb was extracted by alcohol of 75 per cent. The alcoholic extract, freed from resin by addition of water, was treated with plumbic

* Read at the twenty-seventh annual meeting of the American Pharmaceutical Association.

acetate, the precipitate dissolved in acetic acid, reprecipitated by ammonia, decomposed by sulphuretted hydrogen under absolute alcohol. The acid as obtained, tightly enclosed between two well-fitting watch-glasses, was exposed to a temperature of 220° to 240° C. for some time. As no sublimation took place, the absence of all solid volatile acids of the aromatic series was proven.

3. *Treatment of the Herb with Water.*—The aqueous percolate of the herb previously exhausted by ether and alcohol successively was of a brown colour, showed acid reaction, and possessed an astringent bitterish taste. The examination was conducted the same as in the case with the liquid under No. 2; the same tannic acid was alone found. A portion of the percolate concentrated by evaporation gave on addition of absolute alcohol, a copious precipitate readily soluble in water, and proved to be gum associated with a brown inert matter; sugar in small quantities was detected. No alkaloids or nitrogenous body could be detected.

Ten pounds of the leaves subjected to distillation with water yielded a distillate containing very small quantities of a volatile oil, adhering to the sides of the receiver and forming a very thin layer upon its surface, too minute to allow of a separation and subsequent nearer investigation. It imparts to the distilled water an aromatic odour and taste but slightly resembling that of the dried plant. Tested immediately after distillation, it was found entirely neutral towards test papers, and not the slightest reaction was obtained with any of the alkaloid tests, so that it may be safely asserted that the plant does not contain any volatile alkaloid.

By these results it was ascertained that *Eriodictyon californicum* contains—

Volatile oil in small quantities, not further examined.	
Moisture	12·50
Matter extracted by ether	14·98
(Consisting of a bitter, acrid, brittle resin, 8 per cent.; inert green colouring matter, caoutchouc, wax in small quantity, tannic acid in small quantity.)	
Matter extracted by alcohol	10·79
(Consisting of inert resinous matter decolorized by animal charcoal, a peculiar glucoside of the tannic acid series predominating in the mass.)	
Matter extracted by water	18·42
(Consisting of same tannic acid above mentioned, gum, brown extractive inert substance, trace of sugar.)	
Wood fibre and ash	43·31
	100·00

From the above analytical results it is evident that the therapeutical value of the plant rests solely upon its stimulating and astringent effects upon the mucous membrane of the respiratory apparatus, especially the bronchial tubes, due to the action of the brittle acrid resin exciting secretion and promoting expectoration, the astringent tannic acid imparting tone and solidity to the membranes in a state of relaxation. How far in this respect the drug will prove to be equal or superior to the numerous remedies of like therapeutic effect, and how far its reputation amongst the people of the country where yerba santa is found indigenous is sustained when employed by the profession, must be decided by the practitioner.

In this locality the fluid extract of the herb has been used by some physicians quite extensively. A medical friend who has used it on the strength of its repute, and given it what he considers a fair and searching trial in lung and bronchial affections, did not find his expectations realized, and has since dropped the use of it, as possessing no advantages over the remedies to which he heretofore had recourse.

The results of my experience show that a menstruum of alcohol of 70 to 75 per cent. yields the best preparation.

LIP-SALVE.*

Spermaceti	40 parts
Lard, perfectly pure and fresh	80 „
White Wax	20 „
Oil of Sweet Almonds	5 to 10 „

according to the season of the year, are melted together, the mixture coloured with a sufficient quantity of alkanet, by digesting the root with the melted mass, and the latter then suitably perfumed, for instance, with

Oil Bergamot	2 parts
Oil Orange	3 „

The mass is then poured out into moulds. It is customary to pour it into tin-tubes, from which it is removed when cold, and then covered with tin foil.

Cold Cream (Crême celeste).

1. Spermaceti	30 parts
White Wax	24 „
Oil of Sweet Almonds	168 „

are melted together at a gentle heat, the melted mass poured into a warmed porcelain or wedgewood mortar, stirred until it begins to solidify, and then intimately mixed with

Rosewater	70 parts.

After stirring until cold, there may be added, for every 10 ounces of the mixture,

Oil of Rose	2 drops
Oil of Bitter Almonds	3-4 „

This cream is white. The following formula yields a cheaper, slightly yellow, but still very good product:

2. White Wax	166 parts
Olive Oil, finest	500 „
Rosewater	100 „
Oil of Bergamot	15 „
Oil of Bitter Almonds	q.s.

To be prepared as the preceding.

Glycerin-Cream (Crême de Glycerine).

Spermaceti	60 parts
White Wax	30 „
Oil of Sweet Almonds	250 „
Rosewater	10 „
Glycerin	20 „

To be prepared like cold cream, and to be perfumed with oil of rose and oil of bitter almonds.

Almond Cream (Crême d'Amandes).

Lard, perfectly pure and fresh	220 parts
Solution of Potassa, containing 26 per cent. of caustic potash	120 „
Alcohol, 60 per cent.	10 „
Oil of Bitter Almonds	q.s.

Triturate, in a porcelain or wedgewood mortar, the lard and potassa solution, and let it stand a few hours. Then add the alcohol and sufficient oil of bitter almonds to give it the proper flavour. Finally triturate until the mass is uniform, and resembles mother-of-pearl.

This cream has a handsome look, but is not so bland as the first-mentioned varieties.

CEMENT WHICH RESISTS ACIDS.*

Melt together carefully 1 part of caoutchouc (India-rubber) with 2 parts of linseed oil, and gradually incorporate with it 3 parts of white bole, so as to form a plastic mass.

This cement is not at all attacked by hydrochloric, and but very little by nitric acid. When heated it softens but very little. It does not easily dry upon the surface. If this cement is mixed with $\frac{1}{2}$ of its weight of litharge, or minium, it dries up in the course of time, and becomes hard. This is known as "Benicke's Cement."

The Pharmaceutical Journal.

SATURDAY, DECEMBER 27, 1879.

ANOTHER "CREAM OF TARTAR" PROSECUTION.

A CASE was heard before the magistrates at Fareham last Tuesday which may not improbably be of service in moderating the officious zeal of public analysts in instigating prosecutions under the Sale of Food and Drugs Act upon frivolous or insufficient grounds, and by illustrating the vexatious hardship to which tradesmen can be subjected by such ill-advised and unwarrantable proceedings as we have already too often had occasion to comment upon.

It appears that the question what is "cream of tartar" had presented itself to the mind of one of the officers of the Hants Constabulary as being one that was of importance as regards the interests of the public, and thereupon he instructed one of his subordinates to go to the shop of Mr. W. O. SMITH, of Titchfield, and purchase a quarter of a pound of this article. After the purchase was completed Mr. SMITH was informed that the sample was intended for analysis, and the usual offer was made to give him a portion of it under seal to be retained in his possession. Mr. SMITH very wisely accepted this offer, and the sample was thereupon divided into three portions, each being sealed in his presence. One of these samples was forwarded to the county analyst for examination, and the results, as stated on his certificate, showed that it contained 9·26 of tartrate of lime and 0·29 of sulphate of baryta.

This statement of the results of analysis appears to have inspired the officer of the Hants Constabulary with dismay, as indicating that the article sold by Mr. SMITH as "cream of tartar" was not really commercial bitartrate of potash, but a preparation of lime that was not of the nature, substance and quality of the article asked for. Thereupon Mr. SMITH received an undeniable invitation to appear before the county magistrates and answer for the offence he was supposed to have committed. He, unconscious of being guilty of any infringement of the Food and Drugs Act, at once communicated with the wholesale house from which he purchased his "cream of tartar," stating what had happened and asking what he was to do for his defence.

In order to determine first what was the composition of the "cream of tartar" he had sold, the sealed sample was submitted to analysis, the result showing that it contained upwards of 92 per cent. of bitartrate of potash, 6·95 per cent. of dry tartrate of lime, and 0·30 per cent. of insoluble material consisting of sulphate of baryta. These results sufficiently established the good character of the article sold and showed that it was a good sample of "cream of tartar." The amount of tartrate of lime in it was far from being the maximum amount of that ingredient there may be and necessarily always is present in "cream of tartar," as incidental to its preparation, and the amount of insoluble impurity present in the form of sulphate of baryta was so small that the idea of its having been put into the "cream of tartar" to that extent for fraudulent purposes could not be entertained. This view was consistent with the well-established reputation of the wholesale firm from which Mr. SMITH purchased the "cream of tartar," and it was consistent with his own declared practice of always purchasing the best drugs obtainable in the market.

Upon the basis of these facts the President of the Pharmaceutical Society instructed Mr. FLUX to attend at the hearing of the case, as the Solicitor of the Society, in order to take such steps as might be desirable for protecting the interests of the trade in a general way. The evidence given for the defence consisted mainly of a statement of the facts above indicated, together with an explanation that tartrate of lime being a constituent of grape juice, it naturally formed part of the material known as "argol" or "tartar" deposited during fermentation in making wine, and that this tartrate of lime being to some extent soluble in a solution of bitartrate of potash it inevitably became also a constituent of the "cream of tartar" prepared in the usual way from argol or tartar; showing, in short, that no offence had been committed by the sale of the article in question.

Upon this evidence the magistrates unanimously decided to dismiss the case, and the counsel acting for Mr. SMITH then applied to be allowed costs, inasmuch as the prosecution had been instituted on frivolous and insufficient grounds, and because the damage thus done to the reputation of a dealer in drugs by such proceedings was calculated to be of serious injury to him. This application was supported in the same spirit by Mr. FLUX, on behalf of the Pharmaceutical Society, and it was acceded to by the magistrates. By this recognition of the wrongful nature of the prosecution an important point has been gained, and it seems desirable that further action should now be taken with a view to rendering public analysts' certificates subject to some competent scrutiny, before they can be made use of as grounds for prosecutions and causing needless personal vexation, as well as interference with legitimate trade. We purpose next week giving a full report of the case.

PHARMACOPŒIA REVISION IN GERMANY.

THE revision of so important a work as the Pharmacopœa Germanica, which has to be appealed to by the pharmacists of one of the most important of European nations, and not unfrequently by many British pharmacists, would necessarily always present some points of interest to the readers of this Journal; but more peculiarly is this the case when the revision of the British Pharmacopœia and the position of the British pharmacist in regard to it has so recently formed a prominent topic of discussion in the Council of Pharmaceutical Society. We shall, therefore, take the opportunity of culling a few details from a report just published by the Pharmacopœia Committee of the German Association of Pharmacists.

The first Pharmacopœia of the German empire was issued in 1872, so that it had been in use six years when the German Association, during its meeting in Coblentz last year, appointed a Committee to consider propositions made for its improvement. The nomination was left to the executive of the Society, and after some difficulties had been overcome, a strong committee was formed, the professorial element being represented by Dr. Flückiger, the commercial and manufacturing by Messrs. Schering and Trommsdorff, whilst eleven apothecaries represented pharmacy. Of this committee Dr. Brunnengraber was chosen President and Dr. Wilms Vice-President.

Meanwhile, the Imperial Chancellary had invited the different governments to obtain, from those interested, information as to the deficiencies which during use might have become manifest in the Pharmacopœa Germanica, and as to any enrichment of the materia medica that experience showed to be desirable. Several members of the Pharmacopœia Committee were already engaged in the solving of this problem, while as yet no invitation to report had been sent by the Government to the German Association of Pharmacists. It appeared desirable, therefore, to the Committee to ascertain whether a participation by it in the work of revising the Pharmacopœia could be obtained, and if this question were answered in the affirmative, to settle in what way and manner the Committee could help in solving the problem raised.

For the consideration of both these points a meeting of the Committee was arranged to be held in Berlin last April, and at the commencement of the meeting the President was able to announce to his colleagues that a report of their work when completed would be welcomed by the Imperial Sanitary Department. The Committee was therefore in a position to proceed at once to the consideration of the second question. As a result it was arranged that Herr Biltz should send some work already published by him, as a report to the Sanitary Department. Herr Hirsch had also been requested to prepare a report, and had so far advanced with the work that it was ready to put into the printers' hands. It was decided, therefore, to print this as well, and when the other members of the Committee were in possession of copies they should be invited each to draw up a report, taking the work of Messrs. Biltz and Hirsch as a basis. In this way it was hoped that the useless repetition of the same work might be avoided and a better result obtained. In order to secure uniformity in the different articles a series of general principles upon which it was agreed that the German Pharmacopœia should be constructed were formulated. At the General Meeting of the German Association in Hanover, in September last, these general principles were brought forward and agreed to, but unfortunately the meeting was unable to occupy itself with the consideration of the second portion of the work, which has now been issued in the printed form. It is proposed to refer to some of the recommendations contained in this Report in a future article.

Transactions of the Pharmaceutical Society.

GENERAL MEETING—BENEVOLENT FUND.

ELECTION OF ANNUITANTS.

A General Meeting of the Members, Associates in Business, and Associates of the Pharmaceutical Society, and of the Subscribers and Donors to the Benevolent Fund, was held at the house of the Society, 17, Bloomsbury Square, on Friday, December 19, at 12 o'clock, for the Election of Three Annuitants.

Mr. G. W. Sandford, President, in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, who examined the voting papers and brought up the following report:—

Scrutineers' Report.

We, the undersigned Scrutineers, appointed at the Fifteenth Election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us, and report the following result:—

Barker, John	2057
Bowen, Margaret Sophia	664
Dutton, Sarah Ann	1137
Gason, Elizabeth Jane	3335
Hollinworth, Charles Foster	2738
Kennett, Louisa	1581
Watkins, Louisa	1492
Woods, Elizabeth	2672
Yates, Willam Lee	2964

3397 voting papers were received, of which number 56 were informal (44 unsigned) and were disallowed.

J. Robbins, Chairman.
Matthew Pound.
Edward L. Cleaver.
T. Edward Greenish.
Charles J. Mead.
Charles E. Turner.
E. N. Butt.
Walter Hills.

December 19, 1879.

The Chairman declared the following three duly elected Annuitants:—

Gason, Elizabeth Jane.
Hollinworth, Charles Foster.
Yates, William Lee.

A vote of thanks was given to the Scrutineers fo their long and arduous duties.

A vote of thanks was also given to the Chairman.

EXAMINATIONS IN EDINBURGH.

December 17 *and* 18, 1879.

Present—Messrs. Ainslie, Borland, Gilmour, Kemp, Kinninmont, Stephenson and Young.

Professor Maclagan was present on the 18th on behalf of the Privy Council.

MAJOR EXAMINATION.

17*th.—One* candidate was examined, but failed to pass.

MINOR EXAMINATION.

17*th.—Nine* candidates were examined. *One* failed. The following *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bremner, James ....Aberdeen.
Carruthers, Robert ....Dumfries.
Couper, Frederick Thomas ......Edinburgh.
Ellis, John William ....Abergele.
Fidler, Thomas William ....Workington.
Hogg, Andrew ....Liverpool.
Laing, James ....Brechin.
Lubbock, John William ....London.

18*th.—Six* candidates were examined. *Three* failed. The following *three* passed, and were declared qualified to be registered as Chemists and Druggists:—

Moon, George William ....Malton.
Raffan, John.........................Portsoy.
Wright, George.....................Nairn.

MODIFIED EXAMINATION.

18*th.—Two* candidates were examined, but failed to pass.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The usual monthly meeting of this Association was held at Britannia Chambers on December 16, when there was a good attendance of members and associates. The chair was occupied by the Vice-President, Mr. Frank White, who, after the election of new members and transaction of some other preliminary business, called on Mr. Major, B.A., B.Sc., F.R.G.S. to give his promised lecture on "Earthquakes and Volcanoes."

The lecturer commenced by referring to the destruction of Herculaneum and Pompeii, just 1800 years ago, by an eruption of Vesuvius. He then went on to speak of Iceland and its volcanoes, saying that the entire island, which is as large as Ireland, was caused by volcanic eruptions. He afterwards referred to the belt of volcanoes which nearly surround the Pacific Ocean, pointing out that volcanoes are always situated near the sea. He then went on to speak of earthquakes, saying they really were unsuccessful volcanoes. When the hidden forces in the earth can find a vent they cause volcanoes, and when they are suppressed and cannot get out they cause earthquakes. He particularly referred to the great earthquake of Lisbon, when 60,000 persons perished, and concluded a most interesting lecture by pointing out the traces of volcanic eruptions which existed in all the mountains of the world.

The lecture was listened to with great attention and loudly applauded at the close.

After a few questions had been answered by the lecturer, the Chairman proposed a hearty vote of thanks to him, which was seconded by Mr. R. Jackson, and carried unanimously.

Mr. Major suitably responded, and the meeting was concluded.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on December 18, Mr. Warren De La Rue, President, in the chair.

A ballot for the election of Fellows was held. Dr. Messell and Mr. Neison being appointed scrutators. The following gentlemen were declared duly elected:—G. S. Allbright, J. R. Ashwell, T. Blackhouse, E. Buckney, J. Bemrose, W. J. F. Churchouse, M. Cochrane, E. J. Day, W. R. Dunstan, E. Francis, F. Hatton, J. Howard, J. J. Hummel, R. E. Holloway, W. R. Eaton-Hodgkinson, T. S. Humpidge, E. Hughes, R. Jones, J. Knowles, A. Leibius, H. F. Morley, E. F. Mondy, H. Newton, J. Parette, J. W. Smith, J. Steiner, J. Snodgrass, A. Scott, G. Stallard, J. M. Wilson. The following certificates were read for the first time:—W. Macnab, W. B. Roberts, G. Salet, T. Terrell.

The Secretary then read a paper—

On the Specific Volume of Water of Crystallization. By T. E. Thorpe and J. J. Watts.—Some years ago Playfair and Joule pointed out that the volumes of certain highly hydrated salts, as for example, sodium carbonate with 10 molecules of water, also the alkaline arsenates and phosphates with 12 molecules, are equal to that of the water considered as ice which they respectively contain. Thus the molecules of the salt seem to exist in the interstitial spaces of the ice. This law does not hold good for salts less highly hydrated; thus in borax, sodium pyrophosphate, and the normal aluminium sulphate the volume seems to be made up of the water considered as ice, together with that of the base as existing in the free state. Schiff has shown that members of certain classes of hydrated salts have the same specific volume. Thus all the alums have a specific volume of 277; double sulphates, $M_2M''(SO_4)_2$, 207, and the vitriols $M''SO_47H_2O$, 146. The authors have determined the precise relation between the specific volumes of various sulphates of copper, magnesium, zinc, nickel, cobalt, iron and manganese, and their respective degrees of hydration. They have incorporated in the present paper some results placed at their disposal by Dr. Playfair. Details of the preparation and analysis of the various hydrates employed are given. The specific gravity was determined by weighing in benzene at 15° C. The results are contained in the following table.—

Hydrates	0	1	2	3	4	5	6	7
$CuSO_4$	44·4	54·3	67·0	80·0	—	109·1	—	—
$MgSO_4$	44·8	55·6	67·0	—	—	112·4	130·8	146·8
$ZnSO_4$	45·6	54·7	66·6	—	—	113·7	130·2	146·8
$NiSO_4$	44·6	56·5	—	—	—	—	129·0	144·6
$CoSO_4$	44·7	55·2	70·9	—	97·4	114·6	130·1	146·0
$MnSO_4$	45·0	55·7	73·6	86·6	98·2	114·4	—	—
$FeSO_4$	44·5	56·2	67·7	—	100·5	—	—	146·7
Means	44·8	55·5	68·8	83·3	98·7	112·9	130·0	146·2

From these results it appears that in the case, at least, of the so-called magnesian sulphates, the volume occupied by the several molecules of water varies with the degree of hydration. The first molecule, the "constitutional water" of Graham, occupies less bulk than any other; its mean relative value is 10·7; the value of the second is 13·3; of the third, 14·5; of the fourth, 15·4; of the fifth (taking the mean of the most concordant numbers, $ZnSO_4$, $CoSO_4$, and $MnSO_4$) 15·6; of the sixth, 15·7; of the seventh, 16·2. These results accord with the fact that the different molecules of water in a hydrated salt are held with various degrees of tenacity, as shown by the different intensities of heat needed to expel them, the amount of energy required standing in some relation to the degree of condensation in the combined molecule. The authors point out the importance of estimating the amounts of heat resulting from the combination of successive molecules of water with the different sulphates. Graham has already shown that more heat was evolved in the combination of the first molecule than in that of any of the remaining molecules, in other words, that the amount of heat developed is related to the degree of condensation of the combined molecules. As the foregoing numbers express the volumes in cubic centimetres of the equivalent of the salts in grammes, it appears that equivalent quantities of these different sulphates occupy respectively the same volume in space, or in other words the unit volume contains the same number of molecules of the different salts.

Professor McLeod then read—

A Note on the Formation of Ozone during the Slow Oxidation of Phosphorus.—The active substance formed during the slow oxidation of phosphorus is probably either ozone or peroxide of hydrogen; the latter substance is readily destroyed by alkalies, a solution of chromic acid, or a solution of alkaline permanganate, whilst ozone is unaffected either by a solution of sodic carbonate, or by chromic acid, and appears to be only slightly attacked by alkaline permanganate. Air in which phosphorus was slowly oxidizing was drawn through a U tube, 9½ inches long (filled with fragments of glass containing in succession sodic carbonate, saturated with carbonic anhydride, a mixture of potassic dichromate and sulphuric acid, and potassic permanganate, previously saturated with carbonic anhydride), and then into a flask containing a solution of potassic iodide and starch; in all cases the latter solution became blue, both when the U tube was cold and when heated to 100°. Similar results were obtained when a U tube 12½ inches long was used, packed with small pieces of pumice, saturated with solution of sodic carbonate. The effect of heat on the gas was tried. The gas was aspirated through a narrow U tube, which was heated to 150° and 200°, beyond this U tube were placed first a weighed U tube, packed with pumice and sulphuric acid, and secondly, a flask with solution of potassic iodide and starch, acidified with sulphuric acid. The U tube was weighed before and after each experiment, and the blue solution titrated with decinormal sodic thiosulphate. The gas was aspirated at the rate of 1 litre per hour, the following results were obtained.

Gas aspirated.	T. of U tube.	Increase of sulphuric acid tube.	Thiosulphate used.
4600 cc.	cold	0·0026 grm.	2·55 cc.
2760 cc.	100°	0·0008 grm.	1·9 cc.
4600 cc.	150°	0·0026 grm.	3·2 cc.
2760 cc.	200°	0.0006 grm.	1·8 cc.

1 cc. of thiosulphate = 0·017 grm. of hydroxyl, which on decomposition forms 0·009 grm of water, and as at least one half of the hydroxyl might be assumed to be decomposed, an increase of the sulphuric acid tube in the last experiment should be 0·016 grm. instead of only 0·0006. Hydroxyl combines with acids, the gas from phosphorus was exposed to the action of strong sulphuric acid for four days without loosing its activity. It is extremely improbable that ozone and hydroxyl are both formed, as these substances destroy each other. The author therefore concludes that the gas obtained during the slow oxidation of phosphorus possesses the properties of ozone and not those of hydroxyl, the only known peroxide of hydrogen.

Mr. Kingzett had listened to the paper with great interest. Up to the present time no evidence had been put on record to prove that this gas from phosphorus contained ozone, and as he had shown that certain hydrocarbons which had been supposed to produce ozone really formed hydroxyl, he had assumed, in the absence of any evidence, that hydroxyl was formed in this case. After referring to the researches of Cornu, Mr. Kingzett said that he could confirm the observation of Professor McLeod that peroxide of hydrogen and ozone in the presence of an acid did not decompose each other.

After some remarks from the President,

Professor McLeod briefly replied.

Mr. W. H. Perkin then read a paper—

On the Analysis of Organic Bodies containing Nitrogen.—Some years since he wished to determine the halogens as well as the carbon and hydrogen in bodies containing nitrogen. The substance was burnt in oxygen, and the products of combustion passed over a weighed quantity of pure metallic silver. The difficulty arose as to how to get rid of the nitrous fumes. Plumbic peroxide was first tried between the water absorbing apparatus and potash bulbs. This succeeded as far as the carbon was concerned; but as nitrous fumes were absorbed by the sulphuric acid the hydrogen determinations were too high. Plumbic peroxide was then placed in the combustion tube; but great difficulty was experienced in heating it to just the proper temperature. Potassic chromate was then tried, and was found to succeed admirably. It absorbed the nitrous fumes completely, had no action on carbonic anhydride, and could be heated without fear. The author therefore recommends the use of about four to seven inches of potassic chromate in the combustion of all substances containing nitrogen, instead of freshly reduced copper, which is very hygroscopic, and occludes hydrogen, or of silver, which requires an inconveniently high temperature. The potassic chromate should be free from an excess of alkali; a trace of bichromate is not harmful, though bichromate does not work so well as chromate. The chromate should be roughly powdered or granulated by evaporating its solution to dryness with constant stirring, or still better, coarsely powdered pumice, saturated with solution of chromate, may be used. The chromate should be kept at a scarcely dull red heat. The author does not state how many times the chromate can be used. Chromate also absorbs sulphurous acid. It does not retain iodine vapour, but would be probably useful with substances containing chlorine or bromine.

After a few remarks from Mr. Warington, the Society adjourned to January 15.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The last meeting of the Association for the year took place on Wednesday evening, December 17, at 32A, George Street, Hanover Square, when Mr. Davidson read an interesting paper on "Coal." The author began by stating that his remarks would be classified under the heads of origin, formation, varieties, products of distillation, distribution and statistics. He then enlarged upon the geology of coal, calling attention to the great lapse of time since and prior to its formation, and stated that the conditions for the construction of coal were not now present. He then noticed the vegetable origin and differences between peat, lignite, cannel coal, and anthracite, illustrating his remarks by specimens kindly lent by the Pharmaceutical Society.

In the discussion which followed (Messrs. Branson, Jones, Miller, Parkinson, Picard, Piper, Wallis and Wren taking part) it was pointed out that the air was probably more loaded with CO_2 than it is at present and that the plants during the carboniferous period were of very quick growth.

After a vote of thanks had been proposed by Mr. Piper, seconded by Mr. Snow and carried, the meeting terminated.

The next will take place on January 1, 1880.

BRITISH ASSOCIATION.

Buffon.*

BY PROFESSOR ST. GEORGE MIVART, F.R.S., SEC.L.S., V.P.Z.S.

In responding to the honour which the authorities of the British Association have conferred in nominating me to fill this chair, I have deemed it best not to occupy your very valuable time with any matter of detail at which I may happen to have worked, but rather to offer to you a few remarks on questions which seem to me to have a general biological interest.

Last year my esteemed friend, Professor Flower, called your attention to the great name of Linnæus. I propose this year to refer to Linnæus's illustrious contemporary, Buffon—not, however, in the character of a rival of Linnæus. Each was a man of genius, each did good

* Presidential Address to the Biological Section of the British Association, Sheffield, August, 1879.

work in his own way—work still bringing forth fruit. It must be admitted, however, that they were men of a very different stamp, and if it is necessary to express a relative judgment with respect to them, I should myself feel inclined to say that Buffon's mind had the greater aptitude for sagacious speculation, with an inferior power of acquiring and arranging a knowledge of facts of structure.

Various circumstances have concurred to favour our recollection of the merits of the great Swede, and to obscure those of the French naturalist. The well-earned fame of Linnæus is kept ever fresh in our memories by the necessarily frequent references to him in matters of nomenclature. On the other hand, not only are Buffon's claims on our esteem in no similar way brought before us, but those very speculative opinions of his, which are a merit in our eyes, have gained him disfavour with our immediate predecessors, whose opinions and sentiments we more or less inherit.

No one, however, can dispute Buffon's title to our great respect on account of the very powerful effect his writings had in stimulating men's love of nature, an effect which I think is not sufficiently appreciated.

It is fitting that I should call attention to his (once generally recognized) claims in this respect; since my own love of natural history is probably due to the circumstance that his great work was always accessible to me in my childhood, and was one of the earliest books with the pictures of which I was familiar.

Buffon was indeed Linnæus's contemporary, for the same year (1707) saw the births of both. In 1733, he was elected a member of the Academy of Sciences, and six years later was appointed superintendent of the *Jardin du Roi*,* which was the occasion of that work to which he is indebted for his fame, and to perfect which he displayed so much zeal in collecting specimens and in obtaining information respecting the various kinds of animals with which he became acquainted. His *Histoire Naturelle générale et particulière* began to appear in 1749, and in 1767 was published the fifteenth volume, which closed his history of mammals. Herein are contained those numerous anatomical illustrations (due, with their accompanying descriptions, to Daubenton) which have been again and again copied down to the present time. Next came nine volumes on birds, then his history of minerals, and finally, seven supplementary volumes, the last of which appeared in 1789, the year after his death. His life was thus prolonged ten years beyond that of his illustrious contemporary, Linnæus.

Buffon can claim no merit as a classifier. With the exception of the Apes of the old and new worlds (which respectively fill the fourteenth and fifteenth volumes of his work), the beasts treated of are hardly arranged on any system, beyond that of beginning with the best known and most familiar—a system necessarily applicable to but a few forms.

But Buffon deliberately rejected the Linnæan classification—a grave error, certainly, yet one not altogether without excuse. Indeed, some of the objections he brought against that classification have considerable force. Such were his objections to the association of the hippopotamus, the shrew-mouse, and the horse in one order, and of the monkey and the manis in another.† What indeed could be more preposterous than the separation of the bat, *Noctilio leporinus*, from the other bats, and its association with the rodents, on the ground of its having (as supposed) only two incisor teeth above and two below?—an anomaly of arrangement of which you were reminded last year. It scarcely seems possible for the pedantry of classification to go further than this. Yet, perhaps, the association in one group of the walrus, the elephant, the ant-eater, the sloth, and the manatee, was hardly less unphilosophical. Moreover, zoologists should not forget, in blaming Buffon for his want of appreciation of the classification of Linnæus, that one great portion of that classification—the classification of plants—has been superseded by us. Had he lived to witness the publication of Jussieu's *Genera Plantarum*,* it might have given him a truer insight into biological classification, and have led him to endeavour to improve on Linnæus' system instead of only criticizing it.

* The Jardin du Roi was first instituted by Louis XIII. in 1628, and definitively established in 1635. It cannot be affirmed that Buffon enriched the incipient museum—the *Cabinet du Roi*—so much as might have been expected; although the skeletons which served for Daubenton's descriptions were, at least in many instances, preserved. It is to Geoffroy St.-Hilaire that the magnificent museum of the Jardin des Plantes, which now exists, is most indebted.

† 'Hist. Nat.,' tome i., p. 39.

But it is Buffon's speculative views which have most interest for us. Those views exercised a very wide-spread influence in their day, though the time was not ripe for them. Indeed, it is far from improbable that writers whose speculations have been made public at a more propitious season, owe much to their comparatively forgotten predecessor.

Amongst Buffon's various speculations we might glance at his *Théorie de la terre* (put forth in the very first volume of his work), and at his *Epoques de la Nature*, which fills the fifth volume of his supplement. We might consider his speculations concerning the formation of mountain and valley by water, and the evidence that there was present to the ear of his imagination:—

> "The sound of streams, which, swift or slow,
> Tear down Æolian hills and sow
> The dust of continents to be."

That he saw, in thought, the projection of the planets from the sun's mass; the primitive fluidity of the earth, and the secular refrigeration of the sun. Such considerations, however, are foreign to this Section. I will therefore select two which are of biological interest.

In the first place I may refer to Buffon's speculations concerning ANIMAL VARIATION. In this matter Isidore Geoffroy St.-Hilaire has affirmed that Buffon stands to the doctrine of animal variability in a position analogous to that in which Linnæus stands to the doctrine of the fixity of species.

Buffon, in his chapter on the animals of the Old and New World, remarks,† "It is not impossible that the whole‡ of the New World's animals are derived from the same source as those of the old, whence they have descended. . . . . Nature is in a state of perpetual flux." In his chapter on the Degeneration of Animals,§ he sums up saying, "After comparing all the animals, and arranging them each in their own group, we shall find that the two hundred kinds described here may be reduced to a small number of original forms, whence it may be all the rest have issued."

As to the modes and causes of the origin of new forms, he entertained four connected opinions:—

(1). He attributed much modifying efficacy to migrations;

(2). Also to the direct action of external conditions;

(3). He believed largely in the origin of new forms by degradation; and

(4). He regarded each animal as the manifestation of an individuating force, lying, as it were, at the root of the changes manifested by it.

The view that MIGRATION (with isolation) is a necessary antecedent to the origin of new species is one which has been advocated by a modern naturalist, Moritz

* This appeared in 1789.

† *Op. cit.*, vol. ix., p. 127.

‡ He thought that the American jaguars, ocelots, etc., and even the peccary, were positive degradations of Old World forms. He thought that the llama, the American apes, agoutis, and ant-eaters might be examples of such forms; but the opossum, sloths and tapirs he took to be original species. (See vol. xiv., pp. 272, 273.)

§ Vol. xiv., p. 358.

Wagner,* who does not hesitate to affirm† that the formation of a really new species "will only succeed when a few individuals, having crossed the barriers of their station, are able to separate themselves for a long time from the old stock."

In support of his view the author brings forward a multitude of interesting facts, one of the most significant of which appears to me to be the following. It concerns beetles of Tropical America of the genus *Tetracha.* In Venezuela, and in the western part of Central America, he tells us, rivers flow partly through savannahs, where they have undermined the light tufaceous soil, forming deep beds with high precipitous banks. According to Professor Wagner, individual beetles from the highlands have thus been isolated, and in no longer time than has been required by the rivers to undermine the loose soil of the savannah, have given rise to a distinct species markedly different in form and colour. It is to similar causes—migration and complete isolation—that he traces the formation of distinct races of men: a formation he deems no longer possible, while the wide diffusion of mankind renders more and more difficult the evolution of new species of animals of any kind.

Instances which appear to support this view will readily suggest themselves to the naturalist—instances, that is, of forms which are both peculiar in structure and remote and isolated as to their habitat.‡ Thus, for example, even in the group which structurally most resembles us, we have the orang confined to very limited tracts in Borneo and Sumatra, and the gorilla to a small portion of Western Africa. The proboscis monkey is found nowhere but in Borneo, while the singular ape named "Roxellana" (from its wonderfully "tip-tilted" nose) is confined to the lofty and isolated mountains of Monpin in Thibet. The very peculiar black ape (*Cynopithecus*) is limited to Celebes and Batchian, while the baboon, which has the baboon character of muzzle most developed, was found at the extreme south of the African continent.

Again, if we take the group of lemur-like animals (*Lemuroidea*) as having had their home and starting-point in or near their present head-quarters—Madagascar—then some of the most aberrant forms are those which must have migrated farthest. The character which is perhaps the most peculiar of any which the group presents, is the elongation of two of the ankle bones, as we find it in the Madagascar genus, *Cheirogaleus.* But this character is more exaggerated in migrants to Africa—the Galagos—and most so of all in the more isolated emigrant, the tarsier, now found in Celebes and Borneo.

The sub-family of slow-lemurs (*Nycticebinæ*) would, on this view, seem to have migrated in opposite directions, as we find the slender slow-lemur (*Loris*) in Madras, Malabar, and Ceylon; the typical slow-lemur (*Nycticebus*) in South China, Borneo and Java; the potto (*Perodicticus*) in Sierra Leone, and the angwantibo (*Arctocebus*) in Old Calabar. Of these, it is the African forms which have the index-finger most atrophied—a tendency to its atrophy existing in the whole sub-family.

It would, of course, be very easy to multiply instances of the kind; but it would be also easy to cite a number of cases which appear to conflict with the view in question. Thus familiar to us as it is, few animals are more peculiar in structure than the common mole, which gives no present evidence of isolated origin; and the most aberrant of all bats, the vampire (*Desmodus*), is rather widely distributed in South America. Again, with regard to the lemur group, the most absolutely exceptional is the aye-aye (*Cheiromys*), which, on the hypothesis supposed, has remained persistently at the head-quarters of the group, *i.e.*, in Madagascar.

Even, however, if no exception existed to the coexistence now of singularity of form and isolation and remoteness of situation, we could not safely draw any decided conclusion from such facts, because fossil remains show us that forms which have now a very limited distribution were either widely spread in earlier times, or existed in regions very remote from those they now inhabit. Thus, in Eocene times there existed in Europe true opossums (now confined to America), tapirs, and a form like the African potto before mentioned. In Miocene times we had in Europe long-armed apes (creatures now found only in Eastern Asia), with the now exclusively African secretary bird and Cape ant-eater (*Orycteropus*). In the same period the orang—or a nearly allied form—seems to have ranged over India. What are more emphatically old-world forms than the camel, horse and elephant, with the typical porcupine? Yet all these existed in America in Pliocene times. Did we know the tapir in only one of the two widely-separated stations in which it dwells to-day, we might well deem its evolution to be due to migration and isolation. But we know from palæontology that it existed in Europe from the Eocene to the Pliocene period.

Such facts as these do not, of course, disprove the doctrine that migration and isolation are necessary antecedent conditions to specific genesis, but they show how much caution must be used in drawing the conclusion that they are necessary, from the distribution of animals much less likely to be found fossil than mammals are.

But an argument in favour of the views of Buffon and of Wagner may be obtained from our own species, which exhibits some singular coincidences between peculiarity of form and isolation. Among such instances may be mentioned the Tasmanians, the Andaman Islanders, and the Aïnos or Aborigines of Japan. One of the most striking examples is that of the Eskimo—a people representing many peculiarities, some of which exaggerate the characters of the highest races of mankind. Thus, the pelvis differs from the European pelvis in an opposite direction to that by which the Negro pelvis differs from the European, and the same is the case with the proportions of the limbs, while the skulls of the Eskimo have the largest and narrowest nasal aperture of all races, being in this respect the very opposite to the Australians. The Eskimo have migrated eastwards, not reaching the south of Greenland till the fourteenth century, and the race characters are most marked in the most easterly tribes. These facts were brought forward by Professor Flower in his Hunterian lectures for the present year,* when he said that the characters of this peculiar race "must be attributed to those gradual modifications produced by causes at present little understood, by which most of the striking variations met with in the human species have been brought about—modifications more strongly expressed the more completely isolated the race has become, and the farther removed from its original centre of distribution." I think, then, that though we have not data for conclusively answering the question as to how far migration (together with isolation) may be necessary for specific genesis, it is certain that it is of very great efficacy and importance, and that credit is

---

* In a paper read before the Royal Academy of Sciences at Munich, on March 2, 1868. This has been translated by Mr. James L. Laird, and published by Edward Stanford in 1873.

† *Op. cit.*, p. 29.

‡ Isolation, it ought to be remembered, may take place as the result not only of changes in inorganic nature (such as the formation of islands, and the excavation of river beds), but also by the presence of enemies in intermediate tracts, by the circumstance that the food of the species is found only in certain restricted localities, and by whatever other causes determine the extinction of a species in a given place.

* The lecturer also said: "The large size of the brain of all the hyperborean races, Lapps as well as Eskimo, seems not necessarily to be connected with intellectual development, but may have some other explanation not at present apparent." I would suggest that in this case—as in the large brains of Cetaceans—it may be due to the need in their climate of generating much heat to sustain the necessary temperature of the body.

justly due to Buffon for his early appreciation of its importance.

The next question to which I would advert is that concerning THE DIRECT ACTION UPON ORGANISMS, OF THE EXTERNAL CONDITIONS WHICH SURROUND THEM.

Buffon's belief was* that changes of specific form were brought about by change of temperature and climatic change generally, as well as by change of food.

The curious effects of stimulating food on colour—as of cayenne pepper with canaries, and hemp-seed with parrots—is notorious. The direct action of the environment on organisms has, I think, been of late somewhat undervalued. Amongst evidences in favour of its importance, I would refer to some of Mr. Alfred Wallace's observations.† He tells us that in the small island of Amboina, the butterflies (twelve species, of nine different genera) are larger than those of any of the more considerable islands about it, and that this is an effect plainly due to some local influence. In Celebes, a whole series of butterflies are not only of a larger size, but have the same peculiar form of wing. The Duke of York's island seems, he tells us, to have a tendency to make birds and insects white, or at least pale, and the Philippines to develop metallic colours, while the Moluccas and New Guinea seem to favour blackness and redness in parrots and pigeons. Species of butterflies which in India are provided with a tail to the wing, begin to lose that appendage in the islands, and retain no trace of it on the borders of the Pacific. The Æneas group of Papilios never have tails in the equatorial region of the Amazon Valley, but gradually acquire tails, in many cases, as they range towards the northern and southern tropics. Mr. Gould says that birds are more highly coloured under a clear atmosphere than in islands or on coasts—a condition which also seems to affect insects, while it is notorious that many shore plants have fleshy leaves. I need but refer to the English oysters mentioned by Costa, which, when transported to the Mediterranean, grew rapidily like the true Mediterranean oyster, and to the twenty different kinds of American trees, said by Meehan to differ in the *same manner* from their nearest European allies, as well as to the dogs, cats, and rabbits which have been proved to undergo modifications directly induced by climatic change.

It appears then that much may be said in favour of that direct effect of surrounding circumstances on Organisms in which Buffon believed.

Lastly, I would refer to Buffon's belief that new species have arisen by DEGRADATION. This again is an opinion which, after a period of disfavour, or at least of neglect, has been of late revived, and has acquired considerable influence. I may here refer to Anton Dohrn, who has recently advocated the very widely spread and effective action of degradation as a cause of specific change. It will, I think, be generally admitted that such exceptional Copepod crustaceans as *Trachelíastes* and *Lerneocera* are due to degradation, and the probability seems to me very strong that the Rhizocephala, at least many cirripeds, and the certoid worms, are also degraded organisms. Very interesting would it be to know whether existing Ascidians are also examples of degradation, as not a few zoologists now suppose; but most interesting of all is that parasite of cuttle fishes, *Dicyema*, the structure of which has been recently investigated by Professor Edward Van Beneden, and made the type of a new primary division of animals. Should this small worm-like organism hereafter turn out to be a degraded form, it will show what an extreme degree of retrograde metamorphosis may occasionally be brought about. I think then that we have considerable ground for suspecting that degradation has acted much and widely in the field of Biology, and if so, Buffon is fairly entitled to a certain amount of esteem on account of the views he entertained with regard to it in so early a day and in so undeveloped a condition of zoological science. For it must not be forgotten that migration, the influence of external conditions, and degradation, are connected points: parts of one view. Degradation is most conspicuous under violent changes of condition (such as parasitism), while migration only acts by bringing organisms under new conditions.

* *Op. cit.*, vol. xiv., p. 317.

† See 'Tropical Nature,' pp. 254-259.

These reflections lead me to urge upon such of my hearers as may have any unusual facilities for experimental investigation, a course of inquiry which seems to be very desirable.

What is needed in order to solve as far as possible the question of specific genesis, is a knowledge of the laws of variation, which must, I think, be deemed the true cause and origin of species.

We may, I think, accept as true two propositions:

(1). Animals may change in various ways, and amongst them, by degradation.

(2). Changes in the environment with isolation induce and favour changes in form.

I would urge then that inquiries should be pursued in two directions simultaneously.

(A). There might be undertaken one set of inquiries to investigate the effects on different species of the same variations of environment.

(B). Other inquiries might be undertaken with a view to ascertaining the effects of different changes of environment on one and the same species. By series of experiments contrived with these ends in view, and carried on with various selected animals and plants which reproduce with rapidity, we may possibly be able to determine what to attribute to external influences (shown by such influences having the same effects on all), and what to the peculiar nature and innate powers and tendencies of different organisms—shown by the diverging reactions of the latter under the same changes in their environment.

(*To be continued.*)

Parliamentary and Law Proceedings.

An Inquest at Devonport.

The Coroner for Devonport, Mr. J. Vaughan, held an inquest at the Rose and Crown Inn, public house, Pembroke Street, on Thursday afternoon, to investigate the circumstances under which a child, $2\frac{1}{2}$ years old, named Llewellen Frederick George Warren, had come to his death.

The Coroner, at the opening of the inquiry, explained that it had been rendered necessary in consequence of the medical man, who was not called in until the child was dying, refusing to give the requisite legal certificate of death.

The mother of the deceased child was then called, and she stated that the deceased was taken ill on the previous Monday week. Mr. Lamble gave her a bottle of medicine for the child, and told her to put its feet in warm water and salt and mustard, as, if it was a case of measles, that would bring them out. He also told her that if the deceased got worse she had better send for a medical man. She did as she was directed, but on the following Friday the child got worse, not having taken anything nourishing from the time she went to the chemist, except a little brandy and milk, and the next day (Saturday) it became so seriously ill that she then sent for Mr. Horton, surgeon. This was in the evening, but Mr. Horton was not home. She sent again at half-past seven, and he was still absent, but the person she sent was told he would return in ten minutes. When he again went to Mr. Horton's house, however, ten minutes afterwards, he was told that Mr. Horton was in bed. The person who came to the door said Mr. Horton was in bed, and that if he came "he would want his fee," and her husband said "his fee was there." Mr. Horton did not come that night, and she sent again for him between nine and ten o'clock on Sunday morning, and between twelve and one o'clock, in the dinner time, he visited her child, whom he pronounced very ill. It had had the measles very badly. They came out two days after she went to the chemist, and Mr. Horton now said that the child had inflammation of the lungs after measles. He sent it a bottle of medicine and ordered a mustard poultice to its chest. Mr. Horton called again the next day, at three o'clock in the afternoon, but the child was then dead.

The Coroner said the witness ought certainly to have called in a medical man before she did.

Mr. Horton said the witness was entirely wrong as to the time at which she sent for him, because he was in his surgery on the Saturday evening until half-past eight o'clock.

Edward Stacey (asked by the Coroner what time he went for the surgeon on Saturday): Said that from nine o'clock until eleven o'clock he went three times. First a few minutes past nine o'clock, and saw a man who said the doctor was not in, and who put his message down on a slate. He went again just after ten, and was again told that Mr. Horton was not in. At five minutes to eleven he went again, and was then told that Mr. Horton was in but was in bed. He told them the child was dying, and that the surgeon was wanted to come at once.

A Juror: What answer did you get to that?

Witness: The lady who came to the door said that if the doctor did come now he would charge double fee. I said "This is no place to ask about that here—for double fees," and the lady never said anything, but went away.

Mr. Horton: Did you say anything about going for another surgeon?

Witness: Yes.

Mr. Horton was afterwards sworn, and stated that at a few minutes past eight o'clock on Saturday evening he went from home to attend two cases of confinement. He returned about eleven o'clock, and inasmuch as he was suffering from bronchitis and sore throat himself and was particularly tired, having been on his feet all day, he determined to go to bed at once. As he was going upstairs his servant told him that Warren had sent twice, and that he was expecting the messenger there again in about twenty minutes, and he (Mr. Horton) told the servant to tell the person who called that he was gone to bed, and that they must get somebody else. He then went straight to bed, and shortly afterwards Mrs. Horton came to him and told him that Warren had sent again. He accordingly sent down to say that he was very unwell, and that he did not wish to go out again before the morning, but would come then if that would do, but if he did come his fee would be half-a-guinea, to be paid that night. He made those conditions intentionally—he put the charge as a prohibitory fee, because he had been so often called out when there was no danger, and because he did not wish, being ill himself, to go out again.

The Coroner: You did not do it for the sake of the money?

Mr. Horton: Certainly not; I didn't want to go, and I put a prohibitory fee on the case thinking they would decline my services and go elsewhere. Mrs. Horton afterwards brought me up a message that the friend of the father said they would go elsewhere, and I was very glad of it, and went to sleep. Just as I was finishing breakfast, however, the next morning, I had another message from the Warrens to come and see the child, and I sent back word that I would come as soon as I could. Immediately afterwards, however, I had a peremptory message to attend a pressing case of confinement. I went to this case first, and finding that I was not wanted immediately, came straight back to Warren's house. I found the child very ill with congestion of the lungs after measles, and I told the mother that it could not live, and that I could do nothing for it. The next day, not having heard from the mother in the meantime, I called again on going my rounds, and then found the child dead.

The Coroner: You have heard it said that when the child was first taken ill the mother took it to Mr. Lamble, chemist, who prescribed for it, and told the mother that if it grew worse she had better have a medical gentleman at once; do you find any fault with that?

Mr. Horton: I don't find any fault at all. I didn't see what medicine it had. I should like to have seen it in order to have satisfied my own mind.

The Coroner: Mr. Lamble said it was for measles.

Mr. Horton: I don't recognize his right to say so. Measles are a most difficult thing to carry through, even if in a mild sort of way.

The Coroner: But Mr. Lamble said if it grew worse the mother had better have a medical man.

Mr. Horton: Then he was so far right, but he was not right in giving medicine.

The Coroner: He did no more than any respectable chemist would have done, I suppose?

Mr. Horton: That is it; they do it, and they waste time.

The Coroner: Then you simply find fault with Mr. Lamble for prescribing as other chemists prescribe?

Mr. Horton: I don't find fault, but I do think valuable time was thrown away whilst the chemist was prescribing for it.

The Coroner then summed up, and in doing so said that there appeared to be a feud in the town between the medical men and the chemists, who were both a very useful class of men, and who both discharged very proper and important functions. There was no doubt that poor people, who could not well afford to pay a doctor, often took their children to a chemist, in whom they had perfect confidence, instead of going to a regularly licensed practitioner, and there was not a chemist in the town who would refuse to prescribe for them; but this did not appear to give satisfaction to the medical profession, who were naturally jealous of the rights of that profession. In the present case, Mr. Lamble evidently did not intend that the mother should go until Saturday evening without seeking medical help. The mother, however, seemed to have considered that the condition of the child was due to the natural incidence of measles, and went on hoping for a change until medical skill was too late to save its life. No aspersion had been cast upon Mr. Lamble in the matter, and as regarded Mr. Horton, he seemed to have understood from the witness Stacey that he would go elsewhere for medical aid.

The jury returned a verdict of "Death from natural causes."—*Devonport and Stonehouse Gazette.*

Alleged Acceleration of Death by a Soothing Powder.

An inquest was held at Devonport, on Friday, the 19th inst., by the Coroner, Mr J. Vaughan, to investigate the circumstances under which a child named Abraham Hill had come to its death. It appeared that the deceased's parents were in the town on a visit to their friends. On the previous day the child was unwell and the mother gave it a Steedman's powder. There was nothing unusual in her treating the child in this way. She had often done so before, and the powders had apparently invariably had a salutary effect on the child. The child was one year and seven months old, and had an inordinately large head, and its mother had fancied that it had water on the brain; and it also transpired that the mother had had two other children die in a similar manner—namely, in convulsions—though at a much younger age. The child had been a healthy one comparatively speaking, though its mother had many times given it Steedman's powders. The child became very relaxed the night prior to its death, and was more or less relaxed throughout the next day and up to the time of its death. It vomited, and was seized with convulsions, which continued to affect it at intervals up to the time of its death. Mr. Horton, surgeon, ordered the child to be put in a bath, but before this could be done it died. By the direction of the coroner, Mr. Horton made a *post mortem* examination of the body, from which he said he concluded that the child, having previously suffered from water on the brain, and having been much purged and weakened by the entire absence of food in the system, was particularly amenable to the influence of a narcotic, and he thought the convulsions spoken of might have been caused by the drug administered, which he judged contained a certain proportion of opium. From an analysis of one of these soothing powders recently made it was found to contain a certain proportion of narcotic. These powders were never prescribed by medical men. They were a proprietary medicine of which large quantities were sold. He was of opinion that the deceased child had died from the effects of a narcotic administered to it in some form.

The Coroner said the jury would have to specially consider whether the child died from a narcotic, and whether it was administered in the Steedman's powder.

In reply to questions from the jury, Mr. Horton said he could not say whether the powder administered contained opium or not. If it was a soothing powder and did not do so, the powder was simply a fraud in itself, because soothing powders must contain a narcotic. The jury ultimately found a verdict that the child died from natural causes, accelerated by a narcotic given with the best intentions and without the slightest blame to anyone.

Suicide of a Plympton Tradesman.

Mr. John Eastcott, grocer and patent medicine dealer, Fore Street, Ridgway, has committed suicide by taking strychnine. The deceased, who was only twenty-seven years old, had lately given way to intemperate habits. On Friday afternoon, December 12, about three o'clock, he went to bed, and rose about eight o'clock on Saturday morning and opened his shop. He served a customer, and then remarked that he would go upstairs as he was not feeling well. His wife heard groans proceeding from one of the bedrooms, and on asking her husband what was the matter he replied that he had taken a drop of strychnine on a lump of sugar, and that he had poisoned himself because he was ashamed to look people in the face in consequence of having been seen drunk. Medical assistance was immediately obtained, but death ensued about half-past nine o'clock. An inquest was held by Mr. Rodd, county coroner, in the evening, when the jury returned a verdict of "Temporary insanity."—*Western Morning News*.

Dispensing Memoranda.

In order to assist as much as possible our younger brethren, for whose sake partly this column was established, considerable latitude is allowed, according to promise, in the propounding of supposed difficulties. But the right will be exercised of excluding too trivial questions, or repetitions of those that have been previously discussed in principle. And we would suggest that those who meet with difficulties should before sending them search previous numbers of the Journal to see if they can obtain the required information.

Notes and Queries.

[645]. EVANESCENT INK.—Can any reader kindly give me a recipe for making the above ink?

A. J. Hurn.

[646]. COD LIVER OIL JELLY.—A reliable formula for cod liver oil jelly is required, the one given in the 'Year-Book of Pharmacy' has not been found workable. It is cod liver oil, 85 parts, sugar, 8 parts, water, 4 parts, isinglass, 3 parts. It succeeded once by some modification, which has been forgotten, and cannot be hit on again.

"Nos."

[647]. BOISRAGON PILLS.—Will any obliging correspondent state the ingredients in "Boisragon Pills?" I understand they are in use about Suffolk."

St. Rule.

LIQUID GLUE.—The following yields a good product, provided the proper kind of glue is employed:—

500 parts of the best, white, transparent glue are broken into small pieces, covered with 670 parts of distilled water, and allowed to stand until the pieces have become soft, and nearly all the water has been absorbed. Any pieces which may from time to time project beyond the surface of the water are to be pushed under. The mass is now melted on a water- or steam-bath, and 75 to 83 parts of commercial nitric acid, specific gravity 1380, are added very slowly, and with constant stirring. Of course, the glue solution must be contained in a vessel which is not attacked by the acid.

When using a weaker acid than that above mentioned, it may happen that the mixture gelatinizes on cooling. In this case, the mass is to be remelted, and more acid to be added. But it is better to wait a few days before doing this, as the glue sometimes liquefies of its own accord. Too much acid makes the glue too thin, and destroys its adhesive properties.

Another formula yielding a very good product is this: Take of best white glue, or better, of best French transparent gelatine, 8 parts. Cut it fine, cover it with distilled water, and soak it until soft; then pour off any excess of water. Melt it on a water-bath, and add to it 1 part of glacial acetic acid. When thoroughly mixed, bottle it.—*New Remedies*.

Sunday Trading.

Sir,—I am pleased to see the subject of Sunday trading being ventilated in the Journal, and in the hopes that it may lead to some practical alteration of what is at present a thing greatly to be deplored, I am induced to offer a few remarks upon the subject.

That a chemist and druggist is bound, to a certain extent, to trade on Sunday, is one of the peculiarities of his particular branch of commerce. Illness, like time and tide, waits for no man; and it is, therefore, a public necessity that when disease in any form makes itself apparent, that the victim should be able to obtain the requisite remedies, successfully to wage battle against his enemy. But, that it is necessary for anyone to purchase pennyworths of hair oil, half ounces of lozenges, small-tooth combs or tooth brushes, on the Sabbath day, no reasonable man would admit; nevertheless, by opening his shop, by removing one or two shutters, placing the door open wide and by lighting the gas inside and outside, the chemist offers the necessary inducement for the public to purchase these necessary articles which could have as easily been obtained the day previous and would have undoubtedly been so procured had the public been aware of the impossibility of obtaining them on Sundays.

The public do not wish nor expect their butcher, baker, or draper to open his establishment on a Sunday to serve them with meat, bread, yards of ribbon or halfpennyworths of tape; and neither do they wish nor expect the chemist to do so either.

The public require educating into the new state of affairs, and the best way of doing it is by politely refusing to sell anything but *bonâ fide* medicaments required for a specific purpose for use at once. At first, doubtless this plan would meet with some opposition, people have been for so long accustomed to demand anything from a chemist, and at any time, that they have begun to look upon what is but a favour as a right, and I have often been told that we are by law compelled to open on Sunday.

My establishment is situated in a main thoroughfare of the S.W district, and on the confines of two parishes, one very poor, the other one of the richest in the whole metropolis; on either side there are chemists' shops, both within a stone's throw, who open on Sundays, and, save taking down all their shutters, court public patronage for anything which caprice may dictate as on week days. This shop for the past twelve years has been entirely closed all day on Sunday; anything of a necessitous description can always be obtained by ringing the bell, while all other demands are politely refused. Regular patrons knowing these rules do not ask for such things, while casual callers never take umbrage at what their own sense of justice commends as correct. The one great stumbling block to the removal of a great deal of the present amount of Sabbath trading is the low standpoint from which most proprietors view this subject, that of £ *s. d.*

Brown opens; Jones because of his neighbour's delinquency excuses himself, and does likewise, for fear that Brown should net a few stray fish to his (Jones's) detriment. Till this difficulty is removed and the financial is made subservient to the moral and physical, I am afraid that Sunday trading as at present conducted will remain. The few shillings taken on Sunday by openly asking for patronage is poor compensation for the mental and bodily strength expended to obtain them.

Let the chemist stand upon his own rights and, while the willing servant of the public, resolutely but politely decline to be the slave of a captious few who think they are legally entitled to have all their demands satisfied at any time. Chemists as a rule are a class of men who bear a great deal for the sake of their cloth and the moral obligations which it imposes upon them, but one of these is not, that they should keep open shop, when their brother tradesmen are enjoying their "day of rest" after six days' labour.

London, S.W. "SPES."

Sir,—A good deal has been written of late upon the above subject. Will you allow me to add a few words?

I was very pleased with the remarks of "Volo," in a recent issue and would that his plan were universally adopted.

I took a business in this town twenty-three years since, it had then been established twenty-seven years. To my great regret I found it had been the custom to sell on Sunday anything and everything that a country druggist's shop contains; this unnecessary and unchristianlike traffic I determined to discontinue and placing a card inside the window of the shop door, whereon was written, "Medicines only sold on Sunday," I soon found my customers for hair oil, capers, etc., etc., on that day, diminish considerably and in the course of a year or so it became a rarity for me to be asked for anything of the kind on the first day of the week. I have kept to this plan up to the present time, and intend doing so as long as I am in business; should anyone be curious to know how my "returns" were affected by so doing, I can assure them they have considerably increased.

With regard to late closing I consider twelve hours a day quite long enough to be behind the counter. I have never had an assistant or apprentice, yet am thankful to say I have been blessed with good health, and although I am now fifty-three years of age and have brought up a large family I can take a walk of from thirty to forty miles in a day with little inconvenience. Of course I have not neglected the "rules of health:" on rising I have a cold bath, excepting in very severe weather, when I take it with just the chill off. I open shop at 8 o'clock, and as there is from two to six hours' daylight during the greater part of the year, before this time, I get out and enjoy it (many and many a good dish of trout have I brought home before breakfast, that have fallen to my rod). If this plan were more generally adopted, I feel sure the health of members of our trade would be considerably benefited.

When I was an assistant I arranged to have half a day (from 1.30 till 11) once a week, instead of going out at night after closing shop; this was a great boon to me and I believe such an arrangement, where it can be made, will be found beneficial alike to employer and employed.

WILTSHIRE.

P.S.—For the last eight or ten years we have closed our shops here at 4 p.m., one day in the week.

Sir,—After six years' experience as assistant and a like period as principal, I am very fully convinced that in provincial towns (not having had a lengthened city experience I will not venture to speak in reference to that), the whole question lies in this, "Is the principal so penurious as to wish to enslave himself or assistant on the day of rest in order to help his week-day trade?" Absolutely necessity for Sunday trading is almost infinitesimal, to prove which I will state the following facts:—I happen to have the oldest established business in this town, in a central position, to which is attached a good family business and a fair share of poor customers. It is my custom to be absent, otherwise occupied, every Sunday during the following hours, 9.0 to 12.30, 1.30 to 4.0, 6.0 to 9.0. No assistant is in the house, though it is rarely left for domestic reason, and it is seldom that any customer applies during my absence, and I scarcely ever remember having heard a complaint that any hardship has resulted through my inattention. The fact is, people know pretty well when they can find me if they have real wants; and, I might say, it is no use their applying for anything else—they would not get it, and they apply at the time when they know (though we have no light in the shop), I shall be found there. We average about two customers per Sabbath the year round. Facts, sir, are stubborn things.

60, Market Place, Hull. J. CHAS. STOREY.

W. M. MacNaughton.—The preparation is a proprietary one, the formula of which has not been published in this country. It has been alleged, however, to consist mainly of the électuaire lénitif of the Codex.

J. A. H.—The following recipe for a cement for joining leather is given in the new edition of Cooley:—Gutta percha, 4 parts; caoutchouc, 1 part (both cut small); bisulphide of carbon, 8 parts: mix in a close vessel and dissolve by the heat of a water-bath. To be gently warmed before using.

"*Quæro.*"—(1) The chloral hydrate and camphor should be triturated together until they liquefy. See, on the dispensing of chloral hydrate and camphor, vol. viii., pp. 319, 339, 398 and 406. (2) You would do rightly in using the Pharmacopœia preparation.

"*Nemo.*"—See the recipe for tooth wash, before, p. 443.

F. C. Maggs.—Myrtle wax is obtained from two or three species of *Myrica* and is used for hardening candles, making "heel-ball," and by "medico-botanists," for ointments, etc. We believe that its value is less than that of ordinary wax.

A. C. and *T. W. L.*—The oleate of lead in the prescriptions sent is no doubt that referred to in a paper on the treatment of eczema, by Dr. Sawyer, which appeared in the *Practitioner* for November. It is there said to be "prepared by heating a mixture of oleic acid and oxide of lead."

COMMUNICATIONS, LETTERS, etc., have been received from Mr. Plowman, Dispenser, Subscriber.

COTO BARK AND ITS CHIEF CONSTITUENTS.*

BY J. JOBST AND O. HESSE.

One of the authors, in the early part of the year 1873, obtained, through a London firm of importers, a specimen of stem bark from Bolivia, which was called "coto cinchona," although it had no resemblance to cinchona bark. About a year later Professor Wittstein obtained some of the same kind of bark from a Hamburgh firm, who informed him that the bark had been collected from the same districts as the cinchonas, in the interior of Bolivia, and that it was used internally, either in the form of powder or of an alcoholic extract, as a remedy in cases of diarrhœa and colic, and for neuralgia in the face. It had been also recommended in cases of rheumatism and gout.

According to Martens the bark is obtained from a cinchona; hence the name "coto cinchona." Wittstein believes that many of its properties belong rather to the *Rubiaceæ* than to the *Laurineæ* or *Terebinthinaceæ*.

The name coto bark, or coto-coto is met with in Brazil, and is there applied to bark obtained from a rubiaceous species, the *Palicurea densiflora*, Martius. But whether this plant produces their coto bark, or some bark allied to it, is unknown to the authors.

The first coto bark obtained by the authors, and which they term "genuine coto bark," to distinguish it from other kinds which have been lately met with in commerce, has been anatomically examined by C. Hartz,† with whose results the authors for the most part agree.

This bark consists of irregular, flat, and slightly curved pieces of about 0·6 m. long, and 60 mm. broad, by 8 to 14 mm. thick. It is of a reddish cinnamon colour, but somewhat darker on the inner side. As a rule it has the appearance as if the outer layer had been intentionally removed. It has a pleasant cinnamon smell at first, but soon has a pungent irritating action on the nostrils. The taste is pungent, but not bitter, expectorant, or astringent. It has a somewhat unequal texture, the outside forming a granular and tolerably even breaking mass, lying on a coarse fibrous and uneven breaking cellular portion of which the inside consists.

Hartz found that the membranes of all the cells, with the exception of the sclerenchymatous and liber cells, gave a blue reaction like pure cellulose with iodochloride of zinc, as well as with iodine and sulphuric acid. According to him they are all thin walled, and more or less contain a brown coloured substance which belongs to the class of phlobaphen and could be removed by ammonia or potash. The sclerenchymatous and liber cells are, on the contrary, of a gold yellow colour, and are not coloured, even after a month's immersion, by a solution of iodine or rosaniline, on being immediately after washed with glycerine. With the exception of plasma they contain no organized constituent. Their membranes are composed of many concentric porous layers which are very hard, and without previous treatment are not coloured by iodochloride of zinc, or by iodine and sulphuric acid.

The parenchyma cells of the external and internal bark contain a small quantity of tannin which must originally have existed in a soluble form. It occurs along with phlobaphen, and the more abundantly in those cells which are richer in this latter substance. Starch, in single or semi-granules, is present in small quantity in almost all the cells of the parenchyma, and the granules generally exist in greater number in the inner half of the cell. Hartz has also found in the same cell-formation entire cells frequently full of a colourless or slightly yellow-coloured mixture, from which, after extraction by and evaporation of the ether, was obtained a camphor-like smelling substance, crystallizing in prismatic needles.

From coto bark Wittstein* obtained (*a*) an ethereal oil of a pale yellow colour, lighter than water and possessing a biting aromatic taste; (*b*), a volatile alkaloid resembling trimethylamine; (*c*), a yellowish brown soft resin and a dark brown hard resin; also starch, gum, sugar, oxalic acid (as lime salt), tannic acid, formic, acetic and butyric acids.

Jobst has found in the bark a fine crystalline body, cotoïn,† and two other crystalline bodies, dicotoïn and piperonylic acid. The therapeutic action of the bark has been investigated by Dr. v. Gietl,‡ who prescribed the bark for diarrhœa, partly in the form of a powder, and partly as an alcoholic tincture. It was successful in fifteen cases out of sixteen in which it was employed. Direct experiment confirmed the supposition that this action was due to cotoïn.

Whilst these experiments were being made another kind of coto bark came into the market, having much outward resemblance to the bark above described. It was said to have been collected from the shores of the river Mapiri in Bolivia. This bark occurs in pieces of 0·7 m. long, by 40 to 76 mm. broad, and 12 to 18 mm. thick. The fracture and colour of the bark are similar to the "genuine" coto bark, but not unfrequently it has deep whitish furrows on its surface. In smell it is less pungent, somewhat resembling nutmegs, and it has a slightly pungent taste. In order to distinguish this bark it has been named *paracoto* bark, although it is frequently improperly called coto bark.

From the experiments of Dr. Burkart with an alcoholic tincture of paracoto bark it would appear that its therapeutic action is similar to, although somewhat less active than, coto bark. The chemical investigation of the bark now shows it to contain piperonylic acid like "genuine" coto bark, but it has also other constituents which differ from the constitution of Cotoïn and Dicotoïn, viz., paracotoïn, hydrocotoïn, dibenzolhydrocoton, leucotin, oxyleucotin, a volatile oil, a tolerable quantity of liquid resin, and a very small quantity of tannic acid. The tannic acid and resin were not further investigated. The authors have been unable to confirm the statement of Wittstein that the bark investigated by him contained a volatile alkaloid; they have examined large quantities of paracoto bark, but could not discover evidence of the existence of any volatile alkaloid. The therapeutic action of the bark is chiefly due to the paracotoïn.

Of the two kinds of bark, paracoto bark is more frequently to be met with, although there is no difference in their commercial designation. Therefore it is not surprising that some manufacturers have failed to obtain cotoïn. As a rule, the commercial preparation termed cotoïn consists of a mixture of crystalline products such as could be obtained from

* Abstract of a paper in *Liebig's 'Annalen,'* 199, 17—96.

† *Pharm. Journ.*, [3], vol. vi., p. 301.

* *Pharmaceutical Journal*, [3], vol. vi., p. 302.

† *Pharmaceutical Journal*, [3], vol. vi., p. 764.

‡ *Pharmaceutical Journal*, [3], vol. vi., p. 302.

paracoto bark by extraction with ether, etc. But as cotoïn and paracotoïn have a physiological action which is quantitatively different, this confusion has given rise to differences of opinion among medical men as to the action of this substance. The object of the present paper is to prevent the spreading of these erroneous views by describing the characteristic features of these bodies, so that they may be very easily distinguished.

(*To be continued.*)

ASPIDIUM MARGINALE, SWARTZ.*

BY GEORGE W. KENNEDY.

At the last meeting of the Pennsylvania Pharmaceutical Association, held in Reading, Mr. Charles H. Cressler, of Chambersburg, placed on exhibition a living plant of *Aspidium Marginale*, accompanied by specimens of the rhizome and stipes, the oleoresin prepared from the rhizome, and a tape worm expelled by its use. Mr. Cressler claims for it medicinal properties, similar to those of the European *Aspidium Filix Mas.* A partial analysis of the plant was made by Mr. J. L. Patterson, of Philadelphia (see *American Journal of Pharmacy*, 1875, p. 292). He obtained an oleoresin by percolation with ether, which he says will compare favourably in appearance with the best German article obtainable, and isolated filicic acid, and a resin, besides other principles of less medicinal importance.

Professor Maisch obtained a sample of the oleoresin, and gave it to a friend, who by its use was relieved of a tape worm, including the head.

It was suggested at our last meeting, and has been advocated since by the editor of the *American Journal of Pharmacy*, that pharmacists should submit the oleoresin of *Aspidium marginale* to physicians, and that the results obtained be duly recorded, the object being the determination of its true therapeutic effect, and if found efficient, its introduction into the next Pharmacopœia.

In compliance with a promise, the writer made some experiments with the rhizome, which he now proposes to state.

The plant grows abundantly in rich woods and on the hillsides in Schuylkill county, where the writer resides, and is most common in the northern portion of it. The fronds arise to the height of from nine to twenty inches, are from two to four inches in width, ovate, oblong in outline, evergreen, smooth, thickish, and almost coriaceous. The pinnæ are lanceolate, broadest near the base and deeply pinnatifid, the lobes oblong crenate, serrate, the lower ones nearly distinct. The sori or fruit dots are round, somewhat kidney-shaped, and are found close to the margin, from which character this species takes its name. The rhizome closely resembles that of *Aspidium Filix Mas.* The characteristic points for distinguishing the two drugs have been described in an article by Professor Maisch in the *American Journal of Pharmacy*, 1878, p. 292.

Autumn being considered the most favourable time for collecting the drug, the writer gathered a quantity of the fern in the latter part of last October, and separated the greenish portions of the subterraneous parts, consisting of the leaf-stalks and rhizome, which were weighed, and exposed to the air and sun until completely air dry. The loss in weight was 66·20 per cent., and the yield of air-dried material 33·80 per cent. A portion of this was exposed to 120° F., in a common oven, until it ceased to lose weight, the loss amounting to 12·25 per cent., making a total loss of 78·45 per cent., and a yield of the anhydrous article of 21·55 per cent.

The air-dried rhizome was reduced to powder sufficiently fine to pass through a sieve of forty meshes. It was moistened with ether, specific gravity 0·750, packed in a glass apparatus like a Kipp's gas generator, and ether poured upon it until completely exhausted. The ethereal solution thus obtained was of a reddish-brown colour, with a greenish tinge. It was transferred to a glass retort, and the retort placed in hot water, until at least 75 per cent. of the ether was recovered in a receiver kept chilled with ice. Pharmacists not having the facilities for evaporating by steam heat will find this a very convenient process for the recovery of ether, as no serious results can take place from flame. The liquid remaining in the retort was transferred to a shallow vessel or capsule exposed to the air, and evaporated spontaneously until nearly all the ether odour has passed away. Thus prepared, the oleoresin was thick, oily, of a brownish-green colour, opaque, decidedly acid to test paper, and of an acrid and nauseous taste.

In a short time precipitation of a resinous substance took place, and in a longer time filicic acid, in a granular form, was deposited on the bottom and sides of the bottle. The writer is of the opinion that the cause of this deposit is due principally to continuing the evaporation too far, because, as the ether disappears, the remaining alcohol generally found in ordinary ether is incapable of holding the oil, resin, etc., in solution. On the addition of a small quantity of chloroform or stronger ether, a beautiful dark reddish-brown solution is obtained. I would, therefore, suggest that in preparing the oleoresin, stronger ether be used.

Four fluid ounces of the oleoresin were prepared, and of this, three-fourths were given to four physicians, with the request that they would watch its action closely, and report the results at their earliest convenience. Only one physician has, thus far, had occasion to use the oleoresin, with which twelve feet, at one time, and ten feet, at another, in all twenty-two, feet of tapeworm were expelled. Since that time, the patient has not complained, and the doctor believes that the head was discharged. A friend, who has been annoyed with tænia for some time, has been treated with kameela (*Rottlera tinctoria*) and kooso (*Brayera anthelmintica*) with unsatisfactory results, discharging only small pieces of the worm. Since he has been using the oleoresin of *Aspidium Marginale*, a piece eight feet long was expelled at one time, and I hope that, with a continued use of the present treatment, a cure may be effected.

The oleoresin was administered in the following way: —One and a-half fluid drachms were placed in a two-ounce vial, half filled with granulated sugar, well shaken; filled with water, and again well shaken. The patient, after fasting about twenty-four hours, at 10 o'clock p.m., took one-third; at 11 o'clock p.m., one-third, and at 6 o'clock, next morning, the balance, which was followed, two hours afterwards, with a large dose of castor oil. The parasite, or a portion of it, was expelled in a few hours.

Three experiments were made with the view of ascertaining the amount of ethereal extract the drug would yield, one pound being operated upon at each experiment. In each case the yield was about one and a-half ounces, or 9·375 per cent.

On incineration I obtained from the rhizome a small quantity of ash, estimated at 4 per cent., which I found to consist principally of lime, potash, silica, phosphoric, sulphuric and carbonic acids.

The Pharmaceutical Journal.

SATURDAY, JANUARY 3, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

1879.

ALTHOUGH in pharmaceutical affairs, as in most other respects, the past year has been characterized by unusual dullness, it has not been altogether uneventful. In the first place we may refer with satisfaction to the fact that certain questions which have for some time past disturbed the tranquility of the pharmaceutical atmosphere have been either definitively settled or dealt with in such a manner as to do away with the possibility of injurious dissension. During the past year sundry females have been elected members of the Pharmaceutical Society; but as yet none of them have aspired to become also members of the Council, and there are still no signs that this event will at any future time lead to the fulfilment of the dire foreboding that the presidential chair might one day be filled by an old woman. Another event that has been brought about by concession to abstract principle relates to the reporting of the proceedings of the Council of the Pharmaceutical Society. The "gate" has now been opened, and it is believed that when it has been passed the illuminating effect of the pharmaceutical press will be materially augmented. We will not, however, venture to anticipate the consequences of this event, or to predict whether any additional lens-power thus provided will operate by reflection or by refraction. For our own part we will simply state that the report of the Council's proceedings—furnished as hitherto by the official reporter under the direct authority of that body—will still continue to be published in this Journal in the respective weeks when the Council meetings are held.

The Special General Meeting of the Society held during the first days of the year marked the decline of an agitation which, at one time, seemed to threaten the production of disunion and conflict in the pharmaceutical body; but that tendency has now so far subsided that there is little reason to apprehend its revival. Opinions will probably still differ as to the influence exercised by that meeting in respect to the immediate question discussed; but we can at least rejoice to think that it operated like oil on troubled waters, and by affording scope for a little declamation gave vent to some pent-up energy. Soon afterwards the irksome SHEPPERLEY case was decisively brought to an end, and though in some quarters regret was felt that this event was not celebrated after the fashion of an Irish wake, probably everyone will by this time be glad that the case can be treated as a thing of the past. The subsequent attempts to advance reform in medical legislation were of such a nature as to remove any uneasiness that might be felt on the score of interference with the ordinary business of chemists and druggists, and the general expression of public opinion was so unmistakably opposed to such a step that it would have been difficult to demonstrate the existence of any further cause for apprehension. Medical defence associations it is true, still remained in the field, and, perhaps, they have not yet altogether ceased from troubling; but in regard to the subject of counter practice by chemists and druggists it may be fairly assumed that there is no longer much to be feared. At least, this seems to be the natural inference to be drawn from the suggestion offered by Dr. B. W. RICHARDSON in a presidential address, with the object of making medical practice a part of the recognized business of a chemist and druggist, and establishing for that purpose an inferior degree of medical qualification. Though we have no sympathy with this project, its proposition from such a quarter is certainly no slight recognition of the necessity that exists in many instances for the services of the chemist and druggist in advising as to the use of medicine.

The subject of co-operative trading is, next to that of "counter practice," the one which has attracted most notice from chemists and druggists, who, in common with the general trading community, have experienced the injurious effects of the competition set up by what is termed the "store" system. Unfortunately we cannot in regard to this subject refer to any settlement of the questions that it has raised, or to any step that has been taken towards providing an effectual remedy for the evils which retail traders have suffered in consequence of the spread of the "store" system. The propositions that have been put forward with that object have been almost always vague, contradictory, and to some extent impracticable. Some extremely opinionated and often injudicious speeches have been made at public meetings, and much of the evidence given before the Select Committee of the House of Commons was not in any degree better calculated to be of service to the interests of retail traders. In fact they have in general merely suffered and complained, without having apparently formed any distinct and generally accepted idea how they are to help themselves, and at the present moment it seems that such an idea has yet to be developed.

Though chemists and druggists are to some extent situated differently from other classes of tradesmen in regard to the "store" system, the difference obtains only with a part of their business. Under existing conditions a large portion of the business done by them, in many instances, is altogether foreign to pharmacy, consisting simply of hand to hand transfer of articles from the seller to the purchaser, and requiring no greater skill than is necessary for the draper or the grocer in conducting their trades. It is in this department of the chemist and druggist's business that the influence of the "store" system is most severely felt, and hence we have had numerous complaints of the loss of trade in patent medicines and articles of a similar nature by reason of their being sold at the "stores" at reduced prices. The result experienced is no doubt very serious in cases where the trade in such articles constitutes a very considerable proportion of the chemist and druggist's business, and it is natural that it should have given rise to very general inquiry how this destructive competition is to be met. Some have recommended the adoption of the "store" system by selling at the same rates, others have suggested the total abandonment of the trade in patent medicines and articles of such a nature as can be sold by any person of ordinary trading capacity. These two proposals represent extreme measures that are not altogether necessarily alternatives, though they may be taken as having their origin from two incompatible ideas respecting the nature of the chemist and druggist's business. The plan of competing with the "stores" in the matter of price is one which presupposes that the business of the chemist and druggist is in no respect different from that of the grocer or the draper, and if the assumption were correct this plan would probably be the best to adopt, provided the advantages of very extensive sales and immediate cash payments could be secured.

But the assumption above referred to is one that cannot be maintained. This circumstance has repeatedly been testified to almost involuntarily and in no instance, perhaps, more distinctly than by one of the witnesses before the Select Committee, who, as a chemist and druggist himself, and in answer to the question why he did not sell a certain proprietary cosmetic preparation at the same price that the "stores" did, stated that he could not do so. Underlying this statement is to be recognized a sense of the fact that the business of the chemist and druggist is so far different from all other kinds of trade as not to admit of its being conducted upon the same lines and under the same conditions as to rate of profit that would satisfy the requirements of other kinds of business. Closely connected with this view of the matter is the idea from which originates the recommendation to abandon altogether the trade in patent medicines and what are termed druggists' sundries. According to that idea this trade is inconsistent with the business of the pharmacist, and if the practice of pharmacy were an occupation sufficiently separated from other kinds of business that idea might command more general consideration as a guiding principle. That it is not so, however, would be superfluous for us to contend, and that it can ever become so is perhaps more than one can venture to hope. In many cases it would almost amount to giving up business if the sundry trade of a chemist and druggist's shop were discontinued, and even where purely pharmaceutical business is so extensive as to render such a course practicable, we doubt whether its adoption would not entail great disadvantage. It is precisely for this reason that it seems impossible to take as alternative plans the entire abandonment of trade in sundries or the sale of these articles at "store" prices.

The conditions affecting individual cases are so various that regard must be had to the conditions obtaining in particular instances rather than to abstract principle, and looking at the matter from this point of view it seems that the practical alternative is either to maintain prices at such a rate as is compatible with the general character of purely pharmaceutical business, or else to take a lower status and compete with the "stores" in the price of sundry articles.

But though the mixed nature of the chemist and druggist's business introduces some special difficulty in dealing with the "store" competition, as regards the trade in patent medicines and sundries, the conditions under which the purely pharmaceutical portion of that business is conducted furnish reasonable grounds for seeking to protect that portion of the business from being interfered with. It was upon this ground that the prosecution of the London and Provincial Supply Association was undertaken by the Council of the Pharmaceutical Society. The appeal against the judgment given in favour of the "stores" by the County Court Judge has during the past year resulted in a reversal of that judgment, mainly upon the ground that it was not competent for an association of persons, not specially qualified, to do what any one of the number could not lawfully do. This decision of the Lord Chief Justice and Mr. Justice Mellor has been appealed against by the London and Provincial Supply Association, and it was hoped that the hearing of the appeal would have been brought on before the end of the year. Unfortunately this has been impossible, and the matter still remains open. In all probability, however, the case will be heard and decided early in the coming year, and it will then be seen whether the existing provisions of the Pharmacy Act thoroughly suffice for the protection of pharmaceutical business from the interference of unqualified persons, or whether further legislation must be sought for to secure this.

As regards the ordinary trade features of the chemists and druggists' business, it seems scarcely possible to expect the Legislature to enforce restrictions in favour of chemists and druggists, unless the articles sold contain dangerous poisons or in some way come within the scope of the provisions of the Pharmacy Act. That this is the case with many patent medicines is notorious to those conversant with the business, though it is not so well known to the public generally, and it is beyond question that fatal accidents have resulted from the indiscriminate sale of such articles, and from this ignorance on the part of the public.

The status of the pharmacist in Great Britain has been the subject of a large amount of discussion during the year and has been the topic of several presidential addresses. At Sheffield, the President of the Pharmaceutical Conference, Mr. G. F. Schacht, varying his stand-point from the internal one taken at Dublin, from which he was able to recognize the typical pharmacist as an illustration of a high order of citizen, went outside the pharmaceutical body to discuss the estimate of the pharmacist by others. The conclusion was not very flattering, namely, that in the eyes of the public pharmacists are tradesmen neglected by "Society" and credited with being "its obliged and humble servants, slavishly ready to do whatever is told them, and to take for payment whatever cannot be conveniently bestowed on the professional man on the one hand or the co-operative stores on the other." This public estimate of pharmacists, Mr. Schacht considers to be mainly the echo and reflection of that previously adopted by a large proportion of the medical profession, arising mainly from an indifferentism, due possibly to the isolation of pharmacy and its teaching from the general medical curriculum. As a first step towards unification he suggested that every student in medicine,—using the term in the broad sense inclusive of pharmacy,—whatever branch he may intend ultimately to practise, should be brought at some period of his training through one common portal, which might consist of one of the sets of the examinations.

In the Inaugural Sessional Address delivered in Bloomsbury Square in October, Dr. Tilden took up still another position, that of one who was once closely associated with pharmacists, but who has now so far severed his connection with them as to be able to look on their proceedings from the standpoint of an outsider. Some of the passages in this address were very outspoken, the key note being that so far and so long as the pharmacist is a trader he must take with other traders the chances of competition with the "stores" and submit to the neglect of what is called "Society." For an improvement in the pharmacist's position Dr. Tilden looks to the gradual but steady development of the professional phase of his calling, in which he need not fear the competition of the mere trader. As an attempt in this direction may be here mentioned the inquiry set on foot by the Rochdale Chemists' Association, with a view towards the development of the pharmaceutical portion of the business and promoting the transfer of the dispensing of medicine from the medical practitioner to the chemist and druggist.

A similar tone was observable in an address delivered a few days afterwards by Dr. C. Symes, as President of the Liverpool Chemists' Association. Already, urged the speaker, the public regards pharmacy as something above an ordinary trade and the pharmacist as a man of superior intelligence, and although the fact that he is a shopkeeper militates against him with the superficial portion of "Society," yet those who have the most substantial claims to position themselves readily accord to pharmacists their proper status. It was suggested that pharmacists should educate themselves and the public to speak of their places of business as pharmacies and to regard the charges for dispensing as fees or payment for professional work.

In the following month the President of the North British Branch, Mr. J. B. Stephenson, dealt with the same subject. Referring to complaints of the non-recognition of the true position of pharmacy and the pharmacist by the medical profession and the public, Mr. Stephenson said that, as far as his experience went, such complaints were groundless. Assuming as a fact the dual nature of pharmacy as a calling, he wishes to magnify the profession as much as possible, but by no means to minimize the trade. One reason given for this desire was the opinion that the fees at present paid by the public for the professional, or dispensing, portion of the pharmacist's services are insufficiently remunerative, so that if the public insists upon withdrawing from him the profits derived from dealing in such articles as can be obtained from the stores, higher fees will have to be paid for medicine. A prominent feature in this address was a strong protest against the existing traffic in patent medicines. Its effect in changing the calling of the pharmacist from being a compounder of medicine to becoming a salesman of the preparations of others was pointed out, and pharmacists were urged to utilize the prestige of their influence—which had hitherto served to float many of these preparations—in the opposite direction, for the purpose of discouraging and discrediting the whole system

A large amount of correspondence provoked by a pungent letter signed "Hampshire" has also been devoted to the future of the pharmacist. A great number of these letters were occupied principally with the subject of prices, and many of them showed indications that the writers thought the prosperity of their calling would depend upon the price that might be obtained for patent medicines. In fact, the subject of patent medicines has, during the whole year, furnished a running fire of discussion which has been addressed mainly to two questions, first, what should the pharmacist do in the presence of the enormous competition in the sale of patent medicines by grocers and others which has developed during the last few years? and, secondly, can unregistered persons be prevented from dealing, under the cover of the patent medicine stamp, in preparations consisting altogether or in part of scheduled poisons? With respect to the former question, opinions have been very divergent, as in the discussion relating to "stores," many being in favour of adherence to the advertised prices, whilst others would meet their cutting competitors by selling at equally low, or even lower, prices. There have not been wanting those, however, who think with Mr. STEPHENSON that the time has come for the pharmacist to wash his hands of this system of quackery, and like another FRANKENSTEIN do what he can to destroy the monster he has assisted to create.

The second question was brought under the consideration of the Council of the Pharmaceutical Society in July, on a motion by Mr. HAMPSON that the General Purposes Committee should be instructed to take into consideration the largely increasing sale of patent medicines containing scheduled poisons by unregistered persons, and to report thereon especially with regard to the advisability of endeavouring to restrict the sale of such preparations to registered persons. In the discussion it was incidentally stated that the subject had been under the consideration of the Pharmacy Act Amendment Committee, which had arrived at the conclusion that it was not advisable at present to attempt to obtain further legislation on this point. But the PRESIDENT expressed a decided opinion that the Pharmacy Act, 1868, is sufficiently strong to prevent the sale of definite scheduled poisons by unregistered persons, and cannot be evaded by simply sticking a duty stamp on the containing vessel. The motion was agreed to, but no report from the Committee on the subject has yet been published.

The subject was set down as well in the September agenda paper of the Law and Parliamentary Committee of the Chemists and Druggists' Trade Association. This Committee, also, evidently recognizing the difficulty of obtaining legislation without evidence that it would be conducive to the public interest, ordered a circular to be sent out asking for well-authenticated instances in which fatal results have followed from the sale of scheduled poisons under cover of the patent medicine stamp and for suggestions and information on the sale of patent medicines generally. The replies evoked were read at a subsequent meeting of the Committee; their nature was not reported, but they do not appear to have contributed much to the elucidation of the subject, as no step was taken beyond instructing Mr. HAYDON to continue his quest for information.

The modification introduced into the Dental Bill, for the purpose of enabling chemists and druggists actually engaged in the practice of dentistry at the passing of the Act to be registered as dentists, has had a result which seems to have greatly surprised the promoters of this measure. The number of persons so registered in the United Kingdom amounts to 2049, or upwards of one-third of the entire number of persons registered under the Act, and those who desire to see the right to use the title of dentist restricted to persons specially engaged in the practice of dentistry in all its branches have recently sought to make out that the Act was never intended to confer legal recognition upon anyone who was not engaged in the practice of dentistry in that more extended sense. They contend that the mere extraction or stopping of teeth and such minor operations, commonly practised by chemists and druggists, do not entitle them to be called dentists or to obtain registration as such. We have, on several occasions, pointed out in reply to these cavils that we cannot perceive any reason why a person habitually engaged in conducting any dental operations should not be termed a dentist, and though we willingly concede that no person so engaged should assume the designation of dentist unless he is competent to the work he undertakes, we cannot admit that the use of that designation necessarily involves practical acquaintance with the entire range of dental practice as at present generally understood. Chemists and druggists claimed recognition under the Act, inasmuch as many of them had long been in the habit of extracting teeth, and because they apprehended, from the restrictive object of the Bill, that their continuance of that practice would have been construed as an infringement of the law if the Act had not given them recognition. We cannot regard their action in this way as other than justifiable as a measure of self-protection, and although heartily sympathizing with the dental reformers in their desire to establish a high standard of professional qualification and a trustworthy indication of dental skill, we must confess that the objections raised to the registration of chemists and druggists seem to us somewhat illiberal.

The Weights and Measures Act is still practically in abeyance as it affects chemists and druggists, but we have so recently dealt with this subject that it would be useless to reiterate in this place. So far as we can learn the local authorities are not taking any steps to carry out the provisions of the new Act: the only persons active are certain enterprising inspectors who undertake to construe the Act and, according to their lights, to furnish interpretations of it, chiefly with the result of creating confusion of ideas and mystification. It is, however, at least clear that these officers have yet to be taught their business, especially in regard to the verification, stamping and inspection of apothecaries' weights and measures, and in some instances that we are acquainted with they have undoubtedly exceeded their powers by doing things that are not authorized by the Act. As already pointed out it is the local authorities throughout the country who have to lay down regulations for carrying out the provisions of the Act, and until we hear that in any particular instances this is done and approved of by the Board of Trade, the inspectors of weights and measures will really have no authority upon which to act.

In a Parliamentary session that was unusually unproductive of legislation, there was not much effected to interest the chemist and druggist. Medical Bills were introduced, but not passed; nevertheless, they were carefully watched by the Council during the time they were under consideration. Besides this, the Sale of Food and Drugs Act was amended so as to clear up doubts as to what constitutes prejudice to the purchaser, and a new Petroleum Act was passed prescribing a new method of testing the flashing point of hydrocarbon oil.

Several cases of prosecution for breaches of the Pharmacy Act have been recorded besides that against the London and Provincial Supply Association already referred to. Two other prosecutions instituted by the Council have been reported, in one of which it was decided that a patent medicine stamp does not cover the sale of a scheduled poison. There have also been a large number of unreported cases, in which persons have discontinued their illegal practices after being warned, or have paid the penalty without going into court. The Chemists and Druggists' Trade Association has also obtained convictions in six cases under the provisions of the 17th section, and the police in various parts of the country have been similarly successful in ten other cases.

Twenty-six cases of prosecutions under the provisions of the Sale of Food and Drugs Act have been reported as relating to substances that are sometimes, with the exception of the last, retailed by chemists and druggists. These are sweet spirit of nitre (2), cream of tartar (8), milk of sulphur (4), tincture of camphor (1), tincture of rhubarb (1), violet powder (1), castor oil pills (2), annatto (1), soda water (1), baking powder (1), dispensing of a prescription (1), and paregoric devoid of opium (3). There were convictions in twelve of these cases, but it is a significant commentary on the inference sometimes drawn from the returns furnished by public analysts, with respect to the sale of adulterated drugs, that in only two instances, the sale of tincture of camphor deficient in spirit and of milk of sulphur, was the convicted person a chemist and druggist.

Referring next to matters more immediately affecting the Pharmaceutical Society, we remark first that the Council, which now exercises such important functions in the interests of pharmacists, as well as of the public, has undergone a slight change in its constitution. Two of its members, who had served the Society in it for some years, and who retired by rotation, Messrs. Betty and Hanbury, declined to be again nominated. Another member, Mr. Cracknell, who retired by rotation, was not re-elected. The new members elected were Messrs. Richardson, Squire, and Symes. Another vacancy, caused by the resignation of Mr. Fairlie, was filled by the Council selecting Mr. Slipper. Once more the Presidency is held by Mr. G. W. Sandford, succeeding Mr. Williams, who had filled the office during three years; Mr. Schacht was chosen Vice-President, in the place of Mr. Bottle; and Mr. Greenish was again elected Treasurer.

The history of the examinations, although not so stirring as in some previous years, has not been without incident, but the two alterations made in the arrangements may be described rather as confirming practices already obtaining than as presenting any novel features. On more than one occasion since the Preliminary examination has been conducted by the College of Preceptors the questions have included an exercise not strictly within the limits of the Regulations, upon the translation of Latin into English. Although it was understood that these cases were simply tentative and were not allowed to affect the result of the examination, they answered the purpose of calling attention to the "half-process" of examining in the Latin language hitherto adopted, and in March, upon a joint recommendation of the Boards of Examiners for England and Scotland, it was resolved by the Council that after the 31st of December, 1879, candidates for the Preliminary examination should be required to translate simple sentences from English into Latin. The other alteration was the incorporation in the Bye-laws, at a Special General Meeting held on the same day as the Annual Meeting, of certain regulations with respect to the fees paid by candidates who fail to attend or are unsuccessful in the examination room.

In February was published a letter from an esteemed correspondent, adopting the *nom de plume* of Devon, which might reasonably have raised the suspicion that the writer was attempting to demonstrate the truth of the saying that figures may be made to prove anything; for, though professedly it was based on the official statistics, successive paragraphs of the letter contained the different propositions that each candidate in London during 1878 had had to face on the average 13·8 examiners, that there had been more than half as many examiners as candidates, and that in the Major there had been nearly two examiners to each candidate. In the reply to the criticism evoked it became, however, apparent that Devon's object was to raise a protest against the *vivâ voce* examinations on the ground that they deter nervous men and favour "cramming." In his opinion *vivâ voce* examinations are the stumbling block in the way of men trying to attain the higher qualification, and their substitution by an examination mainly written, conducted by examiners appointed only three days previous to the examination day, was suggested as likely to double the percentage of Minor men passing on to the Major examination.

Whatever may be the defects of the present system, however, it can hardly be said to have an unduly deterrent effect, since the number of persons passing the qualifying examinations during the year have been probably amply sufficient to supply the gaps which death or other causes may have made in the ranks, whilst, what is more satisfactory, the number who have passed the Major is nearly equal to the passes and failures combined in the previous year. The total number of candidates examined has been 2296, of whom 134 sat for the Major, 656 for the Minor, 32 for the Modified, and 1474 for the Preliminary examination; this was 365 in excess of the gross total of candidates in 1878. Of the 134 Major candidates, 76 or 56·7 per cent. passed, against 51 out of 81, or 61·7 per cent. in 1878. Of the 656 Minor candidates, 331, or just over 50 per cent. passed, the proportion being nearly the same as in the previous year, and of the 32 Modified candidates 20 passed. The Preliminary examination yielded 783 successful candidates, or 53·1 per cent. of the whole, against 47·6 per cent. in 1878, besides which 47 certificates of other examining bodies have been received in lieu of it.

The subject of the amendment of the Pharmacy Act, 1868, has been under the consideration of the Council on several occasions, and in March a Committee was appointed with power to obtain the necessary legal assistance to draft a Bill embodying the recommendations of a previous Committee on the subject, and to deal among other things with the question of titles.

A considerable amount of interest has been displayed in respect to the revision of the British Pharmacopœia, and the relation in which pharmacists should stand to it. In December Mr. HAMPSON brought forward a motion to the effect that the Medical Council should be asked to receive a deputation to urge upon it the desirability of the Pharmaceutical Council being legally empowered to nominate pharmacists to co-operate with the Medical Council in framing and amending future editions of the British Pharmacopœia. The motion was, however, lost.

Another subject that has been under the consideration of the Council has been the HANBURY Memorial Fund. This has now been closed, the amount invested having reached £400. The Council has now formally accepted the trust of administering the fund, and a die for the medal, which is to be awarded every two years, has been prepared.

A Special General Meeting of the Society was held in January to consider a motion requesting the Council to assist, by a pecuniary grant, the Trade Association in paying the expenses incurred in the defence of the SHEPPERLEY case. The motion was agreed to, but the Council had been advised that it could not deal with the Society's Funds in such a manner. The Annual Meeting was held, as usual, in May, when the principal topic for discussion was the proposed admission of women to membership, which, so far as that meeting was concerned, was decided adversely by a small majority. Notwithstanding this the Council at its meeting in October elected two ladies as members. A Special General Meeting was held after the Annual Meeting to sanction an alteration in the Bye-laws. In the evening of the same day the Annual Conversazione took place at South Kensington. At the October Evening Meeting the annual distribution of prizes given by the Society was made, the PEREIRA Medal once more going to a student in the Society's school. The students were afterwards addressed by Dr. TILDEN.

The Benevolent Fund has again been the medium of a large amount of much needed help. In annuities there has been expended £950, and in grants for temporary relief about £720, making a total of £1670, or £300 in excess of the expenditure in the previous year. Towards meeting this there has been received £1200 in subscriptions and £55 in donations, being about £120 less than the receipts in 1878. In December three new annuitants were elected, bringing the number up to 32, but by the death of Mrs. TRUMPER, a few days since, this has been reduced to 31.

The Society's Library has been increased by nearly three hundred volumes and pamphlets, the donations and purchases having been about equal in number. Some valuable works have been purchased out of the HANBURY Bequest, which is now all spent. The circulation of books has been larger than in the previous year, an increased proportion (about one-third) having gone into the country. The attendance of readers in the Library during the day has been smaller, but during the evening larger, than in the preceding year. The Museum, also, has been enriched by a large number of donations, some of considerable value. It may appear almost invidious to mention some of the donors without mentioning all, but their great value will excuse special reference to the collections of opium products, presented by Messrs. MACFARLAN and Messrs. T. and H. SMITH; of coto and other products, presented by Dr. HESSE; of American drugs, given by the Philadelphia College of Pharmacy; of foreign drugs, by Mr. CHRISTY, to whose business energy many of them owe their introduction; and of Indian drugs, by Dr. DYMOCK.

The usual Evening Meetings have been held during the present year, but it is regrettable to have to record that the attendance on some occasions has been small. No doubt this is affected by the fact that the papers can be perused in this Journal two or three days after they are read at a meeting; but it should be remembered that, apart from the stimulus which the expectation of having a good audience gives to the production of papers many points of interest arise in the discussions following the reading of them, and these discussions are, of course, entirely dependent upon the persons present at the meetings. There were exceptions, however, when the lecture theatre was well filled, on the occasions of two lectures by Professor REDWOOD, on "Electricity as a Source of Light," and one by Professor BENTLEY, on "The Life of the Plant." The papers read at the Evening Meetings, ten in number (against fifteen last year), have been as follows:—"Myrtus Chekan," by Mr. E. M. HOLMES; "An Examination of Distilled Essence of Lemon," by Dr. W. A. TILDEN; "The Estimation of Diastase," and "Extract of Malt," by Messrs. W. R. DUNSTAN and A. F. DIMMOCK; "Note on Plasma," by Mr. W. WILLMOTT; "The Action of Iodine on Rhubarb," by Mr. H. G. GREENISH; "Monguno Bark," by Professor G. DRAGENDORFF; "Note on Shea Butter," by Mr. E. M. HOLMES; "Taraxacum," by Dr. C. SYMES; and "A Method for the Volumetric Estimation of Arsenic Acid," by Mr. W. A. H. NAYLOR. The last evening was devoted to a discussion relating to the new Weights and Measures Act, the subject having been introduced by Dr. B. H. PAUL.

The North British Branch has enjoyed a fair measure of prosperity, and at its Annual Meeting in April the Council was able to present a favourable report. On that occasion Mr. J. B. STEPHENSON was reelected President, Mr. A. NAPIER, Vice-President, and Mr. JOHN MACKAY, to whom the Branch owes so much of its success, was reappointed Honorary Secretary. Evening meetings have been held as usual and several valuable papers read at them have appeared in these columns.

Turning to the sister island we are pleased to have to record an arrangement that has brought this Journal into closer relations with the pharmacists of Ireland. In 1878 the Council of the Pharmaceutical Society of Ireland decided to furnish an official report of its proceedings to this Journal. Early in the present year it made an application to the Council of the British Society, which was acceded to, for the regular supply of this Journal to each of its members, and this arrangement has been carried out. The present therefore presents a suitable opportunity for a brief epitome of the history of this Society.

The Pharmaceutical Society of Ireland was incorporated by Act of Parliament in August, 1875, and held its first meeting on September of the same year. It then consisted of the twenty-one members of Council named in the Act. Since that period 151 pharmaceutical chemists have been registered, 147 having been registered after examination, and 4, as being licentiate apothecaries, were under the Act exempt from examination. About 90 pharmaceutical chemists have been elected members of the Society since its formation, and at the present time it appears to be in a fairly prosperous state. During the year 1879, 71 candidates resented themselves for the Preliminary examination, of whom 60 passed and 11 were rejected. There were 18 candidates for the licence to act as pharmaceutical chemists, of whom 11 passed and 7 were rejected. Since April, 1876, 164 candidates have passed the Preliminary examination of this Society under the new code of regulations, most of whom have to appear for their final examination at some future date. In November last the Council resolved that the certificate of having passed the Preliminary examination of the Pharmaceutical Society of Great Britain should be accepted as equivalent to the corresponding examination of the Irish Society. Lastly, it having been thought desirable to secure, if possible, some alteration in the Act constituting the Society, chiefly in the direction of compelling all sellers of scheduled poisons to become registered, a draft of an amendment Bill was discussed and agreed to by the Society at its annual meeting in October.

The year has not been marked by any of those sensational introductions to the materia medica that occasionally for a time appear to be of such surpassing value, but eventually afford so large a percentage of absolute failures. It has not, however, passed without the mention of a few new drugs, coming principally from Liberia, Japan, and the never-failing stores of the western hemisphere, and affording materials for testing the warrant for a local reputation, which in some cases has been made to cover a wider area by the efforts of public-spirited advertisers. Perhaps, however, the substance that has attracted most attention is the bladder wrack (*Fucus vesiculosus*), which is to be found abundantly on our own shores. Reputed to be the principal constituent of a well-advertised nostrum for obesity, which, whatever it may have consisted of earlier in its history, undoubtedly now contains it, preparations of *Fucus vesiculosus* have come into demand. This alga would seem to be worthy of further investigation, and Mr. CONROY has done useful service in presenting a *résumé* of what has been written about its therapeutics, as well as in indicating a method for its pharmaceutical treatment. Among the Liberian drugs have occurred some bearing such suggestive names as "erysipelas plant," "dysentery plant," "abortive plant," "cream of tartar plant," as well as a comparatively pure elemi resin. Among the Japanese drugs are some that, like the aconite of which the chemical history has been partially worked out, promise to be at least as valuable as their analogues at present in use in this country and America; as, for instance, a species of *Patrinia*, with an odour more powerful than ordinary valerian, and two species of *Coptis* containing berberine. Under the trivial name of "cascara sagrado," the bark of the Californian *Rhamnus Purshiana* has been brought forward as a remedy for constipation, and probably it may possess properties similar to those attributed to the bark of *R. Frangula*. "Yerba reuma" is a name of the same class, and the drug is said to be derived from the *Frankenia grandifolia.* The "herba santa maria," which has been the object of a few inquiries, is, according to Mr. Rey, the *Chenopodium ambrosioides*, L., a Brazilian plant enjoying in its native country some reputation as a neurotic and a vermifuge. Another Brazilian plant, *Ocimum basilicum*, has been mentioned as yielding a juice that is also a powerful vermifuge. The *Myrtus Chekan*, Spreng., a Chilian plant possessing aromatic properties, and said to be useful in the treatment of bronchitis and as a general tonic, was the subject of a paper read at an Evening Meeting by Mr. E. M. Holmes. "Folia carobæ," the leaves of the *Jacaranda procera*, also a South America tree, have been reported as coming into use on the continent as an antisyphilitic and alterative. Lastly, one of the most interesting contributions to the history of the crude materia medica, in which Mr. E. M. Holmes called attention to a long cylindrical bean, occurring sometimes amongst calabar beans of the more orthodox shape, if it did not exactly introduce a new drug, nevertheless pointed to a hitherto unexpected botanical source of it. Turning to the animal kingdom, "ostrich pepsine" appears likely to belie the omnidigestive promise of its name, and if the statements made at the November Evening Meeting as to its non-activity be confirmed, its reputation in this country may be said to have bloomed and withered in a few fleeting months. And a similar fate appears to await the only other recent addition to the animal materia medica, the *Blatta orientalis.*

Besides fresh substances suggested as additions to the materia medica, our knowledge has been advanced during the year with respect to others which possess still, more or less, the character of novelties. "Bidara laut," the wood and bark, probably, of *Strychnos Ligustrina*, used in India as a popular remedy against dysentery and which two or three years since furnished the subject of an animated dispute in Germany, has been examined by Mr. H. G. Greenish, who found a specimen to contain in the dry wood equal to 2·26 per cent. of anhydrous brucia and in the bark the large amount of 7·38 per cent., but no strychnia. It would therefore appear to be a convenient source of pure brucia that might be used in clearing up the physiological doubt whether the action hitherto attributed to brucia has not really been due to its contamination with strychnia. The same experimenter examined also the wood and bark of *Strychnos Colubrinum* and found them to contain both strychnia and brucia, in which they resemble "false angustura bark," as ascertained by Professor Dragendorff and Mr. Shenstone. Incidentally, his observations also suggest the inference that the percentage of alkaloid in the *Strychnos* barks diminishes with the age and thickness of the specimen.

The great interest which has in late years been excited in curari, principally from an expectation that it might be useful in the treatment of hydrophobia, has led to the examination of other species of *Strychnos*, a plant or plants of which genus it is believed furnish its principal constituent. The result has been that several American species have been found to exercise the physiological action characteristic of curari rather than the well-known one of the Asiatic species with which the name strychnia is generally associated, and that some species possess this property in so mild a form as to allow of the hope that soon a definite and manageable preparation may take the place of the dangerous and uncertain one now imported as "curari."

The bark of *Alstonia constricta*, known as the "Australian fever bark," which has also been the subject of a dispute as to its alkaloidal constituent, —some observers saying that it had one and others none,—has been further examined by Messrs. Oberlin and Schlagdenhauffen, who report that they have obtained from it two alkaloids, one crystalline (alstonine) and the other amorphous (alstonicine); the possible relation of the amorphous to the crystalline substance being indicated by its name. This bark has on more than one occasion during the year been confounded with "dita bark," which is obtained from the *Alstonia scholaris*, and was some time since alleged to yield a febrifuge equal to quinine.

Quebracho blanco bark, from the *Aspidosperma Quebracho*, which has been long used in South America for the same purposes as cinchona bark, has come into more prominence this year in consequence of the isolation, by Herr Fraude, of an alkaloid which he has named "aspidospermine," and which is alleged to have a specific action in relieving dyspnœa. Here, also, a similarity of name has induced an almost ludicrous mistake, and a "quebracho colorado" *wood* from the *Loxopterygium Lorentzii*, a plant belonging to a different order, which wood has lately been imported into Europe for tanning purposes, has no doubt sometimes been supplied for the "quebracho blanco" *bark*. Lotur bark, another bark that was formerly looked upon as a cinchona bark, has been investigated by Dr. Hesse, who reports that he has isolated from it three alkaloids, which he has named "loturine," "colloturine," and "loturidine," and which all give an intense blue-violet fluorescence in dilute acid solutions. Amongst the other alkaloidal principles that have been announced as discovered are "anthocercine," from a solanaceous plant, *Anthocercis viscosa*, and "baccarina," from *Baccharis cordifolia*, a Composite plant said to be a cause of sheep poisoning in some parts of South America. In the hands of M. Tanret, also, pomegranate root bark has yielded three other alkaloids, besides pelletierine, but these have not yet been fully described. On the other hand the list of alkaloids has been reduced by two, "mercurialine," a volatile alkaloid attributed to *Mercurialis annua* and *M. perennis*, having been identified as trimethylamine; and the supposed "piturine," from the curious drug "pituri," being reported by M. PETIT as identical with nicotine.

Nor have investigators been lacking for older and more widely known drugs, such as rhubarb, myrrh, veratrum, ginger and others. To take perhaps the most ancient first. Although the curious obscurity which so long has hung about the origin of this drug has not yet been quite removed, a thorough examination, partly of new materials, by Dr. TRIMEN, confirms the opinion that true myrrh is obtained from the *Balsamodendron Myrrha*, Nees, and that the plant grows in Somali-land and on the Red Sea coast of tropical Africa. An interesting account of the different sorts of myrrh has also appeared in a paper by Mr. R. H. PARKER.

On the subject of rhubarb, Mr. H. G. GREENISH has published the results obtained in the analysis of four specimens, named respectively rheum chinense, sibiricum, mandshuricum, and palmatum. So far as commercial value is indicative of quality, these results may be said to be confirmatory of the theory that the most important active principle of rhubarb is cathartic acid, since it is present in much the largest proportion (4·96 per cent.) in rheum chinense, whilst from the mandshuricum and palmatum rhubarbs, although they approach chinense in the amount of chrysophan and tannin present, cathartic acid is nearly absent, being apparently replaced in the latter by mucilaginous matter. The same investigator has made some experiments as to the trustworthiness of the amount of iodine absorbed by rhubarb as an indication of the quality of the root, and reports that it cannot be depended upon, as the absorption does not depend on the active ingredient alone.

Ginger is another substance which notwithstanding the antiquity of its use as a condiment and drug has been hitherto very imperfectly known. Even concerning the essential oil, the only principle that has been supposed to have been studied, very conflicting statements have been made. This reproach has now been removed to a considerable extent by the investigation made by Mr. THRESH. From the ethereal extract, which contains the most important constituents of the rhizome, Mr. THRESH obtained the essential oil as a limpid straw-coloured liquid, sp. gr. ·815, having an odour different from that of ginger and an aromatic camphoraceous taste, and soluble in 25 parts of alcohol of sp. gr. ·815. From the fact that by exposure to heat it became darkened in colour and of higher specific gravity it seems probable that this liquid is a mixture of two or more bodies with different densities and boiling points, and Mr. THRESH thinks that probably the most volatile constituent of the original oil has the finest aroma. Passing by some fatty bodies and neutral and acid resins, which were separated and studied, it may be stated that the active pungent principle of ginger was obtained as a viscid, pale straw-coloured liquid, entirely devoid of odour, with a very pungent, slightly bitter taste, and very soluble in alcohol, even when dilute. This principle has been named "gingerol." Both the aqueous solution of the ethereal extract and an aqueous extract gave indications of the presence of an alkaloid. The value of this investigation was made immediately manifest by the application of the resulting knowledge in the modification of the formula for "soluble essence of ginger."

Continuing their researches upon the veratrum alkaloids, Messrs. WRIGHT and LUFF have this year reported upon the results obtained with the roots of *Veratrum album* and *V. viride*. From the former they state that they have separated, besides jervine ($C_{26}H_{37}NO_3$), three other alkaloids, previously undescribed. Two of these, pseudojervine ($C_{29}H_{43}NO_7$) and rubijervine ($C_{26}H_{43}NO_2$), are crystalline, while the third, named veratralbine ($C_{28}H_{43}NO_5$), is amorphous. Not one of these four is capable of exciting sneezing; but there was also a small quantity of another base observed, which when mixed with veratralbine was powerfully sternutatory, and as this property was lost on saponification, and a small quantity of veratric acid formed, the authors think the presence of veratrine was indicated. From the roots of *V. viride* they obtained, but in much smaller proportion, jervine, pseudojervine, rubijervine, and signs of the base yielding veratric acid. Veratralbine was not detected, or only as a trace, but in its place was cevadine ($C_{32}H_{49}NO_9$), defined as the "veratrine of Merck" by the same authors in their previous paper, when it was obtained from sabadilla seeds. A paper on *Veratrum viride*, by Mr. C. BULLOCK, of Philadelphia, whose name has been previously associated with this subject, is partially confirmatory of these results, though this observer claims to have obtained a much larger yield of alkaloids by the process which he describes. It has also been announced by M. HETET that he has obtained veratrine from the leaves of *Sarracenia purpurea*.

Aconite, also, has been the subject of further research by Dr. WRIGHT, and he has reported to the Pharmaceutical Conference that, like Messrs. PAUL and KINGZETT, he has separated from Japanese aconite a crystallizable alkaloid differing from aconitine, which he has named "japaconitine," and represents by the formula $C_{66}H_{88}N_2O_{21}$. This Dr. WRIGHT supposes may be a dehydrated derivative of an alkaloid differing from aconitine by containing four more atoms of hydrogen; but no trace of this hypothetical base was found. Dr. WRIGHT also confirmed the statement that the Japanese aconite root is considerably richer in crystallizable base than the root of *A. Napellus*. Not the least important statement contained in this report was one that, practically, all the alkaloids present in the roots were extracted by unacidulated alcohol, a fertile cause of decomposition being thus avoided. Dr. WRIGHT reported, also, that he had separated an alkaloidal substance from atis roots (*A. heterophyllum*), but that the numbers obtained on analysis of a small quantity did not answer to the formula attributed to atisine by Mr. BROUGHTON. Another observer, however, Dr. WASOWICZ, has reported that with a substance isolated by him from atis root he has obtained figures closely approximating to those required.

Cinchona has once more contributed its quota to the literature of the year. A remark in a letter to the Secretary of State for India from Mr. J. E. HOWARD, implying the possibility that the unpleasant results alleged to sometimes follow the administration of the mixed alkaloids of succirubra bark might be due to the presence of aricine, or perhaps paricine resulting from its alteration, gave rise to a correspondence, not devoid of asperity, between that gentleman and Dr. HESSE, the most satisfactory outcome of which was a communication from Dr. HESSE, giving a lucid description of the preparation and characters of those two alkaloids. Mr. DAVID HOWARD has put on record the observation that in the bark of *C. officinalis* from the Indian Government plantations the proportion of quinine and total crystallizable alkaloid appears to increase with age (going back as far as 1863), whilst that from *C. succirubra* is known to deteriorate when beyond a certain age. From Dorpat Herr MANDELN has reported that in experimenting on the citrates of quinine he has obtained an anhydrous acid salt, containing one molecule of quinine to one of citric acid; an anhydrous neutral salt, containing three molecules of quinine to two of acid; and a basic salt, containing two molecules of quinine to one of acid and half a molecule of water. Early in the year Mr. W. STEVENSON described a modification of the Pharmacopœia process for the estimation of quinine in citrate of iron and quinine, consisting principally in the use of a saturated solution of quinine in dilute ammonia water in washing the precipitate. Further on, in a useful paper read before the Pharmaceutical Conference, Mr. F. W. FLETCHER described an application of Dr. PAUL's plan of fractional crystallization to the same end. Mr. CHALLICE has also described an improved method of producing the thalleioquin reaction in dilute solutions of quinine. In the more purely pharmaceutical direction, Mr. GILMOUR has called attention to the amount of quinine in EASTON's syrup and the loss which takes place during the washing of the precipitate in its preparation, amounting to 10 per cent. even when care is taken to use the slightest possible excess of ammonia. This loss Mr. E. SMITH has proposed to avoid by dissolving the sulphate of quinine directly in the phosphoric acid and ignoring the small quantity of sulphuric acid, a plan that has been endorsed from the other side of the Atlantic by Mr. DAVIDSON, with a caution to avoid the use of sugar containing ultramarine in making the syrup.

Opium, by its varying composition, still furnishes problems for solution. M. PETIT has suggested a process for its rapid assay, which consists in extracting with cold water, and adding ammonia and then alcohol to the filtered liquid. The crystalline precipitate contains narcotine (varying in some test experiments from 6 to 9 per cent. of the precipitate), but this, when greater accuracy is required, may be estimated by adding the combining equivalent for pure morphia of sulphuric acid, and then titrating the acid left free in consequence of the inability of narcotine to saturate an acid liquor. Professor FLUCKIGER has described another process requiring more time, which consists in extracting the opium with water during twelve hours, filtering, adding to the filtrate alcohol, ether, and finally ammonia water, and allowing the mixture to stand a day or two. In a process suggested for adoption in the United States Pharmacopœia, Professor PRESCOTT subjects the opium to a preliminary treatment with benzole, then digesting it in nearly boiling water, and adding to the filtered liquor successively benzin, ether and chloride of ammonium. The meconates of morphia have been the subject of some interesting experiments by Mr. DOTT which appear to show that a trimeconate of morphia is not formed, but that a definite dimeconate, crystallizing with five molecules of water, is. An amorphous substance which was probably the monomeconate, proved to be very unstable, decomposing into the dibasic salt and free meconic acid.

Ergot, too, has received some further contributions to its history. The investigation of the circumstances attending a periodical fatality and prevalence of foot rot among sheep near Bristol, led Mr. STODDART to the conclusion that they were due to the growth of an ergot upon the ray grass on which the sheep fed. The development of the fungus on the *Lolium perenne* was carefully observed and the inference drawn from its life-history was that for pharmaceutical purposes the ergot of rye should be gathered in the months of August or September, as the fungus then attains its greatest medicinal activity at the close of the vegetative period. Some doubts having been thrown by Herr BLUMBERG upon the nature of one of the alkaloids of ergot,—ergotinine,—its discoverer sent to this Journal a reclamation describing his method of obtaining it in a crystalline form, accompanied by a specimen. Lastly, a solution for hypodermic injection has been suggested by M. YVON, made by exhausting ergot, previously treated with carbon bisulphide, with water containing a small quantity of tartaric acid. It may be remarked here that a similar preliminary treatment of colchicum seed with petroleum spirit, to remove fatty matter, has been recommended.

The report by Dr. Rutherford on the physiological actions of drugs on the secretion of bile has aroused an interest in a whole group of resinoid substances which have been suggested for experiment as cholagogues,—such as euonymin, iridin, leptandrin and juglandin, and information has been supplied respecting their source and preparation. Euonymin appears to be most in request, and there has been some uncertainty in consequence of different samples varying in colour. This variation has, however, been explained by Mr. J. Moss as principally dependent upon the age of the bark from which it is prepared; that with a green colour being from young bark, and the brown, and less active, from old bark. The colour of podophyllin, and the causes affecting it, have been discussed in a paper by Mr. Lloyd. An examination by Mr. Flowers has demonstrated that the milk-juice from *Lactuca Canadensis* contains several principles identical with those occurring in lactucarium prepared from *L. virosa;* and with respect to this substance Mr. Lemberger suggests the removal of caoutchouc by treatment with petroleum spirit, before using it for pharmaceutical purposes.

Extract of malt is a preparation that has come into considerable demand, and is supplied by numerous competing makers, in forms presenting varying physical aspects. Messrs. Dunstan and Dimmock, therefore, did useful service in throwing some light upon their composition. Considering that probably the value of malt extract depends almost entirely upon the diastase it contains, the authors described a process for its estimation, but it is a significant commentary upon this assumption, that in the advertisement of a well-known preparation, which it is claimed is prepared according to Baron Liebig's own recipe, it is put forward as a merit that the extract is perfectly free from diastase.

It will now be necessary to refer to a number of subjects with more brevity. With respect to coto bark and cotoin, although they appear to be making their way into favour, some confusion exists between them and another similar bark and its products. To dispel this Messrs. Jobst and Hesse have published an elaborate paper, the first portion of an abstract of which appears in the present number of this Journal. Pilocarpine also appears to retain a place, and a great improvement in the process of its preparation, by using ammoniated alcohol, has been described by Mr. Gerrard. Araroba, or Goa powder another substance that has assumed considerable importance during the last few years, has had its botanical origin determined, it being attributed to a leguminous plant which has been named *Andira Araroba.* According to Herr Liebermann, araroba does not contain chrysophanic acid, but a substance which he has named chrysarobin, of which the chrysophanic acid that has been obtained by the treatment of araroba has been an oxidation product. Chaulmoogra oil, another new remedy, has been examined by Mr. Moss, who separated from it a new fat acid, which he has named gynocardic acid, and to this Dymock's colour reaction for chaulmoogra oil appears to be due. No alkaloid, or only very slight traces could be detected. The nature of glycyrrhizin has been the subject of further investigations by two chemists, but unfortunately with discordant results, Mr. Habermann looking upon it as an acid containing nitrogen, and Mr. Sestini as a glucoside free from nitrogen. The composition of the milk of the cow tree has been determined, and the actual existence of the curious fermentative principle which has long been attributed to the juice of the *Carica Papaya* has been proved and its separation reported almost simultaneously by two observers. Cows' milk also has yielded to Mr. Blyth two alkaloidal principles, which have been named galactine and lactochrome. Amongst other new bodies that have been made known during the past year are scillipicrin, scillitoxin and scillin, from the squill; kinoin, a crystalline body, from Malabar kino; spergulin, a fluorescent body, from the seeds of species of *Spergula;* teucrin, an acid substance, from the *Teucrium fruticans;* camellin, a bitter substance, said to resemble digitalin in its reactions, from the seeds of *Camellia japonica;* and berberonic acid, formed by the decomposition of berberine. Berberine and its salts have been the subject of several papers, and this is only indicative of the increased attention which is being directed, especially in the United States, to this alkaloid and the plants containing it.

To the literature of pure pharmacy there have been numerous other contributions. Perhaps one of the most ambitious has been that of Dr. Squibb on Repercolation, a process which, it is to be feared, before it could be carried out with the scientific accuracy shadowed forth in the paper, would require much more uniformity of practice and skill in the operators than at present obtains, in this country, at least. A process of Remaceration has also been described by Mr. Rother, based upon principles followed in many beet-sugar factories. An apparatus for continual dialysis, suited to the preparation of dialysed iron, has been described by M. Lebaigue. Extracts have been the subject of a readable paper by M. Schmitt, triturations of one by M. Wesselhoff, and a simple standard for solutions kept for dispensing purposes has been suggested by Mr. Mushens. With respect to pills a gelatine coating has been recommended by Mr. Dimock, and powdered marsh mallow root has been mentioned as an excipient. Mr. Mead, also, has provided a useful formula for preparing suppositories containing green extracts with a basis of gelatine. Spirit of nitrous ether has again been the subject of several communications, in one of which Mr. Smeeton has advocated a return to the Edinburgh process for its preparation. Methods for its analysis have been described by Dr. Dupré, Dr. Muter, and Mr. Rimmington, that of the last-mentioned differing from the others in the separation of all the constituents and in the decomposition of the potassium nitrite formed in estimating the nitrite of ethyl by means of the zinc copper couple. Mr. Allen, too, has described the process followed by him in the estimation of alcoholic tinctures.

Thymol, by its insolubility, sometimes presents inconveniences to the pharmacist. Dr. Symes has noted the fact that milk is a good solvent of this substance, and that thymol liquefies when triturated with chloral and camphor. Some ambiguity appears to exist in certain quarters respecting the characters of thymol and menthol, and this Mr. Mason endeavoured to clear up in a paper read before the Liverpool Association. A similar confusion as to the botanical source has also been apparent.

A clear mistura guaiaci has been suggested by Mr. B. Squire, made by diluting the tincture with glycerine. Mr. Hornsby has also pointed out that if sufficient liquor potassæ be added to tincture of guaiacum it may be diluted with water without producing more than opalescence. Mr. Collier described to the Conference the use of tincture of quillaia in preparing this and similar mixtures, in the emulsification of oils and in the extinguishment of mercury; he also contributed a paper on the chemical history of saponin from soap bark, in which it appears to exist as a lime compound. Tincture of kino has evoked an amount of discussion disproportionate to the frequency with which it is used, and for the avoidance of the gelatinization that occasionally takes place in it,—probably dependent upon the variety of kino used in its preparation,—the addition of glycerine has been suggested, as also have been occasional agitation and exposure to light. The use of a tincture of marsh rosemary root (*Statice Caroliniana*) has been recommended as a substitute for both tincture of kino and tincture of catechu.

The hygroscopic nature of plasma has been the subject of observation by Mr. Willmott. He finds it to be due to the glycerine, which has the property of absorbing moisture from the atmosphere until a certain proportion is reached, and he proposes to substitute a similar quantity of water for some of the glycerine ordered to be used in making the glycerine of starch. Complaints as to difficulty sometimes experienced in preparing a miscible Gregory's powder induced Mr. Gilmour to make some experiments, which appear to indicate that this nonmiscibility is due to the magnesia or other powders being in too dry a condition, and that this objectionable dryness may be produced by the apparatus used in the mixing. Among other communications that have been published may be mentioned formulæ for pharmaceutical preparations of coca and of drosera as well as some medicated solutions of alumina. Recipes for the preparation of some drugs for smoking have also appeared. Taraxacum, in respect to the best time for its collection, has also been the subject of a paper by Dr. Symes, who favours November or December if frost has not occurred.

The formation of nitrites and nitrates under different circumstances has been the subject of considerable attention. Mr. Waring, continuing his researches, has reported that exposure to light prevents nitrification, that presence of carbonate of calcium appears to be indispensable to the growth of the ferment, and that nitrification takes place more rapidly in proportion as the temperature is increased from 50° to 86° F., but that 104° F. is fatal to the ferment. Dr. Davy, following in the same direction, has made some experiments which appear to show that nitrification is not affected by light, but that it requires a supply of air or free oxygen, and that it goes on most rapidly at a temperature of from 70° to 80° F. It was also noticed that in a liquid containing much animal matter the process is stopped or goes on very slowly, or the nitrites and nitrates may be decomposed and disappear after being formed. Sometimes in water containing sewage impurities there is a very rapid formation of nitrites at the expense of the free ammonia. Recently Messrs. Schloesing and Muntz have announced the isolation of the "ferment." The important bearing that some of these observations have upon the analysis of water must be obvious, and may help to explain the inconclusive results of the discussion upon an exhaustive paper read by Dr. Tidy before the Chemical Society, when the one thing most manifest was the uncertainty attending all the present methods of water analysis in the absence of any knowledge of the history of a water.

An examination, by Dr. Tilden, of a specimen of essential oil of lemon obtained by distillation, which confirmed the presence in it of a terpene agreeing with the terebenthene of French oil of turpentine, and of a peculiar terpene, named citrene, further led to the unexpected observation that it was superior in odour to the foreign essence, and, in consequence of the interest excited, the method of its preparation was subsequently described by Mr. Moss. Chamomile oil has been the subject of a series of investigations, from which it appears that it contains isobutyric and angelic acids in combination with isobutyl, and angelic and tiglic acids in combination with amyl and other bodies. Tiglic acid has also been found to be the volatile acid of croton oil and identical with methylcrotonic acid; it has also been proved to be produced from angelic acid by the action of heat. Further, the specific gravity and rotatory power of a large number of essential oils have been determined by Dr. Symes.

A modification of Dr. De Vrij's process of preparing bromide of ethyl has been proposed, consisting principally in the use of a dilute sulphuric acid in the preparation of the sulphethylic acid. Hydrobromic acid has been prepared by the action of bromine upon oil of copaiba, and its composition as obtained by the ordinary methods of preparation, known as Fothergill's or Wade's, has been discussed by Mr. Palmer. A useful modification of the usual process for preparing solution of perchloride of iron, by adding the iron solution to the acid, instead of the reverse, has been suggested by Mr. Shuttleworth, and it has been suggested to extend the change to the solution of persulphate. The influence of sugar on the formation of gallate and tannate of iron has been studied by Dr. W. I. Clark, who has found that its presence up to a certain point (3·2 per cent.) favours the formation of a precipitate when a solution of tannin is mixed with one of ferrous sulphate, but if in greater proportion an increasing retardation takes place. It is curious that the percentage of iron is smaller in proportion as the quantity of precipitate is greater.

Numerous other papers having special chemical interest have been published, but it will be impossible to do more than mention a few of them. Messrs. Dupré and Hake have described two new methods for the estimation of minute quantities of carbon. Mr. Naylor has given a method for the volumetric estimation of arsenic acid, based upon the reaction which takes place between arseniate of soda and iodine. Mr. Allen has suggested the action of nitric acid as a means of detecting an admixture of petroleum spirit with benzol. Mr. Siebold utilizes the colour reaction of iodine to detect the presence of alcohol in chloroform. Dr. Senier has corrected a text-book error as to the saligenin test for salicin. Professor Leeds has published an elaborate investigation as to the influence of light upon iodides. Dr. De Witt has described a new series of colouring matters derived from diazo compounds. Further, the synthesis of several compounds has been reported, such as that of atropine from tropic acid and tropin, of milk sugar, cane sugar, helicin, and possibly salicin. In the application of practical chemistry to manufactures the two most important developments have been Holloway's process of roasting pyrites, a modification of the Bessemer steel process, and Vincent's utilization of beet residues in the preparation of trimethylamine, methyl chloride and other compounds.

Whatever may be the case in other fields, the past year promises to be a memorable one in the history of the so-called elements, whether in respect to the number of substances that have been added to the list, or the increase in the probability that at least some at present included in it will have to give up their claim to the title. The inferences drawn from the spectrum researches of Mr. Lockyer have received some countenance from the experiments of Professor Meyer on chlorine, aided by his improved method of taking vapour densities, and the conclusion of this investigator's research will be awaited with considerable curiosity. Just at the close of the year, too, it is alleged that Mr. Edison has solved the great problem of rendering the electric light available for ordinary lighting purposes.

The annual meetings of societies in which British pharmacists take special interest have been those of the Chemists and Druggists' Trade Association, held in London in May, the British Medical Association, held in Cork in August, and the British Pharmaceutical Conference and the British Association, held in Sheffield, also in August. The American Pharmaceutical Association met in Indianapolis and the German Apothecaries' Association in Hanover, both in September.

Some very interesting lectures have been reported in this Journal during the past twelve months. Besides those of Professor Redwood on "Electricity as a Source of Light" and Professor Bentley on "The Life of a Plant," may be mentioned those of Mr. Perkin on "Alizarin," of Professor Abel on "Detonating Agents," and Mr. Crookes on "Radiant Matter." To these may be added the paper of Professor Claypole on the "Migration of Plants from Europe to America;" one by M. Herlandt on the "Relations existing between the Active Principles of Plants and their Botanical Characters," which we hope to supplement shortly by one on the same subject written by Professor Dragendorff; a continuation by Mr. H. B. Baildon of his "Thoughts on Botany;" and Professor Allman's Presidential Address to the British Association. Nor must we forget to mention the continuation of Dr. Dymock's valuable Notes on Indian Drugs.

During the year some valuable works on pharmacy and the sciences allied to it have been published. Some of these are new, such as Stille and Maisch's 'Dispensatory,' Roscoe and Schorlemmer's 'Inorganic Chemistry,' Blyth's 'Manual of Practical Chemistry,' Allen's 'Commercial Organic Analysis,' as well as the Year-Book of the British Conference, the Report on Pharmacy of the American Association, and the admirable 'Jahresbericht' of Dr. Dragendorff. There have also appeared new editions of 'Pharmacographia,' Wurtz's 'Chemistry,' Cooley's 'Cyclopædia,' and Piesse's 'Perfumery.'

The year has not passed away without death robbing chemistry and pharmacy of many of their votaries, but the most prominent of these have been natives of other countries. Thus Germany has lost Mohr, Sonnenschein and Giessler, France has lost Poggiale, Chevalier and Boutron, and the United States has lost in Dr. Wood one of the authors of the celebrated Dispensatory. Messrs. Mohr and Wood were Honorary Members of the Pharmaceutical Society of Great Britain. In this country we have also had to record the death of Mr. Bartlett, formerly a Member of the Council, and Messrs. Walker, Robinson and Thompson, who have served the Society in the capacity of Local Secretaries.

We have now come to an end of our task. Enough has been said to show that the year 1879, if not crowded with striking events, was not without a useful history. Our last words shall be a hearty wish for the prosperity of pharmacy and pharmacists in the year that is now opening.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The sixth general meeting of the thirty-first session was held at the Royal Institution on Thursday evening, December 18, the President, Dr. Charles Symes in the chair.

The minutes of the previous meeting were read and confirmed.

The President, in calling attention to the new Weights and Measures Act, said: "Those present who were engaged in pharmacy will be aware that recently a sensation has been got up on the question of apothecaries' weights and measures, and that those who appear to be the best informed also appear to be very imperfectly informed as to the actual working requirements of the Act, which, by the way, are of vastly more importance to us than the shapes of the standards. What I wish particularly now to say, however, is that I believe the specially legalizing of these weights and measures is a retrogade step, and one which we shall all sooner or later regret. Now, when we are looking forward to the universal adoption of the metric system, any attempt to prop up one which is rapidly falling into decay, and had already received its death-blow in its expulsion from the last Pharmacopœia, cannot but prove prejudicial."

The President then exhibited a new kind of spirit lamp, which burns by means of a glass wool wick. He said that in Germany a new kerosene lamp has been introduced which burns on this principle, and that a similar wick has been suggested as suitable for spirit lamps. Greater heat is said to be obtained with little or no consumption of wick, and as the flame keeps more closely to the wick the lamp could be moved about quickly without danger of it going out.

Mr. Alex. Watt, F.C.S., F.I.C., exhibited Scheibler's thermo-regulator, and gave a very interesting description of its working, which he practically illustrated.

The paper for the evening was then read, on—

The Chemistry of Tanning.

BY EDWARD DAVIES, F.C.S., F.I.C.

The skins of beasts being the first recorded material used for clothing, the best method of preparing them for use was necessarily one of the first questions presented for solution to the mind of man. Simple cleansing from blood and fat, and drying in the air was doubtless all that was done for long periods of time; but more elaborate methods were gradually practised, with the view of making the skins more supple and of preserving them from the action of the weather, until at last the art of tanning became a recognized occupation among men.

It is not known when the use of oak bark or other substances containing the little understood class of astringent bodies called tannins was found out. The whole history of the art in ancient times is almost a blank, the methods used being no doubt kept secret among the craft and handed on from father to son, unwritten and carefully kept from the world at large.

The chemistry of tanning involves a knowledge of the materials employed, firstly, of the skin, and secondly, of the substances used to change the skin from a body drying into a translucent, horny, hard hide, into fibrous, opaque, flexible leather.

The skin of animals consists, first, on the outside, of a thin cellular layer called the epidermis, horny and dead on the outside and constantly replaced from within; then the *rete mucosum*, in which the colouring matter exists which gives the colour to the skin of man; then the corium, or true skin, a layer varying in thickness in various animals and in different parts of the same animal; this is the layer from which leather is made, and consists of fibres intersecting each other in every direction, connected by a cellular structure which binds them together. On the inner side the skin is lined with a fat-bearing tissue, which separates it from the muscles or flesh. In tanning leather this and the outer layers are separated from the corium by preliminary operations.

The various mechanical portions of the process of tanning will be omitted except when they are connected with chemical action. One of these is the removal of hair, for which the most diverse processes have been used.

1. *Sweating.*—In this method under the influence of moisture, a semi-putrefaction takes place in the epidermis, which becomes disintegrated and loosens the hair.

2. *Liming.*—In this milk of lime is used. The cellular tissues are destroyed, whilst the fibres remain uninjured. It is important not to carry this action too far, or the cellular connecting tissue of the corium will be injured, and the leather irreparably damaged. Lime soaps are also formed with the fatty matters.

3. *The Use of Sulphides.*—Alkaline sulphides and the sulphides of calcium and barium have long been used as depilatories. Rusma, a mixture of 1 part orpiment and 2 or 3 parts slaked lime, is practically used, and this is a good example of an empirical process from which chemical knowledge enables us to deduce a scientific one. A decomposition takes place between the two bodies, by which calcium sulphide is formed, and this substance might just as well be used direct, and the dangerous arsenic avoided. Mr. Warington proposed 3 parts polysulphide of sodium, 10 of slaked lime and 10 of starch. M. Matern, of Antwerp, in 1872, exhibited at Vienna a new depilatory liquid, consisting of slaked lime, soda and sulphur, some sulphide of sodium being formed. In 1873, M. Eitner used this mixture successfully, and then got pure sulphide of sodium, by which bullocks' hides were depilated in fifteen hours. Crystallized sulphide of sodium is used; 1 kilogram is dissolved in 2 litres of water and thickened with 3 kilograms of slaked lime. This is painted on the hair side, working it well in, the hides folded together, put into a warm room about 19° C., covered with a wet rug and left fifteen hours. The hides must be well washed before scraping off the hair, or the hands of the workmen will suffer. Further details will be found in a valuable paper in the *Journal of the Chemical Society*, 1876, p. 982. Sodium sulphide can be easily made at a low price, if a demand should arise, by the reduction of the sulphate.

4. *By the Use of Acid Liquor.*—This is produced by the fermentation of barley meal, giving rise to lactic and acetic acids. This is not available for heavy hides as it swells them too much.

The next operation is the swelling or raising of the hides. When lime has been used to remove the hair it is necessary to remove this from the interior of the hide as it would injure the leather. The hides are put into spent or red tan liquors, which contain gallic and lactic acids. These not only remove the lime, but as the lime has become carbonated the evolution of carbonic acid gas tends to swell the hides and enable the tannin more readily to enter the fibres. Lime is also sometimes removed by the use of the excrements of pigeons, fowls and dogs. The action of this disgusting mixture has been ascribed to uric acid, but it is more probable that ammonium chloride is formed, which is decomposed by the lime, calcium chloride being formed.

All these operations have as their object the preparation of the hides for the true tanning operation, which consists in immersing the hides in a solution containing tannin. This combines with the organic matter of which the fibres of the corium are composed, and forms an imputrescible compound which is leather. Two theories have been propounded to explain this. The first is, that the tannin unites with the fibres in their unchanged state, and the action goes slowly on until the fibres are acted on through their entire thickness, and that the length of time necessary to thoroughly permeate the skin, and the fibres throughout, is the reason why one or even two years have been taken for very thick hides.

The other, advocated by Dr. F. Crace Calvert in the Cantor lectures for 1864, is that the hides are composed of a substance analogous to the organic matter of bones, or osseine, which does not unite with tannin, and that there is a slow transformation of this into the isomeric body gelatine, which, as it is formed, unites with the tannin. The slowness with which thick hides are tanned would be explained by the long time required to bring about this transformation. Although this view has the sanction of such an eminent name, my own opinion is that the first is the correct one, as a simple experiment will show. Hide dried and rasped is shaken up with a dilute solution of oak-bark, from which in a minute or two it will so thoroughly remove the tannin that iron salts will give no reaction. This shows that tannin can unite with unaltered hide.

The chemistry of the tannins is not at all clearly worked out. They are obtained with difficulty in a pure state without decomposition, as they appear to be unstable complex bodies. There are certainly several kinds, differing greatly in composition although possessing certain properties in common. The tannin best known in the separate state is that obtained from nut-galls. Until recently this, when obtained by ether, was supposed to be a pure glucoside of gallic acid; that is, that it was a compound containing the elements of glucose and of gallic acid, less the elements of water.

$$C_{27}H_{22}O_{17}+4H_2O=C_6H_{12}O_6+3C_7H_6O_5.$$

Later investigations have show that it contains varying qualities of digallic acid together with tannin and that pure tannin is almost unattainable. Messrs. Paul and Kingzett (*Journal of the Chemical Society*, 1878, p. 217) state that commercial tannin examined by them in no case contained any glucose and was merely digallic acid, $C_{14}H_{10}O_9$, which with H_2O gives—

$$C_{14}H_{10}O_9+H_2O=2C_7H_6O_5.$$

M. Schiff holds the same view. Schlorlemmer, in 'Chemistry of the Carbon Compounds' says, "there cannot be any doubt that tannin contains a glucoside of gallic or digallic acid. Possibly the tannin as it exists in the nut-galls is a glucoside of digallic acid, and is decomposed by the process of extraction, although this is remarkable, as nothing but ether is used.

The tannin of oak-bark, or quercitannic acid, according to Stenhouse does not give gallic acid when boiled with dilute acids, but a reddish-brown substance. Tannins have been divided into pathological and physiological tannins. The former including the galls due to the injuries produced by insects, the latter are the tannins forming natural constituents of plants.

They may also be roughly divided into two classes, according to the colour which they give with Fe_2Cl_6, some giving a blue-black and others a green. The first comprises the tannins contained in nut-galls, oak-bark, myrobalans, sumach, valonia and divi-divi. The second includes catechu, kino, mimosa bark, larch and birch bark. That this indicates a real difference in chemical composition is shown by their behaviour with tartar emetic in presence of ammonium chloride. The first class give a dense precipitate; the second are only partially precipitated. The tannins from various sources agree in precipitating gelatine, especially in presence of alum or salt, and in precipitating the alkaloids. Tannin decolorizes a solution of iodine in iodide of potassium to a very large extent, forming hydriodic acid and ellagic acid. I have tried to find a quantitative process for estimating tannin upon this reaction, but without success.

The various processes which have been proposed for testing the amount of tannin in various materials present a disheartening prospect to the student. In our ignorance as to the true chemical nature of the tannins all the processes are of the most empirical character, and in the absence of a pure standard tannin to work upon tho results obtained are only relatively true. Two samples of the same material may be compared, but when two different materials are taken their relation to one another cannot be certainly stated. The principal processes are:—

1. The gelatine process. With this I cannot get a distinct end reaction. The solution of gelatine is necessarily so dilute that to produce a distinct precipitate in the filtered liquor a considerable quantity of ether, tannin or gelatine, as the case may be, must be added. Spotting the solution on a mirror, very valuable in many cases, does not succeed any better. In works a gravimetric application of this process is a good deal used. A solution of the tanning material having been made, a known quantity is precipitated with gelatine in a dilute solution, boiled, and the precipitate washed on a weighed filter, dried and weighed; two-fifths of the precipitate is assumed to be tannin. Now the combination of tannin with gelatine has long been known to be of variable composition, according to the circumstances under which it was made, and I have made experiments which show that if to a known weight of gelatine a small excess of tannin from various materials has been added, the precipitate washed and weighed, the results were so astounding in their variation that I hesitate to publish them without repetition.

2. Gerland's tartar emetic process. This process, published in the *Chemical News*, August 1, 1863, is in my opinion the best for those tannins to which it is applicable. It will only do for the iron-bluing tannins. I refer for details to the original paper, noticing a very curious point. Using the author's proportions of 2·611 grams tartar emetic per litre I invariably find any sample of so-called pure tannin which I can get tests about 75 per cent. The author says that he got one which tested 97 per cent. I was therefore glad to read in the paper by Messrs. Paul and Kingzett that they had got 76 per cent. from commercial tannin. Assuming that commercial *pure* tannin is, if not pure, at all events the only attainable standard, Gerland's standard solution should be reduced in strength by one-fourth, and I then find that the results agree in several cases with Neubauer's.

3. Neubauer's process. This consists in using permanganate of potassium in a dilute solution of tannin containing sulphate of indigo. The results are constant for the same sample, but seem to be uniformly too high. The great fault of the process is the necessity for removing gallic acid if present. It must almost necessarily give too high results when we remember that there is a variety of organic matter present besides tannin and gallic acid, and that it is assumed that these exert no reducing action until the whole of the tannin, gallic acid and indigo are oxidized. When the gallic acid is removed by gelatine another organic body is introduced, though it is said to have little or no action. Nevertheless, for substances of the iron-greening class it appears to be almost the only process which we have.

4. Hanmer's method with rasped hide added to a tanning solution, and taking the sp. gr. before and after the removal of the tannin. This is too delicate for practical use, the differences being very small. It is also assumed that nothing dissolves out of the hide in cold water. It is also stated that gallic and other organic acids are absorbed, and I have noticed that the colouring matter of the solution is almost entirely removed. The difficulty of rasping the hide, of which a large quantity is required, is also very great.

5. Wagner's cinchonine process with magenta for indicator. This has failed so completely in my hands that I should feel obliged if anyone would inform me where full details of the process are to be had. Using the proportions given I find that the supernatant liquid is coloured long before all the tannin is precipitated.

Time will not allow of an account of other processes for preparing leather. Any substance which will form an insoluble non-putrescible compound with the fibres of the skin may be considered as a tanning agent. Alum is used in the "Tawing" process, and salts of iron were proposed so far back as 1842, by M. Bordier. He oxidized ferrous sulphate with nitric acid to produce a basic ferric sulphate, in a solution of which the hides are then to be steeped. In 1855 a patent was taken out in England for a similar process. It seems to have fallen into disuse until very recently, when Professor Knapp took out a patent which very closely resembles Bordier's. In the *Chemical News*, January 17, 1879, is a paragraph from a foreign journal entitled "Revolution in Tanning." "Professor Knapp proposes the use of a basic ferric sulphate instead of oak-bark or other tanniferous material. He adds to a boiling solution of copperas the quantity of nitric acid requisite for the peroxidation of the iron and after the reaction is over adds more copperas. The hides are suspended in the cold solution at a suitable degree of concentration, and are ready in from two to four days." To complete the proof of the chaotic state of the chemistry of tanning and of the contradictory statements about it, in the *Journal of the Chemical Society*, January 1, 1879, there is an abstract of a paper by Gottfriedsen, in which he states that an examination of iron-tanned leather had been made by Muntz, who considers that it is not leather at all, and that no combination of oxide of iron with the fibres of the hide is formed. He, on the other hand, affirms that leather so made is more lasting than bark-tanned leather. This review of the state of our knowledge of the chemistry of one of the oldest and most important manufactures, shows how much remains to be done before a perfect explanation of the chemical reactions can be arrived at. As in many other cases practice has got before theory, but a perfect theory must be found before practice can be also perfect, and then, no doubt, time and material will be saved, and still further improvements made in leather.

The paper, which was illustrated with a very fine collection of the various products used in the art of tanning, was much appreciated by those present, and gave rise to a short discussion, in which the President, Messrs. Conroy, Haddock and Watt took part.

On the motion of Mr. Watt, seconded by Mr. Woodcock, a unanimous vote of thanks was passsed to Mr. Davies.

Mr. Davies replied at some length to the points raised in the discussion, and the meeting closed.

ROCHDALE CHEMISTS' ASSOCIATION.

The annual meeting of the Rochdale Chemists' Association was held on Tuesday evening, December 9, in the Town Hall (by the kind permission of the mayor). An excellent repast was provided in the refreshment room, partaken of by over forty persons, comprising members of the Association, their wives and daughters and a few invited guests. Afterwards, the company adjourned to one of the lower rooms.

A report of the work of the Association during the year was read by the Secretary, Mr. J. W. Bamford, which showed that the society had not been inactive, efforts having been made to give the Association a wider constituency; these efforts had, however, not proved very successful. The present number of its members is sixteen, one having died during the year.

The Association not having realized what was desired,—the co-operation of the neighbouring towns of Bury and Heywood,—maintains a very friendly relation with the Association of Manchester, although that relation is not strictly of an official character.

The subject of dispensing the prescriptions of medical men has engrossed a large portion of the energies of the Association. The readers of the *Pharmaceutical Journal* will not be entirely ignorant of those efforts.

A class for the study of chemistry has been commenced, for the exclusive benefit of the apprentices and assistants. This class, although meeting separately, is in connection with the Government science classes of the town.

The President, Mr. R. Robinson, delivered an address, of which the following is a brief abstract:—

The President said that although the Association had not been successful in its efforts to get the medical men to give up dispensing, yet the exchange of ideas and opinions between the two bodies had had the good effect of promoting a more friendly feeling between them, and he thought other associations would do well to take up the question and ever keep it well to the front. It was pleasing to find so many of the young men, the future chemists, ready and willing to take a practical part in their meetings. By a few pleasing experiments some of them would demonstrate that fire, air, earth and water were not the simple bodies they were thought to be, in times not so very remote. As the students progressed in their studies they would find chemistry the most fascinating of all sciences. It enabled us to some extent to look into Nature's laboratory and see and comprehend a few of the wonderful changes continually going on. Reference was made to a few of the products of the combustion of coal, and that probably it only required an extension of knowledge to convert the almost valueless charcoal into the priceless and sparkling diamond. We might ridicule the idea of the alchemist of old attempting to convert the baser metals into gold, but might it not some day be found that gold is a compound of elements which have been chemicaly combined in Nature's crucible? The discoverer of aniline dyes did not convert coals into diamonds, but into something quite as good; he delighted millions by his discovery, gave employment to thousands in making and using his dyes, and last, but not least, realized a handsome fortune. And so it might be with our students: they might not be able to make gold, produce a diamond, or discover a new dye, but they might by research find something quite as profitable to themselves, and perhaps more useful to their fellows, and if they did none of these things they would still have their reward if they diligently sought for the hidden treasures of nature and science.

Mr. W. A. Scott moved the adoption of the report, and referring to the address of the President said that the diamond was first supposed to be of vegetable origin by Sir Isaac Newton, a supposition which was afterwards verified by Cavendish or Priestley, who succeeded in burning it.

Mr. Ellis Lord seconded the motion, observing that the question of the indiscriminate sale of poisons was one to which the Pharmaceutical Society should give its attention.

Mr. Wilkinson, of Cheetham Hill, Manchester, thought the poison question was a very difficult one, and one that might lead to serious injury to the interests of chemists themselves if an attempt was made to put a stop to the evil that had been referred to.

Mr. Hermann Woolley expressed his cordial thanks for being invited to the meeting, and congratulated the Association on its vigorous and healthy tone. Referring to the Association at Manchester, which he and Mr. Wilkinson represented, he said it was a mutual advantage that the union should be intimate. Referring to the subject of patent medicines, he thought the time was coming when the trade in these articles would pass into other hands and the chemist would be left to the prosecution of the duties of his calling pure and simple.

In the course of the evening, Mr. Harold Woolley exhibited a number of Geissler's tubes, and a small model of a magneto-electric engine, working a small pump, which contributed to the entertainment of the meeting.

Mr. Alderman Taylor proposed a vote of thanks to the gentlemen from Manchester, who had favoured the meeting by their presence, and especially to Mr. Woolley for his beautiful experiments. This was seconded by Mr. W. A. Scott, and supported by Mr. Hadfield, and carried by acclamation.

The remainder of the evening was spent in the performance of a variety of experiments by the students of the Association, Mr. Lees producing aniline and Turkey red dye by appropriate reagents.

Mr. Renshaw gave a series of illustrations of the *modus operandi* of chemical analysis, showing variously coloured precipitates from the mixture of colourless solutions.

Mr. W. Bamford performed a number of experiments in frictional electricity.

Messrs. Robinson and Handley concluded the series by a variety of experiments with gases.

A very hearty vote of thanks to the President for his genial conduct in the chair, moved by Mr. Alderman Taylor, and carried with acclamation, brought the proceedings to a termination shortly after eleven o'clock.

HULL CHEMISTS' ASSOCIATION.

The annual supper in connection with this Association was held on Thursday, December 18, at the Cross Keys Hotel, Market Place. The Mayor (Alderman King, M.D.) presided, and amongst those present were the Rev. J. McCormick the Rev. J. Branston, Councillors Field, Thompson, Smith, Myers, Wallis, and Fryer, Dr. Holden (Medical Officer of Health), Mr. O'Donoghue (Clerk of the School Board), Mr. Niven, etc.

The loyal and patriotic toasts having been duly honoured, the Mayor gave "The Archbishop and Clergy of all Denominations." The Rev. J. McCormick and the Rev. J. Branston responded.

Mr. J. Oldham proposed "The Mayor and Corporation," and the toast was acknowledged by the Mayor, who next gave the toast of the evening, "Success to the Chemists' Association. Mr. G. Myers (President) responded.

Mr. Allison proposed "The Town and Trade of Hull." Mr. T. J. Smith responded.

Several other toasts were given, including "The Medical Profession," "The Visitors," "The Lecturer," and "The Officers," "The Pharmaceutical Society," and the "Trade Defence Association," a very pleasant evening being spent.

Parliamentary and Law Proceedings.

Cream of Tartar Prosecution.

At the Fareham Petty Sessions, held on Tuesday, December 23, before F. Bradshaw, W. H. Deane, and F. Bretherton, Esqrs., and Captain Turner, Mr. William Octavius Smith, chemist and druggist, of Titchfield, was summoned upon the information of police-sergeant James Duke, of the Hants Constabulary—local inspector under the Sale of Food and Drugs Act—for that he did sell to James Duke, the purchaser, and to his prejudice, a certain drug, to wit, cream of tartar, which was not of the nature, substance and quality demanded by the said James Duke.

Police-sergeant Duke deposed that on November 14, he in company with another constable went to Titchfield, and at the defendant's shop purchased a quarter of a pound of cream of tartar, and then told the defendant that it was for the purpose of having it analysed. It was divided into three portions, each of which was sealed. One portion was given to the defendant, another retained by him, and the third was forwarded to Mr. Arthur Angell, the public analyst for the county, in order that he might make an analysis of it. This he did and reported that the sample contained the following percentages of foreign ingredients, viz., tartrate of lime, 9·26, and sulphate of barium, 0·29. He also reported that these substances were insoluble, and were not injurious to health.

Mr. Granger, barrister-at-law, said: He appeared for the defendant, who was charged under the Food and Drugs Act with selling, to the purchaser's prejudice, a certain drug, to wit, cream of tartar. He should show that Mr. Smith, who succeeded to the business of Mr. Chitty, got all his drugs from one of the first wholesale houses in London, viz., Messrs. Barron, Squire and Co. His predecessor, Mr. Chitty, had been in the habit of dealing with the firm, and Mr. Smith knowing it to be a first-rate house continued the custom. He should prove, by calling witnesses, that cream of tartar was made from the juice of the grape, and that it was brought over to this country in the form of crystals which only required to be ground to be ready for use. Nothing whatever was done to it except this, and he should prove that the presence of tartrate of lime in it was a necessity which could not be avoided. If it were to be said that unless there was no tartrate of lime in cream of tartar it must not be sold, then that would mean putting a stop to the sale altogether. This tartrate of lime came from the earth, and the analyst himself had told them that it was not injurious to health. He should also call before them Dr. Paul, editor of the *Pharmaceutical Journal*, who would tell them that this cream of tartar came up to the standard of the British Pharmacopœia, which was the recognized standard for all drugs. He had analysed a sample sent him by Mr. Smith, and the result differed slightly from that obtained by the public analyst, but this Dr. Paul would probably be able to explain. He (Mr. Granger) could say with confidence that it was not an offence within the "Food and Drugs Act." It was not a mixture injurious to health, and therefore did not come within the first section, but it came distinctly within the fourth sub-section of the sixth section. The sixth section was to the effect that "no person shall sell to the prejudice of the purchaser, any article, food, or drug not of the nature, substance or quality demanded by such purchaser;" and the fourth sub-section was to the effect that it should not be deemed an offence "where the food or drug is unavoidably mixed with some extraneous matter in the process of preparation." The tartrate of lime was something which was unavoidably mixed with the cream of tartar in the process of preparation. He failed to see how the sub-section could be got over, when he showed them that the cream of tartar in question was the best article of the kind that could be purchased, and he had no doubt the magistrates would consider it their duty to dismiss the summons.

William Octavius Smith, the defendant, was then sworn, and the following evidence was taken. Witness said he was a registered chemist and had succeeded this year to the business of a chemist and druggist at Titchfield, for some time carried on by Mr. Chitty. He found that Mr. Chitty was in the habit of getting his drugs from the wholesale house of Barron, Squire and Co., and knowing that firm by name as one of the first houses in the trade he continued to get all his drugs from it. He produced an invoice from Messrs. Barron, Squire and Co. of a parcel of drugs, including some cream of tartar. This cream of tartar was passed into stock in the condition in which it was received, and he had sold it with the greatest confidence. He had sent the sealed sample given him by the police-sergeant to Dr. Paul for the purpose of having it analysed.

Dr. Benjamin Horatio Paul was then sworn. He said he was a consulting and analytical chemist, and editor of the *Pharmaceutical Journal*, and had had much experience in these matters. He received from the defendant a sample of cream of tartar, sealed with the seal of the Hants Constabulary, on November 15. He analysed it and found that it contained 6·95 per cent of dry tartrate of lime and 0·3 per cent. of sulphate of barium. The remainder consisted of bitartrate of potash. In reply to a question as to how cream of tartar is made, he said it was altogether manufactured abroad in the wine-growing districts, and was made by boiling the argols, deposited in the process of fermentation, in water for the purpose of separating what was insoluble. The crystals thus obtained were then sent over to this country, and only require to be crushed to be ready for use. He did not agree with the public analyst in saying that the ingredients, besides the bitartrate of potash, were insoluble. The sulphate of barium was insoluble, but beyond that the whole was perfectly soluble. He thought perhaps the nature of the soil had something to do with the quantity of these ingredients occurring in the cream of tartar, but the way in which wine was made had probably more. He had never met with a sample without tartrate of lime. A certain portion was an inevitable necessity, as it was impossible to avoid a portion of it becoming mixed with the tartrate of potash. Some of the argols contained as much as from 30 to 50 per cent. of tartrate of lime. The percentage in cream of tartar varied from 1 to 10 or 12 per cent., generally it was about 6 or 7 per cent. In his opinion that sold by defendant was a very good commercial sample. He explained the difference in his analysis and that made by the public analyst, by supposing it to be due to the circumstance that the latter had returned the amount of tartrate of lime as containing water, whereas he had returned it as perfectly dry. The sulphate of barium was not injurious; it was absolutely insoluble.

Mr. Inspector Littlefield: If I go to a chemist's shop and ask for a sample of cream of tartar, should I expect to get such as has been analysed?—Yes, you would get something very like it.

Captain Turner: Does cream of tartar depreciate through being kept in stock, or being opened?—No, not at all.

Can you account for the presence of the sulphate of barium?—I cannot; but the quantity is almost infinitesimal.

Is it possible to extract the lime?—Yes, with considerable difficulty, but not without largely enhancing the price of the article. I do not think if it was extracted that would make any material alteration in its merits.

Is this sulphate of barium found in all samples?—No, not always.

Mr. Frederick Barron, of the firm of Barron, Squire and Co., was then sworn. He stated that he had supplied the shop, now occupied by Mr. Smith, for about sixteen years, but he had a gentlemen behind him whom he had supplied for forty years. The cream of tartar which he sent to Mr. Smith was of the first commercial quality. It was the highest priced article of its kind in the market. The crystals were purchased from the brokers who sold for the manufacturers, and nothing whatever was done to them beyond crushing them.

At this stage Mr. Bradshaw interposed and said the magistrates were all agreed to dismiss the case.

Mr. Granger therefore made an application for costs He said it was surely never the intention of the Act that respectable tradesmen should be brought up in the way the defendant had been. It was a very serious matter, for upon the quality of a chemist's drugs his success and reputation depended. He thought it a case where the magistrates might exercise their right to dismiss it with costs.

Mr. William Flux, of the firm of Flux, Slade and Co., solicitors, who watched the case on behalf of the Pharmaceutical Society of Great Britain, asked to be allowed to say a few words on the question of costs. There had been several cases similar to the present, each in its turn dismissed, and he was anxious that the Society should be able to say that a case had been dismissed with costs. It might be deemed expedient that representations should be made to a central authority with a view to the prevention of similar attacks on the qualities of drugs sold by chemists. The character of a chemist's drugs should be as far above suspicion and as carefully guarded as the personal reputation of anyone should be, and when the qualities of articles sold by a chemist were called in question, he must remain exposed to the suspicions of friends and neighbours, or call upon such gentlemen as were present to attend at great inconvenience and expense to properly support him before the magistrates. As he (Mr. Flux) read the statute, the costs, if awarded to the defendant, would not have to be borne by the policeman who had acted in regard to the purchase, but would fall upon the county, and the dismissal with costs was especially desirable.

The magistrates consulted and said that upon principle they would allow costs, but that some limit should be put to them and they therefore fixed the amount at three guineas.

Excise Prosecution at Aberdare.

At Aberdare Police Court, on Tuesday December 23, (before the stipendiary, Mr. J. Bishop), Daniel Tudor Williams, carrying on business in Gadlys Road, was summoned for selling a bottle of whisky, he not holding a licence entitling him to do so. Mr. W. H. Priest, supervisor of the Methyr district, appeared on behalf of the Excise authorities in support of the summons, and Mr. Kenshole (Messrs. Linton and Kenshole) appeared for the defendant.

John Davies stated that on November 14 he went to the defendant's shop in Gadlys Road, Aberdare, for some salts and a bottle of whisky, which was supplied to him by Mrs. Williams. Defendant's wife at first showed some little hesitation in serving him with the whisky, and said they were out of it, but eventually, however, she let him have the bottle produced, and charged 2*s.* 4*d.* for it.

Thomas Nash Williams, manager of the New Inn public-house, High Street, said that he walked up to the Gadlys Road, with the last witness, who was his son-in-law. He asked him to go into defendant's shop for the bottle of whisky, and saw Davies go into the shop and come out again with it. This was all the evidence in support of the summons.

For the defence defendant's servant, Maria Floud, was called, who stated that she was washing out the shop at the time John Davies came in asked for some salts. When he asked for a bottle of whisky Mrs. Williams replied that she did not keep spirits, and Davies left without it. Ann Griffiths, who was in a room adjoining defendant's shop, also spoke to not hearing Davies ask for the bottle of whisky.

The Stipendiary remarked to defendant's solicitor that it was no use to call such witnesses, because if they did not hear the whisky asked for and sold it appeared that there were others who did.

For the defence it was alleged that the witnesses brought forward were as equally worthy of credence as were those for the prosecution.

The Stipendiary considered the case proved, and fined the defendant £12 10*s.*, one-fourth of the full penalty of £50.

Mr. Priest pointed out that by one section of the Act of Parliament, a person who had held a licence and had been convicted of selling spirits was not again allowed to hold such a licence. The fine was paid. It may be explained that the defendant formerly held a licence, which he did not renew in July last.—*Western Mail.*

COTO BARK AND ITS CHIEF CONSTITUENTS.*

BY J. JOBST AND O. HESSE.

(*Concluded from page* 522.)

Cotoïn.†

To obtain cotoïn the "genuine" coto bark in a powdered state is extracted by percolation with cold ether; the greater part of the ether is distilled off and the still warm residue is mixed with warm petroleum spirit. After proper admixture there separates on cooling a blackish brown oily-resinous mass. The solution is allowed to become completely clear, then decanted off, and allowed to evaporate spontaneously. Cotoïn gradually separates out in large pale-yellow crystals. A great part of the cotoïn remains with the oily residue. This is boiled with water and lime, and the still hot clear brownish yellow solution is saturated with acetic or hydrochloric acid, which causes a reddish white turbidity. After twenty-four hours the solution has become clear, and large glistening yellowish laminæ have been formed, which are often more than a centimetre long, together with pale yellow needles which separate in single crystals or in groups of crystals. Both forms of crystallization belong to cotoïn.

The crude cotoïn can be obtained in a perfectly pure state by one or two crystallizations from boiling water containing animal charcoal. This method of purification only serves for the preparation of small quantities of cotoïn, as it melts in boiling water, and in that condition is only sparingly soluble.

Thus obtained, cotoïn forms pale yellow curved prisms, whilst a chloroform or alcoholic solution of it deposits on slow evaporation large prisms or plates. In the latter case it sometimes is deposited in an amorphous condition crystallizing only after some time. It is easily soluble in alcohol, chloroform, benzine, acetone and carbon bisulphide, but is insoluble in petroleum spirit. It is somewhat more soluble in boiling water than in cold; the latter dissolves very little of it although the solution is rendered tolerably yellow in colour.

Caustic and carbonated alkalies easily dissolve cotoïn, but it is completely re-precipitated on adding excess of hydrochloric or sulphuric acid. Carbonic anhydride precipitates the greater part of it from these basic solutions. It is also soluble in potassium disulphite, but is reprecipitated unchanged on the addition of an acid.

Cotoïn gives a blood-red colour with concentrated nitric acid in the cold, and gradually dissolves on heating to the same colour. A red resin separates from these solutions on cooling or on adding water. Concentrated sulphuric acid gives a brownish-yellow solution. Concentrated hydrochloric acid gives a yellow colour and a yellow solution when heated; but cotoïn crystallizes out unaltered on cooling the solution.

An aqueous solution of cotoïn has a neutral reaction and reduces silver and gold salts in the cold. Acetate of lead causes no precipitation, but the basic acetate gives a yellow precipitate. Ferric chloride gives in a dilute solution a brownish-black coloration, and also a blackish-brown precipitate in a concentrated solution. Ferric chloride gives a deep brownish-red coloration, and an aqueous solution of acetate of lead a yellow crystalline precipitate, when either of them is added to an alcoholic solution of cotoïn. Fehling's solution is slowly reduced by it in the cold, but quickly when heated.

Cotoïn has a bitter taste, and its dust has a sternutatory effect on the nostrils. Its solution has no action on polarized light. At 130° (uncorr.) it melts to a yellowish liquid which solidifies on cooling to a crystalline mass. A trace of the resinous substance considerably lowers the melting point.

Cotoïn is not volatile and is decomposed when heated at a high temperature. It contains no water of crystallization, and shows no loss in weight at 100° or 140° C., if it has been previously dried in a desiccator.

Purified cotoïn gave on analysis numbers corresponding to the formula $C_{22}H_{18}O_6$.

As the aqueous solution of cotoïn has a neutral reaction, it has not therefore the properties of an acid. It dissolves in alkalies, lime and magnesia, to yellowish brown solutions. These solutions, on exposure to air, gradually become of a dark brown.

When cotoïn is dissolved in excess of ammonia and plumbic acetate added to the solution, there is produced a fine yellow amorphous precipitate of triplumbic cotoïn, $C_{22}H_{12}Pb_3O_6$. On adding basic lead acetate to an aqueous solution of cotoïn a yellow amorphous precipitate is produced, containing less lead than the before-mentioned compound.

Tribromocotoïn.—$C_{22}H_{15}Br_3O_6$ (m. p. 114° uncorr.) is obtained in beautiful yellow prisms by saturating a chloroform solution of cotoïn with bromine. It is almost insoluble in cold water, and is partly decomposed at a boiling temperature, but is easily soluble in alcohol, chloroform and ether. Triacetyl cotoïn, $C_{22}H_{15}O_3$, $(C_2H_3O_2)_3$ (m. p. 94° uncorr.), crystallizes in large anhydrous prisms. It is easily soluble in chloroform and ether, with difficulty in cold but easily in hot alcohol.

As above observed, cotoïn is soluble in concentrated hydrochloric without decomposition, but it is completely decomposed when heated with hydrochloric acid in a sealed tube for two hours at 140°, yielding, on adding excess of ammonia to the solution, benzoic acid and a red amorphous substance that is soluble in ether.

By fusion with potash cotoïn is converted into benzoic acid and an oil having the odour of bitter almonds.

Dicotoïn.—When cotoïn was treated with boiling water and filtered, and the insoluble residue boiled with the filtrate, it was observed that leafy crystals separated out as often as this operation was repeated. These crystals were sifted out from the cotoïn crystals, and this method is, in fact, the only one known to the authors of separating dicotoïn from cotoïn.

Cotonetin, $C_{20}H_{16}O_5$, was the name first applied by them to this body, but further investigation showed that the formula $C_{44}H_{34}O_{11}$ is the correct one; hence they have termed it dicotoïn.

Dicotoïn melts in boiling water, in which it is only sparingly soluble. On cooling the solution, pale yellow, glistening laminæ are obtained, as well as crystals similar to those of cotoïn. If after this treatment the melted dicotoïn, or that which is undissolved by water, be dissolved in ether, and the solution be treated with animal charcoal and filtered, there is obtained on spontaneous evaporation of the ether a yellow amorphous residue, which is soon

* Abstract of a paper in *Liebig's 'Annalen,'* 199, 17—96.

† A specimen of cotoïn has been presented to the Museum of the Pharmaceutical Society by Dr. Hesse.

transformed into leafy crystals that melt at about 100°.

The analysis of these crystals showed the fact that dicotoïn is to a great extent transformed by boiling with water into what seemed at first to be an isomeric form of cotoïn, melting at a lower temperature than the prismatic form; but these differences proved on examination to be merely due to an impurity, and these leafy crystals were ordinary cotoïn. Dicotoïn is consequently an anhydride of cotoïn, and stands in the same relation to it as digallic acid to gallic acid. It crystallizes in glistening and almost white laminæ, which are easily soluble in alcohol, acetone, ether, chloroform, ammonia, and sodic hydrate. It is conconverted into cotoïn by being heated with potassic hydrate. It melts at 74—77.°

*Paracotoïn.**

This body is obtained from paracoto bark. The finely ground bark is extracted with ether, and the ether residue after some days solidifies to a crystalline mass. The solid mass, which consists of paracotoïn, oxyleucotin, leucotin, and dibenzoylhydrocoton, is separated by pressure from the resinous mother liquor, and then fractionally crystallized from hot alcohol. Paracotoïn crystallizes out first, and when quite pure gives no bluish-green colour when boiled with concentrated nitric acid, but forms a yellow to brownish-yellow solution.

Paracotoïn crystallizes in beautiful pale yellow laminæ, which melt at 152° (uncorr.), and sublime at a higher temperature, apparently unaltered in composition. It solidifies at 148° to a crystalline mass. It is easily soluble in ether, chloroform, boiling alcohol, acetone, and in benzine, from the last of which it crystallizes on cooling. It is somewhat soluble in boiling water, separating on cooling in delicate laminæ.

Paracotoïn has a neutral reaction, is tasteless, and gives no coloration with ferric chloride. Its chloroform solution has no action on the plane of polarized light. It is somewhat soluble in ammonia, more especially on being heated, and crystallizes out unchanged. Potassic or sodic hydrate dissolves it with decomposition, especially on heating, forming a weak acid, Paracotoinic acid, $C_{19}H_{14}O_7$.

Analysis of paracotoïn, dried at 100°, gave numbers agreeing with the formula $C_{19}H_{12}O_6$, so that it may be regarded in a certain degree as the anhydride of paracotoïnic acid.

Paracotoïn forms a yellowish-brown solution with concentrated sulphuric acid, and with concentrated nitric acid when heated. On cooling the nitric acid solution yellow prismatic crystals separate, probably a nitro compound of paracotoïn, which give protocatechuic acid and a carbonaceous mass when heated with concentrated hydrochloric acid at 140°. The nitro compound is unaffected by being heated for some hours with glacial acetic acid, or with acetic anhydride. Bromine has a peculiar action on paracotoïn. On adding bromine drop by drop to a chloroform solution of paracotoïn the bromine is at first absorbed, hydrobromic acid being evolved, but on adding more bromine there is separated a scarlet red crystalline precipitate. On collecting and washing this precipitate with chloroform, it was found that the portion in contact with the moist air had become intensely yellow, and this change quickly extended to the entire mass, hydrobromic acid at the same time being disengaged. Dried at 100° it lost hydrobromic acid, and acquired a chrome green colour. It appears to be a bromo-paracotoïn, $C_{33}H_{21}Br_3O_{12}$, and in the same manner as paracotoïn it yields paracotoïnic acid and the characteristic smell of paracumarhydrin when heated with a solution of potassic hydrate.

Paracotoïn is converted into protocatechuic acid by fusion with potassic hydrate. On adding sulphuric acid to the fused mass, and then distilling, a small quantity of formic acid distils over.

Paracumarhydrin.—When heated with a solution of potassic hydrate, paracotoïn forms a yellow solution, which soon becomes of a darker yellow, and gives off a volatile body, having a strong smell of cumarin. This volatile body, as well as the non-volatile portion which was obtained by extraction with ether, proved to be a substance which the authors have named paracumarhydrin, having the formula $C_9H_8O_3$.

Paracumarhydrin forms colourless laminæ, which smell like cumarin. It melts at 85° (uncorr.) when directly obtained from paracotoïn by the action of potash, but melts at 82—83° when recrystallized from boiling water, or when obtained in the other manner described. It was found to be impossible to convert it into cumarin, or into the hypothetical body paracumarin, by the action of dehydrating agents.

Paracumarhydrin has a neutral reaction. It is easily soluble in ether, alcohol, acetone, and chloroform, but sparingly so in cold water, although it easily dissolves in hot water, from which it crystallizes on cooling in large colourless laminæ. The formation of this body from paracotoïn would be easily explained by the following equation, $C_{19}H_{12}O_6 + 2H_2O = 2C_9H_8O_3 + CO_2$, but whether its formation may not depend on the production of a crystalline acid body, which was obtained in small quantity, could not be definitely ascertained. Its analysis approximated to the formula $C_9H_8O_4$; hence it may be a homologue of piperonylic acid. It melts at 200°, and dissolves with difficulty in boiling alcohol and in ether, separating in small crystals on evaporation.

Paracotoïnic Acid.—This acid is produced from paracotoïn by the action of baric hydrate, or milk of lime, but preferably by the action of potassic hydrate. Its formation from paracotoïn takes place according to the equation $C_{19}H_{12}O_6 + H_2O = C_{19}H_{14}O_7$. It is obtained as a fine yellow amorphous powder, which easily dissolves in alcohol and in ether, but is almost insoluble in pure water, although very easily soluble in ammoniacal water.

Ammonium, barium, calcium, lead, and silver salts have been obtained.

*Leucotin.**

This is the chief constituent of paracoto bark. It is separated from the crystalline mass remaining in the alcoholic mother liquor from which paracotoïn has been separated by adding glacial acetic acid, in which leucotin is very easily soluble. The expressed solution is evaporated, and the residue crystallized from very dilute boiling alcohol. Thus obtained, it is in the form of small white prisms which are very easily soluble in alcohol and ether, especially on being heated. It is especially soluble in chloroform, acetone, and glacial acetic acid. It melts in boiling

* A specimen of paracotoïn has been presented to the Society's Museum by Dr. Hesse.

* A specimen of leucotin has been presented to the Society's Museum by Dr. Hesse.

water, a small portion dissolving; on being cooled, the solution becomes milky, and then deposits small needles of leucotin. It is not apparently more soluble in alkaline water. It melts at 97°, solidifying on cooling to a crystalline mass. At a higher temperature it becomes brown, and evolves pungent vapours. Its alcoholic solution (2 p. c) has no action on polarized light. It has a neutral reaction, and forms no compounds with bases, not even with lead. With concentrated sulphuric acid it gives a dark yellow solution, and with concentrated nitric acid a bluish green resin and solution; the latter becomes turbid on the addition of water.

The formula $C_{21}H_{20}O_6$ was first assigned to leucotin, but further investigation showed that the formula $C_{34}H_{32}O_{10}$ is the more correct.

Dibromoleucotin, $C_{34}H_{30}Br_2O_{10}$ (m. p. 187°), and *tetrabromoleucotin* (m. p. 157°) have been obtained. By partial fusion with potassic hydrate in the presence of a little water, leucotin is converted for the most part into benzoic acid, together with protocatechuic acid, formic acid, and a new body, *cotogenin*, of the formula $C_{14}H_{14}O_5$. By continuing the action cotogenin is completely transformed into protocatechuic acid. It is believed to be a derivative of protocatechuic aldehyde. It melts at 210°, dissolves with difficulty in cold alcohol, but more easily in hot. These solutions give an intensely green coloration with ferric chloride.

A volatile body, *hydrocoton*, $C_{15}H_{21}O_6$ is formed at the same time by the action of the potassic hydrate on leucotin. Hydrocoton crystallizes in white prisms which melt at 48—49° (uncorr.). It gives dinitrocoton* by the action of concentrated nitric acid.

*Oxyleucotin.**

Most of the oxyleucotin would be found with the paracotoïn, as it is only to a slight extent separated from the latter by crystallization from alcohol; but it can be obtained by heating the mixture of the two bodies with dilute potash or soda, which dissolves the paracotoïn. The undissolved residue of oxyleucotin can be crystallized from boiling alcohol or glacial acetic acid. It forms large white prisms, which melt at 133·5° (uncorr.), and are insoluble in caustic alkalies. It readily dissolves in boiling alcohol or glacial acetic acid, separating on cooling in fine prismatic crystals, but only with difficulty in cold chloroform, ether, and benzine, although readily on warming. It corresponds in properties with leucotin. It contains no water of crystallization, and its now corrected formula is $C_{34}H_{32}O_{12}$.

Di- and tetra-bromo compounds have been obtained. Boiling aqueous solution of potassic hydrate has no action on oxyleucotin, but by fusion it is converted into hydrocoton, cotogenin, protocatechuic aldehyde and acid, benzoic and formic acids.

*Dibenzoylhydrocoton.**

This substance is contained in the crude leucotin, and is best separated from it by its insolubility in glacial acetic acid. It can be obtained in a state of purity by being converted into the dibromo-compound. It contains no water of crystallization, and is of the formula $C_{32}H_{32}O_8$. It crystallizes in white stunted prisms which melt at 113° (uncorr.), and solidify on cooling to a radiating crystalline mass. At a higher temperature it distils almost unchanged.

* Specimens of dinitrocoton, oxyleucotin and dibenzoylhydrocoton have been presented to the Society's Museum by Dr. Hesse.

It is very easily soluble in boiling alcohol (recrystallizing on cooling) and in chloroform, tolerably so in ether and acetone, but is quite insoluble in petroleum spirit, sparingly so in cold glacial acetic acid, although easily on being heated. It is somewhat soluble in boiling water and in hot potash, but separates out on cooling.

Dibenzoylhydrocoton is converted, for the most part, into hydrocoton and benzoic acid by fusion with potassic hydrate and into benzoic acid and unisolated decomposition products by the ation of concentrated hydrochloric acid in a sealed tube at 140°. Di- and tetra-bromo compounds have been obtained

*Hydrocotoïn.**

Hydrocotoïn remains in the resinous mother liquor from which the other bodies have been separated as above described. The resinous mass is treated with weak soda lye, and the solution precipitated with hydrochloric acid. The crude red resinous precipitate of hydrocotin is purified by crystallization from hot weak alcohol.

It crystallizes from a concentrated alcoholic solution in large pale yellow prisms, and from a dilute solution in hard, thin needles, which are often more than 5 c.m. in length. It is soluble in ether, sparingly so in petroleum spirit, but easily dissolves in chloroform, acetone, and in hot ammonia, crystallizing out on cooling. It has a neutral reaction. Ferric chloride gives a dark brownish red coloration as with cotoïn and dicotoïn. Concentrated nitric acid forms a blood-red solution when heated, which deposits a red resin on cooling. This resin dissolves in alcohol to a blood-red colour. It is partly soluble in boiling water, but is deposited in the form of almost white prisms on cooling. It melts at 98°; the formula is $C_{15}H_{14}O_4$.

Bromine, acetyl, and bromo-acetyl derivatives have been obtained.

Fusion with potassic hydrate converted it into hydrocoton and benzoic acid, and heating with concentrated hydrochloric acid in a sealed tube at 140° into benzoic acid and methylic chloride.

Piperonylic Acid ($C_8H_6O_4$).—This acid is obtained from the paracoto bark which has been already extracted with ether, by extracting the bark with lime water. The extract is made acid with hydrochloric acid and then shaken with ether. The ether residue is partly crystalline, and can be purified by re-crystallization from alcohol, then converted into a potassium salt, and the aqueous solution of this salt treated with animal charcoal. "Genuine" coto bark also contains this acid, but only in quantity sufficient to give a qualitative reaction.

The properties of piperonylic acid have been already described by Fittig and Mielck (*Liebig's Annalen*, 152, 40). Many of the salts described by them have also been prepared, in addition to many of its derivatives.

Ethereal Oil of Paracoto Bark.†—By boiling paracoto bark with water an ethereal oil distils over, which has the peculiar smell of the bark; but as the oil has a very high boiling point, a preferable method is to subject the bark to the action of superheated steam. The oil in the distillate can be extracted with ether.

By this treatment the authors have obtained from a large quantity of the bark about one kilogramme

* A specimen of hydrocotoïn has been presented to the Society's Museum by Dr. Hesse.

† A specimen of this essential oil has been presented to the Society's Museum by Dr. Hesse.

of the oil. Freshly prepared it is very mobile, colourless, neutral, and has a peculiar smell. Its specific gravity is 0·9275 at 15°. It has a lævo-rotatory power of 2·12°. It begins to boil at 78°, alcohol (from the ether used) distilling over; the temperature then rises to about 100°, and oil and water come over. The temperature goes up quickly to 160°, at which it remains for some time, gradually rising to 170°—175°, then to 220°—235°, and finally to 240°—250°. At the last temperature yellowish fumes are evolved, and a thick yellow mass remains in the still, which has not been further investigated. The chief part of the oil distils over at 220°—235°.

By repeated fractionation five characteristic oily bodies have been separated. α Paracoten, $C_{12}H_{18}$, b. p. 160° (uncorr.), and specific gravity 0·8727 at 15°. β Paracoten, $C_{11}H_{18}$, b. p. 170°—172° (uncorr.), specific gravity, 0·8846 at 15°.

α Paracotol*, $C_{15}H_{24}O$., b. p. 220°—222°, specific gravity, 0·9262 at 15°. It has a slight smell, and gives, with concentrated sulphuric acid, a deep red mass, and, with concentrated nitric acid, a yellow resin. Heated above its boiling point it becomes yellow, and is partly decomposed. It gradually acquires a yellow colour on exposure to air. This oil appears to be isomeric with cubeb oil, with which it has much similarity.

β Paracotol, $C_{28}H_{40}O_2$, b. p. 236° (uncorr.), specific gravity, 0·9526 at 15°. It is a colourless oil, with a slight aromatic smell. It is somewhat difficult to separate this oil from α paracotol.

γ Paracotol, $C_{28}H_{40}O_2$. This is an isomer of β paracotol, from which it is distinguished by its higher specific gravity, boiling point, and by its very slight action on the polarized ray.

Its specific gravity is 0·965 at 15°, and it boils at 240°—242° (uncorr.). It has a slight smell, is colourless, and becomes very quickly yellow on exposure to air, owing no doubt to oxygen being absorbed.

Physiological and Therapeutic Action of Coto Bark and its Constituents.

The conclusion arrived at by Dr. V. Gietl, who prescribed an alcoholic tincture of the bark, is that "We have in the new ('genuine') coto bark a specific remedy for diarrhœa in its various modifications."

Dr. Burkart has communicated his experience with regard to the employment of the bark itself and of an alcoholic tincture of it (1 : 9). In doses of 0·5 to 1·0 gram, the bark caused hiccough, nausea, a burning sensation in the stomach, and even vomiting. With a dose of 1 gram of the bark the burning feeling in the stomach was very considerable, extending from a quarter to half an hour; finally, most of the bark was vomited. The tincture was even more nauseous. When rubbed on the skin it produced hyperæmia, with a burning sensation.

Dr. Burkart also states that paracoto bark, similarly prescribed, has much the same effect as coto bark, excepting that its action on the skin, mucous membrane, and ulcerous surfaces is extremely slight, so that, to produce an action equal to coto bark, a considerably larger quantity must be used. He has also prescribed an alcoholic tincture of "genuine" coto bark, and his observations are in accord with those of V. Gietl's, but he believes that, on account of its secondary action on the stomach, the bark is not apparently suitable for therapeutic purposes.

For these and other reasons the authors recommend the employment of the active principles of these two barks, cotoïn and paracotoïn, both of which have yielded good results in the hands of Dr. Burkart, who employed cotoïn partly in the form of powder (·05 gram per dose every two or three hours), partly in aqueous solution (0·1 to 0·5: 120 with the addition of a taste corrective) in cases of acute and chronic stomachic catarrh. In cases of chronic stomachic catarrh, with relaxation of the coating of the stomach, it was specially efficacious, and in the diarrhœa of phthisis also causing a reduction of the febrile symptoms.

Cotoïn, in all cases, Dr. Burkart further remarks, is passed by the urine within 4—6 hours after being taken. To detect cotoïn in the urine he used the nitric acid reaction.

Paracotoïn was found to have absolutely no action on the mucous membrane.

Paracotoïn was employed with great success by Dr. Burkart in powder (in doses of 0·1 to 0·2 gram every two or three hours) in cases of chronic and acute stomachic catarrh, and with success in two cases out of three in cholera nostras.

Professor Bälz (Tokio, Japan,) has successfully employed paracotoïn in Asiatic cholera, and, where possible, by subcutaneous injection, in doses of 0·2 gram.

Oxyleucotin, leucotin, and hydrocotoïn have an analogous action, but in such a very slight degree that very large doses of these bodies are necessary to have the same effect as cotoïn and paracotoïn.

SYRUP OF LACTO-PHOSPHATE OF LIME.*

BY EDWARD S. KELLY.

This preparation is not a chemical combination, but a simple solution of phosphate of lime in lactic acid, preserved with sugar. The observations of Dussart mentioned by Dorvault may perhaps be considered the oldest authority upon this subject; he proposed the use of lacto-phosphate of lime, although its chemical formula had not been determined.

He found it useful in rachitis and osseous affections accompanying a bad state of the digestive organs and in dysentery. It was prepared by saturating lactic acid with gelatinous phosphate of lime concentrated over a water-bath to the consistence of honey, forming a white product, soluble in water, partially soluble in alcohol; it was given in the form of pastils and syrup, dose from 1 to 10 grams.

This gelatinous or hydrated phosphate of lime was recommended by Possoz and Collas as being better than the ordinary phosphate of lime. It is prepared thus:—Calcined bone is treated with hydrochloric acid, forming a solution, the acid is neutralized with carbonate of soda, and the precipitate washed and dried, but not enough to render it pulverulent; it contains 2 parts of water to 1 of lime.

Griffith's 'Universal Formulary,' third edition, gives a formula by Chiles for this syrup: solution of chloride of calcium is mixed with solution of phosphate of sodium and the resulting precipitate, after washing, is dissolved in conc. lactic acid and syrup added. As thus prepared it does not contain as much lactic acid as would seem desirable. Nelson, in his 'Druggist's Handbook of Private Formulas,' page 42, No. 111, gives a process which is the same as Neergaard's, except that the amount of sugar is a little larger.

* Specimens of α, β, γ, paracotol have been presented to the Society's Museum by Dr. Hesse.

* Read before the Alumni of the Mass. Coll. of Pharm. From *New Remedies*, November, 1879.

In the *Druggists' Circular*, volume 19, 1875, page 146, is an account of some so-called syrup lacto-phosphate of lime which, being tested, proved to be only solution of phosphate of lime in hydrochloric acid.

The 'Proc. of the Am. Pharm. Assoc.' contain various formulas for this syrup. In volume 19, page 161, is that of Neergaard's which is so well and favourably known. Volume 21, page 188, gives processes by R. Rother and C. Menière, the latter using lactate of sodium and acid phosphate of lime, dissolving each in a little water; the solutions are then mixed with syrup and flavoured. In volume 22, page 80, is Langelle's process, essentially that of Neergaard's. Volume 24, page 104, has a formula in which basic phosphate of lime is used, but the amount is only 3 grains to the tablespoonful. This basic salt is so made as to contain 25 per cent. of water, which renders it soluble, and in this condition it may be kept on hand ready for use; on page 241 of the same volume may be found the formula for its preparation.

The *American Journal of Pharmacy*, volume 45, page 234, contains a note by Brown, of Philadelphia, in which he states that he obviated the troublesome precipitate often met with in this syrup by using glucose in place of sugar.

Volume 48, page 58, of the same journal has the opinion of John W. Watts, of Baltimore, upon a so-called syrup lacto-phosphate of lime, into which phosphoric, lactic, and hydrochloric acids enter, prepared thus:—To the magma of freshly precipitated phosphate of lime the two former acids are added; these not being sufficient to dissolve all the lime, the hydrochloric acid is added, which is also said to be necessary to its preservation, not keeping more than two or three months without it, and being nearly enough to convert all the phosphate into chloride. The formula is given to show the amount of hydrochloric acid which it contains.

Phosphate of lime	℥ss. + gr. 16.
Dilute phosp. acid	ʒvij.
Lactic acid	ʒi.
Hydrochloric acid	ʒvi.
Sugar	q. s.

M.

Neergaard may justly be considered as the man who first brought syrup lacto-phosphate of lime to the attention of pharmacists, and his formula is the one I have adopted without modification; it is as follows:—

Conc. lactic acid	fl. ℥i.
Magma of freshly precipitated phosp. lime.	q. s.
Orange flower water	fl. ℥iss.
Distilled water	q. s. ad. fl. ℥viij.
Sugar	℥xi.

M. S. A.

The magma of phosphate of lime has been prepared both from the precipitated phosphate of lime of commerce and calcined bone; the latter is cheapest and hence used in making the syrup upon a large scale. The lime is put into a porcelain-lined kettle and hot water added, direct heat is applied, and strong, pure, hydrochloric acid added with stirring until the salt is dissolved; it is then removed from the fire and ammonia water *slowly* added (made thus, 880° ammonia, 1 part, and water, 7 parts), with constant stirring (to prevent the formation of hard curd-like masses in the precipitate), until the lime is all thrown down. The magma is now ready to be washed; it has generally been done by transferring to a cotton cloth and taking to the sink, running in water and squeezing out till the washings cease to give a precipitate with an acid solution of nitrate of silver. Of late the washing has been done by decantation, which is less tedious, and must be the process employed in large operations. Hot and cold water have both been used to wash the lime, but that treated with hot water is equally soluble with that treated with cold water. When all the solution of chloride of ammonium has been removed, and the magma transferred to a mortar, the lactic acid was added and by constant stirring made to dissolve the lime to saturation; the acid when saturated being still notably sour to the taste. The orange flower water and distilled water were then added to make the required amount; as the lime does not all go into solution, it is filtered and water added through the filter to preserve the measure. After the solution of the sugar is complete, the preparation is again filtered. Thus prepared, syrup lacto-phosphate of lime is of a light straw colour, pleasant acid taste, and agreeable flavour.

Mr. Neergaard remarks that heat should not be used to dissolve the sugar, as it would make the syrup milky, but no heat is required, as the quantity of sugar is not enough to make a saturated solution.

Having met with the same trouble spoken of by Mr. Brown, namely, precipitation, I have modified my process of late, adding one drachm of hydrochloric acid to each pint of the syrup thus made, the difficulty is obviated.

The character of this precipitate is much like the soft jelly often found floating in the syrup or adhering to the sides and bottom of the bottle; this will redissolve by the application of heat, but may not remain in permanent solution. The odour or colour does not change after this precipitation has taken place; hence the conclusion that it is not a fungous growth.

Although the testimony of physicians as to its therapeutical value does not agree, this syrup seems worthy of a place in the U. S. P. of 1880, and if we can judge by the formulas offered, and the number of manufacturers who quote it upon their lists, it has had a very considerable sale and use. Certainly for pleasant taste we have but few preparations which will favourably compare with it, and in these days this is a consideration both with physicians and those who must take medicines.

THE MINERAL CONSTITUENTS OF CINNAMON AND CASSIA.*

BY O. HEHNER, F.C.S.

The discrimination between ground cinnamon (*Cinnamomum Zeylanicum*) and cassia (cassia lignea and cassia vera) is a matter of some importance, but of considerable difficulty. These spices are imported into this country in very large quantities. Thus during the first forty-three weeks of this year 18,002 packages (of 56 lbs. each) of cassia lignea, against 13,212 packages of cinnamon (each weighing about ¾-cwt.), and during the same period of last year, 45,433 packages of cassia and 13,489 of cinnamon were imported. The wholesale prices of cinnamon fluctuate between 6*d.* and 4*s.* 3*d.* per lb., whilst cassia barely reaches 6*d.* Considering now the extreme similarity between these barks, both botanical and structural, not a little inducement exists to substitute the cheaper for, or mix it with the more valuable spice, and it is a fact, that notwithstanding the large amount of cassia imported, it is almost impossible to obtain it under its proper name at retail establishments. I am informed that cinnamon sticks are never ground, but always sold in their whole state, only cinnamon chips and cassia being powdered. Much cassia, no doubt, is used by distillers of essential oils, manufacturers of mixed spice and of curry powder, but it cannot be doubted that much of it finds its way into the consumer's hands under a name to which it has no valid claim. However this may be, it is important to public analysts that they should be in possession of means to discriminate between the two kinds of bark.

The only test which, as far as I am aware, has been in use, is that founded upon the alleged difference in the behaviour of the decoctions towards iodine. Thus Flückiger and Hanbury direct in their 'Pharmacographia' to "make a decoction of powdered cinnamon of known genuineness, and one of similar strength of the suspected

* Read before the Society of Public Analysts, November 19, 1879. From *The Analyst*, December, 1879.

powder. When cool and strained test a fluid ounce of each with one or two drops of tincture of iodine. A decoction of cinnamon is but little affected, but in that of cassia a deep blue-black tint is immediately produced." But, considering that both cassia and cinnamon contain much starch—as shown by the microscope—it seems *à priori* improbable that cassia starch should act normally towards iodine, whilst that of cinnamon refuses to do so. The different amount of tannin would certainly not explain the distinction, as has been suggested by Pereira, as *both* cassia and cinnamon are rich in tannic acid. But the fact is that decoctions of *both* cassia and the cheaper kinds of genuine cinnamon turn blue with iodine. A few drops of iodine are first decolorized by the solutions, but a point is readily reached when the blue colour permanently makes its appearance, modified, of course, by the yellow colour of the decoction. The finest samples of cinnamon do not react much with iodine, probably because, on account of their immaturity, they contain little real starch. The iodine test is therefore of very questionable value, and genuine cinnamon might by it be condemned as adulterated. It may be admitted that in the case of cassia the reaction is obtained more readily than with cinnamon.

To find, if possible, some real difference between the two kinds of bark, I examined their mineral constituents, believing that the more woody bark, cassia, would contain a larger amount of salts of lime and magnesia than the delicate membranous cinnamon. The following analyses show, however, that this supposition was not entirely substantiated. All analyses were made upon the ash obtained at the lowest possible temperature (below visible red heat), but not recarbonated, that is to say, precisely as they would result in an ordinary analysis.

Insoluble Ash	74·96	71·02	74 78	73·64	72·33	81·66

	CASSIA LIGNEA.			CASSIA VERA.	
	Whole.		Ground.		
Moisture	14·22	11·88	11·05	10·37	11·36
Ash in Bark	1·84	2·54	2·55	4·08	4·85
Lime in Ash	25·29	34·49	28·63	52·72	43·40
Mn_3O_4	5·11	4·94	3·55	1·13	1·53
Soluble Ash	40·58	26·78	30·91	8·36	15·89
Insoluble	59·42	73·22	69·09	91·64	84·11

Examining these figures it appears—*First*, that the *proportion of ash* in cinnamon fluctuates between comparatively narrow limits. Cassia vera contains an amount equal to that of cinnamon, but cassia lignea yields much less. *Secondly*, that the amount of *ash soluble in water* is about one quarter of cinnamon ash, less in cassia vera, more on cassia lignea. *Thirdly*, that cinnamon ash contains less than one per cent. of *oxide of manganese*, cassia vera upwards of one per cent., cassia lignea far more, up to five per cent. This is indeed the most noteworthy feature brought out by the analyses. The amount of manganese has a direct influence upon the colour of the ashes. Thus all cinnamon ashes are *white*, or nearly so, those of both descriptions of cassia *grey or brown*, and the latter, when heated with hydrochloric acid, yield an abundance of chlorine gas. Thus the amount of manganese serves to distinguish cinnamon from cassia lignea with a high degree of probability, and even a comparatively moderate admixture of the latter would thus be rendered evident in the former. The manganese is most readily separated from the ash by means of bromine after the phosphate of iron has been precipitated by acetate of soda.

* By difference.

The difference between cinnamon and cassia vera is not so marked, but the low proportion of soluble ash in this will be a point worthy of notice. But cassia vera is only imported to a very small extent, and it is, as an adulterant or substitute, of far less importance than the cassia commonly so-called, namely cassia lignea. It is, moreover, so mucilaginous that when heated with water it yields a glairy or ropy decoction.

All of the samples, the analyses of which are reported above, were of undoubted purity, and many of them were kindly furnished me by Messrs. J. Travers and Son, to whom I am much indebted. My thanks are also due to Mr. E. Riley for having assisted me in carrying out the investigation.

In the discussion which followed the reading of this paper, Dr. Dupré asked Mr. Hehner whether he had any information as to the places where the cinnamon and cassia came from. It might be that this remarkable amount of manganese was not always found; was there reason to suppose that it was really a characteristic of cassia, or that it was due to a local peculiarity of the district?

Mr. Stewart asked if Mr. Hehner had made any determinations of the quantity of iodine added in each case; it seemed to act much more rapidly with cassia than with cinnamon.

Mr. Hehner, replying to Dr. Dupré, said that he had had one of the samples of cassia lignea for two years, two other samples were quite recent, two cheap cinnamons were recent also, and they gave an ash very rich in manganese, which no doubt proved that they consisted of cassia. He had no doubt that by far the largest amount of ground cinnamon sold was really cassia. In reply to Mr. Stewart, he said cinnamon decoctions required, as a rule, a very much larger quantity of iodine. The test as given in different books was really contradictory. Flückiger and Hanbury say: first add one or two drops, and "a deep blue-black tint is immediately produced," and a few lines further on they say, "But the colour quickly disappears and becomes permanent only after much of the test has been added." No doubt there is a little more starch in cassia than in cinnamon.

CARLSBAD SALT.—(Dr. Uloth.)

The natural Carlsbad Salt, held in solution by the Carlsbad Mineral Spring, contains about 2 per cent. of potassium sulphate, which constituent was usually left out, when preparing the salt artificially. The author directs the following proportions, in order to prepare artificial Carlsbad water:—

Sodium Sulphate, Anhydrous	45 parts.
Sodium Bicarbonate	33 ,,
Sodium Chloride	20 ,,
Potassium Sulphate	2 ,,

Dissolve 4 parts of this in 500 parts of water. *Pharm. Zeit.*, and *Pharm. Centralh.*

DEATH BY MISADVENTURE.

THE London daily paper which lays claim to having the largest circulation in the world has within the last few days informed its readers in an editorial article that, "in spite of all our legal enact- "ments and provisions, gross neglect may still pre- "vail in the dispensing of dangerous drugs." The particular case that has called forth this dictum is of a nature that forbids dissent from the opinion expressed, and probably many who read the article and the details of the case to which it refers will be impressed with a conviction that it is but another illustration of the necessity, insisted upon sometimes in medical journals, for a thorough reform of the system under which poisonous and dangerous medicines are supplied to the public.

To a certain extent such an idea will be justified, not only by the facts of this particular case, but also by those of similar cases that we have lately had to record in this Journal, and so far as those cases are illustrative of the system under which dangerous drugs are supplied to the public we must acknowledge that there is no kind of foundation for objecting, as we recently did, to the demands of the *Medical Press and Circular* for "a speedy and sweeping reform," since it is impossible to read the case reported at page 557 without concurring with the opinion expressed by the jury that there had been gross neglect on the part of those whose duty it was to attend to the management of the drugs.

But while making this admission it must not be supposed that we retract in the slightest degree our objections to the views put forward in the medical journal above referred to, in so far as they tended to throw an imputation upon registered chemists and druggists. The case now under consideration is not one that justifies any such imputation, though in accordance with a common form of popular ignorance the writer in the *Daily Telegraph*, failing to recognize the fact that a place where drugs are sold across the counter is not necessarily a chemist and druggist's shop, makes use of the case to ground an argument as to the necessity for caution being exercised by chemists and druggists to avoid the hasty distribution of poison.

In reality as the sale of the drug which caused the death of the child did not take place in a chemist and druggist's shop at all, but in a shop having, it is true, that semblance, but kept by a regularly qualified medical practitioner, using the designation of a physician, and assisted in the conduct of his business by a licentiate of the Society of Apothecaries. Neither the one nor the other was directly responsible for the mistake by which the child's death was caused, but having left the shop open in the charge of a mere boy, who had on previous occasions manifested a precocious desire to officiate as a dispenser, there was, it must be admitted, too much reason for the censure expressed by the jury, and re-echoed by the *Daily Telegraph.*

Among the cases of death by misadventure a very considerable proportion are not at all the result of any neglect of the precautions prescribed by law for the observance of legally qualified vendors of poisonous drugs, but are due to want of caution or deliberate misuse on the part of the persons who obtain possession of such drugs, either by ordinary purchase or by means of a physician's prescription. Some of our medical reformers would recommend as a remedy against poisoning in this way the adoption of a system like that prevailing in some parts of the Continent, by which it is made impossible to obtain any kind of medicine except by the order of a qualified medical man; others would restrict the use to which prescriptions are to be put by patients for obtaining more than one supply of the medicine ordered. It may be that there are grounds upon which either, or both, of these plans could be advocated as being desirable and beneficial in the interest of the public, either in general or in reference to special instances; but the question whether this be so or not is one for consideration by medical men rather than by pharmacists. The advocacy of any such plans must, however, be founded upon well ascertained facts, not upon mere assumption, and even if it does sometimes happen that in the absence of such restrictions, cases of poisoning occur we contend that there is no ground for throwing blame upon chemists and druggists.

Such restrictions or rather regulation of the sale of poisons as there are in force have been brought into existence by the efforts of the Pharmaceutical Society, and it appears a mere gratuitous exhibition of ignorance to find fault with the authority possessed by that body in this respect. The cuckoo cry about the "facilities afforded for obtaining poisons," so often heard, is one that does not in reality convey any reproach to the registered chemist and druggist, who carries on his business in such a way as to give force to the specific provisions of the Pharmacy Act, and by the timely exercise of his skill and experience offers additional protection to his customers. However thoroughly his duties are performed in these respects, he cannot absolutely provide against a possible misadventure resulting from causes beyond his control. Only three weeks ago we referred to a case, illustrating this fact, in which a physician's prescription was made the medium of obtaining, in a perfectly legitimate way, sufficient poison to produce by its misuse a fatal result. The daily papers of this week report another case of a similar nature in Bayswater, where laudanum sold in accordance with the provisions of the Pharmacy Act was misapplied with fatal consequences. It is idle to talk about the facilities for obtaining narcotic and other poisons, as the jury is reported to have done at the inquest in this case, as if such facilities were unduly afforded by chemists and druggists, and especially is this kind of comment beside the question, so long as some of the most potent poisons can be readily obtained in the form of patent medicines at the grocers or the co-operative stores, without any indication of their dangerous nature to warn purchasers against their incautious use, so long also as the presentation of a physician's prescription enables a person to obtain, either from one or from several shops, a supply of poison that may have fatal effects if misapplied.

We contend, therefore, that the vague complaints often made in a sense detrimental to the chemist and druggist are as a rule without any foundation. The questions they raise are in reality questions for medical practitioners to consider and if possible deal with. Through the agency of the Pharmaceutical Society the drug trade has done its part towards regulating the sale of poison and limiting the facilities of obtaining poisons, and in the exercise of the more special functions of pharmacy the several members of that trade constantly furnish to the public, as well as to medical men, protection against the consequences of accidental mistakes in prescriptions. If in certain cases medical men desire to limit the use that is to be made of their prescriptions it is for them to institute such an arrangement among themselves and with their patients, possibly also with that object to seek the co-operation of the chemists and druggists who perform the supplementary work of dispensing the medicines they order. If it be desirable that a person suffering from neuralgia or the effects of intemperance should not be allowed to procure laudanum or chloral without a physician's order, the grounds upon which such restrictions are to be claimed must first be well made out and supported by the evidence of facts, and then it will be a question between the medica men who seek to impose such restrictions and the public who are to be subjected to them whether they will, on the one hand, be tolerated, and whether on the other, they can be enforced.

Besides the cases of the kind above referred to, there are some in which "death by misadventure" is certainly referable to neglect on the part of the persons who have the management of drugs, and, from the result of many years' special observation, we can affirm that such cases are more frequently traceable to medical men than to chemists and druggists. In stating this, we do not desire to make invidious or unnecessary comparisons, but merely to demonstrate the absence of any adequate foundation for much of the comment upon the subject of accidental poisoning which has appeared in the medical press. If the writer of the article in the *Daily Telegraph* of last Monday would correctly inform himself as to the actual circumstances of such cases we are confident he would perceive that, in regard to the sale of poisons, his special reference to chemists and druggists as requiring advice to observe caution where the public safety is concerned is not so much needed in that quarter as it is in others. In regard to the spirit of his general recommendations, however, we thoroughly concur with him, and in the interest not only of the public, but also that of chemists and druggists, we should be glad to see him at some future time dealing with the subject under the light of more accurate information.

ANOTHER CREAM OF TARTAR PROSECUTION.

At the moment of going to press we learn by telegram that another prosecution for the sale of cream of tartar containing six per cent. of tartrate of lime has been instituted at Romsey, and that the summons was dismissed. The defence of this case was conducted by the Birmingham Association, and we congratulate the executive of that body upon having so successfully followed the lead of the Society.

The number of instances in which prosecutions have been undertaken without any sufficient reason and where there was no foundation for the charge of adulteration is now so considerable, and the needless vexation and trouble caused thereby are so prejudicial, that there seems to be ample occasion for adopting the suggestion made by the President at the late meeting of the Council and communicating with the Local Government Board with the view of effecting some arrangement by which the certificates of public analysts should be subjected to competent scrutiny and consideration before being made the basis of prosecution. At present the decision of the question whether in any particular instance adulteration has been practised or not seems to be left in very incompetent hands, and to be dealt with in a manner calculated to cause much inconvenience and detriment to persons who are entirely blameless.

A CORRECTION.

By a slip of the pen, it was stated last week in our yearly *résumé*, that Mr. Schacht became Vice-Presi- in the place of Mr. Bottle. This was not correct, Mr. Savage having been Mr. Schacht's immediate predecessor in that office, which he had held for three years.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The next meeting of this Association will be held at George Street, Hanover Square, on Wednesday evening, January 14, when a paper on "Benzol and its Derivatives" will be read by Mr. G. W. Bullen.

The name of Mr. John Hurst, Pharmaceutical Chemist, has been placed by the Lord Chancellor on the Commission of the Peace for the Louth Borough. Also, in addition to the pharmacists already mentioned as having been elected to municipal office, Mr. Herbert J. Orchard, Chemist and Druggist, has been chosen Mayor of Newport, I.W.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, January 7, 1880.

MR. GEORGE WEBB SANDFORD, PRESIDENT.

MR. GEORGE FREDERICK SCHACHT, VICE-PRESIDENT.

Present—Messrs. Atkins, Bottle, Churchill, Gostling, Greenish, Hampson, Hills, Robbins, Savage, Shaw, Squire, Slipper, Symes and Williams.

The minutes of the previous meeting were read and confirmed.

The minutes of the meeting for the election of annuitants were also read.

The SECRETARY stated, in reply to a question by Mr. Williams, arising out of the minutes, that the total amount of the Society's investments on the General Fund was about £22,000.

THE BOARD OF EXAMINERS.

The SECRETARY read a letter from the Privy Council, approving of the gentlemen appointed last month by the Council to act as examiners during the present year.

THE REPORTING OF COUNCIL PROCEEDINGS.

The SECRETARY read the report of the Special Committee appointed to make arrangements for the admission of reporters. The Committee recommended that a second table be placed in the Council room for the necessary accommodation of press reporters; and that press reporters should leave the room when the Council resolves itself into committee.

Mr. HAMPSON moved that the report be received and adopted.

Mr. GOSTLING seconded the motion.

The PRESIDENT said he had received one application for admission.

Mr. SHAW asked if the discussion on this motion should take place in committee.

The PRESIDENT thought it would be better.

Mr. HAMPSON saw no necessity for such a course.

The PRESIDENT suggested that the adoption of the Committee's report should be carried first, and then that any discussion on particular applications should take place in Committee.

The VICE-PRESIDENT suggested that an addition should be made to the Committee's report, providing that the editor of any journal which wished to be represented should make application, and that if his application were acceded to, a letter from the Secretary, stating that fact, should be the credential for a person entering the room as a reporter.

The PRESIDENT thought this suggestion was really covered by the resolution passed last month.

Mr. ATKINS thought the Vice-President's suggestion was well worthy of adoption.

Mr. HAMPSON did not see any necessity for hampering the matter with minute regulations of this sort.

The motion for the adoption of the report was then passed unanimously.

Mr. SYMES expressed his dissent from the Vice-President's suggestion.

Mr. SAVAGE moved that the consideration of the application received and the details should be considered in committee.

Mr. HAMPSON objected, and on the motion being put it was lost.

The application was about to be read, when

The VICE-PRESIDENT said he did not understand that the vote just taken was on the question of individual applications.

The PRESIDENT also stated that there were several matters of detail which he thought ought to be discussed, but which he had not been able to get the Committee to go into. These matters he still thought had better be discussed in committee. He thought the Vice-President's suggestion was a very good one, and was not intended to throw any difficulties in the way.

After some further discussion, in the course of which Mr. Squire stated that he had not understood the object of the motion for going into committee,

Mr. BOTTLE moved—

"That only one reporter be admitted from any journal at the same time."

He wished to do so before any application was read, in order that the motion might not have any personal application.

M. SHAW seconded the motion.

Mr. HAMPSON asked if notice ought not to have been given of this motion. It opened the whole question, *de novo*, in his opinion.

The PRESIDENT did not think it was necessary to give notice of such a motion, which only referred to the detail of arrangements to be made, and he thought the sooner the arrangements were made the better.

The motion was carried *nem. con.*

Mr. CHURCHILL said the Council had not yet settled the question of the reports of the committees, which was very important.

The PRESIDENT said he had intended to propose that, inasmuch as there were sometimes private matters included in the reports of the committees, the Council should, if necessary, go into committee to receive such reports, when, under the regulation already passed, the press reporters would be required to leave the room.

Mr. GOSTLING thought such a resolution a very proper one, and he would move it.

Mr. CHURCHILL seconded the motion.

The VICE-PRESIDENT thought the Council might have a broader regulation. The proceedings of committees were supposed to be private, and never published, but simply the fact that the reports were agreed to. If that were the case, and the constituency of the Council were in no way deemed entitled to know the contents of the reports of the committees, would it not be well to make a general regulation that reporters be not admitted until the reception of the reports was concluded? Why should they come into the room simply to be asked to leave it whenever a report was being read?

Mr. WILLIAMS said there was a difficulty in the words "if necessary." How could the Council tell whether it was necessary or not, unless the whole report were read.

Mr. GOSTLING said there would be some member of the Committee present who could say whether the report contained matter which ought not to be published.

Mr. WILLIAMS said in that case there would be a long discussion each time whether the Council should go into committee or not, which was not a practice to be encouraged, as it wasted a great deal of time.

Mr. GOSTLING remarked that as a rule the report of the General Purposes Committee contained details not proper to be published.

Mr. HAMPSON said if this motion were passed it would have the effect of shutting out all discussion of committee work. There had been many interesting and important discussions on reports of committees, and to shut them out would be to curtail the report even in the Society's own Journal.

Mr. SYMES thought the motion was scarcely in accordance with the recommendation of the Special Committee. The suggestion made to the Council was, he understood, that only some special portion of a report should be heard in committee. But, according to the motion, if there were two lines in a report, containing matter of a private nature the whole report would have to be taken in committee. The President himself had suggested that a red mark should be placed against the report of any matter which the Committee thought should be kept private.

The PRESIDENT said the paper from which he had just been reading was the same that he laid before the Committee. It would be quite competent for any gentleman who was a member of the Committee to say there were certain things in the report which ought not to be published. He could not join with the Vice-President in thinking that the reporters should be excluded until all the reports had been disposed of; if so they would only come in sometimes when the diplomas were being stamped, which always formed the last item on the agenda. He was quite willing that the motion should be put in any form which would make it workable.

Mr. Robbins said it appeared to him there was only one committee whose proceedings were of very great interest to the members outside, and that was the General Purposes Committee. But the members of Council all knew that there were a great many questions which came before that Committee which could not be published. The most important part of the Society's work was done in that Committee. What was done by the other committees was of comparatively little importance to readers outside.

Mr. Gostling said he would, at the President's suggestion, put the motion in the following form:—

"That inasmuch as matters of a private nature are sometimes recorded in the proceedings of the various committees, it will be well before such minutes are read, for the Council, if necessary, to resolve itself into committee for the purpose of receiving and considering the report of such private matters."

Mr. Churchill seconded the motion.

Mr. Williams thought the reports of the committees should always be read in committee, and that then it should be an open question whether the discussion should take place in committee or not. The report might contain nothing of a private nature, and might contain matter of great public interest which ought to be discussed openly and reported. That could be decided in two minutes, after the report had been read.

Mr. Atkins thought that all the differences which were now springing up like mushrooms might have been avoided if the Council had clearly made up its mind on the point of whether the reporters should be called upon to leave the room or not. The report of the Committee including that regulation had been adopted without any discussion, and he certainly was not aware that the subject was concluded, or he should have offered some remarks upon it. He felt more and more convinced that the reporters might have been allowed to remain subject to the same honourable regulations as the Council's own reporter. He did not wish to be a prophet of evil after having supported the change, but he thought it would be found that asking the reporters to be continually trotting in and out of the room would be a great nuisance.

The President said he had no fear of the reporters, but the Council ought to retain in its own hands the means of keeping them in order.

Mr. Williams then moved as an amendment—

"That the Council shall resolve itself into committee to receive the reports of all committees, and discussions thereon shall be taken in committee or open Council as decided by the Council at the time."

Mr. Squire seconded the amendment.

Mr. Hampson decidedly objected to the amendment. The report would be perfectly unintelligible if the reporter was unable to start with the text. It was the custom in all public bodies for the reports to be read and extracts from them to be published. It was only an occasional matter which the Council wished to keep private. He thought it very undesirable that either of these motions should pass. These important changes should be introduced in a proper way by notice of motion being given, so that members of Council should have an opportunity of thinking the subject over. He should much prefer to have the reporters present on all occasions and to trust to the honour of those gentlemen. He regretted now that the Council had agreed to the exclusion of reporters when in committee.

Mr. Squire said the question whether reporters shou be present in the room or not had been already decided and it did not bear on this point.

Mr. Savage said it did very largely, because if he understood the proposition aright, under any circumstance the report of a committee must be read in committee, and a resolution was already passed that reporters must leave the room when the Council was in committee, so that during the reading of the report of every committee, however insignificant, and however desirable it might be for them to be present, they must leave the room.

The President said that depended on which proposition was adopted.

Mr. Bottle drew attention to one of the Bye-Laws which said that every committee should present its report to the Council. Now it was proposed that the report should be made to a committee.

Mr. Symes wished to point out that this proposition, though it did not quite undo everything the Council did last month, would undo half or two-thirds of it, for the reports of the committees occupied at least half of the time. Mr. Williams's amendment would prevent the re-reporters coming in until the Council was about to break up.

The amendment was then put and lost, and the original motion was carried by a considerable majority.

Mr. Shaw said of course the responsibility would devolve upon some members of the respective committees, of moving that the Council should resolve itself into committee.

Mr. Atkins said he should move on another day that the reporters be not asked to leave the room.

Mr. Hills said he should move, if it were not too late, that the press reporters should be admitted on the same conditions as the official reporter.

The President said the Council had already decided the contrary. He then read an application he had received from the editor of the *Chemist and Druggist*, saying he should like to send a reporter to all meetings and to be allowed to attend himself occasionally. He asked for the latter favour purely for the sake of insuring accurate information, and he should wish to be regarded as a second reporter from his journal. He had further requested that the agenda paper and other documents furnished to the members of Council might be sent to him. Mr. Sandford had replied privately, acknowledging the receipt of the letter, and saying that as far as the first part of it was concerned he had not the slightest doubt that a reporter would be admitted, but with regard to the other points he could only submit them to the Council. In the meantime he should be glad to know what was meant by the "other documents." In reply to that Mr. Wootton said he had no special documemts in his own mind, he only thought that papers respecting the business of the Society were sometimes circulated, and, if so, he should of course be glad to have them, though not necessarily for publication. Mr. Wootton had also called on him, when he was informed that there were no documents handed to the Council but the agenda paper, except that occasionally reports of committees were circulated which were entirely private until they were in the hands of the Council collectively. Mr. Wootton said he did not make any point of the other documents. The first question, of course, was the admission of a reporter from the *Chemist and Druggist*.

Mr. Hampson moved and Mr. Atkins seconded—

"That a reporter from the *Chemist and Druggist* be admitted to the ordinary monthly meetings of the Council of this Society."

Mr. Williams thought before this motion was passed the Council had better discuss the second question, whether the editor also should be allowed to be present.

The President remarked that the resolution already passed on the motion of Mr, Bottle disposed of that.

The Vice-President said that the letter having been received he considered a certain answer should be sent to it, which should contain the conditions on which the reporter should be admitted. He should also like it to contain a paragraph to the effect he had before suggested, requesting that in the event of any change of the individual representing the journal he should bring that letter as his warranty for entering the Council-room.

The PRESIDENT said no doubt an answer should be sent; but he believed there was a gentleman waiting to come in.

Mr. SYMES thought it would be sufficient if the Secretary, in writing to the editor, called his attention in a footnote to the conditions attached to the admission of the reporter.

The motion was then put and carried unanimously.

The PRESIDENT said the application of the editor of the *Chemist and Druggist* to be himself occasionally present was already disposed of; then came the question of forwarding him the agenda and other documents.

Mr. BOTTLE thought there was no objection to sending him the agenda.

The VICE-PRESIDENT asked if a copy was supplied to the editor of the *Pharmaceutical Journal.*

The SECRETARY said no.

Mr. SYMES thought that was no objection; if he asked for one he would no doubt receive it.

Mr. WILLIAMS said the agenda was a private document, and if it were to be sent to any strangers there should be a resolution to that effect.

Mr. SHAW then moved—

"That the agenda paper of the ordinary Council meetings be sent to the editor of the *Chemist and Druggist,* marked 'private.'"

This was seconded by Mr. SYMES, and carried unanimously.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Bown, John Quinton.
Carter, Francis.
Crook, Herbert.
Eaton, Edward Jarrett.
Greig, James.
Gulliver, William Inchle.
Harburn, Alfred.
Hugill, Arthur Major.
Kirk, William Peele.
Powell, William.
Richardson, William.
Williams, Thomas Henry.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following, having passed the Major examination and tendered their subscription for the current year, were elected "Members" of the Society:—

Bevan, William ....Harwich.
Bown, John Quinton ....Nottingham.
Carter, Francis.....................London.
Crook, Herbert......................Gravesend.
Eaton, Edward Jarrett ....Diss.
Gibbons, Walter ....Manchester.
Greig, James.........................Glasgow.
Gulliver, William Inchle.........London.
Harburn, Alfred ....Bishop Auckland.
Kirk, William Peele ....Retford.
Laxon, Matthew ....March.
Richardson, William Henry ...Lincoln.

The PRESIDENT said he was very glad to see so many who had just become qualified as pharmaceutical chemists joining the Society as members.

Mr. WILLIAMS wished to say a word or two with regard to a lady applying for membership before the next list was put to the vote, and he should move that the Council resolve itself into committee, as it was a private matter.

Mr. HAMPSON thought this was a dangerous precedent. He understood the election of members was always in open Council.

Mr. WILLIAMS remarked that what he had to say was of a personal nature, and ought to be said in committee.

The Council then went into committee.

The Council having resumed,—

Mr. HAMPSON expressed his satisfaction that the Society had decided to elect as a member a lady who for many years had aspired to this position, and that a question which had caused so much excitement in the Society was now thoroughly settled.

Chemists and Druggists.

The following registered Chemists and Druggists who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected Members of the Society:—

Leech, Elizabeth ....London.
Lewis, John Phillip...............Rickmansworth.
Turner, Robert Charlton.........Douglas (I. of Man)

ASSOCIATES IN BUSINESS.

The following, having passed their respective examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society:—

Minor.

Bottomley, Albert Frederic ...Holbeck.
Coleman, Edward James.........Cardiff.
Francis, James.......................Carnarvon.
Lee, Alexander Milne ....Strichen.
Macpherson, Colin Allan .....Edinburgh.
Pearson, Henry......................Nottingham.
Walmsley, Robert ....Brighton.

Modified.

Emsley, Joseph ....London.
Rich, Geo. Benjamin Orridge...London.
Stewart, James......................Grantham.
Thompson, Thomas ....Sunderland.

ASSOCIATES.

The following, having passed their respective examinations and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Adams, Benjamin...................Grantham.
Allison, William Billyard ....Retford.
Bell, Robert ....Lancaster.
Brown, Frederick...................Lincoln.
Brown, John..........................Pontefract.
Burrell, Thomas ....Edinburgh.
Collins, Robert Enos ....Old Leake.
Cox, Frederick John ....Newark.
Crichton, Alexander...............Burntisland.
Crowther, William Fearne ......Beverley.
Dawson, William ....London.
Garrett, John Henry ....Kineton.
Gordon, John ....Bradford.
Haden, Walter Edward ....Lichfield.
Hooper, David ....Southwark.
Logsdail, Henry ....Lincoln.
McDerment, James ....Ayr.
Protheroe, John Godwin.........Christchurch.
Rees, Harding ....South Norwood.
Robinson, Charles Bradshaw ...Great Bridge.

Modified.

Carter, James ....London.
Jones, Thomas ....London.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Allan, Alexander Fergusson ...Greenock.
Astley, Frederick Aspinall ...St. Anne's-on-the-Sea.
Bamforth, Joseph..................Manchester.
Blenkiron, Jeremy ....Shildon.
Boyd, Alexander ....Glasgow.
Brown, Fredk. William, jun. ...London.
Brown, George Wall ....Portsea.
Chamberlin, Charles James ...Barnsley.
Comer, Ernest Edward ....East Dereham.
Cooper, George Henry ....Oldham.
Crow, William Edward ....Louth.
Crowther, Charles J. H. ....London.
Dale, John Dickin ....Stafford.
Dickinson, John George ....Lancaster.
Down, Frank Walter ....Sittingbourne.
Dowty, William ....Evesham.
Elliott, Henry ....London.
Evison, Alfred ....Alfreton.
Gant, Robert Richard ....Norwich.
George, Alfred Walter...........Gt. Yarmouth.
Greaves, John Elijah ....London.
Greener, Michael Hindmarsh...Alnwick.
Hall, Robert Edward ....Camborne.
Hebron, Frank ....Knaresborough.
Hepworth, Harry..................Skipton.
Heron, Frederick Chambers ...London.
Hill, John ....Alford.
Hogg, Tom ....Derby.
Hughes, William ....Llandyssill.
Hunter, George Ackland ......London.
Jones, Ellis ....Portmadoc.
Jones, John Albert ....Liverpool.
Kerr, David ....Oakham.
King, Ebenezer Thomas ....Reading.
Lawrence, Harry ....Dudley.
Leicester, Thomas ....Chester.
Littleboy, Jno. W. Hattherden..Norwich.
Little, Walter G. ....London.
Marlar, John Frederick ....Halstead.
Martin, John........................Redruth.
Martin, John Bennett............Falmouth.
Mayo, Harry........................Towcester.
Miller, Frederick ....Strood.
Moore, Frank Philip ....Aberdeen.
Morgan, William ....St. Clears.
Morrison, Edward ....Kelso.
Northey, Edward John ....Truro.
Paine, Charles ....Belton.
Procter, George Woodyatt ......Sunderland.
Procter, Henry Raithby ....Boston.
Roberts, Rowland..................Holyhead.
Roberts, William ....Chester.
Robinson, John Whiteley ......Knaresborough.
Scholes, William I. ....Pendleton.
Skirrow, William..................Bingley.
Stothert, James ....Atherton.
Sutherland, David Alexander...Edinburgh.
Taylor, John Williams ....Norwich.
Thomas, David Robert ....Aberystwith.
Tomlin, John Percy...............Tunbridge Wells.
Watts, Robert ....Chatham.
Whineray, Edward ....Ulverston.
Wigg, James........................Streatham.
Willett, Frank Augustine ......Oxton.
Withers, William ....West Bromwich.
Williams, Arthur Gore ....Llandovery.
Williams, James Boden ....Manchester.
Wilson, Albert ....Garstang.
Wilson, David Wm. Richard ...Thirsk.
Wood, Arthur Wm. Henry......Ullesthorpe.
Woltz, Alfred Eugène ....London.
Young, Robert John ....Bideford.

Mr. Shaw said it was remarked some time ago that there were no apprentices coming into the trade; but he never before heard such a long list of names read.

Restoration to the Register.

The name of the following person was restored to the Register of Chemists and Druggists:—

George Barlow, Pocklington, Yorkshire.

Additions to the Register.

The Registrar reported that—
Henry Cutting, Selby, Yorkshire,
John Hardcastle, 23, Waterloo Road, Hunslett, Leeds,
Lloyd William Hughes, Ruthin, Denbighshire,
having severally made the statutory declaration that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been duly supported by duly qualified medical practitioners, their names had been placed on the Register.

Reports of Committees.

Finance.

The report of this Committee was read, including a recommendation that sundry accounts be paid.

The Vice-President said there was one item, namely, the Solicitor's bill, which he thought it would be useful should be explained to the Council, and he moved that the Council go into committee for that purpose.

This was agreed to, and the various items having been explained, the Council resumed, and the report and recommendations were received and adopted.

House.

The report of this Committee stated that the house-porter was somewhat recovered in health, and was able to resume his duties, although not fully restored; he was at present sleeping out of the house, but no permanent arrangement had been made.

The report was received and adopted.

Benevolent Fund

The report of this Committee included a recommendation of the following grants:—

£10 to the widow of a registered chemist and druggist. Applicant has had two previous grants of like amount.

£10 to a former member (from 1844 to 1867). Applicant has had several previous grants, beginning in 1867, and amounting in all to £55. He is in very bad health, and unable to do anything.

£10 to the widow of a former member (from 1866 to 1872). Applicant has had three previous grants.

£10 to the widow of a registered chemist and druggist. Applicant has had three previous grants.

The death of Mrs. Trumper, an annuitant, was reported.

Mr. Shaw said the Secretary had stated that a considerable number of the subscribers of 1878 had not subscribed during 1879, and he should like to ask if he could account for that in any way. Another fact which arose out of the late election he wished to refer to, namely, it appeared that the interest taken by the members with regard to the privilege of voting was being reduced year by year. Four years ago upwards of 4000 voting papers were returned, but this year there was a falling off of nearly 1000, notwithstanding that there had been more subscribers. He should also like to know if it were the fact that those who employed canvassing cards were the most successful. He was glad to see that one man had succeeded in obtaining an annuity, viz., Mr. Hollinworth, whom on a former occasion the Committee had declined to relieve because he was still in business, but he believed he had received the largest number of votes this year.

Mr. Williams remarked that Mr. Hollinworth sent no cards out at all, therefore it did not appear that they were of so much importance. He himself had given his vote to Mr. Hollinworth, being, to some extent, influenced by the fact that he had not sent out cards.

Mr. HAMPSON thought the Council must wait for a more lengthened experience before it could draw any conclusions on this point.

Mr. ROBBINS said this might be a convenient time to make an observation with regard to the election, by which subscribers might profit in future. At the last election, as usual, many papers were sent in which were informal, the majority because the voters did not take the trouble to sign their names. But another point, which was perhaps still more important, was this. A very large number of subscribers, he found, from a very laudable desire no doubt, voted for as many candidates as their votes would allow, notwithstanding there were only three annuitants to be elected; thus, if there were eight candidates and a person had eight votes to give, if he gave one to every candidate they would all be in the same relative position as they would have been had he not voted at all, so that he might have saved himself this useless labour which at the same time gave the scrutineers an immense amount of useless work. He hoped the subscribers would use a little more discretion in future and only give votes to as many candidates as there were annuitants to be elected.

Mr. HAMPSON said it must be born in mind that any vote given to a candidate who did not succeed was carried forward to his credit another year, so that every vote given was of some value.

The SECRETARY said the number of voters this year was really in excess of those in the year referred to. The diminution to which Mr. Shaw alluded arose in this way, that the office now, for the purpose of saving the expense of postage, only sent one voting paper to each person entitled to vote, whether he were a member or a subscriber, whereas formerly it was the practice to send a voting paper to each member and associate, and an additional one if he were a subscriber to the Fund.

Mr. SHAW said he had received two papers himself, one having reference to twenty votes which he had in virtue of a donation he had made as treasurer of a fund, and he had another paper with regard to his own personal votes.

The SECRETARY said that was an exceptional case; he should be glad to send him two papers, or even three, every year under the same circumstances.

Mr. SHAW asked if the Secretary could tell the difference between the subscriptions in 1878 and 1879 in round numbers?

The SECRETARY said the number of persons who did not subscribe this year but did in 1878 was 273, representing about £120. There were, however, fresh subscribers in 1879 who were not on the list in 1878.

Mr. ATKINS thought there could not be any great difficulty in finding out why there were not so many subscribers. It was perfectly clear that in the depressed state of trade throughout the country, in which all shared, especially in the agricultural districts, most painfully, many persons could not afford to subscribe, and probably they would have to face the same thing in another form in the shape of an increased number of applications for relief. With regard to the question of canvassing, he had received no cards at all this last year, and his votes had been given perfectly free and unfettered. He regretted to say that the candidate for whom he had voted, considering it was one of the most deserving cases, was one of the failures, but he hoped he would meet with more success another year.

The report and recommendations were then unanimously adopted.

LIBRARY, MUSEUM AND LABORATORY.

The Librarian's report had stated that the average attendance during the preceding month had been, day, 10; evening, 19. Circulation of books, town, 182; country, 74. Carriage paid, £1 18*s*. 9*d*.

The following donations to the Library had been received and the Committee had recommended that the usual letter of thanks be sent to the respective donors:—

Attfield (Professor J.), Chemistry, General, Medical and Pharmaceutical, 7th (U.S.) ed., 1876. From Mr. H. C. Lea, publisher.

Chemists' and Druggists' Diary, 1880. From the Publishers.

Royal Botanic Society of London, Fortieth Annual Report, 1879. From the Society.

Royal Medical and Chirurgical Society, Medico-Chirurgical Transactions, 1879, v. 62. From the Society.

Royal Society of London, Catalogue of Scientific Papers, 1864–73, v. 8, 1879. From the Society.

Tommasi (Dr. Donato):

Nuove Prove in Conferma alla Teoria termica sullo Stato nascente dell'Idrogeno, 1879.

Recherches sur la Constitution des Hydrates ferriques, [1879?].

Sull'Equilibrio termico nelle Azioni chimiche, 1879.

Poggiale, Réduction du Chlorure d'Argent par Tommasi, 1879. From Dr. Tommasi.

The Committee recommended the purchase of the following books for the Library:—

Annals of Chemical Medicine, ed. by J. L. W. Thudichum, 1879, v. 1.

Cavendish (H.), Electrical Researches, ed. by J. C. Maxwell, 1879.

Flückiger (F. A.) and D. Hanbury, Pharmacographia, 2nd ed., 1879. 2 *copies*.

Landauer (J.), Blowpipe Analysis, Eng. ed., by J. Taylor and W. E. Kay, 1879.

Milne (A.), Manual of Materia Medica and Therapeutics, by W. Craig, 4th ed., 1879.

Morfit (C.), Chemical and Pharmaceutic Manipulations, 1850.

Pasteur (L.), Studies on Fermentation, translated by F. Faulkner and D. C. Robb, 1879.

Royal College of Physicians of London, Translation of the New London Pharmacopœia, by J. B. Nevins, 1851.

Stillé (A.), and J. M. Maisch, National Dispensatory, 2nd ed., 1879.

Thomson (A. T.), Elements of Materia Medica and Therapeutics, 1832–3. 2 v.

Thomson (T.), History of Chemistry, 1830-1, 2 v.

The Curator had reported that the average attendance in the Museum had been, morning, 12; evening, 4. He had received letters from two gentlemen, offering specimens for the Museum, and was authorized to accept such as he deemed desirable. An offer to sell specimens of thorite and euxenite had also been received, and acting on the advice of Professor Redwood the Committee had recommended that they be purchased.

The Professors had attended and reported on their respective classes.

A proof of the first sheet of the 'Historical Sketch' had been laid before the Committee by Professor Redwood.

The Council went into committee to consider the question of books missing from the Library. On resuming, the report was received and adopted.

DANIEL HANBURY MEMORIAL MEDAL.

Mr. WILLIAMS said the Council was aware that a memorial fund had been raised in honour of the late Daniel Hanbury, and Mr. Daniel Bell Hanbury, his father, had expressed a wish to have a copy of the medal. A silver copy of the medal had been struck, and was now before the Council, and he had great pleasure in moving that it be presented to Mr. Daniel Bell Hanbury. Those who knew what that gentleman had done for the Society would agree with him that it was only a proper and very inadequate compliment to be paid to him.

Mr. Squire seconded the motion, which was carried unanimously.

Reports of Committees—*continued.*

GENERAL PURPOSES.

The Council went into committee to receive the report of this Committee. It included the usual report of the Solicitor as to cases placed in his hands, enclosing cheque for a penalty and costs which had been received, and also correspondence with various parties.

Several other cases of alleged infringement of the Pharmacy Act were also reported, and in one case a prosecution was recommended.

The report also included a letter received from Mr. Greaves, of Chesterfield, resigning his office as Local Secretary.

The Council having resumed,—

The President moved that the report and recommendations be received and adopted. He said it would have been seen from the report that he had authorized the solicitor of the Society to attend at the Fareham Petty Sessions on the prosecution of Mr. Smith for the sale of cream of tartar said to be adulterated. He did that on his own responsibility, and he thought it right to report to the Committee and to the Council why he had done so, and to ask their approval. Certain words had been introduced into the Sale of Food and Drugs Act, at the instigation of the Society, namely, "Where the food or drug is unavoidably mixed with some extraneous matter in the process of collection or preparation," it should not be deemed an adulteration; the cream of tartar in this case was simply contaminated with the tartrate of lime which was inherent in its preparation, because, according to the Pharmacopœia, bitartrate of potash was to be made from argol, and argol contained tartrate of lime, therefore, he thought that any prosecution of a chemist for selling cream of tartar which contained no more tartrate of lime than 6 per cent. was a vexatious prosecution and a proceeding against which the Council ought to fight. For that reason he had authorized the solicitor to attend as he had previously authorized him to do in the Chertsey case. One great advantage resulted from the solicitor's presence, namely, that at his instance the magistrates granted the defendant his costs, limiting them, however, to three guineas. It was true it was a small sum, but a principle was involved, because it showed that the chemist left the court in a much better position, and that it was considered by the magistrates to be a vexatious prosecution. Arising out of this cream of tartar case, a suggestion had been made that the Council should endeavour to get some referee appointed, beyond the county or district analyst, before whom the adulteration of drugs should be considered before any prosecution was authorized, and it was not altogether inopportune at this moment, because there was now a public prosecutor appointed, who commenced his work at the beginning of the year, and if the Council could possibly make any representation to the Local Government Board which would prevent these vexatious prosecutions, it would be very well to do so. At the same time, he must say that he felt the Society stood on very delicate ground in this matter, because its members should be the last persons to encourage anything like a sophistication of drugs. That could not be too strongly put forward. Anything like real adulteration or admixture, whether injurious to the persons using it or lessening the effect of the article, would at once be discountenanced by that Society, and he did not wish it to be understood that it was its business to defend every one who was prosecuted for adulteration, but rather to establish a general principle that there were one or two articles, such as cream of tartar and sweet spirits of nitre, with regard to which action was taken some time ago, and there might be others, as for instance, scammony, to which the special provision he had just quoted would apply. If an analyst took a parcel of scammony he might find a small percentage which was not scammony at all; all authorities admitted there must be a certain percentage of impurity in it. But the analyst might say it was not the article demanded. In such cases the Society ought to come forward, but not in others, and he should be as careful as anyone to prevent the Society coming forward to hinder a prosecution for real adulteration.

Mr. Hampson thought the explanation of the President was extremely satisfactory. The members of Council must all feel that he had not in any way overstepped the limits of the discretion reposed in him. No one at that board had any desire to countenance adulteration in any possible form, but it must be remembered that that Society, besides having certain important public functions to carry out, was a society of members of the trade, and by its charter was distinctly empowered to protect those who carried on the business of chemists and druggists. Of course the Society could not defend every case that occurred, but it was desirable to take up any typical case, such as would give a warning to analysts who probably did not always understand their profession, or public bodies, when they undertook such vexatious prosecutions as this.

The Vice-President said when he spoke on this matter in committee on the previous evening he had been careful to say that he heartily approved of the course taken by the President; but he expressed his gratification that his action had taken that somewhat informal course, and he was anxious that when the matter was discussed something similar to what had fallen from the President should be stated. The President had made it clear that he had regarded the act as an exceptional one, and one that, if followed at all, must be followed with the greatest caution in the future. He knew it was according to a resolution passed some time ago that private prosecutions might be defended if after careful consideration the Council thought it desirable. That resolution was passed in opposition to his judgment, but it existed, and therefore must be acted upon. But in such cases as this he thought there was a better course open than mere defence, one which the President had hinted at, that the Council should endeavour to establish what might be a standard condition of purity which the law should sanction, or say that all cases should be referred to some such authority as that Society before an analyst was allowed to prosecute at all. Either of those courses would be much more worthy of the attention of the Council than the defence of individual cases as they arose, which must always, to the outside public, appear more or less—no doubt erroneously—as if the Society were defending an impurity, not necessarily an adulteration, but an impurity, which was an awkward position, and one which he should not like to see become the general view of the matter. With regard to this particular case, he did feel that defence of a second case was a little unnecessary. The Society's legal officer had been sent to attend one case, and had got a verdict which was published before the world, and he thought the Council might have rested content with that trial, and referred every other defendant who appealed to it to the case the Society had assisted in making public. Everything had been made clear about the cream of tartar and he did not think the work needed to be done all over again. Certainly he should not be in favour of defending another case next week if it occurred, however much he might approve of the President's action in the past. At the same time he was perfectly content with the declaration of the President as to what his course should be in the future.

Mr. Savage said that but for the observation of the Vice-President he should have thought the explanation of the President was ample to meet the case, but from those observations it seemed necessary that something more should be said. There was a very clear expression in the 6th section of the Sale of Food and Drugs Act, namely, "where the food or drug is unavoidably mixed with some extraneous matter in the process of collection or preparation;"—that was the precise case before them, and he took it if another case were to arise of a similar character the Council would be perfectly justified in taking the same course again. There he differed from the Vice-President; because whatever might have taken place in a case already decided, it must be clearly understood that the evidence adduced there went for nothing in another case; it was no evidence in a court of justice unless the facts were proved, and to do that you must have the solicitor there, and also the evidence previously given. It was necessary for the Society to justify the confidence placed in it, and come forward and support every case of this kind where it was found that injustice was being done to an individual.

Mr. Atkins expressed his gratification that the President had done what he had, and he was very thankful the law officer had been instructed to move in the matter. He maintained that the accused having come out of court in the way he had after the support he had received from that Council, was in a much better position than if he had simply defended the case at his own charge. It gave him a status which he could not otherwise have secured. Therefore he differed from the Vice-President on the general principle. It was not the first time he had heard it cogently argued from his point of view; but he entirely differed from him. The Pharmaceutical Society was formed, amongst other things, for the protection of those who carried on the business of chemists and druggists, and although it might not be desirable to repeat frequent defences of cream of tartar cases, still when a typical case occurred it was not only a privilege. but a duty to step forward and defend it. He would declare as emphatically as anyone that the Society utterly repudiated adulteration; but when it was believed, as in this case, that there would have been a maladministration of justice, seeing that the Society was not formed simply for the promoting of pharmacy, or of education, but to protect pharmacists, it was its duty to come forward. Many men could not efficiently defend themselves in such cases; they lost their nerve when prosecuted, and the Society could give validity to a defence which no individual man could. He knew that great satisfaction had been felt that the Society had acted in this matter, and he hoped the same course would be adopted in future.

Mr. Robbins thought the members of Council must all be satisfied with the step Mr. Sandford had taken in the matter, but they ought not to let it remain where it was. He quite sympathized with Mr. Schacht in his dislike to defending cases of adulteration. He himself would not vote for defending any cases of adulteration, but he contended that this was not such a case. The pure bitartrate of potash was not cream of tartar, but this was a very difficult thing for magistrates to decide, and the Council ought to come to some decision what amount of tartrate of lime in bitartrate of potash might be considered pure cream of tartar. If the Council could not define that point, how could the magistrates, who knew nothing whatever about the matter? He thought it was the duty of the Council to fix on some standard of purity.

Mr. Williams wished to remind Mr. Robbins that to fix a standard for a natural product was impossible. Analysts had tried to do so with regard to milk, but had not succeeded. So it would be found with cream of tartar made in various countries, and according as it was treated with what was called the plastering process or not, so there would be a variation in the amount of tartrate of lime. It was understood that the grape juice itself did contain tartrate of lime, but to what extent had never been established, and it would probably differ with the soil in which the grape grew. Some authorities went as high as 16 or even 20 per cent. of lime in perfectly natural and unadulterated cream of tartar, and therefore it would be quite impossible to fix a standard. He should like to make one more remark with regard to the position of the President. It was not fair that he should be appealed to and that he should have, without any advice, to take serious action in cases which did not give him time to summon the General Purposes Committee. He had before suggested that it would be a good thing for the Council to appoint a small sub-committee of some kind to be consulted by the President on any matter of importance which arose suddenly and required prompt action. The next case might not be of so simple a character, when the advice of a small committee would be both welcome to the President and to the general interest of the Society, and he should be inclined to give a notice of motion to carry out the suggestion.

Mr. Shaw said he understood the adoption of the report had been moved, and there was no amendment; and therefore he thought this discussion was rather irregular. The President had acted very properly in this case, and he hoped the result obtained for the first time of getting the defendant his costs would have the effect of putting an end to these vexatious proceedings.

The President said he was perfectly satisfied with the approval he had received from the Council and hoped no more time would be spent in discussing the subject.

The motion for the adoption of the report was then put and carried unanimously.

Weights and Measures.

The President said he had been informed the other day, by a maker of graduated measures, that he had applied to the city inspector to get his measures marked, and was told that no measure could be marked under the Act except those which contained a given measure as "level full." He (the President) felt that was altogether a mistake, and went to see Mr. Chaney about it. Mr. Chaney laughed at the idea, and said, "You will see our own standards are graduated up to a certain mark, not to the brim." The 46th section of the Act clearly provided for the making of graduated measures, because it spoke of measures partly composed of glass and partly of metal. Mr. Chaney told him that a great deal was in the hands of the inspectors. The Central Board would ultimately give out the standards to be used by all inspectors, but had not yet done so, and therefore the inspectors were not in a position to verify the measures. Still each inspector in his own district must administer the law to some extent according to his own judgment. Mr. Chaney also gave him a report by the Board of Trade, of its proceedings under the Weights and Measures Act, in which it was stated that every information would be given by the Central Board to the local authorities, and the latter were invited to communicate personally with the officer in charge of the standards, or if necessary, with the Assistant-Secretary of the Board. He suggested to Mr. Chaney that the Council might possibly send a memorial to the Board of Trade to endeavour to get some definite instructions sent to all the district inspectors so as to bring them into harmony with one another. It had already been suggested that there should be one uniform mark, and that separate districts should have a little distinctive mark in addition. The President then read the draft of a memorial which he thought it would be advisable to send to the Board of Trade or to Mr. Farrer.

Mr. Symes thought the Society, as a body, had wasted a deal of valuable time over this question, for it was not yet at all ripe. It had been taking cognizance of over-officiousness of local inspectors and giving them an importance they did not merit. He himself thought it would be better to let the matter ripen, for it would be probably years before the Act was carried into force in some localities, and in others perhaps it would never be enforced at all. He thought it would be much better, therefore, to wait until the matter was more ripe before taking further action.

Mr. Hampson said members of the trade were very anxious for information on this matter. He had been in correspondence with several persons who wanted to know how they could get their measures stamped, and who were in a state of trepidation lest they should be pounced upon by inspectors who did not understand their business. There was no doubt that inspectors would require a special education before they were able to carry out the Act of Parliament, but he somewhat demurred to Mr. Symes's remarks, and thought it would be very advisable for the Council to put itself in communication with the Government officers who had special charge of this Act, and, if possible, bring about a uniform method of inspection so as to avoid anything like officiousness or ignorant interference by the inspectors. He certainly thought it would be a long time before the Act was carried out, but there was a law in force, and the trade ought to be prepared for anything which might arise. He thought such a memorial as had been suggested would be a very valuable opportunity of leading the authorities in the right direction.

Mr. Shaw said he had been for many years acquainted with the inspector of weights and measures in Liverpool, who had sought information from him recently on various points. He told him that he had received from the head office in London his first consignment of measures for the purpose of verifying apothecaries' measures, including a 4 oz., 3 oz., 2 oz., 1 oz., ½ oz., 2 drachms and 1 drachm. These were metal cylinders which had to be filled to the brim. From what he stated it was optional with any local board or corporation to adopt the Act or not in reference to that district.

The President said they must all adopt the Act.

Mr. Shaw said he meant as to putting it in operation in their district. At any rate, it had been adopted in Liverpool, and that was the reason why the inspector had been in communication with the office in London. He was now waiting for the larger measures, such as the 30, 40, 20, and 10 ounce measures. He did not know how the verification would be accomplished.

Mr. Williams could not agree with Mr. Symes, that the Council or the Society had wasted time in considering this question. The apothecaries' weights and measures had now been legalized, and it would be a source of great annoyance to many members of the trade if they should be fined for the possession of weights and measures not stamped. Very possibly in some cases the law would not be carried out, but that would be the fault of the authorities, and the Council must assume it would be carried out everywhere. It was evident, however, that the local authorities required instruction, and it was in evidence that the central board was willing to give that instruction. Therefore he thought a memorial, such as proposed, should be sent from the Council, and if necessary, a deputation should wait on Mr. Farrer and settle any question which might arise. It was most desirable that if possible this instruction should be made so simple and uniform that members could not suffer vexatious prosecution.

Mr. Savage said that the Brighton Town Council refused to have anything to do with this Act for some time, but it had now ordered a set of weights and measures.

Mr. Gostling supported the proposition that a memorial be sent, and he hoped there would also be a short epitome of the regulations printed in the Calendar.

Mr. Symes said he did not oppose the memorial being sent; he only thought the Council had helped to fan the excitement which Mr. Hampson had spoken of, and so far, had done nothing to satisfy it.

Mr. Williams reminded Mr. Symes that the matter was forced upon the Council by the conduct of certain local officials in the north.

The following resolution was then carried unanimously, on the motion of Mr. Greenish, seconded by Mr. Williams:—

"That a memorial be presented to the Board of Trade, urging the necessity of uniform practice in verifying and marking measures in the various districts throughout the country."

Report of Examinations.

December, 1879.

Preliminary Examination.

2 certificates were received in lieu of the Society's Examination:—

1 College of Preceptors.
1 University of Cambridge.

On the motion of Mr. Schacht, seconded by Mr. Bottle, it was resolved—

"That the absence from the examination, of which they had given notice to attend, be excused in the case of certain candidates (*named in the Resolution*), a medical certificate in each case having been handed to the Secretary."

Inundations in Hungary.

The President read a letter he had received from Dr Paul, enclosing one from the President of the Pharmaceutical Society of Hungary, thanking the Members of the Council and other subscribers for the aid they had given to meet the distress amongst pharmacists occasioned by the recent floods in that country.

Provincial Transactions.

SUNDERLAND CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The general meeting of the Sunderland Chemists' Assistants and Apprentices' Association was held at the rooms, corner of William Street, on Monday evening, the 5th inst. The chair was occupied by the President, Mr. A. Harding. After some preliminary business had been settled the Secretary (Mr. J. J. Browell) read the reports of the last session. The number of honorary members is 26, of members 22; the average attendance at the meetings had been 12. The income of the past session amounted to £15 8*s*. 11*d*., the expenditure being £4 3*s*. 1*d*., leaving a balance of £11 5*s*. 10*d*. The Association is indebted to Messrs. Barron, Squire and Co. for a donation of £2 2*s*., and to Dr. Muter and Mr. Baxter for their liberal contribution of books.

The reports having been adopted, the President expressed his pleasure at the prosperous condition of the Association, as manifested by the balance in hand as well as by the attendance of members, which he hoped would increase still further, and in speaking of the progress which had been made during the past session congratulated the members on the establishment of the classes which had been formed, and said that he trusted the members would avail themselves of the opportunities now offered by the society and would attend as many of them as possible. A materia medica class had been arranged to be held fortnightly, conducted by Mr. T. Walton. A pharmaceutical chemistry class and botany class were held weekly by Mr. J. J. Browell. The fees of the chemistry class, amounting to 30*s.*, had been expended in the purchase of apparatus, etc. The President then thanked the members for the assistance they had rendered during the past session and hoped that the society would be as successful in the future as it had been in the past and that it would be a means of benefiting the members in more ways than one.

A hearty vote of thanks was accorded to the officers and committee, to those gentlemen who had assisted with contributions of money and books, to those gentlemen of the town who had come forward and given their interesting lectures, and to those members who had read papers.

The election of officers was then proceeded with, the following being the result:—Mr. J. J. Browell, President; Mr. A. Harding, Mr. R. H. Mushens, Vice-Presidents; Mr. C. Rankin, Secretary; Mr. J. Peacock, Treasurer; Mr. J. Humphrey, Librarian; Messrs. J. W. Robinson, R. Leithead, J. G. Johnson, J. Scelly, J. Whitfield, J. Cowey, Committee.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of the Association was held on January 1, 1880, at 32A, George Street, when a paper on the "Examination of Urine" was read by Mr. W. A. H. Naylor, F.C.S., who stated that the acidity of urine is now generally admitted to be principally due to the presence of the acid phosphate of sodium. Qualitative and quantitative processes, illustrated experimentally, were next given for the detection and estimation of uric acid, urea, sugar, albumen, etc., only those methods being recommended which had, in the author's hands, proved satisfactory. In conclusion the hope was expressed that pharmacists would give this branch of analysis the attention it deserves.

After the discussion, a vote of thanks having been proposed by Mr. James, seconded by Mr. Wallis and carried, the meeting terminated.

Parliamentary and Law Proceedings.

Poisoning by Morphia.

On Saturday, January 3, Mr. S. Collier held an inquiry at the Eagle Tavern, East India Road, Poplar, relative to the death of Lilian Selina Holt, aged five, which occurred on the previous Wednesday.

Selina Holt, mother of the deceased, said that on the previous Tuesday the child was unwell, and witness sent a girl named Hammond to Dr. Moore's surgery, at 50, St. Leonard's Road, for a powder. Deceased soon after having the powder given her went to bed, and complained of headache. About seven o'clock next morning her father found her dead in bed, and it was discovered that the powder which had been administered to her was composed of hydrochlorate of morphia.

Frederick Albert Hughes, a lad of thirteen, after being cautioned, stated that he was employed by Dr. Moore, and was accustomed to serve in the shop. Whenever persons called and asked for poisonous drugs he told them, in the absence of the assistant, to call again. A girl called about twelve o'clock on Tuesday, and stated that she wanted a powder for a child of five years. Witness took a bottle from a shelf and handed it to the assistant's wife, who, after placing some of the contents in a paper, handed it to the girl and charged her twopence for it.

Frederick M. Henbeck, L.S.A., assistant to Dr. Moore, said that at the time of the sale of the powder he was out visiting. When he returned the boy told him what had been given to the girl, and witness, finding that the powder had been taken from the bottle in question, exclaimed, "Good God, you have poisoned the child." Witness, not knowing the address of the parents, placed the matter in the hands of the police. The amount of morphia administered was six grains. Witness had repeatedly told Hughes not to serve in the shop. The bottle was labelled "Poison," and was identical in appearance with others on the shelf.

The boy Hughes (recalled) said that he did know what the contents of the bottle were. He admitted having been told not to serve, but on some occasions he was called upon to do so.

The assistant denied that his wife, who was unable through illness to attend and give evidence, served the powder as alleged by Hughes, and although the girl Hammond was called, she could give no positive evidence on the point.

Hughes insisted that the assistant's wife served the powder, and that he merely handed her the bottle.

Dr. Rugg gave evidence, to the effect that deceased died from the effects of the poison; and, after a lengthened inquiry, the jury returned a verdict of death from misadventure, at the same time expressing their opinion that there had been gross neglect on the part of those whose duty it was to attend to the management of the drugs. —*Daily Telegraph.*

The Sale of Vermin Killer.

On Monday, January 5, Mr. L. R. Rowbottom, the Wigan Borough Coroner, held an inquest at Scholes, touching the death of Lucy Fortune, the wife of a compositor, who had committed suicide by swallowing a quantity of vermin killer. After evidence had been given as to the circumstances attending the taking of the poison—

Francis Robert Dawson, registered chemist and druggist, King Street, Wigan, said he knew the deceased by sight. She had been an occasional customer of his, but he did not know of his own knowledge where she lived, or her name. On Wednesday evening last she came to his shop between six and seven o'clock, and asked for a sixpenny packet of Battle's Vermin Killer. He told her he had not got one in stock, but that he had threepenny ones, and she said she would have a threepenny one. He inquired what she wanted it for, and she said destroying rats. He entered the particulars in the poison book, and she signed it. Since Saturday he had weighed a threepenny packet, and previously he had weighed several. The one he weighed on Saturday was thirteen grains, that being the heaviest he had weighed. Some time before he weighed a similar parcel, and it only weighed six grains.

The Coroner: Then there was a difference of seven grains in one of these packets?

Witness: Yes.

The Coroner: You did not know that this woman was a married woman, and of your own knowledge you did not know where she lived. Would you have gone to 105, Scholes?

Witness: I would if I had wanted to find her.

The Coroner: And if you had not found her there, what then?

Witness did not answer.

The Coroner: Why did you not insist on that woman bringing in a witness when you sold her the poison?

Witness: Because it is not the custom of the trade.

The Coroner: Well the sooner it is the custom of the trade the better it will be. If you do not comply with the provisions of the Act of Parliament you will find yourself convicted in heavy penalties which will take the profits off the poison. You knew of your own knowledge that there was sufficient poison in one of these packets to kill anybody?

Witness: I did.

The Coroner: Why did you not insist on the woman bringing a witness?

Witness: If the person had been an absolute stranger I should have insisted on it.

The Coroner: You say you did not know her name, or where she lived. Do you call that knowing a person?

Witness: I knew her as an occasional customer. She had a very respectable appearance, and I knew her by talking to her.

The Coroner: The fact of the woman being a woman of respectable appearance does not prove your knowledge of her. Because she was an occasional customer you considered she was known to you?

Witness: I did.

The Coroner: That is your interpretation of the Act of Parliament?

Witness: It is.

The Coroner: On the 31st December I see you sold poison to other persons—did you know them?

Witness: I knew one of them by sight.

The Coroner: I suppose you take it for granted that if you know a person by sight and he makes a statement that statement is true?

Witness: If I have some knowledge before.

Dr. White said on Saturday morning he made a *post mortem* examination of the body of the deceased. There were no external marks of violence. The body was well nourished and the organs were generally healthy, excepting the vascular state of the stomach and old adhesions on the lungs showing pleurisy. The brain was healthy excepting the vascular state of the base of the brain and the spinal marrow. He had heard the evidence of George Fortune, senior, Mrs. Hodge and Mr. Dawson, and he had come to the conclusion that the woman died from taking poison. Battle's vermin killer, on the authority of Dr. Turner, consisted of flour, Prussian blue, sugar, and strychnia—the latter in the proportion of 23 per cent. Taking the average weight of one of the threepenny packets at 9 grains there would be very nearly 2 grains of strychnia in one. Half a grain of strychnia would be sufficient to cause death.

Mr. Dawson added that on Saturday he analysed a 13 grain packet of Battle's vermin killer and found 2½ grains of strychnia.

Dr. White said he knew the deceased was a very quiet, respectable woman and very anxious to get on.

This closed the evidence, and the Coroner proceeded to sum up. In the course of his observations to the jury he said there were very few Acts of Parliament through which it was impossible to drive a coach and four, and it seemed that the druggists were driving a coach and four through the Sale of Poisons Act. A registered chemist and druggist was entitled to sell poisons under certain restrictions, and one of those restrictions was that he was not to sell it to a person whom he did not know unless he had a witness with him. In this case the deceased was only an occasional customer, he did not know her name, he did not know where she lived, in fact he knew nothing about her, and yet he sold her sufficient quantity of poison to kill a dozen people. It seemed to him that Mr. Dawson had acted very carelessly, for if the woman had given a wrong address there would have been no means of tracing where she got the poison from. He (the coroner) did not believe that the Act of Parliament ever intended that druggists should be allowed to act in that manner. Mr. Dawson had been extremely negligent.

A Juryman: He deserves a good censure.

The Coroner: It is not for me to prosecute him; it is the duty of some other party if they think he has contravened the provisions of the Poisons Act.

The jury, after a short deliberation, returned a verdict to the effect that the deceased committed suicide while in a state of unsound mind.

Dr. White said the question might be asked how it was the contents of the woman's stomach were not submitted to a chemical analysis. He ought to tell the jury that poisoning by strychnia left very slight traces, and he did not think it worth his while to go to the trouble, seeing that there was no doubt as to the cause of death. He condemned the system of selling poisons to persons comparatively unknown to the vendors by chemists, and pointed out the restrictions that were imposed on surgeons in the use of poisons by the Vivisection Act. Something more should be done to limit their sale by other than medical men in view of the facilities that at present existed for obtaining them by people who wished to put an end to their existence.

The Coroner said he fully concurred in the observations of Dr. White, and several of the jurymen expressed similar opinions.—*From the Wigan Observer.*

Reviews.

THE NATIONAL DISPENSATORY, containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicines, including those recognized in the Pharmacopœias of the United States and Great Britain. By ALFRED STILLÉ, M.D., LL.D., and JOHN M. MAISCH, PH.D. With Illustrations. London: J. and A. Churchill, New Burlington Street. [Philadelphia, printed.] 1879. Large 8vo.

This is a very bulky volume of 1628 pages, closely printed, and may well have cost its compilers the "years of labour" they claim to have devoted to its preparation. For they have aimed to produce a digest of all that is of practical importance, not only in pharmacology strictly so called, but also in the medical domain of therapeutics. Clearly their difficulty has been to determine what to exclude without injury to the volume as a book of reference.

As is usual in "Dispensatories" the dictionary plan is strictly followed; every article, crude drug, or preparation being placed alphabetically by its first word. It is probable that this has been found by experience to be the most convenient mode for pharmacists. It would be an improvement to have a copious system of cross references; but this is to a considerable extent supplied by a very full index. For this is a very comprehensive book, and includes a vast number of substances. Besides the official drugs and preparations of the British and American Pharmacopœias, most of those of the German one and of the French Codex are included, and in addition a great number of non-official medicines more or less used find a place either as separate articles or as "allied drugs" under more important or better known substances. Probably the book may be fairly regarded as the most comprehensive of its class and as forming a very full dictionary of the materia medica of to-day. Information especially with regard to many of the drugs at present chiefly or entirely employed in America will be acceptable to English pharmacists.

As an example of the method of treatment the first article may be taken, *Absinthium*. There we find, after the pharmaceutical, botanical and vernacular names, a reference to figures of the plant and a short description, and then follows an account of the chemical constituents. A short description of other allied species of *Artemisia* comes in next, and then we have the pharmaceutical preparations, and an account of the physiological actions and the medical uses of the drug. *Mutatis mutandis* other articles are treated in a similar way or with even greater fulness. Thus the second article, *Acacia*, gives also accounts of the collection and commerce of gum arabic, of its alterations and substitutions; and of numerous other varieties of gum. In the case of mineral substances, of course much attention is necessarily given to the mode of production or preparation, to impurities and adulterations and the tests for them.

The nature of the work does not afford scope for much original matter, but the authors have thoroughly digested their mass of material, and present their *résumé* to the reader well and clearly. In the case of many native American plants somewhat full descriptions are given. Special care seems to have been taken also in the descriptions of the external characters of drugs. A rather striking feature in the book is the absence of all special references to other works, with the exception of the occasional quotation of a figure; much space has been gained by this, at some cost it must be allowed. Scattered through the text are about 200 selected woodcuts of small size and unequal value; some of the microscopic ones are very good.

The prominence given to the physiological actions of drugs is a somewhat novel feature in works of this class. This portion of the subject seems to us also to be particularly well done, the results of the most recent observations being given with brevity and clearness and in a manner which exhibits a full acquaintance with modern research in this important branch of medical science. In connection with the section on the medical uses of drugs is a very full therapeutical index, where drugs are placed under the headings of the various diseases and morbid states in which they are employed. An appendix contains tables of maximum doses of important drugs, of weights and measures and a list of reagents.

The treatment of substances having a definite chemical composition is remarkably good. The authors by no means restrict themselves to the consideration of those occurring in the various Pharmacopœias, but, as far as we can judge, no chemical having any kind of use in medicine or possessing general interest for the pharmacist is omitted.

The processes for their manufacture are clearly and accurately described. In those cases in which any practical difference exists between the processes in the British Pharmacopœia and in that of the United States, both are given in full, and the respective merits of each are impartially discussed.

As a matter of fact, it frequently happens that methods adopted in practical manufacture, on the large scale, differ very materially from those suitable for use by the pharmacist. When this is the case the authors do not fail to give a very readable account of one or more manufacturing processes. Such accounts generally contain a very fair amount of detail without being tedious, and are accompanied by explanatory and critical remarks, which are to the point.

Occasionally, however, exceptions here and there occur. Thus, the description of the preparation of glycerine is very meagre, and this is the more surprising since that body plays a very important part in American pharmacy. We may remark that Tilghman only is mentioned in connection with the manufacture of glycerine by the decomposition of fats by the action of water at an elevated temperature.

Tilghman's process certainly was the first which was applied for this purpose; but it served chiefly to lead up to the method by which nearly all the pure glycerine of commerce is now prepared, viz., the distillation process, first patented by Wilson and Payne in 1854.

The arrangement of matter is not always perfect. For example, under the head of "Properties" we find, in some cases, a description not only of the physical characters of a chemical, but its reactions, the tests for its purity and the methods for its volumetric or gravimetric estimation. In others this matter is divided under the separate heads of "Properties," "Tests," and 'Tests of Purity." Again, under tests may be included the ordinary analytical reactions which take place between the substance and various reagents; or, as is generally the case, a list is given of reactions which the body should *not* undergo in order to prove its freedom from certain impurities.

These are very slight blemishes and, speaking generally, we are bound to state that the articles on the various chemicals in use in medicine and of pharmaceutical interest are as interesting as they are accurate and instructive.

Amid so much excellence it may seem ungracious to point out any of the very few minor errors which occur, but it is impossible to pass without remark the fact that the formula of oxide of glyceryl is given as $C_3H_5O_3$, and those of stearin or tristearin, and of olein or triolein, $C_3H_5O_3$, $3\,C_{18}H_{36}O_2$, and $C_3H_5O_3$, $3\,C_{18}H_{34}O_2$, respectively.

Again, in commenting on the process in the British Pharmacopœia for the preparation of ferri phosphas, it is stated without qualification that the phosphates of iron are insoluble in acetic acid, and no account is given of the means suggested in this country from time to time for wholly precipitating the iron as phosphate. In describing the means adopted in the British Pharmacopœia for the estimation of red and pale bark, the process is said to be the same as for yellow bark, the authors forgetting to mention that chloroform is substituted for ether.

Pharmacy is perhaps the weakest part of the entire contents of the volume.

It must not be inferred from this that we consider the treatment of that subject wholly bad, but we mean that the character of the portion of the book devoted to pharmacy is by no means equal to the high-class quality of the remainder. The general article on pills, for instance, contains no matter that would be of any value to a pharmacist of any experience, while at the same time there is such an absence of detail as to render the article quite useless to a beginner. It would have been far better to have had no general article on the subject, and to have simply discussed the individual merits of each pharmacopœial pill mass.

The book is remarkably free from typographical errors, and the type itself is bold and clear.

The first edition of this work has already been exhausted and a second is being issued. We most heartily congratulate the authors on their well-deserved success, for we can cordially recommend this new 'Dispensatory' as a very valuable work of reference for the medical practitioner and pharmacist.

Year-Book of Pharmacy, comprising Abstracts of Papers relating to Pharmacy, Materia Medica and Chemistry, contributed to British and foreign journals, from July 1, 1878, June 30, 1879, with the Transactions of the British Pharmaceutical Conference at the Sixteenth Annual Meeting, held in Sheffield, August, 1879. London: J. and A. Churchill. 1879.

The Year-Book for 1879 has now, presumably, been issued to most of the members of the Conference, and no doubt most of the readers of this Journal will have already made an examination of the volume. It is not quite so thick a volume as that for 1878, which is due to the first portion, consisting of the introduction and the abstracts of papers published during the year only extending to 310 pages, instead of 390. It may be remarked, however, that the editor, in his Introduction, states that the majority of the abstracts in the present volume will be found to be more condensed than those in most of the previous volumes, although it is claimed that in no case has this abridgment been carried so far as to make the reader unduly dependent on the original article. This statement is fairly confirmed by an examination of the volume, and taken in connection with the evident careful selection of subjects may explain the limitation to the smaller number of pages. The Year-Book for 1879 is marked by the excellencies to which Mr. Siebold has accustomed us in former years, and also, we are bound to say, by the defective arrangement of subjects to which we have before now adverted. But it may be granted that since this is persisted in it is probably intentional, whilst the editor's *résumé* and the index will help to lessen any resulting inconvenience.

The 'Transactions' section of the volume consists of the usual lists of members, followed by the papers read at the meeting at Sheffield, and the discussions upon them, with which the readers of this Journal will be already familiar.

Obituary.

Notice has been received of the death of the following:—

On the 2nd of December, 1879, Mr. George Atkinson, Chemist and Druggist, Wolverton Station. Aged 35 years.

On the 13th of December, 1879, Mr. Samuel Hamand, Chemist and Druggist, Stoke, Devonport. Aged 70 years.

On the 14th of December, 1879, Mr. Robert May Rew, Chemist and Druggist, Regent Street, W. Aged 50 years. Mr. Rew had been a Member of the Pharmaceutical Society since 1870.

On the 20th of December, 1879, Mrs. Susan Trumper. Aged 71 years. Mrs. Trumper was elected an Annuitant on the Benevolent Fund in 1876.

On the 22nd of December, 1879, Mr. John Oates Clayton, Pharmaceutical Chemist, Lowerhead Row, Leeds. Aged 48 years. Mr. Clayton had been a member of the Pharmaceutical Society since 1854.

On the 23rd of December, 1879, Mr. Henry Charles Lowe, Chemist and Druggist, Brooks Bar, Manchester. Aged 57 years.

On the 26th of December, 1879, Mr. John Fegan, Pharmaceutical Chemist, High Street, Exeter. Aged 31 years. Mr. Fegan had been a Member of the Pharmaceutical Society since 1871.

On the 26th of December, 1879, Mr. George Allen, Chemist and Druggist, Congleton. Aged 35 years.

On the 27th of December, 1879, Mr. William Smith, Chemist and Druggist, Nottingham. Aged 45 years. Mr. Smith had been a Member of the Pharmaceutical Society since 1872.

On the 28th of December, 1879, Mr. John Wortley, Pharmaceutical Chemist, Market Place, Durham. Aged 47 years. Mr. Wortley had been a Member of the Pharmaceutical Society since 1856.

On the 31st of December, 1879, Mr. Thomas Haffenden, Chemist and Druggist, Dyke Road, Brighton. Aged 40 years. Mr. Haffenden had been an Associate in Business of the Pharmaceutical Society since 1868.

Correspondence.

"Cream of Tartar."

Sir,—By this time, one might have expected that the very absurd prosecutions in regard to "cream of tartar" would not again crop up. Why, may I ask, are public analysts so fond of making themselves ridiculous? Hardly one has escaped the lash of censure, and not one has proved himself worthy of that confidence which, as a good and worthy member of society, we should place in him. He is too keen, he wants more making-up, he seems ignorant of the good old knowledge hidden in the works of Thomson, Brande, Pereira and others. His new-fangled ideas when put to the test do not stand, and he is too proud to learn, although every facility is now afforded.

In regard to the recent case of prosecution of Mr. Smith, of Titchfield, let me ask, what are the special qualifications of the analyst, Mr. Arthur Angell? Did Mr. Angell consult any authority of note before giving his certificate? and if not, by failing to do so, he has indirectly sanctioned a prosecution which has only proved a police disaster.

I look upon the whole police business, in regard to the Sale of Food and Drugs Act, as a complete and ridiculous farce. The history of such adventures supports such an opinion, and I am laconically reminded of the sentiments of Paracelsus by these repeated prosecutions of cream of tartar vendors. I hope the police and public analysts have not experienced the sensations of Paracelsus when he bestowed the following invective on cream of tartar:—"It is called tartar because it produces the oil, water, tincture and salt, which burn the patient as hell does."

Thomson well says:—"According to him it is the principle of every disease and every remedy, and all things contain the germ of it."

I have no doubt the police and public analysts who have so conspicuously figured of late in these prosecutions have, by a kind of intuition unknown to their honoured personalities, drifted into Paracelsus's views. How otherwise are these puerile prosecutions to be accounted for?

Thomson says:—"All the specimens which I had an opportunity of examining, contained rather more than 5 per cent. of tartrate of lime."

Pereira says:—"As found in commerce it contains 2 to 5 per cent. of tartrate of lime."

Stillé and Maisch say:—"The amount of tartrate of calcium contained in crude tartar varies between 5 and 15 per cent."

In the purified salt, by careful management, it may be reduced to 3 per cent.

But this would enhance the price of cream of tartar so much as to positively crush it out of the market entirely.

A little calcium tartrate, in a medicinal point of view, can do no harm. I have not met with a single case of injury, and I cannot place my hand upon one which has been recorded.

The small quantity of barium sulphate is also innocent; and, even if it could be converted into a soluble or absorbable salt of barium the amount is so small that it could do no harm to the human system.

In the case of cream of tartar when no adulteration is intended, surely no fraud is meant or designed. Calcium tartrate is a constituent of grape juice, and it is soluble in water containing tartrates. In pure water it is almost insoluble.

The presence of a small, nay, a fractional part of barium sulphate, is not worth notice. Thus, we have got the Adulteration Act dragged through the mire, and the last absurd prosecution only shows how honest, upright men are paraded before benches of magistrates, as if it were a crime to act honestly and trade honourably, while quacks and charlatans, with all kinds of show and tomfoolery, base lying and deceit, escape police supervision. Truly, the laws of this country, and its law officers, are not in keeping with our generation, or boasted civilization, justice and probity.

Northallerton. Henry Brown.

"*Inquirer.*"—*India Rubber Cement.*—Probably the following, which has already appeared in this Journal, would answer your purpose:—One part of shellac to ten parts of liq. ammon. fort. (sp. gr. ·880), to be placed in a wide-mouthed bottle in a warm place and frequently shaken during three or four weeks. The mixture first forms a transparent mass, but afterwards becomes liquid.

J. Hicking.—Very much would depend upon the nature of the substance designated by the name. See upon this subject a paper by Mr. Martindale and subsequent correspondence, *Pharm. Journ.*, [3], vol. vii., pp. 471, 507 and 528.

"*Gwendolin.*"—(1) *Lolium perenne, β aristatum.* (2) Not sent. (3) *Holcus lanatus.* (4) The frothing is due to the presence of saponin.

"*Minor.*"—Recipes for preparing transparent glycerine jelly will be found in the number for November 30, 1878, p. 463, and elsewhere.

A. T. Smith—We would recommend you to apply to some medical authority for advice on the subject.

C. E. W.—See the 16th section of the Pharmacy Act, 1868.

Communications, Letters, etc., have been received from Messrs. Jackson, Reynolds, Wilkinson, Dewson, Jones.

CONTRIBUTION TO THE CHEMISTRY OF GURJUN BALSAM.

BY EDUARD HIRSCHSOHN, MAG. PHARM.

In my work, 'Contributions to the Chemistry of the more important Gum Resins, Resins and Balsams,'* will be found experiments which were made with a liquid sold as gurjun balsam. The sample I examined did not solidify on heating, showed a slight fluorescence, and did not give with nitric and sulphuric acids the violet coloration mentioned by Flückiger.† As no sample of the balsam described by Flückiger was at my disposal, I was unable at the time to determine whether any difference, other than the above-mentioned, could be detected between the two specimens by means of the reagents I had employed in the quoted work. Last year Professor Flückiger presented a sample of the balsam he had examined to the Museum of the Pharmaceutical Institute of this town, and the experiments made with this specimen, kindly placed at my disposal by Professor Dragendorff, and a sample of gurjun purchased at a neighbouring chemist's, yielded the following results.

Both samples showed a strong fluorescence in green, and formed on standing a deposit consisting entirely of crystals, the quantity of which in the last-named sample was small in comparison to that received from Professor Flückiger.

On heating in a test tube, the balsam from Professor Flückiger became quite solid, so that the tube could be inverted without any fear of the contents running out, while with the second sample a solidification appeared only after heating for a considerable length of time, and even then it did not become so thick as the first-named sample.

Alcohol (95 per cent.) dissolved both samples with the exception of a white residue.

Ether (*pure*) dissolved also incompletely. The cloudy mixture became on the addition of an equal volume of alcohol nearly clear, and the greater part of the deposit was taken into solution.

Ether and Alcohol (equal volumes) gave an opalescent solution.

Chloroform dissolved, forming a clear liquid.

Solution of Bromine (1 part of bromine in 20 parts of chloroform) added to the chloroformic solution of the balsam (3 drops balsam, 1 c.c. chloroform and 5 drops bromine solution) produced at first no appreciable alteration, but after a time the mixture became intensely green-coloured and retained this colour tolerably long.

Bisulphide of Carbon gave a cloudy solution with the balsam and the reagent recommended by Flückiger produced a deep violet coloration, which in Flückiger's sample was permanent for hours, whilst in the second sample it disappeared in the course of a short time.

Alcoholic Solution of Acetate of Lead (a saturated solution of acetate of lead in 95 per cent. alcohol) produced in the filtered alcoholic solution no change.

Alcoholic Solution of Ferric Chloride (10 per cent. in 95 per cent. alcohol) coloured the alcoholic solutions of the balsam darker.

Concentrated Sulphuric Acid dissolved the balsams with yellowish brown colour, and this solution with five to ten volumes of water gave a white milk; with three to five volumes of alcohol, a flesh-coloured mixture passing into violet.

Alcoholic Hydrochloric Acid (*i.e.* 95 per cent. alcohol saturated with gaseous HCl.) yielded with the balsam a yellowish red tincture, which on the addition of alcohol became violet.

Petroleum Spirit dissolved incompletely.

*Chloral Reagent** coloured both balsams, as well as the residue left on evaporating the petroleum spirit solution, deep green.

To allow of an easy comparison of the reactions previously, and those now obtained, I have tabulated the results as follows.

	Flückiger's Gurjun Balsam.	Gurjun Balsam (*Archiv. d. Pharm*, vii., 6, 1877).
Ether	Solution incomplete.	Incomplete.
Alcohol	" "	"
Ether-Alcohol . .	" opalescent.	Perfectly clear.
Chloroform . . .	" clear.	Incomplete.
Solution of Bromine.	Green coloration.	Yellowish coloration.
Chloral Reagent . .	Green.	Green.
Flückiger's Reagent.	Violet coloration.	Bright yellow coloration.

As will be seen from the above table the two samples of true balsam now examined differ from the one previously experimented upon: (i) in the Flückiger reaction; (ii) they are completely soluble in chloroform, and (iii) give with solution of bromine a green coloration. The slight difference between Professor Flückiger's sample and that from a chemist in this town is due, I am convinced, to the presence of alcohol in the latter, for if it be freed therefrom by distillation the two give identical reactions.

The true gurjun balsam differs from copaiva balsam:—

(i) in the violet coloration produced by Flückiger's reagent in the bisulphide of carbon solution;

(ii) in the incomplete solubility in ether (copaiva balsam gives a clear solution);

(iii) in the negative behaviour of acetate of lead to the alcoholic solution. (Copaiva balsam gives a cloudiness which on warming disappears.)

Dorpat, Russia.

* *Archiv der Pharmacie*, vii., 6, 1877.

† Flückiger proceeded as follows:—One drop of the balsam is dissolved in twenty drops of bisulphide of carbon, and one drop of a previously cooled mixture of concentrated sulphuric and nitric acids added and the whole well shaken. 'Jahresbericht für Pharmacognosie, etc.,' 1876, p. 220.

* *Archiv. der Pharmacie*, vii., 6, 1877.

THE FUNCTION OF CHLOROPHYLL.

The following is a more detailed abstract of the very important communication recently referred to in *The Month* as having been made to the Berlin Academy of Sciences, by Dr. Pringsheim, which appears to throw considerable fresh light on the function of chlorophyll in the life of the plant.

Having been led by previous researches to the conclusion that important results might be obtained by the use of intense light, Dr. Pringsheim contrived an apparatus by means of which the object under view should be brightly and constantly illuminated by a strong lens and a heliostat. If in this way an object containing chlorophyll—a moss-leaf, fern-prothallium, chara, conferva, or thin section of a leaf of a phanerogam—be observed, it is seen that great changes are produced in a period varying from three to six or more minutes.

The first and most striking result is the complete decomposition of the chlorophyll; so that in a few minutes the object appears as if it had been lying for some days in strong alcohol. Although, however, the green colour has disappeared, the corpuscles retain their structure essentially unaltered. The change then gradually extends to the other constituents of the cell; the circulation of the protoplasm is arrested; the threads of protoplasm are ruptured and the nucleus displaced; the primordial utricle or ectoplasm contracts and becomes permeable to colouring substances; the turgidity of the cell ceases, and the cell presents, in short, all the phenomena of death.

That these effects are not due to the action of the high temperature to which the cell is exposed under these circumstances, is shown by the fact that they are produced by all the different parts of the visible spectrum. The result is the same whether the light has previously passed through a red solution of iodine in carbon bisulphide, through a blue ammoniacal solution of cupric oxide, or through a green solution of cupric chloride. If the carbon bisulphide solution of iodine be so concentrated that only rays of a greater wave-length than 0·00061 mm. can pass through it, these effects are not produced, although about 80 per cent. of the heat of white sunlight is transmitted. On the other hand, if the ammoniacal solution of cupric oxide be so concentrated that the whole of the waves of a less wave-length than 0·00057 mm. are absorbed, a rapid and powerful effect is produced, although the amount of heat that passes is very small. It is thus shown that the phenomena in question are not the result of heat.

The next point determined by Dr. Pringsheim is that the effects are not produced in an atmosphere devoid of oxygen. This was the case whether the oxygen was replaced by pure hydrogen or by a mixture of hydrogen and carbon dioxide; while the removal of the carbon dioxide from atmospheric air was altogether without effect on the phenomena. The conclusion drawn is that the decomposition of chlorophyll in the living plant is a process of combustion, which is influenced and promoted by the action of light, and which is not related to the decomposition of carbon dioxide by the plant. When the green colour of the chlorophyll-grains has been partially destroyed, it cannot be restored, even though the cell continues to live; from which it is inferred that the result is not a normal physiological, but a pathological effect. No substance was found in the cells which might be regarded as the product of the decomposition of the chlorophyll, nor was any oil or starch detected in the etiolated cell, nor any formation of grape sugar or dextrin. The assumption is therefore that the products of decomposition are given off in the gaseous form.

The conclusion is drawn that the decomposition produced in the protoplasm and in the other colourless cell contents is the direct effect of the photochemical action of light. That it is not due to the injurious influence of the products of decomposition of the colouring matter of the chlorophyll is shown by the fact that it takes place equally in cells destitute of chlorophyll, such as the hairs on the stamens of *Tradescantia*, the stinging hairs of the nettle, etc. It is, on the other hand, dependent on the presence of oxygen, or is a phenomenon of combustion.

The result of a variety of experiments leads Dr. Pringsheim to the important and interesting conclusion that the chlorophyll acts as a protective substance to the protoplasm against the injurious influence of light, diminishing the amount of combustion, or, in other words, acting as a regulator of the respiration.

He then proceeds to investigate what are the substances which become oxidized in the process of respiration. In every cell, without exception, that contains chlorophyll, Pringsheim finds a substance that can be extracted by immersion in dilute hydrochloric acid for from twelve to twenty-four hours, to which he gives the name *hypochlorin* or *hypochromyl*, and which he believes to be the primary product of the assimilation of the chlorophyll. It occurs in the form of minute viscid drops or masses of a semi-fluid consistency, which gradually change into long red-brown imperfectly crystalline needles. It is soluble in alcohol, ether, turpentine, and benzol, but insoluble in water and in a solution of sodium chloride. It becomes gradually oxidized on exposure to an imperfectly crystalline resinous substance. It is probably an ethereal oil and an invariable accompaniment of the colouring substance of chlorophyll, and even more universally distributed than starch or oil. It has not yet been detected in those plants which do not contain true green chlorophyll, such as the Phycochromaceæ, Diatomaceæ, Fucaceæ, and Florideæ. Starch and oil appear to be reserve substances, produced by the oxidation of the hypochlorin under the influence of light; it being the most readily oxidizable constituent of the cell, more so even than the chlorophyll itself.

That the hypochlorin is present in variable quantity in every chlorophyll grain under normal circumstances, and is subject to continual increase and decrease, may be proved without difficulty. All comparative observations on chlorophyll grains in younger and in older conditions point unmistakably to the conclusion that the collection and increase of the starch enclosed in the ground-substance of the chlorophyll goes on *pari passu* with a decrease of the hypochlorin. In dark the hypochlorin, which does not take any direct part in the transport of food materials, is more permanent than starch; and this again is in agreement with the conclusion that its transformation in the cell into more highly oxidized bodies is hindered by the increased respiration in light.

In the facts here described and the conclusions derived from them, Dr. Pringsheim believes that an entirely new light is thrown on the cause of the well-known fact that assimilation takes place only in those cells of the plant which contain chlorophyll, and only under the influence of sunlight. This substance acts universally as a moderator of respiration by its absorptive influence on light, especially of the red rays, and hence allows the opposite phenomena of respiration and elimination of carbon dioxide to go on in those cells which contain it. A more detailed account of the experiments and results is promised by the author in a future paper.

THE ELECTRIC LIGHT IN AMERICA.

The following interesting letter upon this subject, dated New York, December 30, appeared in the *Times* of Monday last:—

Within the past two weeks Mr. Edison, the inventor, has stumbled upon something which at last bids fair to solve the problem of the illumination of dwellings with electricity. Up to the present winter the efforts of Mr. Edison have been dead failures. All the startling announcements made in his behalf have been premature. None of them have been justified by the facts. They indicated what the inventor hoped to accomplish, not what he had actually accomplished; and as, latterly, it had gradually been making itself known that Mr. Edison had failed, there was beginning to be great scepticism in the public mind as to his ever accomplishing anything important in this field of experiment. About two months ago Edison abandoned his platinum lamp altogether and began to experiment with carbon. He has now hit upon something by accident which not only astonishes the public, but more especially himself and the men in his shops. The most astonished man is certainly Edison himself.

The shops at Menlo Park, a flag station on the Pennsylvania railroad, sixty minutes' ride from New York, were established four or five years ago. They were devoted to the manufacture of electrical apparatus, the perfection of the telephone, the phonograph, the motor, etc. In the summer of 1878 experiments began to be made with the electric light. Edison supposed at first that the whole battle was won when he had found a plan to divide the electric current. He adopted for a lamp a coil of platinum wire, and endeavoured to perfect a regulator of the current which would allow the coil to become luminous without becoming so hot as to melt. He laboured diligently to perfect this device until about two months ago. About 17 feet of fine platinum wire were used in his coil. His first trouble grew out of the tendency of the current to form a voltaic arc between adjacent parts of the coil. Every time that an arc was formed his wire melted and disappeared in a flash of sparks. To insulate the coil with some material which would also become luminous was his constant effort. Zinc was tried and other materials. Wire made of iridium and other hard metals and various minerals were used, but all without success. Then the idea of enclosing the wire in a globe of glass from which the air had been exhausted occurred to him. Weeks and months of costly experiment with this idea followed. The vacuum was useful, as it economized force. The radiation of heat was not so great in a vacuum, and a larger proportion of the energy of the current was saved for maintaining the luminous incandescence of the wire. The experts foresaw failure long before Edison did; and, finally, Edison himself reluctantly came to the conclusion last fall that he was on the wrong track entirely. The man wore himself out very nearly, and the disappointment almost sent him to his grave.

About two months ago the inventor resolved to test the utility of carbon. He was determined not to surrender until that had been done. What inspired him to make this departure was a trivial incident. One day he was busy with some lamp-black and tar, with which he was making some wafers for a telephone. Happening to rub some between his fingers, he found he could draw it out into a thread. The thought came into his mind, "Why can I not make a carbon wire for an electric lamp?" After a little consideration, he began a series of experiments in this direction. He found that he could easily make a carbon wire, as had occurred to him, and that a burner for a lamp could be made from it. After several weeks of effort, he found that a carbon wire, enclosed in a hermetically sealed glass globe, from which the air had been exhausted, would do well for a short time. It made a good light, and was satisfactory in that respect, but it was not durable. Invariably it was soon consumed. He then thought of the idea of taking a simple cotton thread, carbonizing it in a retort, and making coils out of that. All sizes of thread and twine were tried. But even this material would not do. The texture of the carbonized thread was too loose. The material was better than lamp-black and tar, but was not good enough. Then Edison tried common paper. He cut out thin strips of various kinds of paper, which he carbonized as before, by laying them between sheets of tissue paper, enclosing them between cast-iron plates, and subjecting them to intense heat in a muffle furnace. The slips were cut out in the form of a horseshoe. One of these slips, made from Bristol board, was enclosed in a vacuum (if that be a proper expression) in a glass globe; the electric current being conducted to and from it by means of platinum wires. This was three or four weeks ago. The lamp thus made was tried. The horseshoe of carbonized paper became incandescent, and gave a beautiful mellow light, equal to that of one gas burner. It did not consume, and it lasted very well during the first day of experiment. Next day the same lamp was tried again. It behaved beautifully, somewhat to the surprise of Mr. Edison and his assistant. Both men now became very much interested. They instructed their glass-blower to make several lamps with great care; the pump perfected by Crook and Sprengel was used to exhaust the air from the globes; and particular attention was paid to the matter of sealing the stems of the globes (which was done with a blow-pipe). About two weeks ago experiments began with these lamps. They all behaved well, and a few days more served to show that a valuable invention had finally been evolved from the busy brain of the philosopher of Menlo Park. In fact, the lamp appeared to be complete.

A whole crop of new questions now sprang into view, one of them being the durability of the new style of incandescent carbon under a strong current. This question was readily disposed of. One lamp was raised to a power of thirty gas burners with perfect safety, and the capacity of the paper carbon to withstand an intense current appeared to be proved. As it is not the intention of Mr. Edison to make lights for dwellings of greater power than one or two gas burners, he considers that this part of the problem is disposed of. If a burner can be made to give the light of thirty gas burners with safety, it can surely be relied upon to give the light of one or two. Then came up another question. Ten lights could be maintained in the laboratory with the expenditure of one horse power, or eight net in a dwelling. In practical use the current would be turned off and on suddenly. Would not the sudden turning on of a current of electricity, equal to one-eighth of one horse power, rupture the carbon in time? One-eighth of one horse power will drive several sewing machines, and when administered in the form of a blow is all a man would ever wish to have applied to his person. One of the men in the shops was detailed to turn on and off the current of electricity at one of the lamps. The man did this 5000 times, which would be about the number of times that a lamp would be lighted in a dwelling in the course of ten or twelve years. The lamp withstood this test perfectly. Various other questions came up and were promptly solved in the same manner by actual experiment. The state of feeling which reigned in the shops at Menlo Park as these experiments went on, and as it was found that the lamps sustained every test, can better be imagined than described. Every man, from Mr. Edison down, was first astounded and then exhilarated. They have had so many failures that they can now scarcely believe their senses.

There are now forty-five lamps lighted every evening at Menlo Park, and the number is being increased as fast as the lamps can be made. Two or three of the dwellings in the village have been supplied with them, and a dozen or more street lamps along the road leading to the railway station have also been furnished with them. The others are in the shops. One of the latter has now been in use day and night for fifteen days, and is as good as when first put into operation.

The invention of this new lamp has not produced any very striking effect in regard to gas stocks here yet. Scepticism in regard to Mr. Edison's achievements is too strong yet. But a very decided effect has been produced with reference to the stock of Mr. Edison's Electric Lighting Company. There are 3000 shares in the capital of the company, the par value of each being 100 dollars. This stock was down to 20 dollars a share last summer, and a large number of the present holders bought at that price. The rise in value during the last two weeks has been enormous. The Hon. Roscoe Conkling, United States Senator from New York State, bought several shares this past week, and paid 3000 dollars apiece for them. August Belmont, the banker, has bought during the past week at 3500 dollars a share, and will take all that are offered at that price. Drexel, Morgan and Co., bankers, who are already large holders, and, in fact, the principal owners, are also buying at similar prices. There has been nothing like it in the history of stocks in New York city. Very few large holders of shares in the Edison Company are now willing to sell at 3500 dollars; and the majority of the small proprietors are demanding and waiting for 5000 dollars a share. The stock may never go to that height, because experiment may develop defects in the new lamp not yet observed; but the feeling in the company now is one of perfect confidence that the problem of household illumination has been solved, and higher quotations are predicted by them. The company is composed of merchants and bankers of high standing, and few of them are willing now to sell out except for very great inducements.

Mr. Edison himself does not indulge in extravagant assertions. I had a long talk with the inventor to-day, and went with him all over the shops, learning every detail of construction of the lamps and examining the generators, air-pumps, furnaces, motors, and other apparatus. Mr. Edison makes no predictions, but says that he is going on until he has one hundred and fifty lamps of the new pattern burning in the dwellings and streets of Menlo Park. It is his own test of the merits of the new lamp, the object being to develop defects. A few weeks from now he will be able to formulate a clear opinion about the merits of the invention. Wires are meanwhile to be run down to the village of Rahway, four miles distant, in order to test the difficulties of distributing the mains and lamps over a large area. Until the *data* afforded by the whole of this test are collected, Mr. Edison will not declare his final opinion about this matter. He believes, however, that the new lamp can be distributed over a large area, and houses lighted therewith, for the same price as now paid for gas, possibly less, but of the latter he is not certain. The lamps are four inches high, are simplicity itself in construction, and will cost to construct only 25 cents. apiece.

The Sawyer lamp has been left far in the rear by the new invention. Mr. Sawyer has never been able to produce a perfect vacuum, nor to produce a lamp comely enough to be a desirable part of the furniture of a dwelling. It is a straight glass tube ten inches or twelve inches long, and one and a half inches in diameter, and is filled from end to end with heavy copper coils and other apparatus. The light is produced by the incandescence of a pencil of carbon. The tube is filled with nitrogen gas, and sealed at the bottom into a copper base with wax. The light is an extremely beautiful one, mellow as the sunlight, capable of being turned up and down at pleasure, and in every respect delightful; but the apparatus is clumsy and not adapted for the interiors of tastefully furnished dwellings. The lamps will burn five hundred hours and cost 10 dollars apiece. Mr. Edison's lamp is only four inches long. It is sealed with the aid of a blow-pipe, and is thus proof against the accidents to the sealing-wax to which the Sawyer lamp is liable. The vacuum within it is almost perfect. It is comely enough for any apartment. Mr. Cyrus W. Field has lately lent his name towards the formation of a company, with a capital of 1,000,000 dollars, to take up the Sawyer lamp, and introduce it into factories, warehouses, mines, railway stations, public halls, dry docks, and hotels. It has been intended to build a factory, and go into business on a large scale. What the effect of the discovery by Mr. Edison will be on the future of the Sawyer company cannot be predicted, but it is believed that a complete reconstruction and simplification of the Sawyer lamp have now been made necessary.

The only other system which is making any headway in the United States at the present time is that of Mr. Charles F. Brush, of the city of Cleveland, Ohio. It is the one system employing the voltaic arc and automatic regulator for the illumination of large buildings which has emerged from the large crowd of its competitors, and is coming into practical use. The Brush light flickers now and then, but is steady enough for all practical purposes. An arrangement has been made by means of which any number of lights, from one up to twenty, may be run with one machine in one circuit, the power absorbed being exactly in proportion to the number of lights used. It requires fourteen horse power to maintain eighteen lights. This system has now been tried for one year, and is found to meet all the purposes of illumination in factories, warehouses, and large stores. The system is now *un fait accompli*, and it is coming into general use very rapidly. Nineteen-twentieths of all the electric lights in use in industrial establishments in the United States are those of Mr. Brush. They are employed in cotton factories, rolling-mills, printing offices, and stores. The lamps are of two thousand candle power each. They consume from one and a half inch to two inches of carbon per hour, costing about 1 cent. There are now eight hundred of them in use in the United States.

With reference to cost, the experience of the Conant Thread Mills at Pawtucket, Rhode Island, may be cited. There are 38 of the Brush lamps in those mills, replacing 500 gas-jets. The cost of the plant is 2000 dollars, with 65 dollars for each lamp. The carbons are found to cost 1¼ cent. per hour per lamp. One man spends a quarter of his time attending them, which will cost 3 dollars a week. The company finds that the total cost of running the 38 lamps is about 1 dollar 16 cents. per hour, which is a great saving of expense, because the gas formerly consumed cost 5 dollars an hour.

The Riverside worsted mills at Providence, Rhode Island, have been employing the Brush electric light since February last. The company were sceptical at first, but allowed the light to be introduced in the first instance at the expense of the Electric Supply Company. Twenty lamps were hung in the weaving-room, 110 feet long by 100 feet wide, where 110 broad Crompton looms are in operation. The porcelain globes which surround the lamps were painted white on one side, the side toward which the men look; the other two-thirds were clear glass, thus throwing the whole light on their work. The 20 lamps replaced 250 gas-burners. Since February 60 more lamps have been introduced to the mill, and the whole 80 have been subjected to the best test ever made in this country. The manager of the mills has given me the following *data* as the results of his experience with the light:—

"Cost of a 16-light machine, 2000 dollars; cost of double lamps (containing an extra set of carbons into which the current may be switched when the whole set is burnt), each, 80 dollars; number of gas-burners replaced by the 80 lamps, 1000 dollars; cost of 1000 gas-lights formerly per hour, 12 dollars 25 cents.; cost of 80 electric lights per hour, 80 cents.; candle power of the 1000 gas-jets (15×1000), 15,000; candle power of 80 electric lamps (2000×80), 160,000."

Of course, less light would answer in the factory, but the increase of illumination is very much liked. The light is strong, steady, and fine.

The Brush lamp has now taken its place in this country among the other ordinary wares of the market, the utility of the system having been fully demonstrated.

No progress is now being made with the Fuller system. The untimely death of the inventor, just as he was on the verge of success, has proved a great blow to the company.

EXPERIMENTS ON THE COMPARATIVE VALUE OF SOME EXTRACTS OF NARCOTIC PLANTS.*

BY H. BRETET.

The following account of some experiments, limited to the extracts of narcotic plants, have for their object to attract the attention of pharmacologists to the proportion of alkaloids contained in each of different extracts yielded by the same plant.

The Codex admits two extracts of these plants—the alcoholic extract and the extract of the defecated juice. Many medical men prescribe also the aqueous extract or extract prepared by infusion, which, consequently, is kept in pharmacies and is met with also in commerce. I am ignorant as to what motive has caused a preference for the juice extract, which, rationally, ought to be the least active. In fact, even with the best press, the plants retain always at least a fourth part of the natural juice; there would always therefore be a fourth part of the alkaloid lost, assuming that the whole of these were in solution in the plant juices, which is far from being the truth, and it is very evident that the exhaustion of the plant, green or dry, by two infusions and successive pressings is much more complete. The large quantity of product thus obtained has probably led to the supposition that it is produced by the addition only of inert matters to the juice, and that, weight for weight, the extract so obtained is less active; the contrary, however, is the result shown by the titrations I have made.

The only figures that I have been able to find relative to the richness in alkaloids of the extracts upon which I have worked have been published by Dragendorff.* These figures are of very great interest, but they do not allow of comparison; since for that purpose it is absolutely necessary to operate upon extracts yielded by the same plant.

My first experiments were made upon conium. 10 kilog. of leaves yielded 210 grams of extract of defecated juice. I exhausted the residue from this operation with boiling water, by means of two successive infusions, and obtained thus 500 grams of solid extract. To estimate the conia in these extracts I operated upon 10 grams of each. The extract was dissolved in 30 grams of distilled water and 2 grams of bicarbonate of soda were added to the solution. When the reaction had terminated the liquid was shaken with 100 c.c. of rectified ether every ten minutes during two hours; the ethereal liquid was then separated and the agitation was repeated with a fresh quantity of ether. The united ethereal liquids were shaken with 60 grams of water acidulated with sulphuric acid during half an hour, after which the acid liquid was treated with Mayer's reagent (iodide of mercury and potassium) in considerable excess. After twenty-four hours of contact at a temperature of about 30° C. the liquid was filtered, the residue dissolved in 93° alcohol, and this solution evaporated in a previously weighed capsule,—first in a water-bath, and then in a stove at 100° C.,—until the weight was constant.

The residue left by the extract of the defecated juice weighed 0·074 gram.

The residue of the infusion extract weighed 0·105 gram.

The double iodide of mercury and conicine contains 17·69 per cent. of alkaloid. It results from the foregoing experiment that—

* *Répertoire de Pharmacie* for December, 1879, p. 537.

† 'Analyse Chimique de quelques Drogues Actives,' 1876.

10 gr. of extract prepared from defecated juice of conium contained 0·01309 gr. of conicine;—and

10 gr. of extract prepared by infusion from the same plant, after being deprived of juice contained 0·01857 gr. of conicine.

In another comparative experiment, made with an extract prepared from the juice and one prepared by direct infusion of the fresh plant,—

10 gr. of extract from juice contained 0·0159 gr. of conicine.

10 gr. of aqueous extract contained 0·0329 gr. of conicine.

These figures, which, while differing considerably from the former, show results tending in the same direction, were obtained by the same process.

This process is imperfect in itself, when applied to conium, because the salt of conicine is rather soluble in water; therefore I give the preceding figures only as terms of comparison, but as such they have their value, because the manipulation was the same in the smallest details in all the operations.

For plants containing fixed alkaloids, —belladonna and datura,—I have completely modified the analytical method. 10 grams of extract are dissolved in 15 grams of water and 2 grams of bicarbonate of soda added to the solution. When the evolution of gas has terminated I mix the liquid with 10 grams of well-washed wood sawdust* and dry completely in a water-bath; the powder is then introduced still warm into a displacement apparatus and chloroform poured upon it. After twelve hours' contact, the lixiviation is continued with 250 grams of chloroform, and the last portions driven through with water. The chloroform solution is received in a flask containing a titrated solution of sulphuric acid corresponding to a determined volume of an alkaline solution. The chloroform being distilled, the cooled acid liquor is thrown upon a small moistened filter, the flask and the filter being rinsed with water until the united liquids measure 60 c.c. A solution of alkaloids is thus obtained, in which the acid in excess is neutralized by a titrated solution of potash, the volume used giving, by difference, the quantity of alkaloid.

When operating upon alcoholic extracts, it is necessary to modify this process still further, otherwise it gives figures much above the reality and differing among themselves for the same extract.† In estimating these extracts I do not distil off the chloroform, but agitate in the cold with the acid solution, which is afterwards separated by means of a separating funnel. The chloroform, retaining the chlorophyll, is again shaken with distilled water, which is afterwards added to the first solution. The titration is then made as in the other extracts.

I analysed by this method a certain number of extracts of belladonna and datura from various sources; afterwards I made the following experiment:—

Two stalks of belladonna yielded 1550 grams of stripped leaves; these were divided into two equal parts, one of which was dried and yielded 122 grams of extremely dry leaves.

The 775 grams of fresh leaves were bruised and the juice was removed by strong pressure and clarified in the ordinary manner. The coagulum (A) produced by the clarification of the juice was collected carefully. While moist it weighed 20 grams; after drying in a stove its weight remained at 4 grams. It was put aside for the estimation of the atropine.

The clarified juice gave 23 grams of extract of pilular consistence (B).

* The sawdust is cleansed by long boiling in dilute caustic soda, then washed by decantation, first with pure water, next with acidulated water, and finally again with distilled water.

† I am unable at present to explain these variations except by hypotheses, which I refrain from mentioning, wishing to remain absolutely within the domain of facts.

The leaves from which the juice had been removed were exhausted with boiling water and gave 12 grams of very firm extract (C).

The dried leaves were pounded and gave 104 grams of semi-fine powder. 52 grams of this powder, exhausted with boiling water, yielded 18 grams of aqueous extract (D). 52 grams, exhausted with 60° alcohol yielded 16 grams of alcoholic extract (E).

The four extracts were titrated by the process just described. As to the coagulum, 2 grams of bicarbonate of soda were dissolved in 10 grams of water, the coagulum was suspended in this liquid, and then the whole was dried in a water-bath. The powder resulting from this operation was introduced into a displacement apparatus and treated similarly to the extracts.

The alkaline solution employed to saturate the acid contained 1·75 gram of pure and perfectly dry potash per 100 c.c.; consequently each tenth of a cubic centimetre represented 0·00175 gram of potash. The equivalent of this base being 56·11, and that of atropine 289, each division of the alkaline liquor corresponded to $\frac{0·00175 \times 289}{56·11} = 0·009013$ of atropine or daturine, the elementary composition of these alkaloids being the same.

10 c.c. of acid liquor—that is to say the quantity employed for each operation—were neutralized by 90 divisions of the alkaline liquid.

The liquid from the coagulum (A) required only 85 divisions.

The liquid from the extract of the juice (B) required only 86 divisions.

The liquid from the extract (C) required only 82 divisions.

The liquid from the aqueous extract (D) required only 82 divisions.

The liquid from the alcoholic extract (E) required only 75 divisions.

From which it results that—

		Atropine grams.
The coagulum (A) . .	contained	0·009013 × 5 = 0·0450
10 gr. of extract (B) (defecated juice)	„	0·009013 × 4 = 0·0305
10 gr. of extract (C) (leaves deprived of juice) . .	„	0·009013 × 8 = 0·0721
10 gr. of extract (D) (aqueous extract)	„	0·009013 × 8 = 0·0721
10 gr. of extract (E) (alcoholic extract)	„	0·009013 × 15 = 0·1352

From a general review of these experiments the following facts are deducible:—

1 kilogram of fresh leaves deposited upon clarification of the juice 5·16 gr. of albuminous coagulum, containing 0·0580 gr. of atropine.

1 kilogram of fresh leaves yielded 29·60 gr. of juice extract, containing 0·305 per cent., or 0·1067 gr. of atropine.

1 kilogram of fresh leaves, deprived of juice, yielded 15·50 gr. of aqueous extract, containing 0·721 per cent., or 0·1117 gr. of atropine.

1 kilogram of fresh leaves, weighed 157 grams when dried, and yielded 54·94 grams of aqueous extract, containing 0·721 per cent., or 0·3961 gr. of atropine.

1 kilogram of fresh leaves weighed 157 grams when dried, and yielded 48·54 gr. of alcoholic extract, containing 1·352 per cent., or 0·6562 gr. of atropine.

The following are the results of the titration of some other extracts from various sources:—

Alcoholic extract of datura, made in my establishment in 1877: contained 1·442 per cent. of alkaloid.

Alcoholic extract of belladonna of commerce, two samples: contained 1·081 and 1·400 per cent. of alkaloid.

Extract of defecated juice of belladonna of commerce, two specimens: contained 0·090 and 0·270 per cent. of alkaloid.

Aqueous extract of datura, made in my establishment in 1879: contained 0·451 per cent. of alkaloid.

Aqueous extract of belladonna of commerce, three specimens: contained respectively 0·721 per cent., 0·180 per cent., and no alkaloid.

En résumé, in these researches, evidently still incomplete, I have constantly found the alcoholic extract much more rich in alkaloid, which was well foreseen; next to it comes the extract by infusion which, notwithstanding the abundance of inert matters in it, always contains proportionally more alkaloid than the extract of the juice. It follows, also, from the experiment upon the fresh belladonna that the extract of the non-defecated juice, which formerly was always employed, contains more alkaloid than the extract of defecated juice, since the albuminous coagulum always contains a small quantity. Thus, in the present case, a kilogram of fresh belladonna leaves yielded 29·60 + 5·16 = 34·76 grams of extract with feculæ, containing 0·1647 gram of atropine, or 0·473 per cent. in the place of 0·305 per cent. which the Codex extract contains. This confirms the opinion of some of the older pharmacologists, who considered the extracts of Storck to be more active than the extracts of defecated juice.

PHYTOLACCIN: A NEUTRAL PRINCIPLE CONTAINED IN THE SEEDS OF PHYTOLACCA DECANDRA.*

BY EDO CLAASSEN.

The seeds of pokeberries (the fruit of *Phytolacca decandra*, L.) contain an indifferent crystallizable principle which I have named *phytolaccin*, and which is obtained in the following manner: the pulverized seeds of the pokeberries are treated several times with alcohol, the alcohol is removed from the filtrate by distillation, the residue washed with some petroleum spirit (gasoline or petroleum benzine), to remove adhering oil, then perfectly dried on the water-bath, finely pulverized and extracted by means of concentrated ether (or chloroform). The ethereal solution leaves behind, after distillation from the water-bath, a syrup-like liquid filled with acicular crystals which, after separation from the mother liquor, can be obtained perfectly white and pure by recrystallization or washing with a little alcohol. Phytolaccin is tasteless and colourless, and crystallizes in acicular silky prisms, mostly forming radiated tufts. It is insoluble in water, but pretty easily soluble in alcohol, particularly when hot; ether and chloroform dissolve the same very easily, and petroleum spirit somewhat difficultly, even when hot. Diluted acids, as well as concentrated acetic and hydrochloric acids, ammonia or a pretty concentrated solution of sodium hydrate do not dissolve it, even at the boiling point. Cold concentrated sulphuric acid, however, dissolves the same with brownish-yellow colour, turning brownish-red when the solution is heated. Concentrated nitric acid, when cold, has no effect on the phytolaccin; but, when heated, it dissolves the same, assuming at the same time a yellow colour. From a solution in alcohol (which, as I may mention by the way, is tasteless), or in ether, the phytolaccin falls down, on addition of water, as a flocky precipitate. Heated it melts, then turns brown and black and is entirely consumed. It contains no nitrogen, as the reactions for it gave a negative result.

COLD CREAM WITHOUT OIL.

Quince Seed Mucilage	10 drachms.
Almond Oil Soap	15 grains.
Stearic Acid	2½ drachms.
Glycerine	½ drachm.

Rub the stearic acid and the soap together in a warm mortar, add gradually to the mixture the mucilage so as to form an emulsion, and then the glycerine. Lastly add a suitable perfume.

* From *New Remedies*, November, 1879.

The Pharmaceutical Journal.

SATURDAY, JANUARY 17, 1880.

Communications for the Editorial department of this Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE ABUSE OF NARCOTICS.

SINCE the time when, on the motion of Mr. HAMPSON, the Council of the Pharmaceutical Society resolved that the General Purposes Committee should take into consideration the largely increasing sale by grocers, general dealers, and other unregistered persons of patent medicines containing scheduled poisons, attention has also been directed to a particular phase of this subject in other quarters and in a manner that may eventually lead to the adoption of some concerted action on the part of medical and pharmaceutical societies.

The object of Mr. HAMPSON's motion was to restrict the sale of such patent medicines to persons registered under the Pharmacy Act. He argued that the spirit of the Pharmacy Act implied the fitness of such a restriction as one consistent with the interests of the public, and that as a matter of justice to those registered to carry on the sale of poisons on the ground of their being specially acquainted with the nature of these articles, it should be the exclusive privilege of registered persons to deal in poisons. That this argument is reasonable does not need much demonstration, and the undoubted fact that the sale of poisons under the cover of the patent medicine stamp is a growing evil, renders the subject deserving of consideration.

On a subsequent occasion, Mr. HAMPSON, through the medium of this Journal, addressed a letter to the trade asking those who were in a position to give tangible proof that the patent medicine stamp is used to cover sales of scheduled poisons, to furnish him with particulars of such cases, and in all probability we may soon hear something of the information thus obtained.

It so happened that in the same number of the Journal that contained Mr. HAMPSON's request there was a report of a prosecution instituted by the Pharmaceutical Society against an unregistered person at Horsington, for selling laudanum not distinctly labelled, as the Pharmacy Act requires, with the name and address of the seller, and the only attempt at a defence was the statement that the bottle containing the laudanum was stamped with a patent medicine stamp. This circumstance illustrates the existence of a belief that the use of a patent medicine stamp will serve to constitute an exception to the provisions of the Pharmacy Act as regards the sale of scheduled poisons, and it is probably under the influence of this belief that the practice of selling such poisons with a patent medicine stamp attached has become so general.

It is true that the sixteenth section of the Pharmacy Act provides that nothing thereinbefore contained shall extend to or interfere with the making or dealing in patent medicines, but this reservation of rights existing at the passing of the Act does not in any way furnish a justification for the retail sale of scheduled poisons otherwise than as the Act provides in the seventeenth section.

In regard to such cases there is, therefore, no difficulty in rendering the Pharmacy Act effective in repressing such irregular sales of poisons; but in regard to patent medicines the matter is not so simple, since these are in general secret preparations, and although they may contain poisonous ingredients the Pharmacy Act declares that in patent medicines these ingredients are to be exempt from being deemed poisons within the meaning of the Act.

The door is thus left open for the grocer, the bookseller, and the co-operative stores to be the agents in distributing among the public some of the most potent articles of the materia medica, and it is a constant source of complaint by chemists and druggists that the trade in patent medicines is being taken out of their hands in this way. Some of the most popular of these secret preparations contain narcotics, and we have had occasion not unfrequently to record fatal effects that were so intimately associated with the use of such preparations as to make these appear their probable causes. Quite recently a writer in the *Times* has drawn special attention to the abuse of medicinal narcotics as being in his opinion an evil of still greater magnitude than the abuse of alcoholic stimulants. He specially instances chloral and a secret preparation—said by analysts to consist essentially of morphia flavoured with musk and other ingredients—which he describes as having an enormous family consumption, and he represents the present demand for and ignorant employment of such narcotic preparations as being in excess of all reason.

This writer uses as a signature the letters F.R.C.S., and it may therefore be inferred that, from his position and pursuits, he has had opportunities of speaking from actual observation as well as upon the strength of general experience, and, apart from certain suggestions as to the causes of a craving for narcotics, we fear there is too much reason for accepting his opinion as in the main well founded. This is also done by a physician who wrote a day or two afterwards to the *Times* on the same subject and dwelt upon the facilities existing for procuring narcotic drugs as well as the "manœuvring" by which persons contrive to obtain undue supplies of them from druggists' shops. In this writer's experience also, a patent liquid holding morphia is referred to as having been the cause of serious symptoms which for some time baffled his skill, and he points out that it is worthy of inquiry whether the sale of opium or morphia or chloral at "stores" is calculated to promote the abuse of these and other articles deemed "poison." Dr. KESTEVEN followed by expressing the opinion that the Sale of Poisons Act requires amendment and in support of this view he gave an instance of a patent medicine containing opium being purchased with suicidal intent at a druggist's shop by a patient of his. The *Times*, in a leading article, comments upon this correspondence as directing attention to a formidable social evil, though with the admission that the statements made would occasion little surprise to those having had opportunities of becoming acquainted with the extent to which the consumption of narcotic drugs has increased during the last few years. In this article attention is again called to the fact that morphia is the active ingredient of some half-dozen so-called patent medicines which are sold to any customer who may demand them, disguised under names suggestive of their virtues in affording relief from pain.

At the Clinical Society of London the same subject has been under consideration, especially in reference to chloral, and the committee appointed to inquire into it made a report last week, though without arriving at any definite result, but the *Medical Press and Circular* takes advantage of the attempt made to collect information from chemists and druggists to follow up its ill-advised and unworthy abuse of that class by condemning that attempt as "the delusion of folly," inasmuch as the chemist and druggist in the eyes of that misguided journal is solely and simply a *vendor* "interested" in the increased consumption of chloral, in "free trade in poisonous drugs," and carrying on his business so that the claims of society and humanity are subordinated to the sordid desire of gain. *Apropos* of this impudent attack there is a letter in the *Times* from Mr. BALDOCK, and written at the same time, in which he describes an instance where he declined to supply a narcotic drug, and took the trouble to warn his customer against its use, and we have reason to know that such a course is by no means unusual. In the same letter, however, he mentions the way in which the patent medicine stamp permits the sale of poisons without restriction and defeats the object of the Pharmacy Act as being the really dangerous facility for obtaining poisonous drugs.

It is to be expected that the correspondence to which we have referred and the action taken by the Clinical Society will, before long, result in some attempt to deal with the evil that has been thus exposed to public notice. It is therefore possible that the co-operation of medical men with chemists and druggists, which we last week pointed to as being desirable in another case, may soon become a reality, and that the object contemplated by Mr. HAMPSON'S motion last July may receive support from the medical profession as well as the pharmaceutical community, as being one to ensure public benefit.

In regard to some of the points touched upon in the correspondence above referred to, it is to be observed that some very mistaken ideas appear to prevail. Thus the quantity of chloral now sold cannot be a tithe of what it is assumed to be by F.R.C.S., and the President of the Pharmaceutical Society has had to correct the statement of one of the writers by pointing out that chloral is enumerated in the schedule of poisons and was included in that schedule upon the representation of the Council that it should be deemed a poison within the meaning of the Pharmacy Act.

PHARMACY IN NEW ZEALAND.

A MOVEMENT to form a Pharmaceutical Society of New Zealand, inaugurated at the commencement of last year, has we are glad to learn, progressed very favourably, so that by the end of October the number of members who had joined, exclusive of associates and apprentices, was upwards of one hundred. The head-quarters of the new Society have been fixed at Wellington, with Local Committees in Auckland, Christchurch and Dunedin, and its first President is Mr. CHARLES D. BARRAUD.

Notwithstanding the success that has been attained, a large number of chemists and druggists in business, amounting to one-third, have not yet joined the Society, and in the prospect of an attempt being made to obtain a Pharmacy Act for the colony a vigorous effort is being made to induce these to join the common cause.

In anticipation of the meeting of the colonial Parliament a Bill has been drafted, based on the Victoria Pharmacy Act, which is said to work well and which in its turn was founded on the Pharmacy Acts of Great Britain. The main provisions would render examinations compulsory in New Zealand and "introduce means for systematic technical education." There are strong hopes of passing this Bill, since the Wellington Committee has been assured that it will command the cordial support of the Legislature as a measure calculated to afford important protection to the community and as being in accord with the views of a Commission at present sitting on high-class education.

THE CHEMISTS' BALL.

As probably most of our readers are aware, next Wednesday is the day fixed for the Annual Chemists' Ball. It is to take place, as usual, in WILLIS'S Rooms, King Street, St. James's, and we hope that it will meet with a success equal to that which has attended similar gatherings in former years. Particulars as to tickets and a list of the Stewards will be found in our advertising pages.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A MEETING of this Association will be held on Thursday the 23rd inst., when a note on "A supposed Reaction of Aconitia" will be read by Mr. A. G. EVANS. A Report on Analytical Chemistry, will be made by Mr. A. F. DIMMOCK, on "Koettstorffer's Process for the Estimation of Foreign Fats in Butter."

AT a meeting of the trustees of Sir JOSIAH MASON'S Science College, Birmingham, held last week, Dr. W. A. TILDEN was appointed Professor of Chemistry in the College.

THE death is announced of Dr. WILLIAM BUDD, formerly of Bristol, whose name will long be honourably remembered in association with the investigation of the nature of typhoid fever.

Transactions of the Pharmaceutical Society.

The name of

Slater, William Martin ....Ipswich,

should have appeared in the list of Apprentices or Students of the Society elected on the 7th inst. See page 552.

Provincial Transactions.

GLASGOW CHEMISTS AND DRUGGISTS' ASSOCIATION.

The third general meeting of this Association was held in Anderson's College, 204, George Street, on Wednesday, January 7, Mr. Alexander Kinninmont, F.C.S., President, in the chair.

After the minutes of the previous meeting had been read and adopted,

The President called upon Mr. John C. Hunter to give his paper on a "Botanical Visit to Kew Gardens."

Mr. Hunter, after describing some places of interest on the way up the river to Kew, gave a short account of the early history of the gardens, and then mentioned some of the wonderful plants in Museum No. III., such as the *Rafflesia Arnoldi*, from Sumatra, and the *Welwitschia mirabilis*, discovered by the late Dr. Welwitsch in Africa, etc. Passing on to the growing plants, Mr. Hunter then mentioned some of the contents of the large Palm House with its splendid collection of palms and other tropical plants. Afterwards reference was made to the other houses containing the tree ferns, orchids, heaths, not forgetting the Victoria Regia House, and its beautiful specimen of that lily. Mr. Hunter concluded with a short account of the *hortus siccus*, or herbarium of Kew, and its appliances for the promotion of scientific botany.

A collection of some British ferns and other plants was placed on the table to illustrate some of the characters of various plants in Kew spoken about in the lecture.

After some remarks from Messrs. Brodie and Clarke,

The President asked the meeting to award a hearty vote of thanks to Mr. Hunter, which was duly given, and after election of members the meeting closed.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual *soirée* of this Association was held on Thursday, January 1, in the Town Hall, Birmingham.

Messrs. Southall Brothers and Barclay exhibited a number of experiments illustrating the structure and chemistry of various flames; these were arranged and shown in the different compartments of one of the corridors and included luminous and non-luminous flames; experiments showing the production of water and carbonic acid gas; singing flames, and weight experiments, the latter proving that bodies burning in air produce compounds heavier than the substances burned. In the south corridor Messrs. Harris and Co. exhibited a set of crystals in glass, illustrating the science of crystallography; an ingenious apparatus by Reichardt for regulating the temperature of the drying oven; apparatus showing the increased luminosity of phosphorus in rarefied oxygen and its total disappearance in oxygen under a pressure of one atmosphere; the electrolysis of water and of sodium chloride was also demonstrated and explained. Other tables were occupied by vacuum tubes and electric apparatus. Experiments in spectroscopy and pneumatics, and an improved apparatus for the estimation of nitric nitrogen in drinking waters must also be mentioned. The great gallery was occupied by a microscopic display by the members of the Microscopical and Natural History Society. At half-past eight, Mr. Hubert Langford gave a selection of humorous sketches, called "Studio Studies," which were highly appreciated.

During the evening a selection of operatic music was performed by the band; the amusements concluded with dancing at half-past nine. There was a good company, and a most enjoyable evening was spent.

EDINBURGH CHEMISTS' ASSISTANTS' ASSOCIATION.

The fourth meeting of the session was held on the evening of Wednesday, January 7, in the rooms of the Pharmaceutical Society, 119A, George Street; Mr. Robertson, Vice-President, occupied the chair.

The minutes of last meeting having been read and approved of,

The Chairman intimated that the subject for the evening was a debate, "Should Women be admitted as Members of the Pharmaceutical Society?"

The discussion was opened by Mr. Hill, who gave an emphatic approval of the recent action of the Council in admitting women as members.

He was followed by Mr. William Aitkin, speaking on the negative side, and the debate was continued by Messrs. Steward, Maben, Fraser, Hutton, and others, the majority of the speakers being in favour of the affirmative.

Messrs. Hill and Aitken having briefly replied, a vote was taken, resulting in a majority of one for the negative.

Parliamentary and Law Proceedings.

Another Cream of Tartar Prosecution.

At the Romsey Borough Police Court, on January 9, before Messrs. Walter E. Godfrey (chairman) and Charles Dyett, Mr. William Blissett, chemist and druggist, of Church Street, Romsey, was charged under the Sale of Food and Drugs Act, 1875, that "he did at the said borough sell to Edward Kellaway, on December 5, 1879, a certain drug, to wit, cream of tartar, which said drug was mixed with certain materials, to wit, sulphate of barium and tartrate of lime, so as to affect injuriously the potency of such drug."

Mr. Glaisyer, instructed by the Secretary of the Chemists and Druggists' Trade Association of Great Britain, appeared for the defendant.

Edward Kellaway, having been sworn, said he was the superintendent of the police for the borough. On December 5, last, he purchased in Mr. Blissett's shop $1\frac{1}{2}$ ounce of cream of tartar. He told Mr. Blissett it was for the public analyst. It was divided into three parts, one part he left with Mr. Blissett, another part he delivered to Mr. Angell, the borough analyst, and the third part was produced. On December 16, last, he received from Mr. Angell a certificate (produced) stating that the cream of tartar contained tartrate of lime 6 per cent., sulphate of barium very slight traces only, and that tartrate of lime is insoluble, not injurious to health, but is a useless ingredient in cream of tartar.

Cross-examined by Mr. Glaisyer.

Are you specially appointed under this Act?—I am.

By the borough or the county?—By both.

May I ask are you summoned here by the county or the borough authorities?—By the borough authorities.

Who instructed you to buy cream of tartar?—I do not know that I need answer that question.

Were you instructed by your chief or by the town council?—Not by the town council.

Did you buy cream of tartar at more than one place?—No.

Why did you call on Mr. Blissett instead of on some other druggist? This is the second time, you know, that Mr. Blissett has been brought before the magistrates charged with adulterating his drugs.—Why should I not call on Mr. Blissett.

Why call on Mr. Blissett only?—If Mr. Blissett had not supplied me I should have gone somewhere else.

Did the public analyst instruct you to purchase the cream of tartar?—No.

To whom was the certificate of the analyst submitted when it was received?—I received it from the analyst.

Did you issue the summons without reference to anyone else?—No.

Who then gave instructions for the summons to be issued?—I cannot answer that question.

Has the certificate been before any person who is competent to judge of the constituents of the drug in question?—I consider it has.

Did the public analyst give instructions for the prosecution?—Certainly not.

You asked for cream of tartar only?—I did.

You do not know what the constituents of cream of tartar are, I suppose?—No.

Mr. Glaisyer: Will you call the analyst, if you please.

The Magistrates' Clerk: That is for you to do.

Mr. Glaisyer: I beg your pardon, the 21st section of the Act enacts, "At the hearing of the information in such proceedings the production of the certificate of the analyst shall be sufficient evidence of the facts therein stated, unless the defendant shall require that the analyst shall be called as a witness." *Unless* the defendant shall require that the analyst shall be called, his (the analyst's) certificate shall be sufficient. I gave notice by letter to the inspector that the defendant required the analyst to be called as witness.

The Magistrates' Clerk: You required him to be present, and he is here.

Mr. Glaisyer: Then I require the prosecution to call him as a witness, otherwise I submit this case is not complete.

Mr. Angell: Before I am sworn I should like to know, with due respect to the bench, who guarantees my fees and the cost of my attendance here to-day for the purpose of giving evidence.

Mr. Glaisyer: I have nothing to say on that question.

The Chairman of the Bench: On the part of the defendant you have given notice that you would require the analyst to be present.

Mr. Glaisyer: I have given notice that I should require that the analyst should be called as a witness, but——

Chairman of the Bench: I presume then that will carry expenses.

Magistrates' Clerk: The Act distinctly says so.

Mr. Glaisyer: That is not so. The section from which I have already quoted clearly states that the analyst's certificate shall be sufficient evidence *unless* the defendant requires the analyst to be called as a witness. The defendant did require the analyst to be called as a witness.

Chairman of the Bench: It appears to me, from that, that the defendant must pay the analyst's expenses. The certificate is sufficient for the bench.

Mr. Glaisyer: I submit that it is necessary for the purpose of this prosecution that the analyst should be called by them as a witness, as the defendant has required him to be called, and consequently the analyst's certificate is not "sufficient evidence" of the facts therein stated.

Mr. Angell went into the witness box.

Mr. Glaisyer: I have not called Mr. Angell as my witness.

Magistrates' Clerk: You have given notice that he must be here.

Mr. Glaisyer: I should be glad to know whether the bench considers the case of the prosecution is complete without their having put the analyst in the box, I, on the part of the defendant, having given notice that the defendant would require that the analyst should be called as a witness?

Magistrates' Clerk: You have taken a step under the Act which you were entitled to do. You have given notice to make us bring the analyst here; that being so, you must of course pay his expenses.

Chairman of the Bench: We think the defendant is liable for the analyst's fees and expenses.

Mr. Glaisyer: Then may we have that as a point of law clearly stated?

Magistrates' Clerk: No, I think not. Mr. Angell asked a question and the magistrates have decided it.

Mr. Glaisyer: I am not prepared to call Mr. Angell as my witness.

Mr. Angell: I distinctly refuse to give evidence unless my expenses and fees are guaranteed.

Mr. Glaisyer: Then I submit the case for the prosecution is incomplete, and that I have no case to answer—as it now stands.

Magistrates' Clerk: The analyst says he will give evidence if you pay him.

Mr. Glaisyer: The prosecution have put him in the box.

Magistrates' Clerk: That is not so.

Mr. Glaisyer: But Mr. Angell is in the box.

Magistrates' Clerk: You have called him.

Mr. Glaisyer: I have not called him.

Magistrates' Clerk: Then stand down, Mr. Angell.

Mr. Angell here left the witness box.

Mr. Glaisyer: As my client's character as a chemist and druggist is at stake, I feel that I must go on with the case to prove his innocence of the charge brought against him, and to enable me to do this I will guarantee Mr. Angell's fees.

Mr. Angell again went into the box and was sworn.

Mr. Glaisyer: Have the prosecution any questions to ask?

Superintendent Kellaway: Not a word.

Mr. Glaisyer: What is your name?—Arthur Angell.

Where do you reside?—At 4, Portland Terrace, Southampton.

What is your profession?—I am public analyst for the county of Hants and for this borough.

Have you any special knowledge of the constituents of drugs?—That gained through my career only; I have never been in the drug trade.

Have you ever studied at any pharmaceutical school?—No.

For what length of time have you studied pharmacy?—I have never studied at a pharmaceutical school.

Therefore your knowledge is simply that of a chemist?—Quite so.

Did you recommend a prosecution in this case?—Certainly not.

Have you ever recommended that prosecutions should be instituted under this Act?—No. I am not allowed to give an opinion.

Do you suggest in any way articles to be purchased for analysis?—In some instances.

Did you suggest that cream of tartar should be bought?—Yes, amongst other things.

The sample on which this prosecution is based was submitted to you last month and you analysed it?—Yes.

What did you find to be present?—The only foreign materials present were the 6 per cent. of tartrate of lime and a very slight trace of sulphate of barium.

Let us have the whole of the constituents, if you please.—They are stated in my certificate.
