Dr. Franklin H. Martin, Chicago, is chairman of the executive committee, in charge of raising the funds necessary from this country.

#### **Number of Virginians at Mayo Clinic.**

It is interesting to note the large number of University of Virginia alumni, who are or were Virginians, who have been at Mayo Clinic, Rochester, Minn., this summer. These are: Dr. A. S. Moore, formerly of Aldie, and Dr. J. L. Crenshaw, formerly of Rapidan, both on the permanent staff; Dr. J. A. Wilkins, Lynchburg, and Dr. R. M. Gilliam, Petersburg, medical and surgical fellows on the Mayo Foundation, respectively; Drs. Wm. E. Bray and I. A. Bigger, University, who attended for the month of August; Dr. J. S. Horsley, Jr., Richmond, who returned the first of September after several weeks' work, and is connected with the surgical and gynecological department of St. Elizabeth's Hospital, Richmond; and Dr. L. M. Blackford, University, who graduated from the University of Virginia this June and, after a couple of months at the Mayo clinic, entered upon his duties as interne at Union Memorial Hospital, Baltimore, the first of this month.

#### **Dr. and Mrs. W. L. Peple,**

Richmond, are expected home the middle of this month, after spending several months touring the British Isles, France and Belgium.

#### **Dr. and Mrs. James H. Smoot**

And daughter have returned to their home in Woodstock, Va., after an extended visit to New York City, Niagara, Canada and Detroit.

#### **Dr. and Mrs. B. W. Switzer,**

Lexington, Va., recently enjoyed a visit to relatives at Rawley Springs, Va.

#### **Married.**

Dr. Elbyrne Grady Gill and Miss Ruth Meals, both of Roanoke, Va., June 16.

Dr. Mortimer Harry Williams, Roanoke, Va., and Miss Julia Mountcastle, Weldon, N. C., September 8.

Dr. Millard Bridgman Savage, Norfolk, Va., and Mrs. Esther Lenore Gregory, Washington, D. C., July 9.

Dr. Richard Lee Willis, formerly of Chat-ham, Va., a member of the class of '21, University of Virginia Medical School, and Miss Elizabeth Harris, of Crozet, Va. They will make their home in East Orange, New Jersey.

Dr. James Ernest Stokes and Miss Rebecca Marsh, both of Salisbury, N. C., June 28.

#### **The Southern Medical Association**

Is preparing for a big meeting in Washington, D. C., November 12-15, inclusive. Dr. Thomas A. Groover, 1621 Connecticut Avenue, N. W., is general chairman of the local committee; Dr. Philip S. Roy, 1200 Massachusetts Avenue, N. W., vice-general chairman; and Dr. William Cabell Moore, 1824 Massachusetts Avenue, N. W., general secretary. These or Mr. C. P. Loran, secretary-manager of the Association, Empire Building, Birmingham, Ala., will be glad to give any necessary information.

#### **Resident and Travel Scholarships for Physicians.**

The American Child Health Association, 370 Seventh Avenue, New York City, has appropriated \$10,000 for resident and travel scholarships to physicians. These scholarships are for the purpose of affording an opportunity to secure training in child health work which will better fit physicians to fill positions with state and municipal divisions of child health or organizations engaged in child health work, or to enable physicians already engaged in the child hygiene field to secure additional training or experience. The fund will be allotted in amounts suited to the objectives arranged for the respective students.

Applicants eligible for these scholarships will be physicians who are in good standing in their local and state medical societies and shall present evidence of the following qualifications:

(a) Graduation from a Grade A medical school and a license to practice in the state from which they apply.

(b) Real interest in child health.

(c) Either special instruction or practical experience in public health or child hygiene, including school health work. Those who have had such experience will be given preference in the selection of candidates.

These scholarships will be given during the school year of 1923-1924, and during the summer of 1924.

Application blanks and further information will be furnished on request to the American Child Health Association.

#### **Dr. and Mrs. W. W. Bennett,**

Blackstone, Va., spent a most enjoyable vacation on a motor trip through northern Virginia and Maryland.

#### **Dr. Rufus L. Phipps,**

Of Clintwood, Va., was quite seriously injured in an automobile wreck, the latter part of August. It is stated that his arm was broken and shoulder dislocated, in addition to bruises and cuts.

#### **Dr. George H. Reese,**

Petersburg, Va., left the middle of August for Rochester, Minn., where he is attending the Mayo Clinic for several weeks.

#### **The American Roentgen Ray Society**

Is holding its annual meeting in Chicago, with headquarters at Congress Hotel, September 18-21, inclusive. A number of eminent foreign contributors are scheduled for papers, and announcements indicate that treatment by high voltage X-ray will have a prominent place on the program.

#### **Dr. William C. Powell,**

Petersburg, Va., spent some time at Virginia Beach, the latter part of August, enjoying the pleasures of that resort.

#### **Dr. T. E. Chapman,**

Formerly of Norton, Va., and at one time president of the Wise County Medical Society, after spending several years in the far west to regain his health, has now located at Joplin, Mo., where he has taken up active practice again.

#### **Dr. A. G. Brown, Jr.,**

Has returned to his home in Richmond, after a pleasant vacation spent in the New England States. When in Boston, he had the

pleasure of seeing many interesting and instructive cases in the medical wards of the Peter Bent Brigham Hospital.

#### **The Tri-State District Medical Association,**

Comprising the entire states of Iowa, Illinois, Wisconsin and Minnesota and districts of surrounding states, will have their annual assembly in Des Moines, Iowa, October 29, 30, 31 and November 1. Headquarters will be at Fort Des Moines Hotel. All physicians in this State who are in good standing in the State Society are most cordially invited to attend and take part in the program.

This association is a purely post-graduate organization and the entire time of the annual assembly is taken up with scientific study. A number of eminent members of the profession have accepted to take part in the program.

Dr. William B. Peck, Freeport, Ill., managing director, will give more detailed information upon request.

#### **Dr. and Mrs. Stuart McGuire**

Have returned to their home in Richmond, after a visit to Nova Scotia and other northern points of interest.

#### **Dr. Basil B. Jones**

Has returned to Richmond, and will open offices October 1st in the Medical Arts Building. His practice will be limited to diseases and nutritional problems of infancy and childhood.

Dr. Jones graduated at the Medical College of Virginia in 1916, and for four years did special work in pediatrics at the Boston Floating Hospital, Massachusetts General Hospital, and at the Kingston Avenue Contagious Hospital at Brooklyn. He has been in pediatric practice in Los Angeles, California, for the past two years.

#### **Prizes to Members of Richmond Academy of Medicine and Surgery.**

At a meeting of the Richmond Academy of Medicine and Surgery, last year, Dr. J. S. Horsley, of this city, announced that an anonymous friend had offered two prizes, the first, \$100 and the second, \$50 for the two best original papers read before the Academy during 1922. A committee of five was appointed to decide upon these awards, with the result that the first award was made to Dr. Joseph F. Geisinger for his paper on "Reduplication

of the Ureter" which was published in *Annals of Surgery*, May, 1923. The second prize was given Dr. Wyndham B. Blanton for his paper on "The Clinical Significance of Reductions in the White Cells of the Human Blood," published in *VIRGINIA MEDICAL MONTHLY*, April, 1923.

**Dr. H. M. Snead,**

South Hill, Va., is home again, after a visit to his mother at Fork Union, Va.

**Dr. S. W. Maphis**

Returned to his home in Warrenton, Va., recently, after a visit to Hot Springs, Va.

**Dr. A. M. Showalter,**

Cambria, Va., spent his vacation with friends on a camping trip in Maryland.

**Dr. Fletcher D. Woodward**

Has become associated with Dr. John W. C. Jones, Newport News, Va., and will limit his practice to diseases of the eye, ear, nose and throat. Dr. Woodward graduated from the University of Virginia in 1919, after which he served as an interne at University of Virginia Hospital. He completed a two and a half years' service at Manhattan Eye, Ear and Throat Hospital, New York City, prior to becoming associated with Dr. Jones.

**Dr. E. W. Walker,**

Recently of Exeter, Va., is now at Appalachia, Va.

**Dr. J. J. Anderson,**

Formerly of Irwin, Va., after spending some time traveling, has located in Richmond, with offices at 2200 Hanover Avenue. He will be engaged in general practice.

**The Medical Association of the Valley of Virginia**

Is to hold its next meeting in Staunton, September 27, at which time the election of officers will be held. Dr. Hunter McGuire, Winchester, is president, and Dr. Alex. F. Robertson, Jr., Staunton, secretary.

**The Mary Elizabeth Hospital,**

Raleigh, N. C., announces the association of Dr. Verne S. Caviness, practice limited to Diagnosis and Internal Medicine, and of Dr. Powell G. Fox, in the department of General Medicine.

**Dr. and Mrs. Hunter B. Spencer**

Have returned to their home in Lynchburg, Va., after a visit to Canada and Detroit, having returned from the latter place in their car.

**Dr. and Mrs. A. J. Hurt**

And daughter of Chester, Va., left the middle of August for an extended motor trip in New York and in the New England States.

**Dr. Francis J. Ready,**

Clarendon, Va., announces that he has moved his offices to 3301 N Street, Northwest, Washington, D. C., where he will continue in general practice.

**Dr. Walter M. Babb,**

Keyser, W. Va., has been elected president of the West Virginia State Board of Health.

**Dr. Buckner M. Randolph,**

Washington, D. C., having accepted an appointment as professor of clinical medicine and director of clinics in the Medical Department of George Washington University, Washington, announces that he has withdrawn from the general practice of medicine and will hereafter limit his private work to consultations and referred work. His offices will be at George Washington University Hospital, 1339 H Street, Northwest.

**Dr. R. B. Gillespie,**

Formerly of this State, but now with the Public Health Service, has been transferred to Tampa Bay Quarantine, Tampa, Florida.

**Dr. R. A. McBrayer**

Has resigned from the staff of the N. C. Tuberculosis Sanatorium and has located in Shelby, N. C., for the practice of internal medicine.

**Dr. and Mrs. J. A. Riffe,**

Covington, Va., were recent visitors in Richmond.

**Dr. and Mrs. J. Weldon Smith**

And daughter, Farmville, Va., spent their vacation on a motor trip through Eastern North and South Carolina.

**Dr. and Mrs. Wade C. Payne,**

Haymarket, Va., spent a short vacation with relatives in Fredericksburg, Va.

**Dr. and Mrs. L. C. Shepherd**

And daughter, of Norfolk, Va., spent some time in August visiting in Harrisonburg, Va.

**Dr. Allison of St. Louis Goes to Harvard.**

Dr. Nathaniel Allison, dean of Washington University Medical School, St. Louis, has resigned to accept the position as head of the department of orthopedic surgery in the Medical School of Harvard University.

**Dr. Turner S. Shelton**

And family, of Richmond, have returned home after a motor trip through eastern Virginia and North Carolina.

**The American College of Surgeons**

Is to meet in Chicago, October 22-26, the week immediately following that in which the annual meeting of our State Society will be held. Dr. Albert J. Oschner and Dr. Franklin H. Martin, both of Chicago, are president and director general, respectively.

**Dr. D. A. Stanton,**

High Point, N. C., has been appointed a member of the North Carolina State Board of Health, to fill vacancy caused by resignation of Dr. F. R. Harris, of Henderson, N. C.

**Dr. and Mrs. W. J. Knight**

And daughters, Newport News, Va., enjoyed a motor trip in North Carolina in August.

**Dr. and Mrs. Ashby Turner,**

Harrisonburg, Va., went with some friends on a motor trip to Canada and points of interest in the north, last month.

**"Venereal Disease Information,"**

A monthly publication, has just made its appearance in magazine form, and is intended primarily for health officers, physicians, nurses and social workers engaged in venereal disease control activities. It is issued by the U. S. Public Health Service, and the price is 50 cents per year, payable to the Superintendent of Documents, Government Printing Office, Washington, D. C.

See notice under secretary's announcements covering reduced rates to meeting in Roanoke. The reductions apply to dependent members of physicians' families in addition to members.

**For Sale.**

Tidewater Virginia beautiful home and good practice in town of 1,200, with rich surrounding country. Practice will pay for property in a year. Cash required to handle \$2,500. Reason for selling, going to specialize.

If you want a good opportunity and can manage, address No. 273, care this journal.

---

## Obituary

---

**Dr. George Nicholas Acker,**

Of Washington, D. C., died from pneumonia July 22. He was 70 years of age and a graduate of the Medical Department of Columbian University, Washington, in 1874. He was for sometime professor of pediatrics at George Washington University Medical School, Washington, D. C.

**Dr. James Semple Haile,**

Of Chatham, Va., died in Danville, Va., August 12. He was sixty-nine years of age and was formerly a member of the Medical Society of Virginia. Dr. Haile graduated from the University of Maryland, School of Medicine, Baltimore, in 1886, and practiced in Chatham until a few years ago when he retired.

**Dr. Cowles M. Vaiden**

Died at his home, at Ruthville, Va., August 14, in his fifty-sixth year. He graduated from the Medical College of Virginia, Richmond, in 1892, and was for a time a member of the Medical Society of Virginia. He is survived by a daughter, a sister and two brothers.

**Dr. Elijah Filmore Truitt,**

Formerly a member of the Medical Society of Virginia, died at his home in Norfolk, Va., September 2. He graduated in medicine from the College of Physicians and Surgeons, Baltimore, in 1883, and was at one time Norfolk County coroner. Dr. Truitt was also a druggist and a pioneer in the establishment of chain drug stores in Norfolk.

**Dr. Samuel Major Hodes,**

Formerly of Richmond, died August 22, and the interment was made in this city. He was thirty-five years of age and a graduate from the Medical College of Virginia in 1915. Dr. Hodes was at one time a member of the Medical Society of Virginia.

The fact that thousands of physicians are feeding S.M.A. with uniformly successful results, to normal, full-term infants from a few days to one year of age or more, *without any qualitative change, whatsoever,* is convincing proof of the resemblance of S.M.A. to breast milk in all important respects. *~~~~~*

# CALCREOSE

## Intestinal Antiseptis

THERE is good evidence that creosote acts as an intestinal antiseptic but patients object to its use because of its taste and the untoward effect on the stomach.

CALCREOSE (calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, possessing the pharmacologic activity of creosote but free from its untoward effect on the stomach, therefore,

CALCREOSE lends itself admirably to the treatment of intestinal infections in which it is desired to administer creosote. Patients do not object to its use even when taken for comparatively long periods of time and in large doses.

# RABIES VACCINE LILLY

*Complete Fourteen-Dose Treatment Now  
Available in Two Seven-Dose Shipments*

---

Rabies Vaccine, Lilly, ready for use, in syringe containers, is now available in two shipments of seven doses each. Formerly, the first three doses were supplied by the nearest Lilly Depot and eleven daily shipments completed the treatment.

Your druggist can supply the first seven doses from the nearest Lilly Depot; the completing seven doses, 8 to 14 inclusive, will be shipped in ample time for use on the eighth day of treatment.

Dose standardization, high immunizing quality, and marked success attending its application, have won for Rabies Vaccine, Lilly, the preference of many physicians. You can treat your Rabies cases at home with Rabies Vaccine, Lilly.

### BILATERAL NEPHROLITHIASIS.

By ROBERT C. BRYAN, M. D., F. A. C. S., Richmond, Va.

Unilateral stone is far more common than bilateral, the right kidney more often affected than the left. It is well known that Jews are more liable to stone in the kidney than any other race, and the reports of the Johns Hopkins Hospital show there has never been a stone in the kidney of the negro.

The determining factor for the immediate production of stone is the formation of a nucleus, whether it be bacteria, blood clots, shreds of tissue, colloidal matter, parasites, such as schistosoma hematobium or filaria sanguinis hominis. Infection apparently does favor stone formation, but the character of the germ must be taken into consideration. For pyelitis is much more common in the female, eight to one; and stone more common in the male; the colon bacillus, the more frequent cause of pyelitis, is never found in stone. It has likewise been suggested by Rovsing that certain foods that contain alkaline waters predispose to phosphaturia and that certain acids such as grapes and tomatoes produce oxaluria. Rosenbach has produced stones in rabbits and dogs by feeding them oxamid. Cutting off the nerve supply and putting foreign bodies in the kidney immediately start stone production. The most frequent age for stone in the kidney seems to be between twenty and thirty, and each decade following shows a gradual diminution in the predisposition to stone formation.

It is of interesting clinical significance that stone does not occur more frequently on both sides simultaneously. These obscure etiological factors that bring about crystallization should oftener be bilateral. We not infrequently see recurrence of stone on the same side within a few months of a previous operation, the other side escaping this cyclic production. Recently we removed from the left side a stone in the ureter and two months

later a large stone from its corresponding pelvis, which had not shown formerly by X-ray examination. And the question of stone escaping X-ray examination is ever with us, throwing no shadow, which it could not do by virtue of its chemical consistency.

Braesch consummated the question of stone formation recently, at a meeting of the Southern Medical Association in Chattanooga, when he stated:

"In the study of the etiology of urinary concretions, we deal with an abnormal type of crystalline precipitation. To ascertain what mechanism is at fault in causing the atypical deposition and fusion of these crystals into a stony concretion is the problem that has confronted us for some time. The power of the urine in health to hold the constituents of calculi in solution, or to bring about their deposition as isolated entities, is due to the presence of finely divided particles of organic matter, the so-called *protective colloids*. Experiments have suggested that stone formation might be due to one of several factors: (1) the excretion of an excessive quantity of crystalline material beyond the power of the urinary colloids to maintain either in solution or deposition of isolated noncoalescent crystals; (2) a deficient amount of protective colloid in the urine; or (3) the precipitation of normal colloids or masking of their protective activity by bacterial exudates or by foreign colloidal matter excreted as the result of an abnormal metabolism. It has been demonstrated that colloidal matter going beyond the limit of that capable of being handled by the urinary colloidal machinery fusion of crystals occurs and calculus formation took place.

"Experimental production of an excessive excretion of calcium oxalate in the urine over a prolonged period of time would result in the aseptic formation of calcium oxalate calculi. Furthermore, it was shown that the mechanism of such calculus production was related to a change in the morphology of stone-forming crystals from a non-fusing to a fusing or coalescent type. The physico-chemical influence of colloidal matter on crystalline morphology may theoretically, at least, be applied. We may assume that, by enormously increasing the quantity of the crystalloidal calcium oxalate in the urine, we overwhelmed the protective colloids of the urine which were present only in amounts sufficient to maintain the solution or crystalline isolation of the quantity of calcium oxalate normally present. When the quantity of oxalate excreted passed the limit of that capable of being handled by the urinary colloidal machinery, then fusion of crystals and calculus formation took place.

"The second phase of our experimental problem, namely, to produce a deficiency in the quantity or

quality of protective colloid in the urine of animals, has thus far been baffling. However, Lichtwitz has demonstrated that the removal of colloidal matter from urine in vitro, either by extraction with ether or benzine, or by dialysis, uniformly results in a precipitation of phosphates or of calcium oxalate. Furthermore, Schade, of Kiel, in 1909, produced stony masses in vitro by clotting fibrinogen in the presence of freshly precipitated phosphates, oxalates and carbonates, thus giving tremendous impetus to the significance of colloidal factors in stone formation.

"Studies tending to show that bacterial exudates may cause an interference with normal urinary colloids in a manner to bring about an atypical precipitation of the urinary crystals and consequent stone formation have been even more fruitful. Rose-nov and Meisser, working with streptococci from the urine of patients with multiple recurrent calculi, have repeatedly produced calculi in the kidneys of dogs by the method of specific bacteriology. These streptococci were implanted in devitalized teeth of dogs, which developed urinary calculi consistently after an interval of several months. Such experiments can best be explained by assuming that the bacteria have a specific elective activity on the renal tubules, thus producing a low grade inflammation. The exudate from this inflammatory reaction pours out abnormal colloidal matter into the urinary stream. This we may assume so interferes with the normal colloidal balance of the urine that its solvent power no longer obtains, that deposition of fusing crystals takes place and stone formation occurs."

It is interesting to note the prevalence of stone in the right kidney. Is it due to the anatomical association of the renal pelvis on this side with the colon, a transmural bacillary infection being encouraged? Or, is it simply the expression of a congested kidney, slowing of the blood current, stagnation and crystallization from the preternatural mobility of the right side added to the exciting causes as brought out by Braasch?

It is not the intention of the writer to take up the pathology of the kidney in its response to this foreign body, for pyelitis, pyelonephritis, pyonephrosis are progressively in order, the decision to be made is the state of the kidneys, their relative standards to recognized tests, and the probability of a favorable outcome. That kidney showing by chemical and laboratory examinations the highest index is the first to be operated on, and after a reasonable length of time the other organ may be attacked. The value of repeated indigo-carmin, phthalein and thorough urinary examinations, supplemented by complete blood retention tests is evident; in one of our cases this was done five times.

The writer has had the opportunity to notice bilateral lithiasis in several instances and would call attention in one case to that of twins, men, age thirty, who developed and

were operated on within a month of each other for stone in the kidney, both on the left side, there having never been any evidence of stone previously, nor has there been since the operation, which was carried out some ten years ago.

The following cases are referred to as instances of bilateral kidney stones:

(1) T. H. M., age forty-one, male, reported to the hospital March 1, 1920. Ten years ago had pain in left side; since December has had pain in both sides; five or six attacks on the right side and three on left; no hematuria. Cystoscopic examination showed the right ureteral os to be small, slightly reddish, and this side could be catheterized for only a distance of two c. m. The left ureteral mouth is found more posteriorly, behind a distinct brim, the catheter on this side is arrested at eight inches, but a free flow of urine emits from this side, one and one-half ounces in about two minutes, which is under considerable pressure. Four c.c. are further aspirated from the catheter. The left kidney is injected with twenty-four c.c. of a twenty per cent solution of sodium bromide and X-ray taken. X-ray examination showed a stone in the pelvis of the right kidney a little larger than a date seed, dilatation of the pelvis of the left kidney, hydronephrosis and hydro-ureter, probably the size of a cigarette; no stone on this side noted. Urinalysis: *right side*, pale watery, nearly clear, sediment scant, acid, no albumin, occasional blood cell, few pus cells, crystals 0, casts 0, epithelial cells few large round and caudate; *left side*, smoky red, very cloudy, sediment heavy red, acid, albumin abundant, blood bulk of sediment, pus few cells, crystals 0, casts 0, epithelial cells occasional large round, mucus no excess. March 5, 1920, under general anesthetic, the usual kidney incision on the right side was made, there was a very short intercostal space, and the patient being quite stout, it was with difficulty that the kidney was reached. It was, however, finally freed from its bed, dislocated downward enough to bring the upper part of the right ureter into the field. A small irregular hard apparently phosphatic stone was densely wedged in the ureter about two inches beyond the pelvic junction. A longitudinal incision was made over the stone and it was removed, the ureter brought together with two sutures of 00 catgut, drain put down to the site of the ureter, tissues brought together with catgut No. two, silkworm gut through skin. Patient made an

uneventful convalescence, leaving the hospital March 25th. Cystoscopic examination having revealed a stricture of the left ureter and X-ray showing a moderate hydronephrosis and hydro-ureter the size of a cigarette, the patient returned at intervals for dilatation of this stricture. On April 30, 1921, patient returned to hospital complaining of pain in left side so severe he was unable to work. X-ray examination was negative. Cystoscopic examination showed that the old stricture had been dilated so that an olivary bougie went readily to the pelvis of the kidney. This was followed by a No. five French ureteral leaded catheter and there was an immediate flow from this side signifying pelvic distention. The left pelvis was aspirated and 12 c.c. of a heavy flocculent urine withdrawn. Patient was inverted and 9 c.c. of a 1-1000 mercurochrome 220 injected into the pelvis of the kidney and held there four minutes. In view of the history, the repeated outbursts of pain, absence of stone by X-ray examination, the character of the urine, a diagnosis of infected hydronephrosis was made and irrigations of the kidney advised. Urinalysis of the catheterized specimen showed color very pale, nearly clear, sediment scant, faint alkaline, small amount of albumin, occasional blood cell, good many pus cells, crystals 0, casts 0, epithelial cells occasional large round, other sediment few bacilli. Remarks: Stained sediment shows many cocci and bacilli, none acid fast. May 12, 1921, cystoscopic examination showed left os pouting but the crater not unduly red; it is readily catheterized, catheter mounting to pelvis of kidney without apparent pain or embarrassment. Fifteen c.c. of a twenty per cent solution of sodium bromide is injected into the pelvis of the kidney and pyelogram taken which shows a large stone in the pelvis of the left kidney, with kidney much enlarged. The stone apparently was about three-quarters of an inch long. May 17, 1921, under general anesthetic, a left lumbar incision is made, kidney readily reached, but many dense adhesions were found about the upper pole so that it could not be liberated satisfactorily. There were likewise many adhesions anterior and posterior to the hylum of such a dense character we did not dare to break them for fear of rupturing some of the blood vessels. The kidney was very large, varying in consistency, of a dark purplish-blue color, with evidences of an increased intrarenal pressure. Since the kidney could not be brought up in

the wound an incision was made along the lower part of its convex border, finger thrust into the pelvis readily detected the stone, which was apparently in the pelvis of the kidney and projecting downward into the ureter. The incision in the kidney liberated from the pelvis quite an amount of pus and debris which had been dammed back by the stone. The stone was removed with forceps and corresponded with the X-ray picture. Kidney was sewn through with wide mattress catgut sutures, drain placed in the upper angle of the kidney bed and brought out through the lower part of the incision. Muscles were approximated with catgut No. two, silkworm gut through the skin. Patient made an uneventful convalescence and has had no further pain or trouble.

(2) Mrs. W. Y. J., age fifty-nine, married, five children. Reported to the hospital July 27, 1921, giving history of intense pain in both sides and throughout abdomen. The present trouble began in May, 1912, with severe pain in both sides, radiating forward and downward across the abdomen and into the pelvis, pain more severe on the left than on the right side. The attack lasted several hours and was followed by a chill and fever. The acute attack lasted only a few hours, but left side has been sore and uncomfortable ever since. Three years previously had similar attack. Patient has difficulty of breathing at times, with feeling of pressure at angle between ribs. Appetite poor since May, digestion good, no jaundice, somewhat constipated, nocturnal polyuria two to three times, never passed any gravel. W. B. C. 10,000. Urinalysis: straw, cloudy, 1,010, faintly acid, trace of albumin, sugar 0, bile 0, indican 0, acetone 0, blood 0, pus abundant, amorphous matter 0, casts 0, epithelial cells moderate number of squamous, irregular and large round, mucus 0, other sediment bacteria. Renal efficiency forty-five per cent. Cystoscopic examination showed considerable debris and floating cloud in bladder medium which required irrigation for a clear field. Mucosa normal, nothing abnormal is seen, no trabeculae. The left ureteral os is readily catheterized No. five French catheter mounting to the pelvis of the kidney without pain, spasm or trauma and there is an immediate flow of heavy cloudy urine which fills a 20 c.c. test tube in four minutes. The right os is likewise apparently normal, but a No. five French catheter mounts only 20 cm. when it is arrested and will go no further. There is no flow from this

side and when irrigated there is no return flow other than that put in. Patient taken to X-ray room and 4½ c.c. of a twenty per cent solution of sodium bromide injected on the right side and 6 c.c. on the left side and pyelogram taken. It is predicted that there will be no result from the right side as the fluid is noted to return along side of the catheter. One c.c. of phenol-sulphonophthalein is injected in the vein of the left hand and appears in the urine in three minutes on the left side and, since there is no flow from the right side, catheter is not kept in two hours as it is believed the former test showing forty-five per cent represents only the left kidney. X-ray of right side shows a very small kidney with a shadow in the upper portion. The left kidney is normal in size and shows two fairly large stones occupying probably the two lower calyces. July 30, 1921, under general anesthetic, the left kidney incision was made. No attempt was made to deliver the kidney into the wound, but its pedicle was more or less satisfactorily squeezed by the left hand and incision made along the convex border into the lower part of the pelvis. A branching stone filling the lower calyx was felt, but attempt to remove it with forceps was unsuccessful. It was necessary to break through a rather dense cicatricial band constraining this lower calculus before it could be removed. Since we were unable to find the round symmetrical stone shown by the X-ray in the upper part of the pelvis, we were inclined to believe this was a dense fibrosis of the pelvis throwing a shadow. A rubber tube was placed in the lower part of the kidney bed, and through and through mattress sutures of catgut No. two put through the substance of the kidney, three in number, the free edges of the incision being brought together with catgut No. two silk-worm gut through skin. August 1, 1921, about seven p. m., patient died apparently from shock, having never reacted thoroughly.

(3) Mrs. W. C. H., w., age fifty-three. Reported to the hospital October 25, 1922, complaining of pain in right groin, also pain in left side extending from the left kidney into the left iliac region. Twenty-three years ago passed a stone the size of a hazel nut and fifty bird shot stones, followed by frequent attacks of pain so severe as to require morphine. Condition diagnosed as "floating kidney," wore supporter. Three years ago had osteopath and condition became worse. August, 1921, X-rayed and plates showed enlarged left kid-

ney with small stone, right kidney also showed stone not as large as that in left. Operated on December, 1921, large stone removed from the pelvis of left kidney and about a pint of pus evacuated. Left hospital February 3rd, wound still draining; remained home two months; returned to the hospital and a pint of pus was drawn from the left side, drainage tube replaced, which remained in for six months. Wound closed. Physical examination showed well nourished woman, heart normal but for soft presystolic mitral murmur at apex. Lungs negative. Blood pressure 124-84, pulse rate 86. Cystoscopic examination showed bladder capacity normal, mucosa normal, but in the bladder medium heavy tenacious products indicative of a long standing chronic kidney involvement were floating. The left os were small, its crater uninvolved, mucosa normal. This ureteral os was readily catheterized, catheter mounting without any pain or trauma some 20 to 25 cm.; there was no flow, however, from this side although the catheter was irrigated with boric acid solution to assure ourselves there was no blocking of the tube. The right os was swung well to the right, a little difficult to catheterize, its appearance slightly pouting and tightish. This side was likewise catheterized with a No. six French leaded catheter which mounted easily to the pelvis of the kidney and there was an immediate flow of clear amber colored urine which half filled the 10 c.c. test tube in about three minutes. The flow coming abruptly to a stop would indicate that the intrapelvic tension was quite high, expelling its contents under pressure. Two and a half c.c. of a four-tenths per cent indigo-carmin was given into the right median basilic vein at 11:52, appearing at 11:58 along the side of the cystoscope, evidently coming from the bladder. At 12:04 there were evidences of its appearance through the ureteral catheter on the right side. The bladder appearance was taken to be due to a temporary blocking of the ureteral catheter and this test represented the right side exclusively, nothing having been gotten from the left. Patient taken to X-ray and serial X-rays taken. Ten c.c. of a twenty-five per cent solution of sodium bromide injected into the left pelvis and pyelogram taken. Five and a half c.c. of a twenty-five per cent solution of sodium bromide is injected into the right pelvis and pyelogram taken. X-ray showed a large stone in the right kidney and small stone in the left kidney. Urinalysis: pale amber, slight cloud.

sediment scant gray, faint acid, albumin small amount, blood few cells, pus good many cells, crystals 0, amorphous matter debris, casts 0, cylindroids 0, epithelial cells few large round, mucus no excess. Remarks: Stained sediment shows good many clusters of cocci, also of acid fast bacilli. Examination of blood showed W. B. C. 13,600, polys seventy-five per cent, small and large mononuclears twenty-seven per cent, hemoglobin seventy per cent. Renal efficiency November 3, 1922, twenty per cent; November 7, twenty per cent; November 10, thirty per cent; November 19, twenty-five per cent; November 29, twenty per cent. Report on blood showed on November 20, urea 90 mg. per 100 c.c., urea nitrogen 42 mg. per 100 c.c., November 29, 82 mg. urea per 100 c.c. and 38.5 mg. urea nitrogen per 100 c.c.

In consideration of the foregoing the following observations may be stated:

1. Every patient with a stone in one kidney should have both X-rayed as bilateral nephrolithiasis we believe to be more frequent than is supposed.

2. In suspicious cases, indicated by urinalysis and subjective signs, pyelograms with sodium bromide should be used to prove out the presence or absence of stone. This spraying of the stone with a shadow throwing fluid has at times been confirmatory of an opinion which could only be guessed at otherwise.

3. Particular emphasis is laid upon the ingestion of large amounts of water preparatory to operations, or getting the kidney in the "habit of working" so that the strain of operation will be minimized.

4. We believe that the re-formation of stone in a kidney operated upon is caused primarily by the leaving of small particles from the original operation. Irrigation of the pelvis at the time of operation with the double flow catheter would obviate an appreciable per cent of so-called recurrence of stones.

5. In those instances in which the stone has been soft, or examination of it shows some particles or fragmentation have been left behind, we have used a tube put in the pelvis of the kidney for irrigation and drainage for several days. Not only the debris but likewise blood clots which cause much of the pain and distress following the operation are in this way removed.

## BLOOD TRANSFUSION, INDICATION AND METHOD.\*

By HERBERT C. JONES, M. D., Petersburg, Va.

It is the purpose of this paper to give a brief survey of the development of blood transfusion and to discuss modern conceptions of its uses and methods. It is impossible to say when and where the idea of transfusion first originated, probably the first case on record is that of Pope Innocent VIII, who was operated on in April, 1492. "The vital powers of Innocent VIII rapidly gave way; he had for some time fallen into a kind of somnolence which was sometimes so profound that the whole Court believed him to be dead; all efforts to awaken his exhausted vitality had been resorted to in vain, when a Jew doctor proposed to transfuse the blood of some young person. Accordingly the blood of the decrepit old pontiff was passed into the veins of the youth, whose blood was transferred into those of the old man. The experiment was tried three times at the cost of the lives of the three boys, probably air getting into the vein, but without effect to save that of the Pope." This is the first case in which death is ascribed to air embolism.

It was not until the nineteenth century, following the work of Blundell in England, that transfusion was used with any success. Like every other big achievement in medicine, many failures were made. Medical societies even ostracized men who advocated its use. Most of the early advocates used lamb's blood and cases of leprosy and hydrophobia are recorded as cured.

It remained for Blundell to show how the effects produced by a loss of blood could be remedied by transfusion. Eight ounces of blood was withdrawn from the femoral artery of a dog. Most alarming symptoms developed: shortness of breath, convulsions, and loss of sensibility. After some seconds, six ounces of blood were taken from another dog and injected into the femoral vein with the result that recovery of the dog was complete. He then did a second experiment, allowing the blood to flow from the femoral artery to the femoral vein by means of a tube. This experiment offers the basis for the present day cannula method.

In 1875 Guerrin cut the femoral arteries of two horses and connected the peripheral end of

\*Read at the meeting of the Southside Virginia Medical Association in Petersburg, March 1923.

one with the central end of the other, and *vice versa*. This gave a continuity of blood stream and was continued indefinitely until the small horse became plethoric. It was then stopped and both horses made an uneventful recovery.

Landsteiner in 1901 demonstrated the presence of isoagglutins in the blood and divided human beings into three groups according to the kind of agglutin present. A fourth type was added several years later.

G. W. Crile may be called the real pioneer of modern blood transfusion. Around 1900 he perfected a method of anastomosing blood vessels; intima to intima by the employment of a cleverly devised cannula. He put the method into practice experimentally and in clinical research, reporting 225 experimental and 32 clinical transfusions. At first he anastomosed artery to vein and later showed that transfusion could be successfully and more readily accomplished by vein to vein anastomosing. This work stimulated the profession as to the value of transfusion as a therapeutic measure. Many new devices for transferring blood soon appeared. Dr. Crile and his assistants at Lakeside Hospital, Cleveland, Ohio, probably do more transfusions than any other one group of surgeons. They know it to be a safe procedure and their patients are transfused on the slightest indication, both preoperative and postoperative, thus making good surgical risks of questionable cases and shortening their period of convalescence. In late years the method of transfusion at Lakeside Hospital has been changed, a simpler method, which will be described later, being substituted for the arteriovenous anastomosis.

With the development of simpler methods of technique and with the introduction of accurate blood tests, transfusion has lost the danger which once attended its use, until today it is a safe and proved therapeutic measure—rather than a last resort.

Transfused blood increases the bulk of circulating fluid and raises blood-pressure. It provides new oxygen and food for the body tissues. It increases coagulability. It stimulates the blood forming organs and increases the resistance to infection.

Of course the most direct indication of transfusion is hemorrhage, whether it be acute or has been occurring over a long period of time. It is in this group of cases that one sees most marvelous results. A person actually dying

from the loss of blood could be saved with a quart of blood, or less, provided the leaking blood vessel is tied and the cause of the hemorrhage removed. A recent case of the writer clearly demonstrated this fact. Mrs. E, 37 years of age, was taken suddenly with violent pains in the lower abdomen. She became pulseless and semiconscious in less than one hour. Six hours later a diagnosis of ruptured ectopic pregnancy was made. She was given salines under the skin and by the bowel, the abdomen was quickly opened and the ruptured tube and blood vessel tied. The patient was then given 900 c.c. of blood, and before she was removed from the operating room she was conscious and her pulse, beating at a rate of 90, was of good volume. She made an uneventful recovery, her temperature never going over 100½ degrees. She was discharged from the hospital on the twelfth day.

Not only in acute hemorrhage is transfusion of value. Many a woman with a bleeding uterus, whether it be from a fibroid, polyp, or a hypertrophic endometritis, will be made a good surgical risk, and her convalescence shortened.

Shock is second only to hemorrhage as an indication for transfusion. The patient who suddenly becomes pulseless and pale during or immediately following a major surgical procedure can be quickly revived with an immediate transfusion. The blood-pressure in these cases is the simplest guide as to whether the transfusion could be performed. A blood pressure of 80 systolic or lower is an indication for transfusion.

Many surgeons today are wisely resorting to transfusion to prepare their patients for major procedures. Especially is this true for cases in a weakened condition whether it be due to an old pus kidney, a bleeding ulcer of the bladder, or a hypertrophied prostate. So today in many of the large hospitals we have a routine typing of the blood on entrance of the patients when a major surgical procedure is in prospect. Thus a telephone call will bring a donor who is suitable and the family is saved the trouble of hurrying here, there, and everywhere to find some one who will gladly give blood. Routine typing should also apply to typhoid cases.

Hemophilia in the newborn babe offers a great field for transfusion. A 10 c.c. Luer syringe full of whole blood injected into the

anterior fontanel in infants, or intramuscularly into the buttocks, will often stop the hemorrhage whether it be from the umbilical cord, mouth, stomach, or bowel. The blood taken from the father seems to act more quickly. The writer has seen only one such case. Hemorrhage from the cord and mouth are successfully controlled by the injection of blood into the anterior fontanel. The infant's blood does not have to be typed until after the second year. Cases of recovery from purpura hemorrhagica are on record following transfusion. However, in many cases it has been used in vain.

The value of transfusion in the blood diseases, namely, pernicious anemia, splenic anemia, leukemia, and hemolytic jaundice, of course, is not as evident as in hemorrhage or shock. In all of the cases the writer has seen there has been an improvement. This improvement is not so marked when the condition resulting from many of the above mentioned blood diseases is grave. A patient with pernicious anemia will often be free from symptoms for several months following the transfusion, only to have a return of symptoms. These cases should be transfused for the comfort which comes to the patient during the interval following the transfusion. Transfusion certainly has no place in acute lymphatic leukemia, being a valuable therapeutic measure only brought into disrepute. However, in myelogenous leukemia and hemolytic jaundice it is of value in prolonging life. It is a matter of record that a case transfused for a blood condition is more liable to have a reaction following the transfusion. This is probably due to the presence of hemolytic agents in the blood.

In septicemia and chronic suppurative conditions, transfusion offers hope in that the patient's resistance is increased by the introduction of healthy red cells and a consequent rise in blood pressure. It is probably wise to transfuse these cases early because a weakened heart muscle results from the toxins present in such conditions and cardiac dilatation may result from the extra work thrown on the weakened heart muscles.

Recently, research work has been carried out in Toronto General Hospital to determine the value of whole blood in the treatment of extensive burns. It is found that the procedure is of great value, not only in the early treat-

ment of shock but later as a means of combating toxicity. A rapid rise in the total urea nitrogen in the blood in these cases offers an index as to the advisability of transfusion. The writer has seen three cases in which there was a drop in temperature and a general improvement following transfusion performed to combat toxicity following extensive burns.

When to transfuse and when not to transfuse is often a question. In answer to these questions one might say, when in doubt transfuse; as to when not to transfuse, the writer would say, when an increase in the volume of blood might cause disaster to the patient, as evidence of cardiac dilatation or pneumonia.

The minute a question of transfusion arises, a donor should be sought—a healthy young man or woman who will give his or her blood either for friendship or money. As a rule, several members of the family should be typed and from those found to be of the same type as the patient a donor is selected, preferably the most healthy one. The possible donor is then questioned to determine the possibility of syphilis, a Wassermann always being done if the emergency permits, also a complete blood count is usually made and a careful examination of the heart and lungs. Oftentimes the emergency will not allow such a careful examination and then the most available donor is taken.

As to the typing of blood, one might say that it is the most important part and should always be done with care because experience has proved that faulty typing is the cause of most of the misfortunes of transfusion. Requiring about thirty minutes it is a simple procedure in the hands of the trained.

Human blood belongs to one of four types, the type being determined by matching the blood with known serum types; only a drop of blood is required from the patient and donor. The direct method is probably more valuable in determining the amount of reaction a patient will have, but it requires more blood and takes more time to perform.

There are many methods of doing blood transfusion, most of which can be done and give the same results. Some methods are preferred to others because they are simpler and do not require the skill; other methods because they produce less reaction. The direct method is used less today than several years ago, not because it is not a safe and logical procedure,

but because it can only be done right and safely by one skilled in blood vessel surgery. The most universally used method today is the citrate method, or the use of an anticoagulant. It is being used with success, although it has a great drawback because of the number of reactions following the transfusion. These reactions often are most severe; chills and temperature of 105 degrees are alarming and certainly not to be desired. Simpler methods for the introduction of whole blood offer the prospect of less reactions and save the operator no end of embarrassment. Dr. Lewisohn who contributed this method to the profession reports only 20 per cent reactions and chills following many hundreds of transfusions. In the hands of other men the percentage of chills has been much higher. Many other methods in the hands of their respective advocates are safe, and probably the best transfusion to do is the one with which the particular surgeon is most familiar.

The writer will describe a method which in no sense is his own, but a method which is simple and safe and can be used by the average surgeon. It is a method in which the whole blood is transferred, without the use of a pump, from the vein of the donor to that of the recipient by means of a Vincent tube and a simple cautery pump. The Vincent tube is a paraffine tube, cylindrical in shape, capable of holding 350 c.c. of blood. There are two tips, one at the bottom for the insertion into the vein and the other at the side near the top for the attachment of the cautery pump. With stopper intact, it being held by paraffine, and the tube full of blood with the cautery pump attached, the cylinder becomes airtight and pressure on the bulb will force the blood into the recipient's vein. The patient and donor are placed on operating tables with supports for their arms, the left arm being always used in the case of the donor with the forearms extended; the arms are prepared with iodine and alcohol, the preparation extending about four inches above and below the elbow and the arm and hand covered with the usual sterile towels. One per cent novocain is injected along the median cephalic vein at the elbow for about one and a half inches along its course. After anaesthesia is produced, a longitudinal incision about an inch and a half in length is made through the skin along the course of the vein, the fascia is dissected and the vein exposed

about three-quarters of an inch in length. Catgut ligatures are placed around the lower and upper end of the vein. The upper end is tied in the donor and the lower end in the arm of the patient. The untied ligatures act as brakes to control the flow of blood and are tied at the end of the transfusion. An oblique opening in each vein is made with fine scissors, the lumen of the veins being exposed by the application of small mosquito forceps into the walls of the vein. This is done so that the tip of the tube can be inserted into the vein. With the upper end of the vein tied in the arm of the donor and the lower end being held by an assistant by means of the untied ligature, the tip of the tube is inserted into the vein towards the periphery and the tourniquet applied. The tube is gradually filled in from two to four minutes by means of the tourniquet and the squeezing of the hand. When the tube is filled, the cautery bulb is attached and the tube withdrawn, an assistant controlling the bleeding by pulling up on the untied ligature around the lower end of vein. The blood will not run out of the tube because pressure is made on the bulb, the tube then becoming airtight. The tip of the tube is then inserted into the vein of the patient towards the heart and by pressing on the pump, the blood will rush slowly into the vein of the patient. The tube is removed while two or three c.c. of blood still remain to prevent the possibility of air embolized. The assistant pulls up on the upper end of the vein by means of the untied ligature to prevent bleeding back. As a rule three tubes, each containing 300 c.c. of blood, are given, depending upon the condition of the patient and donor. The untied ends of the veins are then tied with the catgut ligatures which have been used as brakes and the wounds closed with clips. The whole procedure can be performed in from thirty to forty minutes. The Vincent tubes are cleaned in boiling sodium salicylate and are then run through the autoclave, dried, and coated with liquid paraffine, the stopper inserted and the paraffine allowed to harden. They are then put up in sterile towels and are ready for use again. The blood will not clot in these tubes in from ten to twelve minutes.

The writer believes this to be a simple method of transfusing whole blood. He has used it on twenty-six occasions and probably has assisted in using it on fifty other occasions.

Very few reactions have been noted and these reactions were not severe, there being an average rise in temperature of about two degrees.

Transfusion should always be performed with the most rigid asepsis and, performed in this manner, is a most valuable therapeutic measure. Wisely employed transfusion will often prove a life-saving resource; unwisely used it will surely become discredited.

### THE SCIENCE OF REFRACTION.\*

By EMORY HILL, M. D., Richmond, Va.

Refraction, like medical practice in general, is both a science and an art. The effectiveness of the art is in direct ratio to the understanding of the science. There is a vast difference between the haphazard results of a practice based on the individual's experience in doing many times what he has never learned to do accurately, and the uniformly good results of making what is a mathematically exact measurement based on well established principles of physiologic optics. General medicine may be practiced by the application of treatment found to satisfy many patients after looking at the tongue, feeling the pulse, and boiling the urine in a test tube to see if it becomes cloudy; but the modern internist is a safer advisor because his treatment is based upon more exact knowledge of the patient's physical arrangements. This contrast is no greater than that between the refraction often done and the refraction which may be done if we seriously undertake it. Refraction as an applied science, rather than merely an art, is my subject. This means substantially the use of objective tests of refraction as a foundation for subjective tests, and this, in turn, resolves itself largely into a question of cycloplegia.

If the curriculum of the medical schools were not already overcrowded, it would be worth the student's time to take a course in medical history. A perspective of the progress of science would teach him to avoid some mistakes of his predecessors, and to cling tenaciously to some of the achievements of past generations. The latter might well be the result of a review of the history of refraction in America. One of the epoch-making events in American medicine was the announcement by Weir Mitchell in 1879 that certain headaches are due to the nervous strain entailed by the use of defective eyes and that such headaches can be relieved by the exact

correction with lenses of the errors of refraction of such eyes. At Mitchell's instigation the science of refraction was put into practical use by Philadelphia ophthalmologists, with the aid of atropin used sufficiently to produce complete and prolonged cycloplegia. It is to be observed that this achievement was not the result of somebody's individually discovered pet method of manipulating lenses, not by "fogging" the vision, not by sitting the patient before a formidable looking instrument called the ophthalmometer and reading off a formula, not by any of the methods taught in a school of optometry; but by the application of perfectly well-known laws of physiologic optics, laid down by Donders in 1864 in his classic work which is not a popular book on the shelves of the present-day specialist. Good refraction was done in other places and can be done today without slavishly following every detail of the Philadelphia method of 40 years ago; but we shall always owe a large debt of gratitude to the men who showed us how to make refraction work about the most mathematically exact thing in the domain of medical science.

A further development in American medicine occurred, perhaps inevitably but to the detriment of ophthalmology, when the era of specialism arrived. It may be doubted whether a practice confined to so narrow a specialty as ophthalmology was possible outside the large cities, or whether the postgraduate facilities available could have supplied the needed specialists for a rapidly growing population. In any event, the desire to enter special practice, and the rewards of such specialization as compared to the modest income of the general doctor, led to an urgent demand for postgraduate instruction, which was supplied by brief courses in eye, ear, nose and throat hospitals and clinics in the medical centres. Quantity production seems to have been the ideal, and the result was the hasty acquisition of rule of thumb methods of doing a routine office practice and the simpler surgical procedures, together with a kind of refraction which has little to commend it over the optician's practice. The situation appears to have grown worse instead of better in the past few years. With the war, graduate study in Europe was abandoned and the staffs of the better ophthalmic clinics in America were depleted. Following the war, a general discontent with medical practice in rural communities and family practice in the smaller towns

\*Read as part of symposium on Refraction at the meeting of the Virginia Society of Oto-Laryngology and Ophthalmology in Richmond, April, 18, 1923.

has developed. Today we find the ranks of our specialty increasing at a surprising rate. It would seem that eye, ear, nose and throat work has a fascination exceeding that of any other branch of medicine. We see very few men going into the specialty through the need for such work in their own communities and their recognized obligation to meet this need by gradually acquiring special knowledge; we see very few men undergoing a rigid training of two, three or four years in the medical centres. On the contrary, we see many men leaving a good general practice to take a few weeks or months of postgraduate study, which is at best a kindergarten course, and settling in a somewhat larger community as full-fledged specialists. I am not competent to pass on the character of their work in otolaryngology, but I venture the opinion that they are exceptionally gifted individuals who can learn to do uniformly good refraction in less than a year of constant practice at the side of an expert; and I am at a loss to know how they ever acquire the necessary experience in a busy routine of isolated practice three-fourths of which bears no relation to ophthalmology.

The failure of the rank and file of ophthalmologists to perform their duty as refractionists is shown in the very general confusion of the layman's mind as to the meaning of the words oculist and optician; we may well ask ourselves if there is a difference as clear-cut as we ought to have made it. The prominence of the so-called optometrist, who is called "Doctor" by his clientele, is embarrassing to us, and I know of no way to lessen the embarrassment except to look our faults in the face and see wherein we have failed to live up to the obligation which was met by our predecessors who took seriously the subject of physiologic optics, used cycloplegics with thoroughness, and devoted sufficient time to refraction to ensure exactness. If otolaryngology is our chief interest, and ophthalmology a side issue, we shall not do good refraction. If surgery is our main concern, we shall not find the tedious routine of refraction work agreeable and it will be neglected. I am well aware that ophthalmology and otolaryngology can be practiced together with faithful zeal and skill; too many members of this society are living proofs of this possibility to let us doubt the fact; but I do deplore the evident and acknowledged lack of interest in refraction among

some of our numbers who do it at all only because it is the conventional thing.

The results of the most painstaking refraction work, as taught by the late Wm. Thomson and S. D. Risley of Philadelphia, by Duane of New York, Jackson of Denver, and others among the masters in ophthalmology, are satisfactory to largely over 90 per cent of our patients. I doubt whether the many short cuts in use in our offices today can show anything even remotely approximating this. Guesses may give 50 per cent of successes, and long experience in guessing may add to the percentage; but guessing is not warranted where certainty is possible, and certainty is possible in nearly all cases. That we cannot obtain 100 per cent of successes is due to some conditions beyond our control and others which we may control if we will. We can refuse to undertake a refraction for a patient who wants to catch the next train. We can demand two days as a minimum for the patient who does not require a cycloplegic, but merely a mydriatic, three days for the patient who requires a cycloplegic. We can elicit a history which shows that the eyes are not alone at fault and insist upon other study of the case to arrive at the cause of the symptoms. We need more intimate cooperation with the family doctor. Eyes are not isolated organs and the ophthalmologist ought not to be an isolated practitioner. We are at a disadvantage when the patient lives at a distance and cannot return for further observation. We are helpless when confronted by the patient who will not acknowledge his difficulties and inadequacies for his business and domestic life, and insists that a pair of glasses shall cure a mind diseased and restore domestic felicity. Eye troubles are sometimes defense reactions and require a psychiatrist instead of an ophthalmologist. Then there are patients who absolutely refuse to consider a refraction as anything more important than buying a new roll of film for a kodak. There remain, however, the very great majority of our clientele who want scientific refraction and will take the time for it. What is their due? With exceptions always to any rule, a routine of thoroughness can be outlined which I venture to state as follows:

Children should be refracted with atropine. Their eyes, if they need any attention, are worth more than two weeks of schooling. Atropine sulphate in 1 per cent solution, used three times daily for a minimum of 3 days,

is necessary for complete cycloplegia. This may be insufficient. It is easy to demonstrate the fact that accommodation still exists, and to continue the atropine one or two days longer. No marked discrepancy should exist between retinoscopic and subjective findings. It is sometimes necessary to prescribe lenses on the basis of retinoscopy alone, and one's retinoscopy should be dependable except in those cases where distorted or clouded media interfere. This thorough routine is especially urgent in squint cases, where a full correction is necessary to abolish that excess of accommodation which brings on excessive convergence.

Young adults may need atropine as much as children. This can be determined by testing the remaining accommodation after homatropin has been used. The history and symptoms of the individual case may point to the need of rest to an overtaxed ciliary muscle. The therapeutic effect of atropine upon the entire uveal tract should not be forgotten. Mydriasis and temporary cycloplegia are by no means the total effect of drugs used for the measurement of refraction. The majority of adults can be refracted satisfactorily with homatropin. A 2 per cent solution used, a drop at a time, until 6 drops have been instilled in the course of 30 or 40 minutes gives sufficient cycloplegia in 1 to 1½ hours in most cases. Any marked disagreement between retinoscopic and subjective findings suggests remaining accommodation and calls for more cycloplegia. Repetition of the drops on a second day, or the use of homatropin three times daily followed by intensive use in the office may be necessary in these cases. Post-cycloplegic tests are of greater value in adults than in children, because fixed habits of ciliary muscle strain interfere with the comfortable use of a full or nearly full correction. This applies to the hyperopic correction only. Of course the cylindrical glass is kept at the strength found under cycloplegia. The optician's argument that cycloplegia is useless if the prescription for glasses is not identical with the findings under cycloplegia is based upon gross ignorance and needs no refutation. Post-cycloplegic tests are of greatest use in persons who are presbyopic.

Myopes are perhaps the most neglected people whom we refract. Young myopes accommodate, because that is the natural and inevitable thing for any eye to do even if the result is futile; and they accommodate because they

usually have an astigmatism which they are trying to overcome. Therefore, myopes need cycloplegia for refraction, and the disastrous results of unchecked myopia justify as thorough use of cycloplegics as does hyperopia. The ease with which myopes can get improved distant vision with lenses is really a misfortune. If it were not so easy to sharpen their vision, they would not be so carelessly treated. Increasing visual acuity is not the only aim of the refractionist; indeed, it may be a calamity if it is secured at the expense of a ciliary spasm.

Cycloplegics are as necessary in people 40 years of age as in younger people, and often more necessary. Duane has called attention to ciliary spasm at this age and beyond. This type of case requires individual study; no hard and fast rule can be laid down. To cease using cycloplegics at 40 years, or 45 or 50 years, is an utterly irrational thing. In general, the older the patient the less cycloplegic is necessary; but this rule has so many exceptions that it cannot be followed. It is taken for granted that the usual observations to exclude glaucoma have been made. The bugbear of glaucoma raised by the incompetents in and out of the profession need not frighten us.

There is no eye in which a small pupil allows the careful study of the eye ground which should be a part of every refraction and the satisfactory retinoscopy which also should be part of every refraction. When cycloplegia is unnecessary, mydriasis is of great value. This need not be extreme mydriasis, but the pupil should not contract sharply when light is thrown into the eye. Old people have small pupils and frequently sclerosed lenses; therefore, they particularly need a mydriatic for refraction. One or two drops of a 2 per cent solution of euphthalmine or eucatropine enables the observer to study such eyes and does no possible harm. The practice of doing manifest refractions without study of the eye grounds in old persons precludes accuracy in fitting glasses and also the discovery of valuable diagnostic signs of local and general disease. Such scant respect for the eyes of the old is responsible for some of the blindness from chronic glaucoma which occurs while the unfortunate victim is waiting for an imaginary cataract to ripen.

In short, refraction is a matter of scientific accuracy if we choose to make it so. Experience increases the percentage of satisfactory

results from the practice of an art; but without a thorough grounding in the underlying science no uniformly good results will follow. If we cannot demonstrate from our case histories over 90 per cent of satisfied patients whom we have refracted, something is wrong with our methods. The largest single factor in good refraction is cycloplegia; other important factors will be considered by the speakers who follow.

### DIAGNOSTIC METHODS IN REFRACTION WORK.\*

By HUNTER H. MCGUIRE, M. D., Winchester, Va.

To attempt to discuss the many and varied problems of refraction work before a body of men whose daily activities are largely concerned with all phases of this branch of our specialty would be an undertaking which would involve, not only an immense amount of labor, but would be a repetition of facts which have been brought out in the mass of literature which has been devoted to this subject.

It occurs to me, therefore, that it would be more profitable for those of us, to whom has been assigned the task of leading the discussion in this symposium, to give our individual views on those methods of examination which have proved to be the most efficient in our experience and to point out, if possible, the relative value of the various methods which have been advocated.

Inasmuch as the large majority of patients who come to us for the relief of ocular troubles are victims of eyestrain resulting from errors of refraction or muscular anomalies and, inasmuch, as our success in ophthalmology is largely dependent upon our ability as refractionists, it is evident that the importance of the subject cannot be overestimated and that nothing should be left undone to make perfect our technic in estimating the error and to give us an unerring judgment in correcting it.

At the outset and before taking up in detail some of the diagnostic methods which have proven useful to me in handling such cases, I wish to emphasize one phase of the subject, upon which I have always felt that insufficient stress has been laid in text books and in journal articles. I refer to the importance of systematic history taking and to the necessity for obtaining from the patient such facts as have a direct bearing upon the treatment of

his case. Study the patient, his occupation, his environment, his habits, the position he assumes in reading and at his desk, his facial expression, his carriage, and his mental makeup. Give him time to tell you in his own language how he suffers, and obtain from him, by direct questions, the symptoms which need correction.

Bear in mind that the presbyopic bank clerk who is constantly shifting his position and thereby altering the distance in his near work, though he may show the same amount of presbyopia, will necessarily require a very different correction from the man of letters who pores over books in a fixed position, in an easy chair, and who, because of his culture, expends a greater amount of nervous energy in his work.

The high-strung neurasthenic type whose symptoms are always exaggerated and who seeks your advice for the relief of manifestations which are either real or imaginary, must be approached in a far different manner than would be necessary in the man of health and vigor, whose mental poise is well established, and who is essentially a more normal individual. The estimation of the error and its correction in the case of the former will necessarily involve a greater degree of accuracy and a more careful attention to detail than would be regarded as essential in the case of the latter.

The seamstress, bending over her task from early morn to late at night, more often than otherwise, in badly lighted and ill ventilated rooms, though she may show the same type and amount of error as her more fortunate sister, who lives under ideal conditions with her eye-work limited to a perusal of the social column in the daily press and a study of the latest fashion charts, will of necessity, require greater assistance to her overworked ciliary muscles and more intelligent advice regarding the proper care of her eyes.

It is with the aid of these few crude examples and the enunciation of certain, which may seem to be very elementary, principles, that I am seeking to drive home a principle which I believe is frequently overlooked in our very busy lives and the observance of which I regard as very necessary if we are to become successful refractionists. And it is simply this: In undertaking the treatment of any refraction case, study the individual as well as his eye. The adoption of such a policy will not only serve to give us the best results in the

\*Read as part of symposium on Refraction at meeting of Virginia Society of Oto-Laryngology and Ophthalmology in Richmond, April 18, 1923.

treatment of these cases but will eradicate from the public mind a misconception, which I sometimes fear has become deep rooted, with regard to the nature of our work and the association of ocular disturbances with general systemic involvement.

The methods we adopt in the examination and treatment of refraction errors should of themselves convince the public that the eye is not merely an optical instrument standing apart and exercising an independent function of its own, but that it is an important part of the human economy with errors and diseases closely associated with other organs of the body and that physicians who have devoted their life's work to the study of its abnormalities are alone capable of correcting them.

The comprehensive study of a refraction case, as is well evident to all of you, involves an immense amount of painstaking labor and many methods have been suggested for determining the type of error and its amount. I shall only discuss, as briefly as possible, those diagnostic measures which, in my daily routine, have impressed me with their value and which have enabled me to solve difficult problems with comparatively little labor and without sacrificing accuracy.

For purposes of description these methods may be divided into objective and subjective determinations. Before taking up in detail the various means of diagnosis, I wish to go on record as saying that it is my firm conviction that the correct interpretation of a refraction error, except in the case of illiterates and young children, can only be made by the use of both objective and subjective methods. I do not believe that one can be depended upon to the exclusion of the other. The true state of the refraction can only be determined by a judicious use of both methods.

With regard to objective determinations I shall limit my remarks to the ophthalmoscope, the ophthalmometer and the retinoscope.

It may seem superfluous to even mention to a body of ophthalmologists the importance of a complete ophthalmoscopic examination in patients who come to us for glasses, and yet all of us know of men of ability who are perfectly capable of interpreting fundus pictures, who seem quite willing to complete their investigations and prescribe for the patient without knowing the condition of the eyeground and the state of the refractive media. If satisfactory central vision is obtained from sub-

jective tests, they seem quite willing to assume that the entire fundus is healthy and the patient is sent on his way rejoicing in the fact that his new glasses are giving him wonderfully acute vision when, not infrequently, an insidious pathologic process is developing in the periphery of his eyeground. In most instances this omission on the part of the oculist is due either to the necessity for saving time both to himself or his patient or to the knowledge that a large majority of refraction errors are unassociated with ocular lesions. It seems to me, therefore, and I have adopted this practice in my daily routine, that the ophthalmoscopic investigation should be the first method of diagnosis to be employed in the study of the refraction error. By means of it we are enabled to determine very quickly whether we are dealing with a diseased or a healthy eye, the type of error can be determined, and its amount can be approximately estimated. With this information in hand, the subsequent procedures can be utilized with a greater degree of satisfaction and accuracy than would otherwise have been obtained. No refraction case should be discharged until a complete ophthalmoscopic examination, if necessary under a mydriatic, shall have been made.

We are all perfectly familiar with the limitations of the ophthalmometer, in that its records are only concerned with the anterior surface of the cornea. Keeping this fact in mind, however, I regard it as a valuable aid in the diagnosis of most astigmatic errors. In high degrees of error, particularly in post-operative astigmatism, it will usually give reliable information as to the axis and approximate strength of the cylinder to be prescribed. In small degrees of astigmatism, with the rule, its readings are not always verified in the subjective tests. This, of course, can be explained by the fact that lenticular astigmatism will frequently be associated with the corneal defect. In astigmatism against the rule, it usually will, in my opinion, give fairly accurate readings. Irregular astigmatism is very quickly recognized by the use of this instrument and by reason of this fact the subjective examination in these cases is made less tedious both to doctor and patient. As an axiomatic fact it may be stated that the ophthalmometric readings, while valuable as aids to diagnosis, should never be adopted in the final prescription for lenses unless they agree with the retinoscopic findings and the subjective tests.

Ophthalmology owes a debt of gratitude to Jackson and Thorington for elaborating and perfecting the technic of retinoscopy. In my opinion, it is by far the most reliable of all the subjective methods for determining the character and amount of the refraction error. While to the beginner it may seem to be a difficult method to master, most observers will agree that if its details are carried out with the precision and care which have been advocated by experts in this means of diagnosis the results will be most gratifying. Constant practice on the various forms of schematic eyes is certainly a valuable method for developing a high degree of efficiency in the performance of this test. In children and illiterates it is, obviously, the one method upon which we can place the greatest reliance, and in these cases, it is my belief that it can be depended upon to the exclusion of all others. While some observers are of the opinion that satisfactory results may be obtained from the retinoscope without resorting to complete cycloplegia, my experience has convinced me that accuracy in this method of diagnosis is dependent upon full relaxation of the accommodation. In executing the test, I have found in my own case, that working at a distance of one meter with a plane mirror and adding or subtracting one diopter, as the type of error indicates, has given me the most satisfactory results, though I realize that this is largely a matter of personal preference.

In the subjective determination of the refractive error and the estimation of the various types of heterophoria, the intelligence of the patient is a potential factor in enabling us to make logical deductions from the findings. Given, however, a fair degree of intelligence on the part of the patient and a non-irritable state of mind on the part of the examiner, the working out of the refractive state resolves itself into a very interesting problem. Even in patients who are mentally alert, I believe it is well, in some instances, before beginning the subjective examination, to explain very carefully that it is not their mental faculties we are investigating but their visual powers and that the latter will be more accurately determined if the imagination is not brought into play, and if for the moment they can forget they have a mind.

I believe that most ophthalmologists are of the opinion that in the diagnosis of the refractive error by the subjective method the results

obtained from the use of the trial lenses and test cards are to be regarded as final and that in the ultimate solution of the problem this procedure may be looked upon as the court of last resort. While in the main I fully concur in this opinion. I think there are certain conditions which materially influence the findings by this method and which, not infrequently, may lead to inaccurate conclusions. Fatigue of the ciliary muscle from too prolonged efforts to bring out the manifest error is certainly one factor to be reckoned with and will often bring about misleading results. It is far better, in my judgment, to make the patient return for frequent short examinations than to persist for a long period in the attempt to measure his error when his muscles are fagged.

Improper or inadequate illumination of test cards is another condition which interferes with accurate results in the subjective tests. The plan suggested a few years ago by a Committee of the American Ophthalmological Society, or some of its modifications, is admirably adapted to office requirements. Reflected light of daylight intensity and evenly distributed over the test object makes an ideal illumination and is far superior, in my opinion, to some of the more elaborate designs in which the source of light is placed behind the test object and the rays directed through some translucent material.

The advantage of conducting the examination amid quiet surroundings must be apparent to all of us. I do not know of anything more disconcerting to the patient or more annoying to the examiner than the presence of solicitous friends or relatives in the refracting room who either persist in prompting the patient or from idle curiosity make a complete investigation of the office equipment and all the while make audible comments when you are endeavoring to secure the intelligent co-operation of the patient. These then are some of the factors which materially influence the findings in the subjective examination and should, if possible, be eliminated if our patients are to secure the best results from our efforts.

The method of procedure in the use of the trial lenses is so familiar to all of you that it hardly seems necessary to go into details with regard to their use. There are, however, certain refinements in trial case accessories and in the construction of trial frames which, in my opinion, have been of great practical value in

diagnosing the refraction error by the subjective method.

In bringing out small degrees of astigmatism and in locating the axis of the cylinder with precision, the cross cylinder is a quick and efficient agent and enables the examiner to employ plus and minus cylinders in the further steps of the examination with a greater degree of confidence in his judgment. It is likewise particularly useful in checking up the final correction to ascertain if the strength of the sphere or cylinder should be altered. This little device which was first described by Jackson thirty-five years ago has not received, in the literature, the attention it deserves. In my judgment it is by far the most useful method of estimating astigmatism and accurately locating the axis of the cylinder by the subjective method. A detailed description of its use and value is given by Dr. Crisp of Denver, in the March number of the *American Journal of Ophthalmology* and I would strongly urge that this article be given your careful consideration.

In some cases of astigmatism where it seems difficult to find the principal meridian of greatest and least curvature, the stenopeic slit is a useful agent in bringing out these meridians and, while I do not employ it as a routine method of examination, it certainly is of value in many instances. Recent advances in the construction and adjustments of trial frames have certainly, it seems to me, been of very material aid in enabling the refractionist to obtain better results and to give him the assurance that his findings are more scientifically accurate than was possible with some of the very crude contrivances we were obliged to use in former years. The independent pupillary and vertical adjustments together with improved methods of raising, lowering and tilting the frame and of placing the trial lenses at the correct distance in front of the cornea are all features which have contributed to more exact results. The more elaborate apparatus which in compact form includes batteries of trial lenses, rotary prisms, Maddox rods and other devices for diagnosing the refraction error and bringing out the various forms of heterophoria constitutes, in my opinion, a distinct advance in the examination of the refraction case, but I do not believe it will ever entirely supplant the trial frame and test lenses. It is a convenient and quick method of diagnosis and has the dual advantage of enabling the examiner to make a

more rapid change in lenses and of producing less fatigue to the patient. The muscle tests embodied in the instrument, by reason of their fixed position and the ability to absolutely level the apparatus before the patient's eyes, are much more to be depended upon and give more accurate results than do the same tests when used in the usual trial frame. I have used practically all makes of this apparatus and as new models have appeared have added them to my equipment and, while I am convinced that they serve a very useful purpose in the examination of the patient, I do not believe that they have yet reached that degree of perfection when it would be safe to discard what might be termed the old fashioned trial case. My usual custom is to examine the patient with this instrument but always check up its findings with the correction in the trial frame and in the final analysis my deductions are based upon the results obtained from the latter. In other words, I feel, as far as the refraction error is concerned, that the trial frame correction more nearly approximates the formula to be given the patient than can be obtained from any other form of instrument.

This communication would not be complete unless some mention was made of the valuable contributions Duane has given ophthalmic science with regard to the importance of testing the accommodation in the examination of the refraction patient. If, as he has pointed out—and I think his position is unassailable—we meet with many cases of subnormal accommodation, we are overlooking a very important factor if we fail to carry out the very simple and quick method he has suggested for estimating the power of the accommodation.

With regard to the use of cycloplegics in refraction work, I can only say that I am a strong advocate of and systematically relax the accommodation in all ages up to forty years of age and, in many patients between forty and fifty, I find it necessary to complete my investigations with the aid of homatropine. With this brief statement I shall not further discuss this portion of the subject, as I understand it will be fully covered by another speaker.

The diagnosis of the various types of heterophoria and the association of these anomalies with the refraction error will likewise be discussed in another paper, so I shall not attempt to do more than to say that I regard these tests as a very essential part of the examination

and in the correction of the refraction error they play an important role. I do feel, however, that the multiplicity of methods which have been suggested for bringing to light the various phorias and for estimating the duetion have created more or less confusion. In my own work in recent years I have largely confined my investigations of muscle balance to the use of the Maddox rod and rotary prism and this one method has usually given me satisfactory results. In executing any of the muscular tests emphasis should be laid upon the necessity for estimating the degree of heterophoria for both the distance and the near correction.

In concluding what I have attempted to present in a rather desultory fashion, I feel that in summing up the whole matter I cannot do better than to quote Duane, whose researches have contributed to such a great extent in putting refraction work on a scientific basis:

"I think the whole matter of handling refraction cases may be summed up in these two maxims: First, let us find out all we can about the eyes we are treating and the symptoms of which they are a part; using to this end every means that experience has proved to be helpful, never doing the work in a hurry, and remembering always that this work of all others requires patience, thoroughness, and accuracy.

"Second, let us constantly bear in mind the fact that we are treating patients, not eyes; that we are handling human beings, not machines; and that we cannot do our best work unless in each case we put ourselves in touch with the individual man before us, showing sympathy for his troubles, consideration for his infirmities, and an understanding mind, to take in all the physical and mental factors which may affect his outlook on life, and determine his need for refractive or other correction."

## THE ETIOLOGY AND PATHOLOGY OF CANCER.\*

By K. D. GRAVES, M. D., Roanoke, Va.

Cancer is one of the oldest diseases with which the human race is familiar. Even back in the days of Moses, the semibarbarian Egyptians recognized and respected it, treating it with caustics and escharotics. The oldest literature of India and Persia carried references to it. Hippocrates was cognizant of its

dangers, and treated it by burning. Celsus, at the beginning of the Christian Era, excised cancer of the breast, advising against removal of the pectoralis major. Even during the dark ages men knew and dreaded it and speculated as to its cause.

The year 1824, in which the achromatic microscope was discovered, marks a new milestone in the history of cancer. An entirely new visualization of this disease was had, due to the study of the cells under the microscope. New theories were evolved in the scientist's study, to be exploded in his laboratory. Another era was ushered in in which practically every observer had a different opinion, each clamorously presenting his views on the subject, each unable or unwilling to admit his fallacies. The theories that cancer originated from the exuded elements of the blood, the specific cancer cell, etc., all had their noisy expounders, demanding recognition which, if given, was short lived.

Finally, Thiersch and Waldeyer proved conclusively the principle of the exclusive epithelial origin of cancer which is now generally accepted. In a word, this theory is that cancer can only arise from the epithelial type of tissue, and not from connective or lymphatic tissue. Cancer in the human is considered as being not hereditary, not contagious, possibly capable of being transmitted by grafting, probably being directly or indirectly influenced by such factors as trauma, irritation, X-ray burns, fetal rests, etc. Of these, probably one of the most important is trauma. Eliminating such factors as casual burns, surgical or accidental cuts, etc., such constant and repeated trauma as produces, day after day, erosion, crushing or bruising, is believed to lead to cancer. This is especially well illustrated in the chimney-sweep's knee.

We often see lesions which, for lack of a more comprehensive term we call "precancerous." Probably a better term would be "early cancerous." Experience has taught us that the little place on the lower lip, or the cervix, indurated and eroded, which does not seem to cause much discomfort but just does not heal up, microscopically often shows signs of activity, such as a few poorly differentiated cells which appear to be breaking through the basement membrane; or erosion with marked thickening of the surface epithelium, with here and there long or short fibrils of epithelial tis-

\*Read as part of symposium on Cancer at meeting of Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

sue reaching down into the underlying connective tissue. These are distinct sign posts marking the cross roads of divergence between benign and malignant growth and, if ignored, we all too soon realize our error and are brought face to face with a malignant reality.

Cancer may be visualized as normal epithelial tissue run amuck. In studying a microscopic slide of an epithelioma, for instance, we see the orderly line of the basement membrane suddenly broken, the cells lose their individual characteristics and become poorly differentiated, and show a marked tendency to spread by extension of growth. Outcroppings of the same type of growth appear deeper in the tissues, and we know by experience that this growth will continue unless checked by heroic measures. Cancer may be said, pathologically speaking, to recognize few laws and no restrictions.

In conclusion, I would say that, although cancer is one of our oldest and most dreaded and dreadful diseases, its causes are among the least well understood. Much has been accomplished in ruling out certain etiological factors. Much remains to be accomplished in the way of positive information. Why, for instance, should the wart on the face of a lady I saw last week, which she had nurtured for fifty years, suddenly take on such activity as to threaten her life, liberty and pursuit of happiness, if let alone? No one knows.

However, the eyes of the medical world are focused expectantly on the cancer problem, and we confidently hope that within the next few years the enigma of the why and wherefore of malignant disease will join the ranks of such diseases as syphilis, malaria and diabetes; which we predict will happen not through the study of manifest malignant changes, but through the careful routine examination and earnest consideration of those early deviations from normal tissue, which are termed "pre-cancerous lesions."

*Lewis-Gale Hospital.*

## SYMPTOMATOLOGY AND DIAGNOSIS OF CANCER.\*

By W. H. RIBBLE, M. D., Wytheville, Va.

The symptoms of cancer, as laid down in the textbooks, are those of a new growth or ulceration. At first, these growths give so little

trouble that the patient looks upon them lightly and does not consult the physician till there is a rapidly growing tumor, with adhesions to adjacent parts, metastases, extensive ulceration, cachexia, etc. When these symptoms have developed, the disease has usually gotten beyond control and 90 per cent of those affected have received their death sentence. To save this large per cent, we must look for the premonitory symptoms and deal with them before they become cancer.

The safest remedy for snakebite is to know the habitat of the reptile and kill the "snake in the grass" before he bites you. The safest remedy for cancer, likewise, is to know *its* habitat and what produces it, so that we may attack it in its incipency.

When a section of cancer is placed under the microscope, we find the fibrous stroma filled with cancer cells, pre-natal epithelial cells, embryonic epithelial cells, or whatever we elect to call them. But all agree that they are epithelial. It is perfectly logical, therefore, to conclude that epithelial tissue is the habitat of cancer and, for the sake of argument, we will state that the cause of cancer is any persistent irritation which may provoke epithelial cells to excessive proliferation.

When the ovum is excited to cell proliferation by contact with spermatozoa, the epiblast, one of the three primitive layers of cells, gets busy, involutes and differentiates into anything from the delicate tissues of the brain to a toenail or tooth, according to what is needed at a particular point to perfect an organism.

After this active differentiation and proliferation has fulfilled its mission of construction, it quiets down to a simple maintenance of the tissue formed. But, let some persistent destructive or irritating agent continue to invade or irritate one of these tissues, and these epithelial cells are again excited to activity. They begin to proliferate rapidly, as they did in the vivified ovum. But they find no new tissue to form so they continue to proliferate blindly till they become so numerous that they cannot live or let live, and we have a cancer. If some of these cells get into a lymph channel, they migrate to glands, the liver, spleen, lungs, kidney, and even the bones, producing secondary or metastatic cancer.

Following up the idea, let us review the most frequent seats of cancer and see if they are not where the peaceful cell life is so

\*Read as part of symposium on Cancer at meeting of Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

molested that it becomes a case of "beware of the fury of a patient" cell.

The uterus is most frequently affected, next the breast, and we must admit that these organs (in the same order) are subjected to more stimulation and irritation than any other organs in the body. Fifty per cent of all cancers develop in the intestinal tract. Of the intestinal organs, the stomach is most frequently attacked, next the rectum, then the colon. (The small intestines are rarely affected). The stomach receives the ingesta, most frequently excessive in quantity, poorly masticated and of irritating nature. It passes into the small intestines in a liquid, partly digested state, with but little to create irritation. Passing into the colon, it becomes more solid, moves more slowly and often "rests," producing an irritating constipation or colitis. In the rectum (the cesspool of the body) it accumulates, becomes still more solid, and often "rests" quite a while and irritates the epithelial lining of this organ.

Fifty per cent of face cancers are located on the lower lip. Watch the lower lip and see how often it is between the teeth, how often it is bitten, moistened and dried, becoming fissured and abraded and how these abrasions are picked and bitten.

Conheim, observing that cancer shows a preference for the orifices, attributed this fact to "rests" from pre-natal embryonic complications: but, is it not just as likely that it is because the epithelium at the orifices is subjected to excessive irritation, by the sphincter muscles and what passes through the orifices?

I have seen cancer of the tongue, buccal mucous membrane and lower lip develop at a point of constant irritation by a rough tooth; one on the anus, where lack of cleanliness matted the hair and caused abrasion; and one on the heel, where a slight wound was kept irritated by a shoe. Does not all of this suggest that, if we look upon these chronic sores and neoplasms as being premonitory symptoms of cancer and deal with them radically, we may save many lives; and likewise, with chronic mastitis, uteri which are chronically affected, and with unyielding erosions of the cervix uteri?

The early symptoms of internal cancer are so obscure that they are seldom diagnostic, so an exploratory operation is being strongly advocated where there is a reasonable suspicion.

Lunger and Neuberger call attention to the presence of spirochetes in the gastric juice as of value in the diagnosis of gastric carcinoma. And Julius Friedenwald and George H. Grove, Trinkler and others have demonstrated the value of "the blood sugar test as an aid to the diagnosis of gastro-intestinal cancer." Articles on these two latter subjects may be found in the second volume of "*The Medical Interpreter*."

I have purposely avoided a rehash of the symptoms and diagnosis of cancer with which we are all so familiar, and simply want to emphasize the fact that our cancer cases are dying and becoming more numerous and that we must do something that we have not been doing to alter this sad fact.

I remember hearing Dr. Joseph Price, of Philadelphia, read paper after paper on the subject of cancer and how he treated it. The last one was after he had lost his youthful enthusiasm and was about to "lay down de shovel and de hoe" and he was honest enough to say in the windup, "Gentlemen, all my cancer cases are dead."

I fear that most of us older men must subscribe to this statement but I hope you younger men may find some means to have better luck.

#### X-RAY TREATMENT OF CANCER.\*

By B. E. RHUDY, M. D., Abingdon, Va.

It is fairly generally admitted that roentgenotherapy has a very prominent place among the so-called remedies or cures for cancer, radium and surgery being the only other therapeutic agents of popular use. Generally speaking, what can be accomplished with radium can be accomplished with roentgen rays and *vice versa*. However, there are cases which seemingly, because of their nature or peculiar location or extensiveness, are better adapted to treatment by roentgenotherapy, while there are others which are probably better treated by the application of radium. There are others which we are convinced should be treated by the means of both agents; especially do we have in mind malignancies of the genito-urinary apparatus.

For the best results the cases must be carefully selected and sometimes it is necessary to combine irradiation with surgery. If irradiation is used in conjunction with surgery, it is

\*Read as part of symposium on Cancer at meeting of Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

best used prior to it, but is also a very valuable prophylactic measure following operation.

It is generally conceded, I believe, that some means of irradiation, such as X-rays in conjunction with the introduction of radium into the uterine cavity, is considered the method of choice for treatment of all cases of primary cancer of the uterus. According to statistics of cases treated at the larger clinics, with irradiation properly carried out, we may expect a large percentage of cures in these cases.

It is stated, especially, by those who are using radium extensively, that operation is probably a mistake after all evidence of the tumor has disappeared; that if a cure has been produced, operation is unnecessary and, if it has simply caused degeneration of the tumor cells and their encasement in fibrous tissue, operation can only serve to destroy the framework of fibrous tissue and free the cells for further activity.

Prophylactic irradiation before and after operation has become quite popular, especially in cancer of the breast, and in many clinics post-operative irradiation is carried out routinely. The pre-operative treatment of breast cancer is much less popular but seemingly rests on a more scientific basis than post-operative irradiation, thereby minimizing the injurious effects of the operation. Objections to pre-operative irradiation are offered by some surgeons such as that the healing of the wound is delayed. On the contrary, a prominent surgeon recently stated that he had observed that in the cases which had received irradiation, the wound healed better and left a better scar. The objection that the operation is made more difficult is the one probably most frequently offered, except seemingly there is some increased tendency to hemorrhage; if performed immediately, it is difficult to conceive that such an objection is valid.

William S. Stone, in reviewing more than 10,000 neoplastic cases which have been under his observation during a service of seven years at the Memorial Hospital, New York City, the majority of which have received X-rays or radium treatment, states that he believes the adoption of pre-operative treatment in mammary cancer will show that the field of applicability of the radical operation should be much restricted, and that it occurs to him that the presence of hard, fixed nodes in the apex

of the axilla makes the case as unsuitable for a radical operation as does the presence of supra-clavicular nodes. It is a question then, how long it will be before the radical operation for breast cancer will be entirely discarded.

The results of the use of X-rays and radium on the osteogenic tumors, which are frequently applied on account of their inaccessibility to surgical procedures, because of their peculiar location, leads one to think that with their earlier recognition by means of clinical history and X-ray study, irradiation may prove to be an efficient substitute for incision and curettage or even amputation.

The treatment of malignant conditions of the skin is probably one of the most useful fields of irradiation as well as the most satisfactory. The malignancies of the skin that we are frequently called upon to treat are the squamous-celled and basal-celled epitheliomata. The basal-celled epitheliomata is one of the most satisfactory types of malignancies to treat because of its slow course and because it frequently does not involve the surrounding lymph nodes. Radiotherapy seemingly is the treatment of choice for these lesions, because of the ease or simplicity and painless application, to say nothing of cosmetic results, the production of a soft and relatively small scar; the latter is often to be considered, inasmuch as these lesions so frequently occur about the face. Frequently it is possible to keep this type of malignancy under control in the more extensive growths and to apparently produce a permanent cure in many of them. Irradiation of superficial lesions should be carried out deliberately, for it is better to give a little too much than to give too little. In conjunction with the thorough irradiation of the entire field of the primary lesion, the regional lymph nodes should be thoroughly irradiated, with the view of closing the lymphatics. We must keep in mind the likelihood of extension by metastasis for we can no more hope for results by treating a portion of the tumor than can the surgeon hope for success by removing only a portion of it.

In dealing with the treatment of malignancy of any part of the human body by roentgen ray therapy we are at once confronted with difficulties, due in the first place to the lack of definite knowledge as to the extent of invasion

of adjacent and deeper structures; in the second place, to the inaccessibility of the deeper parts of the growth to effective radiation; and in the third place, the effect the rays will have on the cells of the normal tissues. To treat properly any malignant tumor, one must know, if possible, the effect of X-ray upon the normal as well as the malignant cells.

There has been comparatively little work done, until just recently, to show the effect of radiation on the normal tissue. The introduction of any therapeutic measure has always been accomplished by an over-estimation of its curative powers which, in the course of time, had to be modified when a more mature judgment prevailed. In roentgen ray therapy, especially when using the more penetrating or short wave length rays, we are threatened with a set-back on account of a variety of injuries resulting from the therapeutic application of the rays. Roentgen injuries have occurred and will occur in the future, and cannot be avoided with absolute certainty, but irradiation is comparatively safe in the hands of a competent operator. These injuries may be divided into two groups: local and general—injuries caused by exceeding the tolerance of tissues and resulting from defects of radiation technique. Local injuries must be distinguished from general or systemic injuries such as acute blood tissue injuries or destruction of the red blood corpuscles. Destructive changes in the blood occur during each therapeutic irradiation which is employed for the destruction of pathological cells; therefore, it is important to have the patient entirely screened or protected from the rays, leaving only the area intended to be treated exposed. Other injuries sometimes caused by irradiation are often spoken of as "roentgen sickness" which may include nausea, vomiting, headache, and perhaps diarrhea. This probably can be much alleviated, in most cases, by proper preliminary preparation, as well as proper screening and ventilation during period of irradiation.

The general health of the patient must be considered also, because of the so-called toxemia which results from irradiation—a subject which deserves much consideration, especially in case of elderly persons. A complete blood count and hemoglobin should be made and repeated at intervals on all cases. This should be used as a guide in carrying out treatment

for any malignancy. Transfusion may at times be quite beneficial.

In observing the general condition of the health, it is important to determine the status of patient, whether certain findings are due to hemorrhage or from a necrotic tumor from cachexia or from metastasis.

Generally speaking, the therapeutic results of irradiation depend upon the size, extent and condition of the tumor; the size, however, is of less importance than the extent and condition. For instance, if it has extended to the bone tissue or cartilage, the results are less favorable. Infected neoplasms respond very unfavorably to irradiation, and a prognosis should be carefully guarded in these cases.

Because of the condensation of such a big subject as treatment of cancer by roentgen ray therapy, one can scarcely do more than generalize; therefore, I have purposely refrained from touching upon the technical phase of this subject; also I have refrained from presenting even a resumé of the results in the cases which we have treated, as too short a period has elapsed since we commenced using roentgen ray therapy in the treatment of malignancies to venture to speak in terms of cure. However, I shall be very glad to report at some future time on a series of cases which we are now treating.

In conclusion, it may be stated with little fear of being too radical that, in addition to supplanting surgery as the method of choice in a number of types of malignancy, irradiation has greatly limited the field of application of radical surgical procedure in many others. The use of X-rays and radium, therefore, have made greater refinement in diagnosis essential. To this end the patient's welfare is best conserved by obtaining the co-operation and knowledge of the internist, pathologist, surgeon and roentgenologist.

### VITALIZING OBSTETRIC RECORDS.\*

By M. PIERCE RUCKER, M. D., Richmond, Va.

Case notes serve at least three functions, two immediate and one remote. First, the act of taking notes promotes accuracy of observation and thoroughness. The second immediate reason for a case history is that it is a guide for the management and treatment of the case, all the more important as methods of precision become more numerous and complicated. Finally, the notes are a permanent record of your work. When properly kept and utilized, they are the raw material for statistical studies. It is to this phase of the question that I wish to direct your attention.

Beginners in medicine are prone to attach too little importance to the two immediate functions of clinical records and too much importance to their statistical use. The fourth year medical student and the hospital interne hear so much about a series of 500 cases of this or a 1,000 cases of the other that they get the idea that the chief use of the record which they are struggling so to keep up, is to fit into some more extended series. When these same sheets are dumped into closets and store rooms in more or less hopeless confusion, the tyro loses heart and his note-taking suffers in consequence.

In my experience with medical students, the best way to promote the habit, I might almost say the love, of history-taking is to make the histories available to the students themselves and to encourage their use of them. The histories of the out-patient obstetrical department of the Medical College of Virginia are indexed and bound, and the bound volumes are kept in the library. The cases are indexed not only by name, but also by parity, presentation, methods of delivery, complications, etc., so that the students can easily find out what the experience of their predecessors has been in any problem in which they may be interested. To further stimulate this interest, Dr. Baughman, as a part of the regular didactic work, assigns to each student some simple problem to be worked out from these records. In this way

the men get in a practical manner, an idea of how provoking it is to have to throw out this case because the race is not stated or that one because the age or parity is left off, or the other one because the ultimate result is not known.

With the idea of making our records even more available, for the last eighteen months I have been working out a system of coding each case, so that it can be put on a card with a number of punched holes in such positions that the cases can be analyzed by machinery as is done in the Census Office and elsewhere. The idea was first suggested to me by Mr. M. N. Fisher, Statistician for the State Industrial Commission, who very kindly made me a provisional code from which the code we are now using has gradually developed. I might say that for the very reason that the code has grown as the work grew, the arrangement is not always logical, and that there are a number of minor changes I would like to make in it, but to do so would necessitate my destroying all the cards that have been punched, and beginning all over again. The code gives a number to each phenomenon we wish to consider, just as the International Classification of the causes of death gives a definite number to each disease or cause of death, the difference being that the code can be changed to suit the needs of any particular study. Pearl\* has shown the uses it can be put to in general hospital work and in the department of urology. The code I submit is designed to meet the needs of obstetrics and minor gynecology.

The technic of using the code is as follows: With the code at hand, the case histories are reviewed and a work sheet is made. (Fig. 1). Each line of the sheet represents a case. This grouping of cases often gives you unexpected information. One group of students may have more than their share of infections and investigation shows a break in technic.

In going over our past records, I was struck with the number of still births a certain group

had (six in twenty-three full term deliveries). These boys had no case to last more than ten hours and no second stage more than thirty minutes. On inquiry it was learned that these two men were accustomed to lighten their labors with pituitrin, but were afraid to put it on their histories. Habitual carelessness stands out glaringly on the work sheet.

The work sheets furnish the data from which the operator punches the cards. (Fig. 2). They should be preserved as a useful summary of the work and as a supplementary index. Suppose, for instance, you wished to look up a recent case and remembered it only by some un-

While there is nothing particularly new in the information furnished by these tables, it is interesting to note in Table II how the numbers in column four, shifted over to the still born column as the duration of labor increased. What is especially interesting about these tables, however, is that the figures upon which they are based were furnished by the tabulating machine in sixty minutes from among 1,200 cards. In other words, the machine reviewed 1,200 cases, discarded those that did not supply the necessary information, separated the remainder into groups, and counted each group within one hour.

#### CONCLUSIONS.

Coding case histories is valuable; first because it causes a careful review of the history and therefore promotes better history taking, second because it puts the data in the most available and usable form.

1600 *Park Avenue.*

#### DISCUSSION.

DR. GEORGE T. MYERS, Norfolk: Dr. Rucker's paper is a step in the right direction. Relative to stillbirths, I think the classification of stillbirths, to a large extent, should be changed. The only thing is the still-birth. In eliminating any surgical condition we are confronted with too large a mortality for stillbirths. If a child is alive during pregnancy, unless the labor is unduly long, my contention is that, if that child is alive prior to the Cesarean operation, I do not see why it should not be delivered alive, unless the case has been neglected.

Statistics are often misleading. I am personally against statistics as a whole. Take the Cesarean section: I contend that it ought not to be done unless it is to save the living child; if other operations have been tried before and failed, then the operation is contra-indicated.

I say again that I think Dr. Rucker's paper is a step in the right direction.

DR. RUCKER, Richmond (closing): I have very little more to say upon the subject. In regard to the Cesarean section, there should be no fetal mortality attending the cesarean section. I merely brought this out to show the limitations of statistics.

Some people think you have proven something if you give a lot of statistics and quote a group of figures. You can readily see how someone inexperienced in statistics can dig out a group of cases and argue for or against the Cesarean section and convince some people.

### THE USE OF QUINIDIN IN CARDIAC DISORDERS.

By J. MORRISON HUTCHESON, M. D., Richmond, Virginia.

From the rather extensive clinical testing to which quinidin has been subjected during the past few years it seems evident that the drug has a distinct field of usefulness in cardiac therapy. Its mode of action is not thoroughly

understood yet certain of its effects are quite constant and there is general agreement as to what cardiac conditions it is apt to influence favorably. Quinidin is not, however, a harmless drug and must be employed with the greatest care if its desirable effects are to be obtained and its dangers avoided.

Save for an occasional allusion to the tonic effect of quinin on the heart, the first reference to the clinical use of cinchona derivatives in heart disease was made by Wenckebach in 1914. His attention had been called by a patient to the effect of quinin on an irregularity known to be fibrillation and in this way he was led to try the drug in a number of similar cases. When his observations were published, the number of favorable results was so small as to attract little attention. Other investigators also obtained comparatively poor results with quinin, but the occasional effect of the drug on fibrillation led Frey to investigate the action of the other three alkaloids of cinchona, and in this way the remarkable properties of quinidin were discovered. Frey reported in 1918 that of 22 cases of fibrillation treated by him with quinidin, eleven regained normal rhythm, and, according to a number of other observers who have repeated his work, these figures indicate about the proportion of cases of fibrillation in which good results may be obtained.

The general effect of quinidin on the heart appears to be depressant, and is exerted directly upon the cardiac muscle. Excitability is diminished so that extrasystole or fibrillation cannot be produced artificially and conduction is lowered in auricle, ventricle and junctional tissues. Various types of block have been produced experimentally but these have rarely if ever been observed in the clinical use of the drug.

The manner in which quinidin acts on auricular fibrillation is still uncertain and is apt to remain so until the nature of fibrillation itself is better understood. According to Lewis and his co-workers, quinidin prolongs the refractory period in the auricle and delays the recovery of the tissue, thus shortening the gap between the crest and wake of the circulating wave and eventually abolishing it and allowing normal impulses to regain control. On the other hand, quinidin also depresses conduction in the auricular muscle, a condition which favors the re-entry of the excitation wave and lengthens the gap. It would seem, therefore,

that the results of quinidin therapy in a given case would depend upon which of these somewhat antagonistic effects predominates.

When quinidin is given to a patient with fibrillation, the first effect is a slowing of the auricular rate with larger and more regular P waves in the electrocardiogram, a condition approaching auricular flutter. This occurs in the majority of cases treated while in about half the cases the rhythm rapidly changes to normal. On the other hand, digitalis, which has been our main reliance in fibrillation, influences the rhythm little or not at all. Its good effects come from diminished conduction in the bundle of His, thus allowing fewer impulses to flow to the ventricle with consequent slowing of the ventricular rate.

Improvement after quinidin therapy comes as the result of restored normal rhythm, and is often most striking in those patients with fibrillation who are uncomfortably conscious of irregular heart action. Cardiac efficiency may also be favorably influenced by the removal of the additional burden of disordered rhythm, but the direct effects on decompensation which follow digitalis administration are not to be expected from quinidin.

Where normal rhythm has been restored by quinidin, it is usually necessary to continue the drug either in small daily doses or intermittently. The duration of the effect is variable, lasting from a few days to several months. Frey states that two-thirds of his cases maintained a normal rhythm for at least one month.

The dangers from quinidin in heart cases are considerable, and should constantly be borne in mind. Certain individuals appear to possess an idiosyncrasy for quinidin just as they do for quinin and alarming symptoms, such as sudden loss of consciousness with standstill of respiration, have been observed to follow even small quantities of the drug. It has, therefore, become customary to precede quinidin therapy by single test doses of 3 to 4 grains of the drug in order to ascertain whether or not any such hypersusceptibility exists. Toxic symptoms, such as giddiness, tinnitus, intestinal cramps, and urticaria invite caution, but are not as a rule of serious import. Marked weakness, precordial distress or increasing breathlessness indicate withdrawing the drug promptly. Increasing ventricular rate, unless it marks the advent of auricular flutter, should also be regarded as a danger signal.

In cases with auricular fibrillation a certain amount of clotting in the auricles is prone to take place, so when normal rhythm is resumed and the auricle contracts fully, these clots may be detached. To this extent, therefore, quinidin favors embolism, and several deaths from this cause have been reported during its use.

Up to the present time, clinical observations on quinidin have dealt chiefly with auricular fibrillation, though the drug has been also frequently used with good results in premature contractions and to prevent the seizures of paroxysmal tachycardia. In the latter conditions small doses have seemed to be effective and the dangers attending its use less than with fibrillation.

Auricular fibrillation occurs either as a transient affair lasting a few hours or a few days or, more commonly, as a permanent malady existing until death. Quinidin is much more effective in the transient than in the permanent type and all observers agree that the shorter the duration of the fibrillation the greater the likelihood of restoring normal rhythm. Where fibrillation is accompanied by definite signs of decompensation, digitalis should be the remedy chosen, as the depressing effect of quinidin on the heart muscle is likely to outweigh the possible benefits to be derived from changed rhythm. Where compensation has been restored, however, and the heart digitalized, quinidin may be used as the seemingly antagonistic action of the two drugs on the auricular muscle has not been apparent clinically.

Quinidin is generally administered in the form of the sulphate. Where no idiosyncrasy is shown to exist, the initial dosage may be three grains three times a day, and this may be rapidly but cautiously increased to as much as fifteen grains thrice daily. If untoward effects occur, or if normal rhythm develop, the drug must be stopped promptly.

The following case illustrates the method of using quinidin and the manner in which a favorable effect manifests itself:

A farmer, aged 30, was admitted to the hospital January 17, 1923. He complained of palpitation, especially at night, and shortness of breath on exertion, with slight swelling of the feet. There was a history of rheumatic fever in early life, and physical examination revealed typical mitral stenosis. The pulse was 90, irregular, and the electrocardiogram showed auricular fibrillation with left ventric-

ular preponderance. Digitalis had been given, but as no apparent effect had been produced it was continued in larger doses for several days. The pulse rate diminished somewhat, but the subjective symptoms continued, so quinidin was begun, giving three grains the first day and increasing the dose to six grains three times a day. At this point the heart rate rose to 130 but as the electrocardiogram revealed an impure flutter the same dose was maintained with the result that on the following day the rhythm was normal. There have been several recurrences of irregular heart action but these are easily controlled by a few three grain doses of quinidin and there has been no further necessity for digitalis. Subjective relief has been marked and, as the result of more orderly rhythm, the cardiac reserve appears to have improved.

It is difficult as yet to estimate the relative importance of quinidin among cardiac drugs. That it will cause the auricle to cease fibrillating has been clearly demonstrated and the clinical results of this change are often brilliant. It is also of value in the management of other disorders of rhythm of less significance. On the other hand it must be remembered that normal rhythm is restored in only 50 per cent of cases to whom quinidin is given according to our present technique of administration, and not all of these show clinical improvement. Wolfert estimates that only about half, or 25 per cent, of the whole number treated by quinidin gain appreciably in cardiac efficiency. These facts together with the dangers incident to the drug itself place certain definite limitations upon its usefulness.

When quinidin therapy is undertaken, it should be with a full knowledge of the condition to be treated and with ample facilities for thorough management and accurate observation of the patient. The classification of arrhythmia is often impossible without the aid of graphic studies, while changes from fibrillation to flutter can be detected only by the electrocardiograph. According to Lewis, "it is a treatment emphatically for the wards rather than for use in an outpatient department." With our present knowledge of the possibilities of quinidin, it should certainly be carefully considered in every case in which the auricles fibrillate, but used only after every contra-indication has been eliminated and under the strictest supervision.

## TWO COMMON DISEASES IN CHILDREN OFTEN OVERLOOKED.\*

By CHARLES E. CONRAD, M. D., Harrisonburg, Va.

I wish to direct your attention to two common conditions occurring in children which are often overlooked. Both occur frequently in the practice of every general practitioner and can easily be detected if looked for. The two I have in mind are acute otitis media and pyelitis. One point I wish to especially bring out in regard to acute otitis media is that you can have this condition existing and the drum almost ready to rupture, or it may go to the stage of rupturing without pain.

What I have to say is nothing new, but as I saw in an article appearing in the *Journal of the A. M. A.*, about encouraging breast feeding: "While we all realize it we must keep repeating it as the surgeons did appendicitis until every man not only knows it but puts it in practice."

Unless there is some direct symptom calling attention to the ears or kidneys, they are often overlooked. The diagnosis of many unaccounted for fevers in children will be cleared up and explained if the ears and urine are examined.

The chief point I wish to bring out and leave with you relative to acute otitis media is, as I stated before, that it can exist without pain, and the best way I know to show this is to give a few histories of it in children who are old enough to tell intelligently what hurts them.

D. Y., age five years. Mother called me on account of child having a fever. On examination, I found the child with a temperature of 103° F. She was not complaining in any way. Throat was normal, lungs normal to percussion and auscultation, heart normal, abdomen soft, not tender, no masses felt, no glandular enlargement, stools normal, urine normal, and, in fact, a complete negative examination except for one ear. The left drum was very red and inflamed but not bulging; right drum normal in appearance. Temperature ranged from 98.2° in the morning to 103.5° in the evening, until the fourth day when it went to 104°. At this time the right ear became involved. Fever from then on dropped by lysis, reaching normal in the afternoon of the tenth day. This child never showed any other complications

\*Read at the meeting of the Medical Association of the Valley of Virginia, in Winchester, May 31, 1923.

during her illness, and at no time did she have any pain in either ear.

E. B., age seven years. In this case I was called on account of the child having fever but presenting no other symptoms. On examination, I found him with a temperature of 106° F. General physical examination was negative except both ear drums were very red and inflamed but neither drum bulging. He had not had any pain in either ear and when asked said they did not hurt him. I ordered some local treatment that night. The next morning, his mother said he had been delirious during the night and, as the drums were bulging, a paracentesis was done by Dr. E. R. Miller of Harrisonburg. There was a very free drainage of pus from both ears, and he never complained of pain except when ears were irrigated. Temperature dropped to normal in four days, and child made a complete recovery without any complications.

E. S., age twelve years. In this case. I found a boy, with temperature 104°, suffering with headache, severe pain in right shoulder joint and back of neck; on examination shoulder very sensitive to pressure and movement, some neck rigidity and pain on being flexed, moderate Kernig; his movements were somewhat jerky, physical examination otherwise negative. The above, with the history of having vomited the night before, made me somewhat suspicious of a meningitis, and I decided if he was not improved in the morning I would do a lumbar puncture. Much to my surprise, when I returned in the morning I found a very different picture. The boy had a normal temperature, looked very comfortable, no neck rigidity nor Kernig, and very little pain in shoulder, but what I did find was a freely discharging right ear which the mother told me had "broken" during the night. As it was in the middle of summer and a very hot spell, I had failed to look at the ear the night before, much to my embarrassment that morning. He had no further rise in temperature and recovered rapidly. At no time did he have any pain in his ear.

M. B., age twelve years. On March 16, child had pain in ear at night which subsided before morning. On 18th, Dr. J. E. Wine, of Harrisonburg, was called and obtained the above history with the addition that she had been well Saturday, the 17th, and had developed a fever that day (18th). When he saw her,

her temperature was 105°. Examination revealed negative physical findings except drum of right ear was red and inflamed but not bulging. She then began to run an irregular fever from 98.6° to 99° in morning, with chill and temperature from 103° to 105° in evening, going up to 106° on 22d. On 23rd, drum was bulging and paracentesis was performed by Dr. E. R. Miller. There was only a slight amount of thick drainage. After this, her temperature did not go above 103° until 27th when it reached 105° again. At this time she was seen by another physician and given calomel and laxatives with no result on temperature. She developed an acute rheumatic arthritis of right ankle joint April 1. I saw her in consultation April 2, physical findings were negative except rheumatic joint, as stated above, and a bulging right ear drum, with old incision healed except for a small opening at top of incision which was plugged with thick pus; temperature then was going to 105° in p. m. Some days she would have two chills with highest rise in temperature after second chill. Dr. Miller opened the drum on April 3, obtaining a thick plug of pus, at which time the child's condition looked desperate. After this, temperature did not go above 103°. On the 6th, Dr. Wine and I noticed what appeared to be a furuncle about inner one-third of the external auditory canal, and on April 8 we expressed quite a bit of pus out of the furuncle. When we first saw the furuncle there was a red line running from it to the drum which was quite apparent on the 8th. After this was opened and drained, her temperature never went above 100° and she only had chilly feeling but no real chill. By the 11th, she was free from fever, and discharge had stopped. From that time, she made an uneventful recovery. At no time did she have pain in the ear except for the one night at beginning, and this subsided before morning. This child was very septic and for several days we feared a fatal ending. The very interesting thing in her case was the very thick pus which would not drain from the opening in the drum and its burrowing under the skin, presenting itself as an apparent furuncle in the canal.

I will not go into detail as to pus in the urine, or what is called pyelitis, as much has been written and talked about it in the past few years. I only take it up to draw your attention to it again as a very frequent source of

unexplained fever in children. The fever is usually of a fluctuating type, and the child appears during an acute attack much more ill than the physical examination will account for. One symptom I do want to bring out, and that is the color of the child. If you will notice these cases carefully, you will find they often have a peculiar pearly-gray color. Another thing to remember is that a single negative urine examination is not sufficient to exclude pyelitis, for pus may be absent from the urine one day and the next day or a few days after pus may come down in showers.

Let us remember that acute otitis media can occur without pain and that no physical examination in a child is complete without looking at the throat and ears and, in an unexplained febrile condition or in a child who is apathetic and not doing well without a definite reason, be sure to examine the urine.

I fully realize this paper has nothing of scientific interest, but, dealing with two very common conditions met with in children, if it will gain closer observation from any one along this line, I feel it has been worth presenting.

---

### DISCUSSION

DR. KENNETH BRADFORD, Staunton: The lesson brought out in this paper cannot be over estimated. It is very important to every practitioner. Even the title itself is a lesson: it convicts us of sins of omission. These diseases are common. The other lesson is that, as they are commonly overlooked, it behooves us to bear them in mind when general examination shows no cause for the temperature, especially during the dentition period and after and during any acute infection. In case of pyelitis, it is well to bear in mind the fact that it often occurs in connection with gastro-intestinal infections, especially infectious diarrhoeas. Another important point is that in a case of infectious diarrhoea, if the diapers are not properly disinfected, they will very likely infect the patient through the urethra and give rise to a case of pyelitis. It is so common as to be axiomatic that when you have fever in a young child with no apparent cause you usually have either otitis media, pyelitis, or pneumonia, the last of which can, of course, be differentiated very soon.

DR. J. E. LINCOLN, Lacey Spring: Could you state absolutely that the case had no previous evidence of scarlet fever?

DR. CONRAD: Yes.

DR. C. P. HARSHBARGER, Port Republic: I feel that I want to say a few words in substantiation of what Dr. Conrad has said as to diagnosis of pyelitis in children, especially small children. I had a case last winter and called Dr. Conrad in consultation. It proved to be influenza with a tendency to pneumonia.

After seeing it several times I found a temperature which I could not explain by the symptoms on auscultation and percussion. After the child was apparently well of the influenza, she was still sick with pyelitis. Until that time I had had difficulty in getting a specimen of urine. The first specimen showed pus and blood. Many of these children get sick, especially in cross roads country, and are all seen by the general practitioner. That is why it is important for us to make an early diagnosis.

A few years ago I was called to see a lady who had, as I thought, symptoms of appendicitis, tenderness at McBurney's point, high temperature, chill, and I made an error in diagnosing this case. The symptoms were so prominent that it looked like operation. I called in Dr. Deyerle. After going very thoroughly into the case he found pyelitis.

Soon after that I was called to see a child with very moderate symptoms, not definite as to exact cause. The child was three years old. It turned out to be a clear case of pyelitis.

In my early years of practice I overlooked many cases of pyelitis. Now there are very few that I overlook on account of experience. A few months ago I was called to see a patient, and as soon as I saw her in this attack I suspected pyelitis. She had had a spell exactly like this in the winter and a prominent physician had said that she had appendicitis. I got a specimen of urine and found that it was loaded with pus. There was pain over McBurney's point, which was the symptom in the winter. She had pain over the urethra and over the back at this time. A few days after that she came up for life insurance examination. The symptoms had then subsided, but the specimen was still loaded with pus. There was another case in which the physician had made the same mistake of diagnosing appendicitis.

We cannot lay too much importance on the urinary examination in all cases of little children with temperature without apparent cause.

DR. H. G. MIDDLEKAUFF, Weyers Cave: A family of five children had influenza about the middle of January. Apparently all got well. In May, one child became sick and I saw it with a high temperature, no other symptom. The ears showed nothing. I gave castor oil and the next day he was well. A couple of days later another child did the same thing. The parents gave calomel and he got well without my seeing him. Another child did the same thing. In a few more days the baby got sick. The only way this child complained was just to lie still all day. (It had been a very active baby). If you lifted it up it did not raise its head. No diagnosis had been made in the other children. This child had peculiar symptoms, and the family was alarmed. The first day I saw it the ears were apparently normal. The child just presented the symptoms of lassitude and slight temperature. The next day the ear drums showed redness, and there was some slight glandular enlargement of the neck. With local treatment it cleared up. In a few days he presented the same symptoms again, but cleared up readily. He has apparently recovered.

All these cases go to prove that there may be otitis media without pain.

DR. CONRAD, *closing*: I have noticed this year with small children a rather large tendency to pyelitis after influenza, in which they continue to have an unaccountable temperature.

## AN UNUSUAL ACCIDENT DURING DELIVERY AT TERM.

### Report of a Case.\*

By B. H. MARTIN, M. D.,  
and  
ARTHUR S. BRINKLEY, M. D.,  
Richmond, Va.

**NAME:** Mrs. C. A. N.; white female; age 24; married. Occupation, housewife.

**PAST HISTORY:** Usual diseases of childhood; operated on for appendicitis five years ago, otherwise negative.

**FAMILY HISTORY:** Negative for cancer; one sister died of tuberculosis.

**MENSTRUAL HISTORY:** Menstruation started at 14 years of age; always regular; duration four to five days, with normal flow. Last menses February 15, 1922.

**MARITAL HISTORY:** Married 1915; three pregnancies before this one, all boys, fully developed, and delivery normal, now living and well; no miscarriages. Husband's health excellent.

**GENITO-URINARY:** No unusual vaginal discharge; no venereal sores; some nocturia during pregnancies, has to get up once or twice during night, no pain on urination.

**CARDIO-RESPIRATORY:** Negative except complained of difficulty in breathing on admission to hospital; pulse rate 90; volume fair.

**GASTRO-INTESTINAL:** Appetite good; constipation occasionally, otherwise negative.

**PRESENT ILLNESS** The patient menstruated last on February 15, 1922. She had been seen at regular intervals during parturition by Dr. Martin. Nothing unusual was noted—apparently normal pregnancy. She started in labor about ten A. M., November 8, 1922—occasional pains. She was seen by Dr. Martin at noon; he made an examination, and thought very probably it was a breech presentation. Dilatation of cervix at this time was about two inches in diameter—occasional pains. He left the patient in charge of an attendant and returned early in the evening, intending to give chloroform and deliver her. On a second examination he found that he was dealing with a face presentation. The cervix was fully dilated, and labor pains were about five minutes apart. At 9:45 P. M. she was given a little chloroform by inhalation, and five minims of pituitrin by hypodermic. She had a very severe pain soon after administration of pitui-

trin, and several slight pains for the next thirty or forty minutes. There was a moderate flow of dark blood coming from the vagina. Finding that the oncoming head had made no advancement, he washed up to do a version. The chin seemed to be locked behind the pubis. On introducing the hand, he found the baby was out of the uterine cavity, and his hand was in the abdomen. A version was quickly done, and a dead child delivered. Very little bleeding followed delivery. The hand was introduced again, and this time it entered the uterine cavity, and the placenta was easily delivered. On further examination he found that the vaginal vault was almost completely torn away from its attachment to cervix, only a small bridge of tissue holding posteriorly. He packed the vagina with sterile gauze, and called Dr. Brinkley over the 'phone. At this time, 10:40 P. M., the patient was lying quietly in bed, and, with the exception of being a little pale, showed no evidence of shock or severe hemorrhage—pulse 80 to 85, and very good volume. She, however, complained of rather severe pain in both iliac regions, radiating in her hips, and down her thighs; also some difficulty in breathing when deep inspirations were taken. With sterile vaginal retractors, the vagina was inspected to see how much bleeding there was, and also to get a better idea of the condition we were dealing with. There was a good deal of oozing from the torn surfaces, so the vagina was packed tightly with sterile gauze, and the patient sent to The Retreat Hospital in an ambulance, and operated on immediately by Dr. Brinkley.

Under gas, oxygen, ether anesthesia, an incision was made for pelvic work, extending from the umbilicus to the pubis, and about one inch to the right of the median line. On opening the peritoneal cavity, a small amount of free blood was revealed, and also some large clots in the torn part of both broad ligaments. The uterus was well contracted, and there was no evidence of a rupture in the uterus. The clots and free blood were quickly removed, and the uterus was found to be suspended only by the tubes on either side and a small bridge of the vaginal attachment posteriorly, which was about one and a half inches wide. Both broad ligaments were lacerated up to the pelvic brim on either side, and the tear on the right side extended through the vaginal wall

\*Read at a meeting of the Richmond Surgical Society, February 6, 1923.

practically to the vulva. The uterine arteries were as cleanly dissected out as if some one had done a careful dissection, but were not torn away from the uterus at the main point of entry. They were pulsing, and the small branches had stopped bleeding. The uterines were quickly clamped and severed between the clamps. The left tube and ovary were markedly injured, and the blood supply practically cut off, so it was thought best to remove the left tube and ovary with the uterus. The broad ligament on this side was doubly clamped and severed between the clamps. The right tube and ovary seemed to have a pretty good blood supply, so they were not removed. The broad ligament and tube were doubly clamped close to the fundus of the uterus, and severed between. The only attachment left was the small bridge of tissue at the posterior cervico-vaginal junction. This was clamped off, and the entire uterus, with left tube and ovary attached, was removed. The vagina was then repaired, starting at the lowest angle, and suturing it over with a whipped suture of No. 1 tanned catgut. The uterine arteries were then doubly ligated; the ovarian arteries were doubly ligated, and the vagina was then closed with a purse-string suture of No. 1 tanned catgut, reinforced with several interrupted mattress sutures of the same material. A cigarette drain was inserted in the vagina before the purse-string suture was tied; the stump of the right broad ligament and tube was fixed to the vaginal vault for support. The peritoneal reflection of the bladder, which had been torn away from the anterior surface of the uterus, was then used to help cover over the raw surface. Both broad ligaments were whipped over, and all the raw surface was completely covered with peritoneum. The cul-de-sac was then carefully sponged out with saline sheets, and about three quarts of normal saline poured into the abdominal cavity. The appendix had been removed at a previous operation.

The wound was then closed in the following manner: A continuous mattress suture of No. 1 tanned catgut in the peritoneum; a lock suture of the same in the muscle; a lock suture of the same in the fascia, reinforced with six interrupted mattress sutures of the same material. Eight silkwormgut interrupted sutures were then inserted in the skin to include the fascia, and the ends were clamped to be tied later. The skin was then closed with a mat-

tress suture of No. 1 tanned catgut. The silkwormgut sutures were tied over a roll of iodoform gauze, and a sterile dressing and bandage were applied. A retention catheter was then inserted, in order that the bladder could not become distended with urine. The patient left the table in fair shape; pulse around 120, and volume fair, considering the amount of blood she had lost.

**POST OPERATIVE ORDERS:** Flat in bed; hypodermoclysis 500 c.c. stat., and 50 c.c. q. 4 h.; continuous rectal saline, glucose, and soda, gravity method—saline pts. 1, glucose oz. 1, soda drs. 2; caffein-sodio-benzoate grs. 2, q. 6 h. hypo.; digalen min. 15 hypo. Q. 6 h., alternating so as to get stimulation every three hours; morphine grs. 1/6 q. 4 h. S. O. S.; water freely.

**GROSS PATHOLOGY:** The specimen consists of an uterus about the size of a small infant's head, with left tube and ovary attached. It is well contracted, and there is no tear in the uterine wall or in the cervix. The uterus is now incised to see if there is any pathology on the inside. The interior of the uterus is clean, with no evidence of placenta or membranes. There is no laceration in the uterine wall.

November 9th, second day after operation, the patient had a fair night only, complained of air hunger at times; pulse good; volume ranging from 112, just after returning from operating room, down to 88 at 8:00 o'clock A. M.; temperature 100; respiration 22; moderate amount of drainage from vagina, tinged with blood. Blood count: Reds 2,696,000, whites 15,000, polys 85%, lymphocytes 15%, hemoglobin 55%. Urinalysis: Color, amber; turbidity, very cloudy; reaction, acid; specific gravity, 1032; albumen, large trace; acetone, slight trace; blood corpuscles, few; pus cells, occasional; crystals, abundant amorphous urates; casts, few hyaline and rare granular; epithelia, few.

November 10th, third day after operation, uncomfortable night, complained of severe pain at times in lower abdomen and hips, moderate amount of distention, highest temperature 101.4, pulse 96, respiration 24, taking water freely and expelling gas back in proctoclysis can. Sherman's vaccine No. 35 was ordered, starting with 1/2 c.c. hypo. first day, increasing to 1 c.c. daily. Mammary glands were very tense and painful; belladonna ointment and bandage applied; wound inspected, healing

nicely; liquids, except milk, every 2 hours ordered.

November 12th, fifth day after operation, patient had a fairly comfortable night; temperature went to 102 during night, pulse 100, respiration 24; expelling a large quantity of gas and feces through proctoclysis can; moderate quantity of thick, bloody looking vaginal discharge, excreting a fair quantity of urine; nauseated once or twice during night, and vomited a little light green fluid early in A. M. She was given a pint of hot soda water; it was vomited back immediately, and she felt better. Two hours later compound licorice powder drs. 3 was given, followed in four hours with S. S. enema, which returned clear. Two hours later she had a very large dark brown stool. Bowels moved three times after this, abdomen soft, and patient fairly comfortable. Proctoclysis discontinued. Blood count: Whites 16,000, polys 90, lymphocytes 10, hemoglobin 60. Urinalysis: Color, orange; turbidity, hazy; reaction, acid; specific gravity, 1025; albumen, large trace; acetone, heavy trace; blood corpuscles, few; pus cells, numerous; crystals, triple phosphate; casts, negative; sediment, moderate amount. Bicarbonate of soda, dr. 1, t.i.d., and sweetened drinks q. 2 h., were ordered.

November 14th, seventh day after operation, patient had a rather uncomfortable night; complained of severe pain at times in lower abdomen; scanty vaginal drainage; highest temperature 100, pulse 92, respiration 22. Later on in the day the cigarette drain in the vagina was loosened up; this was followed by a marked increase in vaginal drainage, with small pieces of sloughing tissue. Feeling very much better; wound dressed, healing nicely; modified soft diet ordered.

November 16th, ninth day after operation, had a very comfortable night. Later on in the day she began to have an uncomfortable feeling in the region of the bladder. Catheter removed, and found to be stopped up with sediment; another inserted, and about 18 oz. of urine drawn off, and bladder irrigated with warm boric acid solution, and two drs. of 10% argyrol injected. Catheter removed and patient voided normally during day; very comfortable after catheter was removed. Highest temperature 99.4, pulse 96, respiration 20; moderate amount of serous vaginal discharge;

blood urea, 25 mg. per 100 c.c.; urea nitrogen, 12.5 mg. per 100 c.c.; Wassermann, negative. Urinalysis: Color, straw; turbidity, very cloudy; reaction, strongly alkaline; specific gravity, 1020; albumen, trace; acetone and diacetic acid, negative; blood corpuscles, occasional; pus corpuscles, occasional; crystals, few triple phosphate; casts, negative; sediment, large amount. Acid sodium phosphate grs. 10 with urotropin grs. 7½ in large glass of water was ordered given every four hours. Bicarbonate of soda discontinued.

November 20th, thirteenth day after operation, patient has been very comfortable for past few days. Temperature has been normal since November 16th; pulse today 88. Expelled cigarette drain from vagina; small amount of vaginal discharge. Wound dressed, no evidence of infection; healing nicely.

November 23rd, sixteenth day after operation, the patient has been doing well. Normal temperature, pulse 90. Sutures removed, no evidence of infection. A little straw colored serum oozed out of one of the stitch holes about middle of the wound; very little vaginal drainage. Blood count: Reds 2,976,000, hemoglobin 50, whites 7,000, polys 80, lymphocytes 20. A urinalysis showed the following: Color, amber; reaction, acid; specific gravity, 1020; albumen, trace; acetone and diacetic acid, negative; casts, negative; blood and pus corpuscles, a few; sediment, slight.

The patient had an uneventful recovery from now on. Allowed to sit up on November 30th, twenty-third day after operation, and left for home December 4th, twenty-seven days after operation, feeling very good. January 9th, 1923, the patient reported for examination. The abdominal wound had healed by primary union. With a bivalve vaginal speculum the vault of the vagina was inspected and found entirely healed. She was looking well and had no complaint.

### REPORT OF UNUSUAL CASE OF MASTOIDITIS.\*

By L. LEROY JONES, M. D., Portsmouth, Va.

Irving M., aged 5 years, had been suffering with acute sore throat, before I saw him on January 28th, in consultation with Dr. E. H. Claud. There was no previous medical history that had any particular bearing on his

\*Read before the Virginia Society of Oto-Laryngology and Ophthalmology, in Richmond, April 18, 1923.

present illness other than an earache and rising in the left ear, one year ago. Examination of his ears at this time, showed the left ear normal and slight redness and bulging of the right ear drum. An opening of the ear drum was advised. The parents having been told that the child's tonsils and adenoids should be removed, desired that a general anaesthetic be given and all three be done at the same time, as they did not want the child hurt. After a thorough physical examination it was decided there was no contraindication to this procedure, so patient was taken to the hospital and given ether, tonsils and adenoids removed, and a wide and deep myringotomy performed. There were no complications. The patient was taken home the following day, ear discharging freely, and no pain.

Patient was seen in my office two days later, his condition being exceedingly satisfactory, with the usual amount of discharge from his ear that we ordinarily see from acute otitis media. There was no pain or temperature. The patient continued to be perfectly comfortable; but when he returned to my office on the eighth day after his operation there was a slight purulent discharge from his ear, with very little tenderness over the tip and antrum on deep pressure. There was no sagging on the posterior wall of the canal. An X-ray was advised and taken of the mastoid at this time, which showed the following: Both right and left sides showed marked density and cloudiness throughout the process with complete loss of cell definition. No portion of either process appeared pneumatic. It appeared to be a chronic sclerotic process on both sides, with possibly some active infection.

The child having had a history of similiar infection in the opposite ear one year previous, and the X-ray showing apparently the same pathology in both, I did not advise operation, but observation and local treatment. Patient was seen by me daily in my office for another week, at which time the ear had ceased to discharge and the drum appeared normal; hearing normal. No discomfort, no temperature or evidence of ill health.

On March 3rd the patient was sent to me from Dr. Claud's office with the following history: No discharge from the ear or any sign or symptom of ill health, other than a slight cold, since he was last seen by me. Child had

been playing around the house as usual and for the first time a swelling behind the right ear was noticed this morning. An examination of the patient's ears revealed the following: Left ear, negative; right ear, no discharge; drum appeared normal; no sagging of the posterior wall of the canal. Behind the ear there was a swelling and tenderness over the entire mastoid area, and looked as if there might be pus in a small area directly over the antrum. I advised that the child be taken to the hospital for mastoid operation. Ether was given and, on exploring the mastoid, it was observed that the whole mastoid area was of a purplish color and appeared to be spongy and necrosed. There were two small eroded areas about 1 cm. in diameter, one being over the tip and the other over the antrum. From this area I began to scoop out with the curette necrosed bone, pus and granulation tissue. No chiseling was necessary. The mastoid cavity proved to be totally destroyed. The destruction and the copious amount of pus and granulation tissue reached up to the dura, which was exposed over an area adjacent to the upper portion of the tympanic ring. The dura appeared to be thickened and hard. The sinus was exposed to the extent of  $1\frac{1}{2}$  inches and found to be literally swimming in pus and granulation. The wall of the sinus was hard and indurated, pale blue in color. Pulsation could not be detected. The simple mastoid operation having been practically completed, and contemplating opening the sinus to determine definitely whether or not there was a thrombosis, also contemplating a jugular operation, I was informed by my anaesthetist and the family physician that the patient seemed to be in very poor condition, for further operative measures, and it was thought wise, both by Dr. Claud and myself to defer the opening of the lateral sinus for 24 hours. So the wound was closed with one stitch, with a rubber tube drainage and a light gauze packing. The pathological findings were explained in detail to the parents, immediately after the operation, and also the fact that other operative measures of a more serious nature would probably have to be resorted to the following day, the prognosis being probably unfavorable. The following day, March 4th, the patient's temperature remained normal and, when seen by me, was sitting up in bed playing with toys and with the exception

of a temperature of 99.3 on the third day after operation, which an enema relieved, his temperature remained normal. He was discharged, entirely well, on the sixth day of April, without ever having his lateral sinus operated upon.

The case is of unusual interest to me, in that we have here an extensive and total infection of the right mastoid, including a perisinus and epidural abscess and lateral sinus thrombosis, with such an atypical history—no pain, temperature or discomfort, either before or after operation. There was no discharge from the ear for over two weeks before the operation, during which time the child appeared perfectly well in every detail, and during which time very extensive destructive changes were taking place. How can any organism be virulent enough to give these destructive changes and at the same time not be virulent enough to give any other symptoms, such as elevation of temperature and some evidence of discomfort, or at least, ill health. I think that this patient unquestionably had a thrombosed lateral sinus, because on inspection the walls appeared diseased and thickened and on palpation the vessel was hard and no pulsation could be detected. The infection being of a low virulence, the thrombosis became organized and the collateral circulation became established sufficiently to take care of the obstruction.

This case was a lesson to me, in that we should be extremely cautious in our prognosis, even when most extensive pathological changes are found. The parents of this child were led to believe by me that the child was seriously ill and at the same time there was no evidence of it as far as their observation was concerned, either before or after the operation.

### INSULIN TREATMENT OF DIABETES.\*

By J. D. WILLIS, M. D., Roanoke, Va.

The discovery of an effective extract of the internal secretion of the pancreas by Dr. F. G. Banting and collaborators, at the University of Toronto, has proven to be an epoch-making event in the diabetic world.

Dr. Banting first conceived the idea of preparing a potent extract from the atrophied pancreas while assisting in physiology at the Western University Medical College, London.

He came to Toronto and, by arrangement with those in charge of the Department of Physiology of the University of Toronto, began, May 17, 1921, an attempt to obtain the pancreatic extract by a new procedure.

His first work was done in collaboration with C. H. Best and conducted in the Department of Physiology at the University of Toronto under the direction of Professor J. J. R. MacLeod. He also received the aid and support of Professor V. E. Henderson of the Department of Pharmacology, on whose staff Banting held an appointment. The clinical application was made with the assistance of W. R. Campbell and A. A. Fletcher, in the clinic of Professor Duncan Graham in the Toronto General Hospital and in other institutions. Through the support of the Connaught Laboratories, under the direction of Professor J. G. Fitzgerald and Professor R. DeFries, facilities were obtained for the first small production of insulin, for clinical trials, prepared by a method elaborated by C. H. Best and J. B. Collip. The basis for this work was the appreciation by Banting that, upon ligation of the pancreatic ducts, there develop degenerative changes in the acini of the pancreas but not in the islet tissue. This observation was taken advantage of in the preparation of an active extract of islet tissue. Further experiments proved that trypsinogen and its derivatives were antagonistic to the internal secretion of the pancreas, and the failures of other investigators were thus accounted for.

The first pancreatic extract used by these investigators was obtained from the atrophied pancreas of the dog after the pancreatic ducts had been ligated for a period of ten weeks. The atrophied pancreas immediately upon removal was extracted in ice-cold Ringer's solution and then purified. It was found that this extract injected into diabetic dogs invariably reduced the percentage of sugar in the blood and in the urine.

Next, taking advantage of an observation that no enzymes were found in the fetal calf pancreas until after the fifth month, the pancreas from fetal calves was extracted in Ringer's solution and, after purification, injected into diabetic dogs, causing definite reduction in blood and urinary sugar.

Finally, a potent extract of islet tissue was obtained from adult beebes' pancreas by ab-

\*Read at meeting of Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

strating with 95% alcohol immediately after the death of the animal. The resin-like residue obtained by this process was re-dissolved in saline and injected subcutaneously into a diabetic dog, with the result that the percentage of blood sugar fell from .35 to .08 in three hours, and the urine became sugar-free. This was repeated with similar results. An extract, which could be kept sterile, had thus been obtained from the whole gland of the adult beef. The administration of this extract prolonged the life of totally depancreatized dogs from 19 to 70 days.

The next step in experimentation was the use of a potent, soluble, protein-free extract of the adult beef pancreas in the treatment of seven cases of diabetes mellitus. It was found that, in the human cases, following injection of insulin, there was a fall in blood sugar and a rise in respiratory quotient, indicating carbohydrate utilization. Patients reported complete relief from the subjective symptoms of the disease. By continuing injections of the extract the blood sugar would become normal if the dosage was adequate and ketonuria was abolished.

As a tentative basis for the physiological assay of insulin one unit is considered as the amount necessary to cause the blood sugar of normal rabbits weighing one kilogram to fall to .045% within four hours. This dose is decidedly active in lowering blood sugar in diabetic patients and is estimated to make possible the patient's utilization of one to four grams of carbohydrates.

Insulin now available for treatment is in strengths of five, ten and twenty units per cc. The remarkable lowering of blood sugar by insulin makes it necessary that extreme caution be taken in its administration. Generally speaking it is best to give insulin fifteen to thirty minutes before a meal, either once, twice or three times daily, according to the severity of the disease. Frequent blood sugar estimations must be made, in order to intelligently control the dosage. There is great danger in reducing the blood sugar below the low normal of .08%. The outward manifestations of lowered blood sugar below normal are weakness, nervousness and sweating. At this stage immediate consumption of sugar in the form of oranges, corn syrup, or candy affords ready relief. If the reduction in blood sugar should be as low as .045%, there will develop a state

of coma and convulsions. Glucose solution intravenously is necessary should such a serious state develop.

Insulin is an adjunct to the dietary treatment of diabetes, and the success in this treatment is largely dependent upon the intelligence and cooperation of the patient in carrying out dietetic instructions. A minimum supporting diet, low in carbohydrates, should be taken as a diet basis to work from. When the blood sugar of the patient reaches normal limits there should be a gradual increase in diet up to the caloric requirements of the individual. The well-known Joslin outline of diet is well adapted to this increase.

The insulin dosage will have to be increased or decreased, as determined by blood sugar estimations. It is desirable to use as little insulin as possible after the blood sugar has reached normal. It is possible in many cases to discontinue insulin very soon after blood sugar becomes normal. A sudden drop in blood sugar from a rather high concentration to normal is often seen. This is a dangerous period because of the likelihood of carrying the reduction below normal. This sudden drop in blood sugar is believed to indicate the resumption of function of the islet tissue of the pancreas, either wholly or in part. Stengall states that there is just as much reason to believe that a sick pancreas may recover by rest as a sick kidney.

Today I wish to give you my experience with five cases treated with insulin.

"Mrs. R. K. B." Age 35. Known to have had diabetes for the past two years. Weight: Two years ago, 165; one year ago, when I first saw her, 117. At that time she showed 2.22% sugar in 24-hour specimen of urine, with a trace of acetone and diacetic acid. She entered the Shenandoah Hospital and was treated for two weeks by the Joslin dietetic method. At the end of two weeks she was discharged on a diet consisting of 85 grams carbohydrates, 50 grams proteins, and 85 grams fat, totalling 1,300 calories per day. This diet was sufficient to maintain her weight at about 110 pounds, sugar-free except for an occasional spill-over.

At the time of starting insulin treatment, February 27, 1923, her weight was 106 $\frac{3}{4}$ . Twenty-four-hour urine specimen showed 3 $\frac{1}{2}$ % sugar, and there was a good trace of acetone and diacetic acid. Blood sugar was

.23%. She was put on approximately a 1,000 calory diet consisting of 40 grams carbohydrates, 30 grams proteins, and 80 grams fats. She was given five units of insulin hypodermically 15 minutes before each meal for two days. It was then increased to ten units before each meal. The fourth day the blood sugar reached .16%, and on the ninth day it reached .11%. At this time the urine sugar was a mere trace, and on the eleventh day there was no sugar in the urine and the blood sugar was .08%. She had gained two pounds in weight. She was discharged at the end of two weeks with a diet of 1,200 calories and had gained from 106 $\frac{3}{4}$  to 109. Two weeks later her weight was 115; urine sugar-free; blood sugar .07%.

This patient was entirely relieved of all subjective symptoms and was able to resume her normal activities, which she had been unable to do for two years. At the present time she is holding her weight around 115, sugar-free, on a calory diet of 1,500. She is now taking ten units of insulin before breakfast and before supper.

"Mr. J. W. D." Age 66. Has known that he had diabetes for the past two years. Complained of excessive thirst and polyuria. He ate ravenously, would drink four glasses of fluids during the meal, and get up soon to drink more. He averaged getting up once each hour at night to void. His blood sugar was .26% and urine sugar 6 $\frac{1}{2}$ %.

Insulin treatment started March 6th; ten units 15 minutes before each meal. Diet consisted of carbohydrates 40 grams, proteins 30 grams, fats 85 grams. Calories 1,000. The second day after starting treatment the excessive thirst was relieved, he voided three times at night, and within three days' time he said he felt like a different individual. All the depression and other subjective symptoms of the disease had disappeared. At the end of one week the blood sugar was .08% and urine sugar negative. He was discharged from the hospital on the eighth day, his weight 214 pounds.

Insulin was continued with this man, ten units before breakfast and before supper for one week. At the end of this time the blood sugar was .07% and urine sugar negative. Ten units of insulin were continued before breakfast for another week and at that time the blood sugar was .08% and urine sugar

negative. His weight remained 214. At this time the insulin was discontinued and diet continued which provided 1,800 calories, consisting of carbohydrates 60 grams, proteins 80 grams, fats 130 grams.

He has continued up to the present time on this diet and has retained his weight with no increase in blood sugar above normal, no return of glycosuria, and no return of the subjective symptoms.

"Mrs. A. O. S." Age 39. Weight 72 pounds. This patient had moderate thirst and an acetone odor to the breath. Blood sugar .21%. Sugar in the urine 8 $\frac{1}{2}$ %. She was known to have had diabetes for the past two years. Insulin treatment started March 20th. She was given 15 units 15 minutes before each meal and a 1,000 calory diet consisting of carbohydrates 40 grams, proteins 30 grams, and fats 80 grams. On the eighth day the blood sugar reached .06% and the urine sugar was negative. She was discharged from the hospital at the end of two weeks and had gained six pounds. She has continued the insulin and now takes ten units before breakfast and before supper. She now weighs 86 pounds. All subjective symptoms of the disease have disappeared.

"Mr. S. B. C." Age 63. Was brought in as an emergency with shortness of breath, which was thought to be a state of acidosis. He had had a large carbuncle on the back of neck for one week. Upon examination it was found that he had a badly decompensated heart, and the shortness of breath was largely resulting from this complication. The blood sugar was .32% and urine sugar 4%. This man was given 15 units of insulin every three hours for three doses, then every six hours. He died thirty hours after being brought to the hospital from myocardial decompensation of the heart. At no time did he develop a tendency to coma. This patient had had diabetes for the past seven years.

"Mr. J. A. S." Aged 70. Rather emaciated. Was in a state of extreme drowsiness at the time I saw him in consultation. By the time he could be transported to the Shenandoah Hospital he was more comatose and soon become decidedly comatose. Blood sugar was .30% and urine sugar 7%. He was given 15 units of insulin every two hours for four doses then every six hours. At the end of 12 hours there was decided clearing of mentality.

By the second day all signs of coma had disappeared. There developed a profuse expectoration of slate colored offensive material, which was evidence of a gangrenous lung area. By the third day the blood sugar was .08% and urine sugar negative. He was by this time on a 600 calory diet consisting of 10 grams of carbohydrates, 60 grams of proteins, and 40 grams of fats. Patient continued to improve with lessened expectoration. On the sixth day he suddenly died with what was thought to be cerebral embolus.

### A FEW POINTS ABOUT THE ACUTE ABDOMEN.\*

By W. DENNIS KENDIG, M. D., Kenbridge, Va.

The diagnosis of the diseases of the abdomen presents many difficulties. Those of a sub-acute or chronic nature are easier of diagnosis because there is sufficient time to make an exhaustive examination. Acute conditions of the abdomen may demand immediate attention, and for this reason the course of treatment should be early determined upon. The first step is to make a diagnosis. If a diagnosis is made, then the nature of the disease will determine what is best to be done. Some cases, however, on account of indefinite diagnostic symptoms and lack of time, baffle the most astute diagnostician. Such cases, in many instances, while not presenting a definite diagnostic picture, show positive signs of some serious acute condition within the abdomen. This has been called the acute abdomen.

The examination of such cases includes a painstaking history, a careful physical examination, a complete urinalysis, a full blood count, and such other diagnostic procedure as may be indicated and the circumstances will permit.

The most important symptom is pain. At times pain may be so characteristic in its location, severity, and character that the nature of treatment can be determined on this one point alone. Pain is the physician's and surgeon's greatest aid in bringing the case to operation. In the absence of pain it is hard at times for the laity to appreciate the importance of operation, even when recommended by competent men. I wish to advise against the early use of morphia in these cases, especially before a diagnosis is made, unless absolutely

necessary. It interferes with the diagnosis and sometimes causes a delay in getting patient's consent to surgical treatment. It is needless for me to say in acute abdominal pain never to give cathartics, but use enemas. An abdominal pain, not relieved by an enema, or certainly an enema and washing out of stomach, is generally a surgical case, and needs careful watching. In the examination of a case, the facial expression is very important, as sometimes the record sheets may show that probably the patient is improving, yet there is about him that unexplainable expression that indicates he is fatally sick. This has been called the "peritoneal face." Other important general symptoms are posture, character of pulse, fever, tumors, abdominal distention, tenderness, rigidity, condition of the skin, nausea, constipation, or diarrhoea, vomiting and hemorrhage.

The diseases which may cause the acute abdomen are appendicitis, acute cholecystitis, perforated gastric or duodenal ulcer, acute intestinal obstruction, ectopic pregnancy, strangulated hernia, acute salpingitis, acute pancreatitis, mesenteric thrombosis, and twisted pedicle of an ovarian cyst. Appendicitis as the causative factor is indicated by general abdominal pain, which localizes in the right iliac region, nausea or vomiting following pain, and abdominal sensitiveness. The temperature is elevated slightly during first twenty-four hours, then higher, quickened pulse, and increased leukocyte count.

Acute cholecystitis as the causative factor is indicated by pain in the right upper quadrant, fever early, localized tenderness over gall bladder, and rigidity of right rectus. It is hard at times to differentiate this from acute appendicitis, as the pain may be referred to the right iliac region or the appendix may be high, or the gall bladder lower. Then too, they both may exist at the same time.

Perforated gastric or duodenal ulcer as the causative factor is indicated by sudden onset of continued upper abdominal pain and nausea simultaneous in onset, subnormal temperature, weak pulse, cold wet skin, shallow and painful breathing, anxious countenance, flat rigid abdomen, and sometimes history of indigestion, "gas and hunger pain."

Acute intestinal obstruction as the causative factor is indicated by obstinate constipation, vomiting, paroxysmal pain, with gurgling and

\*Read at meeting of Southside Virginia Medical Association in Petersburg, March 13, 1923.

exaggerated peristalsis and progressive distention of abdomen. Temperature, etc., are later.

Ectopic pregnancy as the causative factor is indicated by sudden onset with regular and colicky pains, sometimes very few but excruciating, and localized more to one side; no fever, decidua, history of irregular periods, mass to one side of uterus, hemorrhage and shock much greater than visible loss of blood.

Appendicitis, cholecystitis, perforated gastric or duodenal ulcer, acute intestinal obstruction and ectopic pregnancy usually are the cause of a large per cent of cases of the acute abdomen, although the other causes mentioned are the causative factor occasionally. The patient, at the first time he is seen, may no longer be suffering from the original lesion, but from its effect, such as peritonitis, following perforation, hemorrhage of an ectopic pregnancy, gangrene, or toxemia from a strangulated hernia.

After making a diagnosis or determining the so-called acute abdomen, the main question is what is best to do. If seen early, operate immediately, but if seen later and the patient shows signs of progressive peritonitis developing, with the distended "silent" abdomen, rapid thready pulse, persistent vomiting, and mental acuteness, it is much safer to resort to the conservative treatment, or the Ochsner-Murphy method. In this way many times the patient is carried through who would have succumbed to operation. Operation can then be done later when thought best. Bottomley advises in early cases of peritonitis to operate at once, but in later cases to institute the Ochsner-Murphy treatment and start an hourly or half-hourly pulse chart. A pulse that shows a steady rise in rate at the end of two or three hours demands operation immediately, but a steady falling pulse rate shows that the infection is being overcome and operation may be safely postponed.

To illustrate the foregoing remarks, I wish briefly to report a few cases. Only the positive findings are given.

CASE No. 476. Age 24, white, housewife. Referred to hospital Sunday, June 25, 1922, 4:45 P. M. When first admitted, patient had a temperature of 102, pulse 120, very thready. She gave a history of a pain in the stomach starting three days previously, which had localized in abdomen. At this time patient was very much collapsed, heart sounds were

weak and irregular, abdomen slightly distended, and had board-like rigidity. She was immediately given 700 c.c. saline by vein, and heart stimulants. This revived her considerably. Leukocyte count at this time was 16,000; diagnosis, acute abdomen, and, from history, of appendiceal origin. Patient's abdomen was opened 6 P. M. of the same day. Right rectus incision. Ruptured gangrenous appendix was found, free pus in abdomen abundantly. Pus was aspirated with suction pump. Appendix tied off, not invaginated, and drains inserted. Patient's condition did not change during operation; no stimulation was given. After two more intravenous injections of saline at 6 hour intervals patient's recovery was uneventful.

CASE No. 582. Age 35, white, housewife, multipara. *History of present complaint*—Patient felt perfectly well when retiring the night of February 23, 1923. About three A. M., February 24, she was awakened with a severe pain in the abdomen; some nausea, no vomiting, pain remained about the same day of the 24th; she was admitted to hospital at 9 P. M., February 24th. At this time patient was rather collapsed, pulse rate 100, but weak, skin and mucous membranes pale. Pain was relieved somewhat with morphia administered previous to moving to hospital. Slight murmur was heard with systole over the mitral area. Abdomen was distended, and slightly rigid, felt spongy to palpation, and indefinite spongy mass could be made out on the right side. Blood examination showed 3,000,000 reds, 10,000 whites, and 60% hemoglobin. From the physical findings, the blood picture and a history of irregular menses, a diagnosis of acute abdomen caused by ectopic pregnancy with internal hemorrhage was made. There was no bleeding from the uterus. Abdomen was opened 4:30 A. M., February 25, 1923; right rectus incision; free blood gushed out of the abdominal cavity, when opened. The bleeding point was found to be a ruptured right tube. Blood clots were cleaned out of the abdomen, the tube removed and abdomen closed with no drainage. Patient is still in hospital and making an uneventful recovery.

CASE No. 379. Age 12, colored. Referred to hospital August 2, 1922, 5 P. M., and gave the following history before admission. Was taken ill five days ago with a pain in stomach; two days later pain localized over appendix,

and remained there 24 hours; since then pain has been over entire abdomen. On admission the abdomen was so rigid that no pathology could be made out. Pulse rate 104, rather weak, temperature 99; leukocyte count 9,000. With so much rigidity, the significant history, and the low blood count indicated a grave prognosis as the reaction of the body was not good. Diagnosis acute abdomen. At operation the same day a gangrenous appendix was found, free pus in abdomen, and a general peritonitis. Appendix was tied off, drains inserted, and abdomen closed. Patient died at 1:40 the next morning. This patient, we think, would probably have done better with conservative treatment or Ochsner-Murphy method.

CASE No. 579. Male, age 28, white, laborer. *Previous history*—Ten years ago patient was shot in abdomen with shotgun. Abdomen was opened at this time and some blood removed but no perforation of the intestines was found. Several weeks after this operation was done, abdomen was opened again for what he called "locked" bowels, and six inches of ileum was removed. During the past six or eight years patient has been bothered with constipation, and pain in abdomen. At one time he was in the hospital, and was told that he had adhesions. *Present complaint*—Patient went to work as usual, about 10 A. M. Was taken with a pain in the stomach and had to go home. There was no result from cathartics taken that night. Next day, Tuesday, his condition was worse, with pain in stomach and abdomen, and physician was called. The following day the patient was brought to hospital, at which time he was in severe pain, temperature 100, pulse 106, respiration 24, and was vomiting a green fluid almost constantly, and had to be catheterized. Pulse was weak, abdomen very rigid and slightly distended. Leukocyte count was 31,000. Diagnosis acute abdomen. Abdomen was opened at 6 P. M. same day; right rectus incision; intestines were ballooned with gas, and gangrenous from strangulation and abdominal cavity was filled with a thin watery pus. Long section of the small intestines was made, including the adjoining parts of jejunum and, ileum being gangrenous, were removed, and cut ends were sutured together by an end-to-end anastomosis. Peritoneal cavity was washed out thoroughly with normal saline, drains inserted and abdomen closed. Patient's condition was very bad at this time; pulse bare-

ly palpable, rate 149. Patient was put on heart stimulants, and morphia, gr. 1/6, every four hours; saline by vein every eight hours for three days; stomach washed out every six hours for several days. Vomiting continued for four days after operation and was relieved only by lavage. At present there is no drainage from abdomen. Patient is eating general diet. Patient is still in hospital and doing satisfactorily.

After all is said and done, the causative diagnosis of the acute abdomen is at times very difficult and sometimes impossible, but the crux of the situation is this: when in doubt, act, and act promptly and intelligently. A clean abdominal section made under proper conditions will do no harm. Neglect to act promptly will often cost the life of the patient.

#### DUTIES AND ADVANTAGES OF THE "WHOLE-TIME" COUNTY HEALTH OFFICER.\*

By P. M. CHICHESTER, M. D., Leesburg, Va.  
Health Officer, Loudoun County, Virginia.

In taking up a subject of this nature, I am not blind to the fact that it is not a subject usually discussed before practitioners. As a rule, a considerable gap exists between the State health authorities and the general practitioner. Doctors who have followed public health or preventive medicine as a specialty should be placed on the programs of the various societies more often, so that a close co-operation and feeling of good will may exist. It is a special branch of medicine and should be treated as such. Since my experience began, I have had the existence of this gap too frequently brought to my attention not to be aware of it. This difference, I know, is not without some foundation. There are two outstanding facts, which I believe are responsible for the existence of this feeling:

First, a lack of sympathy for and understanding of the general practitioner by the health authorities. This is not true of all health authorities.

Second, the great tension under which the physician works at all times, and a lack of knowledge of the health laws along with a lack of knowledge of some of the things which are so essential to the thorough working of a health department. This also is not true in every case. To lessen this gap, the "preventive specialist" should more frequently take part

\*Read before the Medical Society of Northern Virginia, Maryland and District of Columbia, near Norbek, Md., May, 16, 1923.

in these meetings for the purpose of each becoming more familiar one with the other.

The man whose entire efforts have been spent in technical public health knows little of the difficulties of the physician in general practice. He knows a certain law exists and he knows a physician is supposed to comply with this law. I feel fairly safe in saying that I suspect a large majority of the physicians present have had, at some time or another during their practice, a communication from the health authorities, which has been considered uncalled for and possibly a little harsh. If you will recall, however, these letters are graded—that is to say—a first one to remind, and that followed by one more to the point, and this second letter usually comes as a result of previous trouble along the same lines. As a rule, this is the only means the health officer has of transmitting a certain health principle to the physicians. We have to admit that they, both physicians and the State boards of health, are somewhat out of touch with each other. The State health authorities are not always to blame, nor are the physicians. There must be a closer contact. Little can be accomplished by a correspondence school. The physicians cannot learn public health in that way, nor can the health authorities learn the difficulties of the practice of medicine. Preventive medicine or public health is just as much a branch of medicine for a specialist as pediatrics or surgery.

The health commissioners with whom I have had experience are all men of the highest professional type; but the work is so vast that they can only act in a supervisory way and the detailed work must be left to many subordinates, a great many of whom, through necessity are learning public health and can be readily classified as lacking, to a degree, in sympathy and understanding, but it must be so. There are men of inexperience on the public health side so far as the practice of medicine is concerned, as well as men of inexperience among the physicians so far as the public health is concerned. You cannot expect the high type of efficiency in the man who is using the position as a "stepping-stone." When he reaches a certain state of efficiency he steps on to the next class, because the salary is not sufficient to hold him and cannot be made sufficient. In comparison to its value to the people there is less available money for public health or preventive medicine than any other

public institution. As I have said before, this state of affairs is not entirely to be placed at the door of the departments of health. Some of the physicians in some instances, I am sorry to say, thoroughly justify a strained situation between themselves and the public health servants. Often this strained situation is unavoidable, sometimes neglect and occasionally indifference. I am not accusing the medical profession, of course. I only have in mind certain instances which have occurred in my experience.

Tact and experience are necessary, on the part of the health officer, in handling all such situations. I am sorry to say this essential is sometimes lacking. The physician cannot be expected to know all the "ins and out" which are absolutely essential for good public health work. He must have experience. In the medical profession, like any other, experience is the best teacher. I should say this is particularly true of medicine. So true is it that no man will impose himself upon the public now-a-days, without first serving an internship in a good hospital. After he gets this preliminary experience, he then begins practicing. Along with this practice he becomes acquainted with his health department at long range. His health department only asks co-operation and requires compliance with the laws, but the practitioner, occasionally, looks upon the health department as an abstract organization which only annoys him concerning reports and vital statistics.

Along with his practice the practitioner gains more and more experience in medicine, and more and more knowledge of the workings of his health department, but it is a slow process, as I have said, through a correspondence course. His time is full, all of it. He probably never sees any of the representatives of his health department. Practically the only point of contact is through the mails. This is very unsatisfactory as we all know.

Practically all the time the physician isn't spending in looking after his practice, he is reading medical literature, attending meetings, taking special courses,—in every way making himself better fitted to relieve human suffering. It is a noble idea, a noble thought, a noble calling. His mind and efforts are concentrated on the ill individual and in making every effort to relieve him. It is no wonder he does not know much about the health department. Particularly so long as Public

Health is not made a course in each medical school he should be able to talk in person with his health officer and tell him his troubles (for he surely has them). It isn't right for him to have to take his course at long range. Every community of a certain population should have a trained and practical man to look after its disease prevention.

Compliance with the law is a duty which is imposed upon us all, no matter what profession we follow, whether we be preachers of the gospel, lawyers or physicians. Because of the importance of health, there are a great many laws pertaining to it, and the physician is at times put to it pretty hard to comply to the letter. There should be a local health officer to aid him in every way possible.

I say the general practice of medicine is a wonderful, noble, Godlike profession. But, what of the men or group of men who are working equally as hard along almost the same lines, only applying their efforts to the public instead of the individual, and who are attending meetings, reading literature and taking special courses for the purpose of becoming as efficient as possible in preventing a good deal of suffering the practitioner is relieving?

Relief of suffering, and cure if possible, are essential and the individual sees that, and sometimes willingly pays for it—occasionally very dearly. He is supposed to pay directly for it. (He doesn't always, however.) He pays indirectly, through his taxes, for his preventive physician. He should have this servant close at hand where he can call on him directly and quickly, and feel sure that the health officer has a personal feeling for his particular case. He cannot see the results so well. When he is enjoying good health it may be on account of good milk, water, food or sanitary surroundings or an inoculation or vaccination, or all of these factors combined which are responsible for his happy state, or it may be due to health education received at some period of his existence. I say again, he should have his trained man at hand all the time to look after these things so vital to his health and happiness. As it is, his mind reverts to his last spell of illness and to the physician, who (to use his pet expression) "Pulled me through." He gives all the credit to his physician (where a great deal does belong), and to himself, when as a matter of fact a portion of the credit should be given the health officer, who should always be at his side armed with good health laws and

personally equipped with knowledge which make it possible for him to live happily and in good health. Could any profession be more noble?

Now, gentlemen, after explaining the situation as I have found it, and having brought out some of the advantages of the whole-time county health officer and some of the difficulties which must be overcome, I want to state to you in a brief way what I consider the duties of a "whole-time" county health officer, and to show further the advantages to the county and the physicians in having such an officer.

Certain health laws exist, and are necessary and reasonable. The fact that they exist makes it our bounden duty to comply with them. The fact that they are necessary and reasonable makes this duty easier.

At first glance, one would say that the health officer is working in opposition to the physicians. Is that true? No one would dare say that the physicians are working in opposition to the health officer. This would be equivalent to treason. But if they do not co-operate, and neglect and shirk their duties, they are working against the health officer, whose work stands for health and happiness in the community. I know it is the desire of every true physician to join in all the work for the public good.

Good public health work will eliminate a certain very objectionable class of work from the physician's practice. What true physician, these days, will not give up that portion of his practice on such diseases as diphtheria, typhoid and kindred maladies? The chances of unavoidable accidents are too great in such troubles for him to want them. What physician is not ready and willing to turn over (all but the treatment) to his health officer any of his communicable diseases, thereby relieving himself of the responsibility of the quarantine and the control of such diseases? In the country he cannot do this unless he has a whole-time health officer. To aid the practitioner in this way is a very decided duty of a health officer.

The whole-time county health officer fills in the gap between the State authorities and the county. He is the connecting link. He is constantly in touch with local affairs. He knows the local authorities and local needs. General principles are necessary, but each community has to have special modifications of these general principles. It is the health officer's duty

to apply these principles to the best advantage, always bearing in mind the local conditions.

Bearing the foregoing statements in mind, the whole-time health officer's duties are clearly cut out. We can place them under four heads:

First. His duty to the State.

Second. To the public.

Third. To the physicians.

Fourth. To the individual.

There is no special significance in the order named. His duties to each are equally binding.

His duty to the State is simple. He should be acquainted with the State health laws, and see that these laws are carried out. He must be tactful and in every way possible obtain results before resorting to force by law. He must keep the community under his jurisdiction in close touch with the unit head. To work conscientiously at all times.

His duty to the public is to see that his community enjoys the benefits of good health which are obtainable through close co-operation with the local physicians, and through educational propaganda; to see that each preventable disease is so isolated as to safeguard the surrounding public; to advocate vaccinations and inoculations of various kinds to protect the public; to call out all the resources possible from State and other sources to aid as far as possible in producing a state of good health in his community. He must bear the responsibility of the general health in his section. Burdens should be placed upon him which he must bear or he should get out for the next man.

His duty to the physicians is important and requires great tact. He must always bear in mind that the physicians and schools are the foundation of his disease control work; that he must say and do nothing that will in any way influence the feeling or opinion of a particular patient towards his physician, except to encourage confidence in the family doctor. The health officer must maintain the closest friendship with the physicians and, last but not least, he should prepare himself so that he can be of assistance to the physicians in clearing up difficult and doubtful diagnoses of the communicable diseases. The physician should feel that he is calling in a good, free diagnostician. In other words, he should be somewhat of a specialist in the communicable diseases, particularly from a diagnostic standpoint. A physician, who has primarily the individual in

mind, hates to put them to any unnecessary inconvenience; so the health officer should be such a man that the physicians can call on him without fear of any rash statements or action. None of us knows it all. We are all human and therefore, subject to error, but as I have said, experience counts for a great deal, and the health officer should have had experience in the diagnosing and control of communicable diseases, so that the general practitioner, who sees comparatively few such diseases, can call freely on his health officer.

The health officer's duty to the individual is simple, but nevertheless important. He should always consider the individual's feelings—making the burden of quarantine and all other burdens as light as possible, but always safe for the other man. He should lead the individual by education and persuasion rather than force.

A health officer should have two main qualities—leadership and technical ability. Of the two, possibly leadership is the more essential. He can gather about him, if needs be, skilled workers, but he must be able to lead these workers.

The whole-time county health officer comes nearer giving the rural practitioner the same advantages that the city practitioner enjoys than anything else. Every physician should be an advocate of good health. Our training calls for it. We take the "oath" when we graduate. With a health officer at his disposal, a physician can relieve his mind of the details of any situation pertaining to public health, if he will only report these conditions to his health officer as he comes across them in his practice.

To summarize: let me say that the county health officer has decided duties to the State, to the public, to the physicians and to the individual.

He gives to the State, to the public, to the physicians and to the individual his skill and time. He is due from the State, public, physicians and individuals a hearty co-operation. Without this co-operation he is compelled, at times, to resort to force, and his work is greatly handicapped.

He probably adds to the physician's practice because in his various investigations the health officer is constantly referring to family physicians people who would probably never have come to the doctor until too late. He asks in return that the physicians comply with the

law. That is reasonable, I think. The health laws of the State are our guide—they are essential and reasonable. I think a man should be thoroughly acquainted with these laws before he takes up medicine, and if he doesn't like them and doesn't pledge himself to comply with them he should choose another profession. He is dealing with too precious a commodity—life. It is the health officer's duty to see that they are carried out, and it is the individual's duty to carry them out. There is no law which, at times, does not work apparent hardship on some people. If we disobey or disregard the law, whether that law be of man or God, we are punished. It may be a slow process and it may be a slight one, but it is sure. I often feel like calling the laws pertaining to health "The laws of nature" or "The laws of God."

Anyone who objects to or disregards the principles of the health officer necessarily objects to the principles of the clergyman and the pedagogue. They are working for the three essentials of human happiness—a sound soul, a sound body and a sound mind. There can be no real happiness without a sound body. The straightest way, however narrow it may be, to this happy state of existence, is through *prevention*. The health officer works along these lines.

### TREATMENT OF PULMONARY TUBERCULOSIS.\*

By H. R. EDWARDS, M. D., Richmond, Va.

The chief factor in the treatment of tuberculosis, whether in a sanatorium or in the home, is REST, and this means rest of both mind and body. It is not enough to rest the body, if we allow the mind to be excited, for there is just as great and sometimes greater loss of energy by mental drain than by physical exertion. Physical rest is obtained by rest in bed or in a reclining chair in the open air, the details of which have to be altered to suit the individual cases and surroundings. Mental rest is a most important step in the treatment. Phthisiophobia is a condition present in more or less of the patients treated, and one of our first steps should be to reassure the patient and gain his confidence, explain to him that the process is a long one at best, but if followed

methodically there is no reason to believe that he cannot regain his lost health. This of course does not apply to the advanced case and those who we believe will not be able to respond to the treatment, but to the earlier cases or those with advanced disease yet who take care. There is nothing gained by not telling the patient the absolute truth, and explaining to him the various steps to be taken and why they must be taken. The only cases in which there is any excuse for not telling the truth are those of children below the age of understanding and others so far advanced that there is no hope for them. In both of these cases the parents or those responsible should be told, and they should be made to feel responsible for the proper carrying out of precautions.

Next in importance to rest is fresh air. The patient should live in this day and night. Fresh air may be warm or cold the same as stale air; proper ventilation, sleeping porches, window tents, roof tents, or bungalows, are advisable; if they cannot be had, there is always the possibility of opening windows. In outdoor sleeping the patient should be protected from draughts or exposure to rain and wind.

No less essential is proper diet. It is a most important part of the treatment of tuberculosis and will require considerable thought, especially for the bedridden case. The details of this phase will be taken up a little later.

### SANATORIUM TREATMENT

The purpose of the sanatorium is to give the patients an intensive demonstration of the method of taking the cure. It offers systematic regimen and supervision, the most salient factor in the treatment of the disease. The usual sanatorium, unless making a speciality of the advanced cases, is best suited to the earlier cases or to those who are showing good resistance. That is to say, a case according to physical examination may be in a moderately advanced or a far advanced stage of the disease, yet ambulatory and able to react should he be permitted to take intensive rest and treatment. Much depends upon the morale in a sanatorium; if there are mixed cases the frequent deaths are discouraging to the others, and not only to them but they discourage the other early cases at the places from which those patients came. Most cases look alike to the laity; and a death at a

\*One of a series of lectures and demonstrations to a class of physicians in tuberculosis held under auspices of the Health Bureau, Department of Public Welfare, Richmond, Va., February 15, to April 15, 1923.

sanatorium scares them so terribly that they will not go there for treatment.

For those of a suitable type for sanatorium treatment, it would be far better to have them in a sanatorium for a few months, chiefly to learn how to take care of themselves. Eventually, they must resort to home treatment, and it is far easier in the beginning of the treatment to learn how to conduct it with others in the same condition than to learn alone.

The sanatorium teaches the danger signs, how to take exercise, and when to stop. It further gives the patient some training in occupational therapy, and in many instances patients engaged in harmful occupations before their entry to the sanatorium are able to master a new source of income before they leave. This is very important, for what is the good of arresting a case and then allowing it to go back to the same old conditions, which means in short time another break down with an advanced condition and a consequent prolonged intensive treatment?

#### HOME TREATMENT

Eventually all sanatorium cases must resort to this type of treatment, and 95% of our active cases are taking it from various reasons. Sanatorium facilities are not adequate, finances interfere, and various other causes.

The fact that so many thousands of cases do improve and even cure themselves at home is ample reason to assure us that it is a perfectly feasible plan and can be done, that while it may be a little more difficult yet it is possible. Ideal treatment would be expensive; but, while we hold up an ideal to strive for, it is quite evident that all will not reach it. Still they can come as near as possible; and in this emergency the physician will be required to use his ingenuity constantly.

A few general considerations should suffice for a guide to the proper method of approaching this phase of the treatment. The patient should have separate quarters, that is he should sleep alone. The preferable place for his room and porch, if it is possible, would be a southern or eastern exposure, adequately protected from the elements, yet giving him the maximum amount of sunshine and fresh air throughout the year. If there is a pleasant scenic view, that should be taken advantage of. Often a room to the rear of the house is better than on the front, for then the patient is not so

constantly exposed to the passer-by. While active, that is maintaining a temperature of 99.5° or over, he should be in bed; after the acute activity has subsided for a few days to two weeks, he may be allowed to sit in a reclining chair in the open air. If it is not possible to have a sleeping porch, it is practically always possible to have some sort of a window tent arrangement whereby a patient can be in the fresh air day and night—the windows can always be opened. While in bed, use the minimum amount of bed clothing that is required to maintain body warmth. Remember that much depends upon the protection from beneath as to how warm the patient will be.

Separate dishes should be used, and they should be washed thoroughly immediately after every meal, in hot soap suds and water and finally rinsed in boiling water. When the case becomes closed, if this precaution will be pursued religiously, there will be no danger in using the dishes with the rest of the family.

Avoid hangings and draperies in the sick room as well as carpets; there should be nothing there but what can be easily cleaned or boiled.

#### CLIMATIC TREATMENT

Much in the past has been attributed to climate, and no doubt change of scenery and surroundings will have beneficial effects, but we have found that under proper living conditions we have been able to effect cures quite as well in the lower as in the higher altitudes, though the latter are, of course, more stimulating than the lower ones. There is a certain type of advanced case that does better in high altitudes than in lower; but usually when an advanced case has been treated in an extremely high altitude he would better stay there than attempt to return to a lower one. Here in Virginia the small variation in altitudes is not marked enough to make any material difference. The chief thing about climate is to get a plenty of pure fresh air with the maximum amount of sunshine and of days which the patient may spend out-of-doors.

#### EXERCISE

This is one of the most abused methods in our treatment, and one very simple if given the proper thought. I have many times told patients able to take exercise of say an hour twice a day that they could do anything they

wished provided they did not tire themselves. This of course would not include piano moving, mountain climbing, and strenuous exercises as tennis, baseball, etc. Many patients have suffered relapses days to weeks after some indiscretion in exercise. Hemoptysis often can be traced to over indulgence at some previous time.

Exercise should not be attempted until the patient has had a normal temperature for at least two weeks, and then only gradually, by walking the first day not more than 15 minutes morning and afternoon. Walking should be slow and on the level, if there is a slight grade take that in the first half of the walk, so that the return can take advantage of the down grade. It should be regular; the same amount each day. That is, suppose a case has 15 minutes b. i. d. and he wishes to save this up for a several hours' trip at the end of the week, he will invariably do himself damage. Regularity and systematic endeavor is the only way to attempt it. In case the temperature should be increased or there should be coughing, expectoration, or definite fatigue or dyspnoea from which the patient does not recover within an hour or less after his return, he should stop exercise. If his weight does not remain constant, but he loses gradually or his appetite does not remain as before he started it, he should take the rest again, and at each time begin all over again.

Exercise can be graduated from 15 minutes b. i. d. for the first week, increasing it 15 minutes if the case is able to stand it without any unfavorable symptoms each succeeding week until he is able to do two hours b. i. d. Even with this amount taken in the open air, many cases will show fatigue when returning to their former occupations.

Occupational therapy, as weaving, basketry, reed work, and metallurgy is ideal; croquet is perhaps the best game to play. Some sort of occupation should be encouraged wherever possible, for it makes the patient more interested, improves his general morale, and avoids the invalidism so disastrous to many.

#### SPECIAL TREATMENTS

*Artificial Pneumothorax* is a very valuable procedure in the treatment of certain types of cases; it should not be used, however, until the other more common means at our hand have

been exhausted and then only with the consultation of another physician.

Its indications are in those cases with a unilateral lesion to begin with. There are occasionally cases with a slight amount of healed tissue on the good side that are able to take gas, but it should be slight indeed. Hemoptysis that will not respond to any other method; cases showing a rapid spread of disease on one side, when all precautions as to rest, etc., have been tried faithfully; or those who have observed the "cure" for a long period, yet show active toxæmia without necessarily a spread of the disease, are its chief indications. The X-ray should be used in all these conditions before giving gas, if possible, as a diagnostic aid.

The idea in artificial pneumothorax is to put at rest more completely the diseased lung. Once started it often must be continued for months, though it is possible to decompress the lung and have healing continue. It is a method of resort only when the more simple methods fail, and then after careful consultation, X-ray, etc.

Its technic is too large a subject to enter into here.

*Violet Ray* is usually given in the mercury vapor lamps, the vapor being developed in quartz tubes; it is an artificial sunlight from which the irritating red rays have been removed and the healing violet or blue rays maintained. It is questioned by many, and lauded by as many more. In my own experience I have seen actual improvement in the following types of cases, glandular, intestinal, throat, bone and joint cases, and this seems to be the impression in general. In lung cases it is not so good, though as a psychic factor it may help. I have seen many cases with slight pulmonary lesions improve remarkably with violet ray treatment, but I doubt its value except from a psychic viewpoint. The mechanism of its action is not definitely known. Some strain the fact of the pigmentation caused, and some various other factors. We really understand it but little, yet it is evident that some types of cases are benefited.

*Heliotherapy*.—Sunlight in moderation and under supervision is a great factor in the same types of cases as mentioned above; more has been done with it in Europe than here, especially among the children and those with glandular and bone disease. Exposure should

be graduated in dosage and over small parts of the body at first, and never if streaks or fever appear.

*Deep Therapy X-ray.*—Its use is new and enough evidence has not been accumulated thus far to recommend its use as a general agent.

*Dietetic.*—Volumes could be written on diet but I will only mention the salient factors here. It should be nutritious and include rich milk, eggs, fish, fowl, meats in moderation, especially to those in bed, grains, fresh vegetables, fruits. High protein dietaries increase the burden on the kidneys and other eliminative organs, increase metabolism with an increase in respiration and on the whole should be restricted as much as possible. Alcoholics are never necessary. Meals should be regular t. i. d., except for those who are below weight, and if it does not affect their appetite at meals, provided they are showing a gradual gain in weight, broth, milk, eggnog, cocoa, and the like may be given between meals and before retiring at night.

The guide as to the amount to feed should be the weight chart; regular weighing on the same scales with the same clothing should be practiced. A slow gain in weight is much better than a rapid gain. It is essential that the patient regain the weight that was normal before his illness began and perhaps a few pounds (5-10) over, before he can feel that his weight is not a factor to be given special attention. Flabby flesh is injurious, the gain in weight should be associated with the gain in strength, and the hard firm flesh is the kind that will stay.

#### SPECIAL REMEDIES

Among the most common remedies used are cod liver oil, dram 1, t. i. d., creosote, ggrts. 15-20 to tolerance and then reduce to 5-6 ggrts., guaiacol carbonate, especially good in cases with wheezing, hypophosphites, arsenic, iodoform, etc. Most of these remedies have their place, but that place is not near as important as it was once considered to be, and it is always best to avoid their use as much as possible if the case can be induced to observe proper rest and other precautions. There is always danger of upsetting digestion.

Tuberculin has been much touted and in a limited number of cases is still capable of some good. It is best administered in a sanatorium under constant observation. The supply

should be fresh and renewed often; it is not a method to be used by the average practitioner. Its benefit is theoretically due to the stimulative action it is supposed to have on scar tissue formation. It is given in logarithmic doses infinitesimally small, and gradually increased over long periods of time, keeping just below the point of reaction. It is always used in conjunction with rest, fresh air, and proper diet, and it is often a question just which factor should receive the most credit.

#### TREATMENT OF SPECIAL SYMPTOMS

*Cough.*—First determine the cause; if catarrhal or nasal, treat accordingly. Cough syrups are irritating and to be avoided. Inhalation of tincture of benzoin with carbolic acid; formalin; or creosote, alcohol and chloroform, equal parts, is good. A morning cough on rising often responds to hot water and soda bicarbonate. Those due to throat coughs are helped by cocaine solution if severe, or bland gargles in the milder cases. Pleuritic cough responds to counterirritants, iodine, and in severe cases to morphia, which should be used only as a last resort. Pleurisy jackets, and strapping help. Heroin 1/6—1/2 gr. is used but is not a practical permanent relief. Stimulative expectorants as ammonium chloride gr. 3-5, or infusion of wild cherry are helpful. Avoid dust, smoke, and tobacco. Rest does more permanent good than anything else.

*Fever.*—If temperature is 99.5° or above, the bed is the only place, drugs should be avoided as long as possible; in a few cases some drugs as acetanilid gr. 2-3; phenacetin gr. 3-5 may be used; the cause is increased absorption of toxin and the best way to minimize this is to put the patient at absolute rest and keep him there for two weeks after the temperature has returned to normal. This helps to prevent the liberation of toxin.

*Night Sweats.*—Use alcohol sponges, sponges of alcohol and tincture belladonna, and avoid drinking large amount of liquids at night. Atropine, gr. 1/120—1/60, sulphuric acid 1% solution, agaricin, gr. 1/8—1/4, are accepted medicinal remedies.

*Gastro Intestinal.*—Regulate diet, correct constipation and use all simple methods before trying drugs; they only, as a rule, relieve symptoms and do not strike at the cause of the complaint. Vomiting in the morning or after coughing is controlled with cerium oxa-

late quite easily, gr. 8, an hour before the expected attack, as they often come at quite regular intervals.

As diarrhoea will be considered under complications, I will say no more now than that alum, whey, and broths are beneficial. Bismuth, acetate of lead and opium, thymol, salol and benzo-naphthol, are recognized remedies.

*Hemoptysis.*—A fair percentage of tuberculous cases have blood-spitting in some amount during the course of their disease; when it is small they do not become as alarmed as when it amounts to ounces. Coming so often in the early morning hours it is distressing indeed, for there is the sensation that it may not stop and the prospect of gradually bleeding to death causes a great deal of mental unrest. The pulse rate and tension are increased, which consequently tends to prolong the bleeding if not to increase it. So the first thing we must do is to reassure the patient if possible, gain his confidence and help him to believe that it will not amount to much and, if he can calm himself, it will be all right. This is not easy to do and is only possible if the patient has confidence in his physician.

If the blood-spitting is in the form of "streaks" only, carefully examine the condition of the gums, or other conditions in the mouth, nose, or throat that might be responsible. If it is suspected or definitely known to come from the lungs, the patient should be cautioned to observe more rigid rest, avoid all exertion or sudden expenditure of energy, and go to bed until it has ceased, and further to remain there for from five to seven days after. Many times this will avert a more serious hemorrhage. An examination should not include the expiratory cough for rales, as auscultation for ordinary breathing is sufficient. If there is a rise in temperature, the more necessary is it for the patient to be put to bed, for this indicates either a spread in disease or the absorption of toxin into the blood stream. Patients on exercise should stop until the streaking is over for a week, and then on returning to it make it gradual, though perhaps not over as long a period as in the beginning. Limit the amount of hot liquids especially, and give no stimulating foods. Iced drinks are best for a day or so, and they should be restricted. Bits of ice in the mouth are best for thirst.

Should these streaks become frequent, that is throughout the day, or even develop into frank hemoptysis of a dram or more at one expectoration, the patient should be put to bed absolutely and kept there for from one to two weeks after the bleeding has ceased or longer, depending upon the amount and the condition of the case. In those with large hemoptysis, reassurance of the patient is the first step. They should be put in a semi-reclining position, usually about 30° is the most favorable, an ice cap applied to the chest, and suitable basins provided for expectoration, which will not require the patient to exert any effort. When the amount is in ounces, a hypodermic of morphine should be administered. Never attempt any examination, except auscultation on ordinary respiration, and that is to be done with caution. Heat to the extremities, and bits of ice for patient to hold in the mouth should be given. Coagulin and serum is often good and, if the hemorrhage is not too large, will help to control it. Pearls of amyl nitrite, hypodermic injections of nitroglycerine, gr. 1/100, may be used to lower blood pressure. Atropine sulphate, gr. 1/100 to 1/50, often helps to check a hemorrhage. The numerous serums on the market have a place in the checking of hemorrhage. It is well to familiarize one self with them and use selected ones in conjunction with the above measures. Ergotol is used by some but is dangerous as there is always a secondary relaxation of the vascular system which may result in an even greater hemorrhage. The diet should be reduced to dry stuffs, no hot liquids or stimulating foods at all. The food is best given in form of toast, or crackers and cold milk. Some cases of small hemorrhage can be relieved by bits of salt in the mouth.

When the bleeding does not respond to the above, or there is a single large hemorrhage of say a pint or more at one time, with continued bleeding following it, and if the patient is known to have definite involvement of one side and it is determined that the blood is coming from this side, artificial pneumothorax should be considered, and not delayed more than a day if the foregoing means have failed to check the process. It may be necessary to continue the gas treatment for some time, as there is often great danger of repeated bleeding as soon as the decompression reaches a certain point.

Any patient with hemoptysis of one ounce or more at any one time should not be allowed to exercise or be out for a minimum of one week to ten days, and this time increased in length as the amount of bleeding is increased. The healing process in the lung where there is a constant movement is more difficult than on the exterior of the body where we can apply pressure and ligation to control bleeding.

In conclusion, let us recapitulate by putting the greatest emphasis on absolute rest during the clinically active stage of the disease, the maximum of pure fresh air and proper diet, the prophylactic treatment of all those exposed to tuberculosis to prevent new cases, exercise or vocations to be resumed under precaution always. Emphasis on the fact that sanatoria are for the most part educational centers best suited to the earlier cases. It is possible to conduct the "cure" at home, provided we have the co-operation of the patient, a prerequisite to the successful treatment of any case.

1110 Capitol Street.

### SIGNIFICANCE OF A PROLONGED COAGULATION TIME OF THE BLOOD.\*

By J. S. HORSLEY, Jr., M. D., Richmond, Va.

Prolonged coagulation time of the blood is either in itself pathological or an accompaniment of a pathological condition. The diseases in which pathological hemorrhages most frequently occur are hemophilia, chronic jaundice, purpura, and melena neonatorum. Purpura itself is really a symptom and not a disease and may occur with hemophilia.

The theory of the coagulation of blood most universally accepted in America is that of Howell, of Johns Hopkins. This theory in his own words is as follows: "In the circulating blood we find as constant constituents fibrinogen, prothrombin, calcium salts, and antithrombin. The last named substance holds the prothrombin in combination and thus prevents its conversion or activation to thrombin. When blood is shed, the disintegration of the corpuscles (platelets) furnishes material (thromboplastin) which combines with the antithrombin," and at the same time liberates more "prothrombin; the latter is then activated by the calcium and acts on the fibrinogen."

forming fibrin which is the foundation or basis of the blood clot. Thus,

Antithrombin antagonistic to prothrombin:

Thromboplastin + antithrombin frees prothrombin:

Prothrombin + calcium = thrombin:

Thrombin + fibrinogen = fibrin.

An abnormality in any of these four fundamental constituents of the phenomenon of coagulation will correspondingly alter the blood clotting time.

Howell and Holt described two new substances, in 1918, which are connected with the process of coagulation of blood: I. A phosphatid, designated as heparin, which is obtained most readily from the liver (dog). It possesses two characteristic reactions, (1) it retards or prevents coagulation of blood, both in the body and when blood is shed; (2) it causes a marked increase in antithrombin when added to blood or serum. II. Pro-antithrombin, an antecedent or mother substance for antithrombin is present in plasma and serum in considerable quantities and is converted promptly to antithrombin by heparin. Heparin inhibits clotting mainly by preventing the activation of prothrombin to thrombin. It acts as an antiprothrombin rather than as an antithrombin. Theoretically it is suggested that heparin and prothrombin are normal constituents of the circulating blood (not demonstrated for heparin) and together fulfill the function of safe-guarding the fluidity of the blood; e. g., preventing intravenous clotting. When blood is shed or when in other ways thromboplastin (cephalin) is added to blood the protection afforded by the heparin is overcome and thrombin is formed in amount sufficient to cause clotting. It is suggested that variations in the amount of heparin in the blood may suffice to explain some of the known abnormalities in coagulation, hemophilia, for example.

An excessive amount of oxygen, the restriction of food, the ingestion of large quantities of water, smoking of tobacco, are said to delay coagulation time. The injection of certain chemicals, particularly the extract of the head of the leech, called "hirudin," retards clotting. The coagulability of blood is also prolonged by certain snake venoms and after poisoning with chloroform or prussic acid. The effect of hirudin and of snake venom is believed by

\*Read before a meeting of the Junior Clinical Club, Richmond, Va., May 21, 1923.

Howell to be due to the antithrombin contained in these substances. According to Whipple an excess of antithrombin is responsible for a large number and great variety of clinical forms of delayed coagulation, such as occur in septicemia, pneumonia, endocarditis, miliary tuberculosis, general vascular thrombosis, etc.

Drinker and Drinker have found that, in cats and rabbits, rapid progressive hemorrhage causes a decrease in the coagulation time, with an occasional exception. This is accompanied by a decrease in the amount of antithrombin. The latter may be due to simple dilution of the blood by an influx of fluid from the tissues or to a decrease in the amount of antithrombin formed. Most of the fluid entering the blood after hemorrhage comes from the abdominal region. This fluid is, according to Drinker and Drinker, lymph, not tissue juices. Lymph contains prothrombin and antithrombin in the same concentration as blood plasma, but much less material which may produce thromboplastin. There is, therefore, a relative excess of antithrombin in lymph which explains its long coagulation time. Addition of thromboplastic material to lymph causes it to clot firmly and promptly. In experiments carried out by these authors they found that the prothrombin changes did not offer any explanation for the decrease in coagulation time which occurred. The fibrinogen, estimated by the heat coagulation method, decreased as the hemorrhage progressed. Antithrombin decreased in amount when the coagulation time decreased and remained practically constant when the coagulation was unchanged. Platelets did not vary with rapid progressive hemorrhage. The results seem to differ from those obtained by Hanzlik and Weidenthal, who state: "Results of four experiments performed by us showed the coagulation time to be invariably and markedly shortened as the hemorrhage progressed." They, however, worked on dogs; but this hardly seems to explain the wide discrepancy. Experimentally this point still remains unsettled.

As yet the whole subject of normal coagulation of blood is in a theoretical stage and that of the significance of abnormal clotting time is even more theoretical. This is a step in the direction of the real facts, whatever they may be; but the true value of these numerous factors must be judged by their confirmation by

both experimental and clinical findings. Already some very practical points have been derived and applied successfully in the treatment of certain hemorrhagic diseases.

The cause of melena neonatorum is not definitely known, but it seems probable that it is not due to disease of the blood vessels themselves or to an infection, but is a congenital malformation of the blood, the exact nature of which is not known. Transfusion of whole blood is a specific treatment for this disease.

Prolonged coagulation is characteristic of true hemophilia. It also occurs in some forms of purpura of the secondary type, particularly in those in which the liver parenchyma is greatly damaged. Fibrinogen is produced in the liver and a deficiency of it is the probable immediate cause of the hemorrhagic tendency in certain diseases of the liver, such as acute yellow atrophy, cirrhosis of the liver, yellow fever, and in certain forms of poisoning, as phosphorus and chloroform. The coagulation of the blood is normal or only very slightly prolonged in all forms of idiopathic purpura (purpura hemorrhagica), and in most forms of secondary purpura, such as scurvy. In all these conditions it is likely that there is some defect in the formation of fibrin ferment.

Adis concludes that hemophilia is due to an inherited defect in the prothrombin, whereby it is less readily activated than normal. Sahli thinks the prolonged coagulability is due to a deficiency of thromboplastin and that this in turn comes from some defect both in the blood corpuscles and in the endothelial cells. Minot believes that the blood platelets in hemophilia are normal in quantity, but deficient in quality, probably lacking prothrombin. One of the most important methods of treating hemophilia is by serum therapy. It is the prothrombin in fresh serum that probably gives it its therapeutic value in checking hemorrhage.

The absence of the proper amount of calcium salts together with the somewhat obscure influence of such diseases as malaria, yellow fever, scurvy, jaundice, hemophilia, pernicious anemia, leukaemia, and alcoholism decrease the coaguability of the blood. Ottenberg and Lee suggest that the delayed coagulability in obstructive jaundice is due to the blood calcium entering into some sort of combination with the bile pigments.

At St. Elizabeth's Hospital we have ob-

tained very excellent results in the prevention of postoperative hemorrhage from cases of chronic obstructive jaundice by following the preoperative treatment suggested by Walters of the Mayo Clinic. Five c.c. of a 10% solution of calcium chloride in redistilled water are given intravenously, daily for three days, each time preceded by a determination of the coagulation time of the venous blood. If at the end of this time the clotting time has not been lowered to less than nine minutes, operation is postponed until such a reduction is obtained. Besides giving calcium chloride intravenously, large quantities of carbohydrates are given by mouth and glucose solution by proctoclysis, in order to increase the supply of glycogen to the tissues of the jaundiced patient. This is the food of choice for patients in toxic states as shown by Opie, and in cases of liver deficiency, as demonstrated by Mann. Large quantities of water by mouth increase the body fluids and help eliminate bile pigments.

In treating pathological hemorrhage, the main issue is to correct the cause of the prolonged clotting time. The exact cause is not always known, and when this occurs the following general measures should be resorted to: (1) Arrest of hemorrhage locally by surgical procedures, application of cephalin, blood platelet extracts or some of the other numerous similar preparations; (2) Attempt to correct the systemic cause of hemorrhage by whole blood transfusion, preferably given by the direct method. We get best results by using the silver cannula of Bernheim, connecting directly the radial artery of the donor with a vein of the forearm or elbow of the patient. The reactions that follow this are practically nil, and the blood elements are altered less than by any other method of transfusion, except direct union of the artery and vein by suture, which requires a good deal more skill and time. Transfusion not only furnishes the deficient blood constituents which promote a normal clotting time and stop the hemorrhage, but also replaces the lost blood. Carter and others have shown that the intravenous administration of citrated blood, which is very extensively used, will temporarily decrease coagulation time. Sodium citrate solution injected intravenously has a similar effect (Gerster). There are, however, two very good reasons why the citrate method of transfusion is inferior to the whole blood method. (1)

The number of the platelets is greatly diminished and their character is altered considerably by the citrate method. In hemophilia the replacement of normal platelets is most important. (2) Reactions of varying degree and severity follow in about 50% of all citrate transfusions. This factor is negligible in transfusion of whole blood by the direct method.

#### SUMMARY

1. The mechanism of both normal and abnormal coagulation of blood is still in a theoretical state.

2. From the few facts known already practical points in the treatment of hemorrhagic diseases have been successfully derived.

(a) Deficiency of fibrinogen in diseases of the liver.

(b) Deficiency in prothrombin and in the quality of the blood platelets in hemophilia.

(c) Deficiency of calcium salts, as in chronic obstructive jaundice.

3. Calcium deficiency may be treated successfully by intravenous injections of calcium chloride.

4. The general measures of treatment when the direct cause of prolonged coagulation is not known are:

(a) Arrest of hemorrhage locally by surgery, cephalin, etc.

(b) Correction of the systemic cause of hemorrhage by whole blood transfusion, preferably by the direct method.

## THE PROBLEMS OF RURAL COMMUNITIES AS REGARDS PHYSICIANS.

By J. M. MILLER, M. D., Crockett, Va.

That rural communities have problems to solve in securing and holding competent physicians will, I think, be readily admitted by all who have given the matter any serious thought. We may, however, differ in opinion as to why it is that physicians hesitate to locate, and after locating, do not remain for any length of time, in country districts.

In my opinion, there are several reasons for this, two of which are of paramount importance to any physician who contemplates locating in the country, and several others whose importance will vary, depending upon the individual case.

The first reason we will consider, for the scarcity of country doctors, is one that will apply as well, though in less degree, to the towns and cities. Compared to the population in this country, there are fewer young men devoting themselves to the study of medicine today, than there were a few years ago. The reason for this is not difficult to find. The course of study is so long, and the cost so great, that many worthy young men, and women too, are barred from even commencing this study. The two years of preliminary college work, plus the four spent in the medical school, and, if he is to be well rounded, the one or two spent as an intern in some good hospital, consume from six to eight of the very best years of a man's life. The cost connected with this preparation will average probably one thousand dollars per year. Thus, the capable, intelligent young man with this capital can, by applying himself industriously and intelligently to business, have as much money at the end of the eight year period as the average country physician will have accumulated in a life time of arduous toil.

While money should not be, and in most of cases probably is not the sole factor, influencing us in choosing our work in life, still it is one of the things that must be considered.

In considering the reasons that apply exclusively to the scarcity of physicians in rural communities, I would mention, first, the absence of good roads. You, whose practice is altogether in the larger towns and cities, or in those rare country districts so fortunate as to be blessed with good roads, have no concep-

tion of the deplorable, damnable, condition of dirt roads, for three or four months in the year. They are either so muddy that a horse (for an automobile is not to be considered at this time) sinks almost, if not quite, to his knees, in old mother earth, at each step, or, if the weather is cold and the roads are frozen in this condition, they are as irregular as the surface of an angry porcupine's back, and the horse, if he is so fortunate as to stay on his feet, flounders from one eminence to a corresponding depression, almost wrenching his limbs from their sockets, to say nothing of the damage done to the small of the back and central nervous system of the rider. The means for successfully navigating, going over, or through these roads, as the case may be, has never yet been discovered, and probably never will be, so long as man remains the type of animal he is today. These roads in winter are the continual night-mare of the country doctor. The fear of being called to negotiate, by some means or other, some eight or ten miles of their uneven surface, is often his last conscious thought before dropping into a troubled sleep.

The next reason I would give for the scarcity of doctors in the country is the smaller scale of fees prevailing here. Instead of being smaller, I claim they should be larger in country than in city practice. One of the main factors considered in determining amount of compensation for our services is based upon amount of responsibility assumed by us in treating a case. The responsibility of a country doctor is much greater than that of his city brother. By reason of his isolation he must necessarily be more or less of a specialist in all that appertains to the practice of medicine. Of course, I do not mean that he must be a skilled specialist in all of these different branches of medicine but, if he is successful, he must know enough of each one to know when and where to refer his patients for proper special treatment when the necessity arises. You in the larger towns and cities, when you meet with a puzzling, perplexing case, can, in a few minutes, secure a competent consultant, but we in the country cannot do this; we must often bear the responsibility alone. Another reason, why we should receive greater remuneration for our services is, as has already been intimated, because of the greater difficulty we have in reaching our patients. The city man can reach his in ease and

\*Read at the meeting of the Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

comfort, while we, often, reach ours with great difficulty and discomfort.

Among other reasons that could be mentioned why some physicians do not locate in the country is often the absence of proper school facilities, for their children, and high class educational entertainments for themselves and families. There are only 340 accredited high schools in the State of Virginia. Of course, most of these are in the towns and cities, leaving quite an inadequate number to be distributed amongst the various districts of the one hundred counties of the State. The physician with a large family, located in a community without good schools, cannot give his children the education often deserved, unless he has financial means other than that derived from his practice.

The physician and his family seldom have the opportunity of hearing an address or lecture, or seeing a play or picture that is truly worth while, without going to some town or city more or less remote from them. In the matter of moving pictures though, I believe we country people are to be congratulated on their absence. While some of them are, and no doubt at sometime most of them will be, of great educational value, they, as at present conducted, are probably conducive of more harm than good, and will continue to be, until purged of all such characters as "Fatty Arbuckle" and his kind.

So much for the problems confronting rural communities in securing and keeping physicians. What, of the solution of these problems? The first reason given for the scarcity of rural physicians is the comparative scarcity throughout the whole country. I am inclined to believe this the most difficult of solution of any of the problems mentioned. None of us, in order to secure more doctors, would, for a minute, be willing to lower our medical standards. We think too much of our beloved profession, to be willing to sacrifice quality, for quantity. Perhaps, until living conditions and traveling facilities are much improved in the country, thus inducing more to locate there, the State or Federal government, or both, may have to lend a helping hand, by advancing to worthy young men and women, carefully selected, the financial means necessary for them to apply themselves to the study of medicine. If the proposition to require these State aided graduates to practice for a certain number of years in some designated country district

smacks too much of the abolition of one's personal liberty, they could be required, when they become financially able, to pay back with interest the amounts advanced, thus creating a perpetual loan fund for the use of poor but worthy students. As the graduates become more numerous, some of them, by the sheer force of economic necessity, would naturally gravitate to the remoter rural districts.

The second problem, that of bad roads, is one to be solved chiefly by the community itself, perhaps, aided by the State and National governments. I am speaking now of the prosperous community. These communities can and, if the matter be properly and forcibly presented to them, most of them will, with or without aid, build good serviceable, hard surfaced roads. There is a field here for much missionary work, and I believe that the time has come when we physicians should endeavor by every means within our power to show these people the conditions that confront them, and state firmly the results that must inevitably follow, unless these conditions are remedied.

As to the road problem in those communities that are not prosperous, it must be solved, if solved at all, by Federal and State aid. The proposed bond issue is woefully inadequate to even alleviate, let alone cure, bad road conditions in remote rural sections. Nor would an issue of one hundred million do this. Some other means, with or without this issue, must be devised by our law makers, if these sections are to have the roads of which they are so badly in need.

The problem of small fees in country practice can be remedied by the medical profession and by it alone. The majority of country practice is necessarily among the farming class. The farmer is proverbially careful and cautious in the expenditure of his hard earned dollars. Most of them, however, are fair and recognize a good business proposition when properly presented to them. If once convinced that, in order to obtain first class medical service, the fees must be materially increased, they will yield with the best grace possible. So, this is simply a matter in which the physician must educate his clientele. Of course there must also be co-operation among the physicians themselves.

The problem of good schools is one that any prosperous community can solve for itself, and in the wake of good roads and good schools will naturally follow wholesome, legitimate,

and educational entertainment, recreation, and social intercourse.

In conclusion: Can these country communities secure and retain competent physicians? Yes, if they will pay the price. If they will make living conditions in the country attractive enough; otherwise, not. Unless this is done, physicians will continue in ever increasing numbers to shun and forsake the country and it will not be many years until a competent doctor in remote rural sections will be a *rara avis*, if, indeed, not entirely a thing of the past.

### TETANUS: ITS ETIOLOGY, PROPHYLAXIS AND TREATMENT, WITH A REPORT ON CASES.\*

By C. F. GRAHAM, A. B., M. D., Wytheville, Va.

Owing to the fact that for some unaccountable reason or reasons there has been in the past few years quite a noticeable increase in acute tetanus, in certain localities, notwithstanding we have at our command what I may call almost a perfect prophylactic, and as I have in the past two years personally treated, or been associated in the treatment of, four cases, after some trepidation I decided to write on tetanus as viewed by a general practitioner.

"1. From a study of the authorities on this subject it will be learned that in this country throughout the registration area deaths from tetanus have been rather uniform. 2. On the other hand in the British Isles tetanus infection is rising due to some cause and this rise began even before the war. 3. There has been, however, a marked diminution from the single class of tetanus cases due to accidents with Fourth of July fireworks. From this cause in 1903 there were 415 deaths, in 1908 seventy-six and since 1911 proper prophylaxis and the sane Fourth idea have reduced these almost to a negligible degree."

In this country tetanus is most frequent in the Hudson Valley, Long Island, and the Atlantic States. A few years ago it was almost unheard of in Wythe County and the author can remember only one death from tetanus recorded prior to the last two years.

In the two years ending December 31st, 1922, however, there have been seven cases of acute tetanus in the county with four recoveries. Four of these cases came under the author's observation and will be reported in this paper.

Tetanus is an infectious disease caused by the inoculation of the bacillus tetani in an initial wound. There are two main clinical varieties, the acute and the sub-acute, the acute developing in from one to ten days, usually seven, and the sub-acute in from ten to twenty-one days.

#### ETIOLOGY

*The predisposing causes of tetanus* are punctured, lacerated, and bruised wounds especially of the head and extremities which have been contaminated with dirt, particles of clothing, etc.; gun shot wounds, especially those of blank cartridges, all wounds containing foreign bodies, and those received in or near stables, manure pits, hog pens, chicken coops, and in fields where horses or cattle have been kept; also wounds contaminated with street dirt and all wounds where there is much destruction of soft parts with suppuration. The physician should bear in mind too that the removal of an encapsulated splinter or other foreign body has been known to be followed by tetanus, due to the freeing of spores into a freshly made wound and the destruction of the protecting membrane by the surgical procedure. *The exciting cause* of tetanus, of course, is the micro-organism itself which, gaining entrance through the wound, there multiplies and produces its toxin some of which, gaining admittance into the circulation, becomes fixed in the protoplasm of nervous tissue and some is absorbed by way of the peripheral nerve filament and, traveling along the axis-cylinders to the nerve center, becomes fixed to the nerve cells, thereby producing the characteristic nervous manifestations.

#### PROPHYLAXIS

The author wishes to state that he considers the prophylaxis of tetanus absolutely its most important treatment and the handling and cleansing of any wound which may be potentially the harbinger of a tetanic infection should be carried out with the utmost care and, in all cases where there is the slightest chance of this infection developing, anti-tetanic serum should be administered. My main object in writing this paper is to stimulate the more frequent use of anti-tetanic serum, especially as there is an apparent increase in the incidence of this disease in our section.

The method of treating the wound and the antiseptics of choice depend to some extent on the conditions existing. If the wound is a

\*Read at the meeting of the Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

small punctured one, it should be well opened, thoroughly cleaned with hydrogen peroxide, cauterized with phenol and iodine, and then left open to heal, being dressed with some loose dressing that will not exclude air. If the wound is of large extent with much laceration and much foreign matter present, it should be thoroughly cleansed, the foreign matter being entirely removed even if to do so necessitates an anesthetic. The surgeon must bear in mind that extensive mutilating surgery can accomplish little and may even be harmful. Hydrogen peroxide should then be freely used, the wound dried, then painted with iodine. If too extensive for this, pour ether over wound and use wet dressing of Carrel-Dakin solution. Phenol solutions, permanganate, boric acid and bromine water solutions are also recommended. Personally, I always use peroxide of hydrogen, whatever other solutions are subsequently used as this is one place the peroxide acts as a good antiseptic as well as a cleansing agent since it gives off quite a lot of oxygen and the tetanus bacillus, being highly anaerobic, cannot stand oxygen. Also remember never to close a wound too closely but rather to allow healing by granulation. It is better to have a scar than a death. Next, all these cases should receive a prophylactic dose of tetanus antitoxin, 1,500 units, as soon after injury as possible and, if pus develops in the wound, if the wound be punctured so deep, or if the injuring instrument pass through any of the sinuses as the antrum of Highmore, or a gun shot wound of face or head or any injury where it is uncertain all foreign matter has been successfully removed, a second prophylactic dose of 1,500 units should be administered on the eighth or tenth day. Also, all cases coming to the physician for the removal of a foreign body, as splinter or wire from the finger, or piece of nail or a bullet from the foot, should receive the prophylactic dose of antitoxin. Even though the incubation period of acute or sub-acute tetanus has elapsed, as stated before in this paper, the surgical procedure of removing a foreign body which has been imbedded any length of time may break down the protecting wall and allow tetanus spores that were dormant to become active. A case is on record in which tetanus developed seventy days after the initial lesion. If these procedures are carried out the physician will be rewarded by almost 100 per cent prevention of tetanus and in those cases developing, following initial

doses of prophylactic serum, cures are much more readily obtained.

#### DIAGNOSIS

An early diagnosis of tetanus is not always an easy matter, yet it is a very important one, as the sooner active treatment is started the more favorable the prognosis. It is well that the general practitioner familiarize himself with its symptoms, especially the earlier ones, as it is to him that most of these cases first come.

The diagnosis is made on the clinical history of a wound, the type tetanus may be suspected in, the proper incubation period, together with tonic spasms of the following muscle groups not necessarily near the wound: masseters, posterior cervical, abdominal wall, spinal muscles, and the flexors of the extremities. These convulsions occur spontaneously, or follow either optic, acoustic, or tactile stimuli. Opisthotonos may occur and also the so-called sardonic grin. There is an increase of reflexes; those in the wounded limb often show "double jerk," throwing the muscles of that limb into tonic spasm. There is a rise in temperature, usually slight, as compared with the pulse rate which is rapid, poor in tension and volume; however, hyperpyrexia may occur and is sometimes the cause of death. Sweating is profuse and cyanosis often marked. Lock-jaw usually occurs but is often not complete. Patient complains of severe thirst and exhaustion, and death sometimes occurs from exhaustion. The mentality usually remains clear to the end and patient suffers horrible mental and physical anguish.

It must be differentiated from strychnine poisoning and tetany. In strychnine poisoning, a history of the use of the drug is important. In strychnine poison the muscles of the jaw are rarely ever involved and never early. Between the spasms there is complete relaxation of the muscles, while in tetanus it is only partial. In tetany the spasms are bilateral and symmetrical and are chiefly confined to the muscles of the distal portions of the extremities. There is also the peculiar conical shaped involvement of the hands, and the feet are semiflexed at the ankle and the toes strongly flexed.

#### TREATMENT

For convenience, we will divide the treatment of active cases into general management; local treatment of wound; medical therapy or

symptomatic treatment; and specific or antitoxin therapy.

*General Management:* Patients with tetanus should be placed in as quiet a section of the home or hospital as possible. The room should be darkened and all external stimuli avoided. No company should be permitted and even the family excluded except those needed to care for the patient. Patient should be placed on soft and liquid diet that is nourishing. Fluids should be forced. If jaws become locked, highly nutrient enemata or feeding by tube through mouth or nose may be resorted to.

*Local Treatment of Wound:* The wound should be opened and freely drained, after a thorough cleansing and cauterization. In some cases there is no evidence of a wound, the puncture or abrasion having entirely healed even without scar.

*Medical Treatment:* The medical or symptomatic treatment of acute tetanus is mainly palliative, as it can hardly be considered curative unless we consider the phenol treatment of Bacilli, or the magnesium sulphate treatment of Meltzer curative. Most of the authorities consider these curative only secondarily by their sedative action on the central nervous system; however, phenol is thought by some to neutralize the toxin of the tetanus bacillus. In a recent talk on this subject with a veterinarian, I learned that they use the phenol treatment along with serum therapy with apparently excellent results, similar to those obtained in the Italian and French Armies.

If the magnesium sulphate treatment is employed, the physician must bear in mind that hypodermic or intraspinal injections of magnesium sulphate solution, while it usually entirely stops the spasms, are not without great danger, as they are very depressing to respiration. Chloral hydrate in from 5 to 10 gr. doses and potassium bromide in from 10 to 20 gr. doses every three or four hours will usually aid materially in controlling the paroxysms. If the combination of chloral and bromide does not control the attack sufficiently, or if there is much pain, morphine sulphate in  $\frac{1}{8}$  gr. doses every four hours is indicated or morphine  $\frac{1}{8}$  gr. and artopine  $\frac{1}{200}$  gr. may be used.

*Specific Treatment or Serum Therapy:* A study of the literature on this subject shows some difference of opinion as to routes recommended. Matthias Nicoll lays great stress on

the intraspinal route, and S. O. Freedlander recommends keeping the blood stream as highly saturated with antitoxin as possible, while Wm. H. Park states that although antitoxin injected into the spinal canal and nerve trunk will block some if the toxin get free, it will not affect that already fixed to the nerve tissue, and the major portion is probably absorbed from the canal into the circulation and then has its effect by bathing the tissues through the blood stream and lymphatics. Therefore, as yet no arbitrary rule can be laid down for the antitoxin treatment of developed tetanus, except to say that the best results have been obtained by getting the patient thoroughly saturated with antitoxin as soon as diagnosed or better still as soon as it is strongly suspected since delay may mean death. I consider all tetanus cases should be hospital cases but recommend that, unless the hospital is within an hour or two journey, the physician obviate the delay by immediately giving the suspected patient 10,000 to 20,000 units intravenously and 10,000 units intramuscularly. Unless this is done, a delay of a few hours awaiting the train and the subsequent trip may result adversely.

#### REPORT ON CASES

CASE 1. A negro, male, fourteen years of age.

*Complaint:* Convulsions.

*Present Illness:* Seventeen days after having received a gun shot wound at base of spine, from blank shell, patient complained of stiffness of jaws, back of neck, and felt generally badly. On evening of 18th day, after having had several convulsions, I was called in and found an unmistakable case of developed tetanus.

*Physical Examination:* Temperature 102, pulse 130, respiration rapid and some cyanosis. Profuse sweating and patient very excited, reacting to the slightest stimuli of any type. Risus sardonius and opisthotonos present. Marked rigidity of neck, back and abdominal muscles. Jaws partially locked. Patient able to swallow, but with some pain and difficulty.

*Treatment:* Morphine sulphate  $\frac{1}{8}$  gr., 1 dose. Bromide of potassium ten grains every four hours. Forced water and liquid nourishment. 6,000 units of tetanus antitoxin intravenously immediately. This amount was all that was available at time. It was necessary to wire for

larger amounts. Wound cleansed and dressed. Second day, 19th day after injury, routine treatment, 15,000 units antitoxin intravenously; 5,000 intramuscularly. Third day, patient more quiet, convulsions less severe and less frequent. No antitoxin. Pulse, temperature and respiration improved. Fourth day, routine treatment; 10,000 units antitoxin intravenously. Patient apparently about the same as third day. Fifth day, patient had a relapse and looked much like he did on first, except cyanosis and opisthotonos were more marked. Patient died early on sixth day apparently from exhaustion. Convulsions had ceased.

**CASE 2.** A white adult, male, about thirty-five.

*Complaint:* Felt very badly and had headache two days. Slight stiffness of neck and back muscles; one spell of jerking or trembling of muscles.

*Present Illness:* Eight days before coming to us, patient fell on a rock in branch in his barn lot, cutting through his overalls, pants, and underclothes, bruising skin over knee cap and cutting it slightly. Then cleaned out stable and bedded horses for night. Applied iodine to cut and bruises on retiring.

*Physical Examination:* Temperature 100, pulse 120, respiration increased. Patient very nervous and fidgety, not characteristic of him when well. Wound on knee cap healed with slight scar. Slight swelling present with stiffness of knee joint. Very slight rigidity of neck and back, and masseter muscles. Jaws not locked. Knee jerks exaggerated and, following testing of same, slight convulsion of muscles of body generally. Patient's second convulsion.

*Treatment:* 10,000 units tetanus antitoxin intravenously. In fifteen or twenty minutes patient had moderate anaphylactic reaction although a desensitizing dose of antitoxin had been administered one hour previously to the intravenous dose. Became moderately cyanosed, complained of inability to get breath, severe gastric pain, and profuse sweating. One c.c. 1/1000 solution of adrenalin, ¼ gr. morphine, and 1/150 gr. atropine were administered hypodermatically. Patient apparently normal in twenty minutes or half hour. About three hours after second convulsion, patient had a third of about the same intensity, and about three hours later, while en route to hospital, a fourth

of very much less severity. Wound was well opened and drainage established. Loose wet dressing applied; 10,000 units antitoxin were given intramuscularly. Patient went on to an uneventful recovery.

**CASE 3.** The third case developed in a young man seven days after he had had two of his fingers blown off by the bursting of an old automobile casing. He complained of slight stiffness in back of neck and of having had several spells which he described as making him feel that he was about to float away in air. During these spells there was some slight trembling which could not be definitely called a convulsion, and patient became very nervous and anxious about himself. Temperature 101, pulse 120, respiration increased. Some slight cyanosis, sweating during spell, and a very, very slight tendency to opisthotonos. Reflexes increased but taking of same did not precipitate an attack. As patient's family did not wish serum used at home, he was rushed to hospital and treatment instituted in next two or three hours. This patient, I learned after his recovery, had received one large dose of antitoxin intravenously. He had one convulsion after arriving at hospital and the physicians attribute his quick recovery to the earliness with which treatment was instituted.

The following is not a report on a developed case but is given for what it is worth, as I have had two cases similar to it. The fourteen year old daughter of the case reported above as case two, while playing bare-footed, fell in same barn lot as her father, bruising and cutting her leg, not sufficiently however to stop her from continuing her play in and out of the barn. The wounds suppurated. On morning of fifth day after her injuries her father brought her to us, complaining of severe headache and general aching. Temperature 100, pulse 120, respiration normal. The child was nervous but reflexes not exaggerated and there were no definite symptoms of developed tetanus. Wounds were thoroughly cleansed and dressed. Prophylactic dose of tetanus antitoxin administered. Child returned for examination and treatment, on evening of next day (about thirty hours). The wounds were healing nicely, temperature and pulse both normal, and child stated headache and general bad feeling had left her in about six hours after her visit to office previous days.\*

\*Case four not reported on.

## SUMMARY

1. Tetanus infection seems generally to be on the increase and especially in certain localities.

2. The prophylaxis of tetanus is its most important treatment. Preventive doses of tetanus antitoxin should therefore be administered in all cases where wounds have been received that are likely to be infected, and a second dose given eight or ten days later, if conditions warrant, in addition to the local treatment. In some instances even a third injection may be necessary.

3. Developed cases of tetanus, in addition to radical cleansing, removal of infected tissues, and symptomatic sedative treatment, should receive large doses of tetanus antitoxin intraspinally, intravenously, and intraneurally, or intramuscularly.

4. Tetanus cases are best handled in a hospital but the general practitioner should not delay administering an intravenous or intramuscular curative dose of antitoxin if many hours must elapse before transmitting patient to hospital.

## AFTER TREATMENT OF OBSTETRICAL CASES.\*

By H. R. FAIRFAX, M. D., Bristol, Va.

To prevent infection is of first importance. The eyes of the infant and open uterine veins of the mother are perhaps the most frequent points of entrance. Next come lacerations of soft parts of the mother. Immediately after the baby is born, see that any obstruction to respiration, as membranes over mouth and nose, or mucus in throat, are removed. Cleanse eyes with a solution of boric acid, then put a drop or two of nitrate of silver solution, one per cent, in each eye. This should be done in every case, whether you suspect gonorrhoea or not. You had better use it in a thousand unnecessary cases than to neglect to use it in a single necessary case. It is surprising how many doctors in some sections still neglect this very important precautionary measure. A large per cent of the people in asylums and in-

stitutions for the blind, might be now enjoying life in the open with two good eyes, but for the neglect of some careless midwife, nurse or doctor.

I tie the naval cord three times. Some may ask why. First and second, to protect the child, and third to protect the mother, and, if there should be twins or triplets, to protect them. I had a friend who had the misfortune to lose a baby patient by not tying the cord but once, and as it was not tied tight enough, it slipped. The second ligature would more than likely have saved the child's life. I usually clamp the cord first with an artery clamp at points to be tied. This cuts through Wharton's jelly, leaves a nice groove for the ligature, bruises vessels in the cord, thus lessening the chance for hemorrhage or for ligature to slip.

If there is a laceration more than a small slit in the mucous membrane, I prefer to make immediate repair of the perineum. We can not hope to get as good union as we would at a later day, on account of the congestion and bruised tissues, but to leave an open lacerated wound, in my opinion, greatly increases the danger of infection.

The nipples should be bathed in boric acid solution just before and after each nursing for the first few weeks at least. If inclined to crack, zinc oxide ointment applied after each nursing gives much relief, hastens the healing and thereby removes another focus for infection. If the breasts are over distended and the baby is unable to keep the milk nursed out, the breast pump, hot applications and massage of the breasts may be necessary to keep the mother comfortable. The milk is thick and glands, especially in the primipara, are hard for a few days. Massage with the thumbs from without in towards the nipple will help to soften the glands, give the mother relief, and frequently prevent abscess or pressure necrosis. In multipara, where the breasts are large and heavy, the figure of eight sling is recommended. For the first twenty-four hours liquid or very soft diet is best.

Now comes the question as to the length of time the patient should remain in bed. I was taught that the ninth or tenth day was the earliest a patient should be allowed to get out of bed. It is still a disputed question and after twenty years' experience I am convinced that this length of time is not always necessary and in many cases the patient will fare better if

\*Read at meeting of Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

allowed to be up earlier. My object in preparing a paper on this subject was, if possible, to get a discussion to bring out the ideas and compare the experience of others along this line. In the earlier years of my practice I had many obstetrical cases among women of foreign birth and in the mountain section of one of our neighboring states. Most of these women were strong and robust and frequently, while I was away, did as they pleased, which was to get up on the second or third day and, by the end of the tenth or fourteenth day they were doing their usual house work, with sometimes washing and ironing included.

About five or six years ago I read an article in one of the medical journals by Dr. W. S. Gardner, of Baltimore, in which he advocated letting obstetrical patients up early, if they were strong and robust. Let them be propped up in bed the second day, he said, and get out in a rocking chair for a short while on the third or fourth day. His claims were, a shorter period of confinement, better drainage and, as a result, fewer cases of infection, with more rapid recuperation. Since reading that article I have adopted that treatment, or rather advocated the early getting out of bed, but insist that the patient keep in the reclining position, and not stay up over one-half hour at first, then double the time each day and, after a day or two, divide the time, half in the morning and half in the evening.

I have had many women to tell me, that they felt better after getting up on the third or fourth day than they did in previous confinements on the ninth day.

I feel sure that many will disagree with Doctor Gardner and me in this and will say, subinvolution, relaxed abdominal walls, and other troubles follow such treatment. After five or six years' experience with this method and many subsequent examinations, I can truthfully say, so far as I can tell, my patients have had fewer infections and no more displacements of uteri and subinvolution than those in previous years, who were kept in bed for nine or ten days. If a patient has had a laceration, an unduly long labor, an instrumental delivery, or severe hemorrhage, I do not insist on her getting out quite so early, but wait a few days longer until she regains more strength, in other words, until she feels able to get out. She is instructed to have some one to assist her when she gets up, then, if she becomes faint, has a

hemorrhage or much pain in her back, she is to return to bed at once.

In a recent letter of inquiry to Doctor Gardner, he makes the following reply: "My ideas about the value of the upright position after labor have not changed. The only difference is that all the labor cases that are normal that I see are in the hospital and I always insist that they have a Gatch bed and they are put in a partial sitting position for a part of the time from the very first. The instruction to the nurse is, 'Do not allow this patient to lie continuously on her back.' Since these patients are never flat on their backs for twenty-four consecutive hours and, after the first few days, sit bolt upright in bed, I do not bother much about what day they actually get into a chair, but tell them that they may get up whenever they want to. The infected cases, whether at full term or miscarriages, are put at once in the upright position without reference as to how long it has been since delivery and without reference to the type of infection. The higher the fever, the straighter you set them up. In the infected cases I do not simply tell them to get up, but have them bring in the old rocking chair and put them in it while I am there."

I usually give ergot or one of its derivatives, ergotole, ergotin, etc., soon after the delivery of the placenta and find, if the clots are expelled and uterus well contracted, that there will be fewer after pains, also fewer cases of subinvolution. Have patient or assistant to hold uterus in contracted condition for half-hour or longer as necessary. Keep bowels open, one action a day at least, and castor oil perhaps is the best if a purgative is needed. If this is given in hot sweet milk, it is practically tasteless. I usually prescribe a tonic, as I. Q. & S., to be taken for ten days or two weeks and this I believe will shorten the period of recuperation.

From two to six weeks after confinement a final examination is advised and, if the cervix is found lacerated, or there are other injuries or displacements, they may then be remedied or corrected.

### POTT'S DISEASE, WITH SPECIAL REFERENCE TO ITS DIAGNOSIS.\*

By Wm. F. FOGERS, M. D., Bristol, Va.

Credit for the first description<sup>1</sup> of the condition which has since borne his name has been ascribed to Percival Pott, who in 1779, pub-

\*Read at the meeting of the Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

lished an account of this deformity in an article on palsy from spinal caries. Pott described the deformity and the sequelae of this condition although its tubercular nature was not mentioned. The discovery of the tubercle bacillus by Robert Koch, over one hundred years later (1882) shed new light upon the entire question of diseases of the bones and has helped solve many previously obscure problems of this nature.

Pott's disease is variously designated as tuberculosis of the spine, tuberculous spondylitis, vertebral tuberculosis, caries of the spine, angular curvature of the spine, kyphosis, hump-back, etc.

Tuberculosis of the spine is a very common form of spondylitis. It may develop in persons of all ages, including the later years of life, but is most frequently found in children up to the tenth year. The condition is fairly well divided as to sexes, being encountered, perhaps, slightly more often in the male. It usually follows in the wake of lowered vitality, malnutrition or unhygienic surroundings and frequently, in childhood, closely upon an attack of measles, scarlet fever or whooping-cough.

The disease is essentially due to infection of the vertebra with tubercle bacilli, but its influence on the system, as contrasted with tuberculosis of other bones and joints, seems to be exerted to a greater degree on the entire mechanism of the body. Among the additional predisposing causes, traumatism and heredity claim an indefinite amount of consideration. The particular injury to which the patient may trace the beginning of the trouble may have been but a means of precipitating the latent condition. The question of the likelihood of the predisposition to hereditary transmission, as also the question as to whether the condition is primary in the vertebral column or secondary to tuberculous disease elsewhere in the body is still debatable. Nor does the fact that the pulmonary tubercle is generally found at autopsy help to throw any light on the subject. According to Tubby's<sup>2</sup> observations, the sequence of events in children, in the majority of cases, is as follows: tuberculous dactylitis, glands, coxitis or other variety of arthritis persisting for some months or a year, followed by the onset of spinal caries—rarely is the reverse order of events observed.

It affects, primarily, the marrow of the vertebral body, the bony structures, such as the

pedicles, laminae and lateral masses escaping invasion at the start. More often the anterior portions of the body are affected than elsewhere. In most cases the whole body of the vertebra is attacked, spreading from one to the other beneath the anterior ligament. As this osteomyelitic process advances, the bone becomes affected, softened, and gradually is crushed by the superimposed weight. The collapse of the vertebrae causes an angulation at the point of disease, the upper portion of the vertebral column falling forward, so that, at the point of angulation, one or more of the vertebra become prominent behind, producing the well-known deformity of "hump-back," or kyphosis. The infection is usually confined to one or more adjacent vertebra, rarely to two separate portions of the spinal column.

Among the various conditions consequent to a tuberculous lesion here, as elsewhere in the body, is the softening and breaking down of the tuberculous tissue and the formation of a tuberculous abscess, generally known as cold abscess. This may rupture the anterior ligament, at any time, and may finally reach the surface. In high cervical disease it usually reaches the posterior wall of the pharynx as a retropharyngeal abscess; in the dorsal region the abscess usually lies in the mediastinum or penetrates between the ribs and appears behind the diaphragm. In the lower dorsal and lumbar regions, it follows the course of the psoas muscle and appears above or below Poupart's ligament. In still other cases it penetrates the loin above the crest of the ilium, the outer border of the erector spinal muscle forming a lumbar abscess. Although most abscesses follow one of these courses, all sort of deviations are possible—into the lungs, pleura, intestines, bladder, scrotum, etc., sometimes disappearing without ever reaching the surface. As a result of displacement of the bones, the spinal cord may be compressed, producing symptoms of a compression myelitis.

In order to properly diagnose tuberculosis of the spine, a full understanding of the symptoms is also essential.

In children there is languor, loss of flesh and strength, lack of endurance and disturbance of sleep. If carefully watched, it will be noted that, whether standing or sitting, the child supports himself by the arms, by means of a table or chair. Stiffness in walking is observed, rigidity of the spine being one of the most characteristic symptoms. In walking, the

child first places his feet with care, to avoid a sudden jarring, shifting most of the weight to the toes. Another characteristic feature is evidenced when, in picking up an object from the floor, the patient instead of bending his back, holds himself stiff and straight. Pain is noted early, and is a constant symptom of Pott's disease. It may be either local or referred, the latter being by far the more difficult of diagnosis in the early stages. It is usually referred to the distribution of the peripheral nerves from the cord at the level of the disease. In other words, if the diseased vertebra is in the cervical region, the pain will be referred to the back of the neck or below the occiput. In the dorsal region the pain is referred to the chest or, when lower down, to the abdomen. Epigastric pain, in the majority of cases, is often wrongly interpreted as stomach or intestinal disease when, in reality, it is the result of tuberculous disease on the dorsal spine. Two cases of this kind suggest themselves to the writer, one in which a woman was operated for gall-stones, and which later developed into a typical case of Pott's disease with resulting severe deformity, the other case being that of a young girl erroneously operated upon for appendicitis. Both these diagnoses hinged on the finding of a psoas abscess. These abscesses are secondary to disease of the vertebra. It should be noted that signs and symptoms of acute inflammation, such as pain, heat, redness and tenderness, are missing in these abscesses. Fever is either slight or absent, unless there is a mixed infection; likewise is leukocytosis either slight or absent, unless the skin is perforated and there is a mixed infection. When the abscess approaches the skin and becomes palpable, the usual signs attendant upon similar conditions, such as fluctuation particularly, are present. If perforation of the abscess is imminent, the overlying skin becomes thin, shiny, slightly reddened and, finally, purple. The abscess consists of a creamy, so-called tuberculous pus, mixed with cheesy matter.

A psoas abscess gives the signs of a tense elastic tumor in the lower lateral quadrant of the abdomen. It is found below Poupart's ligament, the communication between the abdominal tumor and the swelling of the thigh may often be made out by palpation. Pressure upon the abdominal swelling increases the tension in the thigh, and vice versa, thus differentiating the condition from

*hernia*. In some cases a psoas abscess will present posteriorly upon the buttock. Those abscesses which follow the course of the psoas muscle are attended, first, by limitation of motion in the hip joint and, later, by a gradually increasing flexion of the thigh on the affected side, which cannot be overcome. It is usually not difficult to differentiate these abscesses from *tuberculosis of the hip joint* by the presence of an intra-abdominal tumor, in the former, and by kyphosis of the spine in the dorsal or lumbar region, respectively.

One of the main diagnostic features of the fairly well advanced stage of vertebral tuberculosis is the deformity caused by the collapse of the bodies of the affected vertebra. The result is a prominence of the vertebra in the back at the level of the disease, and angulation of the vertebral column. The kyphosis is most marked in the dorsal region where the spine is normally convex backward. Paralysis usually follows spinal deformity, but when these symptoms are reversed, confusion results.

A history of the case is essential. Often there will be elicited the history of a fall, a bruise or the like, which was perhaps unheeded at the time. In order to study the spine and to insure thorough observation, the patient should be stripped at the time of examination. It is often possible to make a probable diagnosis of Pott's disease by watching the motions, attitudes and general behavior of the patient. In the case of a child, it may at once be observed that so long as he is lying down or is held in the arms in such a position that the weight of the body does not compress the diseased vertebra, he will remain quiet and appear fairly comfortable. When placed in the upright position, however, he will immediately begin to cry. If the disease is advanced sufficiently, the deformity of the vertebra may be recognized at a glance, if situated in the dorsal region. The deformity will be less marked in the cervical and lumbar regions. One of the simplest means of detecting the presence of rigidity of the spine, as well as its locality, is to place the patient prone on a table and, by lifting the legs and thighs off the table, to observe the behavior of the different portions of the spine. As the patient is lifted from the table, the affected portion of the spine will remain absolutely rigid. If the disease is in the lumbar region, the muscles of the back will be thrown into spasmodic contraction. If in the cervical region, the rigid

position of the neck will be striking, even upon casual observation. In any case, if the patient is seated in an upright position, downward pressure upon the top of the head will call forth expressions of increased discomfort and pain. In the presence of tuberculosis in other regions of the body the cervical spine should always be palpated, and the pharynx and lateral regions of the neck examined for the presence of abscesses. Examination of the back should always be thorough. This may insure the finding of primary or secondary conditions. Difficulty in diagnosing the condition of the back may be due to lack of knowledge of the part, lack of thorough routine examinations, or failure to understand the mechanism involved. Many cases of pain in the back are encountered in connection with industrial work. In addition to the history of trauma, and a possible correlation of the occupation to the pain, a search for infection must not be omitted. Special attention must also be directed to posture and balance.

The following important points must also be included in order to ascertain all possible diagnostic signs: general condition, facial appearance, testing of reflexes, examination of the heart and vessels, thorax and pelvis, and above all, a full inspection of the spine accompanied by X-ray photographs.

The X-ray as a means of diagnosis is, unfortunately, of little worth in the early stages of the disease; later it is of value. The diagnosis of the first stages will have to be made on the symptoms and physical signs. Tuberculin tests have proven of the same assistance here as in tuberculosis of joints in other parts of the body.

The conditions which Pott's disease simulates are varied and numerous. They include, among others, *spinal fractures, torticollis, back strain, scurvy, rachitis, hip disease, spastic paralysis, pelvic abscess, sarcoma, carcinoma, sciatica, arthritis, spondylitis deformans, sacroiliac disease and syphilis.*

*Typhoid spine* may be mistaken for Pott's disease, but may be differentiated by its more acute onset, and by the fact that it occurs late in the course of typhoid. In typhoid spine the kyphosis seen in Pott's disease is rarely found. Where a bony ankylosis of two vertebrae occurs, typhoid spine may be suspected.

A positive Wassermann test and various other signs, combined with a history of syphilis, will differentiate *syphilitic arthritis* from tu-

berculosis of the spine. In children, the former condition is rarely found. There is usually less deformity, and the distinct kyphosis is lacking. When doubt exists, antisyphilitic treatment will settle the diagnosis.

*Fractures or severe strains* are among the conditions difficult to diagnose from Pott's disease, and in some cases, particularly in the cervical region, the differentiation is impossible unless confirmed by the X-ray. Treatment by fixation will cure the symptoms, even if of long-standing, only if disease is absent.

In view of the frequency of spinal caries, its importance to the general health of the patient, particularly in its connection with the spine—the central axis of the body—the subject is one which demands our earnest study and consideration. The question of diagnosis alone is an inexhaustible one, regarding which one is hardly able to do more than suggest its possibilities in a short article. Many textbooks deal at great length with this most interesting and tremendously important condition. In one of the most recent, Ely<sup>3</sup> regards the condition as a much more favorable one than have most of our previous writers on the subject and, in closing, the writer takes great pleasure in quoting from this publication, sounding, as it does, a more cheerful note than the prognosis usually called forth in connection with this condition:

"Until recently, the prognosis of tuberculosis of the spine was bad, but modern methods of treatment have changed the outlook. Prognosis in simple Pott's disease now is good. Abscess formation makes the prognosis unfavorable. Disease of the cervical region, on account of the proximity of vital structures, has an added danger. Under operative treatment, Pott's disease can be brought to a standstill within six months. Without operation, three years may be said to be the minimum duration of treatment. Perhaps by strict attention to details and by vigorous measures, the hump may sometimes be made a trifle smaller. Under modern methods of treatment the enormous humps, so frequently seen in former days, are growing rarer."

## Roanoke—The Convention City.

Bird's eye view of Roanoke, taken from aeroplane.

"They call me the Magic City, I who am young and strong—  
They call me the Magic City, but the name that they give is wrong.

I was not built by magic, though the wand of a fairy I claim  
For the valley that's known as Roanoke, and the river that ripples my name.

I was not built by magic, but by sons of an ancient race,  
Bold and dauntless of spirit, seeking a building place.

With the will and the strength of giants, fearless of struggle and strife,  
They came from the vales of pioneer trails, steeled in the efforts of life.

Here by the crystal waters that flow from the mountain breast,  
In the calm of the scented meadows, harboring peace and rest,  
They set to the task of building in the alchemic mist of dawn,  
And hammers rang as the builders sang of the work of their brain and their brawn."

To those who attend the annual meetings of the Medical Society of Virginia, with some degree of regularity, Roanoke probably needs no introduction. Those who have not attended a Roanoke meeting for some years may be interested in knowing what sort of a city it is at this time.

A young town, its age has not yet reached the fourth decade. Men not yet by any means aged have ploughed corn and hunted wild game where now stand imposing eight-story buildings and busy marts of trade, and surrounding these the homes of close to sixty thousand people. Protected by the encircling mountains, she enjoys a climate that knows naught of the extremes of heat and cold which other less favored regions may experience.

Hotel Roanoke, headquarters for meeting.

Surrounded by a rich agricultural country, Roanoke has an abundance, not only for her own support, but also to supply localities that consume more than they can produce. Broad, smiling, acres of grain, and of garden crops, and of alfalfa, lie just beyond her

outskirts. Factories and mills, whose bustle and whirl never stop by day or by night, are part and parcel of her life, and whose pay-rolls furnish the sinews of war measured in hundreds of thousands. Two railroads, with wide-stretching arms extending east, west, north, and south, supply adequate and ever-busy facilities for communication with the world at large.

Space forbids mention of all the civic, and cultural, and patriotic organizations, —the Rotary, the Kiwanis, the Lions, the Men's and the Women's University Clubs, the Thursday Music Club, and Parent-Teachers' Association,—to name only a few; while of course there is a wide-awake Chamber of Commerce, and a Wholesale Merchants', and a Retail Merchants' Association in the business circles of the place.

Pre-eminently a city of churches, and of notably good church attendance, she has organizations of all the leading Christian faiths, and handsome edifices are dotted thickly within her boundaries. Largely a town of young people, Roanoke has had to exert every energy to keep pace with her amazingly fast-increasing school population, and it has been well-nigh impossible to build schools fast enough to

house the youth demanding educational facilities.

In addition to its splendid public schools, Roanoke and vicinity lay claim to three of the best known colleges in this State—Virginia

Municipal building.

College, beautifully situated within the city limits, Hollins College, a short ride from the city, both for girls, and Roanoke College for boys at Salem—all recognized as among the best in Virginia. Fond memories are aroused in many by the mere mention of the names of these colleges and their fame extends far beyond the boundaries of our State.

Of hotels there are some half a dozen, attractive in appearance and modern in every way, with cheerful, comfortable rooms, and a cuisine that will satisfy even the most fastidious; while of cafes and restaurants, they are beyond numbering. Hotel Roanoke, where the meetings will be held, is perhaps the most imposing in appearance, located on a slight elevation, with wide-sweep of shaded lawn, whose maples touched by the breath of October, reflect all the tints of the glorious autumn sunsets. For those preferring the intimate close touch of the town the Ponce de Leon, or the Lennox, or the several other hostleries, stand always open.

In the hospital line five commodious and excellently equipped establishments for whites, and a large and well-appointed one for colored people, supply every need in the way of medical and surgical treatment. Near at hand is also the State Sanatorium at Catawba, and even nearer that of Mount

Virginia College.

Regis. both treating tuberculous cases.

Within the corporate limits of the city, eight minutes' ride on a trolley is Mill Mountain, a steep rampart one thousand feet above the town, ascended by cable cars, the view from

whose summit is unsurpassed. A small hotel on top, noted for its chicken and waffle suppers, is a well patronized rendezvous in the social life of the community.

The Roanoke Academy of Medicine is well

Crystal Spring, Roanoke's chief water supply.

Elks' Home.

Public Library in Elmwood Park.

known throughout the State as one of the live and active medical organizations; and it is at this time working with the utmost earnestness to make the 1923 meeting a thorough success. It is the hope of every fellow of this local society, that ALL members of the State Society, and every doctor in the State who can lay aside

his work for even a day or two, will attend some if not all the sessions at this meeting.

DON'T FAIL TO SEE THE MAGIC CITY. The ladies will find much of interest in Roanoke, while the members are engaged in matters scientific.

Park Street High School.

## Proceedings of Societies

### The Southwestern Virginia Medical Society

Held its regular meeting at Abingdon, September 19 and 20, with an attendance of about sixty. The following officers were elected for the ensuing year: President, Dr. S. S. Gale, Roanoke; vice-president, Dr. D. L. Kinsolving, Abingdon; and secretary-treasurer, Dr. E. G. Gill (re-elected), Roanoke. The next meeting will be held at Radford, March 20 and 21, 1924. Two new members were received at this time: Drs. A. B. Graybeal, of Grant, and Hall, of Radford.

Drs. J. C. Motley, J. J. Giesen and Arthur Hooks were elected delegates to the Roanoke meeting of the Medical Society of Virginia, and Drs. T. K. McKee, W. W. Chaffin and H. R. Fairfax, alternates.

### Botetourt County Medical Society.

Present officers of the Botetourt County Medical Society are Dr. E. W. Dodd, Buchanan, president, and Dr. P. K. Graybill, Fincastle, secretary. Dr. E. P. McCulloch, Troutville, was elected delegate and Dr. A. W. Hammond, Amsterdam, alternate to the Roanoke meeting of the Medical Society of Virginia.

### Alleghany County Medical Society.

Present officers of the Alleghany County (Va.) Medical Society are: Dr. J. A. Riffe,

Covington, president; Dr. J. M. Emmett, Clifton Forge, vice-president; Dr. H. M. Anderson, Clifton Forge, secretary; and Dr. W. M. Revercomb, Clifton Forge, treasurer.

### The Danville (Va.) Academy of Medicine,

At its regular meeting on September 11, elected the following officers for the ensuing year: President, Dr. C. B. Pritchett; vice-president, Dr. H. J. Langston; secretary-treasurer, Dr. Samuel Newman. Dr. R. Bruce James was elected delegate to the State Society meeting in Roanoke.

## Book Announcements

**Surgery of the Spine and Extremities.** A Text Book for Student and Practitioners. By R. TUNSTALL TAYLOR, M. D., F. A. C. S., Professor of Orthopedic Surgery, University of Maryland and College of Physicians and Surgeons, etc. Philadelphia, P. Blakiston's Son and Company, 1012 Walnut Street. 8vo. 550 pages, with 604 illustrations. Cloth. Price \$7.50.

**A Textbook of Chemistry for Nurses.** By FREDUS N. PETERS, A. M., Ph.D., Author of several books; Professor Organic Chemistry, Hahnemann Medical College, Director of Laboratories and Professor of Chemistry and Metallurgy, Kansas City Dental College; Instructor in Chemistry in Kansas City Central High School for 23 years; etc. Illustrated. Second Edition. St. Louis, C. V. Mosby Company, 1923. 12 mo. 302 pages. Cloth. Price \$2.50.

## Editorial

### Discovery of Anesthesia.

Medical men everywhere feel a keen interest in the fascinating story of the discovery of anesthesia. But particularly in the South this important historical medical event is of especial interest for reasons to be discerned in the perusal of the gripping recital by Dr. J. Marion Sims, reproduced in the editorial space of this journal, under circumstances given in the subjoined letter.

Richmond, Va.,

June 22, 1923.

TO THE EDITOR:

Dr. P. A. Wilhite of Anderson, S. C. has recently been a patient at St. Luke's Hospital, and while here showed me a copy of the VIRGINIA MEDICAL MONTHLY issued in May, 1877, containing the original article on "The Discovery of Anesthesia" by J. Marion Sims.

I was so much interested in the paper that I got my stenographer to make me a type-written copy. Knowing your interest in medical history, I send a copy of the article to you, believing that possibly some day you may reproduce it either in whole or in part in the VIRGINIA MEDICAL MONTHLY.

STUART MCGUIRE.

### THE DISCOVERY OF ANESTHESIA.

By J. MARION SIMS, M. D., New York.

Long before the days of Horace Wells and of Morton and Jackson, we were on the eve of the discovery of anesthesia. In 1790, Priestly discovered nitrous oxide gas. In 1799, Sir Humphrey Davy experimented with it, and in 1800, he published his Researches, Chemical and Philosophical, chiefly concerning Nitrous Oxide Gas and its Respiration, in which he says, "As nitrous oxide in its extensive operations, appears capable of destroying physical pain, it may probably be used with advantage during surgical operations, in which no great effusion of blood takes place." Sir Humphrey Davy had inhaled the gas repeatedly for headache and other painful affections and, finding relief for the time, he suggested its use as an anesthetic in surgery, and if he had been a surgeon, there is no doubt he would have used it as such. But his great idea was lost to the world for more than forty years.

There are four claimants for the honor of the discovery of anesthesia, viz.: Crawford W. Long, of Athens, Ga.; Horace Wells, of Hartford, Conn.; W. T. G. Morton and Charles T. Jackson, of Boston. I propose to give a plain statement of facts bearing on the question, leaving the reader to draw his own conclusions.

The claims of Long have never been fairly stated in connection with those who came after him. I am ashamed to say I was wholly ignorant of them until a very recent day, and I believe that the great mass of the profession are in the same category with me. I became acquainted with the facts of Long's labors by mere accident.

In October, 1876, Dr. P. A. Wilhite, of Anderson, S. C., came to New York to consult me about the health of his daughter. Her case required a surgical operation, and it was necessary for her to take ether, which was given by Dr. Harry Sims. After the operation was over and we were waiting to see our patient fully restored from the effects of the anesthetic, the conversation naturally turned upon the wonders of anesthesia, when Dr. Wilhite said, "Doctor, I assisted at the first operation ever performed under the influence of ether." I said, "But how could this be when you have never been in Boston, and the first operation under ether was by Warren, of Boston, in October, 1846, or as some claim by Marcy of Hartford, in January, 1845." Dr. Wilhite then told me that he had assisted Dr. Crawford W. Long, of Georgia, in extirpating a tumor from the neck of Mr. Venable in March, 1842, while he was completely anesthetized by the inhalation of sulphuric ether—that Mr. Venable was as profoundly anesthetized as the patient then lying before us—and he also said that he had assisted Dr. Long to operate on other patients under the influence of ether in 1843 and '44, while he was a student of medicine in Dr. Long's office. He declared that Long was the real and original discoverer of anesthesia, and he believed that he would be so acknowledged if all the facts in the case were fully set forth. He further said that he presumed that he (Dr. Wilhite) was the first person who had ever profoundly etherized any one—and it was under these circumstances. Dr. Wilhite says that from the time he was ten years old (1832) he was familiar with the use of ether by inhalation as an excitant; that the boys and girls in his neighborhood near Athens, Ga., were in the constant habit of using it; that there was hardly ever a gathering of young people that did not wind

up with an ether frolic. Old fashioned "quiltings" were very common in his day and time, and in the evening the boys and the young men would go to these for the purpose of a dance or an ether frolic. On one occasion he met several young people at Mr. Ware's, about five miles west of Athens, at a quilting. The girls and boys all finished the evening by inhaling ether. Some would laugh, some cry, some fight and some dance, just as when nitrous oxide gas is inhaled. It was in the fall of 1839. Wilhite was a romping boy of seventeen. All the boys and all the girls had inhaled ether, some of them more than once. They were looking around for new subjects for it, when Wilhite saw a negro boy at the door who seemed to be enjoying the sport. Wilhite invited him to come in and try the ether. He refused. Other young men then insisted on his taking it. He refused again in a most positive manner; whereupon some of the thoughtless young men caught hold of the boy and called Wilhite to give him ether. He struggled violently but they threw him down and held him there while Wilhite poured out some ether on a handkerchief and pressed it firmly over his mouth and nose. He fought furiously. They persisted, thinking it was great fun. After a long struggle the boy became quiet and unresisting. The young men then let him alone. They were greatly surprised that he did not get up immediately and say or do some foolish thing for them to laugh at. He lay quietly and with stertorous breathing. They tried to arouse him but could not. They then became greatly alarmed, and sent one of their number on horseback for Dr. Sydney Reese, of Athens, five miles away. The messenger rode with all possible speed. He fortunately found Dr. Reese at home, who lost no time in going to Mr. Ware's. On his arrival he found the negro lying on his back still soundly asleep. The young ladies had left the frightful scene. Young Wilhite and his principal accomplice, thinking that they had in mere play murdered their fellow being, were so much alarmed that they contemplated making their escape from the country, but the timely arrival of Dr. Reese soon restored their courage. Dr. Reese heard the history of the transaction. He then threw water in the face of the sleeping negro, slapped him, raised him up, shook him violently, and after a little he was raised to consciousness, greatly to the relief of all present. The doctor then gave the youngsters a lecture on the dangers of such frolics, and cautioned them against a repetition of their heedless act. This, of course, broke up the ether frolics in this neighborhood. Dr. Wilhite thinks it was more than an hour from the time the messenger started for Dr. Reese, till he returned with him to Mr. Ware's. The distance to Athens and back was ten miles, and all

this time the negro boy was profoundly narcotized. This is unquestionably the first case in which sulphuric ether was ever given to the extent of producing complete anesthesia.

Dr. Crawford W. Long, now of Athens, Ga., was born in Danielsville, Madison County, Georgia, on the 1st of November, 1815. He graduated at the University of Georgia (then the Franklin College), in 1835. He studied medicine and graduated at the Medical Department of the University of Pennsylvania, in 1839. He then went to Jefferson, Jackson County, Georgia, where he practised medicine for many years. In 1842 he had four students in his office, viz.: P. A. Wilhite, John S. Groves, D. I. Long and H. R. P. Long. The two last were relatives of Dr. Long, and they are both dead. Wilhite and Groves are still living (1877). Dr. Long was twenty-seven years old. His pupils were all from

nineteen to twenty-one; they were on the best of terms with each other, the Doctor entering into all the sports of his pupils with a hearty good will, while he never neglected his duties as their teacher.

On one occasion, they were talking about the inhalation of nitrous oxide gas, when one of his pupils asked him to make some for them. He said he did not have suitable apparatus for it, but that the inhalation of sulphuric ether would produce precisely the same exhilarating effect. One of the young men present said he had inhaled ether while at school, and was willing to do it again. They were all anxious to witness its effects. Dr. Long got some ether immediately and gave it to the young man who had previously inhaled it. He then inhaled it himself, and afterwards gave it to all present. After this, the young doctor and his pupils indulged occasionally in ether frolics.

On several occasions, Dr. Long became furiously excited and could not be controlled. On recovering from the ether intoxication, he frequently noticed that his arms and hands were badly bruised, and yet he was not conscious of having felt any pain at the time he was under the influence of the ether. He also noticed the same thing in his pupils.

They were often badly hurt by falls and blows and were not conscious of pain at the time. These facts, repeatedly observed suggested to his mind the idea of using ether to prevent the pain of surgical operations. He frequently spoke of this to his students, and at last he determined to give it a trial. Wilhite encouraged him by relating the case of the negro boy he had playfully and unintentionally put under the influence of ether for an hour or more in the Fall of 1839.

Dr. Long, having made up his mind to try the experiment with ether on the first favorable opportunity, says (*Southern Medical and Surgical Journal*, Dec. 1849):

"The first patient to whom I administered ether

J. MARION SIMS, M. D., LL. D.  
Taken from portrait in the Valentine Meat Juice Company's offices, Richmond, Va. (Courtesy of Col. Mann S. Valentine, Jr.)

in a surgical operation, was Mr. James M. Venable, who then resided within two miles of Jefferson. Mr. Venable consulted me on several occasions with regard to the propriety of removing two small tumors situated on the back part of his neck, but would postpone from time to time having operations performed, from dread of pain. At length I mentioned to him the fact of my receiving bruises while under the influence of the vapor of ether, without suffering, and, as I knew him to be fond of, and accustomed to inhale ether, I suggested to him the probability that the operations might be performed without pain, and proposed operating on him while under its influence. He consented to have one tumor removed, and the operation was performed the same day. The ether was given to Mr. Venable on a towel; and when fully under its influence I extirpated the tumor. It was encysted, and about half an inch in diameter. The patient continued to inhale ether during the time of the operation, and when informed it was over, seemed incredulous, till the tumor was shown him. He gave no evidence of suffering during the operation, and assured me, after it was over, that he did not experience the slightest degree of pain from its performance." This operation was performed on the 30th of March, 1842.

"The second operation I performed upon a patient etherized was on the 6th of June, 1842, and was on the same person (Mr. Venable), for the removal of another small tumor. This operation required more time than the first, from the cyst of the tumor having formed adhesions to the surrounding parts. The patient was insensible to pain during the operation, until the last attachment of the cyst was separated, when he exhibited signs of slight suffering, but asserted after the operation was over that the sensation of pain was so slight as scarcely to be perceived. In this operation the inhalation of ether ceased before the first incision was made."

In a certificate sworn to by James M. Venable, on the 23rd of July, 1849, he says: "In the early part of the year (1842), the young men of Jefferson and the country adjoining were in the habit of inhaling ether for its exhilarating powers, and I inhaled it myself frequently for that purpose, and was very fond of its use. While attending the Academy, I was frequently in the office of Dr. C. W. Long, and having two tumors on the side and rather back of my neck, I several times spoke to him about the propriety of cutting them out, but postponed the operation from time to time. On one occasion, we had some conversation about the probability that the tumors might be cut out while I was under the influence of sulphuric ether, without my experiencing pain, and he proposed operating on me while under its influence. I agreed to have one tumor cut out and had the operation performed that evening (afternoon), after school was dismissed. This was in the early part of the Spring of 1842. I commenced inhaling the ether before the operation was commenced, and continued it until the operation was over. I did not feel the slightest pain from the operation, and could not believe the tumor was removed until it was shown to me. A month or two after this time, Dr. C. W. Long cut out the other tumor situated on the same side of the neck. In this operation, I did not feel the least pain until the last cut was made, when I felt a little pain. In this operation, I stopped inhaling the ether before the operation was finished. I inhaled the ether in both instances from a towel, which was the common method of taking it." Dr. Long's four students, Wilhite, Groves and the two Longs, also E. S. Rawls (now Dr. Rawls), and Andrew J. Thurmond, were

present and assisted at the operation. Dr. Wilhite tells me that the etherization of Venable was as complete as it is ever made now-a-days, and that Venable always declared that he felt no pain during the operation.

On the 3rd of July, 1842, Dr. Long amputated the toe of a negro boy, Jack, belonging to Mrs. Hemphill. Jack felt no pain, having been completely anesthetized.

On the 8th of September, 1842, Dr. Long excised, without pain, three small cystic tumors from the head of Mrs. Mary Vincent, who was etherized for the purpose.

On the 8th of January, 1845, Dr. Long amputated two fingers for a negro boy belonging to Mr. Ralph Bailey, Sr., the patient being fully etherized and feeling no pain whatever.

\* \* \* \* \*

Now let us see how the followers of Long worked out the problem of anesthesia without any knowledge whatever of his labors.

Horace Wells, a native of Hartford, Windsor County, Vermont, studied dentistry in Boston, and at the age of 21 (1836), he opened an office in Hartford, Connecticut, to practice his profession. His mind was early turned to the subject of preventing pain in the extraction of teeth. In August, 1840, Dr. L. P. Brockett, of Brooklyn, N. Y., then a medical student, went to Wells to have a molar tooth extracted, the operation was difficult and so painful that Wells said that there ought to be some method of mitigating such suffering, and that he thought a man might be made so drunk by the inhalation of nitrous oxide gas as to prevent the pain of dental and other operations. This shows how deeply impressed this subject was upon the mind of Wells at that early date. On December 10, 1844, Mr. G. Q. Colton delivered a lecture in Hartford, Connecticut, on "Laughing Gas," and after the lecture he administered the gas to Wells and several other gentlemen. One of them (Mr. Cooley), while under its influence, fell over some benches, and was evidently badly injured; when he returned to consciousness, Wells rushed up to him and inquired if he was hurt.

He replied "No." Wells then said, "You must have been hurt, for you struck your legs against the benches." The young man then, at Wells' suggestion, pulled up his pantaloons; the blood was running down his legs and his knees were badly injured. When again questioned by Wells, he said, "I did not feel any pain at the time." Wells then turned to a friend (Mr. David Clarke), who was near by, and an eye witness to all of this, and remarked, "I believe a man by taking that gas could have a tooth extracted or a limb amputated and not feel the pain." So thoroughly was Wells convinced of this fact that he told his wife on their way home that he intended to take the gas the next day and have a tooth extracted. On arriving home he left his wife, and went to see his friend, Dr. Riggs, to announce his great discovery, and his intention to take the gas for the extraction of a tooth. Riggs tried to dissuade him from it, but his mind was made up, and he said, "As the young man did not feel pain at the time he was hurt, why cannot gas be used in the extraction of teeth?" Early next morning (December 11th), Wells called on Colton and engaged him to go to his office at ten o'clock and give him the gas. Wells did not seem to feel any pain. He remained unconscious for a few moments, and on coming to, he exclaimed, "A new era in tooth pulling. It did not hurt me more than the prick of a pin. It is the greatest discovery ever made."

From that moment Wells' enthusiasm was un-

bounded. He immediately began the administration of gas, and daily extracted teeth under its influence, and other dentists in Hartford adopted the same practice with like success. Dr. Marcy, then of Hartford, on witnessing Wells' operations, told him that when a student at Amherst College, he, with other students, had, for amusement, often inhaled nitrous oxide gas and also the vapor of sulphuric ether, and that the effects of the two were identical; and he suggested to Wells to try ether as a substitute for the gas. On this hint Wells tried it. He inhaled it himself and he says, "I found it very difficult to inhale the vapor of ether in consequence of the choking sensation. For this reason and the reason that Dr. Marcy and myself came to the conclusion that nitrous oxide gas was not so liable to do injury, I resolved to adhere to this alone."

About a month after the discovery of anesthesia by Wells, Dr. Marcy (January, 1845), gave the vapor of sulphuric ether to a sailor for the extirpation of a small wen on the side of his head. The patient was insensible and the operation successful, but Marcy, after this experiment, still advised Wells to stick to the gas as being more agreeable, and, perhaps safer than ether. Wells continued the use of the gas, and the dentists, (Riggs, Terry, Braddock and Crowfoot), and the doctors in Hartford were all convinced of its value as an anesthetic. But Wells felt that his great discovery should be laid more broadly before the profession of the world, and early in 1845 went to Boston for this purpose. Through his former pupil and partner, Dr. Morton, dentist, he was introduced to Dr. John C. Warren, Dr. Charles T. Jackson, Dr. Hayward and others. Dr. Warren received him kindly, and Wells remained in Boston several days with the expectation of giving the gas to a man who was to submit to an amputation at the hands of Dr. Warren. For some cause the operation was postponed. Wells was then invited to address the class at the medical college on the subject. He did so at some length, and then administered the gas for the extraction of a tooth. Unfortunately, the gas-bag was removed too soon; the patient was not sufficiently anesthetized; he screamed out and said he felt the pain of extraction, and the experiment was therefore a failure. Wells was hooted at and unfeelingly hissed out of the amphitheatre by the thoughtless young men present, and he was pronounced a charlatan and his anesthetic a humbug. He returned home greatly mortified at his failure, was taken suddenly ill and did not recover his health for many weeks.

In 1841-42, Morton was a pupil of Wells. In 1843, Wells established Morton in Boston, and for a while he was his partner. In 1845-46, after Wells' discovery of anesthesia, by the use of nitrous oxide gas, they had frequent interviews, sometimes in Boston and sometimes in Hartford. After Wells' unfortunate visit to Boston, Morton became greatly interested in the subject of anesthesia. Notwithstanding Wells' failure in Boston, Morton subsequently witnessed his continued success with the gas in Hartford, and was anxious to try it again in Boston. During one of his visits to Wells in Hartford, in 1846, Morton asked Wells to show him how to make the gas. Wells not having time, referred him to Dr. Charles T. Jackson to make it for him, as he was a chemist. On returning home, Morton called on Jackson for this purpose. Jackson told Morton that the manufacture of nitrous oxide gas required some nicety of manipulation, that there was danger of his getting nitric instead of nitrous oxide, and that he was too busy at that time to make it for him. Morton explained that he wished to use it to render patients

insensible for the extraction of teeth. Jackson then told him to use the vapor of sulphuric ether, saying that it was perfectly safe, could be easily procured, and that the students at Cambridge often inhaled it for amusement.

On the evening of the day (September 30, 1846), that Morton had this interview with Jackson, he gave the ether to a patient, and extracted a tooth without pain; and on October 16th he gave it in the Massachusetts General Hospital to a patient who had a tumor excised from the neck by Dr. John C. Warren. On the next day (October 17), he gave it to another patient for Dr. Hayward, who excised a tumor from the arm. He gave it also for Dr. Bigelow with equal success; and from that time it came rapidly into use by the whole profession throughout the civilized world. On October 27, 1846, Jackson and Morton published to the world, by letters patent, the discovery of letheon as an anesthetic, but it was seen at once that their letheon was nothing more or less than pure sulphuric ether. Jackson soon resigned his interest in the patent to Morton, and sent a communication to the French Institute, claiming the honor for himself for the discovery of anesthesia by ether. Morton then set up his claim as the real discoverer, giving Jackson credit only for some unimportant suggestions. While Jackson and Morton were sending bulletins to the Institute of France, Wells sailed for Europe in December, 1846, to lay his claims before the French Institute as the real discoverer of anesthesia. His mission was a failure and he returned home in March, 1847, to prepare the documents upon which his claim was to be presented to the Institute. And thus the tripartite war was waged with great fury, Morton and Jackson denying everything to Wells, and denying everything to each other.

They denied that nitrous oxide gas had any anesthetic properties. Wells brought forward his Hartford experience, and he gave the gas for surgeons in general practice, proving that prolonged operations could be performed under its influence. Dr. Marcy excised a large gland, the patient being under the gas for fifteen minutes; Dr. Ellsworth amputated a thigh; and Dr. Beresford excised a large tumor under its influence—all in Hartford. But notwithstanding all this, Wells saw nitrous oxide gas supplanted by sulphuric ether as an anesthetic—ether which he had tried and rejected. He saw his claims as the great discoverer of anesthesia unrecognized abroad, disputed and set aside at home, and he was disappointed and dispirited. He then went to New York to lay his claims as the discoverer of anesthesia before the profession of the great metropolis. Soon after his arrival in New York, he showed signs of mental aberration, and on January 14, 1848, in a fit of madness, he ended his life with his own hands.

\* \* \* \* \*

Now let us summarize the facts set forth in the foregoing historic sketch. We know:

1st. That since 1800, the inhalation of nitrous oxide gas produced a peculiar intoxication, and even allayed headache and other minor pains.

2nd. That Sir Humphrey Davy proposed it as an anesthetic in surgical operations.

3rd. That for more than fifty years the inhalation of sulphuric ether has been practiced by the students in our New England colleges as an excitant, and that its exhilarating properties are similar to those of nitrous oxide gas.

4th. That the inhalation of sulphuric ether, as an excitant, was common in some parts of Georgia forty-five years ago, though not practiced in the Colleges.

5th. That Wilhite was the first man to produce

profound anesthesia, which was done accidentally with sulphuric ether in 1839.

6th. That Long was the first man to intentionally produce anesthesia for surgical operations, and that this was done with sulphuric ether in 1842.

7th. That Long did not by accident hit upon it, but that he reasoned it out in a philosophic and logical manner.

8th. That Wells, without any knowledge of Long's labors, demonstrated in the same philosophic way, the great principle of anesthesia by the use of nitrous oxide gas (1844).

9th. That Morton intended to follow Wells in using the gas as an anesthetic in dentistry, and for this purpose asked Wells to show him how to make the gas (1846).

10th. That Wells referred Morton to Jackson for this purpose, as Jackson was known to be a scientific man and an able chemist.

11th. That Morton called on Jackson for information on the subject, and that Jackson told Morton to use sulphuric ether instead of nitrous oxide gas, as it was known to possess the same properties, was as safe, and easier to get.

12th. That Morton, acting upon Jackson's off-hand suggestion, used the ether successfully in the extraction of teeth (1846).

13th. That Warren and Hayward and Bigelow performed important surgical operations in the Massachusetts General Hospital (October, 1846), on patients etherized by Morton, and that this introduced and popularized the practice throughout the world.

## News Notes

### Roanoke Welcomes You!

Doctors of Virginia, this applies not only to you but also to the ladies in your families.

Roanoke, one of the most progressive of the cities of Virginia, is pictured somewhat in detail under the heading "Roanoke—The Convention City," in this issue of the journal. Her citizens are enthusiastic and ever active in promoting the interest of their city and are truly "given to hospitality." You will find this out for yourself if you can avail yourself of the opportunity of attending the fifty-fourth annual meeting of the Medical Society of Virginia in that city, October 16, 17, 18 and 19.

Programs of this meeting should be in the hands of all members, having been mailed the first part of this month. If you have not secured your railroad certificate for the one and a half fare for the round trip, apply at once to the Secretary at the Society's offices in Richmond. The scientific and social features will be interesting. We will have as invited guests men whom you will wish to meet and hear. Good papers will also be presented by members. The ladies will find much of inter-

est in the work of the Woman's State Auxiliary to the Medical Society of Virginia and in the social affairs arranged for them.

If you have not made hotel reservations, it would be well to attend to this prior to reaching Roanoke. There are five hotels in Roanoke, as follows: Hotel Roanoke, Shenandoah Hotel, Ponce de Leon Hotel, Lenox Hotel, and Raleigh Hotel. Railroad schedules make Roanoke very accessible from all parts of the State.

A large attendance is anticipated and you will wish to be "among those present."

At the time of going to press, the following is list of delegates appointed from the various component societies of the State Society. If you have not yet appointed a delegate, it is not too late for representation. If impossible to have a meeting to elect delegates, have president of your local society make the appointment.

### DELEGATES

*Arlington County Medical Society*—Dr. Stacey T. Noland; *alternate*, Dr. R. N. Sutton.

*Bedford County Medical Society*—Dr. W. O. McCabe; *alternate*, Dr. J. A. Rucker.

*Botetourt County Medical Society*—Dr. M. T. McCulloch; *alternate*, Dr. A. W. Hammond.

*Danville Academy of Medicine*—Dr. R. Bruce James.

*Dimwiddie County Medical Society*—Dr. F. J. Wright; *alternate*, Dr. J. M. Harwood.

*Fairfax County Medical Society*—Dr. F. M. Brooks; *alternate*, Dr. Tom Williams.

*Floyd County Medical Society*—Dr. C. W. Thomas; *alternate*, Dr. J. L. Harvey.

*Nelson County Medical Society*—Dr. J. B. Woodson; *alternate*, Dr. D. C. Wills.

*Piedmont Medical Society*—Drs. J. C. Flippin and Lewis Holladay; *alternates*, Drs. J. H. Neff and John W. Scott.

*Richmond Academy of Medicine and Surgery*—Drs. J. A. Hodges, M. W. Peyser, W. B. Blanton, E. G. Hill, A. L. Gray, M. E. Nuckols and M. P. Rucker; *alternates*, W. L. Peple, G. A. Ezekiel, Manfred Call, C. F. Ross, Fred Hodges, W. Nelson Mercer, and T. W. Murrell.

*Roanoke Academy of Medicine*—Drs. Claude Moore and T. Allen Kirk; *alternates*, Drs. J. D. Willis and J. R. Garrett.

*Rockingham County Medical Society*—Dr. J. E. Lincoln; *alternate*, Dr. George G. Snarr.

*Southampton County Medical Society*—Dr.

R. L. Raiford.

*Southside Virginia Medical Association*—Dr.

George H. Reese.

*Southwestern Virginia Medical Society*—Drs.

J. C. Motley, J. J. Giesen and Arthur Hooks;  
*alternates*, Drs. T. K. McKee, W. W. Chaffin  
and H. R. Fairfax.

*Wise County Medical Society*—Dr. G. B. Setzler;  
*alternate*, Dr. C. B. Bowyer.

*Norfolk County Medical Society*—Drs. E. C. S.

Taliaferro, P. St. L. Moncure, Julian L.  
Rawls, J. D. Collins and A. A. Burke.

*Warren-Rappahannock-Page Medical Society*

—Dr. D. M. Kipps.

*Medical Association of the Valley of Virginia*

—Dr. F. M. Leech.

### Dr. Susan Field,

After spending sometime at Lincoln, Nebr., has returned to Farmville, Va., and resumed her duties in the Normal School in that place.

### Southern Medical Association.

This Association is to hold its seventeenth annual meeting in Washington, D. C., November 12-15, inclusive, under the presidency of Dr. W. S. Leathers, of Jackson, Miss. This promises to be one of the "biggest" meetings in the history of the Association. There will be twenty sections and many papers of interest will be presented. In addition to the scientific program there will be golf, alumni reunions and entertainments for members and their wives and daughters.

The New Willard will be general hotel headquarters for this meeting. There are many excellent hotels in addition to this and accommodations will be ample.

It is planned to have an alumni dinner of the various medical schools represented in the membership. The time for this dinner has been set for Wednesday evening, November the 14th, and dining rooms have already been engaged. The Committee in charge wishes to know approximately the number of diners to be expected at each of these reunions and asks that those who expect to attend notify Dr. Tom A. Williams, Chairman of this Committee, 1746 K Street, Washington, D. C., by the end of October. Associated with Dr. Williams in looking after alumni from schools in this section are: Drs. R. B. Carmichael, Virginius Dabney, J. D. Thomas, W. H. Wilmer, W. B. Mason and B. M. Randolph.

The President of the United States will receive informally the members of the Southern

Medical Association and their wives, Thursday, November 15th, at 12:30 P. M. at the White House. Of special interest to the ladies will be the reception at the Washington Club on Tuesday afternoon, where Mrs. Woodrow Wilson will be the guest of honor. The usual reception to the President of the Southern Medical Association will be held on Tuesday night at the New National Museum, one of the most beautiful public buildings of Washington, a detachment of the Marine Band furnishing the music. Other special entertainments are being arranged.

Physicians who play golf are urged to bring their clubs. There will be a golf tournament at which the usual prizes will be offered. Play will be over the championship course of the Columbia Country Club.

Reduced rates have been granted by railroads on the certificate plan. Each member of the Southern Medical Association will receive a certificate without application for it. Any physician who is a member of his state and county medical society, although not a member of the Southern Medical Association, who desires to attend this meeting, can have the benefit of these reduced rates by requesting a certificate from the Association office, Birmingham, Ala.

### University of Virginia News.

The one hundredth continuous academic session of the University of Virginia was formally opened September 27th, with a record attendance in all departments. In the department of medicine there was an increase of twenty-three over last year in the registrations on the evening prior to the formal opening; six of the fifty-four women who had registered to that time were in the department of medicine.

Among the gifts to the University, announced by President Alderman, were a portrait of Dr. Richard Henry Whitehead, former dean of the department of medicine, which was given by members of the medical faculty and students; \$10,000 from an anonymous donor for the establishment of the Richard Henry Whitehead scholarship in medicine; and \$1,000 from Dr. Seale Harris, of Birmingham, Ala., for the establishment of a scholarship in memory of his father, Dr. Charles Hooks Harris.

An unusual distinction has come to the second year medical class in that two of its members, Benjamin May Baker, Jr., Machipongo, Va., and Eldridge H. Campbell, Jr.,

Carbon, W. Va., have won the Rhodes scholarship. They left the 29th of September for England where they are to study at Oxford University as Rhodes scholars.

#### **Medical College of Virginia.**

At the opening of this school the middle of September, 530 students were matriculated in the three departments of medicine, dentistry and pharmacy—the largest enrollment since 1914—and more than 100 applicants for the study of medicine were rejected because of lack of space in the lecture rooms. It is apparent that something should be done to take care of students from this section who do not wish to go to schools further from home.

Dr. R. D. Thornton, for ten years a member of the teaching staff of the Royal College of Dental Surgeons of the University of Toronto, and known throughout Canada as an authority on dentistry, has been added to the dental faculty of the school. He will have the position of superintendent of the dental infirmary and professor of operative technic.

#### **Dr. Thomas D. Jones**

Has returned to his home in Richmond, after spending a year in postgraduate work at several New York hospitals and serving during the summer months as senior house physician on the Boston Floating Hospital for Children. He will move his offices to the Medical Arts Building, this city, upon its completion.

#### **Secretary, N. Y. State Department of Health.**

Dr. Matthias Nicoll, Jr., State Commissioner of Health of New York, has appointed Dr. Edward H. Marsh, of Brooklyn, as secretary of the New York State Department of Health, to succeed Curtis E. Lakeman who has resigned to take up a different work in New York City.

#### **Civil Service Examinations.**

The U. S. Civil Service Commission announces open competitive examination for the following examinations, applications to be rated as received until December 28, 1923:

Junior medical officer, to fill vacancies in the positions of physician in the Indian Service, surgeon in the Coast and Geodetic Survey, and physician in the Panama Canal Service for duty outside of hospitals;

Graduate nurse, and graduate nurse (follow-up), for filling vacancies in the U. S. Veterans' Bureau and in the Indian and Public Health Services.

Both examinations are open to all citizens of the United States who meet the require-

ments. These may be obtained from the above named Commission at Washington, D. C.

#### **Dr. Joseph L. Spruill**

Recently resigned as state clinician of the tuberculosis sanatorium, at Sanatorium, N. C., to accept the position as superintendent of the Guilford County Tuberculosis Hospital, at Jamestown, N. C.

#### **Dr. B. B. Bagby,**

Formerly of West Point, Va., but now in charge of the Henrico County Health Unit in its malaria control work, has moved his home to Richmond and is at 1402 Avondale Avenue.

#### **Dr. R. E. Mitchell,**

After spending two years in post-graduate work at the Brooklyn, N. Y., Eye and Ear Hospital, has returned to his home in Richmond and will limit his work to diseases of the eye, ear, nose and throat. He will have offices in the Medical Arts Building, which is to be completed shortly.

#### **Dr. H. B. Mulholland**

Has returned to the University of Virginia as instructor in Internal Medicine, after a service at Peter Brent Brigham Hospital, Boston, Mass.

#### **Dr. Tom A. Williams,**

Washington, D. C., by invitation, addressed the Delaware State Medical Association at their annual meeting at Middletown, October 10, his subject being Fundamentals in Psychotherapy.

Dr. Williams recently published a book entitled "Dreads and Besetting Fears, Including States of Anxiety."

#### **Dates Selected for A. M. A. Meeting.**

The Board of Trustees of the American Medical Association has selected May 19-23, 1924, as the dates for the Chicago meeting of the Association.

#### **The American Roentgen Ray Society,**

At its annual meeting in Chicago, last month, elected Dr. Hollis E. Potter, Chicago, as president and Dr. George Winslow Holmes, Boston, as president elect. Dr. William Duane, of Harvard University, Boston, was the recipient of the \$1,000 Leonard prize, for the best original research in the field of roentgen ray, radium, or radio-activity.

#### **Dr. W. S. Rankin,**

Raleigh, N. C., State health officer of North Carolina, has applied for a year's leave of

absence, that he may work with the State Health Department of New York, upon their request.

#### **Dr. and Mrs. O. J. Henderson**

And son, of Montgomery, W. Va., recently visited friends in Northumberland County, Virginia. Dr. Montgomery is an alumnus of the Medical College of Virginia and has many friends in this section.

#### **Child Health Station in Newport News.**

The Newport News, Va., Child Health Station has opened offices in the building occupied by the American Red Cross. Dr. C. B. Ransome, health officer of Newport News, is chairman of the committee in charge of this work.

#### **Dr. and Mrs. O. L. Watkins,**

Rustburg, Va., were recent visitors in Richmond.

#### **Dr. E. W. Perkins**

Announces his removal from Reams, Va., to 109 Franklin Street, Petersburg Va.

#### **Dr. E. S. Barr,**

Recently medical director of the Philadelphia Hospital for Mental Diseases, at Byberry, Philadelphia, is now connected with Highland Hospital, Asheville, N. C. Dr. Barr graduated from Medical College of Virginia in 1916 and is a member of the Medical Society of Virginia.

#### **The American Association of Obstetricians, Gynecologists and Abdominal Surgeons,**

At its annual meeting held in Philadelphia, in September, elected Dr. James F. Baldwin, Columbus, O., president, and Dr. James E. Davis, Detroit, secretary.

#### **Interchange of Health Officers in the United States.**

An event which may be fraught with far reaching consequences for world health is the Third General Interchange of Health Officers arranged by the Health Section of the League of Nations which is now taking place in the United States.

Representatives from France, England, Italy, Russia, Poland, Spain, Holland, Belgium, Greece, Yugoslavia, Germany, Switzerland, Norway, Mexico, San Salvador, Brazil, Chile, and Canada, delegated by their respective governments to participate in a course of study and observation, arrived in America the first week in September and will remain for approximately three months. This group numbers among its members many of the most

eminent sanitarians of the world. Until September 22 the delegates remained in Washington, studying national health organization as administered by the U. S. Public Health Service.

Following the close of the course of study of the national health agency, the delegation of visitors separated into three groups, one of which came to Virginia, another to North Carolina and a third to Alabama, where about three weeks will be spent in studying state and local health departments. Richmond, Va., Raleigh, N. C., and Montgomery, Ala., are the Southern cities which were selected for study. From these places the groups will proceed to Massachusetts, New York and Pennsylvania, respectively, for the purpose of studying the health administration in three Northern States and small cities. Syracuse, N. Y., Allentown, Pa., and one of the smallest cities of Massachusetts, yet to be designated, will be visited for a short period. Following this the groups will make a study of health administration in Boston, New York and Philadelphia. Present plans call for a reassembling of the entire delegation in Washington late in November for a final conference.

#### **To Aid Hospital Reconstruction Work in Japan.**

Dr. Rudolf Teusler, formerly of Richmond in which place he was visiting at the time of the earthquake in Japan, has returned to Tokyo to aid in the reconstruction work of St. Luke's Mission Hospital in that city, of which he is director in charge. In a communication received by Dr. Teusler before leaving this country, it was stated that all of the American physicians at the Hospital were safe, but no report was made as to the twenty-two Japanese physicians and the eighty nurses at the institution.

St. Luke's Hospital was established in Tokyo twenty-three years ago and was filled with patients at the time of the catastrophe. It is feared that many were killed by the earthquake and in the fire which followed. The foundation of the new St. Luke's Hospital, which had been completed as far as the first floor, was also destroyed.

#### **Dr. Wm. N. Botts,**

Appalachia, Virginia, who for the past two years has limited his practice to diseases of the eye, ear, nose and throat, has gone to New York where he will take work in that specialty from October 1st to January 1st, 1924.

Upon his return from New York, Dr. Botts will open at Appalachia, a hospital devoted exclusively to the medical and surgical treatment of eye, ear, nose and throat diseases.

#### **Jewish Maternity Hospital to Have New Building.**

The Jewish Maternity Hospital, of New York City, has purchased lots at the northeast corner of Fifth Avenue and 108th Street, New York City, on which it will build a 12-story hospital building with 150 beds. The estimated cost is to be \$1,000,000.

#### **On Democratic Committee.**

Drs. Roderick Dew, Woodford, and A. L. Martin, Naulakla, have been elected members of the new democratic committee of Caroline County, Virginia.

#### **Parke, Davis and Company,**

Detroit, Mich., announce the appointment of Dr. Earl Miller as Director of the Department of Experimental Medicine, to fill the vacancy following the death of Dr. Ezra Read Larned, who was the originator and organizer of this department and occupied the position as head of the department until his death. Dr. Miller was assistant to Dr. Larned for twelve years and has a wide acquaintance among medical men interested in clinical research work.

#### **Dr. I. E. Fuller,**

Recently of Axton, Va., is now located at Witt, Va., where he will continue in general practice.

#### **Dr. R. R. Goad**

Advises us of his change of address from Dublin, Va., to Hillsville, Va.

#### **Dr. Leland E. Cofer,**

Formerly of Richmond and an alumnus of the Medical College of Virginia, has been appointed director of the division of industrial hygiene of the New York State Department of Labor. Dr. Cofer has been a member of the U. S. Public Health Service for about thirty years and served two terms as an assistant surgeon general in the Service.

#### **Married.**

Dr. Russell LaFayette Cecil and Miss Eileen Cumming, both of New York City, September 26. Dr. Cecil was formerly of Richmond, Va.

Dr. Patton K. Pierce, Tuscaloosa, Ala., and Miss Helen Hammer, of University (Va.) Hospital Training School, July 25. Dr. Pierce made his home for a while after graduation at University, Va.

#### **New Surgeon With Woman's Medical College, Philadelphia.**

Dr. W. J. Bransfield, a well known surgeon of Philadelphia with a most excellent war record, has been appointed clinical professor of surgery at the Woman's Medical College of Pennsylvania, in Philadelphia.

#### **Medical Section, League of Nations.**

Announcement has been made that the medical section of the League of Nations will hold a two weeks' meeting in Philadelphia, beginning November 11. Arrangements for the visit of the delegates is being made by Dr. J. Blair Spencer, director of the Department of Public Health of that city. The program will be of a technical nature and public health problems in all their phases will be studied.

#### **Cancer Campaign.**

It was decided that instead of holding a single National Cancer Week this year, a series of six cancer campaigns will be held, one month being devoted to the subject in each of six regions in the United States and Canada. The Virginia campaign will be in force from October 15 through November 14. Our State Society meeting coming at the beginning of this period, it has been decided to have the chairman of the Virginia division, Dr. Robert C. Bryan, Richmond, give a talk on "The Cancer Problem" on opening night of the meeting in Roanoke. The campaign work calls for devoting three weeks in each region to making ready for the campaign and devoting the fourth to carrying out the activities.

In connection with this campaign work, it may be interesting to note that during 1922 there were in Virginia 1,364 deaths from this one disease. The ratio of cancer deaths among the white population is about three and a half times that among the colored population, and the disease is more prevalent among females than among males. From these figures, the need of education in prevention of cancer is apparent.

#### **Dr. Paul C. Colonna**

Announces the removal of his office to 42 Park Avenue, New York City. His work will be limited to orthopaedic surgery. Dr. Colonna is a graduate of the Johns Hopkins University Medical School in the class of '20.

#### **Dr. Frederick E. Hamlin,**

Staunton, Va., left the first of October to take a two years' course in eye, ear, nose and throat work at the University of Pennsyl-

vania. Upon the completion of this course, he will give up general practice and specialize along these lines.

Dr. Hamlin had made his home in Staunton since 1915 and had many friends in that section. On the evening of September 25, a number of his professional colleagues tendered him a complimentary banquet at Beverley Hotel, as an expression of their high esteem and to wish him Godspeed in his new career.

#### **Miss Rose Z. Van Vort,**

After ten years' work at Stuart Circle Hospital as superintendent and principal of the School of Nurses, has resigned to take up organization work. Her resignation will be effective December 15.

#### **The American Medical Editors' Association**

Will hold its fifty-fourth annual meeting at Auditorium Hotel, Chicago, Ill., October 25 and 26. Dr. Henry O. Marcy, of Boston, is president of the Association, and Dr. F. H. McMechan, Avon Lake, O., secretary.

#### **Notice to Wives and Daughters of Doctors.**

As the Constitution and By-Laws of the Woman's Auxiliary to the Medical Society of Virginia will be formally adopted at the meeting of the Medical Society of Virginia, October 16-19, inclusive, all members of the Auxiliary are urged to attend. Even though delegates have been appointed, every one will be entitled to vote, and a large attendance is desired.

#### **The Bedford County Medical Society,**

At a recent meeting, elected the following officers: President, Dr. W. O. McCabe, Thaxton; vice-president, Dr. R. A. Bennett, Huddleston; secretary-treasurer, Dr. J. A. Rucker, Bedford. Drs. W. O. McCabe and J. A. Rucker were elected delegate and alternate, respectively, to the Roanoke meeting.

#### **Location to Exchange.**

Wish to exchange Richmond property—new brick buildings in most rapidly developing part of the city (rented for \$2,268 a year) for a doctor's home and small farm in the country. Prefer small neat house in good roads' community, near railroad. Address "Exchange" care this journal. (Adv.)

#### **Wanted Physician.**

Richmond doctor wishes physician to take

charge of his practice for the month of November or December. Address reply with references to No. 275, care this journal. (Adv.)

---

## Obituary

---

#### **Dr. William L. Hudson,**

One of the most beloved and prominent physicians of Northern Virginia, died suddenly September 17, while making a professional call. He was stricken with apoplexy shortly after reaching the home of a patient, and expired before a doctor could reach him. Doctor Hudson was born in Luray, Va., 74 years ago and, after completing his academic education at local schools, studied medicine at the Louisville Medical College, from which he graduated in 1874. Dr. Hudson had practiced in Page County for the past forty years and was for a number of years a member of the Page County Board of Health and was also coroner of Page County. He was also for sometime a local surgeon for the Norfolk and Western Railway Company. He joined the Medical Society of Virginia in 1904. Dr. Hudson is survived by his wife and four daughters.

#### **Dr. John Alexander Williams,**

A well known surgeon of Greensboro, N. C., committed suicide September 23, in a private sanitarium near Baltimore, by severing an artery in his right leg and bleeding to death. Dr. Williams was fifty-two years of age and graduated from the University of Virginia Medical School in 1895.

#### **Dr. James Widgery Marshall,**

Of Leesburg, Va., died at Johns Hopkins Hospital, Baltimore, September 29, following an operation for the removal of a blood clot. He was born in Iowa, fifty-one years ago and studied medicine at George Washington University Medical School, Washington, D. C., from which he graduated in 1901. Dr. Marshall moved from Washington to Loudoun County, Virginia, about ten years ago, on account of his health. Last spring, he went to Vienna, Austria, to take up post-graduate work, which he finished and was on his way home when he was paralyzed. He was brought to the Loudoun Hospital and later taken to Johns Hopkins Hospital. His wife, a brother and two sisters survive him.

S. M. A.

To be used only on the order of physicians. For sale by druggists

Requires only the addition of boiled water to prepare

Formula by permission of The Babies' Dispensary and Hospital of Cleveland

# The Results are Smiles

**T**HE best way to sum up the results of feeding S. M. A. to infants deprived of breast milk is to say that the results are smiles.

Nobody but a physician experienced in infant feeding knows how important happiness is as an indication of well-being in his little patients.

S. M. A. babies are uniformly happy because they are uniformly well. They grow and develop normally, and are normally free from rickets and spasmophilia.

The key to this result of happiness may be found in the fact that thousands of physicians are feeding S.M.A. to normal, full-term infants varying in age from a few days to one year or

more, *without any qualitative change whatsoever.* In other words, S.M.A. could not be so used unless it resembled breast milk in all important respects.

Incidentally, the smiles produced by S. M. A. are not confined to the babies. They are shared by the physician, pleased at the assistance which S.M.A. gives him in his work, and by the parents, whose smiles are of gratitude to the physician.

We do not distribute samples of S.M.A. broadcast to the medical profession, but to any physician who wishes to observe results in his own practice, we send a supply sufficient to enable him to do so. Please address:

## CALCREOSE

### 137 Miles

of brown coated CALCREOSE tablets were manufactured in 1922; that is, the tablets, laid in a row close together, would span that distance. To traverse it an automobile, traveling at a speed of 25 miles an hour, would require 5 hours and 25 minutes.

The number of physicians prescribing CALCREOSE is indeed, impressive.

CALCREOSE (Calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, which possesses the pharmacologic activity of creosote but apparently does not cause gastro-intestinal disturbances.

## TOOLS FOR INDIVIDUALIZED INFANT FEEDING

The Physician needs a special set of "tools" for infant feeding in order that his instructions will be faithfully carried out by the mother and that he will receive her complete co-operation and willing assistance.

These two items are important if the physician's talent is to have full scope.

Mead's "tools" are the kind that the physician has always wanted.

Please check off the items that interest you and mail this ad. to us. Everything on this list is free with the exception of the Baby Scales.

### PRESIDENT'S ADDRESS BEFORE MEDICAL SOCIETY OF VIRGINIA.\*

By JOHN STAIGE DAVIS, M. D., University, Va.

*Fellow-Members of the Medical Society of Virginia:*

My first impulse on this occasion of our fifty-fourth annual meeting is to try to express my grateful appreciation of the great honor done me by election to this office, though I fear that you may yourselves feel some regrets, when you finally escape from the mutual ordeal of this hour.

I wish too to thank my associates in the Council, our energetic secretary and the several committees, whose cheerful and efficient work is responsible for the success of this meeting. The splendid program will compensate you for this preliminary pain.

The regular profession is now confronted in this State with an insidious effort to undermine its prestige and impair its efficiency by bills that will be presented to the next legislature to license various healing cults. We should stand together, Fellows, and use every endeavor to prevent this calamity, which has been victoriously met in several of our sister states.

The letter sent out by our efficient secretary during the past summer sufficiently sets forth our proper attitude. In it is shown that nothing unreasonable is asked. No special school or therapeutic method is discriminated against, but we should insist that all who profess to heal should possess a decent education and know the structure and functions of the human body, which they propose to regulate.

Be sure to see that your representatives are properly posted and their intelligence can be relied upon to direct the right action.

To judge from the perusal of the addresses of my illustrious predecessors on this occasion,

the difficulty I felt in selecting a subject is not unprecedented, as most of them have confessed a similar embarrassment.

MEDICINE IN COLONIAL VIRGINIA appealed to me because of that tendency so strong in those descending the western slope of the hill of life to dwell upon the past. Distance in time as well as space lends enchantment. The subject is not untouched since the revered Dr. W. P. McGuire included some of it in his presidential address before you in 1894 and President Lyon G. Tyler too spoke on certain aspects of it in 1910, and I hereby acknowledge my deep obligations to both; but it seemed to me feasible to view it from a little different angle on this occasion, which I hope you will survive.

It has been said that in all history the man of action comes first with his weapon, then the poet telling of his deeds, and much later the philosopher and scientist.

"Achilles had his Homer, but no Plato or Hippocrates." So the medicine of early days was overshadowed by the triumphs of our arms.

Physicians do not seem to have been very prominent at first as there is no mention of any in "The Declaration of the State of the Colonies and Affairs in Virginia with the Names of Adventurers and Summes Adventured in that Action" (1620). It is described therein "As a Country, which nothing but ignorance can think ill of and which no man but of corrupt mind and ill purpose can defame." The first two medical men who set foot on our soil were William Wilkinson and Thomas Walton, the latter being Surgeon-General of the London Company. They sailed with Captain John Smith in December 1606, and landed in 1607, founding Jamestown the following spring (May 14th, 1607). They first had to subsist on crabs and sturgeon, and suffered much from malnutrition. This was a great and hazardous adventure.

The next year Dr. Anthony Bagnall, Sur-

\*Read at fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

geon, appeared and accompanied his colleagues on a voyage to Nansemond, which became the site of Norfolk. He was a great sportsman and with Captain Smith is said to have killed 148 ducks in three shots. At the same time the record tells of Dr. Walter Russell, designated Doctor of Physic, in contrast with previous "surgeons." His first ministrations, however, were decidedly in the latter role, for he was called upon to treat Captain Smith for the wound of a stingray, which he sustained in removing the fish from his sword. Its fin penetrated the wrist an inch and a half and caused such pain and swelling that "we all with much sorrow concluded his funeral and prepared his grave in an island, as himself directed, yet it pleased God by a precious oyle Russell at the first applied to it, when he sounded it with a probe (ere night) his tormenting pain was so well assuaged that he ate of the fish for his supper, which gave no less joy and content to us than ease to himself; for which we called the Island Stingray after the name of the fish." The cure was completed by eating the fish so Captain Smith thus strengthened the popular idea of the virture of a dog's hair for the bite and lent some support to the homeopathic principle of "Similia similibus curantur" as well as to the more modern view of desensitization.

Both of these doctors seem soon to have returned to England—for Smith had later, (1609), to go back there for treatment for wounds due to an explosion.

Dr. Laurence Robertson came two years afterwards (1610) with Lord De La Ware and was made physician general to the colonies and was given 500 acres of land with ten servants to support the dignity of the office. He went on a voyage with Captain Chester, on the Margaret and John, and was mortally wounded in a battle with two Spanish men-of-war, which attacked them. When he fell the captain caught him in his arms exclaiming, "O. what a disaster is this!" and received the noble answer unsurpassed in history, as Dr. Tyler observed, "Fight on brave men—the cause is just and the Lord receive my soul." "Courage, resolve, sense of right, and faith in God find here powerful expression." After his death the London Company selected Dr. John Pott to succeed him. He was a Master of Arts of Cambridge and recom-

mended as well as practiced in Chirurgerie and Physic, and expert also in distilling (a qualification that might be commendable even now). He was made Councillor to the Governor, Sir Francis Wyatt. His experiences were very varied and involved him in several serious offences. In revenge for a treacherous massacre by the Indians in 1622, he was accused of poisoning them for which his enemies at home succeeded in getting him dropped from the list of councillors. As his name was restored two years later he must have been exonerated. In 1629 he became acting Governor during the absence of Colonel West in England, and was the only medical man to hold this office except the first Governor Floyd.

The next year when Harvey became Governor, Dr. Pott was accused of stealing cattle and found guilty, carrying the death penalty and loss of estate! This sentence was suspended by the Governor until the King's pleasure could be learned, as he was declared to be the only qualified physician in the colony. His devoted wife, Elizabeth, went to the Mother Country and so successfully plead his cause before the crown council that the sentence was pronounced "rigorous if not erroneous" and recommended a pardon, which was granted.

In the quarrel about the possession of Maryland, Dr. Pott ardently espoused the cause of the Virginia Colonists and was one of the daring councillors, who had the nerve to arrest the Governor (Harvey) and send him back to England in 1635. For this outrage the King ordered the conspirators to appear before him, but here Pott's name vanishes from the record so it is inferred that he died. Before he left, he had moved from Jamestown Island to a more healthy place called the Middle Plantation, which afterwards became the nucleus of Williamsburg.

The mortality in the colony at this time was terrible—one out of five emigrants was lucky to survive the first year, a period accordingly called the "seasoning" time. Malaria and dysentery were the chief causes of death.

The clergy were really the first physicians and the colony found it necessary in 1631 to pass laws regulating them rather severely, eight years before the Assembly got after the doctors.

The doctors were largely apprentices at-

tracted to Virginia by lack of restriction and pecuniary prospects. The fees were so excessive that masters preferred to let their servants die rather than incur the expense of treatment. This became so bad that the General Assembly passed an act in October, 1639, requiring the doctor in every contested case to declare upon oath the true value, worth and quantity of the drugs administered, whereupon the court would fix the charge. Four other acts were passed (in 1646, '58, '62 and '92 respectively) along the same lines, though the last two seemed to admit some injustice to the doctors and allowed them to add 50% to 100% to the cost of drugs. These acts were designed more to prevent extortion than to exclude quacks and did not at all meet the requirements of the profession.

Dr. Tyler gives an interesting specimen of a bill in tobacco made by a French physician, Mode soon anglicized into Moody:

Geo. Light, Dr., June 20th, 1657.

An Electuary against Vomiting.....	30
A cordial .....	30
A julep .....	25
A Glister .....	25
A Phlebotomy to J. L. ....	20
A Glister and administering.....	50
A dose of physic .....	50
A laxative sirup .....	20
A phlebotomy to ye mayd .....	20
Stomach powder .....	40

Tobacco (the currency) cost 12½ cents a pound so that phlebotomy, the cheapest medical operation, cost \$2.50.

As a further example of this kind of thing the following extract is striking:

A VIRGINIA DOCTOR'S MEDICINES, 1729.

(From *Order Book, Richmond County*),  
August 6, 1729.

The attachment obtained by Doctor James Black, from Wiloughby Newton, Gent., one of the Magistrates of this County against the estate of Doctor Wm. Bruce for one thousand six hundred thirty-eight pounds of Tob'co, being returned served on the said Wm. Bruce's estate, and the said William Bruce being now called, but not appearing, on the moc'on of the pl't Judgment is granted him against the estate of the said Bruce for the fores'd sum of one thousand six hundred thirty-eight pounds of Tob'co (makeing oath in court it is justly due) with costs and one att's fee als

Exo. The said Return is admitted to Record as followeth:

A List of Medicines attacht for Doctor James Black:

Aq fort 3 V's, Sp't sal arm, ol Cary; Ol Jun, Ol ment, Ol cham, ol pul, Bals hel Ter, Syr Sp Ceoro, Spt Nit Dul, Spt Vit, Pul Cast Rus, Spt Sal, Spt Sal Dule 2 Glass, Lap Contrary, puk (or pub or pul) Lental Rubr, Sal am vel, Gull Gamba, Balls Peru 2 voils, Sal mer Glaub; sp Ceti, Ther Venet 2 Viols, Precip Aur, Arg Vivum, Gum Camp, ol Ther, mer Ruper Precip, pul Gasconi, Tinc Cath, Bals Copre (or Copsie or Capsie) Ol Suc (or Sac) Ol Guf; Gum Scam, ant Drap, Oc Cañororum, Torch Echel cane, Alb Rhasis, Fl Benz, Pul grid flors, Turp min'r, Caus Lan, Sal vit, Bals Lucat, Ung Newtritum, Ol anisi, Gum Gall Col Sptt, Emple ple minio, Gum Guiadi Gum my'r, Rad Satery, Lap Calam, Gro: mart. asting, Pul Castory, Cro. Executed me Jno. Hammond S (ub) S(heriff)\* (57 medicines, 11 books).

Malaria, as stated, was a terrible scourge along the rivers and swamps where most of the settlers lived.

Nearly a century later Geo. Hain, who settled in Culpeper County, had such a hard time that he solemnly declared that this country was "only fit for Doctors and Ministers." Whether these callings are opposite extremes of a moral series or classified together as the highest and best qualified for the hereafter we are not distinctly informed. Social distinctions were much greater in the 17th than the 19th century when negro-slavery had equalized most white people. In 1673 a tailor named Bullock attempted to run a horse race with a Dr. Matthew Sladen in York Co., and was fined 100 pounds sterling (not tobacco) for the offense. Horse racing was considered a sport for gentlemen only and it was offensively presumptuous for a tradesman to indulge therein. Nothing seems to have been done to the Doctor, who so disgraced himself.

High charges again became notorious and offensive. A certain Dr. Totum in 1681 had the court record the fact that he would not

\*Spelling and punctuation have been exactly followed.

visit any patient in York Co., for less than 10 shillings.

The quality of the profession gradually rose in the next forty years, during which time there was no further legislation about medicine. Men with academic degrees began to appear such as Dr. Archibald Blair of York, brother to the founder of William and Mary College. Some are credited with notable contributions, such as Dr. Richard Bryan of King George Co. who was given 250 pounds sterling for the discovery of a cure for dysentery, and Dr. John Tennant, Sr., of Spotsylvania Co., who published a pamphlet on Snake Root as a diuretic and also one on pleurisy in 1736.

In spite of great progress and success the people again began to chafe under the excessive cost and lack of skill of some pretended physicians and in 1726 another act was passed on the subject with the following preamble: "Whereas, they are wont to demand excessive fees and to exact unreasonable prices for the medicine which they administer and do too often for the sake of making up long and extensive bills, load their patients with greater quantities thereof than are necessary or useful, concealing all their compositions as well as to prevent the discovery of their practice as of the true value of what they administer, which is become so grievous, dangerous, and intolerable as well to the poorer sort of people as to others and doth require the most effectual remedy that the nature of the thing will admit." It was accordingly enacted that no surgeon or apothecary, who had served an apprenticeship to those trades, should charge more than certain specified rates, according to distance traveled, which could be doubled by those who had college degrees (thus intimating the value of and giving financial inducement for a liberal education). No remedy was to be administered without at the same time giving the patient an itemized statement of its ingredients and their prices. Surgery was still in the hands of the barbers up to 1745 when what Dr. Tyler calls the "art of barbering" was abandoned by surgeons and socially diverged very widely.

Virginia enacted no further laws on this subject for 150 years and during the Revolutionary War the only legal requirement was the payment of a fee to the state. Nevertheless, the innate love of mankind and the desire to serve his fellows according to the Golden

Rule, served in a measure to protect our calling. The number of university graduates increased until the tone of the profession was largely dominated by them. Some of the more prominent medical men about the time of the Revolution were Dr. Thomas Walker, of Albemarle, the explorer of Kentucky, of whom more later; Dr. George Gilmer, who called himself in his will "Chirurgeon Surgeon"; Dr. John Brodie; Dr. Wm. Pasteur, Mayor of Williamsburg in 1775; Dr. Hugh Mercer, Major General and a hero of the Revolution; Dr. Wm. Carter, who had charge of the hospital in Williamsburg, and Dr. Matthew Pope of the one in Yorktown.

Native Virginians now began to come to the front and many of the wealthier ones selected Edinburgh, Scotland, as the best place for medical study. Twenty-three Virginians did so according to Dr. McGuire. This was probably due to the success of several Scotchmen, who settled in Virginia at the suggestion of George Washington, who had met them in Braddock's army.

Study abroad was not an absolute specific and some exemplified the adage

"How much the fool that hath been sent to Rome  
Exceeds the fool that hath been kept at home."

Some honorary M. D.'s were conferred on benefactors, which was then translated to mean *Multum Donavit*: much as LL. D. was thought by some in my early days to mean Laying the Law Down. On the James River canal boats M. D. stood for mule driver!

Dr. John Munson Galt was Surgeon General of Virginia and physician of the first Lunatic Asylum, established in 1772 at Williamsburg, and Dr. James McClurg ranked among the first physicians in America.

In 1761 a small group of Virginia Medical students in Edinburgh formed a club whose constitution was drawn by Theoderic Bland, who with Dr. George Bland afterward held important military offices in the colonies. This instrument consisted of eight articles to which each member pledged himself and is the first recorded utterance on the subject in all history, recognizing the dignity and honor of the profession. So our state may well be proud of it. No one was eligible who did not declare on honor his intention of taking a degree. He had to make it his endeavor for the honor of the profession not to degrade it by hereafter

mingling the trade of apothecary or surgeon with it! Anatomy was affirmed as the true basis of medicine and each member in turn had to teach this branch and give a demonstration of the subject on his own person to the others in his room, whether in repose or action we are not informed! At this time Dr. Bland sent a petition to the Council and House of Burgesses of Virginia on behalf of the Virginia students in Edinburgh, protesting against the unguarded state of the practice in our State "which lay open to the intrusion of every pretender to medical art, who may then practice not less to the dishonor of medicine itself than the destruction of mankind," and asking that the right to practice be confined to those who had been properly licensed and honored with a doctor's degree. Nothing was done, alas. History repeats itself in this day and the danger is again acute.

James McClurg, already mentioned, one of the prerevolutionary graduates of Edinburgh, was sent to Hampton to open the first hospital in America (though a "guest house" for the sick had previously been established opposite Jamestown and called Mount Malado), and inoculate there for small-pox. The son of a British Naval Surgeon, he was a graduate of William and Mary, the University of Edinburgh, and had studied in the hospitals of Paris and London. He wrote an essay on Human Bile which was translated into every European language on account of its original and individual character. In 1779 he was elected to the chair of medicine at William and Mary, authorized that year. It only lasted one session, but was the first attempt to teach the subject in the state and the third on this continent. Dr. McClurg soon afterward moved to Richmond, and was a member of the Federal Convention in Philadelphia, which framed our present Constitution, which, however, he failed to sign. After half a century of distinguished service he died in 1825.

Irritation with an ingratitude to the faithful physician is an ancient occurrence. In 1792 a certain Jacob Rubsamen of Chesterfield County put in his will, "Currey, the quack doctor, has an account against me. It is rascally and unjust." The doctor took a noble revenge by having the clerk inscribe just below the testament a certificate from the eminent Dr. McClurg as to his excellent standing.

After this time without any special law ex-

cept that of decency and simply by the force of public opinion, a regular medical degree became by custom essential to the practice of medicine. Let us see that it is not changed now.

Amongst the distinguished medical men of this time may be mentioned Dr. Nathaniel Chapman of Fairfax County, (1780), who migrated to Philadelphia where he achieved great distinction as professor in the University of Pennsylvania, a prolific writer, first President of the American Medical Association and founder of the American Journal of the Medical Sciences. Ephraim McDowell, (1771) of Rockbridge County studied in Edinburgh and practiced in Danville, Va. He performed the first operation for ovarian tumor and was accordingly called the Father of Ovariectomy. Benjamin Winslow Dudley of Spottsylvania County, (1783), a pupil of Brodie and Abernathy, performed the first lithotomy in this country. He was an advanced apostle of asepsis and attributed his success to the free use of hot water. Several others of great distinction will be referred to later.

The study of medicine in the colonies began at the early age of 14 or 15 when a lad was apprenticed to a practitioner for 6 or 7 years. During this probationary period he was expected to bleed, draw teeth, run errands, compound drugs, attend to his master's horse, if he owned one, and see that it was properly fed and groomed. Every manual effort was unseemly for a real doctor, whose entire work was supposed to be intellectual, so the apprentice fell heir to all physical endeavors. For medical books he could revel in his master's library of possibly twenty volumes. More frequently his learning came from the limited experience of his preceptor or his own.

Colonial diseases are enumerated as age, ague fever, apoplexy, and suddenly bruises and scalde, bleeding, cancer, gangrene, pleurisie, quinsie, and sore throat, and some less refined expressions as dry-belly ache, plagues of the guts and divers sore distempers. Our modern names are more euphonious, but the sensations and sentiments they awaken persist. The rising tide of independence, which culminated in 1776, is shown in the distinction applied to venereal troubles as the King's Evil.

Hygiene was very rudimentary, though Force which also figures largely in the reports.

tells us "There shall no man or woman dare to wash any unclean linen within the Palliza-does. . . nor reach and make clean any kettle, pot, or pan within twenty feet of the old well upon pain of whipping."

Ventilation was unknown and during the winter the old dwellings got an odor that was irreverently styled "the prayer meeting smell," a composite perfume in which the barn, the dairy, and the dwelling house, accentuated by perspiring piety, seemed to struggle for precedence. To wash the feet in January was considered a particularly vicious way of tempting Providence. A physician of the times, when asked his plan of treatment replied somewhat poetically:

"First I pukes them, then I sweats them,  
Then if they wants to die, I lets them."

Quackery was rampant in colonial days as now. A Boston paper in 1737 contains the following item:

"A young man without any liberal education by living a year or two in any quality with a practitioner of any sort, apothecary, cancer doctor, cutter of stone, bone setter, tooth drawer, (observe the contempt for persons who did anything mechanical), with the essential fundamentals of ignorance and impudence, is esteemed to qualify himself for all the branches of the medical art as much or more than gentlemen in Europe, well born and liberally educated (and therefore modest likewise) have traveled much, attended medical professors, frequented city hospitals and camp infirmaries for many years. How dismal it is to observe some apothecaries shops wainscotted with advertisements recommeending quack medicines for the profit of the shop, but destruction of their neighbors." This is not unfamiliar at this day.

As to therapeutics, the Indians used water and herbs and the Indian Medicine Man was regarded as a sacred intermediary between the Great Spirit and Man. He had to possess four requisites.

1. Recognition of the sanctity of human life. His hands must not be stained with human blood.

An unsuccessful operator might find himself disqualified by this token.

2. His words must never deviate from the truth for the Great Spirit manifests its value in the regular order of nature.

3. He must be slow to anger as God is forbearing.

4. He must be deliberate and prudent of speech.

Even they had quacks, of whom much more is heard. An advertising "healer," a keen observer of human nature, who used his acumen sorely to his selfish advantage.

Chemical (mineral) and Galenical (vegetable) therapeutics divided the doctors into two schools. Famous remedial agents were drawn from most unpromising sources, such as soot, manure, and urine, and human blood. Sow bugs receive most honorable mention. Much reliance was placed on nature to eradicate poisons, so the urine was especially studied and portents drawn from it. When it was black or green, death was inevitable. Urine was a precious extract and one doctor was fined 40 shillings for supplementing a scanty specimen with a personal contribution. The colonists soon heard of and experimented with the properties of dandelion, wormwood, blood comb, and plantain, the last called the Englishman's foot in the belief that it sprang up wherever the paleface trod.

Dr. Carney has collected some gems of medical lore dating back to 1672—such as, picking the gums with the bill of an osprey or a thorn from the back of the dogfish is good for tooth ache. Bear's grease relieves aches and cold swelling. The heart of a rattle snake is an antidote for its bite. Watermelon is good for fevers. "Perilous" coughs are relieved by a mixture of fifteen herbs boiled, cooled, and supplemented by powdered lice. For consumption was advised twelve red garden snails boiled in a pint of milk, which was then strained and drunk on an empty stomach each morning for three months. Hysteria was called "the vapours" and appeared in many puzzling shapes. The patient (suspiciously referred to as "she") has no relish for anything, something seems to rise into the throat and almost stops the breath. She has great heaviness and dejection of spirit. A cloud seems to hang upon her senses. "She is continually out of humor, she knows not why, and out of order, she knows not where." To escape the disorder she must suffer none of the little disturbances and disappointments of an empty world to prey upon her mind and ruffle her sweet temper. The physician was to forbid all sorts of drams and not allow even one pinch of snuff

or a drop of tea, which makes people miserable and "lumpish."

There were no women physicians in Virginia in colonial days, but three attained distinction in New England.

A few words now as to some distinguished medical men of the time and their achievements. Dr. F. J. Corte delivered an oration in Williamsburg, June 12, 1782 on Ancient Medical Philosophy Teaching the New World before the Society of the University of Virginia! This was nearly half a century before it was founded! The third Jewish physician to come to America appeared in Virginia early in the 18th century in the person of Dr. Siccary, a Portuguese and credited by Thomas Jefferson with the introduction of the tomato, long known as the "love apple." He said that whoever could eat enough of them would never die and himself certainly attained a very old age in this faith. Dr. Isaac Levy is the next Jewish practitioner in Virginia (1779-1786), in that wild region then known as "The Illinois Country." He was a sort of combination of merchant, financier, and physician, though he figured repeatedly in the French records as plaintiff for services in the last capacity. In 1782 he sued one Butean, for 100 pounds sterling for his service bill. The defendant claimed he was not entirely cured, so the court ordered the plaintiff to continue his treatment until he was cured on condition that the defendant faithfully followed directions. The doctor soon complained that the patient was disobedient. The defendant explained that he had taken the 60 pills prescribed in two days instead of seven a day as directed in order to be cured more speedily. Whereupon the doctor replied that such a course would have killed him several times over and so got judgment in his favor. Another distinguished physician was Robert Honyman, of Louisa County (1762). His memory was said to be marvelous and he never visited a patient again who questioned his bill. He bequeathed to his son (who was ordered to pass them on to posterity) his diploma, his thermometer (which must have been more substantial than modern instruments) and a rib in his iron chest which had been that of James V. King of Scotland.

After Braddock's defeat George Washington got acquainted with a number of subsequently distinguished Virginia physicians whom he induced to settle in this state. They

were mostly Scotch and fond of Botany. Among them Dr. Hugh Mercer deserves special mention. He settled in Fredericksburg, Va., won high distinction in the Revolutionary War and was killed at Princeton in 1777. His monument is nobly inscribed: General Mercer, a physician of Fredericksburg, Va., "distinguished for his skill and learning, his gentleness and decision, his refinement and humanity, his elevated honor, and his devotion to civil and religious liberty." In 1902 Congress directed that a similar memorial be put up in Fredericksburg, the scene of his professional labors, 125 years after his death. Dr. John Mitchell (1680-1768) while an M. D. was more of a botanist. He lived at Urbanna in Middlesex County and was the friend of Linnaeus, who named the Partridge vine after him—*Mitchella Repens*. A similar honor befell Dr. John Clayton of Gloucester, for whom the Spring Beauty was called *Claytonia*. Another of Braddock's army was Dr. Andrew Robertson, who landed in Richmond County, where he was entertained by a Scotch merchant, whose daughter was ill. Dr. Robertson relieved her and, keeping her in mind, later placed her firmly in his heart, where she reigned as his fourth wife when the favorable opportunity came. He was noted for his distinguished charity and attention to the indigent sick. Dr. Alexander Somervail was another of the group and settled in Essex County, where he is credited with being the first to distinguish typhoid and malarial fevers. Dr. Adam Stephens operated on liver abscess in Stafford County at this time. Dr. Thomas Walker of Albemarle County (1714-94), was the first operator for osteomyelitis. He lived at Castle Hill and was the guardian of Thomas Jefferson. He was the first to explore Kentucky, as already noted, and established the line between North Carolina and Virginia. He died and was buried at Castle Hill "in a grove to which purple Redbud and white dogwood lend in succession the beauty of their vernal bloom and where the oak, tulip tree, and fragrant wild grape make a bower for the birds, which in spring and summer ceaselessly carol his requiem." Dr. William Brown of Alexandria was assistant Surgeon General to the Continental Army. Dr. William Cabell, the founder of the celebrated family of that name, was born at Warminster in England, graduated in London, and came to America in 1724.

After a recall home, he returned in 1741 and went up the James River 50 miles beyond any existing settlement, where he built a house well called "Liberty Hall" near Warminster, which he founded and named after his birth-place. Despite an exalted churchmanship, he was devoted to and kept good race horses on which he was always willing to risk a small stake. He dedicated a portion of his residence to hospital purposes and performed operations there. He had troubles with his neighbors. A Mr. Dickie of upper Tye River, sued him for abusive language. The doctor's excuses were that Dickie had interrupted his survey and even tried to break the chain so he said, "I had to apply the *Words of Solomon to him.*"

Before 1769 the title Doctor was unknown in the colonies. Doctor William Richman was Physician and Director General of the Hospitals in Virginia. June 15, 1776, Williamsburg was chosen as his headquarters. He was afterwards Director General of all Southern Hospitals. He was charged with neglect of duty because the North Carolina and Virginia Troops at Alexandria had smallpox from failure to inoculate, but he was afterwards acquitted. Inoculation was violently resisted at times, and Capt. Walke was almost mobbed in Norfolk in 1753 for taking some of his sailors, who had been exposed to smallpox, eight miles inland to a stockade and inoculating them there. Dr. Wm. Baynham of Essex County was long considered a most eminent surgeon and famous for his accurate knowledge of anatomy. He performed two successful operations for ectopic pregnancy. Dr. James Craig was Washington's chief physician in his last illness and with Dr. Dick, made the celebrated report to Congress as to his refractory behavior to venesection. They took fifteen quarts "in spite of" which they said he died. Some others held legislative offices, such as Drs. Theoderic Bland and Arthur Lee, who gave up medicine for law, and Wm. Jones who were members of Congress. Thacher's history (1828) enumerates 17 specially distinguished physicians in Colonial Virginia and 39 surgeons in the Continental Army.

The poor tone of the profession, which was permeated with quackery, was responsible for the aphorism current at the time (1649), "He that sinneth before his Maker let him fall into the hands of the physicians."

Our forebears were impressed with the

music of the Bull Frogs whose so-called impertinences to the Yankee settlers after the Civil War used to amuse Weir Mitchell. He told me that they seemed to sing, Bull Run, Ball's Bluff, and Chickahominy, and other disastrous memories to the Federal troops. Dr. Schoeff, surgeon to the Hessian troops, observed that our towns had no signs except notices of taxes, elopement of wives, horses stolen, and new doctors settled. He said Virginians were a comely race, but do not give much attention to the exact sciences. "They read, but they do not study." He complained that he had to drink many healths and it was absolutely necessary to drain the bowl, a hardship that some might now bear with resignation if not fortitude.

Offensive advice as to health was once given to General Washington by an interested friend who had a patent medicine to sell. He commenced grandiloquently: "Dear Sir, Health is a grand object with man, but it becomes all important when the preservation of it in any one person comprehends all the relations of a people, when like a focus the views of all direct to a single point. Permit me therefore to lay before you some leading principles, some conclusions, and some consequent practice for the security of health." He then unfolds a remarkable scheme of medication with "Cremer Tarter." It worked as an antacid, neutralizing superabundance in the stomach, and thereby arrested all diseases in their incipency by giving their elements "into the hands of the scavenger to be swept through, properly corrected, so as to be without acrimony to embarrass the way." To this the General responded briefly, thanking him for his "interest" with these words, "Having through life been blessed with a competent share of it (health); without using preventatives against sickness and as little medicine as possible when sick, I can have no inducement to change my practice—against the effect of time and age no remedy has ever yet been discovered, and like the rest of my fellow mortals, I must (if life is prolonged) submit and be reconciled to a gradual decline."

Our Virginia colonial physicians are credited with a goodly number of valuable publications, specially noteworthy of which were an Essay on Polygala Seneca by J. Tennant (1736). "The causes of different colors in people of different climates" and "Letters on Yel-

low Fever," by J. Mitchell, (1743) which was even then considered not contagious, and Flora Virginiana, by J. Clayton (1745). John Jones' work on Wounds and Fractures, (1776) gave him the name of Father of American Surgery. Thomas "prepared" the system by calomel for smallpox inoculation in 1745 in a long paper.

*Consultations* were unpopular, being chiefly distinguished for gross controversies even at the bedside of the patient. In Massachusetts no operation could be performed "without the consent of all healthy and sober men present, whether doctors or not," and as idle and curious people collected around the sick then even more than now, it can be inferred that there was little surgical intervention.

Courtships were matters of fact not sentiment and required more than "the tautologies of a long winded speech or else the suitor might fall under the contempt of her frown, or his own windie discourse" and "fail to melt with his her crimson lips' disdain!" Belleship of widows is especially noticeable. Debutantes seemed powerless against their fascinations. Washington, Madison and Jefferson, each succumbed to them. An unmarried girl over 25 was regarded as a confirmed old maid and designated as a "pitiabie spectacle"! The extreme youth of the eligibles may account for the attractions of the widows who were more sophisticated.

Jefferson did not seem to approve of hospitals without qualification—he says, "In the care of the sick in the family of a good person, every member is emulous to do them kind offices, where they are visited by all their neighbors, who bring them the little rareties, which their sickly appetites may crave, and who take by rotation the nightly watch over them without comparison better than in a general hospital, where the sick, the dying and the dead are crammed together in the same room and often in the same bed. Nature and kind nursing save a much greater proportion in our plain way, at a smaller expense and with less abuse." Hospitals must have been badly run, as General Washington wrote to Congress in 1776, protesting against the dishonesty and incompetence of many regimental surgeons.

Fellows, I have dwelt thus long and trespassed on your patience because there is to me as I go on in life an ever increasing inspira-

tion and pleasure in the past. I love to contemplate it. "On that deep retiring shore frequent pearls of beauty lie." As Dr. Osler says, "this was the formative period of our existence. This professional ancestry with all of its struggles, hardships, and ingenuity has imparted the impulse which we develop. With the irrevocable past into which they have gone, lies our own future, since our condition is the resultant of forces, which in the intervening generations have molded the profession of a new and mighty empire. From our vantage ground, we can trace in literature how the great streams of our ancestry have blended into the broad current of American medicine on which we are afloat.

"Adaptiveness, lucidity, and thoroughness may be called the characteristics of the Anglican, Gallic, and Teutonic influences we have experienced, and it is our duty to see that these influences whose combination gives to medicine on this continent its distinctively eclectic quality are maintained and extended," and that the torch of healing which these heroic spirits kindled and raised may continue to shed uncontaminated its beneficent rays upon our land. In the words of one of our old professors—"Fresh and fair are the various beauties of our Virginia's natural landscape, but brighter and fairer still are the exalting and ennobling memories of those times, which from worlds not quickened by the sun pour over all her borders the light

"that consecrates  
Whate'er it shines upon."

### A BRIEF ANALYSIS OF COUE'S METHOD, AND ITS FALLACIES.\*

By J. ALLISON HODGES, M. D., Richmond, Va.

It is a matter of professional opinion as to the advisability of criticising, or refuting the many new and irregular methods suggested these days for the treatment of disease. On the one hand, it is contended that discussion promotes advertisement, and on the other, that proper refutation and denial is demanded of the physician in justice to his patients. Obviously, in cases where wholly untenable claims are made, and it is sought by the proponent to substitute a new method for the old and tried system, whose basic principles have stood the

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

test for more than a thousand years, and, moreover, whose elimination may mean the total loss of the element of time, which is so valuable in the treatment of many cases, it becomes imperative, in my opinion, that the regular profession should express its disapproval and denial of such unwarranted and unscientific assertions. Such considerations as these are the excuse for this brief study of Couè's Method, as practiced by him recently in this country.

This method, like all previous pseudo-scientific medical cults, has been the vogue recently, because of the ignorance and credulity of the public in such matters, and because of the fact that there is some distorted truth in nearly every error, or, what is of more importance, the whole truth is not sought, nor taught, and herein lies the great fallacy of Couè's method and teaching.

His basic principle is suggestion, in which all scientists concur in degree, but he authoritatively asserts that this power is only efficient through auto-suggestion. In other words, while he says that "from our birth to our death we are all the slaves of suggestion," yet he proceeds to say that in order to secure self-mastery which he denominates as "Health," we must "discipline suggestion, and direct it in the way, we ourselves wish." Later, however, he teaches that not "wishing," but "the imagination" is the instrument wherewith the all powerful tyrant of suggestion is conquered, and that we become masters of ourselves, entirely through ourselves, not by wishing nor willing, but by imagination, initiated and made effective wholly and solely within ourselves, that is, with no outside suggestion whatever, not even from Couè himself. May I ask, in passing, how the countless thousands that have gone before, have maintained health without this knowledge, or how the thousands that shall follow that know nothing of this special Couè brand of treatment shall survive?

The preceding statements are sufficient to show how garbled truth may be utilized by the empiric to the detriment of scientific teaching, and to the glory and benefit of the blatant advertiser of a new cult.

But to be more specific, it may be well to consider very briefly the power of suggestion, as it is exemplified most usually in hypnotism, or mesmerism, and note if there are any differences perceptible or demonstrable between these

procedures, and the method used by Couè.

The phenomenon of hypnotism is mystical, but interesting. In my opinion and from observation of the methods of such notable scientists as Charcot, and others, I am convinced, speaking in a popular way, that the mental states during such a process are entirely passive and quiescent, all the faculties of the mind being in abeyance to the directions of another, and that it is necessary only to be able to concentrate and hold the attention of the one hypnotized, and while so absorbed, either by looking at you, or while holding his hands clasped, or otherwise, and this mental state is further tested by some command, such as to evoke a question of the hypnotized person's ability to do, or not to do, such and such an act, and then the dominating personality of the person hypnotizing is directly stamped upon the other's mental state, and the hypnotized patient finds that nothing can be done, except as directed or inhibited by the hypnotizer himself, that then the hypnotic state is complete; in other words, the patient for the time being is mentally vacant, except for the faculty of attention, and is so absorbed in that act, that the hypnotizer can readily impress his personality and directions upon him, thus, for the time being, completely dominating him. If, however, the patient is not able to concentrate totally, and thus put the brakes on his other mental activities, he is incapable of being hypnotized, while on the other hand, if he can give absolute and perfect attention, he can be hypnotized, for the mental machinery for the time being is inactive, dormant and receptive, and subject to external direction by another. In addition, if the patient wishes and believes that certain things can be accomplished, he is that much more willing to be mentally influenced, without bringing into play any of the dominating faculties of his mind. It is in such a state as this, that *willing* to do a thing, is its virtual accomplishment, for willing is to a remarkable extent dependent upon wishing, and wishing, when intense, breeds power. Again, should "the wish or desire be the enemy of the will, nothing can be accomplished until this desire shall become the will's ally"; in some cases, this can only be produced, by the use of the imagination, correctly speaking, the representative faculty, and it can be accomplished by depicting vividly to yourself the sad consequences, for example, that would occur if

the habit was not broken, and at the same time, picturing to yourself quite as vividly the happy consequences that would ensue from the breaking of it. This is the only instance in such mental processes when the imagination is of use and, if diligently exercised, a sincere wish of freedom from a vicious habit will develop, and out of this wishing will grow effective willing, and the possible amelioration or cure of some functional disease, or acquired evil habit. When this does not occur, Bruce says that nine times out of ten, perhaps oftener, contrary desire (or wishing) and contrary belief, account for ineffective willing.

Monsieur Couè uses exactly the same procedure that is used by the hypnotist, except that he says he requires his patients to suggest to themselves while conscious, whereas he maintains the hypnotist suggests to his patient while the patient is unconscious, but if this be true, why the need for any set formula at all? This distinction seems to me to be a difference without demonstrable proof, but it is upon this theory that Couè announces his dogma that self-mastery is health and the cure of disease, and that imagination, not the will, is the instrument through which conscious auto-suggestion accomplishes it; in other words he bases his cure upon the power of the imagination, and not upon the will power, and yet on page 14 of his new book, "My Method," he writes as follows:

"I cannot too strongly insist that in the practice of auto-suggestion, the exercise of will must be strictly avoided, except in the initial phase of directing or guiding the imagination on the desired lines"—an admission, which to my mind nullifies the basal facts of his teaching, for how can he so definitely limit the imagination, and autocratically say to the will: "thus far, and no farther shalt thou go?"

If his directions to the patient, or his management of the patient, or his suggested mumbo-jumbo formula, "every day in every way I am getting better and better," drawled twenty times like a litany, and in order to avoid distraction of attention, even having the patient count off the numbers on a piece of string tied in twenty knots, is a whit different from the method of hypnotist, I am incapable of appreciating it, for, in addition, he seems to forget entirely that the patient is not receiving an auto-suggestion, that is, a suggestion personal to himself and born within himself, as

he claims, but that he is receiving suggestions from the outside, else why should the patient recite the formula, which bears the brand of Couè, or why should he count the beads in a certain and regular way?

On the contrary, this is but a Couè trick, in order that while the patient's attention is directly engaged, he himself may stamp upon the receptive faculties of the patient's brain, the facts he desires to plant, so as to produce the desired harvest. In fact, it would seem, that, like others, he thinks that every method has tricks but his own, and yet he finds it necessary time and time again to proclaim "I am no healer!" and yet proceeds to heal!

He quotes Pythagoras and Aristotle as believers in the power of imagination, but even though he appeals to the oracles of the ancients, and says in his writings, but mind you, not to the patient, "Don't concentrate, but just leave it to the unconscious," yet he can adduce no authority for the statement, that imagination is more powerful than the will, although he explains that Caesar and Napoleon succeeded in battle because of their great imagination, and so it was left to him, who is a meek man and like Uriah Heep, "an humble man" to discover a great discovery, namely, that imagination makes even character, and besides, heals almost all diseases, thus making Couè, the discoverer of this fallacy, a new prophet of a new creed. In accomplishment, the human will has always been considered the prime factor, and it is unnecessary to name some of the highest authorities in the scientific world from the time of the great logician and philosopher, Sir William Hamilton, to the present day who believed and taught exactly the opposite that Couè teaches, and yet I mention to you his own countrymen, Dr. Paul Du Bois who teaches that self control is secured by strengthening the will, and Dr. Jules Payot who shows the means possible for will training and the result of linking your will with work, and thus securing physical and mental efficiency, and also Dr. Charles B. Patterson, Dr. Alfred Schofield, and H. Addington Bruce, whom I have quoted, all proving the power of will over imagination, even to the point of emphasizing the practice of medicine, as being largely "the will to be well."

Unfortunately, the writing of many books has been this author's undoing, for his work, "Self Mastery through Conscious Auto-Sugges-

tion" both by title and precept does not appeal to the "unconscious," while in "My Method," just off the press, p. 7, he writes that "the subconscious is dominant over the conscious" also, in the first named book, he does not directly claim to cure diseases that really exist, but in his last, he names specific and organic diseases (pp. 37-43), which can be cured by auto-suggestion, namely, ulcers of the stomach, tumor of teeth, diabetes, sciatica, asthma, wasted tissues repaired, tuberculosis benefited, sinusitis (after eleven operations) cured, etc.—all of these patients having "directed their subconscious minds to the idea of healing" through auto-suggestion, and yet, he was no healer!

The most amazing statement of Couè, however, is his method of influencing and healing the infant, and his directions to the parents:

"The latter (parents) should wait until the child is asleep, and then one of them should enter his room with precaution, stop a yard from his bed, and repeat fifteen or twenty times in a murmur all the things they wish to obtain from the child, from the point of view of health, work, sleep, application, conduct, etc. He should then retire as he came, taking great care not to wake the child. This extremely simple process gives the best results, and it is easy to understand why. When the child is asleep, his body and his conscious self are at rest and, as it were, annihilated; his unconscious self, however, is awake; it is then to the latter alone that one speaks, and as it is very credulous, it accepts what one says to it without dispute, so that, little by little, the child arrives at making of himself what his parents desire him to be."

"I say with all kindness," says Dr. Wylie, "that any one who can possibly believe such a statement to be true must not only annihilate his will but also his conscious intelligence and degrade himself to the condition of an individual who would accept a statement which has neither reason nor science connected with it in any way. In other words, it is the perfection of inane credulity. The hallucinations which have been expounded in this country by such men as Sir Arthur Conan Doyle seem like beams of radiant light and intelligence compared with a statement of this kind."

Dr. Couè says anybody can suggest to himself to get well. What kind of a formula would any one suggest? What shall one sug-

gest who has never heard Couè? Is his the only "get-well-quick" formula?

It is useless, however, to pursue this subject further, when upon the fly-leaf of one of his volumes, he informs the gentle reader that "with a little practice, the physical or mental distress will have vanished in 20 to 25 seconds," a result that would require the suspension of all the laws of Nature, and yet, he was no miracle-worker! In my opinion, if any diseases were healed by this magician, untutored and unlearned in medical science, as he proudly and cleverly proclaims, they were diseases, or rather the idea and habit of diseases, that the patients did not have, but may have thought they had, for science has never yet demonstrated that "suggestion" under any "syndicated" name, can cure any disease that actually exists. If, as Couè says, any one can suggest to himself to get well, what formula, will be necessary? If you take Couè's formula, at whose suggestion are you doing it, at yours, or his? But, "mark well, I am no healer!" (p. 5, "My Method.")

In conclusion, it would seem that it is vain to hope that conversion from error, as we see it, by means of argument, will ever rid us of cormorants that feed upon the profession and its clientele, but let us at least express the wish, as we cherish the hope, that if there be "rank weeds in the garden of science, that when they have done their permitted mischief and rotted, they may serve to manure the soil which they have dishonored, and show that, in the plans of Providence, the vilest things are not without their purpose!"

107 East Franklin Street.

## MEDICAL AND SURGICAL IMPRESSIONS OF SOUTH AMERICA.\*

By P. W. BOYD, M. D., Winchester, Va.

The purpose of the cruise to South America by some members of the American College of Surgeons was:

1st: To hold in the principal capitals of South America a series of scientific meetings that would seal more strongly the mutual friendships of the surgical professions of North and South America.

2nd: To observe and study first hand scientifically equipped medical schools, hospitals, and institutions of tropical medicine.

\*Read before the Medical Association of the Valley of Virginia, at its meeting in Winchester, May 31, 1923.

3rd: To enable the Fellows of the College and their families to take an ideal winter trip into the fascinating tropics and semi-tropics of our southern continent, at a time when our own continent is buried in winter.

For the cruise, the College selected and chartered the S. S. Vandyck of the Lamport and Holt line. Wiser choice of a steamship could not have been made. Each member was furnished with ideal accommodations with every facility for entertainment and enjoyment during the cruise.

We left New York February, 10, 1923, about noon, in the midst of a snow storm. By the next day the climate had changed and one could note the warmth from the Gulf Stream. By the third day we were dressed in summer clothing and went in swimming.

Our first stop was Havana, reaching that port about 6 A. M. A committee of surgeons from Havana visited our ship and invited us to shore to visit the hospitals and points of interest. We were tendered a reception in that city by President Senor Dr. Alfredo Zayas at his palace. He was assisted by his wife and the newly appointed United States Ambassador Gen. Enoch H. Crowder. We were in this port only twenty-four hours.

February 18th, we reached Cristobal. As soon as our ship docked, a committee of surgeons came aboard inviting us to visit the Canal Zone and Panama. At eight thirty we took the train at Colon for the fifty mile trip across the Isthmus. The first stop was at Gatun where we inspected the great lock and dam—the most wonderful construction one can imagine. A large British ship was just going through the lock and we had the privilege of seeing her pass through. We crossed the Canal on the bridge of the gates and passed over the breast of the dam which makes the Gatun Lake by damming up the Chagres river. This floods a great part of the valley and backs up against the continental divide. The lake surface is 85 feet above sea level. The dam is 8,400 feet long, one-half mile wide at the base and slopes gently to a width of 100 feet at the top and 105 feet above sea level. At the center of the dam is a wonderful spillway of 14 gates. The surface of the dam has been planted with grass and shrubbery. On the east wing is a nine hole golf course. All along we could see beautiful tropical flowers. We spent about one hour at Gatun Lock, then boarded the

train for Gamboa at the northern end of the cut. The railroad runs around the edge of Gatun Lake. We could see how the water had inundated the swamp, making the huge lake of fresh water from which the cities of Colon and Gamboa get their water supply.

At Gamboa we took a steamboat and passed through the cut as far as Pedro Miguel. The channel of the canal makes a number of turns and is about 300 feet wide in the cut, 42 feet deep in the Atlantic sea level section, 45 feet deep in the lake section including the cut, 45 feet at Pacific sea level. Beside the cut at several places was shown how the hillside had slid into the Canal, by dredges constantly at work. There are buoys and lights all along the channel so that a boat is as safely conveyed through by night as by day.

At Pedro Miguel we entrained for Panama and were driven to Hotel Tivoli for luncheon. This hotel is built upon a hill and is approached through a beautiful street on each side of which were wonderful royal palms, roses and other flowers of brilliant reds and purples.

A most impressive ceremony during the trip took place at Panama when the stone laying ceremonies at the General Gorgas Memorial occurred.

This ceremony took place Sunday afternoon in the presence of a throng of citizens of the Panama Republic and upon a site facing the Pacific Ocean. Upon this site will be built the buildings for the Institute of Tropical Medicine as a memorial to Gen. Gorgas, commemorating the wonderful work he did in making it possible to build this great Canal. The ceremony was presided over by President Senor Dr. Belisario Poiras, who delivered an address suitable to the occasion.

After this we visited the wonderful Ancon Hospital, one of the oldest landmarks of the Canal Zone. It came into existence in 1883 and has been intimately connected in building the canal under both the French and American regime. It is the hospital where nearly all the military and civil people are sent when in need of hospital treatment. Many persons from the Central and South American Republics seek admission for treatment, so its renown is more than local. One of the surgeons from Cartagena stated they usually sent to Ancon such operations as gastro-enterostomies and that type. The old buildings were of

frame construction, of pavilion type, tile roofing and unscreened.

It may be interesting to recall that many cases of minor injury and illnesses admitted to the hospital developed yellow fever within a short time after admittance. A large percentage died. The records show that in six years, 1,200 patients died in the old yellow fever ward known as St. Charles. It is believed that more people died in this ward from yellow fever than in any other building now standing in the world. It is strange that a noble act and love for things beautiful should result so disastrously to those for whom it was designed to benefit, as will be demonstrated by the following incident.

The Sister Superior of Ancon Hospital was a lover of flowers and attempted to make the grounds a beautiful garden of plant life. There exists on the Isthmus an ant known as the "umbrella" ant, so called because it carries bits of leaves umbrella fashion. To prevent destruction of the plants by these ants the flowers were surrounded by a low concrete wall with a narrow, shallow gutter filled with water over which the ants could not navigate. These pools of fresh water were ideal places for breeding the yellow fever mosquito, so that the patients admitted to the hospital located in the beautiful flower garden became victims of these disease producing mosquitoes.

Americans took charge of the Ancon Hospital in May 1914. Since then the United States Government has built extremely beautiful buildings, the most attractive group from an architectural point of view being the one comprising the new Ancon Hospital supplanting the original wooden buildings. The style of architecture is the modified Italian renaissance; plan adopted is the pavilion, structure reinforced concrete, all roofs are covered with red tile, inside walls and ceilings concrete, plaster painted with a washable paint. Porches and outside openings are copper screened against insects. The floors are six inch red tile in the wards. The four operating rooms are white hexagonal tile. Laboratory and diet kitchens are on each ward, some kitchenettes and small dining rooms for ambulatory patients.

The rates for the private rooms are \$7.50 per day; ward rates \$5.00 per day. They can accommodate 1,200 patients. However at this time there were only 350.

Our visit was about 9 P. M. I could not imagine such quiet in a hospital. All lights out, nurses on duty going about their work with flashlights. At the present time there are 75 graduate nurses employed. They have eight-hour duty. There are separate wards for the different colored peoples, yellow, black and white. Each ward is separate in every respect as to baths, laboratories, diet kitchens, etc. Ancon Hospital is by far the best one we saw in South America.

At Caracas we visited the hospital connected with the Medical College. The building is one story and built upon the pavilion plan, painted yellow and blue with red tile roof. We entered the driveway, passing through the large iron gate into a court yard, and from here into the administrative building, offices, etc. Leading off from this court yard we went from one ward to the other through a covered corridor with sides open. On either side are beautiful tropical plants and flowers of all kinds. The open corridors are about 100 feet long and lead to the various wards.

We first visited the gynecological ward which was well filled, then the obstetrical and surgical wards. The beds were pretty and white, wards clean, painted light green, with tiled floors. The sterilization is done by high pressure steam boiler. They use up-to-date sterilization equipment of the Swiss type. A group of medical students accompanied us through the building and were quite an intelligent looking bunch of young men. The operating room and some of the wards were screened but the majority of the wards were not. We saw no female trained nurses.

The hospital at Trinidad is located in beautiful grounds. The exterior of the building is most attractive, two stories high and built upon the same pavilion plan. The wards are very long, 80 x 40 feet, and divided by a railing 2½ feet high going across the room. This divides the medical and surgical wards. Everything is very clean but old fashioned. The operating room is the only part of the building screened. Since it is nice and warm it is not necessary to have window glass so every thing is wide open, except the operating room. The equipment is only fair. There is a wonderful X-ray building, but no X-ray equipment at all.

An English nurse is acting superintendent and under her native black women, rather

elderly, at least 40 or 50 years of age, are caring for the patients. The food served was a horrible messy looking porridge or soup. The beds in the wards were very far apart and clean. The most attractive ward was the children's. Here the cribs were screened by mosquito netting. The obstetrical wards joined the children's, adjoining this is a nice, fairly well-equipped delivery room. Off from this was the typhoid ward well filled, there being considerable of this disease present. One hundred feet away was the tubercular ward, holding about 50 patients.

The most beautiful place we visited was Rio de Janeiro. The setting God gave to this city to make it beautiful cannot be described; it must be seen to be appreciated. The people of Rio are cordial. It is more of a residential than a business center, though there is a great deal of shipping from this point. Ships from all over the world can be seen in the harbor.

The first medical institute visited was the Oliver Cruise Institute for Tropical Medicine. We visited the laboratory and Museum of this Institute where we were shown the beetle, eggs and larvae that caused Chagas Disease. The Oliver Cruise Institute is about eight miles in the country. The buildings are handsome and well arranged. Practically all the laboratory work for the general hospitals of Rio is done here, specimens being sent there each day.

From here we visited the Misera Cordio, Rio's largest municipal hospital of 1,500 beds. The building like all large hospital buildings in South America is built on the pavilion plan with corridors on each side and large openings into these corridors but no screens. Some of the windows have window lights with here and there blue glass. The purpose of this blue glass was to keep out the flies. They claim a fly will not go by such a light, though the wards were full of flies. I counted as many as ten on one bed. We were shown through by an old French doctor and an English nurse. The hospital is under St. Vincent's Sisterhood. The wards were clean and well filled. In the surgical ward we saw some interesting work—one Albee graft for Potts' Disease, of three months' duration, which had healed by primary union, with good result; a number of interesting fracture and abdominal cases. The medical wards were full of patients. They are given much medicine which is placed by the patient's bedside and they are allowed to take it as they desire. The wards are clean and fairly well

cared for. Have no female nurses in charge. The female patients are cared for by maids; males by orderlies.

The laboratories are well fitted though most of the work is sent to Oliver Cruise Institute. The X-ray equipment is elaborate and of modern type. The records are well kept. They use the card index system. The bedside records are quite full and well kept. The kitchen is unusually good with modern ranges and equipment. The hydrotherapy plant was most complete, being in a separate building. There are two pools for sea water baths, (water being piped at least one-half mile from the bay), electric, turkish and shower baths, etc. The patients are all sent to this building for hydrotherapy treatment, even douches.

The San Francisco Hospital of 250 beds located in a beautiful part of the city has been recently remodeled. It looks more like an American hospital than any we saw. The wards and operating rooms are screened. It is in charge of five American nurses who are attempting to start a training school employing native women, though the better class of women do not take up training as they consider it a menial occupation. Most of the equipment of the operating room is of French design as the Portuguese lean strongly toward the French. Many of the doctors go there to study. We saw the chief surgeon, Dr. Vas, do an appendectomy and an hysterectomy, both of which were skilfully and well done. Anesthetic used was ether. Our impression of the San Francisco hospital was quite pleasing.

One of the visiting nurses, Miss Dawson of Canada, employed by the Rockefeller Institute, took us to the leprosy hospital. We saw in all South American cities leprosy hospitals or colonies. This one in Rio is located close to the bay. The building is quite large and handsomely constructed, every thing tiled and white paint. Where there are any window panes they are of blue glass. There were about 90 patients in the hospital at this time, in all stages of the disease. One poor fellow had lost both legs and walked on boots turned backward, i. e., the toe of the boot; he was also blind in both eyes. They went about the ward at will, a number of them blind, others with legs, arms and fingers gone, and others with sores all over their faces and hands. The patients would follow us about and were very curious. Evidently they had few visitors.

The hospital was well cared for, every thing being scrupulously clean, though we saw no places of amusement. Flowers were planted in the patios, shower and tub baths in any quantity. In the dining room for the blind was a table built in the shape of an X so they could get their food more easily. One patient who was confined to bed had been in the hospital for 24 years.

We visited in Santos the Santo Casa de Misera Cordio hospital. Connected with this hospital is a cathedral founded in 1543 which is still a part of the building. Dr. Gomahey showed us through and was very courteous. The wards are large, holding about 50 patients, and are fairly well furnished. The beds are of white enamel. Spread over the foot of each bed is a red blanket. There were patients in the beds, many on pallets beside the beds and on the floors in the corridors. Many of them had uncovered cuspidors by their sides, literally covered with flies. The medicines were in glasses or bottles by their sides and could be taken by the patients at will. There were medical and surgical wards, men and women, of course, separate; whites and blacks in the same wards. The hospital is managed by a sisterhood.

There are two operating rooms well equipped with modern sterilizing apparatus, one French make, the other Kny-Scherer. There was quite a variety of instruments, bone and laparotomy especially. The X-ray laboratory was equipped with German transformer, fluoroscope, high frequency, violet rays and all modern electrical equipment. The kitchen was modern in every way. Floors and side walls were of tile; there were large ranges and cooking utensils. Every place was clean, the room having been just flushed out with water. Lying on the tables were about 100 freshly dressed chickens literally covered with flies. Close by was a fine incinerator and steam sterilizer for sterilizing bedding.

On the fifth floor of the hospital, which is up against a high hill, is the tubercular ward which accomodates about 100 patients and is separate in every way from the other wards. This has been recently built and is entirely modern especially as to ventilation. The doors and windows open out on to a veranda, from which one gets a beautiful view of the city below and the harbor with the Santos mountains in the distance. We were taken up to the ward in an elevator which refused to work

when we came down, so we walked down the stairs on the side of the hill through a court yard. Every where tropical plants, flowers and trees, making quite a pretty picture.

The greatest need in the hospital is the female trained nurse. The patients receive practically no nursing and after the operations get but very little care. The post-operative patients are never given enemata or sedatives. Patients are nauseated and have gas distention and are uncomfortable to a degree. I am sure they must lose numbers of patients they would not if they were given proper treatment. In this hospital the private wards were very few and unattractive.

I do not think South America can equal North America in surgery or medicine but in research work they are ahead of us, in some instances doing wonders. We visited the snake farm at Sao Paulo which is a most interesting place. The laboratory is quite a handsome building and has all modern equipment. The stables contain quite a number of horses to be used for the laboratories. A number of men are employed in this institution. There is an enclosure where they keep the snakes. We were told that snakes would not multiply in captivity, and they live but a short while, as they will not eat. It requires about 1,000 snakes a month for this work. These they obtain from the natives who trap them and bring them to the institute and sell them. In Brazil there are about seven different varieties of rattlers beside other kinds of poisonous snakes. The keeper goes among them fearlessly and does not hesitate to pick them up at will. He has a stick about three feet long with a piece of metal on the end at right angles. This he places back of the snake's head holding him on the ground, then reaches down with the other hand catching him by the neck. The virus is obtained by holding a glass dish in front of the snake; when he strikes, he spits out the virus in the dish.

The efficiency of the serum was demonstrated to us. Some of the snake's venom was injected into a pigeon which died in one minute. Another pigeon was given a dose of the serum, then some of the virus that was used in the other pigeon and he was not even made sick. The person who has been bitten by a snake should have the serum as soon after being bitten as possible. Whenever any one goes into the interior he is advised to carry the serum with him.

The prettiest and best equipped private hospital we visited was the Sanatorium Castro, Buenos Aires, owned by Dr. Castro. The superintendent, an elderly gentleman, and the chief nurse, a Sister, showed us through. The building cost \$250,000.00, is attractively furnished and fitted up with the latest equipment in all departments, X-ray, other laboratories, operating room, etc. The rooms were en suite consisting of a large room with two beds, small sitting room and private bath, all very well furnished. In the larger room one bed is for the patient, the other for a member of his family who usually accompanies the patient to the hospital and assists in nursing and caring for him, for, as in most of the hospitals in South America, you do not see the trained nurse. The cost for such a room is \$18.00 per day. We did not see any operations at this time.

At Alvear Hospital, one of the largest municipal hospitals, we saw a clinic conducted by Drs. Sole, Propelo, Valdez and San Martin. This was most interesting.

The majority of the surgeons in Buenos Aires use spinal anesthesia.

In the large operating room of Alvear Hospital, which is on the first floor, we saw three operations going on at the same time; one for hydatid cyst of the liver, one for duodenal ulcer, and the third for amputation of the leg just above the knee. In none of these cases was spinal anesthesia satisfactory, as in each instance the patient had to be given chloroform to complete the operation. The operations were done skilfully and quite rapidly. There were no trained nurses to assist and each operator was assisted by a doctor who was an interne. The surgeons prepare the patients and instruments. The patient is brought to the operating room shaved, but there is no other preparation. They use iodine as we in North America do in preparing the site for operation. The surgeons use very few instruments. Solutions and dressings are handed him by an orderly who seems very proficient. This day we saw four operations for hydatid cysts, two of the liver, one of the lung, and one of the transverse colon. This disease seems to be very prevalent in Argentine.

One of the most skilful surgeons we had the pleasure of meeting was Dr. Artemeo Zeno, professor of surgery at Rosario Medical College. Dr. Zeno speaks English as well as

French quite well. Besides being an M. D. he has a B. L. degree.

The Medical College is well built and wonderfully well equipped, the building being only two years old. They have every facility for teaching medicine. The anatomical laboratories, not only in this school but in others we visited, are very interesting, as they teach regional anatomy by transverse and longitudinal sections of the body. Specimens are kept in large glass jars. In some instances bodies of adults are thus preserved. The specimens are wonderfully well prepared.

All medical schools have a six years' course but, owing to the number of holidays, which is more than fifty a year, the total number of school days is no more than our four years' course. They have adopted the clinical method of teaching. For this purpose each college has connected with it a large hospital.

In Montevideo we saw some very interesting work in block anesthesia which was most satisfactory. We saw an operation for hydatid cyst of the lung. The operation was done in two stages, a portion of the rib over the site of the cyst was excised and, as the pleura had not adhered to the lung at this part, the surgeon soaked a piece of gauze in iodine, then squeezed it out as dry as he could, packed it into the wound upon the lung. This was to be left in ten days, thus producing adhesion between the lung and pleura. After this time the cyst was to be aspirated.

In Uruguay we saw a number of cases of goiter. Quite a number were operated upon while others were being treated by administering blood obtained from sheep which had had their thyroid glands removed three months. They were bled and the blood mixed with equal parts of glycerine, which is a preservative and will keep in stock for several weeks. Two drams of this is given three times a day. The surgeons claim many cases are thus cured without operations.

In each country we visited the medical profession extended us cordial greeting and their hospitality was genuine. Some of these surgeons have visited the American clinics but most of them attend the French and German ones.

Quite a delightful feature of the cruise was the scientific meetings held aboard the ship during our voyage. Every other day for an hour interesting papers were presented. These

papers and the discussions following were very instructive and beneficial.

The visit could not have been better planned or more profitably conducted. It was certainly delightful.

### THE FAMILY PHYSICIAN IN THE PUBLIC HEALTH PROGRAM.\*

By MARY EVELYN BRYDON, M. D., Richmond, Va.  
Director Child Welfare, Va. State Board of Health.

I have come before you, the family physicians of Virginia, to report what your Bureau of Child Welfare has accomplished during the past five years since it began work under the State Board of Health; to bespeak your interest and sympathetic co-operation with the program which is going on in the State; and to get your assistance in perfecting our future plans.

You have no doubt many times in the past few years been consulted by parents accompanied by children bearing in their hands printed notices which had called the parents' attention to some physical defect in the child, discovered by a teacher in the schools, or by a clinician at a community conference of parents of infants and preschool children. Did you give a passing thought to the agencies which caused these parents to consult you?

One of these active agents so interested in the health of school children is the teacher. It is her duty to co-ordinate the teaching of personal hygiene and community health with instruction in other subjects, and it is primarily to the interests of this work that she be fully cognizant of the present status of the health of her pupils. In order to acquire this knowledge at first hand she has been intrusted with with such part of the annual physical inspection of the pupils as lies within her power to perform.

The enrollment of school children last year in the rural schools of the one hundred counties of Virginia was 356,153. Of these 272,688 were inspected by their teachers. The physical defects thus brought to light were reported to the division superintendents who in turn reported to the State Board of Education. By a careful study of the figures you will note that approximately 60% of the rural school children were found to have some defect obvious enough to be detected by a lay observer.

The West Law, passed in 1918, resulted in establishing school inspection in Virginia and provided for the following points:

*First:* Employment of school nurses;

*Second:* Employment of physical education directors;

*Third:* Training of teachers in physical inspection, school hygiene and physical education;

*Fourth:* Physical inspection of school children.

Prior to 1918 little had been done in the State for child welfare outside of a few cities and a few counties. Such cities as were trying out medical inspection of schools were employing a few physicians on part time, and a few graduate nurses with little public health training, to demonstrate this health work. In the counties little other than a few surveys and demonstrations had been undertaken.

The West Law required that all of its provisions to be undertaken by either the State Board of Health or the State Board of Education should have the approval of the other. The State Board of Health was the first to take the initiative and, although the Act carried no appropriation, straightway employed a physician to undertake the task of carrying out the provisions of the Law.

The training of teachers in health education received attention first. During each of the first two years after the passage of this law, five lectures were given in the summer schools and in as many of the winter normal schools and colleges as the one person employed could visit. These lectures, ten in number, were made into a course, and a correspondence course of twelve lessons was offered by the State Board of Health. Before another year passed, a demand had arisen for this health educational training to be put on a college basis, and the course was raised to a minimum requirement of thirty-six hours in the normal schools and colleges. This course in Health and Physical Education was given last year in eight normal schools and seventeen accredited colleges of the state, and 1,928 students received this instruction as a necessary preparation for entering the teaching profession in Virginia.

The course itself, both for the normal schools and for the Correspondence Course, was most carefully worked out. The several parts were submitted to specialists in the various subjects

\*Read by title at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

and all carefully supervised by both State Boards.

The course consists of three main divisions:

1. Physical defects and their control;
2. Communicable diseases and their control;
3. Health Education which includes:

First Aid and Prevention of Accidents,  
Care of School Plant,  
Personal Hygiene,  
Physical Training,  
Mental Hygiene.

Side by side with the development of the teachers' training courses in Health and Physical Education in the normal schools and colleges, there developed in the state school system the desire for putting into effect the health training thus received. At first the sentiment was toward the employment of school nurses and doctors to do this part of the work, but the recruiting of nurses was too slow and the scarcity of doctors brought the realization that, if children were to have their defects discovered and corrected, the teachers would have to do most of the inspection. Furthermore, it was soon noted by the teachers themselves that while the inspection devolving upon them gave them more work in the school, the results were gratifying in that they became not only more conversant with the physical side of the children themselves, but such inspection as they were able to do formed a basis upon which they could build their health instruction in the schoolroom. This plan was also productive of getting more parents interested in the health of their children and in having children's defects corrected. One of the outstanding criticisms that this part of our work has had to face has been the confusion in the minds of the medical profession, as well as in the minds of the educational authorities, in regard to the definition of the words "physical inspection."

When we decided to ask the co-operation of the teaching profession, it devolved upon us to differentiate carefully between the terms "medical examination" and "physical inspection." Teachers, physicians and other well informed people might protest that teachers as a class are not able to make physical inspections with any degree of accuracy. That is indisputable if by the term "physical inspection" is meant such an examination as would be made by a trained physician; but it does not

require years of training in medicine to determine whether a child's sight is obviously defective or his hearing impaired. An ordinarily intelligent person can determine whether a child is a mouth or nose breather, and knows that if exclusively the former, there is something wrong, requiring medical attention. The distinction that is made between "inspection" and "examination" has been illustrated by the simile of a person buying a desk. The prospective purchaser looks the desk over, feels it to see if it is well finished, opens the drawers to see if they run smoothly, pushes against it to see if the joints are solid, etc. That is inspection. If it is found that one of the drawers will not open properly, or that there is a rough place on the surface that will interfere with writing, he refuses to buy it until it has been sent to an expert cabinet-maker. This expert "examines" the desk and determines the cause of the defects and institutes the proper measures for repairs.

The ideal plan would be for each child to have annually a complete medical examination, given by his family physician. If this could be done, the work of the teacher in the schoolroom would be a sinecure as far as inspections are concerned. Her work under those conditions would be directed solely towards training the child in maintaining his health by inculcating health habits. But as we appreciate the present impossibility of realizing this object, we utilize the teacher for a simple inspection in the schoolroom. Then, when those defects which are so apparent that they may easily be recognized are discovered, the parents are notified of the necessity of taking the children to their family physician who is thus enabled to "examine" them and effect the necessary corrections.

The inspection consisted from the first of only a few essential points. The teacher is required to weigh and measure each child, determine if he is underweight by comparison of his present weight with the table printed in the manual of instruction; test his vision by the eye chart supplied for the purpose; test his hearing by the conversational voice at twenty feet, and look at his teeth. Teachers are not required to look at tonsils. This is the work of the school nurse. Not only is complete instruction for making the inspection given the teacher during her training, but full instructions are sent out yearly from the State

Board of Health office, and all county teachers' institutes have been visited each year where it is possible to send a speaker on this subject. After doing the inspection, the teacher records on proper cards her findings of each child. These she keeps as a record for the school. She is also furnished with the special form—which you have seen—on which she records the defects found, and these she sends to the parents of her respective pupils.

There are two admitted difficulties in the way of physical inspection by the teachers. One is the suspicious attitude of the parents; the other is the unwillingness of the teacher to undertake the work. Both of these difficulties are due to misapprehension of the facts.

It is natural that parents, like other people, will not believe that a layman can do the work of a professional; but the answer to that objection is: We do not ask a layman to do professional work. Our physical inspection is so simple that anyone intelligent enough to be a teacher will be sufficiently intelligent to make the required inspections.

The other objection also vanishes with a comprehension of the work and its relation to the ordinary duties of the teacher. Many teachers have been distinctly unwilling to undertake this new work; but few, if any, have remained unwilling after they have been made to understand how they can aid in the physical well-being of their pupils, and the extent to which health and strength contribute to mental development.

We do not claim that our teachers are inerrable. It may be that some of them regard this health work as an auxiliary of education and not as a part of it, and that others are too scrupulous in making inspections. It may be that an occasional teacher will suggest remedies for defects, although they are cautioned against doing so. It may be that sometimes a teacher may make the mistake of sending a child to the doctor for treatment when treatment is unnecessary. But these exceptional instances do not weigh against the mass of favorable experience.

We are now working toward an end that will, if reached, reduce still further the demands upon the teacher. We are striving to have all children made physically fit before they enter school; and we hope for the day when the majority of the patrons of our public

schools will have their children receive medical examinations regularly.

In some of the counties in Virginia plans are already being worked out by the health authorities to provide for the inspection of children of preschool age and the correction of defects during the summer previous to the opening of school.

Our fundamental proposition is that all authority over the class-room should be vested in the teacher, and that to introduce a doctor or nurse as a temporary authority is subversive of that proposition and fundamentally unwise.

We have chosen to consider the child as a unit, neglecting no element of his personality. We attempt to provide for his normal development, physically, mentally, morally and spiritually. We try to keep constantly in mind the relations of these factors in development; and we believe that the child's guidance, other than that given at home or by the church, should be left, so far as possible with one person. If that be a proper conclusion, the obvious director must be a teacher.

In 1919-20, 31,161 children were inspected in fifty counties; in 1920-21, 127,187 children were inspected in seventy-seven counties; in 1921-22, 193,099 children were inspected in ninety-two counties; and in 1922-23, 272,688 children were inspected in one hundred counties. You will note that there has been steady improvement in the number of children inspected as the years have passed until this past year. Every county and every city reported some inspection.

The West Law required that all of its provisions undertaken by either the State Board of Health or the State Board of Education should have the approval of the other. This requirement has been strictly adhered to from the first.

This work is now in charge jointly of our State School Nurse and the State Rural Health Supervisor, the latter being employed jointly by the two state departments. As we see it, Health and Physical Education does not end with the detection of defects. Not only must the defects be corrected but the child must be taught the personal application of health in the school-room.

This is being done through

1. A daily inspection by the teacher for symptoms of common diseases as well as for cleanliness of person and teeth;

2. Hygiene instruction provided for in the curriculum;

3. Physical Training.

The direct follow-up work in relation to the physical inspection of school children is done by the public health nurses of whom we have forty in thirty-four out of one hundred counties in the state. However, the teachers in innumerable instances where they have no nurses have interested themselves in getting this part of the work done, realizing as they do the tremendous advantage in having physically fit children to teach.

The correction of defects with which the Child Welfare Bureau has been directly interested has been developed mainly through dental clinics. One of the results of physical inspection which first attracted public attention was the appalling number of dental defects. The Bureau, having in the second year of its organization received an appropriation for the school work, employed a dentist on full time to develop this part of the work. Little headway was made at first but after getting the co-operation of the State Dental Association and demonstrating the need for the correction of dental defects to the school authorities in the rural districts, school dental clinics have become part of the health propaganda in a large number of our counties as well as in a few of the larger cities. Last year our state dentist employed for the work on full time ten dentists; on part time one dentist. In these clinics 21,349 children obtained an opportunity to have their mouths put in order.

The reports that have been received from twenty-nine county nurses show that 22,913 children were corrected last year as a direct result of the physical inspections by school teachers. You have probably seen all these children who required treatment other than dental, because the letter on the back of the notice to parents directed them to go to their family physicians or dentists for examination and treatment.

Little has been done for those children found to be underweight of whom there are 50,000. This year, however, demonstrations in nutritional classes are contemplated and much benefit is hoped to accrue for this service.

This gives you very briefly an outline of the clinics and other correctional methods with which the Child Welfare Bureau has been con-

cerned during these past few years following the physical inspection by teachers. But the clinics and the other correctional measures put on by the county public health nurse have been serving as temporary measures while the people, the public, the school authorities, the physicians, and the parents were slowly awakening to the real policy that underlies the facts in the case. The theory that lies at the foundation of all these health measures consists of certain fundamental principles:

*First:* It is the parents who should assume the whole responsibility for the health of their children;

*Second:* The family physician is the only trained authority on this subject accessible to them and he should have constant supervision over the health of the whole family, but particularly over the pregnant mothers, infants and preschool children;

*Third:* No parent should allow a child to enter school any year of his school life until his physical fitness to receive his education has been ascertained by his family physician.

It is therefore necessary that both the family physician and the parents understand the relationship that they bear to each other and that the terms of this relationship is not a matter of dollars and cents, important as that is from an economic standpoint, but a matter of the health of little children; the health and efficiency of the future citizens of Virginia.

To bring this very self evident fact to the attention of both the family physician and the parents, an added feature in the program was developed. This was made possible by the acceptance by the Legislature in 1922 of the Sheppard-Towner Act providing for the promotion of Maternity and Infancy Welfare. This soon developed the idea in the minds of those charged with carrying on this phase of health work that all work dealing with the health of school children should start with the child in prenatal life. To this end activities were directed towards reducing the infant and maternal death rate and towards the establishment of health ideals among parents and guardians of children.

It is estimated that 33.4 per cent of the 70,000 births in Virginia are delivered by midwives. Fully two-thirds of the more than 5,500 midwives in the state are colored and are in the main ignorant, dirty and superstitious. To eliminate the worst, to train and

supervise the best, and gradually to raise the standard, a supervisor of midwife education was employed and, in the one year that the work has been organized, forty-six classes have been held in twenty-seven counties with an attendance of 630 midwives. Most of them are illiterate, therefore the training they can receive must necessarily be simple. They are taught first of all the four things the State requires the midwife to do before she can charge for her services:

1. Secure a Midwife Permit at once from the local registrar and sign the Pledge Card;
2. Obey the Safety Rules on the back of the Permit;
3. Register every birth before ten days;
4. Put two drops of one per cent nitrate of silver solution in the eyes immediately after birth.

They are also taught the fundamentals of cleanliness and whatever obstetrical information they can assimilate.

We realize the need for intensive prenatal work, but this Bureau has not yet undertaken that phase of the work, except that a Correspondence Course for Mothers is being established by which it is hoped mothers may be trained in the care of themselves before and after childbirth, thus giving the child a fair start in life. Recently, the physicians of the state were sent a general outline of this course together with a copy of the first lesson and a statement apprising them of the purposes of the course. Those of you who looked over this material, I am sure, received the idea that such a course will go far towards eliminating the midwife and, by training the mothers in the fundamental principles of personal health, the physicians will have a more intelligent group of mothers to care for and the maternal death rate will be materially lessened.

Even before this Bureau received Federal Aid for promoting maternity and infancy welfare, it was felt that there was a crying need all over the state for bringing to the attention of the parents their own responsibility in the prevention of disease, the correction of defects and the training of infants and preschool children in proper health habits. Therefore, to demonstrate this point, child welfare conferences have been conducted in many communities. During the past year 1,877 children under six were given medical examinations. Parents were asked to bring well babies to the

conference and no child was examined except in the presence of the mother or guardian. Every mother had to give the name of her family doctor and the individual records of the examination were sent as far as possible to their physicians. The records were explained to the parents and they were advised to visit their family physicians regularly. Thus the doctor may be able to correct defects and to give advice in regard to keeping the child in a physically fit condition.

The reports of nurses and others doing follow-up work indicate that much interest has been aroused by these clinics and that more attention is being given to the health of the child under school age.

It is, therefore, to the family physician that the Bureau of Child Welfare turns for sympathetic co-operation in the reduction of the maternal and infant death rate, in preventing sickness among infants and preschool children, and in maintaining the child's health. Every family with children should be under the supervision of an all-around practising physician. It is to this family physician that the mother is being directed for advice in regard to herself and her children before they get sick.

Child hygiene work, as thus seen, is a big problem and one with a diversity of interests. Our plan is still in process of evolution as are all human efforts worth while. There are difficulties to be overcome but we are optimistic about these and are looking forward to the realization of our ultimate aim: the day when every mother assumes the responsibility of the health of her family under the guidance of her family physician and every school child—white and colored, city and country—in the State of Virginia is in a physically fit condition.

1110 Capitol Street.

### INSULIN IN DIABETES MELLITUS.\*

By ALEXANDER G. BROWN, Jr., A. B., M. D., Richmond, Va.  
Associate Professor of Medicine, Medical College of Virginia.  
Internist, Stuart Circle Hospital.

Insulin (Lilly) has been released. This extract of the islets of Langerhans in the pancreas has been tried out, and the clinical observations made upon its action in the human diabetic have been summarized and have been recently placed before the profession. For a year, now, this extract has been subjected to

\*Read before Richmond Academy of Medicine and Surgery, May 8th, 1923.

careful testing in the hands of selected clinicians. A few clinics in this country and Canada, under the general control, by agreement with the Lilly Research Laboratories, Eli Lilly and Company, have been supplied weekly with Insulin. The data obtained, the results secured, conclusions reached, have been collected. Each clinic is now permitted to place the findings of the investigation before medical associations and to publish the same for general dissemination.

It is needless to commend the Toronto group and its collaborating Research Laboratory of Eli Lilly and Company for the high ground they have taken in this scientific inquiry. Their caution and wisdom in handling this new product, which so immediately gripped the public mind and which received such widespread broad-casting in the lay press, met every requirement of the highest professional standards in scientific procedure.

Insulin is an aqueous solution of the active principle from the islets of Langerhans in the pancreas. The story of its discovery may be briefly told. Dr. F. G. Banting and Mr. C. H. Best, a second year medical student, of the Department of Physiology in the University of Toronto, under the general guidance of Prof. J. J. R. Macleod of that University, with other collaborators, during the year 1920-1921, evolved this new pancreatic product. The hypothesis upon which the investigation took shape came from the thought in Banting's mind that, as the acini but not the islets of Langerhans degenerated after the ligation of the pancreatic duct, an extract of the islets may be obtained. This ground-thought started the train of investigations. The ligation of the pancreatic duct of a series of dogs was performed. After ten weeks the pancreas was taken out. Healthy and unimpaired islands were found, although the acini were destroyed. From these, the extract was made. On July 30th, 1921, the experiments with the extract obtained were begun. Four cubic centimeters of the extract were injected intravenously in a partially depancreatized dog (blood-sugar before injection was 0.20 per cent): (a) one hour later it was 0.12 per cent; (b) two hours after the injection of the extract, 20 grams of a stomach tube. At the end of five hours the animal excreted only 0.2 grams, whereas the same depancreatized animal, prior to the inglu-  
cose was introduced in the stomach, through

jection of pancreatic extract, had in the same period of time excreted 16 grams following the use of 25 grams of glucose. This, together with other confirmatory experiments, pointed out rather clearly, that the extract exercised a reducing influence upon the percentage of sugar in the blood and consequently upon the amount excreted in the urine.

Banting and Best performed a further series of experiments with the resulting conclusions: (1) that extract from the whole pancreas of a normal animal would reduce blood-sugar, but that it was weaker; (2) that boiling made the extract useless; (3) that extract was destroyed by pancreatic secretion itself, and (4) that introduction of it in the rectum was attended by no effect on blood-sugar.

A great advance was made in quantity production by the discovery, in November 1921, that pancreas of the fetal calf, of less than five months' development, possessed no secretory function, but possessed islands of Langerhans with interal secretion. From the fetal calf pancreas, then, large quantities of pancreatic extract were obtained, without the destruction of the gland itself; and this was used subcutaneously rather than intravenously in reducing the blood-sugar of a diabetic dog from 0.30 per cent to normal and in rendering the urine sugar free. The subcutaneous method was found to be slower in getting-in, but its effect was much more prolonged, in its reducing effect.

The further advance in the development of insulin was a discovery that 0.7 per cent solution of tricresol did not harmfully affect the active principle of the extract, and that the active principle was obtainable from the fresh tissue of the pancreas with 25% alcohol. By this method it was found possible to get the active principle from the entire gland. This extract was potent in its effect in reducing the blood-sugar of a diabetic dog from 0.35 per cent to 0.08 per cent in three hours, making the urine sugar free.

The next step in the development of insulin was the production of a soluble extract which could be administered subcutaneously without fear of producing a local or systemic reaction. By the assistance of Professor J. B. Collip such a potent soluble extract was produced. This was done by eliminating to a minimum protein, lipoid, alcoholic soluble constituents, and there was left a product free of salt, which

was isotonic and capable of being passed, for sterilization purposes, through a Berkefeld filter. This extract was Insulin.

It was necessary to find out the potencies and dangers of this new agent. It was important also to observe any by or ill effects of the potent principle. So insulin was tested on normal rabbits. It was tested on rabbits with hyperglycemia, caused, (a) by puncture of the floor of the fourth ventricle, (b) by the administration of injections of adrenalin and (c) by asphyxia.

(a) The normal rabbit, with blood-sugar of 0.167 per cent, was given 4 c.c. of the pancreatic extract. In thirty minutes blood sugar had fallen to 0.137 per cent; in two hours to 0.065 per cent. In three and a half hours the animal showed symptoms of rapid breathing, dilatation of pupils, protrusion of eye balls and convulsive movements, the animal tossing itself from side to side. These convulsive seizures occurred about every fifteen minutes. Fifty minutes after convulsions began, the blood-sugar was found to be 0.028 per cent. At this point in the experiment the animal was injected subcutaneously with four and a half grams of pure dextrose in a one per cent solution. In six minutes, the rabbit improved; in 10 minutes it was sitting up and hopping around; next day the animal was hyperexcitable; in four days, although taking food, normally died of convulsions. Post-mortem of the rabbit showed the pancreas was atrophied.

(b) In the next experiment 5 c.c. of the extract was administered subcutaneously to an animal with a blood sugar of 0.129 per cent. In forty-five minutes the blood sugar was 0.077 per cent. In three and a half hours, the animal showed similar signs as presented in the previous experiment. Five grams of dextrose in 30 c.c. of water was subcutaneously injected, and in five minutes the rabbit was apparently restored to normal, although the blood sugar had fallen to 0.056 per cent. The blood sugar rose for a short time and then declined, and in three hours and fifteen minutes, the animal was in convulsions.

From these experiments it was concluded that the level of sugar in the blood at about 0.045 per cent in 1 kilogram rabbit was always attended by convulsions and this phenomenon was taken as a unit-measure of insulin. Rabbits were also rendered hyperglycemic by

puncturing of the floor of the fourth ventricle. In five perfectly normal rabbits hyperglycemia was produced by this method and there resulted a remarkable increase of blood sugar; in one case 0.46 per cent was attained, while two rabbits, treated in like manner, previously injected by suitable amounts of insulin, showed no increase of blood sugar. Also, by the administration of one c.c. of 1-1000 solution of adrenalin a marked increase of blood sugar was produced. But similar injections of adrenalin, in animals previously treated with insulin, showed blood sugar below normal and in cases treated simultaneously blood sugar remained about the same or slightly above normal.

(c) In asphyxia experiments the animals were gassed; two rabbits were subjected to 45 minutes of gassing; they were allowed to rest for a week and gassed again; one rabbit after the first gassing showed a blood sugar of 0.35 per cent; after the use of the insulin, the second gassing was followed by so great a fall in the blood sugar that the animal died in convulsions.

#### INSULIN IN HUMAN DIABETES.

On January 10th, 1922, Banting and Best administered the first injection of insulin in human diabetes. By February 22, 1922, seven cases were under treatment. The observations made on diabetic animals were reproduced in diabetic humans. The fall in blood sugar and the rise in respiratory quotient with the return of normal blood sugar level were observed and acidosis disappeared. Symptoms of patients were relieved. Patients improved clinically. In November, 1922, Professor Macleod's paper on "Insulin and Diabetes" pointed out that enough clinical study of the treatment of diabetes by the subcutaneous administration of insulin had then been made to justify the statement that when insulin is administered subcutaneously in adequate dosage it is capable, within a remarkably short time, of removing the cardinal symptoms of the disease for a period of several hours. To suppress the symptoms permanently, however, the injections must be repeated, the practice at present being twice or thrice daily. So long as the administration is maintained, the patient is able to assimilate more carbohydrate than without it, and he gains in weight, in physical and mental vigor, so that the despondency and apathy, so prominent in those cases, disappear.

Macleod further states that whether the diabetic's condition is in any degree cured by the rest which is given to the damaged pancreatic function by insulin cannot yet be stated. It is perhaps in the adolescent forms of the disease that these results have been most marked, he adds, but there can be no doubt that when insulin comes to be more available its exhibition along with intelligent control of the diet will have the same beneficial results in all serious forms of the disease.

Macleod further says that in cases of threatened coma its value is undoubted, and this is also the case when it is used as a precautionary measure against post-operative risk in surgical practice.

#### PREPARATION ON A LARGE SCALE AND ITS PROTECTION FROM COMMERCIAL EXPLOITATIONS.

Realizing that the publication of the discovery of insulin and its remarkable effects in improving diabetes might occasion a widespread demand for the product before adequate study of it had been made and before standardization and quantity production had been brought about, the Toronto group proceeded to safeguard the production and to standardize and regulate its distribution through this probationary period by applying for patents covering its production and to hand these over to the University of Toronto, which should assume the function of censuring approved manufacturers. Patents were applied for in Canada, the United States, Great Britain and other countries. The committee of the University, because of unexpected difficulties in producing a non-irritating preparation of insulin of constant potency by the Collip method, when made on the large scale production in the Connaught Antitoxin Laboratories, decided to collaborate with a firm engaged in the manufacture of extracts from slaughter-house material. This firm agreed, for clinical purposes, to distribute a sufficient number of free samples of their preparation to various physicians specializing in the treatment of diabetes in properly equipped clinics. This collaboration between the University of Toronto and this firm continued under the terms of this agreement to such period as was required to study clinically the large scale production of insulin by these widely-distributed groups.

#### GENERAL COMMENTS UPON INSULIN.

*Dosage.*—The unit of insulin is the amount

required to lower the normal blood sugar of a one kilogram rabbit to 0.045 per cent, at which point convulsions generally occur. This unit when injected into a human diabetic will enable the patient to utilize or store from 1 to 4 grams additional carbohydrate, depending on the severity of the case. The Research Laboratories modified these statements by notifying physicians using the product that too great reliance could not be placed in this standard unit because the uniformity of the product was not established, but later, about January 1923, certain concentrations were made, and a more uniform product was produced. The first insulin which we received was accompanied by these comments from Lilly. "The Iletin with which we are now supplying you is a concentrated preparation containing 8 units to the cubic centimeter. Each unit is capable of causing combustion of from 2 to 3 grams of sugar in the diet." Dosage of insulin is expressed in units, as before said.

*The Method.*—It is customary to give injections subcutaneously of insulin, one-half to an hour before the principal carbohydrate meals, once, twice or three times daily according to the blood sugar, and the plan adopted for the carbohydrate distribution in the daily regime of diet. The remarkable power of lowering the blood sugar by insulin makes necessary great caution in its administration. In severe cases, when it is necessary to give 24 to 20 units a day for any period of time, it is desirable to keep a close watch on the blood sugar. In mild cases in adults it is better to use small injections, say 10 units before each meal, or 5 units before each meal, according to the needs of the patient. In the case of coma when the blood sugar is high and the patient is in extremis, intravenous injections of 100 to 150 units in the space of 24 hours have been given, using hour-doses and observing carefully urine examinations and the repeated blood sugar examinations, as well as the clinical course of the patient's symptoms. When the coma is profound and the blood sugar is very high, as in one case that came under our observation with blood sugar 0.58 per cent, hourly subcutaneous injections of 10 units were given, properly guarded by repeated investigations of the blood sugar and the urine for sugar.

In mild adult cases 10 units given subcutaneously before principal carbohydrate meal will enable the patient to increase the carbohydrate

limit in the diet and keep the blood sugar near normal level, which will make for a better general body tone and well-being.

*Dangers.*—Insulin when given too long before a meal or in too large doses causes a lowering of blood sugar below a normal level, hypoglycemia. This condition is dangerous and is characterized by such acute symptoms as a sense of weakness, nervousness and sweating, followed by unconsciousness which may end fatally. Delirium or convulsions may occur in hypoglycemia. This condition may be quickly overcome by the immediate ingestion of some forms of carbohydrate such as orange juice, glucose, or cane sugar. When in a coma, glucose or sugar may be administered by the mouth through the stomach tube; if the patient's condition seems critical, 5 to 20 grams of glucose may be injected intravenously in a 5 to 50 per cent sterile solution. This use of carbohydrate gradually returns the blood sugar to normal and the patient improves. Subcutaneous use of 5 to 10 minims of a 1 to 1,000 solution of adrenalin chloride may be used in hypoglycemia and may obviate the necessity for an intravenous glucose injection.

*Laboratory Control.*—The administration of a product that may so quickly alter the blood of its normal sugar, must be carefully and cautiously controlled by laboratory examinations. The continued administration of insulin should be checked by periodic and repeated blood sugar estimations and by daily examinations of urinary sugar. If the laboratory control is not possible, more caution should be exercised in its administration. The urine examinations that are characterized by periodic or transient glycosuria are safer than urine examinations with total and persistent sugar-free results. It is better to have a higher than normal blood sugar with only slight loss of urinary sugar, than to have a persistent and constant sugar free urine and a too low blood sugar of an unknown level on account of infrequent laboratory tests for blood sugar.

*Insulin an Adjunct to Diet.*—Insulin is only an adjunct to the dietary management of diabetes. It can not be considered a cure for diabetes. It is a great and potent product which can be used in connection with an adjusted and selected diet for the control of an excessive hyperglycemia and its attendant poisonous manifestation. Its discovery and practical use mark a new era in medicine be-

cause it gives the physician the use of an internal secretion which may be applied to the rescue of a patient from a serious condition; to enable the patient to increase the use of carbohydrate without producing an excessive hyperglycemia, and to help mild cases to reach a near-cure by quickly and completely assisting the carbohydrate mechanism and in this way enabling it to return to its normal function before irrevocable damage has been done. The same precautions of careful diet and searching study for focal infection should be followed whether with or without insulin.

*Personal Experience With Insulin.*—It will be recalled that in a former place in this communication, it was stated that the Toronto group were collaborating with a limited number of selected diabetic specialists in this country and Canada. At the time I had under treatment a number of cases of diabetes, but all of these were yielding to the management followed in diet. One of my cases, which had been classified as a severe type, had gone off to "Christian Science," had abandoned all dietary restrictions, and was relying altogether upon "prayer," "faith," and unrestrained ingestion of every sort of food. Realizing the advantage that would accrue to the patient with whom I was in touch through the family, I made request to Toronto for a supply of insulin and received a letter saying the request could not be granted immediately on account of the shortage of insulin but that Lilly & Company would send some insulin at earliest possible date. Fortunately, Lilly, on November 16th, 1922, started sending me 200 units of insulin each week. In this way my service at the hospital began to receive weekly shipments of insulin. It has been used by me practically daily since that time. Attention is called to the case report of the first patient on whom insulin was used in Stuart Circle Hospital:

#### CASE REPORT.

Mr. F. M. Reg. No. 10-1710, Medical Service, Dr. Alexander G. Brown, Jr., Stuart Circle Hospital.

White, male, age 29.

*Occupation*—Wholesale clothier, admitted November 15, 1922.

*Family History*—Father living, age 59, health fair. Mother living, 59, health fair (diabetes); two brothers, health good; five sisters, health good. On admission patient's condition is poor. He breathes with difficulty; he is emaciated; he is weak; his mental state is stupid and he appears to be on the verge of coma.

*C. C.*—Weakness, nausea and fatigue; dyspnea; semi-comatose condition.

*Present Illness*—About 18 months ago patient had an excessive appetite and great thirst; was voiding large quantities of urine; was weak and unable to attend to business. Came to hospital and after treatment left with urine sugar free. Two weeks later was injured by auto, sugar reappeared and has continued. Was in hospital twice after that; states that his tolerance was injured. On leaving hospital after last time his appetite increased and he ate anything he wanted; was treated by Christian Science. Now he is very weak; has shortness of breath and is exhausted on slightest exertion. Appetite poor; thirst less than formerly. Has some dyspnea. States that he has recently had pains in joints while on protein diet.

*Past History*—Childhood diseases: Never had any serious sickness, though he has always felt weak and not up to normal. States that nine years ago this trouble began, but that he got along all right until eighteen months ago.

*Central Nervous System*—Is nervous, irritable, does not sleep well.

*Physical Examination*—General appearance is that of an emaciated, rather nervous individual, who is very weak and depressed, suffering with air hunger. Skin yellowish, dry, slightly roughened, warm.

Eyes, normal in size and contour.

Eyes react, freely movable, conjunctivae reddened.

Mouth: Tongue red. Mucous membrane red.

Teeth show evidence of much repair. Gums reddened but do not appear to be swollen.

Thorax moves uniformly on inspiration.

Lungs: Breath sounds clear, but increased and noisy in quality.

Heart regular in rate and rhythm. Sounds are decreased, no murmurs heard.

Arterial radial pulse small, regular, easily compressed.

Blood pressure, 100/58.

Abdomen, flat-soft, no areas of tenderness or rigidity.

Kidneys and spleen not palpable.

Liver one finger below costal margin.

Extremities negative.

November 15th. Urine was loaded with sugar, acetone and diacetic acid; his blood sugar was 426 mgs. per 100 c.c. of blood.

November 16th. Iletin, 8 units every hour, was given hypodermically and frequent urine examinations for sugar were made, without obtaining any change as to sugar or diacetic acid.

November 17th. 10 units of Iletin were given every hour with an examination of urine made half hour afterward, without obtaining any marked change in laboratory findings but with noticeable improvement of patient's clinical side.

November 18th. Iletin, 10 units, was given the patient every hour very early in the day. Urine sugar began to noticeably diminish. Following the fourth dose on this day the collected urine showed that it required 40 drops of urine to 5 c.c. Haines' solution to produce sugar reaction. Acetone and diacetic acid very faint trace. No more was given that day. Blood sugar was 168 mgs. per 100 c.c. of blood.

November 19th. Iletin, 10 units before lunch and supper. Urine, 2 drops to produce sugar reaction, acetone and diacetic acid very faint trace.\*

November 20th. Iletin, 10 units before breakfast and supper. Urine, 10 drops to produce sugar reaction, acetone and diacetic acid faint trace.

November 21st. Iletin, 10 units before breakfast, dinner and supper. Urine, 7 drops to produce sugar reaction, acetone, diacetic acid negative.

\*Three urinalyses were made daily at this time.

November 22nd. Iletin, 10 units before breakfast, dinner and supper. Urine, 7 drops to produce sugar reaction, acetone and diacetic acid moderate amount.

Diet adjustment estimated on basis of 130 lbs., weight 59 kilo. Per diem: 32 grams carbohydrate. 42.5 grams protein; 210 grams fat.

November 23rd. Iletin, 10 units before breakfast, dinner and supper. Urine, 2 drops to produce sugar reaction; acetone and diacetic acid negative.

November 24th. Iletin, 10 units before breakfast, dinner and supper. Urine, 2 drops to produce sugar reaction; acetone and diacetic acid, faint trace.

November 25th. Iletin, 10 units before breakfast, dinner and supper. Urine, 6 drops to produce sugar reaction; acetone and diacetic acid, faint trace.

November 26th. Iletin, 10 units before breakfast, dinner and supper. Urine, 2 drops produced sugar reaction; acetone negative, diacetic acid moderate.

November 27th. Iletin, 10 units before breakfast, dinner and supper. Urine, 12 drops, produced sugar reaction; acetone, very faint trace; diacetic acid, very faint trace.

November 28th. Iletin, 10 units before breakfast, dinner and supper. Urine, 100 drops produced sugar reaction; acetone and diacetic acid, very faint trace.

November 29th. Iletin, 10 units before breakfast, dinner and supper. Urine, 24 drops produced sugar reaction; acetone, negative; diacetic acid, negative. Blood sugar, 153 mgs. per 100 c.c. blood.

November 30th. Iletin, 10 units once a day. Urine, 50 drops produced sugar reaction; 35 drops produced sugar reaction, acetone and diacetic negative; 5 drops produced sugar reaction, acetone very slight trace; diacetic acid, negative.

#### DIET—DETAILS OF THE DAY.

8 A. M.	Grams	Proteins	Fats	Carbo- hydrates
Apple	90			12.8
Broiled fish	82	16.4	5.8	
Bacon	88	12.8	37.5	
Cream, 20%	78	1.95	15.6	3.5
Butter	15		12.75	
Coffee		----	----	----

Noon—Iletin 10 units, hypodermically, whiskey,  $\frac{1}{2}$  ounce.

1 P. M.	Grams	Proteins	Fats	Carbo- hydrates
Turkey	50	14.2	9.2	
Butter	25		21.25	
Cauliflower	75			
String Beans	75			
Spinach	75			7.2
Tea		----	----	----

4 P. M.—Whiskey  $\frac{1}{2}$  ounce.

6 P. M.	Grams	Proteins	Fats	Carbo- hydrates
Turkey	90	25.6	16.6	
Bacon	50	7.3	21.3	
Butter	50		42.	
Fish, broiled	40	7.8	2.8	
Lettuce	50			
Sauer Kraut	75			
B. Sprouts	45			
Celery	50			7.3
Tea		----	----	----

8 P. M. Whiskey,  $\frac{1}{2}$  ounce.

December 1st. Iletin, 10 units once a day, noon. Urine, 12 drops produced sugar reaction; 18 drops produced sugar reaction; acetone trace, diacetic acid trace.

December 2nd. Iletin, 10 units once daily, noon.

Urine, 10 drops produced sugar reaction, acetone and diacetic acid, faint trace.

December 3rd. Iletin, 14 units once daily, noon. Urine, 2 drops to produce reaction; no acetone, no diacetic acid.

December 4th. Iletin, 14 units once daily, noon. Urine, 15 drops to produce sugar reaction; faint trace acetone and diacetic acid.

December 5th. Iletin, 10 units once daily, noon. Urine, 5 drops to produce sugar reaction; no acetone; faint trace diacetic acid.

December 6th. Iletin, 20 units once daily, noon. Urine, 3 drops to produce sugar reaction; very faint trace acetone; moderate amount diacetic acid.

December 7th. Iletin, 20 units once daily, noon. Urine, 4 drops to produce sugar reaction; trace acetone and diacetic acid. Blood sugar 280 mgs. per 100 c.c. blood.

December 8th. Iletin, 20 units once daily. Urine, 5 drops to produce sugar reaction; acetone trace; diacetic acid trace.

December 9th. Iletin, 20 units daily. Urine, 7 drops to produce sugar reaction; acetone trace; diacetic acid, negative.

tive; diacetic acid, very faint trace. Blood sugar, 230 mgs. per 100 c.c. blood.

December 19th. Iletin, 20 units once daily. Urine, 7 drops to produce sugar reaction; acetone, very faint trace; diacetic acid, very faint trace.

December 20th. Iletin, 20 units daily. Urine, 5 drops to produce sugar reaction; acetone, faint trace; diacetic acid, very faint trace.

December 21st. Iletin, 20 units once daily. Urine, 7 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

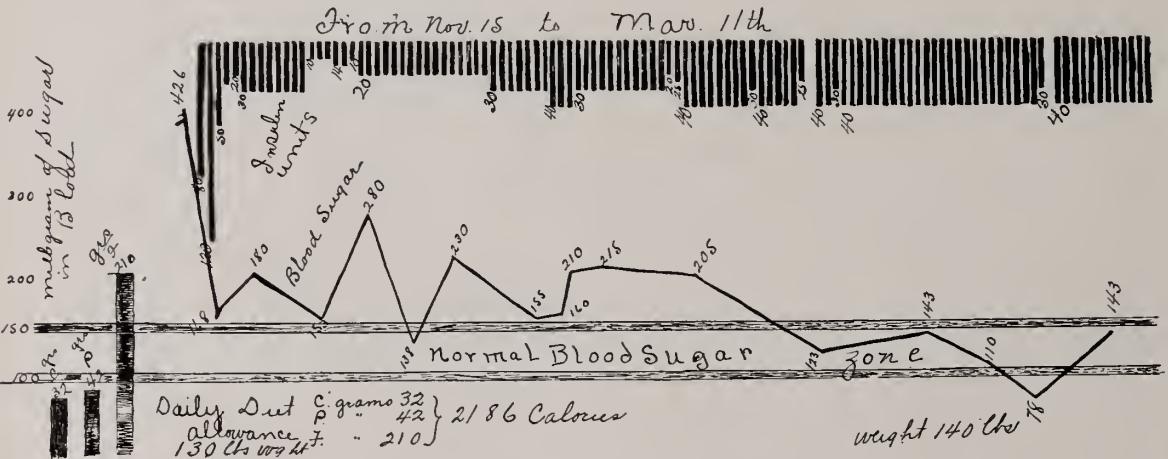

December 22nd. Iletin, 30 units once daily. Urine, 7 drops to produce sugar reaction; acetone, very faint trace; diacetic acid, very faint trace.

December 23rd. Iletin, 30 units once daily. Urine, 2 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 24th. Iletin, 30 units once daily. Urine, 4 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 25th. Iletin, 30 units once daily. Urine, 4 drops to produce reaction; acetone, negative; diacetic acid, negative.

December 26th. Iletin, 30 units daily. Urine, 10

December 10th. Iletin, 20 units daily. Urine, 1 drop to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 11th. Iletin, 20 units once daily. Urine, 8 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 12th. Iletin, 20 units once daily. Urine, 30 drops to produce sugar reaction; acetone, negative; diacetic acid, negative. Blood sugar, 138 mgs. per 100 c.c. blood.

December 13th. Iletin, 20 units once daily. Urine, 7 drops to produce sugar reaction; acetone trace; diacetic acid, negative.

December 14th. Iletin, 20 units once daily. Urine, 3 drops to produce sugar reaction; acetone, very faint trace; diacetic acid, very faint trace.

December 15th. Iletin, 20 units daily. Urine, 9 drops to produce sugar reaction; acetone, very faint trace; diacetic acid, very faint trace.

December 16th. Iletin, 20 units daily. Urine, 3 drops to produce sugar reaction; acetone, negative; diacetic acid, very faint trace.

December 17th. Iletin, 20 units daily. Urine, 3 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 18th. Iletin, 20 units once daily. Urine, 5 drops to produce sugar reaction; acetone, nega-

drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 27th. Iletin, 30 units daily. Urine, 10 drops to produce sugar reaction; acetone, faint trace; diacetic acid, negative. Blood sugar, 155 mgs. per 100 c.c. blood.

December 28th. Iletin, 30 units daily. Urine, 25 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

December 29th. Iletin, 20 units twice, morning and afternoon. Urine, 35 drops to produce sugar reaction; acetone, negative; diacetic acid.

P. M., negative for sugar, acetone and diacetic acid.

December 30th. Iletin, 20 units twice, morning and afternoon. Urine, sugar, acetone and diacetic acid all negative. Blood sugar, 160 mgs. per 100 c.c. blood.

December 31st. Iletin, 20 units twice, morning and afternoon. Urine, 20 drops to produce sugar reaction; acetone, faint trace; diacetic acid, negative. Blood sugar, 210 mgs. per 100 c.c. blood.

January 1st. Iletin, 30 units once. Urine, negative sugar, acetone and diacetic acid.

January 2nd. Iletin, 30 units once daily, noon. Urine negative.

January 3rd. Iletin, 30 units once daily, noon. Urine negative.

January 4th. Iletin, 30 units once daily, noon. Urine (noon), 12 drops, to produce sugar reaction; acetone, heavy reaction; diacetic acid, trace. Blood sugar, 215 mgs. per 100 c.c. blood. Urine (after), negative; sugar, acetone, diacetic acid.

January 5th. Iletin, 30 units once daily, noon. Urine, 10 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

January 6th. Iletin, 30 units once daily, noon (65934-722843). Urine, 35 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

January 7th. Iletin, 30 units once daily, noon. Urine, 37 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

January 8th. 30 units iletin once daily, noon. Urine, no examination made.

January 9th. 30 units iletin once daily, noon (67316-725703). Urine, 9 drops to produce sugar reaction; acetone, trace; diacetic acid, negative.

January 10th. Iletin, 30 units once daily, noon. Urine, 19 drops to produce sugar reaction; acetone trace; diacetic acid, negative.

January 11th. Iletin, 30 units once daily, noon. Urine, 3 drops to produce sugar reaction; acetone, negative; diacetic acid, negative.

January 12th. Iletin, 10 units, A. M., noon, and P. M. Urine, 2 drops to produce sugar reaction; acetone, very faint trace; diacetic acid, negative. (This examination made after second dose).

January 13th. Iletin, 10 units A. M., 15 units noon, 10 units P. M. Urine, 3 drops produced sugar reaction; acetone, very faint trace; diacetic acid, negative.

January 14th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 7 drops produced sugar reaction; acetone and diacetic acid, negative.

January 15th. Iletin, 10 units A. M., 20 units noon, 10 units P. M. Urine, 4 drops produced sugar reaction; acetone and diacetic acid, negative. Blood sugar, 205 mgs. per 100 c.c. blood.

January 16th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 2 drops produced sugar reaction; acetone and diacetic acid, negative. Protein, 65 grs.; fats, 210 grs.; carbohydrates, 25 grs.

Urine examinations were made about 5 o'clock P. M.

January 17th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 2 drops produced sugar reaction; acetone and diacetic acid, negative.

January 18th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 13 drops produced sugar reaction; acetone and diacetic acid, negative.

January 19th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 3 drops produced sugar reaction; acetone, faint trace; diacetic acid, negative.

January 20th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 16 drops produced sugar reaction; acetone and diacetic acid, negative.

January 21st. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 5 drops produced sugar reaction; acetone and diacetic acid, negative.

January 22nd. Iletin, 10 units A. M., 15 units noon, 15 units P. M. Urine, 1 drop produced sugar reaction; acetone, moderate amount; diacetic acid, negative.

January 23rd. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 1 drop produced sugar reaction; acetone, faint trace; diacetic acid, negative.

January 24th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 1 drop produced sugar reaction; acetone, very faint trace; diacetic acid, negative.

January 25th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, no examination.

January 26th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 2 drops produced sugar reaction; acetone, very faint trace; diacetic acid, negative.

January 27th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 1 drop produced sugar reaction; acetone, very faint trace; diacetic acid, negative.

January 28th. Iletin. Urine, no examination.

January 29th. Iletin, 10 units A. M., 10 units noon, 15 units P. M. Urine, noon, 2 drops produced sugar reaction; acetone, heavy; diacetic acid, negative. Blood sugar, 123 mgs. per 100 c.c. blood.

January 30th. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 1 drop produced sugar reaction; acetone, heavy; diacetic acid, negative.

January 31st. Iletin, 15 units A. M., 15 units noon, 10 units P. M. Urine, 1 drop produced sugar reaction; acetone trace, diacetic acid, negative.

February 1st. Iletin, 15 units A. M., 15 units noon. Urine, 1 drop produced sugar reaction; acetone trace, diacetic acid, negative.

February 2nd. Iletin, 15 units A. M., 25 units noon. Urine, 1 drop produced sugar reaction; acetone, positive; diacetic acid, negative.

February 3rd. Iletin, 20 units A. M., 20 units noon. Urine, no examination.

February 4th. Iletin, 20 units A. M., 20 units noon. Urine, no examination.

February 5th. Iletin, 20 units A. M., 20 units noon. Urine, 1 drop produced sugar reaction; acetone, positive; diacetic acid, negative.

February 6th. Iletin, 20 units A. M., 20 units noon. Urine, 1 drop produced sugar reaction; acetone, trace; diacetic acid, negative.

February 7th. Iletin, 20 units A. M., 20 units noon. Urine, 2 drops produced sugar reaction; acetone, trace; diacetic acid, faint trace.

February 8th. Iletin, 20 units A. M., 20 units P. M. Urine, 1 drop produced sugar reaction; acetone, positive; diacetic acid, negative.

February 9th. Iletin, 20 units A. M., 20 units noon. Urine, 1 drop produced sugar reaction; acetone, heavy; diacetic acid, negative.

February 10th. Iletin, 20 units A. M., 20 units noon. Urine, no examination.

February 11th. Iletin, 20 units A. M., 20 units noon. Urine, fast.

February 12th. Iletin, 20 units A. M., 20 units noon. Urine, 1 drop produced sugar reaction; acetone, positive; diacetic acid, negative. Blood sugar, 140 mgs. per 100 c.c. of blood.

February 13th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 14th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 15th. Iletin, 30 units A. M., 10 units noon. Urine, 1 drop produced sugar reaction; acetone, positive; diacetic acid, negative.

February 16th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 17th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 18th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 19th. Iletin, 30 units A. M., 10 units noon. Urine, 1 drop produced sugar reaction; acetone, heavy; diacetic acid, negative. Blood sugar, 110 mgs. per 100 c.c. of blood.

February 20th. Iletin, 20 units A. M., 10 units noon. Urine, no examination.

February 21st. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 22nd. Iletin, 30 units A. M., 10 units noon. Urine, no examination. Weight, 144 lbs. Diet: Carbohydrates, 47½ grams; proteins, 67½ grams; fats, 150 grams.

February 23rd. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 24th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

February 25th. Iletin, 30 units A. M., 10 units noon. Urine, no examination. Diet: Proteins and fats, fast on carbohydrates for 24 hours.

February 26th. Iletin, 30 units A. M. Urine, no examination. Blood sugar, 78 mgs. per 100 c.c. of blood.

February 27th. No Iletin. Urine, 1 drop produced sugar reaction; trace acetone, diacetic acid, very faint trace.

February 28th. Iletin 30 units A. M., 10 units noon. Urine, no examination.

March 1st. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 2nd. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 3rd. 30 units A. M., 10 units noon. Urine, no examination.

March 4th. Iletin 30 units A. M., 10 units noon. Urine, no examination.

March 5th. Iletin 30 units A. M., 10 units noon. Urine, 1 drop produced sugar reaction; acetone, trace; diacetic acid, negative. Blood sugar, 143 mgs. per 100 c.c. of blood.

March 6th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 7th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 8th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 9th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 10th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

March 11th. Iletin, 30 units A. M., 10 units noon. Urine, no examination.

Patient contracted erysipelas of neck, face and scalp and died in eight days.

All through the infection the blood sugar maintained a near maximum normal level and there was no evidence that the patient died from diabetic coma.

1135 West Franklin Street.

## OCULAR COMPLICATIONS OF NASAL SINUS DISEASES.\*

By WALTER EYRE LAMBERT, A. B., M. D., F. A. C. S.,  
New York, N. Y.

Executive Surgeon of New York Eye and Ear Infirmary.

My excuse for presenting this subject about which so very much has been written since the article of Van der Hoeve, 1911, is that we still have much to learn both as to the diagnosis and treatment of the ocular complications of sinus disease, and that it is a subject of interest to all members of the Society, and not restricted to the ophthalmologist alone. When you think of the close relation of the accessory sinuses to the orbit and the optic nerve, and the frequency of inflammatory disturbances in these sinuses as the result of common colds, *et cetera*, it is really quite remarkable that we do not see more ocular complications.

Young<sup>1</sup> has recently made a report on the study of the relation of the sphenoidal and ethmoidal sinuses to the optic nerve in thirty post mortem specimens. He found that in ninety per cent of these specimens, the bone between the nerve and the sinus was so thin that a horse hair could easily be seen through it. In four specimens, there was actually a hiatus in the bone. Ostia in the bone were commonly found in the lateral wall of the sphenoidal and ethmoidal masses: these led into the sinus giving passage to numerous blood vessels. From these findings, the development of optic neuritis from diseased post-nasal sinuses can be explained. A virulent infection might easily spread through so thin a bone, and in a certain proportion of cases, there are actually hiatuses in the bone that would permit the extension of infection. In addition the numerous blood vessels connecting the orbit with the sinuses constitute a relationship of considerable danger.

The investigations of Onodi have shown that the optic nerve is frequently in close relation to the posterior-ethmoidal cells and the extreme thinness of the intervening walls makes its involvement more likely in disease of the ethmoid, than in disease of the sphenoid. The anatomical peculiarities which occur, as for example a sphenoidal or posterior-ethmoidal sinus of one side being in close contact with the optic nerve of the opposite side, explain the contra-lateral ocular disturbance, as was

\*Read at the meeting of the Virginia Society of Oto-Laryngology and Ophthalmology in Richmond, April 18, 1923.

the condition in a case of mine, which shall be reported later.

It is not my purpose to deal with the ordinary and obvious ocular complications of sinus diseases, such as orbital cellulitis, but with the affections of the deeper structures, such as uveitis, choroiditis, optic neuritis, especially retrobulbar neuritis. We know all of these conditions may be due to some cause other than sinusitis, especially in the sphenoid and posterior ethmoid.

Uveitis, resulting from disease of the sinuses is, I think of more frequent occurrence than we realize, but the etiology of some cases of uveitis is very obscure. Peter<sup>2</sup> reports a case of uveitis occurring in recurrent attacks, alternating between the two eyes. X-ray examinations showed a clouding of the right sphenoid and the posterior ethmoid areas. Careful rhinological examination by two specialists showed no evidence of sinus involvement even after turbinectomy. Later, however, evidence of sinus disease was found by a third rhinologist. Operation confirmed the diagnosis. The author is of the opinion that a careful study of the posterior sinuses should be made in every case of uveitis of obscure origin.

Affections of the optic nerve are those in which we are particularly interested, and the diagnosis in such cases, especially an early diagnosis, is of the utmost importance. While it is very easy for the ophthalmologist to diagnose a papillitis, a papilloedema, or a retrobulbar neuritis, it is extremely difficult to be sure of the cause, but we do know that acute or chronic sinusitis does produce these conditions and, having eliminated the other causes, it is our duty to promptly enlist the co-operation of a rhinologist.

In 1911, Van der Hoeve<sup>3</sup> published several cases illustrating the importance of enlargement of the blind spot, as an early sign of optic neuritis due to posterior nasal sinus disease. In some of the cases, central scotoma appeared soon after, but in others the enlargement of the blind spot was the only defect in the visual field observed for some time. In his 1922 article<sup>4</sup>, he again refers to enlargement of the blind spot and central scotoma as characteristics of optic neuritis due to sinus disease, but notes that these same symptoms may also be present in optic neuritis due to other causes. He concludes, therefore, that the ophthalmologist has in the eye no sign at

all to distinguish the origin of a retrobulbar neuritis.

He thinks the X-ray is of great value in the diagnosis of sinus disease without definite clinical symptoms, especially if the sinuses be photographed in different directions. For a study of the sphenoidal sinus, Van der Hoeve uses the bi-temporal and occipito-caudal method according to Pfeiffer, and for the ethmoidal sinus, the Rhese method, with the patient lying face downward and the tube over the protuberantia occipitalia. Yet even with the best technique, there are cases in which the roentgen examination is negative. Therefore, "the rhinologist cannot say with absolute certainty that a person has no sinus affection." This opens the question as to whether in optic neuritis of unknown origin, the nasal sinuses should be opened. Van der Hoeve believes that this must be determined in each case by consultation between the ophthalmologist and the rhinologist. He does not wish to express the dogmatic opinion that the operation should be performed in these cases. In favor of this operation he notes, however, that in some cases the opening of the sinus, even when nothing definitely pathological has been found, has resulted in permanent or temporary improvement in the optic nerve condition.

He reports a case with retrobulbar neuritis and choroiditis with marked enlargement of the blind spot for colors in a man who had undergone several operations for sinus disease. The roentgen ray in this case showed the ethmoid region clear except for a rectangular spot close to the optic foramen; at operation, purulent secretion was found in some of the ethmoid cells at this point, and after the opening and draining, the visual symptoms were completely relieved.

Vail<sup>5</sup> (1919) reports three cases of optic neuritis due to hyperplasia of the ethmoid bone. The characteristic eye findings in these cases, he notes, are monocular blindness, sluggish response of pupil to direct test and dull pain on deep pressure, the latter not always present. Where vision is present, it is eccentric with a large central scotoma. If the case is seen earlier, there is a central scotoma for colors and enlargement of the blind spot.

There is often no definite pathological lesion in the nose. In some cases in which the middle turbinate is normal, it is shrunken with cocaine

and adrenalin, and evidence of hyperplasia of the ethmoid may be obtained by observing small polypi hidden beneath it. The most frequent clinical symptoms of ethmoid hyperplasia, Vail notes, are sneezing followed by a watery discharge, transitory impairment of nasal respiration, especially at night, frequent head colds. There is no pain and no purulent discharge and the symptoms noted are slight and cause the patient no great discomfort. In some cases even these slight symptoms are not present.

Bordley<sup>6</sup> in 1920 reported eleven cases of optic neuritis due to posterior nasal sinus disease, of which four showed scotomas of sufficient dimensions to extend beyond the blind spot. These scotomas were absolute when patients were first seen. In the other seven cases, the condition varied from a loss of perception for red to absolute scotoma. All were progressive up to the time of the nasal operation. In eight cases, the scotoma disappeared entirely from twenty-four to thirty-six hours after the operation. The most prompt response was observed in patients with the greatest changes, in whom these changes developed with the greatest rapidity. Bordley believes that where a careful examination has excluded all other causes of an optic nerve lesion and the visual disturbances are progressive, an operative exploration of the ethmoidal and sphenoidal cells is justified.

In a later article, 1921, Bordley<sup>7</sup> states that in involvement of the optic nerve from sinus disease the most common alteration is an enlargement of the blind spot, which is of spindle form gradually overspreading a preceding and advancing scotoma for color. In one hundred and two patients with sinus disease, he found this as symptom thirty-one times. Other central and paracentral scotomata are of less frequent occurrence, but more important from a visual standpoint. The central change varies from a mere disturbance in red and green perception to a positive scotoma for colors and white. In sinus disease this alteration is usually unilateral and more rapid and definite than in optic neuritis due to other causes. There are, however, exceptions to this rule. In the diagnosis of sinus disease, Bordley says intra-nasal examination is often entirely negative. The roentgen ray is in his opinion the best method of diagnosis, but only if several radiographs are made from different positions

by an experienced radiographer, well acquainted with anatomic variations in the size and position of the sinus. A single negative radiograph is of no value in excluding sinus disease.

Crane<sup>8</sup> in 1921 reports three cases of optic neuritis due to posterior sinus disease. In two of these cases, there was a history of influenza and some nasal trouble since the acute attack. In only one of the cases was pus observed on post-nasal examination. In all, the septum was deviated and the middle turbinate enlarged. Operation in the two cases, in which patients were seen during the early stage of the optic neuritis, restored the vision completely. In the third case, there was no active sinus infection; the ethmoidal cells showed proliferation and the sphenoidal sinus contained mucopurulent fluid with some polypoid degeneration of the mucous membrane.

From the study of over thirty cases of optic neuritis, associated with disease of the posterior and nasal sinuses, White<sup>9</sup> has come to the conclusion that abnormalities in the size and position of the middle and superior turbinates is an important factor in the etiology of this condition and, in the diagnosis of these cases, special importance should be attached to any abnormalities of the turbinates. A deflection of the nasal septum is also frequent in these cases. Suppuration of the sinuses that can be definitely diagnosed by the rhinologist is comparatively rare. The roentgenograms are often negative, because the infection is so frequently exudative and non-suppurative. With more careful technique and a more careful timing of the plates, a slight cloudiness has been shown in some cases and the author hopes that absolutely negative reports may not be so frequent in the future. In the ophthalmological examination, White states that a central scotoma with ability to see sideways persisting for some time suggests an optic neuritis of nasal sinus origin. A careful neurological examination should be made to rule out brain tumors, and multiple sclerosis, and a general examination to rule out other infections and toxic conditions that might cause the optic nerve lesion. If all other causes can be definitely ruled out, White believes a semi-radical sphenoid operation is justified, even if no nasal pathology can be demonstrated. A complete ethmoid exenteration is not necessary in his

opinion unless indicated by definite pathological conditions in the ethmoid labyrinth.

White has found that involvement of the optic nerve in posterior nasal sinus disease may be due to direct extension of the infection, toxemia originating in the accessory sinus lesion; infection by way of the blood stream from focus in the sinus; and, finally, to extension by hyperplasia, probably more important as a predisposing factor in other conditions than as a cause *per se*.

Stark<sup>10</sup> (1921) says that in the ophthalmological diagnosis, where the visual symptoms are not of too sudden onset, central scotoma for color and enlargement of the blind spot are the two signs most characteristic of optic neuritis due to sinus disease. Exophthalmos may also be observed in these cases. From the nasal standpoint, the common symptoms of sinus infection are not usually present. A deflected septum or middle turbinate pressed against the lateral wall are more frequently observed. Both transillumination and roentgenography should be used in diagnosis, although the roentgen ray findings are frequently negative. A careful general examination must be made to exclude other causes of optic neuritis.

Gallaher<sup>11</sup> (1921) reports four cases with blurring vision and intermittent blindness; central scotoma was present in two cases; central scotoma for colors in one case; and in one case it was not reported by the oculist. In three cases, deflection of the nasal septum was found. This was corrected and the ethmoids and sphenoid opened. In the fourth case, the nasal operation was done without definite diagnosis of nasal abnormality. In all cases, improvement followed operation. In two cases, restoration of normal vision was complete. He says that in making an ophthalmological diagnosis, the two most important points to consider are the condition of the blind spot and central scotoma for colors.

In making a rhinological diagnosis, too much importance must not be attributed to the fact that no pus is present. Any nasal defect or systemic disease which produces nasal inflammation should be considered as possible etiological factors in retrobulbar neuritis due to ethmoidal-sphenoidal disease. In cases where no pathological condition can be demonstrated in the nose, it is entirely justifiable to open the posterior ethmoids and sphenoid, rather than jeopardize the patient's vision. If sup-

uration is present in the ethmoidal-sphenoidal cells, the optic nerve may become involved by direct extension of the infection, or by toxins. In cases, with low grade inflammation, the inflammation and hyperplasia may extend to the neighboring parts, involve the orbit, and cause pressure on the optic nerve, especially by the swelling of the periosteum of the optic foramen.

Sluder<sup>12</sup> reports no cases in his article, but states that optic neuritis in his experience is "not uncommonly secondary to post-ethmoidal and sphenoidal diseases." It has a good prognosis if the nasal lesion is operated on early—i. e., within three months and if performed "comprehensively."

In diagnosis of these cases, other possible causes of the optic nerve lesion should be constantly kept in mind and carefully eliminated; if the lesion is accompanied by several dioptries swelling, it is difficult, if not impossible, to differentiate it from a lesion due to intracranial pressure. The nasal diagnosis in these cases is not always easy; optic neuritis is not necessarily secondary to suppuration of the para-nasal cells. In the rhinological examination, special attention must be paid to the slightest changes in the appearance of the mucous membrane of the post-ethmoidal-sphenoidal region.

Cutler<sup>13</sup> notes that in involvement of the optic nerve due to posterior sinus disease, the enlargement of the blind spot in the early stages may be so slight as hardly to attract the attention of the patient. Yet, if neglected, permanent injury to the nerve and blindness may result. The author regards this so-called Van der Hoeve sign as of more importance in diagnosis than ophthalmoscopic examination. This sign may be considered positive when the scotoma for colors is considerably larger than for white, when the extent of the scotoma for white and colors is decidedly greater than normal, when the size of the scotoma is greater in one eye than in the other, when the size of the scotoma changes during the course of the disease.

Among the symptoms suggestive of sinus origin of optic neuritis, Cutler notes orbital tenderness, fleeting oedema of the upper lid, slight ptosis, insufficiency of accommodation, pain on pressure of the eye backward. He cites one case in which the patient, on awakening, noticed blurring of the vision, left eye.

Examination showed a large ill-defined scotoma extending over the region of the blind spot to the fixation point with small absolute scotomas above and below, the extent of the scotomas varying daily. Rhinological examination was negative, but a radiograph taken at an usual angle from below showed faint clouding of the posterior ethmoid cells. The posterior sinuses were opened and irrigated; although no pus was found, the visual condition cleared up absolutely after the operation. The X-ray, Cutler believes, is usually inconclusive, but may give corroborative evidence. Even though the vision is seriously impaired in cases of optic neuritis of sinus origin, recovery may be prompt and complete after operation with adequate draining of the sinuses, if the neuritis is not of too long standing. In the more chronic cases where the nerve has been organically impaired, improvement is less marked.

Redding<sup>14</sup> reports eight cases of optic neuritis due to sinus disease in which the visual disturbances ranged from slight enlargement of the blind spot to complete blindness in one eye. Two of the patients had had an attack of influenza, and one complained of frequent "colds in the head." Two patients had more or less constant headaches of the deep orbital type. Seven of the eight cases were X-rayed and all were negative. All of the eight cases were sent to a rhinologist for operation and, in all, either pus or a thickening of the mucous membrane was found in the posterior ethmoid or sphenoid, or in both sinuses. In all these cases, there was some improvement in the vision, and in the cases where the visual disturbance was comparatively slight and of short duration, the vision became normal.

The author concludes that in cases of optic neuritis, in which all other causes can definitely be ruled out, even though the nasal condition is apparently normal, and the X-ray negative, "the diagnostic limit has not been reached until exploratory puncture of the posterior ethmoid and sphenoid sinuses has been made." The X-ray should be used routinely in every case but a negative finding does not prove the absence of diseased sinuses.

Hajek<sup>15</sup> reports twelve cases in which no definite relationship between the posterior sinuses and the optic nerve lesion could be determined, although they were of the type usually considered to be of the posterior sinus

origin. In three of the cases, there was enlargement of the middle turbinate; in these cases, some improvement followed the nasal operation, but in two of the three, there was a recurrence of the visual symptoms. He concludes that unless there is a definite demonstrable pathological condition in the nose and sinuses, the nasal origin of optic neuritis is very questionable.

Maller<sup>16</sup> does not agree with this opinion of Hajek. He believes that the ophthalmological findings, rather than the rhinological, must determine the necessity for operation on the nasal sinuses.

King<sup>17</sup> reports a case with very remarkable restoration of vision after operation on sinuses. One eye was totally blind when the patient was first seen, but the fundus was apparently normal. The other eye was normal. X-ray showed the right ethmoid and both antrums cloudy. A simple exenteration of the anterior and posterior ethmoid was done and the anterior inferior wall of the sphenoid removed. Five days after operation, the patient counted fingers at two and a half feet, and within two weeks vision was improved to 20/40. A Wassermann test made then was found to be four plus. Anti-syphilitic treatment was immediately given. Ten days after the operation on the first eye, vision of the left began to fail and within a few days was practically nil. In view of the four plus Wassermann, the operation on left side was deferred. As no improvement took place at the end of another week, operation on the left side was made with the result of an improvement of vision to 20/40.

Dr. Northcott reports a case where headache was the only symptom, both eyes normal. Some time later, patient returned complaining that one eye was tender under pressure and felt lame. Vision and fundus were still normal. About a week later, vision was reduced to 15/50 with a central scotoma, and a large blind spot, and definite papilloedema. Next day vision was only 15/100. X-ray of sinuses and sella was negative. Under nasal shrinking, vision was increased to 15/50. The posterior ethmoid sinuses were then opened by rhinologist with the result of an uninterrupted recovery with complete restoration of vision.

The following case with a very tragic termination, reported by me at a meeting of the American Ophthalmological Society in 1918, is a striking example of the importance of

prompt and active surgical interference, where X-ray and clinical evidence of any sinus disease are negative. As Sir James McKenzie said, "let us not be exclusively laboratory physicians."

The patient had been under my care since 1896, when she consulted me for severe headaches, which she referred to her eyes. She was using the proper correction for her error of refraction, but I found she had a small amount of hyperphoria. I did not regard this of great importance but did prescribe a prism of three degrees, which apparently gave immediate relief. That the hyperphoria was the cause of her eye strain was proven subsequently by an error in making the glasses, prism being misplaced. All the symptoms returned with use of new glasses and, when properly made, she had immediate relief, and continued to have perfect comfort with eyes for many years. In March, 1917, Mrs. S. consulted me again. For some time previous to this visit, she had been in very poor health and had been under the care of several physicians in Boston. I found no change in her eye condition and referred her to a physician in New York with the suggestion that she had some sinus trouble. X-ray showed a "root fragment pushed into the right antrum. The antrum also showed distinct occlusion of its air space, which possibly may have been caused by the displaced root fragment. The rest of the sinuses appeared quite normal. There was considerable constriction in the nares, caused by the deviated septum and enlarged turbinates. The sella was smaller than the average. There was no evidence of any infection about the teeth."

The antrum, when operated on April 6, 1917, was found to contain considerable amount of green pus. Permanent draining was established through the nasal cavity. A bacteriological report of cultures from the antrum showed streptococcus viridans. Blood culture was negative. Headaches were relieved and apparently an uninterrupted recovery was made, although a slight septic temperature occurred occasionally. On May 7, 1917, she complained of blurring vision of the left eye. Headaches returned and the patient was running a temperature of from 100 to 101. When seen May 8th, pupil was moderately dilated, no reaction to light, and not even light perception. An ophthalmological examination showed a marked though moderate papillitis, arteries

small and a sluggish segmented circulation in the veins. Right eye was unaffected, vision being perfectly normal.

Dr. Weeks saw the patient with me and we thought there was a partial occlusion of the central artery, probably a thrombosis of septic origin. Two days later, the right eye became affected and a similar ophthalmic picture presented itself, vision being reduced to fingers. A definite diagnosis of retrobulbar neuritis was then made and an immediate operation advised, but operation was deferred until next day when an X-ray was made and found negative. Two days later vision right eye had slightly improved and we were able to demonstrate a distinct central scotoma for form and color, tenderness on pressure on the globe, and pain on movement of the eyeball. Operation was then again considered but, after consultation with two well known rhinologists, it was regarded as futile. Vision of the right eye failed rapidly and, in about three days, the patient was totally blind, atrophy of both optic nerves supervening.

There was no question in my mind that we were dealing with an acute retrobulbar neuritis of septic origin, the disease having extended from the antrum to the posterior ethmoidal cells and the sphenoid. The fact that the left eye was the first to become affected, whereas it was the right antrum that was diseased, is not uncommon. This contra-lateral visual disturbance in nasal sinus disease has been frequently observed by Onodi. As the process was so acute and so intense, it was of course extremely doubtful if an operation would have relieved the condition, but I think it should have been performed.

I might continue indefinitely relating cases where remarkable results have been obtained by treatment of, or operation upon, the adjacent sinuses. The great question to be considered, however, is when are we to decide upon operative interference, and what are some of the early diagnostic symptoms of ocular complications originating in the accessory sinuses? From the authors quoted, we must conclude that the enlargement of the blind spot is very important evidence, and the careful mapping out of this should be done not once but frequently. If the other obvious causes of optic nerve disturbances can be eliminated, even though the clinical and X-ray evidence of diseased sinuses be wanting, an operation

upon the posterior ethmoidal and sphenoidal cells is justifiable.

## PSYCHOLOGY IN MEDICINE.\*

By GREGORY STRAGNELL, M. D., New York, N. Y.

I have decided to give an informal talk on certain phases of the interrelationship existing between psychology and medicine. There are among psychopathologists two groups, in two camps more or less. On one side are workers like Cotton, who attribute practically all mental or psychological disturbances to organic factors and try to remedy them by removing what they consider the underlying condition. The physicians in this group usually have their favorite scapegoats. One attributes all evil to teeth, another to tonsils, still others are very fond of blaming the colon. This is no doubt a hangover of homeopathic medical magic. The other group more logically finds that psychological disturbances have a definite psychological origin. And some of us who handle these cases sometimes come to a point where we are confused and want to know what really is the difficulty. During the few years in which I have worked on the problem, I confess that I have reached no complete explanation. The few ideas that I shall present appeal to me from both the theoretical and the practical point of view. In order to present the situation as I see it, I am going to cite a few cases.

The first one is of a girl who came to me, not for a mental or neurotic disturbance, but for a hyperthyroid condition. On examining her, I found that she presented all the earmarks of what one would expect of a hyperthyroid condition, not only symptoms but markings—practically no hair on the outer part of the eye-brow, typical bluish, regular, pearl-like teeth, very fine hair, skin a translucent pink. There had been loss in weight; pulse from 160 to where it could not be counted. From the little anatomical markings we may conclude that I was dealing with a definite underlying organic condition. There was something wrong primarily with the thyroid mechanism. I am stressing that because it is what makes the difference in this case. She came to me; I examined her, went over her case and did nothing in the way of medication. I did not even give her any psychological treatment. I listened to her story and that was all. She kept coming once or twice a week, and within two weeks the pulse was down to about ninety. She had begun to take on

weight and the entire picture had changed. There had been no surgery and no medicine. What had happened? Going into details, she had been going along working in a dressmaker's establishment. She had accumulated a few additional worries, mother's health, the problem of whether she still loved her lover or whether he still loved her; not one big exciting trouble; just an accumulation of little things heaped on top of the responsibility of facing the realities of life which she was doing so bravely. The mere fact that she was able to relieve her mind by talking to me, going over the situation with someone, and feeling that she had someone to lean on, enabled her to release the tension which had brought about the activation of the faulty thyroid mechanism. Here is an interesting point: Supposing I had used some psychological method on her? Then there would be a question as to whether the treatment had cured her. Supposing she had been treated by a surgeon or by internal medication? A doubt comes to my mind. If any of these methods had lessened the thyroid activity, reduced the pulse rate, etc., would she have been cured? Perhaps.

What I want to show is that there was an underlying organic condition which had been activated by an added psychological load and the overloading increased the metabolic rate to more than she was able to handle. By releasing the tension caused by the surplus load by her talks with me, she was able to make a temporary adjustment. After this temporary adjustment was made, if it could be carried over to a permanent condition and she could have understood her condition from a psychological point of view, then she would have reached a state of well-being with the exception of the primary faulty thyroid condition which she would have been able to handle on a compromise. Whether this would have been the ideal situation I do not know. Perhaps it would have been best to have brought her to a mental cure and then employed some form of medical treatment.

Another case is that of a man who was referred to me by a physician. His complaint was impotence. He was forty years of age, very intelligent. He had been to a number of genito-urinary men who found nothing organically wrong. They did not seem to think that his disability mattered but he seemed to think that it did. He came to me in despair. With the impotence he had a marked depres-

sion. Which was the primary condition, I am not sure. I went into the history and found a strange picture. I found that (he was a widower) he had been having promiscuous relations with the wife of a friend and, just before this impotence, there came an episode which made discovery likely and following this the impotence appeared. This I considered a purely psychological effect. I went into the history at great length. The condition did not clear up at first. Potency did not return. When I questioned him more minutely we got back to some very early childhood impressions. An important episode which had left a lasting impression was that when a boy he had seen his parents in the sexual act and this memory affected the present situation. He now had a feeling of fear that he would be caught in the act. In the childhood picture there was a triangle consisting of the parents and himself and in the second triangle he was taking the father's place in the sexual act and he was fearful that someone would replace him in the role of onlooker. There were countless other details which were revealed from a study of early childhood patterns, his dream life, his likes and dislikes. . . . The Oedipus triangle was portrayed in all its details. The result in this case was that the man was cured and he established his sexual life on a new licit basis. We have a picture of an apparently organic affection which is completely removed by searching out the underlying psychological cause of the situation.

This man, by the way, presented another interesting point. All his life he had been doing what so many try; that is to prove his potency to the world in one way or another. This is interesting because it is so frequent. A great many apparently love relations which are not based on love in any sense of the word, are merely an attempt to prove potency, continually trying to add conquests merely for the sake of reassurance. In this case the patient had a feeling of relative impotency on account of the pattern which his early childhood experiences had established. He then tried to have as many conquests as he could in order to compensate for his unconscious feeling of inferiority. You can see this everywhere--vicarious attempts to prove potency.

To revert to endocrinology, not from a strictly endocrinological point of view but merely from the viewpoint of the little ear marks that we take advantage of in diagnosing

diseases and trying to determine whether they are either organic or psychological: A little girl of seven was brought to me because of difficulty in school, and this difficulty had been brought about by her sexual development. Her condition might be called *pubertas precox*. She was sexually developed to the point of maturity. She had first menstruated at the age of three. Her breasts were fully developed and her hips were those of a mature woman. There was well marked pubic hair. Mentally she was a child of seven, there had been no change. She was a nice sweet little girl. Her sexual development began after an attack of diphtheria which no doubt had caused a stimulation of her gonads. What the pathology was I don't know. I would be interested to follow it up and to examine its ramifications. I tried to get as much as possible of the family history in the various branches and I found the following:

She was an only child. An aunt of hers who had been married eight or nine years was sterile and anxious to have children. A sister of this aunt had never menstruated at all. I found a third aunt in another branch of the family whose menstruation was irregular. Now we have recently been working on the theory that the lateral incisor teeth have a close connection with the development of the gonads in both male and female. It is not thoroughly worked out but there is evidence to show a close relationship. An interesting point was that in each of the cases the lateral incisor teeth were missing in the women. In the little girl they were present. I went into the history further to see what this deficiency was which was manifest as a strain through the family and by anatomical landmarks. What had happened; what psychological effect had it had? What were these women doing to compensate for a defect which they undoubtedly realized unconsciously? I found an extremely neurotic group of women. The woman who had irregular menstruation had a feeling of tremendous inferiority. She was shy and would blush on the slightest provocation. She did what I have seen few women do, stutter. She was afraid of men, did not like to meet them. In every way she ostracized herself and made her life a torture. The woman who did not menstruate at all presented a similar picture; hated men and avoided them. She had no frank erotic relationship with women but very close friendships. The third was the woman who

menstruated but had no children and this was the most interesting of all. She, in her desire to have children, tried all sorts of what might be called illicit experiments. There was no question of morals, merely her frenzy to fulfil her biological role. Her effort to secure children at any cost resulted rather disastrously finally. She contracted syphilis; it became known to her husband and there was a separation.

The ramifications of the underlying psychological defect with the effort at compensation resulted in a defect both organic and psychological. In the little girl the gonadal segment had been attacked by diphtheria and the gonadal tissue broke down, resulting in the menstrual cycle being pushed ahead. In the other female members of the family we see psychological attempts at compensation. In those cases an understanding of the organic and psychological factors would have avoided a great many of the disturbances which had occurred.

Of course you are all familiar with the toxic psychosis of pregnancy. We have a woman going along making her ordinary adjustment in her life and she becomes pregnant. She may go on to lactation and finally present a psychological disturbance. What is this underlying psychological disturbance? There is apparently no added difficulty psychologically; no added psychological load during the pregnancy. But in the pregnancy there is an added physical load which lowers the resistance and the buried conflicts come to the surface. Of course this may be so in any physical illness. The extra load may be psychological or physiological. Careful investigation is necessary. The origin of the mental disturbance that the woman is having is not on the surface; it is down deep. We find a woman who has had one or two children and should be happy having fulfilled her biological role. There are no financial difficulties. Apparently the marital situation is satisfactory. The break may take any form; the woman may be depressed. It makes no difference what form is encountered. There may be flighty thinking for a few hours or a chronic condition lasting several years. The underlying mechanism is the same. We find invariably in those cases that there have been conflicts in that person's life which have never been settled. We all have them. We settle them on a basis of compromise habitually when we are active. These conflicts along

with household duties and added strain of pregnancy make adjustment from day to day more difficult. What is the nature of these conflicts and how can we discover them? Frequently they go back to early childhood. Perhaps they may appear foolish but not to the persons affected.

One case was of an intelligent woman, third baby, and on investigation I went back into her early life and found there had always been a feeling of great inferiority. She made her adjustments at a tremendous effort. All this went back to an early episode of childhood. I don't say that this caused it but I do say that it served as a nucleus. When she was a little girl she was going down the street to school and saw a man expose his genitals. She did not think much about it and went over to play with some other little children. She told them about seeing the man. She did not tell her parents. The next day the mother of the children called her aside and said: "You have been a very naughty girl and are not to play with the children any more." She felt mortified. She told no one. This had a great deal to do with her taking up the profession of nursing later; her desire to find out about these things for herself; the impulse to peep had been emphasized by the exhibition she had witnessed. Her whole life was distorted by this and one or two similar things. The incidents had been buried and never settled. She was able to make adjustments from day to day, hour to hour, but with the added load of pregnancy she broke down.

We frequently have great difficulty in placing our finger on the underlying condition and for that reason have to take advantage of a great many little clues as it were.

In relation to this I recall the case of a boy of fifteen, suffering from dementia praecox complicated by many compulsions. He would pick up every piece of paper he found and write in German "Four sisters, four sisters, four sisters," all over the paper. He covered every piece of paper he found with these words. He had been in the hospital four months and he was finally turned over to me for examination. I found that that little symptom was the root of all his difficulties. It went back to an incest situation. His mother had been pregnant and he was very jealous of the father. His mother was still his ideal and his deeply rooted sexual object. He resented her being pregnant. There were sisters enough.

These two words "four sisters," remained the symbol to him of the situation. He had four sisters already and did not think his mother should have another child. He was extremely jealous. He had a low order of mentality. He thought he had discovered a new secret in masturbation. He wanted to tell his father of his great discovery. The real reason for this was that if his father masturbated he would not have sexual relations with the boy's mother. He wanted the mother for himself. The nature of the situation was explained to him and he made a fair adjustment being able to secure employment as a laborer. It shows that we have got to trace out as far as possible the little things.

Then there are cases of postural tensions. Postural tensions include the way a man sits, shakes hands, walks, smiles and countless other everyday activities. Many pathological conditions may be revealed by a careful observation of these and many other little traits. They may take extreme forms where a patient will attempt to remove an offending segment from which he fears the gratification of some tabooed desire, as in the case of a male homosexual who attempted to cut away his rectum with a pair of nail scissors. Another tried to perform a symbolic castration by tearing out his eyeball. Numerous examples are shown in Kempf's book on *Psychopathology*. Many suicidal efforts reveal this effort of removal of a troublesome area or segment. I had a patient under my care whom I saw in consultation with Dr. L. Pierce Clark, who clearly showed this mechanism in repeated suicidal attempts such as cutting his wrist and neck with the blade of a safety razor. There are countless degrees. We must observe the little things. A patient may rub his lips, stroke his ear, scratch his nose. We should search to find the meanings of these unconscious acts.

A study of endocrinology frequently gives us a suggestion as to the earmarks of various endocrinologic imbalances. Pituitary types show some most interesting cases. I recall the case of a boy who wanted to create perpetual motion. He came to me with a marked depression. Toxic absorption was present from some abscessed teeth. He immediately got better after they were removed. The depression was removed but his underlying psychological disturbance remained. Now we know that the pituitary has to do with the sense of time. It also in some way has to do with orderliness

and rhythm. It has a tendency to have a great deal to do with a man's occupation. If the pituitary is disturbed in women, an irregular menstrual flow results. This boy's interest in machinery was undoubtedly influenced by his pituitary and, as we went into the case in question, it was found that the manifestation was also a symbolic compensation for sexual impotence. He was trying to create perpetual motion as compensation for his inability to reproduce. It was a complicated mechanism. When he told me of the perpetual motion I immediately suspected a pituitary disturbance which was a compensation for an initial gonadal deficiency. What happened? He was shown the underlying cause and has become very successful in inventing practical things.

Another case will show how a pituitary mechanism was brought into play. A man was brought into the hospital with a chancre over his right eye. He was a truck driver on a brewery wagon, had had no education whatever and was extremely illiterate. He was given mercury and iodides. He had a virulent infection on account of the brain tissue being directly attacked by the syphilitic virus. Strange to say, as he was convalescing he asked for paper and pencil and made a most marvelous architectural design. It was shown to architects and they were astonished. I don't know what the whole story is but I do know that the pituitary was activated. He also began to play wonderfully on the flute. He was taken to an opera and on his return played the entire score on his flute. The music and drawing were both pituitary manifestations.

I could give more instances. If I have jumbled the situation, so much the better for then I have presented the situation as it really is. There are many workers in this field; most of them tell us that they know all about it, just what percentage of mental disturbance are organic, psychological, endocrinological. And I will have to see certain cases they have diagnosed and I will know all the time that the men who have made the diagnoses are enthusiastic but don't know what they are talking about. My colleagues will show me other cases like the thyroid one I mentioned and will say that they have cured the patient. They will get to fighting about the situation bitterly, sincerely. I am of the opinion that in this case the condition was both organic and psychological. My feeling in the matter

is that the less you try definitely to settle matters the better. The more you try to investigate and add to what knowledge you have without trying to make it prove a conclusive picture, the wiser you are. If we knew all there was to know there would be no chance for some to say this and some that. The most we can do is to say this little part of evidence seems to fit and we are trying to work the thing out.

I believe the people who are putting all the stress on the organic are doing it because they are unwilling to probe into the psychological side. And those on the other side are over-enthusiastic over a new toy.

There is just one other case. A woman with gastric ulcer had been to the Johns Hopkins Hospital. She had had many types of treatment. She came to me because she was afraid of snakes or something of that sort. Her gastric ulcer disappeared shortly after she came to see me and I am absolutely sure that in this particular case the gastric ulcer was due to the tension of a purely psychological situation. But every gastric ulcer does not happen this way. I know this one did. However, every case of gastric ulcer can be benefited by probing into the psychological background, whether the condition is organic or functional.

There are many things to understand. We must take into consideration even the things the patients themselves are not aware of to which they attach no significance. Even dreams are important in these instances if we are familiar with the technic of interpretation. Everything must be taken into consideration if you are going to discover the psychological phases of our difficulty.

#### DISCUSSION.

DR. WALTER COX, Winchester: In this connection I want to present a case history and remedy. About our only effort is to remedy the evident organic condition but I think this paper is illuminating in showing that these cases have no discoverable organic basis and therefore it behooves us to take measures along his line. Most of us have little experience or ability along this line. In one case, a young woman, thirty-five, school teacher, had been practically disabled for about twenty years by a curious, very frequent nocturia. She was worn out by losing sleep at night. It had a very interesting outcome. Every attempt was made to find an organic cause. Resorted to all kinds of specialists. It turned out to be a trauma at the age of fourteen. While riding a bicycle, she ran into a car loaded with bricks. This was followed by very profuse first menstruation and neurasthenia. An attempt was made to remedy the condition by trying palliative organic methods. Tried stretching the urethra and did her harm. She was very bright and had some knowledge of the subcon-

scious. I told her that I was going to talk to her a little while and if she believed what I said I would promise her cure. That was going pretty strong, but I did it. I explained the mechanism of micturition and showed her that during consciousness during the day she had no trouble. At night the subconscious impression of helpless injury caused trouble. She has had no trouble since then. The result was a very striking example of conditions brought to our attention so ably by Dr. Stragnell.

DR. J. H. DEYERLE, Harrisonburg: I have had several patients who ceased menstruating during the menstrual period. One followed typhoid fever, the other was, we think, probably a tuberculous condition. I would like to have Dr. Stragnell's opinion about it.

DR. STRAGNELL: In regard to the last question, first I don't see why it should not be reasonable to assume that it was not a purely organic thing, always with the reservation that there may be a psychological element back of it. We know that in tuberculosis very frequently there is a shutting down of the menstrual flow. The forces of resistance are trying to overcome the ravages of disease, and conserving energy wherever possible. There is also a complicated calcium metabolism going on in tuberculosis, typhoid fever and menstruation of which we know little. We do have cases, however, where menstruation is suppressed solely through unconscious mechanisms. I have seen cases of pseudopregnancy caused by these same factors. I can recall several cases where examinations were made and where the fetal heart sounds were supposed to be heard and and there was merely psychological pregnancy.

It is interesting to see the role that intercurrent infections play on growth and metabolism. I saw a girl about a year ago who was having the second dentition and while the teeth were emerging she had influenza and the laying on of the enamel was arrested, showing an upset calcium metabolism with injury to the delicate cells. That is also interesting if followed on through the work done by Mott, Such and others regarding the postmortem examination of gonadal cells in dementia precoc. During the period of adolescence or embryonal growth, the cells are subject to a sort of trauma. We know that the object of all our lives is to continue to reproduce. In those who do not care to live, the first impulse is to destroy life. This is easily effected through an unconscious self-destruction of the gonads at puberty.

As to the question of nocturnal enuresis, it is interesting to me not only as the case was told but because of some of the more remote psychogenic factors involved. One or two cases similar to this one have come under my observation.

A boy twenty-one years old came to me, not for that trouble, but with dysphagia. He came first of all on account of not being able to swallow any food excepting milk. He said that if he swallowed he choked. Of this he was afraid. Incidentally I found that he would go home Saturday at noon and stay in bed until Monday morning. He had milk every three or four hours during this time. He had to get up to urinate every hour or so. It was an interesting picture. The boy in that particular case was trying to get back to an infantile state unconsciously, having his mother bring him milk every few hours, etc. He was urinating frequently just as when a baby. It was a reduplication of the infantile picture. He had just got out of school and had to make his living. Consciously he was willing to work but his unconscious impulse was to be a baby again. After the explanation of the condition the boy's symptoms cleared up. He understood the mechanism

of the unconscious impulses and was perfectly able and willing to assume his responsibilities and now leads an adult life without going back to his infantile week-end parties.

Two more cases: One of a young man, very successful, came to a colleague of mine on account of a compulsion of going to a Turkish bath once or twice a week and sneaking off to one corner, wrapping himself in a towel and urinating or defecating as the case might be and hiding the result of his performance. Now can you explain this in any other way than as a desire to get back to the infantile diaper condition?

Every psychopathological situation we encounter has a motive. There is nothing that is done that has no definite goal. It may not seem logical but it has invariably a definite core and that core in the majority of cases is infantile. It may seem very fantastic but, when we understand it, it clears things up. You cannot dismiss it by saying that a man is crazy. This young man was not. The compulsion when investigated revealed a purpose. The purpose was to gratify an infantile craving and to relive a pleasure period of his life.

The other case was another one of nocturnal enuresis in a woman of thirty-five, beautiful and apparently physically normal. There was exactly the same underlying mechanism. She did not come for this symptom but because of an assortment of phobias. Again an infantile craving to get back to the days and nights of her childhood. These psychic impulses have been little understood until recently. Now we can probe into the unconscious and, through understanding, effect cures.

## THE RADIUM TREATMENT OF CHRONIC MYELOGENOUS LEUKEMIA, WITH A REPORT OF FIVE CASES.\*

By I. A. BIGGER, Jr., M. D., University of Virginia.

The characteristic findings in chronic myelogenous leukemia are a great increase in the white cell count, large numbers of neutrophilic myelocytes in the circulating blood, and a secondary anemia. The bone marrow is firm, pinkish gray or yellow and homogeneous, showing great myelocytic proliferation, but little erythroblastic tissue. The spleen is large, firm, and deeply notched. Its structure somewhat resembles that of the bone marrow. The liver tissue is often partially replaced by myelocytes. The pathological process is apparently primary in the bone marrow.

Remissions occur normally in chronic myelogenous leukemia, and may be brought about by the therapeutic use of benzol, X-rays, or radium; or by intercurrent infection. The most satisfactory remissions have been obtained through the use of radium, and cases entirely resistant to benzol or X-rays have responded satisfactorily when treated with radium.

Radium was first used in the treatment of

\*Read before the Piedmont (Virginia) Medical Society, November 25, 1922.

myelogenous leukemia by Renon and Degrais in 1910. They reported twelve cases in 1914 and numerous cases have been reported since that time, practically all giving satisfactory temporary remissions.

The radium may be applied over the spleen, over the marrow of the long bones, or in both places. The most rapid remissions are obtained by treatment over the spleen, and it is apparently less dangerous. Intensive treatment over the long bones may cause injury to the erythroblastic tissues with a resultant severe aplastic anemia. A very large number of myelocytes are collected in the spleen and are more easily exposed to the radiations than in other parts of the body. The dosage varies considerably with different workers; Metcalf advises massive doses at infrequent intervals, but the majority of observers advise moderate doses at intervals of from four to six weeks until the leucocytes fall to 15,000 or thereabouts.

Here following radiation over the spleen, one notes rapid fall in the number of white cells in the circulating blood; the spleen decreases rapidly in size but not so rapidly as the decrease in the white blood count; there is an increase in the number of red cells and hemoglobin content, with a rapid improvement in the patient's general condition.

The remissions may last for months or even years, showing there is more than a mere destruction of myelocytes in the spleen and circulating blood. The prolonged remission may be due to the destruction of large numbers of myelocytes in the spleen and blood stream; radiation over the spleen causes a fibrosis, thus retarding the formation of myelocytes in that organ; a small part of the rays are carried to the bone marrow producing an inhibitory effect on the myeloblastic tissue, and it is possible a leucotoxin is formed by the action of the rays on the myelocytes in the spleen.

Although the remissions may last for months or years, there is always a recurrence and subsequent remissions are increasingly difficult to obtain.

**TECHNIQUE OF APPLICATION.** In our series of five cases of chronic myelogenous leukemia, treated with radium, we have used the following methods: One hundred milligrams of radium bromide was used routinely; raised one inch from the surface and screened by one millimeter of lead. The area over the spleen

was divided into areas two inches square, each area receiving 300 milligram hours.

#### REPORT OF CASES.

**CASE I.** Mrs. E. C., white, age 21 years, admitted to the University of Virginia Hospital, April 3, 1922.

*Complaint:* Weakness and abdominal discomfort.

*Family history and past history:* Negative.

*Present illness:* The patient has noticed gradually increasing weakness since May, 1921. In September, 1921 she began having attacks of generalized abdominal discomfort accompanied by headache, nausea, and diarrhea. She did not menstruate from September, 1921 until January, 1922. In December, 1921 she passed considerable blood by bowel. Patient first noticed a mass in the upper left abdomen in September, 1921. Rather rapid growth since that time.

*Physical examination:* Pale, poorly nourished woman, apparently about 25 years of age. Palpable inguinal and axillary glands.

*Abdominal examination:* Abdomen distended. Palpation reveals a mass extending from the left costal margin to the brim of the pelvis, firm, smooth, and deeply notched. The liver is only slightly enlarged.

*Examination of blood shows:* White blood cells, 278,000 per c. m. m. of blood; Red blood cells 3,500,000 per c. m. m. of blood; Hemoglobin fifty-five per cent (Dare); Differential count shows neutrophilic myelocytes, fifty-two per cent; Wassermann negative.

April 8th—4,200 mg. hrs. of radium; 300 mg. hrs. to each of fourteen areas.

April 17—White blood cells, 56,000 per c. m. m. of blood; Red blood cells 3,650,000 per c. m. m. of blood; Hemoglobin fifty per cent (Dare).

April 22nd—White blood cells, 58,000 per c. m. m. of blood.

April 25th—White blood cells, 60,000 per c. m. m. of blood.

May 1st—White blood cells, 30,000 per c. m. m. of blood.

May 6th—300 mg. hrs. radium to each of 9 areas—2,700 mg. hrs.

May 8th—Red blood cells, 4,920,000 per c. m. m. of blood.

May 8th—White blood cells, 32,000 per c. m. m. of blood. Hemoglobin eighty per cent (Dare).

May 13th—White blood cells, 12,000 per c. m. m. blood.

At this time the spleen reached to the level of the umbilicus and to the midline. Her general condition was very much improved. Heard from on June 25, 1922, stating that she was very much improved. She did not return for further treatment.

CASE II. C. M. Female, colored, age 38 years. Admitted to the University of Virginia Hospital on February 8, 1922.

*Complaint:* Nausea, weakness, and a tumor in the abdomen.

*Family history and past history:* Negative.

*Present illness:* The patient noticed a mass in the upper left abdomen about six months before admission. It has increased rather rapidly in size. Patient is always nauseated after meals.

*Physical examination:* The patient is a poorly nourished, anemic white woman apparently about 35 years of age. Inguinal glands are palpable.

*Abdominal examination* shows a firm, smooth mass extending from the left costal margin to within two inches of the pubis. Deeply notched, and evidently an enlarged spleen. The liver extends two inches below the costal margin.

*Examination of blood* shows: Red blood cells, 3,800,000 per c. m. m. of blood; Hemoglobin seventy per cent (Dare); White blood cells, 560,000 per c. m. m. of blood; Differential count shows sixteen per cent neutrophilic myelocytes; Wassermann negative.

February 14th—White blood cells, 690,000 per c. m. m. of blood.

February 17th—400 mg. hrs. of radium applied to each of sixteen areas—6400 mg. hrs.

February 24th—White blood cells, 202,000 per c. m. m. of blood.

March 3rd—White blood cells 114,000 per c. m. m. of blood.

March 3rd—400 mg. hrs. of radium applied to each of eleven areas—4,400 mg. hrs.

March 10th—White blood cells, 62,000 per c. m. m. of blood.

March 17th—White blood cells, 27,000 per c. m. m. of blood.

March 17th—400 mg. hrs. radium applied to each of three areas—1,200 mg. hrs.

March 26th—White blood cells, 10,000 per c. m. m. blood. Neutrophilic myelocytes six per cent. The spleen reaches nearly to the level of the umbilicus, and within one inch of the midline. General condition very good.

July 20th—General condition very good.

White blood cells, 55,000 per c. m. m. of blood. Red blood cells 4,800,000 per c. m. m. of blood neutrophilic myelocytes fourteen per cent. She was found to be about four months' pregnant.

July 20th—300 mg. hrs. radium applied to each of six areas—1,800 mg. hrs.

September 1, 1922—White blood cells, 23,000 per c. m. m. blood; Red blood cells, 4,500,000 per c. m. m. blood. The spleen reaches about two inches below the costal margin.

September 2nd—300 mg. hrs. radium applied to each of three areas—900 mg. hrs. total.

October 12th—White blood cells, 64,000 per c. m. m. blood; Red blood cells, 4,000,000 per c. m. m. blood; neutrophilic myelocytes forty one per cent. Temperature on admission ninety-nine degrees.

October 14th—300 mg. hrs. radium applied to each of six areas—1,800 mg. hrs.

October 16th—White blood cells—30,000 per c. m. m. blood.

October 17th—Delivered of seven months' (stillborn) foetus. Patient had two weeks of practically normal puerperium.

November 7th—White blood cells, 21,000 per c. m. m. blood. Temperature 103 degrees. Blood cultures and Widal test negative. Smear negative for malaria.

November 17th—900 mg. hrs. radium, 300 mg. hrs. to each of three areas.

November 20th—White blood cells, 17,500 per c. m. m. blood. Myelocytes six per cent; Myeloblasts twenty-four per cent.

November 23rd—White blood cells, 14,500 per c. m. m. blood. Temperature 104 degrees—105 degrees. The spleen reaches almost to the brim of the pelvis.

November 24th—Lethal exodus. Autopsy refused.

CASE III.—Mr. J. R. White, age, 62 years. Admitted to the University of Virginia Hospital, September 12, 1922.

*Complaint:* Weakness and a tumor in the upper left abdomen.

*Family history and past history:* Unimportant.

*Present illness:* He has noticed a gradual loss of strength during the past three years. The mass in the upper left abdomen was not noticed until one week before admission.

*Physical examination:* Well developed and well nourished white man apparently 60 to 65 years of age. No glandular enlargement. Temperature normal. Abdominal examination shows the spleen reaching from the left

costal margin to the umbilicus. The liver is not enlarged. Wassermann is negative. White blood cells, 140,000 per c. m. m. blood. Red blood cells 4,600,000 per c. m. m. blood. Hemoglobin eighty per cent (Dare). Neutrophilic myelocytes thirty per cent.

October 11th—2,100 mg. hrs. radium, 300 mg. hrs. to each of seven areas over the spleen.

November 2nd—White blood cells, 12,000 per c. m. m. blood; Red blood cells, 5,000,000 per c. m. m. blood; Neutrophilic myelocytes five per cent. The spleen reaches about two inches below the costal margin. General condition good.

March 5th—White cells, 11,200 per c. m. m. of blood; Red cells, 3,000,000 per c. m. m. blood; Hemoglobin sixty-five per cent (Dare); Neutrophilic myelocytes one and five-tenths per cent. Spleen just palpable. General condition good.

CASE IV. Mrs. L. A. White, age 45 years. Admitted to University of Virginia Hospital, May 11, 1922.

*Complaint:* Persistent nausea and weakness.

*Physical examination:* A rather anemic, obese, white woman, with no glandular enlargement.

*Abdominal examination* shows a small easily reducible umbilical hernia. The spleen reaches about four inches below the left costal margin. The liver projects about 1 inch below the right costal margin.

May 11th—White blood cells, 47,000 per c. m. m. of blood; Red blood cells, 3,400,000 per c. m. m. of blood; Hemoglobin eighty per cent (Dare); Neutrophilic myelocytes thirty-one per cent.

May 19th—2,400 mg. hrs. radium. 300 mg. hrs. to each of eight areas over spleen.

May 22nd—White blood cells, 42,000 per c. m. m. of blood.

June 1st—White blood cells, 69,000 per c. m. m. of blood.

June 5th—3,200 mg. hrs. radium. 400 mg. hrs. to each of eight areas over spleen.

June 13th—White blood cells, 19,500 per c. m. m. of blood.

July 22nd—White blood cells, 5,000 per c. m. m. blood; Red blood cells, 4,000,000 per c. m. m. blood; Neutrophilic myelocytes ten per cent. The spleen was just palpable beneath the left costal margin, and general condition was very much improved.

March 12th—White blood cells 70,000 per c. m. m. blood; Red blood cells 3,800,000 per

c. m. m. blood; Neutrophilic myelocytes forty-two per cent.

March 18th—1,800 mg. hrs. radium. 300 mg. hrs. to each of six areas over spleen.

April 4th—White blood cells, 12,000 per c. m. m. blood. General condition good.

CASE V. B. F. Admitted to University of Virginia Hospital, June 22, 1922. White, female, age 12 years.

*Complaint:* Weakness and an abdominal tumor. The mass in the upper left abdomen was noticed about thirteen months before admission to the hospital. Has increased rather rapidly in size, and accompanying this there has been a progressively increasing weakness. One month before admission to the hospital patient had a severe nasal hemorrhage. Physical examination shows an anemic, poorly developed, and poorly nourished white girl apparently 10 to 12 years of age. No glandular enlargement.

*Abdominal examination.* The spleen almost entirely fills the left side of the abdomen, and extends about two inches to the right of the midline, firm, smooth, and deeply notched. The liver is only slightly enlarged.

Temperature on admission 100 degrees F.

White blood cells, 257,000 per c. m. m. blood; Red blood cells, 2,670,000 per c. m. m. blood; Hemoglobin fifty per cent (Dare).

June 26th—3,000 mg. hrs. of radium. 300 mg. hrs. to each of eleven areas over spleen.

July 7th—White blood cells, 51,000 per c. m. m. blood.

July 13th—White blood cells, 17,000 per c. m. m. blood.

July 13th—1,200 mg. hrs. radium. 300 mg. hrs. to each of four areas over spleen.

August 17th—White blood cells, 9,000 per c. m. m. blood; Hemoglobin seventy-five per cent (Dare); Neutrophilic myelocytes one per cent. The spleen reaches about two inches below the left costal margin. General condition excellent.

November 25th—White blood cells, 55,000 per c. m. m. blood. 2,400 mg. hrs. radium applied. 300 mg. hrs. to each of eight areas over spleen.

March 10th—White blood cells, 47,000 per c. m. m. blood. 1,500 mg. hrs. radium. 300 mg. hrs. to each of five areas. Patient in very good general condition, but has had several severe nasal hemorrhages.

## CONCLUSIONS

(1) We have obtained very satisfactory temporary remissions in all of our five cases of chronic myelogenous leukemia treated with radium.

(2) Case No. II developed an acute leukemia, and there was a lethal exodus.

(3) Radium seems to have no effect on the acute leukemias.

(4) Surface applications over the spleen with moderate dosage seems the safest and most efficient plan of treatment.

(5) With our present methods radium is not curative, but is our most satisfactory agent in the treatment of chronic myelogenous leukemia.

(6) With improvement in the technique of application we should obtain more satisfactory and more lasting remissions.

## EYE INFLAMMATIONS CAUSED OR INFLUENCED BY DENTAL SEPSIS. REPORT OF CASES.\*

By CLARENCE PORTER JONES, M. D., F. A. C. S.,  
Newport News, Va.

Just how does focal infection act in the mischief wrought is an unsettled fact, whether by bacterial invasion through the bloodstream or lymph stream, by toxins or perhaps both.

From my record for this year (1923), six months, I pick out 13 cases; from each I learn something worth while.

## IRITIS: FIVE CASES.

Mrs. A., 56 years, history of rheumatism, negative Wassermann. Seen first on April 19. There was a plastic adhesion of iris to lens capsule; it was impossible to get a dilatation of the pupil worthy of the name, although 3 per cent atropine was instilled every 3 hours, finally every hour, this supplemented by daily

subconjunctival injections of atropine, 1/150 grain. On May 3, all of her teeth, eleven in number, were extracted, each tooth or its gum being infected. On May 5, all pain had disappeared, there being a maximum dilatation of the pupil. Treatment was discontinued and she has remained well. The striking point here was the apparent "iron bound," so to speak, adhesions to the lens capsule, melting away like snow in 48 hours after the removal of the focus.

Mr. H., 29 years, iritis and episcleritis. Negative Wassermann. There was pyorrhoea alveolaris in four teeth. Prompt and thorough dental care for twenty days caused a disappearance of the symptoms.

Mr. E. C. H., 58 years, iritis, positive Wassermann. He had an attack about a year ago, whose acute symptoms, pain, photophobia, etc., disappeared spontaneously upon the extraction of an abscessed tooth; he was remanded to an internist for general treatment. In January he was suddenly seized with a most violent uveitis, same eye. The usual remedies were vigorously employed, 3 per cent atropine every hour, without any but a moderate dilatation of the pupil, and without any relief from pain. A limited amount of morphine was allowed, as his suffering was intense. This condition lasted for three weeks till his dentist was prevailed on to remove the crown from two teeth, exhibiting hidden necrosis with a most foul odor. These teeth were extracted. In six hours all pain was gone and a sufficient pupillary dilatation was now easy to get. The usual treatment was continued till the cornea became clear and the eye became quiet, which required ninety days, yet there was no more pain or discomfort. He returned to work two days after the teeth were extracted, and has been at work ever since.

Mrs. G., 34 years, uveitis. Positive Wassermann. Last September she had fine opacities of the vitreous of the left eye and a mild iritis, which cleared up promptly after extraction of nine pyorrhoeic teeth. Similar to the last case, she was taken in February, with uveitis of a most violent type, in the same eye. Being encouraged, a more prompt study of her case was made. Roentgenograms of the sinuses showed no pathology; those of the jaws revealed two teeth with apical abscesses. These were extracted. In thirty-six hours every vestige of pain was gone and has not returned.

\*Read before the Ophthalmic and Aural Section of the Norfolk County Medical Society, June 28, 1923.

She resumed her work, proof reading, in three weeks after the teeth were extracted.

Wm. J., colored, 63, iritis, positive Wassermann. The case presented difficulties in diagnosis in its early stage, symptoms so much like glaucoma that it was necessary to measure the tension, which was 38 m.m. (McLean), several days later, however, unmistakable signs of iritis were present. As in the other cases, a satisfactory pupillary dilatation was impossible to obtain. His mouth was a veritable dental "Curiosity Shop," queer shaped teeth, a variety of colors, several sometimes in the same tooth, the gums were all infected and each tooth was either pyorrhoeic or abscessed. All teeth, seventeen in number, were extracted, nine one day and eight the next. All pain and discomfort disappeared within twenty-four hours, the pupil readily dilated and the patient resumed his business, a fish merchant.

The facts learned from these last three cases compel me to regard focal infection as an important element in syphilitic iritis. We should not say with a cynical shrug of the shoulder, "there you are," and let it go at that, when we find syphilis; but look most diligently for contributing causes and remedy the same. The sudden relief from pain and the easy dilatable pupil in all five of the cases is indeed spectacular.

#### CORNEAL ULCERS. TWO CASES.

Mr. A., 26 years, two ulcers on right eye. One was about 2 m.m. in diameter, the other smaller; negative Wassermann. He was seen March 29. Most careful treatment was instituted with no apparent improvement, until two abscessed teeth were extracted, on April 11. Pain was relieved, and on April 19, he was dismissed, healing being complete. I saw him five days ago and he has remained well.

Mrs. R. L. H., 43 years, was seen May 20, with a large superficial central ulcer of the left cornea. She had a variety of dental disorders—gum abscesses, cavities, broken teeth and pyorrhea. She was sent to a careful dentist, who immediately begun to clean up the premises. In the meantime, she came daily for treatment of the ulcer, but had no relief from pain or apparent healing. There was remaining one suspicious tooth, which she seemed to regard as a pet, and was loath to part with. Finally, on June 16, she consented

to its extraction, it being abscessed at its apex. The next day she returned in a happy mood; she informed me she slept through the night without waking, and that she had no pain whatever. The ulcer has healed, and, owing to its shallowness, the scar is thin, allowing 20/50 vision.

I learn from these two cases, in the language of the pugilist, "Something must be holding it up," and it behooves us to search for this something and remove it.

#### GLAUCOMA. ONE CASE.

H. E., 52 years, was seen first time over two years ago. His right eye was glaucomatous; it was divergent and amblyopic since childhood, the nerve head was cupped, vision reduced to light perception. The tension was 88 m.m. (McLean); the fellow eye was normal, tension 29 m.m. He said that he had recently had an attack of tonsillitis, that for several years he had had three or four attacks of tonsillitis each year, and that each attack was always followed by severe pain in his blind eye, together with some nausea. This would last for about two weeks, then he would have relief till the next tonsillitis, etc. He had a negative Wassermann. I enucleated his tonsils while he was suffering from the glaucoma attack. There was prompt relief from ocular pain, the tension dropped about 20 m.m. and the eye remained quiet till February, this year, when the glaucomatous pain returned. His tension then was 96 m.m. (McLean). Roentgenograms of his sinuses showed no pathology; those of his jaws revealed an abscessed anterior molar tooth. This was extracted. The pain straightway left the eye, the tension dropped to around 65, and the eye became quiet, and is still so. Was not glaucoma induced by focal infection? Is it not fortunate for him that the useless eye was attacked instead of the fellow eye?

#### EPISCLERITIS. TWO CASES.

There was nothing spectacular in either case, the ages being 38 and 41, respectively. Each showed a negative Wassermann. Each had relief from extraction of abscessed teeth. In even recent years one is at times desperate in observing the extreme slowness oft times in the progress of this disease. While two swallows do not make a summer, yet I gleam a ray of hope from the results here.

OPACITIES OF THE VITREOUS, WITH MENTAL SYMPTOMS. ONE CASE.

W. A., 54 years, was seen March 27. He complained of suffering from a vague headache, as he expressed it, and tiny yellow butterflies in front of his right eye; said about 4 o'clock each day he began to lose himself, not knowing just where he was. He is a school principal and always would go immediately home, which was a few hundred feet from his school, to be with his family. Said he had a feeling, if the family would leave him alone, that something would come and get him. About 9 o'clock this feeling would leave him and he would get a fair night's rest, thus going through this cycle day after day. He had a negative Wassermann. The ophthalmoscope showed fine opacities in the vitreous of the right eye. The roentgenograms showed nothing except a canine tooth with an apical abscess.

The dentist did what I consider a questionable thing, i. e., drilled to the tip of the tooth, cleaning out the abscess, leaving the tooth *in situ*. However, the vague headache and mental symptoms disappeared promptly. The "yellow butterflies" ceased to "fly" in about three weeks. He is now well and has had no return of the symptoms.

Comment on this case is difficult to make. Its understanding is hard. The results are most gratifying.

MIGRAINE. ONE CASE.

Mrs. L., 37 years, complained of ocular migraine of three months' duration, seizures lasting about six hours, three or four per week. Her refraction was measured to find her eyes emmetropic, and her muscles balanced. She had four impacted wisdom teeth and two pyorrhoeic teeth. A dentist gave her careful attention. She is not well, although she has seizures much less frequently, and much less severe, so there is encouragement.

ORBITAL NEURALGIA. ONE CASE.

Mr. S., 72 years, was seen May 17. He was the most intense sufferer from this symptom I ever saw. He had received morphine in half grain doses for ten days, yet his expressions were pathetic, moans, groans and screams. The left eye was injected and was the seat of the pain. There was no disturbance of vision and the ophthalmoscope showed no pathology. The

conjunctiva was red. There was some increase of pain upon exposure to light, but a draught of air, even the breath from a bystander, would bring on a paroxysm lasting about three minutes, of the acute suffering as above described. Roentgenograms of his sinuses showed no pathology, but his seven teeth, all he had, were abscessed. These were extracted.

I lost sight of him till last week, when the dentist received a letter from him saying he is well and about his business. He is a farmer.

A careful study of one's cases is not only a duty to the patient, but it adds zest to one's life's labor.

ASPIRATION OF CEPHALHEMATOMA OF THE NEW BORN.\*

By BURNLEY LANKFORD, M. D., Norfolk, Va.

Cephalhematoma and caput succedaneum are not the same condition, though they are given as synonymous in Dorland's dictionary.

Some months ago the former condition developed in a child delivered by me, the course of which was different from the usual one, and which gave me some little concern. Active treatment, such as will be advocated below, would have influenced this untoward course for the better. True cephalhematoma must be differentiated from caput succedaneum and from meningocele. It is much less frequent than caput, and more frequent than meningocele. Briefly the points of difference are the following.

A caput is always present at birth, a hematoma may be present then or it may develop within three days. A caput is a rapid effusion of serum, a hematoma is a slow effusion of blood. A caput tends to decrease after birth, a hematoma may, and usually does, increase for several days and may continue to increase for a week after birth. With a caput present, the skin over the swelling is darker than the rest of the scalp; with hematoma there is no discoloration of skin. A caput never fluctuates but has a doughy feel. A hematoma does fluctuate. The swelling produced by a caput may cross a suture line; that of a hematoma does not. The *feel* of the underlying bone around a caput does not suggest a depressed fracture; that around the edge of a hematoma does feel exactly like a depressed fracture.

\*Read before the Norfolk County Medical Society.

Last, a caput disappears within a few days, a hematoma is *said* to disappear within one to three months, but all of them do *not*.

A meningocele pulsates with the heart, and becomes tense when the infant cries, which characteristics should easily and quickly differentiate it from either of the other two conditions.

All text books say that cephalhematoma requires no treatment unless suppuration ensues. This I believe to be not good advice, and for several reasons. The case below is cited as one reason.

The infant a male, was born to a primiparous mother of thirty-four years, after a spontaneous labor. The pelvic measurements were all adequate. The perineal stage of labor was a little longer than the average, due to very resistant outlet muscles. Neither of these factors however (time and resistant muscles) were more marked than hundreds of other cases showing no hematomas in the babies.

At birth this infant's head showed no swelling other than a small caput. Twenty-four hours after birth the nurse called my attention to a swelling over the right parietal bone, which she said was just becoming noticeable. This continued to increase for several days, finally becoming approximately 8 cm. long, 4 wide and 3 deep. Forty-eight hours after birth an occipital swelling appeared, which within two days became approximately 3 cm. in all three dimensions. Following the let alone advice of the past, these were let alone, the parents *and* grandparents assured that the tumors would disappear within a few weeks, a month or two at most.

Neither of these swellings seemed tender at any time, nor did they seem to give the baby any discomfort. The reason for reporting this case is to question the wisdom of the usual "let alone" advice. Six months after birth there still remains marked deformity of the baby's skull, and the condition, while not serious nor dangerous, has given the parents a deal of concern and brought into disrepute the prognosis given at time of birth. These swellings, after about ten days, began to give a parchment like feel to the palpating finger, they daily grew thicker and harder and after a month were apparently solid bone, and as such they have remained. This could all have been avoided if the effused blood had been aspirated as soon as it stopped collecting.

The cause of hematoma of the new born

cannot always be determined. Certainly trauma during passage of the birth canal, whether spontaneous or the result of instrumental delivery, often seems to be the cause. When trauma, associated with the hemorrhagic diatheses, occurs in the same birth, the conditions would seem to be just right for this type of hematoma.

If the swelling comes on early and increases rapidly, it will be good therapy to give a subcutaneous injection of whole mother's blood, 10 c.c. followed in a few hours by 10 more. When the swelling has ceased to increase, it seems to me that the proper treatment should be aspiration. This should be done with a rather large sized needle, attached to a Luer syringe, so that suction may be applied. By the use of a needle, syringe and suction, rather than a trocar, a much smaller opening is possible and the risk of infection minimized. The hair should be shaved and the skin carefully prepared with iodine and alcohol. It may be necessary to repeat the aspiration twenty-four or forty-eight hours later.

Since the above case, I have treated two cases of cephalhematoma in the new born by the above method, with perfect results.

### THE ROENTGENOLOGIST AND THE REFERRING PHYSICIAN: THEIR RELATIONS.\*

By J. E. HARRIS, M. D., Winchester, Va.

The purport of this short paper is not scientific as can be inferred from its title. Instead of occupying the happy and coveted position of a veteran in this field of special work, I am only a private in service. However, as far back as the year 1904 I owned and operated an X-ray machine in conjunction with my general practice, but it was not until this last year that I gave up general practice and began to devote all of my time to this line of work as a specialty. This being the case it would be breach of good judgment for me to attempt to discuss scientifically the many problems that now confront us in the X-ray field of diagnosis. The great trend of the profession today is towards the fields of specialism which makes it incumbent upon those doing special work to strive the more persistently to be original in their special lines. Unless I could present to you some new phase of the work

\*Read at the meeting of the Medical Association of the Valley of Virginia in Winchester, May 31, 1923.

in my special line, it would be unfair for me to consume your time by presenting a paper based altogether upon what others have already accomplished.

I think the ambition of every man doing special work should be not to do some one thing as good as some one else but to do it better—certainly we should have high aspirations and not be content with even a moderate degree of perfection in our special lines. Every line of business today is becoming saturated with progressive ideas and the science of medicine is no exception to this rule. We cannot practice medicine and surgery today as we did even twenty years ago, because we are living in an atmosphere of forward progression; therefore, the specialist must strive to be as near perfect as possible. *Efficiency* should be the watchword and not *commercialism* as is often the case.

The roentgenologist occupies rather a unique position when compared to men doing work in other special lines—in that the roentgenologist deals with the patient only through the referring physician, which creates an obligation that does not exist in other special lines; therefore it can be readily seen that the relations existing between the referring physician and the roentgenologist of necessity should be most cordial and inspired by real confidence from both sides; if this be the case it will redound to the pleasure and helpfulness of all parties concerned.

The moral obligation from both sides is too important to be overlooked. I am convinced that all medical ethics is founded upon one great principle, and that is the treatment that one gentleman deserves and should receive from another.

When a physician or surgeon chooses to refer his patients to the roentgenologist for examination, he should have the full satisfaction of knowing that the patient will be dealt with scientifically and conscientiously.

The roentgenologist has a moral obligation to both patient and referring physician and just how best to exercise this obligation is a thing that the roentgenologist can only determine.

We should be guided by the golden rule and learn to give and take, as it were. Within the past few years roentgenology has taken a permanent stand in the ranks as a recognized specialty in the diagnostic field. While this

is true we must not forget that the roentgen ray has its limitations of usefulness.

We must not expect it to reveal the things impossible. If you will keep in mind the physical laws relative to all light rays, you will readily understand that we are dependent upon the density of tissues to the ray penetration for our findings.

We are handicapped oftentimes by unusual circumstances and conditions over which no one has any control and for that reason our patience is often taxed to the limit of endurance before we can conscientiously report our findings. Often we have to request a second examination in order to verify the findings in the first, before we can report.

Quite often delayed reports seem to displease the referring physician.

In the rush of business and for the want of time, it is sometimes perplexing for the referring physician to have to wait for a report and I am sure every roentgenologist shares this feeling with him; but on the other hand, the roentgenologist deserves some consideration and the delay and the time consumed in his painstaking procedure should commend itself to you rather than provoke you, so that your co-operation in this matter will be appreciated by all roentgenologists.

The value of the science and the usefulness of it are no longer questionable in the minds of progressive medical men and modern surgeons. The usefulness of it to a given community, however, depends largely upon the frequency with which it is used. Just how much help the roentgenologist can be to the referring physician depends somewhat upon how much they seek to use him.

All physicians and surgeons frequently have obscure cases coming up for diagnosis and many of these will have been the rounds from one physician to another for sometime until they have gotten into what we term the chronic stage. This class of patients not only deserve a large share of our sympathy but demand oftentimes the taxing of our professional skill to its limits; and it is in these cases that we should exhaust every means at our disposal in order to make a correct diagnosis.

Should we succeed in these cases, we should not aspire to the one pecuniary reward as full payment for services but that greater reward which lies in the fact that we have discharged our conscientious as well as professional duty in accomplishing something that was not only

necessary but something that had not been accomplished before.

While roentgenology is comparatively of modern creation, at the same time its usefulness is so apparent that we should banish the idea from our minds that it is a new thing in the line of scientific discovery. Its use has certainly passed the experimental stage; yet, at the same time, a large percentage of the profession have very vague ideas as to its limitation and usefulness. Time and service will certainly correct these ideas.

It was predicted that after the late war the public would have thrust upon it a large number of men who, for the want of time, were poorly trained in the use of the X-ray and, for pecuniary reasons, would seek to use the roentgen ray unscientifically, but I am glad to say that this has not been the case to the extent that was predicted, because in many states an examination of proficiency is being required of both technicians as well as roentgenologists. While it is true the country needs and demands more men in this field of work, yet I believe there should be an increase in quality as well as quantity.

They should be more conservative in their ideas and broader from an educational standpoint. In passing, it might be well for me to state the difference between an ordinary technician and a roentgenologist.

A technician is one who (often a layman) is master of the technique in operating the machines and making the exposures but without medical training. The roentgenologist is one who is not only master of the technique but has a thorough knowledge of medicine and has been well trained as such. The average technician can never make a safe roentgenologist, due to his lack of medical knowledge. The roentgenologist must be a well trained medical man and have a thorough knowledge of anatomy, pathology and histology and, if he has had several years of general practice to his credit, it will prove an invaluable asset. The correct interpretation of the X-ray findings as depicted on the plates or films is the real scientific part of the work and to be proficient in this requires close attention and constant study in conjunction with good sound judgment.

While I am a firm believer in the use of the rays and think that we should use them more than we do, yet I think we should always have a good reason for subjecting a patient to an

X-ray examination—we ought to expect to accomplish something by the examination. It is true not every examination is positive, but quite often we are more pleased to render a negative report than we are a positive one. Its use should have a real value and to use it for the want of something to do should be discouraged. In the hands of unscrupulous operators it is being used with great success to play upon the receptive minds of the neurotics.

But I am glad to say that the referring physician does not contribute to this kind of fakery because, as these fakirs are known to the referring physician through the victims, he does not refer his patients to this class of men.

Oftentimes the roentgenologist is inclined to disregard all other clinical data except that which is depicted on the plates or films by the rays; to do this I think is a great mistake, as certainly in many cases the X-ray findings should be only a link in the diagnostic chain. Not one of us is infallible and we are all liable to make mistakes; if we do, we should do the square thing by admitting it and then seek to correct it.

Of course the roentgenologist should realize his obligation to both patient and referring physician. A square deal is what one physician demands from another and, if this rule is adhered to, the relations between the roentgenologist and the referring physician will be most pleasant.

Ordinarily speaking, the referring physician sends his patients to the roentgenologist only for examination and not for treatment, unless so specified; therefore, after the X-ray examination, it would be highly unethical for the roentgenologist even to suggest a line of treatment in the case, or to suggest that certain physicians or surgeons be consulted in the case. This is a matter to be decided by the referring physician and the patient and not by the roentgenologists. To be guilty of this would be a breach of confidence on the part of the roentgenologist who should be a friend and consultant, as it were, to every physician and surgeon within his territory. They should bear the most cordial relations towards each other and be free to work amicably together for the good of the cause. I further think that it would be most unwise for any roentgenologist to ally himself exclusively with any clique or set of physicians in a community because the services of the roentgenologist should be

at the command of every physician in the community in which he lives. He should so conduct himself towards the profession that, when physicians referred their patients to him, they would feel that not only would the patient be cared for scientifically but that the referring physician would get a square deal as well.

It is assumed, of course, that when you refer patients to the roentgenologist you have confidence in his ability and integrity and this same degree of confidence should be reciprocated by the roentgenologist.

When the referring physician receives the report from the roentgenologist, should it not meet with his wishes and approval, it would be unfair for him to evidence his displeasure by making an unkind criticism of it, by word or act, to the patient. I have heard of this being done in some instances and, while it may be self-serving for the referring physician at the time, it will in due time invariably be brought back to the roentgenologist, most likely by this same patient or some of his friends.

If the referring physician is not satisfied with the report, he should seek to assure himself of its correctness by communicating with the roentgenologist and, if necessary, go to see him and get an explanation. If this is done I am sure that an agreement satisfactory to all parties will be reached.

It is well to remember that every film in the office of a modern roentgenologist is on file by name and number, can be found instantly, and that these films and all records relative to his cases are always open to the inspection of the referring physician.

These films are legally the property of the roentgenologist. The patient has no claim on them at all but has a right to a copy of the report of the examination in his case. The fees charged by the roentgenologist are not for the film or plate made but for the opinion of the roentgenologist based on the X-ray findings in the case. The charges are not made as so much per plate or exposure but it is for what these plates or films reveal, whether there be one or twenty.

To maintain a conservative attitude in this work is most necessary and at the same time quite difficult as we are prone to see too much rather than too little. The best work and the best results demand full co-operation from both sides. Impatience on the part of the referring physician will soon lead to the sever-

ance of cordial relations. You should demand good and prompt service from your roentgenologist and in return you should give him your moral support rather than condemn him for his painstaking procedure.

#### DISCUSSION.

DR. W. M. PHELPS, Staunton: I am glad that Dr. Harris has had opportunity to present the subject of the roentgenologist in his relation to the referring physician. It is an important subject, and some physicians seem to have vague ideas as to the relations that should exist. One day a patient who had been in my office went by with some friends, and, pointing to the office, said, "That is the place where they made an electric picture of my stomach." Some of the indefinite directions as to what the referring physician wants often remind me of that lady. We must remember that roentgenology is only one factor in the diagnosis, and in order to make it valuable it is necessary that the roentgenologist and the physician co-operate, and the referring physician should familiarize himself with the procedure of roentgenologic work, and send with the patient definite data as to what he wants done. A tentative diagnosis from the physician would help the roentgenologist in determining the best technic to use to bring out the points required.

DR. F. M. HANGER, Staunton: I just want to speak a good word for X-ray work in my line. I had the good fortune to become a specialist before the X-ray was in existence, and well I remember how I would blunder along in diagnoses in cases of ethmoiditis and maxillary and other nasal sinus infections. I could not determine where the pus was coming from. Then, again, in doubtful cases of mastoiditis when you want to know whether an operation is necessary, X-ray is indispensable. X-ray now makes you sure whether the bone is involved and operation indicated. I feel that it has not made me careless in my work, but when I have a sinus trouble to examine, why worry, just leave it to the X-ray man and he helps me out. I have used trans-illumination for many years; but, barring the maxillary sinus, it is misleading and cannot be relied on. I feel now that I don't know how I ever got along without it. I think it one of the greatest blessings to the specialist, almost as great as the ophthalmoscope. Just think of the ignorance on the part of the specialists, in the old days, before they could look into the eye and determine just what disease was to be found there. Every eye that became blind or nearly blind was called amaurosis. They just guessed as to what was wrong; there was nothing definite. It is invaluable to us, and to the general practitioner, to examine the eye and know definitely what we are doing and what is best for the patient.

#### FOCAL INFECTION FROM THE SPECIALIST'S VIEW POINT.\*

By D. L. RAWLS, M. D., Suffolk, Va.  
Eye, Ear, Nose and Throat Department, Lakeview Hospital.

The subject I have selected not only concerns the eye, ear, nose and throat specialist, but all branches of medicine as well. It is often very difficult to draw a distinct line between the

\*Read at the meeting of the Southside Virginia Medical Association in Petersburg, March 13, 1923.

various fields of medicine, for they merge into each other, but for practical purposes we have what we call border lines. Suffice it to say, however, we must have some knowledge of all, in order to accomplish the greatest good for both patient and doctor. It does not matter whether we are general practitioners, general surgeons, ophthalmologists, oto-laryngologists, gastrologists, neurologists, or what not, the idea is, we must be alert to recognize the S. O. S. call, so to speak, that the victim may be rescued from an infected grave.

The question often arises, as to whether the medical science of today is not developing too much into specialization. All of us recognize that the constantly increasing range of medical knowledge has necessitated specialization, and that we probably have not yet reached the limits. The potent factor in this great change has not only been increased medical knowledge, but the modern desire to become more efficient. This metamorphosis of the physician from a general practitioner to a specialist has not only made great strides in medical science, but has unquestionably had its drawbacks. It is not our aim, however, to grow apart but, to the contrary, to become more and more intimate with each other.

I don't know of any topic in the whole category of medicine which is more important than the subject of focal infection. Here it is we come together, shoulder to shoulder, in order to make a diagnosis. All of us well know that, with all our modern equipment and knowledge, it is often very difficult to locate some obscured focus of infection that is doing untold damage to the patient. When we think of the anatomical structure of the head, with its multiplicity of minute ramifications, we can readily understand why this is the most frequent seat of all the human body, for focal infection. While there is no question that a great majority of the foci of infections causing local and systemic diseases occur in some part of the head, yet we must not ignore other infecting areas of the body, as the gall-bladder, appendix, prostate glands and seminal vesicles, pus tubes, infected bronchi, etc. The fact that so many infecting foci occur in the field embraced in our specialty places a great obligation upon us, not only to search with painstaking care every possible area of infection within the field of our special work, but also to inform the profession in general of the great danger that is often lurk-

ing in this region, such as the tonsils and adenoids, teeth, and the alveolar processes, salivary glands and ducts, the middle ear and mastoid cells, the nasal accessory sinuses, lacrimal glands and duct, etc.

The microorganisms that are most frequently found in the above structures are the staphylococci and streptococci of various forms, pneumococcus, diphtheria and pseudodiphtheria bacillus, tubercle bacillus, grippe bacillus and micrococcus catarrhalis. These organisms reach the system either through the blood stream or the lymphatics, more frequently by the former. After reaching the general circulation they find lodgment in the capillaries and terminal arterioles, producing capillary embolism. When bacteria are halted in the blood stream, there is produced at the site, proliferation of the endothelial lining and an exudate of leucocytes and plasma cells. It would be easy for a focus in chronically diseased tonsils or elsewhere in the head to cause serious lesions in distant organs without attention being directed to the primary focus. It is remarkable how many people go about harboring these infected foci with no local or systemic symptoms. However, when one's resistance is lowered by overwork, bad hygienic surroundings, undernourishment, exposure to heat and cold, or excess of any kind, the confined focus may become active and there ensue symptoms of both local and constitutional disease.

Some of the diseases which may have their origin in foci of infection in the head are rheumatism, endocarditis, pericarditis, myocarditis, chorea, pleuritis, arthritis, nephritis, gastric and duodenal ulcer, cholecystitis with and without gall-stones, pancreatitis, neuritis, appendicitis, myositis, adenitis, thyroiditis, osteomyelitis, spinal myelitis, and bronchial asthma. When we think not only of the damage this infection is doing at its original seat, but the great destruction it has done and is now doing in other parts of the body, it behooves us one and all to get busy and eradicate the foci. Even in far advanced cases, by removing the cause, we have minimized the amount of infection, thereby increased the resistive power of the patient, and cured many systemic diseases.

The question now arises, what is the best means of stamping out this infection? First, I should say preventive methods. It would seem that we, as specialists and general prac-

tioners, should do our part in educating the public to take those precautions which will in a great measure safeguard them from this infection. I will not take your time in describing all the various means of prevention nor will I dwell on the treatment, only mentioning a few. Patients with acute colds should be taught that they are contagious and to cough and to sneeze into gauze to be subsequently burned, just as our tuberculosis patients are required to do. Earache is not to be regarded lightly and requires more than the instillation of sweet oil or laudanum. The public should be instructed in reference to the importance of oral hygiene, teeth, etc. Children should be observed closely for mouth breathing and recurrent attacks of sore throat, for here is the starting point of most focal infections.

I think we, as physicians, with the co-operation of the school board, should devise some means, by which the school children can be examined thoroughly, annually, by competent physicians. We know it is going on now and that some unqualified people are attempting this work; while these may be doing their best under the circumstances, they have not had the proper training in this line. If children were examined properly and treated accordingly, most of what we call focal infection would be a thing of the past.

As I have said in the beginning I will not dwell on the treatment, for the field is too wide and time will only permit the relation of a few facts. There are two well established methods of relieving an individual of an infected focus—one by entire removal and the other by drainage. For an example, in chronic tonsillitis we resort to the former, and in acute sinusitis we do drainage. So serious for the patient is the systemic disturbance arising from foci of infection in the chronic tonsil, that we are rarely justified in the use of halfway measures, as incision of the crypts or the use of the cautery or curette.

In conclusion, I wish to say, as Dr. Joseph C. Beck has well said, "That all those who believe that focal infection is a hobby would do well to adopt it, rather than remain on the outside making unjust and severe criticism without really giving the subject a fair trial."

## Reports of Cases

### CLINICAL CASE REPORTS.\*

(1) Report of Clinical Case by DR. KENNETH BRADFORD, Staunton, Va.

In May, 1921, I presented before the Association a case of splenomyelogenous leukemia in a young man then running a white blood count of 185,000. He had an enormous spleen. Diagnosis made in February was leukemia. He had received radium treatment once prior to the meeting. I told at that meeting of the very severe reaction following the treatment by radium. After six weeks he improved and was able to be at the meeting. He has had in all eleven radiations. Last year he was able to spend five months in college. This year he has been at college since March 1st. He has now increased in weight 15 lbs. The spleen is almost normal in size. The white blood count is under 5,000. I feel that he is not cured, and will need radiation the rest of his life, but it is well worth while if life can be prolonged in cases almost hopeless until something more curative comes out.

#### DISCUSSION.

DR. .... Have you used nothing but radium?  
DR. BRADFORD—No, nothing.

(2) Report of Clinical Case by DR. M. J. PAYNE, Staunton, Va.

I wish to report a case of reversed Colles' fracture. This is an unusual fracture. This subject was discussed when I presented a report of the case at the Association of the C. & O. Surgeons. It is the only case of this fracture I have seen in my experience. The injury was sustained by a young man falling from a motor cycle when it collided with an automobile. In this fracture the typical Colles' is reversed, that is, you have the gardener's spade deformity, instead of the silver-fork. The ordinary signs of fractures exist but the deformity is the reverse of the Colles.' This is a very rare fracture. It was described by Callendar in 1864 or 1865. The interesting part of the fracture is the difficulty in retaining it in proper position by the dressings usually employed for the fore-arm. I believe these fractures will be very much more common in the next few years on account of the

\*Reported at the meeting of the Medical Association of the Valley of Virginia in Winchester, May 31, 1923.

wonderful increase in automobiles. The mechanism of the production of this fracture is exactly similar to that of Colles' fracture, though the resulting fracture is reversed. It comes from falling on the back of the outstretched arm, with the hand turned under. Of course, the bone first gives away on the posterior aspect.

The reduction that I found satisfactory is essentially the procedure laid down by Levis for the treatment of Colles', only the steps in reduction are reversed. It is reduced by hyperflexion, then traction, and forcible hyperextension. This is the only way reduction can be done. In the case of the young man I mentioned, the angulation was so great that I thought it would be compound, so I reduced it without X-ray, and then rayed it. I did not have it exactly right and had to repeat the manipulation. It was all right after the second effort. The difficulty experienced was in keeping the end of the radius and the head of the ulna in proper position. Ordinary flat splint will not do this. You cannot use the hyperflexed position as in Colles' fracture. I used the reversed position, the "cock-up" Jones splint, the "Crab splint," and kept the hand hyperextended in that way, and then the fracture stayed in perfect position. Remember that the ulna is the most fixed bone of the fore-arm and the radius must be fixed properly in relation to the ulna.

(3) Report of Clinical Case by DR. WALTER Cox, Winchester, Va.

I have a most interesting case which I have had under treatment over three years: longer than any routine case of the lymphatic type. I ascribe her cure almost entirely to the use of X-ray in the hands of Dr. George Pfahler.

It is a question, however, as to whether some cases classed as lymphatic leukemia may not be merely cases showing a very great hyperleucocytosis. You get leucocytosis up to forty and fifty thousand in infectious diseases. A certain amount over this is called lymphatic leukemia.

I saw the patient the first night and made a tentative diagnosis of probable leukemia. When I made the clinical examination the next day I found a curious condition. The lymphatic nodes in the groins and neck were very much enlarged. The leucocytis was well over 100,000. The diagnosis was adopted and later confirmed. She came back from a trip and

they called me again: she was in a curious condition. There was a very great purpuric lesion over the hand and left side of the neck. I found that a woman doctor had given her a bottle of benzol. Benzol is reported as a two-edged sword. There has been facial paralysis of the left side from benzol. After this cleared up, there was a leucocytosis of 200,000. Dr. Pfahler treated her three times and sent her back with a leucocytosis of 15,000. Always as soon as she gets back to twenty or thirty thousand she goes back for treatment. She seems to be perfectly well now. The blood is now holding around 14,000. Clinically she is entirely well.

RICHMOND, VA., October 15, 1923.

I respectfully submit herewith a statement taken from the books and records of the Virginia Medical Monthly and Medical Society of Virginia, which shows in detail all cash receipts and disbursements from January 1, 1922, to December 31, 1922, inclusive.

I have examined the books and records and verified the cash balances in bank, both at the beginning and end of the year, and I hereby certify that all facts shown in the above statement are true and correct to the best of my knowledge and belief.

L. B. EDWARDS.

STATE OF VIRGINIA,  
CITY OF RICHMOND, TO-WIT:

This day personally appeared before me, John Maurice Miller, a Notary Public, in and for the City, in the State aforesaid, L. B. Edwards, who by me being duly sworn according to law, deposes and says that the facts set forth in the above statement are true and correct to the best of his knowledge and belief, and acknowledges the signature attached thereto to be his own.

Subscribed and sworn to before me this 15th day of October, 1923.

My commission expires February 12, 1925.

JOHN MAURICE MILLER,  
Notary Public.

**Report of the Delegates from Virginia to the  
American Medical Association Meeting.**

The beautiful city of the Golden Gate, together with the entire state of California, united to welcome the seventy-fourth Annual Session of the American Medical Association in the most elaborate and whole-souled fashion.

To begin with, each visitor was presented on arrival with a handsome souvenir book of welcome, containing 222 pages, gotten up in the most elegant style, and entitled "Medical California." On its cover page, decorated with a giant tree and an ancient convent, is the inscription "California Welcomes the A. M. A."

A brief description could not possibly do justice to the publication, which is filled with engravings of the beautiful places of the state, and a description of the various hospitals and colleges, together with local and state Medical Societies. The most minute directions are given in regard to meetings, entertainments, public places and clinics.

The State Society meeting occurred immediately preceding the A. M. A., and several other National Societies held their annual gatherings. All are detailed in the book.

Elaborate clinics and entertainments for the visiting profession were held at Los Angeles, San Francisco, Santa Barbara, San Diego and other points, preceding and following the national gathering.

Large numbers of visiting doctors and their families traveled on special trains, which combined with the trip to San Francisco a sight-seeing tour covering much of the western section.

The hospitality of the profession and laity of San Francisco, and the entire state of California, was lavish and delightful. Never has the Society been more beautifully entertained.

The various meetings, both business and professional, were well attended and inspiring.

Speaker Warnhuis, of the House of Delegates, the retiring President, Dr. DeSchweinitz, and the incoming President, Dr. Wilbur, each of them in his official report, laid great stress on the effectiveness and thoroughness of the productive work being performed by the A. M. A., not only for the cause of organized medicine and the profession at large, but also for the good of the country and humanity. They gave full credit to Dr. Simmons and his splendid corps of assistants.

The death of Dr. Craig, for eleven years the untiring and devoted Secretary of the Association, was noted by all with deepest sorrow, and with expressions of the warmest affection for his memory. His successor, Dr. Olin West, from Tennessee, has already proven his adaptability and fitness for the position, and endeared himself to the membership by his affable manners and deep interest in the work.

The finances of the organization are in such good condition that, notwithstanding the heavy cost attendant upon the erection of a large addition to the home building, the Board of Trustees will probably be able shortly to announce a reduction in fellowship dues.

Since the last session a Bureau of Legal Medicine and Legislation has been established, with Dr. Woodward, formerly Health Commissioner of the District of Columbia, at its head, and has already accomplished effective results, especially in connection with the Prohibition Act and Narcotic Law, bringing about a better understanding between the Government and the profession, and protecting the profession in any infringement of its rights and customs.

In the future, proposed changes in these laws will be properly submitted to the Bureau of the A. M. A. before adoption.

Protest against the training of veterans in chiropractic have been so successful that assurance has been given by Gen. Hines that no future contracts will be made for such training.

The new journal "Hygeia," published by the A. M. A., for the benefit of the public, has been received with tremendous favor and already accomplished great good for the profession. It is earnestly desired that the members of this Society take every possible step to encourage its wide distribution in Virginia, by making it available for their patients, and by urging subscriptions on the various social and welfare organizations.

The Council on Health and Public Instruction laid further stress on the advisability of the local societies urging upon the public the necessity for periodical health examinations and proposes shortly to publish in the Journal a blank form for such procedures.

The Council on Medical Education and Hospitals

reported a reduction in the number of medical colleges from 83 to 81, making the present number just half of what it was in 1906. There has been a gradual increase in the number of medical students with marked improvement in curriculum and teaching facilities.

In reference to the problems of Medical Practice, the Council considers that the modern training of general practitioners is a matter which will have to be given more consideration; that from eighty per cent to ninety per cent of all cases of illness can properly be cared for by well qualified and resourceful general practitioners; and that the need for specialists should not be over emphasized, the trouble at the present time being that many physicians are posing as specialists without having first obtained the essential training.

The problem of the scarcity of physicians in the rural sections is again given full consideration, the principal suggestions being as follows:

"It is believed that any community that can support a physician can get one if its citizens are willing to pledge themselves to guarantee an income of from \$2,500 to \$3,000 a year and to interest the community in the physician's support. This plan has worked out satisfactorily in a Middle West community where the physician selected secured from his practice an income larger than the amount pledged, so that the guarantors have not been called on to pay out any money."

The Council gave considerable attention to Group Clinics with the following conclusions:

"Group medicine is a type of practice which, if properly organized and conducted, will afford efficient service to the fifteen or twenty per cent of the sick and injured who may require special treatment. However, there is an opportunity afforded the groups efficiently to aid the general practitioner in consultations, and in the diagnosis and treatment of his patients. The attitude of the group in its relations to the general practitioner should be characterized by the same fundamental principles and standards of ethics that apply to the individual physician who is called into consultation by the general practitioner.

"Some of the larger and properly conducted group clinics are also providing graduate instruction both in general practice and in the specialties. Groups that develop research work and furnish a high quality of treatment can add materially to their service to the profession by providing residencies for those who seek to develop proficiency in the various specialties."

Referring to the problem of Nurse Training, the Council feels that such training should be improved and standardized; arranged for the appointment of a general committee to handle the situation, and suggested that the length of the course be reduced to twenty-eight months.

The Council called attention to the inadequacy of post-graduate medical schools and suggested additions and improvements.

Dr. Pusey, of Chicago, was elected President, and that city named for the 1924 meeting.

The Woman's Auxiliary held very large and enthusiastic sessions and planned to extend their branch organizations into every state and important local section. Virginia was honored by having two of its delegates named as officers.

In the A. M. A., Virginia, although represented by a very small attendance of fellows, was further honored with the Chairmanship of the Council on Scientific Assembly and the Chairmanship of the Reference Committee on Miscellaneous Business.

Your delegates would urgently suggest that, if pos-

sible, steps be taken by the State Society so as to insure a full representation in the House of Delegates. On more than one occasion the absence of one or more delegates has caused considerable inconvenience and trouble.

In conclusion, your delegates would urge that the State Association be brought in as close contact as possible with the national body by more effective organizations, by the attendance on the national meetings of the Secretary and other officers of the State Society, and by a larger attendance of the fellows and a wider participation in the affairs of the American Medical Association.

Respectfully submitted,

SOUTHGATE LEIGH, *Delegate*,  
J. ALLISON HODGES, *Alternate*.

### Meeting of Executive Council,

At Westmoreland Club, Richmond, April 27, 1923.

Present: Drs. R. L. Williams, Chairman, L. T. Price, Garnett Nelson, D. H. Mason and R. L. Page.

Absent: Drs. M. J. Payne, H. A. Burke, W. W. Wilkinson, Isaac Peirce, G. W. McAllister, T. G. Hardy, H. B. Spencer, Hugh McGuire, F. H. Smith and P. E. Tucker.

Quorum for the transaction of the business before the Council found present, and meeting was called to order by the chairman.

Motion by Dr. Page, seconded by Dr. Nelson, that the date for the annual meeting of the Society be fixed as October 16th to 19th, inclusive. Unanimously adopted.

Report of the program committee was read to the council.

Motion by Dr. Mason, seconded by Dr. Page, that the recommendations of the program committee be adopted. Unanimously approved.

Motion by Dr. Nelson, seconded by Dr. Mason: That the Medical Society of Virginia reimburse those members of the Executive Council living outside of Richmond, for actual expenses incurred in attending called meetings of the Council in Richmond. Unanimously approved.

Motion by Dr. Price, seconded by Dr. Nelson: That, in the event an Academy of Science or similar organization establish a suitable home for professional organizations in Richmond, the headquarters of the Medical Society of Virginia be established in that building, provided rental cost does not exceed fifty dollars per month. Unanimously adopted.

There being no further business before the Council, a motion to adjourn was adopted unanimously.

### The House of Delegates

Met Wednesday morning, October 17th, at nine o'clock, Hotel Roanoke, Roanoke, Virginia, the President, Dr. J. Staige Davis, presiding.

Quorum found present and meeting called to order by chairman.

The report of the Secretary-Treasurer of the society was presented and by unanimous vote was accepted.

At this meeting matters of general interest and pertaining to the welfare of the organization, the practice of medicine generally and the public health, were discussed.

Reports covering the activities of the State Board of Medical Examiners in prosecuting violators of the Medical Practice Act were made, followed by discussion by several members present.

Motion duly made and seconded that the president appoint a committee to consider the problem of the quacks and to draw up suitable resolutions

which should cover the position of the regular practitioners with reference to violators of this law. Unanimously adopted. The president appointed the following: Drs. J. Allison Hodges, A. L. Gray, J. W. Preston, F. H. Smith, P. St. L. Moncure, I. C. Harrison, and Isaac Peirce.

Meeting adjourned.

### The Executive Council

Met October 17, 1923, at Hotel Roanoke, Roanoke Va.

Roll call and all found present. Meeting called to order by the chairman, Dr. R. L. Williams.

Minutes of last meeting read and approved.

Dr. J. Allison Hodges was given the privilege of the floor and offered the following resolutions providing for the creation of a Public Health League in Virginia.

### RESOLUTIONS PRESENTED TO THE MEDICAL SOCIETY OF VIRGINIA FOR THE ESTABLISHMENT AND ORGANIZATION OF A PUBLIC HEALTH LEAGUE FOR THE STATE OF VIRGINIA.

In view of the fact that the science of medicine today seeks to improve and effect not only the treatment and cure of disease, but also its prevention and conservation, therefore, to that end, in order that the Medical Society of Virginia may enlarge the scope of its professional activities and civic usefulness, be it

*Resolved*, 1. That the Medical Society of Virginia endorses the formation of a State Public Health League, which shall have authority to formulate its own government, except as hereafter provided, and whose aim and purpose shall be to study and solve, if possible, the economic, educational, legislative and public health problems of organized medicine, and whose membership shall consist of all regular practising physicians in the State, the members of the Woman's Auxiliary to the Medical Society of Virginia, and such other persons, as shall join the organization;

2. That, until changed by either or both organizations, the President of the Public Health League shall be nominated by the House of Delegates and elected biennially by the Medical Society of Virginia for a term of two years' service;

3. That the other officers of the Public Health League shall be appointed for a similar term of service by the President of the Medical Society and its Executive Council, and the President of the League, and its executive committee, except that for the present term of office of one year, that all necessary officers required for the establishment of the League, shall be appointed within one month after the date of passage of these resolutions by the in-coming President of the Medical Society of Virginia;

4. That all members of the Medical Society of Virginia in good standing shall automatically become members of the Virginia Public Health League, without further cost, except the initiation fee of one dollar, when they enroll their names as members of any district, county or city branch organization of the League;

5. That a "contact" committee, which shall also constitute the Executive Staff Officers of the League, representing the Medical Society and the League, and composed of the President and Secretary of the Medical Society of Virginia, the President and Chairman of the Executive Committee of the Public Health League, and the Executive Secretary of the League, who shall be a layman, and who would be the executive secretary of this committee, shall ap-

point the chairmen for the various committees needed, these chairmen being empowered to appoint the members of their own committees, with the approval of the executive staff officers above-mentioned;

6. The committees for the present, shall consist of the following:

Committees on Cancer, Tuberculosis, Health Instruction and Public School Education, Social and Mental Hygiene, Legislation and Industrial Relations, County Sanitation and Institutional Reforms, Hospital Survey and Standardization, Pre-Natal Care and Child Welfare, and Conservation of Vision, and School Children's Health, and these committees shall co-ordinate their work as far as possible with like committees of this Society, the A. M. A., the State, City and National Government, or other accredited bureaus or organizations;

7. That the chairmen of these committees, together with the executive staff officers named, shall meet once every six months, or as may later be determined, in one of the cities in the state to discuss what has been accomplished, and to consider the plans for future work;

8. That a summarized report of the work accomplished annually, shall be presented each year through the executive officers of the League at the annual meeting of the Medical Society of Virginia;

9. That at some designated city in the state, at such times as may be deemed advisable by the Executive Staff Officers, a Health Exposition for the education of the public, shall be held, at which a display of the progress of Medicine and its accomplishments shall be made;

10. That in furtherance of the above recommendations, if deemed feasible and advisable by the Executive Staff Officers, a Health Exposition shall be held during 1924 in the city of Richmond.

These resolutions received the unanimous endorsement of the Executive Council.

Dr. Clarence Porter Jones offered the following resolution:

*Resolved*, That the Medical Society of Virginia endorse the Lye Legislation Program of the American Medical Association, for a proper POISON label to be placed on lye and similar products offered for sale, and

That the Legislative Committee give every assistance to the Hon. E. W. Milstead, of Newport News, a member of the Legislature, who has volunteered to sponsor a bill identical or similar to the Lye Legislation Committee's bill of the American Medical Association, which is now a law in Florida and Pennsylvania.

This resolution received the unanimous endorsement of the Executive Council.

Dr. Jones also introduced the following resolution (a similar one having been offered by Drs. Greer Baughman and Garnett Nelson, of Richmond):

The Walter Reed Medical Society of Virginia, in session at Yorktown, October 10th, 1923, unanimously voted to submit the following to the Medical Society of Virginia:

*Whereas*, Dr. Walter Reed, born and reared in Virginia, after distinguishing himself in the defence of his country and making many discoveries in medicine, finally gave his life for science and is regarded as one of the heroes of medicine;

*Be it Resolved*, That the Medical Society of Virginia undertakes with a deep sense of gratitude to preserve the memory of this great Virginian, by a

suitable memorial at the University of Virginia and by marking his birth place in Gloucester County, and his boyhood home in Harrisonburg, with tablets, so that his career may be an incentive to each generation.

That a committee of five shall be appointed by the President of the Medical Society of Virginia for the purpose of formulating plans, preparing suitable inscriptions, soliciting funds, and arranging a suitable ceremony for the unveiling of these tablets.

That the Medical Society of Virginia pledge as the first contribution one hundred dollars to this fund.

CLARENCE PORTER JONES,  
LONDON E. STUBBS,  
HARRY A. TABB.

This resolution received the unanimous endorsement of the Executive Council.

The following nominations were made for the consideration of the House of Delegates and the Society: For President, Dr. W. W. Chaffin, Pulaski; First Vice-President, Dr. Hunter H. McGuire, Winchester; Second Vice-President, Dr. R. B. James, Danville; Third Vice-President, Dr. O. T. Amory, Newport News; Secretary-Treasurer and Business Manager, Agnes V. Edwards, her salary being fixed at \$3,000.00. She is authorized to employ an office assistant at a compensation not to exceed \$800.00 annually. The term of office of the Secretary-Treasurer is to begin January 1st, 1924, while the term of office of the incumbent, G. H. Winfrey (resigned), is to terminate December 31, 1923.

Nominations for the House of Delegates of the American Medical Association: Dr. J. Allison Hodges, Richmond; Alternate, Dr. R. C. Bryan, Richmond; Dr. Southgate Leigh, Norfolk; Alternate, Dr. E. C. S. Taliaferro, Norfolk. The terms of the above named delegates to expire in 1925. Alternate for Dr. Jos. T. Buxton (whose term as delegate expires in 1924), Dr. J. Staige Davis, University.

The following standing committees were nominated:

*Auditing*—Dr. Paul W. Howle, Dr. Garnett Nelson.  
*Automobile Insurance*—Dr. A. L. Gray, Dr. M. W. Peyser, Dr. Paul W. Howle.

*Hospitals*—Dr. S. S. Gale, Dr. J. S. Horsley, Dr. Southgate Leigh, Dr. A. M. Willis, Dr. S. H. Watts.  
*Judiciary*—Dr. W. F. Drewry, Dr. Virginius Harrison, Dr. Hugh Nelson, Dr. Frank Hancock, Dr. Bernard Kyle, Dr. J. A. Owen, Dr. J. L. Early.

*Legislative*—Dr. H. U. Stephenson, Dr. J. Bolling Jones, Dr. C. H. Rolston, Dr. T. S. Hening, Dr. J. W. Preston, Dr. P. E. Tucker, Dr. J. W. Hope, Dr. S. W. Maphis, Dr. G. A. Stover, Dr. Israel Brown and Dr. C. B. Bowyer.

*Library*—Dr. I. C. Harrison, Dr. Stuart McGuire, Dr. Southgate Leigh, Dr. Isaac Peirce and Dr. R. J. Payne.

*Committee on Co-operation with State Department of Health in its Child Hygiene Work*—Dr. Ben Rosebro, Dr. Mary E. Brydon, Dr. L. T. Royster, Dr. J. S. Davis and Dr. G. A. Stover.

*Committee on Co-operation with State Nurses' Association*—Dr. J. A. Hodges, Dr. A. M. Willis, Dr. R. C. Fravel, Dr. Joseph T. Buxton, Dr. C. J. Andrews, Dr. E. Barksdale, and Dr. J. C. Flippin.

*Membership*—Dr. J. A. White, Dr. Geo. J. Williams, Dr. J. E. Knight, Dr. F. H. Smith and Dr. C. E. Conrad.

*Publication*—Dr. A. G. Brown, Dr. A. L. Gray, Dr. B. R. Tucker, Dr. Paul Howle, Dr. E. L. Kendig.

*Necrological*—Dr. C. M. Edwards, Dr. S. T. A. Kent and Dr. T. J. Sims.

*Cancer*—Dr. R. C. Bryan, Dr. J. S. Horsley, Dr. J.

Bolling Jones, Dr. I. C. Harrison, Dr. C. R. Grandy, Dr. J. T. Buxton, Dr. P. W. Boyd, Dr. M. J. Payne, Dr. D. P. Peters, Dr. Hugh Trout, Dr. F. H. Smith, Dr. S. B. Moore and Dr. S. H. Watts.

*Public Health and Education*—Dr. R. K. Flanagan, Dr. James Morrison, Dr. C. B. Bowyer, Dr. W. S. Keister and Dr. J. H. Hiden.

*Transportation*—Dr. J. B. DeShazo, Ridgeway, Va.

A petition from the Russell County Medical Society, requesting a charter from the Medical Society of Virginia, was presented and granted by a unanimous vote. The secretary of the Council was instructed to draft a letter to be sent to the officers of this society recommending that this county society join with other counties in that part of Virginia in organizing a district society.

Council adjourned.

### The House of Delegates

Held a meeting Thursday morning, October 18th, at Hotel Roanoke.

Roll call dispensed with by unanimous vote as soon as a quorum was found present.

Report of the Executive Council was presented and unanimously approved.

The committee appointed to draft suitable instructions to the Legislative Committee of the Society covering attitude of the Society regarding the enforcement of the Medical Practice Act, reported as follows: That the legislative committee of the Medical Society of Virginia, in conjunction with the State Board of Medical Examiners, be instructed to examine the medical practice laws of other states and to draw up a model bill to be presented for the revision of our present medical practice act, if, in the judgment of our legislative committee, such a revision is deemed wise. That the legislative committee be instructed that, in the proposed revision of our medical practice act the educational requirements, both preliminary and professional, should be fully safeguarded whether or not the revised medical practice act is presented to the General Assembly.

This report was unanimously adopted.

Report from the Library Committee was presented: This committee recommends that the Medical Society of Virginia enlarge the library now owned by the state organization, which is in the office of the Society in Richmond, this enlargement to be accomplished by the voluntary gift of books and money to the society and that we secure from our members ten thousand dollars to make the library an effective agency for raising and maintaining our scientific and professional standards.

This report was unanimously adopted.

Motion, duly seconded, that in future all money received from commercial exhibits be given to the local society entertaining the state organization. Unanimously adopted.

Motion, duly seconded, that the Medical Society of Virginia accept the invitation received from the Augusta County Medical Society and other organizations in the Valley, to hold its next meeting in Staunton. Unanimously adopted.

The following nominations were made by the House of Delegates: To be members of the Executive Council from the State-at-Large: Drs. H. H. Trout, of Roanoke, and W. B. Martin, of Norfolk. From the First Congressional District: Dr. C. P. Jones, of Newport News; from the Third Congressional District, Dr. A. L. Gray, of Richmond; from the Tenth Congressional District, Dr. P. K. Graybill, of Fincastle.

A vote of thanks was extended Dr. J. B. DeShazo for his services in securing a reduction in railroad rates to Roanoke for members of the Society.

A vote of thanks was extended the retiring secretary, G. H. Winfrey, for the satisfactory and efficient services rendered the Society during his connection with the organization.

Meeting adjourned.

These proceedings of the Executive Council and House of Delegates having been considered by the Medical Society of Virginia, Thursday, October 18th, were unanimously approved.

Immediately following the adjournment of the Society the Executive Council was called and the following officers were chosen: Dr. R. L. Williams, Chairman; Dr. L. T. Price, Clerk.

Adjourned.

At the last meeting of the Society, a rising vote of thanks was tendered the Roanoke Academy of Medicine and people of Roanoke for the splendid entertainment provided for the Society.

### Norfolk County Medical Society.

At the regular monthly business meeting on October 1st, 1923, the President, Dr. Chas. W. Doughtie, appointed the following standing Committees for the year 1923-24:

*Surgery and Gynecology*—Drs. C. Carroll Smith, *Chairman*, N. F. Rodman, E. T. Hargrave, C. J. Devine, G. R. Berkeley.

*Medicine and Public Health*—Drs. R. U. Burges, *Chairman*, J. A. Strickland, H. M. Doles, W. B. Newcomb, F. C. Rinker, M. J. Doyle.

*Obstetrics*—Drs. Geo. W. Schenck, *Chairman*, Burnley Lankford, C. J. Andrews.

*Children*—Drs. Franklin D. Wilson, *Chairman*, W. P. McDowell, W. Spigel.

*Eye, Ear, Nose and Throat*—Drs. H. R. Etheridge, *Chairman*, A. D. Morgan, J. Warren White, Jos. Hume, E. A. Land.

*Membership*—Drs. Southgate Leigh, *Chairman*, G. B. Gilmore, J. D. Stroud.

*Ethics*—Drs. E. C. S. Taliaferro, *Chairman*; C. R. Grandy, H. S. Baker, R. L. Williams, H. R. Drewry.

*Finance*—Drs. D. Lee Hirschler, *Chairman*, S. G. Gill, S. H. Graves.

*Library*—Drs. Frank Hancock, *Chairman*, W. B. Martin, J. L. Rawls.

*Hospitals*—Drs. J. H. Culpepper, *Chairman*, I. Brown, W. B. Newcomb, L. Berlin, R. L. Corbell, J. D. Collins.

*Nursing*—Drs. Lomax Gwathmey, *Chairman*, Foy Vann, B. A. Doggett, W. L. Harris, M. N. King.

Among the matters of interest which came up at this meeting was the announcement from

the Woman's Auxiliary of the Norfolk County Medical Society of the organization of that body and the expression of a willingness to aid the Society in any way possible. Mrs. R. L. Payne, Sr., is the President.

In recognition of his long and faithful service to the Society, Dr. Lawrence T. Royster was elected to Honorary Membership for life, and tendered a dinner on the eve of his removal to take up the duties of Professor of Pediatrics in the University of Virginia.

Election of delegates to the House of Delegates of the Medical Society of Virginia resulted in the choice of Drs. E. C. S. Taliaferro, P. St. L. Moncure, J. L. Rawls, J. D. Collins and A. A. Burke. LOCKBURN B. SCOTT,  
*Secretary.*

At the meeting of the Surgical Section on October 8th, Dr. Foy Vann read a paper on "Osteomyelitis," and Dr. L. F. Magruder one on "Limitations of the X-Ray in Diagnosis of Osteomyelitis." Abstracts of these papers are given herewith:

#### **Osteomyelitis.**

Dr. Vann stated that ancient evidences of the destructive effects of osteomyelitis may be found in the Medical Museums, while the modern evidences are to be found among the plates on file in X-ray laboratories. The crippling results of the disease may be found among the procession to orthopaedic clinics. Treatment has not exactly kept pace with our understanding of the disease.

The etiological organism is usually of the staphylococcus group, less frequently of the streptococcus, occasionally a typhoid. Colon bacillus and pneumococcus have been found. Bone destruction is less extensive in the three latter.

The infection is blood-borne and, after having been established, shows a predilection for bone tissue.

The age incidence is that of youth and trauma may have bearing on the immediate outset. While no bone is exempt, the femur and tibia lead the procession.

The mention of four stages describes the pathology:

1. Acute stage, stage of infection, suppuration and general intoxication.
2. Sub-acute stage, stage which begins when drainage has been established, with the cessation of toxic symptoms.

3. Chronic stage, formation of sequestra, involucrum and sinuses.

4. Chronic stage of localized bone abscess.

The symptoms are the same as the outset of any acute infectious disease. Pain and temperature are out of proportion to the objective symptoms. If the outset is abrupt and there is added prostration and pain in an extremity, osteomyelitis should be strongly suspected. Have in mind syphilis, typhoid fever, acute bursitis of the shoulder (if the humerus is painful), sub-periosteal fracture of epiphyseal separation, scurvy, tuberculous knee (if the tibia is painful and the physician is called at night), traumatic periostitis, cellulitis (erysipelas), acute arthritis. A history, temperature and examination of the blood eliminates all except the last two. The skin manifestation of erysipelas is usually convincing, especially if it has hurdled by a joint. Pain and spasm on passive movement are characteristic of an acute joint. A co-existing bone and joint infection is doubtful.

Treatment of the acute stage should be prompt, decisive, preferably after the manner in which the dentists drill into a tooth socket and release tension. Such treatment renders the questions of dressing and after-treatment unimportant. The treatment is wholly surgical, but the responsibility for an early diagnosis and early application of the treatment rests with the physician. X-ray is of value in the diagnosis in all stages except the first. Treatment of the sub-acute stage should be conservative, expectant in the chronic, plastic in the stage of localized bone abscess. Curette is not employed except in the late sinus and bone abscess, and even here not blindly on account of the difficulty in distinguishing between infected and vascular and sclerosed bone. The radical operation has been wisely abandoned.

Eradication of a bone sinus is a distinct problem. The difficulty increases when near to a joint or in a poorly covered bone. For this purpose a soft tissue transplant is more effective than any heretofore tried methods, and a pedicled muscle transplant seems best. Chemical sterilization has been tried and its efficiency established. This is more dependent on the surgical technique than any particular chemical employed.

It is difficult to know when a chronic osteomyelitis is cured.

### Limitations of the X-Ray in Diagnosis of Osteomyelitis.

Dr. L. F. Magruder, in his paper on the above subject, said that chronic osteomyelitis is in reality a bone sclerosis. The X-ray findings in these cases are fairly typical and helpful as a guide to the surgeon. The striking and predominant finding is extensive new bone formation with but little bone destruction. The normal relation of cortex to medulla is lost. There may be islands of lessened density and less frequently sequestra.

Acute osteomyelitis might better be called myelitis osteitis as the myelitis precedes by several days the osteitis. During the early stages of acute osteomyelitis the infection extends along the lines of least resistance. The entire medulla may be destroyed before the cortex is involved through the Haversian canals. Before there is breaking down of the cortical bone substance, the X-ray is of no value in diagnosis. In cases where early drainage is not established the destructive process extends to the cortex through the Haversian canals, giving rise to sequestra which will vary in size and shape, depending upon the location of the Haversian canals involved.

One of the most dangerous laboratory reports is a negative X-ray finding during the early stages of an acute osteomyelitis.

In cases where acute osteomyelitis is suspected, the surgeon is justified in drilling through the cortex for diagnosis just as much as he is justified in doing a spinal puncture or aspirating the pleural cavity. By so doing he may not only establish a tentative diagnosis but may conserve a member.

The meeting of the Medical Section on October 15th was called to order by the Section Chairman, Dr. R. U. Burges.

Dr. Martin presented a paper outlining the Value of Insulin in the Treatment of Diabetes. The anatomy and physiology of the islands of Langerhans were briefly reviewed. Charts were shown demonstrating the effects of insulin in lowering the blood sugar in man, and a case of diabetic coma complicated by infection that was treated with insulin and recovered was reported.

Dr. Fitchett discussed the Dietetic Treatment of Diabetes, Both With and Without Insulin as an Adjunct. He emphasized the im-

portance of properly balanced diet and of preserving a correct carbohydrate-fat ratio.

### The Walter Reed Medical Society

Held its autumn session in Yorktown, Va., October 10 and 11, under the presidency of Col. L. A. Thompson, of National Soldiers' Home, Va., Dr. L. E. Stubbs, Newport News, was at the secretary's desk. The attendance was large, the papers excellent, and altogether this was one of the best meetings of the Society. There were several distinguished visitors from out of the State and other sections of Virginia. The social features were also most enjoyable. On the first day dinner was served the visitors by the ladies of Yorktown, and on the second day an oyster roast was tendered them by the First National Bank of Yorktown.

The next meeting will be held in May 1924, the time and place to be decided upon later.

### The Patrick-Henry Medical Society

Held its regular meeting October 5th, at Stuart, Va. Dr. R. R. Lee, of Martinsville, read a paper on "Pulmonary Tuberculosis: Diagnosis and Treatment," and Dr. J. A. Shackelford, of Martinsville, presented a paper on "Tuberculosis of the Hip Joint and Sacro-Iliac Strain."

The officers elected for the present year are as follows: President, Dr. J. A. Shackelford, Martinsville; Vice-President, Dr. G. T. Divers, Stuart; Secretary-Treasurer, Dr. G. B. Dudley, Jr., Martinsville. This society meets every other month and the next meeting will be held at Martinsville, December 7, 1923.

### The Roanoke Academy of Medicine,

At its regular meeting held October 1, elected Dr. H. B. Stone president; Dr. S. Beverly Cary vice-president; and Dr. M. A. Johnson secretary-treasurer. All of the above are of Roanoke.

### Warren-Rappahannock-Page Medical Society.

Dr. Giles B. Cooke, Front Royal, Va., and Dr. L. C. Haynes, Flint Hill, Va., are at this time president and secretary, respectively, of this Society.

### The Medical Association of The Valley of Virginia

Held its last regular meeting in Staunton, September 27, Dr. Hunter H. McGuire, Winchester, presiding. The meeting was a most interesting one. During the morning session,

papers were read by Dr. R. P. Bell, Staunton, Dr. J. H. Deyerle, Harrisonburg, and Dr. J. M. Emmett, Clifton Forge. In the absence of Dr. H. I. Pifer, Winchester, Dr. Charles E. Conrad, Harrisonburg, gave a brief talk on the subject which Dr. Pifer had selected—Treatment of Infantile Diarrhea. After lunch, the program was resumed and papers were read by Dr. J. E. Harris, Winchester, Dr. G. S. Hartley, Clifton Forge, Dr. Grant Preston, Harrisonburg, and Dr. M. J. Payne, Staunton. All papers were freely discussed.

This Association voted to join with the Augusta County Medical Association in inviting the Medical Society of Virginia to meet in Staunton in 1924.

Officers elected for the ensuing years are: President, Dr. J. M. Emmett, Clifton Forge; Vice-Presidents, Drs. D. M. Kipps, Front Royal, A. L. Tynes, Staunton, and B. P. Dutton, Winchester; Secretary, Dr. A. F. Robertson, Staunton; Treasurer, Dr. J. M. Biedler, Harrisonburg; delegate to the Roanoke meeting of the Medical Society of Virginia, Dr. F. M. Leech, Lexington.

The next meeting is to be held in Harrisonburg in the Spring of 1924.

## Book Announcements

**Dreads and Besetting Fears.** Including States of Anxiety, Their Causes and Cure. By TOM. A. WILLIAMS, M. B., C. M., Neurologist to Freedman's Hospital, Washington, Boston, Little, Brown and Company. 1923. Mind and Health Series. 12 mo. Cloth. 217 pages. Price, \$1.75, at book-sellers.

This book is the work of a widely-known psychiatrist of Washington, D. C. So noted a writer as H. Addington Bruce says of him: "Few other specialists in this country have had so varied a practice as he in the management of fear states." His book shows extremely wide reading, both with respect to scientific matter as well as general literature. He explains the phenomena of fear, and traces its psychic mechanism, revealing unsuspected sources and causes all unknown. He decries the preponderating importance attached to the sexual sphere by a certain school of psychologists, "Women are not more chaste than men," he says, "but dread social disapproval more." He shows the intimate relation often

existing between the physical and the mental, especially when the psychical is out of balance. "Timidity does not connote mental inferiority." "Anxiety is merely chronic fear." "A terrier hunting a rat is under great tension, but he is not timid." His illustrations are exceedingly apt; they are many times taken from his case records, and the ultimate outcome showed that he placed an unerring finger on obscure causes.

He also points out the grievous errors unwittingly made by those in charge of young children, who implant in them oftentimes the seed of fear which later springs up with disastrous consequence. His accounts of methods of dealing with certain types, in order to relieve them, is full of value. He takes issue with certain theories as to the part heredity plays, attributing greater weight to environment. "Just as Pawlow conditioned and re-conditioned the responses of his dogs, so are we able to induce fear and to dispel fear in human beings. It is more difficult because human mentality is more complex, but the skill exists in many who have acquired mastery of psycho-pathology."

He sketches the advantages and the disadvantages of fear. "Fear is the mother of prudence, \* \* fear is the foundation of respect for others." "The fascination of some women for men of sinister repute is in part due to their fear"; the *motif* in "Trilby" and in "Elsie Venner" by Oliver Wendell Holmes. "Fear is the first of the four natural limitations which must be transcended if true nobility is to be achieved, is declared in "The Research Magnificent," by H. G. Wells.

To some it may seem as if in certain passages the author is very technical, but he is exceedingly accurate in his choice of words.

As to the remedy for fear, it may be summed up in a few words—substitute some other emotion. Just how this may be done is the function and office of the psychiatrist to show. Not every case is alike, and as diverse as are the causes, so manifold are the phases of treatment. The author, however, stresses the futility of the patient saying "I am not afraid." a mere negation of the fear instinct—which is simply all the time calling his own attention to its existence.

E. P. TOMPKINS, M. D.

**Obstetrics for Nurses.** By CHARLES B. REED, M. D., Obstetrician to Wesley Memorial Hospital, Chicago. St. Louis. C. V. Mosby Company. 1923. 12 mo. 399 pages, with 144 illustrations including two color plates. Cloth. Price \$3.50.

**Principles of Bacteriology.** By ARTHUR A. EISENBERG, A. B., M. D., Director of Laboratories, St. John's Hospital; Pathologist to Lakewood Hospital; Serologist to St. Ann's Hospital, Cleveland, Ohio, etc. Second Edition. St. Louis. C. V. Mosby Company. 1923. 12 mo. 214 pages. Cloth Price \$2.25.

**Pediatrics.** By Various Authors. Edited by ISAAC A. ABT, M. D., Professor of Diseases of Children, Northwestern University Medical School, Chicago. In eight octavo volumes, totaling 8,000 pages, with 1,500 illustrations, and separate Desk Index volume free. Now ready, VOLUME I, containing 1,240 pages with 284 illustrations, and VOLUME II, containing 1,025 pages with 180 illustrations. Philadelphia and London. W. B. Saunders Company. 1923. Cloth, \$10.00 per volume. Sold by subscription.

**Habitual Constipation.** Its Causes, Consequences, Prevention, and Rational Treatment. Set forth in non-technical language. By ISMAR BOAS, M. D., professor of Medicine in Berlin. Translated by THOMAS L. STEDMAN, M. D., formerly editor of the Medical Record. Funk and Wagnalls Company. New York and London. 1923. 12mo. 299 pages. Cloth, \$2.00 net.

**International Clinics.** A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on all branches of Medicine and Surgery. By leading members of the medical profession throughout the world. Edited by HENRY W. CATTELL, A. M., M. D., Philadelphia, and Collaborators. Volume III. Thirty-third Series. 1923. Philadelphia and London. J. B. Lippincott Company. 1923. 8vo. 312 pages. Cloth.

**A Manual of the Practice of Medicine.** Prepared Especially for Students. By A. A. STEVENS, A. M., M. D., Professor of Applied Therapeutics in the University of Pennsylvania. Eleventh Edition. Entirely Reset. Philadelphia and London. W. B. Saunders Company. 1923. 12mo. 645 pages, illustrated. Cloth, \$3.50 net.

**Gynecology.** By WILLIAM P. GRAVES, A. B., M. D., F. A. C. S., Professor of Gynecology at Harvard Medical School. Third Edition, Thoroughly Revised. Philadelphia and London. W. B. Saunders Company. 1923. 8vo of 936 pages with 388 half-tone and pen drawings and 146 microscopic drawings, 103 of the illustrations in colors. Cloth, \$9.00 net.

**Introduction to Medical Biometry and Statistics.** By RAYMOND PEARL, Ph.D., Professor of Biometry and Vital Statistics, John Hopkins University. Philadelphia and London. W. B. Saunders Company. 1923. 8vo. of 379 pages, illustrated. Cloth, \$5.00 net.

**The Examination of Patients.** By NELLIS B. FOSTER, M. D., Associate Physician to the New

York Hospital; Associate Professor of Medicine at Cornell University, College of Medicine. Philadelphia and London. W. B. Saunders Company. 1923. 8vo. of 253 pages, illustrated. Cloth, \$3.50 net.

**A Text-Book of Anatomy and Physiology.** For Schools of Nursing, Normal Schools and Colleges. By JESSE FEIRING WILLIAMS, M. D., Professor of Physical Education, Teachers College, Columbia University, New York City. Philadelphia and London. W. B. Saunders Company. 1923. 12mo. of 523 pages; 369 illustrations, 25 of them in colors. Cloth, \$3.00 net.

**Rubber and Gutta Percha Injections.** Subcutaneous Injections of Rubber and Gutta Percha for Raising the Depressed Nasal Bridge and Altering External Contours. By CHARLES CONRAD MILLER, M. D. Chicago. 1923. Oak Printing and Publishing Company. 12 mo. 99 pages. Cloth, \$1.75 prepaid.

### The U. S. Civil Service Commission

Announces open competitive examination for trained nurse and trained nurse (psychiatric), to be held throughout the country on December 5, for male and female nurses. If interested, secure full information and application blanks from the Commission, at Washington, D. C.

### Camp Sevier Veterans' Hospital to be Closed.

The hospital for disabled veterans, located at Camp Sevier, is to be closed and all patients will be transferred to U. S. Veterans' Hospital at Oteen, N. C., at which it was reported there were approximately 300 vacant beds.

### Ancon Hospital Damaged.

A heavy rainfall, early in October, caused a landslide at Ancon Hill, which did considerable damage to the Ancon Hospital buildings. The isolation ward was buried under tons of earth, but none of the patients was injured. No damage was reported to Panama Canal.

*"Thank God every morning when you get up that you have something to do which must be done, whether you like it or not. Being forced to work, and forced to do your best, will breed in you temperance, self control, diligence, strength of will, content and a hundred virtues which the idle will never know."*—Kingsley.

## Editorial

### Late Syphilis in Nervous System.

Serologic examination of the spinal fluid in cases that may be called late syphilis discloses some interesting facts in connection with the Wassermann and other tests for syphilis. The phrase, late syphilis of the nervous system, has in recent years come to include a rather large group of diseases of the nervous system which, in former years, owing to the variations of symptomatology and differences of pathology were rather independently considered. So, it is interesting to bring under consideration in this comment upon late syphilis in the nervous system an etiologically related group of diseases and to present to our readers the summary of some important examinations done in the Dermatological and Urological Clinic at Tokio, as reported by the U. S. Public Health Service in *Venereal Disease Information*, Volume IV, number 7, page 256.

"1. In tabes dorsalis (19 cases) the Wassermann reaction of the spinal fluid was positive in 73.68 per cent of the cases, consequently more frequently positive than in the blood (68.42 per cent). The Lange reaction was exactly parallel with the spinal fluid Wassermann, the phase 1 reaction with the blood Wassermann. Among the cases with positive blood Wassermann there were 84.61 per cent with positive spinal fluid Wassermann and Lange reaction, 69.23 per cent with positive phase 1

reaction. Of the cases with negative blood Wassermann 50 per cent gave positive spinal fluid Wassermann and Lange reaction, 66.7 per cent positive phase 1 reaction.

"The spinal fluid in tabes dorsalis gave consequently in more than half the cases some pathological reaction, particularly when the blood Wassermann was positive. From the negative result of the Wassermann reaction alone a conclusion as to the integrity of the spinal fluid was not admissible.

"2. Dementia paralytica (9 cases) gave 88.88 per cent positive spinal fluid Wassermann, a somewhat lower per cent than in the blood (100 per cent). The Lange reaction was positive in 100 per cent, the phase 1 reaction in 66.66 per cent of the cases. The four reactions approached each other in their positive value, in their negative only the blood Wassermann and the Lange reaction agree.

"3. In syphilis spinalis (35 cases) the spinal fluid Wassermann was positive in 48.57 per cent of the cases; this was less than that of the blood (51.42 per cent). The Lange reaction gave a positive result in 68.57 per cent, the phase 1 reaction in 57.14 per cent. Only with a positive result of the Wassermann reaction in the blood could a positive result of the three spinal fluid reactions in greater range be counted on; the negative blood Wassermann, on the contrary, permits no such conclusions.

"4. In syphilis cerebri (11 cases) the spinal fluid Wassermann was found positive in 18.18 per cent of the cases, much less frequently than in the blood (54.54 per cent). On the other hand, the Lange and phase 1 reactions were positive in 63.63 per cent of the cases. The results of the three spinal fluid reactions differ very much from each other in the positive reactions; in the negative results an approximation, though not a clear one, may be shown. All in all in this group there was shown an apparent divergence of the results of the reactions.

"5. In tertiary syphilis (51 cases) the spinal fluid Wassermann was positive in 14 per cent, the Lange and phase 1 reaction in 50.98 per cent of the cases. In cases with positive spinal fluid Wassermann the other two spinal fluid reactions gave for the most part a positive result; in cases with a negative spinal fluid Wassermann, on the contrary, such an approximation was not demonstrable. The Lange reaction in negative cases agreed for the most part with the Wassermann reaction. There

existed, however, no agreement between them and the other two reactions. In cases with a positive phase 1 reaction the Lange reaction was for the most part positive. Respecting the negative reaction, the phase 1 reaction agreed almost completely with the Wassermann reaction. The other reaction was quite irregular.

"6. When one compares, respectively, the results of the spinal fluid reaction of tertiary syphilis with tabes and paralysis, one finds no agreement in the positive results.

"7. The highest percentage of positive spinal fluid Wassermanns were found in paralysis (88.88 per cent), the second highest in tabes (73.68 per cent); in cerebral syphilis, spinal syphilis, and syphilis III this per cent was very low. The blood Wassermann only agreed in paralysis with the spinal fluid Wassermann; in the other conditions this was not the case. With the exception of tabes, the positive Wassermann reaction usually appeared more often in the blood than in the spinal fluid. According to the author's experience, the reacting body in the spinal fluid originates in the blood serum from which it reaches the spinal fluid through a permeability of the meninges increased by a pathologic irritation.

"8. The Lange reaction was found positive in paralysis in 100 per cent, in tabes in 73.68 per cent, and in the other conditions in over one-half of the cases. It represents, therefore, the most significant spinal fluid reaction. As to the reacting body in this reaction, the author regards it as a kind of soluble protein substance.

"9. The phase 1 reaction was positive in tabes in 68.42 per cent, in paralysis 66.66 per cent, in cerebral syphilis 63.63 per cent. In the other conditions the percentage was less than 60.

"10. Among the nervous symptoms which were most often met with in syphilis III, the most frequent were the sensory irritations (headache, pains in the shoulders or limbs, ringing of the ears, etc.). On the contrary, motor disturbances appeared seldom. Among the objective symptoms one found most frequently an increase in the reflexes, most often that of the knee.

"11. The nervous symptoms in syphilis III appeared most often in the sixth to eleventh year of the infection. (Tetsuo Kagawa, *Archiv fur Dermatologie und Syphilis*, Berlin, February, 1923, p. 322.)"

### Spinal Fluid Findings in Early Syphilis.

The foregoing discussion of the spinal fluid in late syphilis is only more interesting than the following comments in incipient and early syphilis. The two summaries may well be considered together and so we freely quote this abstract from the U. S. Public Health Service. *Venereal Disease Information*, Volume IV, number 5, page 171.

"The material for this study consisted of 375 patients of the venereal military hospital in Lodz, cases ranging from the earliest period to the end of the fifth year after infection. They were divided into four groups for convenience in study.

"1. *The pre-exanthematous stage of lues*—This group includes 51 patients, with a period of infection up to seven weeks. By a study of these cases it was found that infection of the spinal fluid could take place in this stage, although relatively seldom (7.8 per cent.) Pleocytosis is the most frequent sign of spinal fluid infection in this stage (7.8 per cent). With regard to the specificity of the globulin reaction in this stage, it should be taken with a certain reservation. It seems to occur seldom (2 per cent). A positive Wassermann reaction of the spinal fluid was not found in any of these cases.

"2. *The exanthematous stage*—This group includes patients between the eighth week after infection and the end of the fourth month. Of the 72 patients of this group, 52 were untreated and 20 only very insufficiently treated. Infection of the central nervous system, according to the spinal fluid findings, existed only in one-third of these cases. In comparison with primary syphilis, the proportion is much greater (33.3:7.8). Pleocytosis is the most frequent and characteristic reaction in this stage (37 per cent). Its proportion to the other reactions is as follows: Pleocytosis: Wassermann reaction: Globulin=37:14:12.5. The globulin reaction appears least frequently (12.5 per cent). This, as an isolated reaction, is least characteristic and must be accepted with a certain reservation. The Wassermann reaction appears relatively seldom in this stage (14 per cent). In cases with pathological spinal fluid the proportion of the Wassermann reaction to pleocytosis is 40:91. A weak isolated Wassermann reaction in the spinal fluid may occur with strong blood serum reaction as the result of a diffusion of the reagin from

the blood serum into the spinal fluid. The pathological spinal fluid may be found more often with papular than with macular eruptions.

“3. *Stage of local recurrence*—This group includes cases from the 17th week to the end of the second year after infection. Of the 208 cases in this stage only 27 were untreated, the remainder, 181, had received extremely irregular and insufficient treatment. Practically no difference was found in the spinal fluid of the two groups. This infection of the central nervous system is more easily shown in this stage than in the preceding. Pleocytosis appeared in this stage almost as frequently as in the other reactions, but did not play such a dominating role as in the stage of the so-called first exanthems. Differing from the other stages where pleocytosis occurred more frequently (31:27) and especially as an isolated reaction, here it appears usually with other reactions. The globulin reaction appeared in this stage usually with the other reactions. Where clinical evidences of affection of the nervous system were present, it was always found. We found it in this group much more frequently than in the previous stages (25.5:12.5). The Wassermann reaction appeared most frequently in the stage of local recurrence. In comparison with the previous stages, much more frequently (30:14) and much stronger. Pathological spinal fluid with negative blood serum Wassermann reaction was met much more often in this stage than in the preceding. The blood findings alone are not sufficient to determine the relationship of general syphilization to infection of the central nervous system. This stage is the most valuable for the first examination of the spinal fluid. Pathological spinal fluid is encountered in this stage in many cases with, as well without, skin manifestations. Specific alopecia and leukoderma give a high per cent of pathological spinal fluids (60 per cent, 52 per cent).

“4. *Latent lues*—This group includes cases from the third to the sixth year after infection—patients with latent lues, with late local recurrences and gummata. Pathological spinal fluid could be demonstrated less often in this stage than in the stage of secondary local recurrences. Here we find pleocytosis least often (11.5 per cent), most often the Wassermann reaction (25 per cent). The globulin reaction commonly accompanies the organic nervous manifestations. Every one of the separate

pathological reactions is in this stage, a warning sign to be observed, especially in cases with negative serum blood Wassermann reactions. Between severe skin manifestations and a pathological condition of the spinal fluid there seems to be an antagonism. Of 12 cases with ulcerating gummata the spinal fluid was only once weakly pathologic. (J. Leyberg, *Dermatologische Wochenschrift*, Leipzig, Jan. 20-27, 1923, Nos. 4 and 5, p. 53, p. 86.)”

### Comments on Treatment of Syphilis.

ARSENIC CONTENT OF SPINAL FLUID. The examination of 239 spinal fluids taken from 151 patients, after intravenous administration of silver arsphenamin, demonstrates the following facts:

1. Arsenic passes into the spinal fluid.
  2. Arsenic can be found in the spinal fluid at the end of two hours, in an amount as large as 134 mg. per 100 gm. of dried specimen.
  3. Arsenic can be found in the spinal fluid as late as seventy-two hours, in an amount as large as 192 mg. per 100 gm. of dried specimen.
  4. In general, the arsenic content in the spinal fluid falls after the first two hours. It rises slightly between twenty-four and forty-eight hours and, at the end of seventy-two hours, is present in greater quantity than at any time between two and seventy-two hours. (Leon H. Cornwall and C. N. Myers, *American Journal of Syphilis*, April 1923, page 287.)
- MERCURY VERSUS ARSPHENAMIN IN THE TREATMENT OF SYPHILIS.

“Brooklyn Diagnostic Institute. The injurious effects of the use of arsphenamin are discussed. In addition to its toxicity in many cases tolerance which is almost an immunity to the drug on the part of the parasite is established, with the result that further progress with arsphenamin treatment alone is impossible. The author recommends mercury as the most valuable ally in the treatment of syphilis. He also has found from his experience the best method of administration to be by inhalation, for the following reasons: (1) Inhalations are free from nauseous taste and the unpleasant gastrointestinal disturbances occurring with oral administration. (2) Their absorption is as rapid as administration by any other method, not excepting the intravenous or subcutaneous. (3) Compared with injections they have no unpleasant, unesthetic features. (4) They are definite in dosage. (5)

They never cause serious symptoms or fatalities such as often accompany hypodermic injections of mercury or arsphenamin. (Jacob Gutman, *American Journal of Syphilis*, St. Louis, April, 1923, p. 347.)

#### TREATMENT OF GENERAL PARALYSIS BY MALARIA.

"City of London, Mental Hospital, Dartford. The author describes the treatment of general paralysis by a subcutaneous injection of from 2 to 4 c.c. of blood from a patient suffering from benign tertian malaria. Typical malaria develops in about a week and is allowed to run through 10 to 12 attacks, after which it is cured by the administration of quinine in doses of 1 gm. for 3 successive days, then in doses of 0.5 gm. for 14 days. This is the course of treatment observed by the author while in Vienna. In no cases did the malaria persist. During the febrile attacks and occasionally after there is very often an exacerbation of mental symptoms, consisting chiefly of auditory hallucinations and delusions of persecutions. In the majority of cases these symptoms promptly disappear when the febrile attacks have terminated. Following upon the febrile attacks and going parallel with the quinine treatment, weekly doses of neosalvarsan are administered intravenously, commencing with 0.3 gm.; six doses in all are given, in the scale of 0.3, 0.4, and four of 0.6 gm.

"Complete observations were made of 296 cases so treated. Of these 112 showed complete remission with the disappearance of mental disturbances and a return of former business capacity. Sixty-eight per cent of those observed showed remissions in spite of the fact that many advanced cases were included. Of the total for whom complete remission was claimed, only three have relapsed or showed any tendency to relapse.

"This form of treatment is difficult in England because of the absence of the malaria parasite. Once a single case has been inoculated the infection may be transferred to other paralytics, though this involves the transference of syphilitic blood. In Vienna this method of continuous transference is used.

"In general the histological changes in cases showing remission under malaria treatment were those of the so-called stationary paralysis of Alzheimer, with an almost complete absence of the changes usually found in progressive general paralysis. (W. L. Templeton, *British*

*Medical Journal*, London, May 26, 1923, p. 895.)

#### BISMUTH AS A SUBSTITUTE FOR ARSPHENAMIN.

"The use of bismuth in the treatment of syphilis is discussed. Although the end results of bismuth therapy are not yet obtainable, its use in cases where the invading spirochete has apparently acquired a degree of tolerance for mercury and arsphenamin is of value. Authors using bismuth report that the drug is unusually stable and of low toxicity when given subcutaneously or intramuscularly. Under treatment with bismuth the spirochetes disappear from the primary sore after the first to the third injection. The effect of the drug upon the Wassermann reaction is as satisfactory, if not more so, than the effect of arsphenamin. (*American Journal of Clinical Medicine*, Chicago, May, 1923, p. 375.)

#### NEW BISMUTH THERAPY OF SYPHILIS.

"The author discusses the value of bismuth therapy of syphilis. The hydroxide and the iodoquininate of bismuth have been generally adopted as the most efficient for routine use as well as least painful and toxic. Both salts are insoluble and are administered in oily suspensions by intramuscular injections. The dosage of each is from 6 cgm., the minimum initial dose, to 15 cgm., the usual maximum. The average course consists of 10 to 15 injections, usually three a week, totaling 1 to 2 gm. of bismuth. This is followed by a rest period of about one week, after which the course is repeated.

"Bismuth acts as a true antibody and is the most potent spirocheticide available. In the majority of cases in the primary stage studied no spirochete could be demonstrated 24 hours after the first injection. The effect of bismuth upon the Wassermann reaction compares favorably with that of salvarsan. Bismuth also has the power of rendering the serum negative in the so-called arsenic-fast cases. In tabes dorsalis the specific action of bismuth is most marked. Tertiary syphilis, on the whole, reacts well to bismuth therapy. Successful results have also been obtained in treating hereditary syphilis with bismuth. The potency of the drug would seem to be partly associated with its excretion. It is eliminated chiefly by the salivary glands and the kidneys and into the cerebrospinal fluid, where it is most effective.

"Seventy per cent of the patients bear bis-

mouth well. In 30 per cent of the cases some sign of toxicity presents itself, such as a mild form of stomatitis and salivation. A more severe form may be gingivitis which may go on to ulceration. No serious manifestations of toxicity have occurred. Cessation of the administration of the drug is followed almost at once by a disappearance of the toxic signs.

"The place of bismuth in the routine treatment of syphilis, according to the practice of most of the large European clinics, is as follows: First an intensive attack upon the infection with salvarsan (or neosalvarsan), consisting of a course of 8 to 12 intravenous injections, totaling approximately 10 gm.

of neosalvarsan, followed by a rest period of about one week. Bismuth is next administered by a course of 10 to 15 intramuscular injections. After another rest interval the treatment is continued by mercury in one or another of its forms. (C. I. Gross, *Canadian Medical Association Journal*, Montreal, April, 1923, p. 265.)"

### Our New President.

The highest honor at the disposal of The Medical Society of Virginia was worthily bestowed, at the Roanoke meeting in October, by the election of Dr. William W. Chaffin, of Pulaski, to the presidency of that organization.

His professional qualifications are such as to merit honor, while his intellectual attainments, his genial courtesy, and his consideration for others, will make his elevation doubly acceptable to his brethren of the profession.

Dr. Chaffin was born in Wythe County, Virginia, May 5th, 1868. He took his collegiate course at Washington and Lee University. He graduated with the degree of M. D. from Jefferson Medical College, Philadelphia, in 1893, and joined the Medical Society of Virginia the same year. After graduation he was an interne of Jefferson Hospital and of the Episcopal

Hospital, Philadelphia, and later of Gouverneur Hospital, New York.

He located in Pulaski in 1895. During his residence there he has been a public spirited citizen, closely identified with every effort made for the advancement and improvement of the town and community, and has served for a number of years as a member of the City Council. By his energy and devotion to his profession he has built up a large practice both in medicine and surgery. After a service to his people of twenty-eight years, he is still the same faithful physician going about doing good.

Dr. Chaffin was one of the first members of the State Board of Health. He has been on the State Medical Examining Board since 1911. He was a charter member of The Southwestern Virginia Medical Society and served one term as its President. He is a member of the American Medical Association, The Southern Medical Association, The Tri-State Medical Association of the Carolinas and Virginia, Chairman of the Pulaski County Board of Health, and has been a Surgeon of the Norfolk and Western Railway since 1896.

In the long, long ago, in the dim and distant past, at the time "When the memory of man runneth not to the contrary," some one said:

"Physicians! Pray to the Gods for a fair measure of the love of Science, a good memory, a quiet manner, the accurate use of your hands and senses. Pray even for opposites, for humility and pride, for plodding business ways and for the wings of ambition, for a will both stubborn and flexible, and above all for that one gift which has been the making of the best men in our profession, the grace of simplicity of purpose."

It is not known whether Dr. Chaffin ever offered this prayer, but it is well known that he has received the blessing, and those who know him best esteem him most.

W. W. CHAFFIN, M. D.,  
President Medical Society  
of Virginia.

## News Notes

### The Roanoke Convention.

The recent meeting of the Medical Society of Virginia will long hold many pleasant memories for those who were fortunate enough to partake of the hospitality of this progressive Virginia city. Dr. John O. Boyd, general chairman of the Committee on Entertainment, and his able co-workers, did everything that could be desired for the comfort and entertainment of their visitors. There was a registered attendance of 502, including the ladies, who evinced great interest in the Woman's Auxiliary, which held two sessions. Mrs. J. W. Preston, chairman of the Ladies' Committee, and her associates provided several attractive entertainments and rides for the ladies, in addition to the buffet dinner and dance on Wednesday evening and the barbecue at Lakeside on Thursday, in which both the doctors and the ladies participated. The President, Dr. John Staige Davis, of the University of Virginia, saw that the scientific and business meetings were on schedule time, so that there was plenty of time for pleasure as well as work.

The commercial exhibits were most attractive and always had a number of visitors.

An innovation at this meeting was the golf tournament, which it is hoped may be made an annual event. Dr. Fred M. Hodges, Richmond, won the first leg on the cup donated by the Roanoke Academy of Medicine. Dr. F. C. Rinker, Norfolk, was runner up, and Dr. Stuart Michaux, Richmond, won third place. Dr. J. W. Carroll, Lynchburg, had low gross score.

Dr. W. W. Chaffin, Pulaski, was elected president for the coming year and Staunton was selected as the 1924 place of meeting, the date to be decided upon later. The full list of officers is given under Society Proceedings, elsewhere in this issue.

The one regret of the meeting was the resignation of Mr. G. H. Winfrey as secretary-treasurer of the Society, his resignation to be effective December 31. During his four years as secretary-treasurer, Mr. Winfrey has, by his efficient service and genial personality, won for himself many friends among the doctors who will be interested in hearing of his continued success in the years to come.

### Woman's Auxiliary, Medical Society of Virginia.

The annual meeting of the Woman's Auxiliary was held in the parlors of the Hotel Roanoke on Wednesday, October 17. Mrs. R. Lloyd Williams, of Norfolk, presiding, Mrs. R. W. Miller, Richmond, in the absence of Mrs. Burnley Lankford, of Norfolk, was appointed acting secretary. Report from the delegates to the American Medical Association at San Francisco was read by Mrs. J. Allison Hodges, and reports from city and county Auxiliaries, recently organized, were also read. The report of the committee on Constitution and By-Laws was read, and each article voted upon separately, and this report, with a few corrections, was unanimously adopted. The meeting was the largest that has been held, and was an unusually enthusiastic one.

The Auxiliary met again on Thursday morning, and was addressed by Dr. Seale Harris, of Birmingham, Ala., who told of the arrangements and program outlined for the Auxiliary at the meeting of the Southern Medical in Washington on November 12-15; by Dr. R. Lloyd Williams, of Norfolk, Chairman of the Executive Council of the Medical Society, who expressed the thanks of the society for the aid of the Auxiliary; and by Dr. J. Allison Hodges, of Richmond, who spoke of a further opportunity for service in assisting the State Public Health League, just being organized by the Medical Society. Much interest was displayed by the members in this movement, and the desire to aid the physicians in every way possible was unanimous and most encouraging.

As the Constitution calls for the bi-annual election of officers, the following elected in Norfolk in 1922, hold over for the coming year: President, Mrs. R. Lloyd Williams, Norfolk; Vice-Presidents, Mrs. J. Allison Hodges, Richmond; Mrs. S. S. Gale, Roanoke; Mrs. Southgate Leigh, Norfolk; and Mrs. W. E. Anderson, Farmville; Recording Secretary, Mrs. Burnley Lankford, Norfolk; Treasurer, Mrs. Starke Sutton, Norfolk.

### The American College of Surgeons

Held its annual meeting in Chicago, October 22-26, with a very large attendance. Five hundred and twenty-seven surgeons, representing North and South America, were elected to fellowship. Of these, five were from Vir-

ginia, as follows: Drs. Arthur S. Brinkley, Paul W. Howle and Ben H. Gray, from Richmond; Dr. O. T. Amory, Newport News; and Dr. J. M. Emmett, Clifton Forge. The following were elected, honorary fellows: Surgeon General Hugh S. Cumming, of the U. S. Public Health Service, Washington; Sir Wm. I. de Courcy Wheeler, President of the Royal College of Surgeons of Ireland; and Mr. A. E. Webb-Johnson, Fellow of the Royal College of Surgeons of London.

The 1924 meeting will be held in New York City, the exact date to be named later. Dr. A. J. Ochsner, Chicago, is president; Dr. Charles H. Mayo, Rochester, Minn., president-elect; and Dr. Franklin H. Martin, Chicago, continues as secretary-general.

### Erratum.

In our October issue we published an article by Dr. William R. Rogers, of Bristol, Va., entitled "Pott's Disease, with Special Reference to its Diagnosis." Some "printer's devil" must have been turned loose on Dr. Rogers' paper as, in making a slight correction marked in the proof, Dr. Rogers' name was butchered to read "Wm. F. Fogers, M. D."

We wish to apologize to Dr. Rogers on our own behalf as well as for the printer, that such liberty should have been taken with his name and that he should fail to receive proper credit for his most excellent paper which was the result of much study.

### Married.

Dr. A. S. Priddy, superintendent of the State Epileptic Colony at Madison Heights, Va., and Mrs. Mamie H. Mitchell, Alexandria, Va., October 20.

Dr. M. E. Mease, Sandy Level, Va., and Miss Annie Edwards, Lynchburg, Va. October 13.

Dr. Robert Wilson Selby, Middleburg, Va., and Miss Mae Diller, or Rehoboth Church, Va., November 1.

Dr. Marshall L. Boyle, Jr., Richmond and Miss Elise Leckie, Lynchburg, Va., October 20.

Dr. Robert Minor Baker and Mrs. Ruby Gornto Jones, both of Jacksonville, Fla., October 18. Dr. Baker is originally from Richmond and Fredericksburg, Va., but has practiced in Jacksonville, Fla., for several years. He is a member of the class of '18, Medical College of Virginia.

### Dr. E. L. Kendig,

Victoria, Va., has been commissioned by Governor Trinkle as a member of the Board of Visitors of the Medical College of Virginia, Richmond, to fill the vacancy caused by the death of Dr. H. S. Myers, of Amherst County.

### Dr. W. C. Harman,

Dolphin, Va., was recently in Baltimore, Md., on a business trip.

### Dr. R. E. Mitchell,

Richmond, has completed a course on eye, ear, nose and throat work at the Brooklyn Eye and Ear Hospital, and has opened offices at the new Medical Arts Building, at Second and Franklin Streets, this city. While waiting for his offices to be completed, he has been taking a special course on bronchoscopy and esophagoscopy, given by Dr. Chevalier Jackson, of the University of Pennsylvania. He will complete this course about the twentieth of this month.

### Dr. F. P. Coombs,

Recently of Mt. Jackson, Va., announces his removal to R. F. D. 2, from Morgantown, W. Va.

### The Association of Surgeons of the Norfolk and Western Railway

Held its ninth annual meeting in Cincinnati, O., September 12 and 13. Hotel Gibson was headquarters for the meeting, Dr. W. E. Anderson, Farmville, Va., president, and Dr. T. D. Armistead, Roanoke, Va., secretary-treasurer. The scientific and business meetings were held on the 12th, and, though the Association was organized primarily as a social rather than a scientific gathering, there was a good program. Among the interesting papers read were those by Dr. George Tully Vaughan, Washington, D. C., and Dr. C. C. Coleman, Richmond, on cranial injuries. At the business meeting, Dr. Robert Carothers, Cincinnati, was elected president for the coming year, and Dr. T. D. Armistead, was re-elected secretary-treasurer. The 1924 place of meeting is to be selected by the Executive Council.

Dr. Carothers, chairman of the local committee of arrangements, had secured theater tickets for the first evening, for the surgeons their wives and daughters. The second day was devoted to golf, a trip to the zoo, and any other amusements desired.

Dr. Richard Lee Willis, Chatham, Va., and Miss Elizabeth Harris, Crozet, Va., recently. Dr. Willis graduated in medicine from the University of Virginia in 1921, at which time he was appointed as interne at the Post-Graduate Hospital, New York City.

Dr. David Thomas Tayloe, Jr., and Miss Eleanor Berry, both of Washington, N. C., October 2.

#### **Dr. Allen F. Voshell,**

Instructor in orthopedic surgery at the University of Virginia, addressed the Danville Academy of Medicine at its regular meeting in October. The following day he held clinics for crippled children in that vicinity.

#### **Dr. Elbert B. Talbot**

Returned to his home in Richmond, early in October, after spending sometime in New York City.

#### **Dr. Mary Evelyn Brydon,**

Director of the Bureau of Child Welfare of the Virginia State Board of Health, represented Virginia at the meeting of the American Child Health Association, held in Detroit, October 15-17, inclusive.

#### **Dr. and Mrs. Fitzhugh Banks**

And family, of Richmond, spent the summer months at their former home in West Virginia.

#### **Dr. Easley's Home Destroyed by Fire.**

The home occupied by Dr. E. M. Easley, near Rushmere, Va., was completely destroyed by fire, early in October. The cause of the fire is not known but it is presumed to have been caused by defective wiring of the electric lighting system. The loss was covered by insurance.

#### **Dr. J. Blair Fitts,**

Richmond, is out again after undergoing an operation for appendicitis, in October.

#### **Huntington Eye, Ear and Throat Hospital**

Is the new name by which the former Moore-Beckner Hospital, of Huntington, W. Va., will be known. Drs. Thomas W. Moore and William F. Beckner are physicians in charge.

#### **Dr. Charles K. Mills,**

Philadelphia, was elected president of the American Neurological Association, at its annual meeting recently held in Boston.

#### **Dr. and Mrs. C. H. Iden,**

Berryville, Va., were visitors in Richmond in October.

#### **Member W. Va. Health Council.**

Dr. Olin H. Jennings, Williamson, W. Va., has been appointed a member of the West Virginia Health Council, to succeed Dr. Benjamin F. Shuttleworth, of Clarksburg.

#### **The Seaboard Medical Association of Virginia and North Carolina**

Will meet in Newport News, Va., December 4, 5 and 6, 1923, under the presidency of Dr. Joseph T. Buxton of that city. An elaborate program is being arranged. There will be two mammoth public meetings one dealing with medical education and the other with child welfare. An intensely scientific feature, from a general standpoint, will be "A Study in Color Photography," by Dr. Henry O. Reik, of Baltimore. Extensive social features also will be provided.

This organization is one of the most alive in the United States and owes much of its success to having each paper discussed, some one being appointed to lead the discussion in each case. Dr. Clarence Porter Jones, Newport News, is secretary, and Dr. George A. Caton, New Bern, N. C., treasurer.

#### **Mexican Society Honors American Surgeons.**

The Academy of Medicine of Mexico City, at a recent meeting, unanimously elected to honorary membership Drs. W. J. Mayo, of Rochester, Minn., and A. J. Ochsner, of Chicago.

#### **The Association of Military Surgeons of the U. S.**

At the annual meeting of this Association, held at Carlisle Barracks, Pa., the time was mostly given up to practical demonstrations, only two papers being read. There was an attendance of over 250. Col. Gilbert E. Seaman, M. C., Milwaukee, of the Wisconsin National Guard, was elected president.

#### **Col. J. Fulmer Bright, M. C.,**

Richmond, commander of the 183rd infantry, was detailed to represent the State of Virginia at the convention of the National Guard Association, held in Denver, Colo., the latter part of October.

#### **Dr. L. Emmett Holt,**

Eminent pediatricist of New York City, has been assigned as visiting professor of pediatrics to the Peking (China) Union Medical College, by the Rockefeller Foundation. He started with these lectures in October and will

give a three months' series, telling the physicians of China of our latest methods in child culture. Upon completion of this service, Dr. Holt will visit a number of foreign countries, making a survey of child health methods. He will not return to this country until next summer.

#### **The Lewis-Gale Hospital Clinic,**

Roanoke, Va., announces the entry to its staff of Dr. Linwood D. Keyser, for the practice of surgery and urology. He will have offices at the Lewis-Gale Hospital.

#### **American Public Health Association.**

At the meeting of this Association held in Boston in October, there was a registered attendance of more than 800. Among the matters receiving special indorsement of the Association was the periodic physical examination of apparently healthy persons, and all citizens of the countries represented in this organization are urged to have such medical examinations made. The next annual meeting is to be held in Detroit. Dr. William H. Park, director of the Bureau of Laboratories of the New York City Health Department, was elected president, and Dr. James A. Hayne, commissioner of health of South Carolina, executive secretary.

#### **News of St. Elizabeth's Hospital, Richmond.**

Dr. J. S. Horsley, Jr., who recently returned from working in the Pathological Department of the Mayo Clinic, Rochester, Minn., is now first assistant to Dr. J. Shelton Horsley at St. Elizabeth's Hospital, Richmond. Dr. A. I. Dodson is confining his work entirely to urology. Miss Myra Stone, who has been superintendent for several years, has resigned and will be succeeded by Miss Rose Z. Van Vort, who has been with Stuart Circle Hospital, this city, since its opening. She will inaugurate a training school for nurses at St. Elizabeth's.

As a token of love and admiration, the general duty nurses at St. Elizabeth's presented Miss Stone with a gift just prior to her departure. She will rest for several weeks before undertaking other work.

#### **Chiropractors Live Hard in South Carolina.**

According to the *Journal of the A. M. A.*, the Cherokee County (S. C.) Medical Society protested against the city of Gaffney granting a license to a chiropractor who came there from North Carolina. The president of the

Society stated that, if this chiropractor received a city license to practice in Gaffney, a warrant for his arrest would be sought on a charge of practising medicine without a license from the State Board of Medical Examiners.

#### **Dr. L. F. James,**

Richmond, is now in New York City, where he is taking a post-graduate course in gynecology and obstetrics.

#### **Drs. Willis and Johns.**

Dr. A. Murat Willis and Dr. Frank S. Johns, Richmond, who have been associated in surgery for ten years, announce a formal partnership under the name of Drs. Willis and Johns. Their offices are at Johnston Willis Sanatorium, this city.

#### **The Richmond Academy of Science**

Has been organized with Dr. J. Allison Hodges, of this city, as president, Mr. George Bryan, a prominent attorney of this city as vice-president, Wortley F. Rudd, Medical College of Virginia, treasurer, and G. H. Winfrey, secretary. The board of directors the first year consists of a number of prominent physicians, lawyers, ministers, architects and engineers. A site has been secured on West Franklin Street on what was formerly the campus of Richmond College. It is confidently hoped that a suitable building, with an auditorium, will be constructed in the near future, providing headquarters for the various professional and scientific organizations of the city and state.

#### **Christmas Seal Sales**

Will be held throughout the country this year, as in the past, to help in the big educational campaign carried on by the National Tuberculosis Association and its 1,200 state and local associations. In 1907, 300,000 seals were sold; in 1922, 3,842,500; and for 1923, over one billion seals will be for sale. The work done by tuberculosis organizations is so well known to the profession that it is unnecessary for us to give it in detail. Do your bit.

#### **Dr. and Mrs. L. T. Royster,**

Who have made their home in Norfolk for a number of years, have moved to University, Va., where Dr. Royster has accepted the appointment as professor of pediatrics.

#### **Child Welfare Clinic.**

At a recent meeting of the members of the McGuire Newton Memorial Foundation, it

was decided that this foundation should be a trust fund, the income from which will be at the disposal of the trustees for child welfare work in Richmond. This fund will be in the form of a perpetual endowment, will be unlimited, and contributions will continue to be received.

### **The New Competition.**

Many progressive manufacturers and merchants say that the cut price bait is losing its attraction. They are paying less attention to this method of getting more business, and more attention to the idea of quality merchandise service. They believe the results so far achieved justify the statement that their customers will be better served and their own profits enhanced by giving more attention to quality, and less to price.

Real service is what counts. While many people will shop about for prices, the great majority are better satisfied with quality merchandise and good service at a fair price. This makes for confidence—the corner stone of satisfaction.

Mr. Charles Wesley Dunn, Counsel for a number of large manufacturers in this country, has given this problem a great deal of thought. His conclusion is that we are now approaching the time when the real competition will be in merchandise and service rather than in price.

As a nation, we have developed to the highest degree the science of quantity production. Now, with characteristic American progression, it is only natural that we are experiencing a very definite trend toward the development of *quality* production.

### **Dr. C. P. Hutchison,**

Purcellville, Va., was called to Westhampton College, Richmond, last month, by the illness of his daughter.

### **Dr. E. M. Chitwood,**

After spending some time in New York, taking post-graduate work and placing particular emphasis on diseases of children, has returned to his home in Wytheville, Va.

### **Dr. E. S. Lester,**

After several months at Bluefield, W. Va., returned to his former home at Danville, R. F. D., 2, Va., the first of November.

### **Dr. Howard L. Mitchell,**

Of Callands, Va., is now taking a special course in eye, ear and throat work at the

Episcopal Eye, Ear and Throat Hospital, Washington, D. C.

### **Dr. Henry E. Davis,**

Medical inspector on the staff of the Richmond health bureau since last April, has resigned to engage again in the private practice of medicine. The medical inspection work will be handled by Dr. G. R. Maloney, the other medical inspector, until Dr. Davis' successor is appointed.

### **The Near East Relief,**

Incorporated by an act of Congress, is feeding approximately two hundred thousand children located in orphanages and other institutions in Armenia, Syria, the Caucasus, Greece and the Isles of Aegean Sea. This is the largest child feeding clinic in the world. To carry on this work, the Near East Relief, 151 Fifth Avenue, New York City, makes various appeals to collect clothing, money and food. Milk has been successfully used as an article of diet for infants and older children, and an appeal is especially made for condensed milk.

Any contribution you may be able to send to the above given address will be much appreciated and will be used for the maintenance of these little ones.

### **Dr. W. C. Rosser,**

Rustburg, Va., is one of the board of directors of the Campbell County Bank, which has just applied for a charter to do business at that place.

### **Dr. E. Govan Hill,**

Of Richmond, returned home the latter part of October, after attending the Seale Harris Clinic, in Birmingham, Ala., where Dr. F. G. Banting demonstrated the use of insulin.

### **Major Allen J. Black,**

Of the medical corps, U. S. Army, formerly of Virginia, has been transferred from Fort Terry, N. Y., to Fort Andrews, Mass.

### **Dr. Z. G. Phipps**

Announces change of his postoffice from Bridle Creek, Va., to Galax, Va.

### **Dr. Henry Clay Smith,**

For some time of Crewe, Va., has moved to Williamson, W. Va.

### **Slogan Wanted for Savannah.**

The city of Savannah, Ga., through its Board of Trade, want a slogan or motto which will help sell the city to the world at large. A cash prize of \$100 is offered for the best slogan in

the contest. The contest is open to anybody, anywhere, and contestants may submit as many slogans as they desire but, to be eligible, all slogans must reach the "Savannah Slogan Committee, Board of Trade, Savannah, Ga.," by noon, December 15, 1923. The slogan should be brief (within five words, if possible), clear-cut, and reflect in as few words as possible the advantages of Savannah. Write each slogan plainly on a blank sheet of paper and put your name and address at the top of the sheet.

The committee will not answer inquiries about the contest by correspondence.

"Savannah's advantages include fine harbor and marine terminal, unsurpassed rail transportation facilities, unexcelled climate, physical beauty and an almost continuous flood of golden sunshine. It is a veritable forest city of beautiful homes and offers unsurpassed opportunities in industry."

**Dr. Charles W. Putney,**

Recently of Covington, Va., has located in Central Building, Staunton, Va., for the practice of general medicine and surgery.

**Dr. A. C. Fox,**

After a number of years in Waynesboro, Va., has moved to Lincolnton, N. C., and will limit his work to pediatrics.

**Nobel 1923 Prize Awarded.**

The council in charge of making the Nobel prize awards has given the 1923 prize jointly to Dr. Frederick G. Banting, of London, Canada, and Dr. J. J. R. Macleod, Toronto, for their discovery of insulin. They will receive \$20,000 each.

**Dr. Clifton M. Miller,**

Richmond, was one of a large party of Kiwanians to attend the district convention in Baltimore, in October.

**Dr. E. N. Lillard**

Announces change of his address from Graves Mill to Brightwood, Va.

**Major Richard G. Simmons,**

Roanoke, of the medical officers' reserve corps, in charge of the U. S. Veterans' Bureau at that place, has been assigned as regimental surgeon of the 317th infantry. He will continue his present work with the Bureau.

**Mississippi Valley Medical Association.**

Dr. Charles A. L. Reed, Cincinnati, O., was elected president of this Association at its meeting held at Hot Springs, Ark., last month. Dr. John L. Tierney, St. Louis, is secretary.

**The Southern Surgical Association**

Is to hold its annual meeting at White Sulphur Springs, W. Va., December 11, 12 and 13, under the presidency of Dr. James F. Mitchell, Washington, D. C. Dr. H. A. Royster, Raleigh, N. C., is secretary. Dr. H. H. Trout, Roanoke, Va., is chairman of the committee of arrangements. This Association met at White Sulphur Springs also in 1916.

**Dr. Charles R. Robins,**

Richmond, was appointed by Dr. J. S. Davis as representative of the Medical Society of Virginia, to appear with a committee before the Governor in October, urging an appropriation for building a road between Williamsburg and Jamestown.

**Dr. Gerald A. Ezekiel,**

Richmond, announces the removal of his offices to The Brunswick, 1652 West Grace Street, this city, with entrance on Allen Avenue. He has added a great deal of new equipment to his offices.

**The Kentucky State Medical Association.**

At its annual meeting recently held at Crab Orchard, Dr. Frank Boyd, Paducah, was elected president, and Dr. A. T. McCormack, Louisville, was re-elected secretary to serve a term of five years.

**Major Herbert C. Mallory, M. C.,**

Who has been stationed in Richmond for little more than a year, sailed from San Francisco, October 23, for the Hawaiian Islands, where he has been assigned to duty.

**Salvation Army Hospital Opened.**

On the afternoon of October 21st, the Evangeline Booth Home and Hospital was opened for inspection of the advisory board and woman's auxiliary, that they might see the repairs and improvements made. The home is located in Highland Park, this city. The hosts on this occasion were the medical staff, composed of Dr. Robert C. Bryan, chief of staff, and Drs. Ben H. Gray, Paul Redd, Thomas W. Murrell, Clifton M. Miller and Garland M. Harwood.

**Dr. Richard H. Meade, Jr.**

A former Richmonder, who studied first at the University of Virginia and later at Harvard, graduating from the Harvard Medical School in 1921, has been appointed a medical missionary to St. James Hospital, Anking, China. He will assist Dr. Henry R. Taylor, formerly of Norfolk, who is now in charge

of this hospital. Dr. Meade received his appointment through the domestic and foreign mission board of the Episcopal church and will leave for China next August.

#### **The Red Cross Roll Call**

Is now on. When the humanitarian work done by this organization is recalled by doctors, they, of all people will wish to continue membership. If not now a member, there is not better time to pay \$1 for membership.

#### **Cancer**

Is a new practical quarterly journal devoted to the study of and reporting of cases of cancer. It made its initial appearance in October, under the editorship of Dr. L. Duncan Bulkley, of New York, one of the country's best informed men on this subject. He has several prominent doctors associated with him. The publishers are F. A. Davis Company, Philadelphia, and the price is \$5.00 per volume in North America.

#### **Dr. Duncan Eve, Jr.,**

Nashville, Tenn., was elected president of the American Association of Railroad Surgeons at its meeting in Chicago, last month.

#### **Dr. Robert P. Kelly**

Has returned to Lynchburg, Va., after spending six months at the Chicago Lying-In Hospital with Dr. Joseph B. De Lee and staff. Dr. Kelly will continue to limit his practice to obstetrics. This appointment was quite an honor, Dr. Kelly being the first Virginian to have received it.

#### **Dr. and Mrs. Adam T. Finch,**

Chase City, Va., were recent visitors in Richmond.

#### **Dr. and Mrs. E. A. Terrell,**

Fredericks Hall, Va., spent several days in Washington, the latter part of October, after attending the marriage of their son, Mr. E. A. Terrell, Jr., to Miss Virginia Andes.

#### **Dr. Thomas E. Hughes,**

Formerly of Wright, Fowlkes and Hughes, announces the removal of his offices to the Medical Arts Building, at Franklin and Second Streets, Richmond, Va. He will limit his practice to diseases of the ear, nose and throat.

#### **Dr. Susan A. Price,**

Who has been connected with the medical staff of the State Hospital at Weston, W. Va., for the past year, will spend this winter in taking a vacation and rest in Baltimore, Md.

#### **Dr. and Mrs. Edward Sandidge,**

Of Amherst, Va., recently enjoyed a vacation on the Eastern Shore of Virginia.

#### **Virginia Baptist Hospital to Open Soon.**

At a recent meeting of the board of trustees of the Virginia Baptist Hospital, of Lynchburg, Va., it was announced that it is expected the hospital will be ready for occupancy about the first of April, 1924. Several memorial rooms have already been provided for in this hospital.

Miss Mary F. Cowling, of Lynchburg, has been appointed superintendent of the new hospital.

#### **Dr. T. N. Davis, Jr.**

Has been elected surgeon, for the coming year, of the Lynchburg, Va., Post 16, American Legion.

#### **Dr. Eugene Rogers**

Has returned to his home in Covington, Va., after an extended visit to relatives in Chicago, Ill.

#### **Dr. J. K. Hall,**

Of Westbrook Sanatorium, Richmond, recently visited friends in Buckingham Co., Va.

#### **Dr. Clarence Campbell,**

Until recently of Sparta, Va., moved to Williamsburg, Va., about the first of November, and will continue the practice of general medicine in that place.

#### **Dr. Joseph T. Buxton,**

Who was recently operated upon by Dr. George W. Crile, at Lakeside Hospital, Cleveland, Ohio, has returned to his home in Newport News, Va., and resumed his work.

#### **Dr. E. L. Sutherland,**

After practising for sometime in Roanoke, Va., has located in Charlottesville, Va., and will limit his work to diseases of the eye, ear, nose and throat.

#### **Dr. C. S. Dodd**

Returned to his home in Petersburg, Va., the latter part of September, after visiting abroad and spending three months in post graduate work at the University of Vienna.

#### **Dr. R. D. Garcin,**

Richmond, after an illness of several weeks, has resumed his practice.

#### **Dr. Thomas F. Wheeldon,**

Richmond, has been appointed medical officer, with the rank of captain, of the permanent field artillery examining board for the Third Corps Area, recently established in Richmond.

**Dr. John H. Neff,**

Of the faculty of the University of Virginia, was the principal speaker before the Richmond Chapter of the University of Virginia Alumni, at their monthly dinner, the latter part of October.

**Charles Street: Its History and Growth**

Has been published again this year by the Charles Street Association of Baltimore, Md. This little pamphlet tells of many of the places of interest to visit in and around Baltimore and also of the places to shop while there. It contains only 30 pages. Headquarters of the Association are in Fidelity Building, Baltimore.

**For Sale,**

One Wappler Bedside unit. capacity 30 M. A. on 110 volt, alternating current, complete with tube. Carefully used one year. Cost \$885; price \$600, easy terms. Write "X. Y. Z.", care this journal. (Adv.)

**For Sale:**

Eye, ear, nose and throat practice better than \$7,000 annually, at Leesburg, Va. Office thoroughly equipped; every type of instrument necessary; hospital advantages. Lovely section of country. Apply to Mrs. J. W. Marshall, Leesburg, Va. (Adv.)

**Location Open for Physician.**

We have just been advised that Dr. I. H. Thomas, of Sterling, Loudoun County, Va., has retired from practice and that the people in that community are in need of a physician. A petition to this effect from the citizens of that community has been received at the offices of the State Board of Health, Richmond.

**Wanted—**

Assistant physician, Mental Diseases, \$1,800—\$2,000 and maintenance. Assistant physician, Tuberculosis, \$1,140—\$1,500 and maintenance.

Apply State Employment Commission, 22 Light Street, Baltimore, Maryland. (Adv.)

---

## Obituary

---

**Dr. Robert Graham Wiatt,**

Assistant professor of roentgenology at the University of Virginia, was instantly killed by an automobile, on the night of November 2. He had just reached Gloucester, Va., that day, for a visit to his mother and, with a little nephew, was on his way to a basket ball game

when he was run down by the car. His neck was broken and leg badly fractured. Dr. Wiatt was born in Gloucester County, Va., 29 years ago and studied medicine at the Medical College of Virginia from which he graduated in 1914. After this he served an internship at Stuart Circle Hospital, Richmond. Prior to entering the medical corps in the World War, he practiced in Richmond. Upon his return he located at the University and, at time of his death, was assistant professor of roentgenology in the Medical Department of the University of Virginia. Dr. Wiatt is survived by his wife, a son by his first marriage, his mother, and several sisters and brothers.

The interment was made in Gloucester County, with Masonic honors.

**Dr. Henry Samuel Myers,**

Formerly of Forks of Buffalo, Va., owing to despondence and ill health, committed suicide on the evening of November the 2nd, by firing a bullet through his temple, while in his room at Amherst White Sulphur Springs, Va. Death resulted immediately.

Dr. Myers studied medicine at Medical College of Virginia, from which he graduated in 1892. He had been a member of the Medical Society of Virginia since 1894. Dr. Myers had practiced in Amherst County since that time and once represented his county in the State Legislature. He is survived by three children.

**Dr. Henry Enos Tuley,**

One of the best known physicians of Louisville, Ky., died October 21, at the age of 53 years. He graduated from the Medical Department of the University of Louisville in 1890 and later from the New York Polyclinic Medical School and the Kentucky School of Medicine. Dr. Tuley was for twenty-five years the secretary and, for the past year, president of the Mississippi Valley Medical Association. At the time of his death, he was dean and professor of pediatrics at the University of Louisville, Medical Department. He was also an interested worker in the American Medical Association and the Kentucky State Medical Association.

**Dr. Nicholas Perkins Oglesby,**

A member of the Medical Society of Virginia, of Dublin, Va., died from heart disease, in Cincinnati, September 12. He was 49 years of age and graduated from Starling Medical College, Columbus, Ohio, in 1904. He was a Spanish-American War veteran.

# A Food to Keep Babies and Young Children Well

Adapted to Mother's Milk

If you are prescribing S. M. A. we shall be glad to send you an additional supply so that you will have some on hand for any emergency. If you have never used it we should like to send you some so that you may observe results in your own practice.

Infants fed on S. M. A. look and act and grow like breast-fed infants. Their flesh is firm, they develop normally, and they are normally free from rickets and spasmophilia. In addition, S. M. A. is so simple to feed that the physician can rely on his directions being followed to the letter. To be used only on the order of a physician. For sale by druggists. Formula by permission of The Babies' Dispensary and Hospital of Cleveland.

PLEASE USE THE COUPON

The Laboratory Products Co.  
1111 Sweetland Bldg., Cleveland, Ohio

## CALCREOSE

### 137 Miles

of brown coated CALCREOSE tablets were manufactured in 1922; that is, the tablets, laid in a row close together, would span that distance. To traverse it an automobile, traveling at a speed of 25 miles an hour, would require 5 hours and 25 minutes.

The number of physicians prescribing CALCREOSE is indeed, impressive.

CALCREOSE (Calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, which possesses the pharmacologic activity of creosote but apparently does not cause gastro-intestinal disturbances.

### SURGICAL STUDIES IN THE SO-CALLED FUNCTIONAL PSYCHOSES.\*

By JOHN WILLIAM DRAPER, M. D., F. A. C. S., New York, N. Y.

Surgical studies looking to the relief of the mentally afflicted are not new. It is the trend which is new. Heretofore, such surgical work as was done was directed largely, if not exclusively, toward the relief of malformation, both congenital and acquired, of acute infections, and toward the removal of tumors. With the advent of aseptic surgery a great deal of work was done upon the female pelvis and upon the cranium. The results were disappointing. It was reluctantly to be admitted that the application even of aseptic surgery could avail little or nothing in raising the discharge rate at the State Hospitals for the insane. With the acceptance of this depressing fact it was natural that the views of the fatalists should again predominate; and that those who sought to interfere with so-called "inevitable" events, were returned to the discard. For from time immemorial there has existed in the study of this branch of human disorder, as indeed of all human disorders and all fields of human endeavor, two diametrically opposed schools or systems. The one viewed the problems from a theistic or spiritual standpoint; the other, usually much in the minority as regards numbers, based its reasoning upon material standards. It urged, then as now, a physical basis for life, and that, as there could be no function without form so there could be no aberrant function without aberrant form. The protagonists of these two schools have left traces of active and interesting strife dating back to early Egyptian history, but the written record of the conflicting standards by which human beings have sought to interpret the limitations, both physical and mental, imposed by disease upon their own kind, has been more definitely

chronicled since the early days of the Christian era. Anyone who is interested in studying the cause of the divergent opinions, which at present exist in the viewpoints of the men who have given their lives to the study of the insane, will recognize at once that these differences are due to the presence today of these two great schools of thought. They may be referred to as theological and scientific, and the divergencies of opinion so strongly marked in the circumscribed field of psychiatry are the natural result of the age-old conflict between theology and science.\* But, as there is good in each, let us hope that these two schools may soon be brought into productive co-operation.

After a five years' experimental study of the intricate physical conditions to be found in the bodies of patients who are mentally afflicted, it would seem to the writer urgent that the exponents of the metaphysical school should hasten to join forces with the physicists, as the growing school of the literal adherents of Virchow may properly be termed. For while it is true that in the last generation, and even earlier, many of the props have been taken from the metaphysical interpretation of medicine, particularly as regards the causation of ordinary bodily ailments, there yet remains and will always remain a halo of interest and a just reverence due the supernatural. Is it not true that a curb has been put upon our tendency to explain by physical interpretation problems, both of mind and body, because of the fear that in so doing we may violate that something within us which grants reverence to the supernatural and which causes us to fear that our religious beliefs may be damaged or taken from us by the interpretation of mysteries upon physical facts. Most of us are demologists and it is easy to believe in the miraculous origin of insanity. However, the amazing discoveries of modern science, far from weakening our reverence for the unattainable, go far to strengthen and sustain it. Witness

\*Read by invitation at the fifty-fourth annual meeting of the Medical Society of Virginia, October 16-19, 1923.

\*J. W. Draper, *The Conflict between Religion and Science*, Appleton and Co.

the new proof of the immortality of the light wave which travels unaltered through thousands of light years. Is not this vibrant energy indeed a part of ourselves and what therefore is to be feared of facts which make its relationship to us clearer? Is the proof that the safety coefficient for the kidney is identical with that of a steel bridge a disturbing fact? To me it suggests a probable relationship between vertebrate life and an inert element—a matter of deep religious import! However this may be, it is true today that the great stronghold of the metaphysical school lies in the interpretation and treatment of disorders of the mind. From having once occupied an impregnable position of complete autocracy regarding the ailments of the body, the metaphysicians have come step by step, as these have been placed by scientific study upon a natural physical basis, to occupy an insignificant position in the interpretation and treatment of bodily conditions. Not so in the domain of the mind. Here the philosophically minded modern representatives of the ancient theurgists of the Nile hold as undisputed control as did their learned progenitors. For the voice of the Virchowist who is working in psychiatry is small indeed. Perhaps it is the not far distant memory of the fate which overtook the purely philosophical interpreters of bodily disease, first at the hands of the Greeks, then of the Alexandrian school and then of Virchow, that leads this school today to resent the intrusion of modern scientific methods. The reports of the National Committee of Mental Hygiene show that, since 1880, functional insanity has increased in the United States four hundred and sixty-eight per cent while the population has increased only one hundred and twelve per cent. Metaphysical therapeutics, therefore, has signally failed.

When about five years ago Henry Cotton,\* the able Director for the past twenty years of the State Hospital for the insane at Trenton, having in his efforts to do something for the insane exhausted the fields of organotherapy and heredity, turned his attention to a study of toxemia as a causative factor in mental disorder it was certainly an auspicious move. For it gave to modern surgery the opportunity to treat through the removal of hidden foci of infection patients who hitherto had been

looked upon as having nothing the matter with them physically. Amid a storm of disapproval he has conscientiously striven to show that in all so-called functional cases there is a physical basis for the disturbance of function. It has resulted, in his own words, simply in an enlargement of the toxic group long recognized and adhered to by the English writers and practitioners in spite of the rising tide of psychoanalysis. In the course of this work he has changed the nature of this great New Jersey institution from a custodial home, where seventy per cent of those who were committed to it remained to suffer and to die, into a modern hospital where, as a result of modern surgical and medical therapeutics, eighty-six per cent of the so-called functional group are discharged to their homes. When it is considered that these statistics are based upon the cold figures of a state institution; when it is known that no less than four hundred thousand dollars have been saved for the state by the introduction of these methods during the past five years; most of all, when the relief of human suffering worse than any bodily pain is considered, surely it is time that unbiased attention be given to this important matter. It is time that the profession as a whole should take a hand in the problem of the insane.

The treatment of the insane at Trenton differs fundamentally from that in vogue elsewhere in this one respect. Once it is recognized that the patient belongs to the great and rapidly increasing group of so-called functional psychotics, rather than to the senile, congenital, alcoholic or syphilitic groups, the mental phenomena are immediately relegated to the background and the physical condition of the patient is given intensive study and care. Now this simply means that he is put into a pavilion which is as nearly as possible represented by your splendid modern hospital at Roanoke. The case is approached by historical, X-ray and objective methods, just as though the patient were one suffering from so-called rheumatism, heart or kidney disorder, or any other condition now commonly known to result from focal infection. You will gather rightly from this that persons presenting a so-called functional psychosis could and should properly be treated in a general hospital. This assumption is entirely correct. For, as may be observed in the surgical wards of the State Hospital, there is little or no trouble in the administra-

\*Defective Delinquent and Insane, Princeton Press, 1921.

tion of modern surgical therapeutics to this distressed group of the mentally afflicted.

The most common site for the focal infections is of course oral, while the next most common is in the cervix. In five years' duty as attending surgeon to the State Hospital, I have never yet seen a patient with the diagnosis of a so-called functional psychosis free from well-defined and generally multiple streptococcus and colon bacillus infection. Not alone are the teeth involved, sometimes those which look the best are in reality the worst, but painless osteomyelitic lesions have often extended into the body proper of the maxillary bones and in many instances into the antra. The painlessness of these focal lesions constitute their gravest menace.\*

The tonsils should always be removed in a psychotic, whether pus can be expressed from them or not, because in a notable number of instances large abscesses have been found in the centre of a tonsil after removal which from the outside appeared to be perfectly normal. Less than one per cent of the group of fourteen hundred patients detoxicated by operation at the State Hospital and discharged during the past five years have been free from oral infection. Eighty per cent of all the female patients have presented infection of the cervix. A few patients among these do not have sufficient leukorrhoea to annoy or distress them, so that it is important to remember that the character of the infection rather than its extent is a point worthy of careful consideration. Except when the uterus, the ovaries and the tubes are evidently damaged beyond repair, and this decision is not reached until after prolonged observation and always after the cervix has been enucleated by the Sturmdof method, the pelvic viscera are never touched in this clinic. We consider that the Sturmdof procedure is a most beneficent one. This is doubtless because it is based upon the modern understanding of the causes and of the methods of extension of gynecological disease. Briefly, this is that the infections known to be destructive to the ovaries and tubes never or almost never travel upward through the uterine canal, but always laterally through the lymphatics. Easy practical proof of this is to be obtained by any one who, on finding a mass in the pelvis, will, instead of opening the abdomen, enucleate the

compound racemose glands of the cervix and wait a matter of six months. Unless the secondary focus in the pelvic straits is of sufficient size and of such duration as to permit of its being self-continuing, the mass at the expiration of this time will usually have disappeared or have undergone sufficient recession, both in size and in tenderness, to render abdominal operation unnecessary. This infection is non-venereal.

Among the males, as reported by the late Frederick Smith,\* one-third show extensive non-venereal pathology in the seminal vesicles and it is evident that in these there is also often concurrent involvement of the prostate. The treatment, therefore, of pelvic infection in the male for the purpose of relieving a psychosis is much more difficult than in the female.

Personally, having been deeply interested for more than twenty years in the problem of the cause of death in intestinal obstruction and in the vaguely understood condition now rather loosely known as gastro-intestinal toxemia, I have given most of my time at the State Hospital to this phase of the work. When the director of a hospital has reason, based upon the results of five years' study, to expect a discharge rate of over eighty per cent, he naturally begins to suspect that there is something serious the matter with a given patient who remains in the hospital beyond the average time after the usual oral, dental and cervical work has been done. Such patients should be carefully studied by the X-ray to find if there are any abnormalities, either functional or morphological, in the alimentary canal. Not infrequently there is marked delay on the left side of the colon and we have found that in many instances this is due simply to unrecognized rectal disease. A chronic folliculitis or a simple intermuscular fissure will often cause not only the left-sided delay referred to, but will actually bring about amazing interferences with gastro-duodenal function. I have repeatedly seen this to occur, not only among psychotics, but among their first cousins, the psychasthenics and neurasthenics. Nor are they "Virginia" cousins, but more closely related than at present generally believed. These unfortunates frequently fail to empty the stomach after eight hours. When it is recalled, however, that in addition to the

\*Draper, J. W., Preventive Surgery, Jour. N. J. Medical Society, 1922.

\*Amer. Jour. Urology, 1922.

well-known nervous equipment of the rectum there is to be added no less than five recently recognized connections of this important organ to the sympathetic system, it is not to be wondered at that profound abdominal reflexes originate there. Direct radial section in the posterior mid-line of both sphincters almost invariably restores stomach function and relieves the nervous symptoms. Again, this procedure is well within the hands of any competent surgeon; it is simply for him to get the opportunity to practice it upon the psychotic patient.

But there remains fifteen per cent of psychotics who do not improve in spite of all this minor operative procedure and of the well-recognized and vitally important treatment by vaccines and sera. These patients themselves or their parents will always give to a person qualified to ask it the characteristic surgical history of chronic intestinal disease. They have been constipated for years, often since birth; they have had chronic bilious disorder; they have had nausea, vomiting, vertigo; sick headache; they have failed in school; they have had "nervous breakdowns" or have been called "neurasthenics" for years. About twenty-three per cent of them have had the appendix removed because they presented in most instances, I believe, evidence justifying that operation. But they have not been improved. Satterlee has found a similar condition among so-called "neurasthenics." Indeed, one of the most important results of our surgical studies among the adjudged insane is the proof that in many ways the psychoses should be considered as *terminal conditions* of antecedent neurasthenia, schizophrenia, psychasthenia, nervous breakdown, etc., all of which are now known to be due to physical causes. The psychosis is often a symptom only of a general toxicosis. By the usual methods, therefore, it is as easy to determine that a given psychotic patient has a so-called right-sided surgical abdomen as would be true in the case of any other gastro-intestinal invalid. In the past five years I have removed the colon in whole or in part in three hundred cases at the State Hospital. All this mass of diseased tissue has been carefully studied and preserved in the pathological laboratory of the hospital. The lesions do not spread to the ileum via the lumen, but, if at all, through the lymphatics. There is evi-

dently a law that the lumen of a viscus does not transmit infection, as noted in the case of the uterus and also of the ureter. James Ewing, pathologist to Cornell University and consulting pathologist to the hospital laboratory, has generously given enough of his time to furnish a report upon the condition of the excised bowel. This report has been published in full. (*American Journal of Medical Sciences*, No. 3 Vol. CLXIV, p. 322). Its importance and authenticity, however; are so great that I quote from it as follows:

"I have examined sixteen specimens of colon and ileum removed at operation. The great majority of the specimens show very definite gross anatomical lesions which have resulted from chronic intestinal stasis and the ensuing chronic catarrhal inflammation. In several cases the lesions are extremely marked, in many they are well marked, while in a few there are no definite changes that can be regarded as more than minimal variations from the normal. The most marked and constant lesion is pigmentation of the mucosa . . . this is lodged in large polyhedral cells and . . . is fully recognized as a sign of chronic intestinal stasis and intoxication. It is sometimes associated with anemia and at times with severe and even fatal dystrophies of nervous and muscular tissue. Pouching of the intestinal wall from one to two cm. in depth was observed in most of the cases. The wall of the pouches was thin, the mucosa at the bottom generally eroded, sometimes ulcerated. Through such erosions and ulcerations it is obvious that absorption of fluids and bacteria readily occurred. In general the impression gained from the study of these specimens was that the clinicians were dealing with extensive and somewhat unusual grades of chronic intestinal stasis and catarrhal inflammation with its sequels. The isolation of various bacteria from the mesenteric lymph nodes does not appear to have particular significance. More important is the demonstration of hernias, pouching, thinning of wall, pigmentation and ulceration of the mucosa which together form an impressive anatomic basis for the theory of intestinal intoxication, which undoubtedly existed in severe degree in the cases exhibiting such lesions."

"Finally, I would venture to express my personal opinion that extirpation of the af-

fectured portions of the cecum and colon was justifiable and probably the only effective means of relieving the condition found in the advanced cases, while in others, with slight changes the condition could have been met by less radical means."

It is to the last paragraph of this important report that I would direct your particular attention. It voices the desire of every clinician, certainly that of every surgeon who has done a colectomy, that some tangible means must soon be found by which to recognize the presence of these destructive conditions in the colon, whether they be bands or other abnormalities and to correct them before the pathological conditions in the bowel have advanced to such a degree as to render extirpation of the cecum and colon, in Dr. Ewing's words, "justifiable, and probably the only effective means of relieving the condition." In spite of the high mortality, I have felt amply justified in creating this unique group of three hundred pathological colons removed from psychotic patients, if for no other reason than to prove that something must be done for the relief of this type of the mentally afflicted before the bowel is irreparably damaged. This should and can be done before the patient is committed, for the pre-psychotic symptoms are usually well defined. I believe that no one has contributed more sound and practical data upon this problem of prevention than Alfred S. Taylor. His work upon intra-abdominal adhesions is, and will remain, a classic.

During the past six months I have had immeasurable help and encouragement from Dr. John W. Churchman, who has taken charge of the laboratory. Not only has he inaugurated studies upon the permeability of the diseased colon and upon the practicability of using the dyes with which his name is so closely associated, but he has made a surgical analysis of the results of the last 164 colectomies, particularly in relation to mortality. It is encouraging to have the active co-operation of so highly trained and versatile a surgeon, because it gives much added confidence and certainty to this experimental surgical research. Dr. Churchman's tables will be published at a later date, but briefly they place the operative mortality at thirty-one per cent. This can undoubtedly be lowered by a further systematic study of the cause of death, but the operation will always remain a formidable one. Aside from proving a very direct relationship be-

tween the mental symptoms and the diseased bowel, the most important outcome of these studies today is that a pre-psychotic diagnosis must be made, and such preventive treatment be instituted as will save the colon from degenerating to such a degree as to necessitate colectomy. There is no *problem in medicine more pressing* than that which relates to the causation and treatment of the so-called functional psychoses. If we can take the age-old mystery out of insanity and place it upon the same practical footing as other bodily diseases, taking the good from each school, it will result in saving millions of dollars to the state and untold human suffering.

### A NEW SYSTEM OF DIETETICS IN THE LIGHT OF EUROPEAN EXPERIENCE WITH THE PROBLEM OF NUTRITION.\*

By SAMUEL NEWMAN, M. D., Danville, Va.

Late Volunteer Physician, Children's Clinic, University of Vienna.

During the recent war, and the years following it, the problems of nutrition occupied a very prominent place in the minds of the European peoples. Germany, because of the effective blockade against her, was particularly concerned with the problem of nutrition from every angle. It is to be expected that just as in surgery some great lessons have been taught by the war, some lessons should also

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia, in Roanoke, October 16-19, 1923.

have been taught by it in the field of nutrition. We would naturally expect to find in the German literature a summation of all our present knowledge of nutrition and practical methods for the rational feeding of large groups of people as well as individuals, as a consequence of the war and post-war experience.

Time will not permit me to bring this vast subject of nutrition even under a cursory review. I shall confine myself to a brief consideration of a few of the principles underlying a system of nutrition which was put into practice on a very extensive scale, and which I had an opportunity to study in Eastern and Central Europe as member of a Medical Commission and as a student at the Children's Clinic of the University of Vienna.

#### ENERGY REQUIREMENT.

Rubner<sup>1</sup> laid down the thesis that basal metabolism stands in relationship to body surface—not to body weight. The validity of this thesis has been recently reaffirmed by Lusk<sup>2</sup> on the basis of careful work. Rubner used the Meeh-Vierordt formula for the calculation of body surface. In this country the formula of DuBois is used, for which greater accuracy is claimed. However, in practice, because the use of formulae or charts is necessary, determinations of energy requirements are not made on the basis of surface area.

In 1914 Professor Pirquet, at the University of Vienna, began to work out a system of nutrition having as its basis quite different considerations from those enunciated by Rubner, yet incorporating his thesis that energy requirement is proportional to body surface. Pirquet discovered that in normal individuals there is a relationship between the sitting height, expressed in centimeters, to the body weight, expressed in grams. The sitting height—distance from top of head to sitting level—raised to the third power approximates ten times the body weight. Expressed in mathematical formulae, we obtain the following values:

$$Si^3 = 10 bw$$

$$Si = \sqrt[3]{10 bw} = 10 bw^{-\frac{1}{3}}$$

$$Si^2 = \left(\sqrt[3]{10 bw}\right)^2 = 10 bw^{\frac{2}{3}}$$

In the understanding of this last formula lies the core of the theory of basal energy re-

quirement. The body surface is a function of two-thirds power of its volume. A simple example will make this clear. An infant weighing seven pounds will have a basal requirement of about 200 calories per day. The question now arises, will the basal requirement of an adult weighing 140 pounds, be 20x200, or 4000 calories? Our answer is no. Why? Because body surface is not increased by simple proportion to body weight. The increase in surface of bodies of similar density is a function of the two-thirds power of their volume.

By using Pirquet's formula the basal requirement of an individual can be obtained in terms of calories, as shown by Faber<sup>3</sup>, by multiplying the square of the sitting height with 0.2 of a calory, or:

$$Si^2 \times 0.2 \text{ cal.} = \text{Basal metabolism.}$$

A person with a sitting height of 90 cms. will, therefore, have a basal requirement of  $0.2 \times 90 \times 90 = 1600$  calories. The validity of this formula is established by the fact, as Faber has shown, that nearly the same values are obtained by it per meter of surface area as those of Rubner by using the Meeh-Vierordt formula.

In practice we are concerned with more than the energy requirement sufficient to cover basal metabolism. In prescribing a diet we must also provide for growth, in case of a child, and occasionally, for fat accumulation. All these values are obtained in the Pirquet system of nutrition by simple relationships to the sitting height of the individual in question. In order to be able to work with Pirquet's method, we shall have to acquaint ourselves with a new unit of nutrition which Pirquet has introduced. This unit is the value of 1 c.c. of milk of standard composition, and to which Pirquet has given the name *Nem* (Nutritionis elementum).

#### BIOLOGICAL VERSUS CHEMICAL VALUE OF FOODS.

In the last century, the consideration of, and the approach to, all problems of nutrition were in the light of chemistry. A great deal of valuable work has been done on the chemical analysis of foods, the work of Atwater in this country being particularly noteworthy. Soon after 1900, Fischer revealed the great variation in the composition of proteins from different sources, thereby introducing the idea of *quality* in nutrition.

The epoch making researches of Funk, McCollum and others have taught us the importance of the biological analysis of food stuffs. The splendid work on the deficiency diseases and vitamins is the result of the biological method of food analysis. The chemical analysis of a food no longer gives us a clue as to its adequacy. A food may be chemically right yet biologically wrong. McCollum rightly maintains that the practice of regarding calories as the factor of prime importance in the planning of the diet is inadequate.

The calory is a physical and chemical conception; it is expressive of the chemical era in nutrition and of the notion that heat production is the chief manifestation of life, instead of to regard heat as the by-product of vital functions, such as food intake, growth and reproduction. In place of the calory, Pirquet proposes a concrete unit which even the laity can readily visualize and with which every other food should be compared by the biologic method, a procedure now carried out in testing the adequacy of a diet with regard to the quality of protein or vitamin content.

Pirquet adopted 1 c.c. of milk (of standard composition), as the unit of nutrition. Milk, of all other foods, is physiologically best adopted to our digestive apparatus; it contains all food elements; the quality of its proteins is high; and provides for growth during the most active period of life. Milk is the most perfect physiological food. With the addition of small traces of iron, McCollum<sup>4</sup> was able to maintain an omnivorous animal in a condition of normal growth and reproduction.

As a method of comparing the nutritional value of other foods with that of milk, Pirquet suggests the physiological method of substitution, instead of the chemical method of determining food values by the amount of heat they will yield by complete oxidation in the calorimeter. For example, a normal infant fed on milk would be given the food to be tested in place of a certain quantity of milk. If the infant will grow on this food, its nutritional value as compared with milk can readily be obtained.

Pirquet has thus opened up a new field of investigation in the field of nutrition. It must be admitted, however, that Pirquet and his school did not follow their own lead. His milk-unit (nem) values of food have not been worked out on the basis of physiological substitution, but were simply obtained from the

best established caloric values. Yet Pirquet's unit, the nem, is something concrete and replaces, at least for practical dietetics, the somewhat indefinite and abstract conception of the calory concerning which there arises no little confusion even among medical men. In the first place, not all of us remember, when we speak of calories, which one is meant; the large or small calory. In the second place, to speak of nutritional needs in term of calories, especially to a lay public, is like speaking of colors in terms of wave length. The fuel value of food is defined by Atwater and Kent<sup>5</sup> in the following terms:

"By fuel value is meant the number of calories of heat equivalent to the energy which is assumed the body would be able to obtain from a pound of a given material, provided the nutrients of the latter were completely digested."

Besides this definition of Atwater and Kent, I shall place the Pirquet definition of *food* value, rendered into English.

"By *food* value is meant the number of milk units contained in a given food as compared with an equal weight of milk."

We thus see that in the Pirquet system of nutrition we do not go out of our element in order to seek for a definition of food value. We drop the caloric term *fuel* value, and substitute for it *food* value in its broadest physiologic significance. We shall next consider another point in the Pirquet system of nutrition, the question of the minimum protein requirement in our daily diet.

#### PROTEIN MINIMUM.

The optimum protein requirement of man in his daily diet has been a subject of considerable controversy. As it is well known, nitrogen or protein equilibrium may be maintained on different amounts of protein food. An excess of protein is not stored in the body but is used as an energy food. Chittenden<sup>6</sup> has been the chief advocate of a low protein diet. The Swedish physiologist, Hindhede, has performed a remarkable series of practical experiments whereby he demonstrated that people may be maintained on a high level of efficiency during long periods of time on a diet made up chiefly of potatoes, which is poor in proteins. The daily protein intake of Hindhede and his associates was about 39 grams.

In times of war the question of protein in-

take is more than of mere theoretical interest. Proteins are the most expensive foods and, for the sake of economy, it becomes necessary to spare them as much as possible. The function of proteins should be limited to the rebuilding or renewal of wasted tissues in the body and not made to supply heat or energy, as it happens when an excess of it is taken. Schick<sup>7</sup> well said that it is as rational to use the expensive animal proteins for the purpose of supplying body heat as it would be to use window frames, doors, and piano wood for the purpose of heating our stoves. Yet, on the other hand, it is important not to go below the protein minimum. Without sufficient proteins in our food to cover tissue waste and body growth, in children, national efficiency will soon be undermined.

The question of protein minimum is very important also from the clinical standpoint. Clinicians believe that the consumption of proteins above the optimum is not only an unnecessary luxury but also a harmful habit. The excess of protein is a harmful load on the kidney. The caloric value of 1 gram of protein in the calorimeter is 5.7 large calories. The oxidizable value of protein in the human body is about 4 calories. The non-oxidizable part of the protein molecule must then be excreted by the kidneys. A B. Macallum<sup>8</sup>, in discussing recently the question of the intestinal mucosa as a portal to disease, calls our attention to the possible effect of proteins on another organ than the kidneys. Macallum makes the following significant remarks:

"It is probable that excess in diet, especially in its protein constituents, may task the capacities of the epithelial cells and diminish their power to react normally, with the result that they allow to pass through them, and to the underlying tissues and the circulation, the products of intestinal putrefaction, which in their healthy vigorous condition they do not permit to enter them. This would explain some of the pathological results of a high protein diet."

A. B. Macallum, then, takes for granted the injurious effect of a high protein diet from a bacteriological standpoint. In accordance with the older theory that the intestinal lining is synthesizing the amino acids which were formed in the process of digestion into body proteins, it is readily understood how an ex-

cess of proteins in the foods will overwork and exhaust the intestinal cells.

In the Pirquet system of nutrition the protein minimum is taken to equal ten per cent of the total caloric value per day. An adult with a caloric requirement of 3,000 would need 300 calories in proteins, or 75 grams of proteins. Pirquet does not state the protein requirement in absolute figures. He only says that whatever quantity of food one consumes the protein minimum should be ten per cent of the total caloric value. This idea seems very reasonable, since, as we know, the utilization of body proteins will vary with the amount of total food taken. If larger quantities of food are consumed, more secretions will be necessary and a proportionate larger tissue waste will result. The basis for the protein minimum in Pirquet's system of nutrition is human milk. Standard human milk has 1.7 per cent protein. One gram of protein yields 4 calories, or 6 nems. One hundred c.c. of milk will therefore have 10 nems in protein value.

Time will not permit me to discuss one more point in the Pirquet system of nutrition, that of food concentration. By food concentration is meant the relation of food value to weight, or  $\frac{\text{food value}}{\text{weight}}$ . Internists and pediatricians are fully aware of the importance for the clinic of the subject of food concentration. As much as the subject of food concentration is of extreme importance in dieto-therapy it never rested upon a rational system. For instance, when one reads about thick cereal feeding in cases of pylorospasm he is never sure of the caloric value of the cereal per unit of volume or weight. Pirquet introduced system into this subject by adopting a logical standard of food concentration. Any food which contains 1,000 nems (milk units) in one liter of volume, or kilo of mass, is called *equal* food. This means it is equal in concentration with the natural food, milk, which also has 1,000 nems in a volume of one liter. I will not dwell longer on this point, yet I have shown how Pirquet standardizes and rationalizes the whole subject of dietetics.

I shall now summarize the main points in this paper and will demonstrate the actual working of this system of nutrition from my own cases. This system is not diet-kitchen play but daily life through many years in the great Children's Clinic of the University of Vienna.

The feeding program of hundreds of thousands of children in Europe was carried out in accordance with this system, and with most magnificent results. Personally, I had experience with this system for more than two years and with most gratifying results.

#### SUMMARY.

1. One c.c. of milk is the unit of nutrition. This is called *nem* and is equal to  $2/3$  of a calory.

2. The nutritional requirement of every individual can be obtained from his sitting height.

3. Minimum, optimum, and maximum requirements can easily be obtained in terms of milk units by simple relationships to the square of the sitting height.

4. The relationships of food value to food weight are standardized and designated by a logical terminology.

5. This system of nutrition is the basis of the Vienna pediatric school and enjoyed a trial and successful application on the most extensive scale.

#### ILLUSTRATIVE CASES.

CASE 1.—W. M., boy, nineteen weeks old. Full term, forceps case. Birth weight: 8.75 pounds. Artificially fed since second week. Present weight: 7 pounds, 10 ounces. Per cent underweight: 45. Diagnosis: Athrepsia; decomposition; and capillary bronchitis.

Treatment: The sitting height of the baby is 35. 0.3 of the sitting height squared (3den. siqua) is the minimum food requirement of the child. It was started with this minimum. The baby retained the food. On the following day I added 2den. siqua; that is 5den. siqua have been given ( $35 \times 35 \times 0.5 = 600$  nems—or 6 hectonems). The food concentration was that of whole milk. The food was gradually increased, taking the maximum ( $35 \times 35n$ ) after two weeks of treatment. Together with the increased nem, or caloric, intake the concentration of the food has also been increased; that is, more calories and lesser volume. In five weeks the child gained 5 pounds and 3 ounces, the percentage of underweight being only 14. Throughout these five weeks the protein intake did not exceed 10 per cent. A normal child should have gained during the same period at the same age 24 ounces. Our patient gained

83 ounces. This atrophic infant has manifested a "living potential" of  $3.45 \times 24$ .

CASE 2.—F. A., boy, thirty-one weeks old. Premature, forceps delivery. Birth weight: 5 pounds. Artificially fed since birth. Present weight: 7 pounds, 10 ounces. Percentage of underweight: 43.5. Diagnosis: Athrepsia and acute intestinal intoxication.

Treatment: Sitting height of infant is 36. The first day only the minimum was given. On the following day 5den. siqua ( $36 \times 36 \times 0.5$ ) were given. At the end of the second week the food intake had been increased to 8.5den. siqua. The food concentration was  $3/2$ ; that is 1,000 calories (1,500n) are contained in one liter (1 and  $1/2$  times the concentration of milk). In three weeks the child gained 34 ounces (2 pounds and 2 ounces.)

The ingredients of the food formulae in both these cases consisted of whole cow's milk; Mead's Dextri-Maltose; a few grams of barley flour; and water.

CASE 3.—B. L. C., girl, six years and seven months old. Diagnosis: 20 per cent underweight due to faulty food habits. Treatment: The sitting height of the girl is 61 cms. She has been given a diet of 5den. siqua. ( $61 \times 61 \times 0.5 =$  nearly 2,000 nems). The diet was made up of special articles with the idea of assuring myself that the patient should eat in excess of the diet. From August 14th to October 2nd of this year the patient gained 10.5 pounds. The normal gain for a period of six weeks at that age is about 9 ounces. The girl therefore gained  $\frac{168 \text{ ounces}}{9} = 17.5 \times$  normal gain.

### DIARRHOEA IN INFANTS.\*

By St. GEO. T. GRINNAN, M. D., Richmond, Va.

The large mortality caused by diarrhoea in infants is an important field for preventive medicine. Many mothers have lost the first child from diarrhoeal trouble and a life was sacrificed in order to educate her to save those that came later. While there is much to be learned in the prevention and treatment of diarrhoea in infants, valuable information has been acquired. Diarrhoea is still one of the largest causes of death in infants under two years of age. The disease is largely preventable. The various departments of public health have done very valuable work in instruction of mothers, and making milk safer.

Diarrhoea in infants is the result of several causes. The classification most commonly used now is infection, fermentative and mechanical. Diarrhoea is not common in breast fed infants. In the case of breast fed infants diarrhoea is almost certainly infectious and not fermentative. Some obstetricians give an infant six per cent solution of sugar water while waiting for milk to come in the mother's breast. This is a bad habit. Plain water and not sugar water should be given. The habit of giving any purgative to a new born infant is dangerous. A purgative is often used in icterus neonatorum with only harmful results.

I know one physician who lost his first two children before he learned to remove from the breast an infant suffering from breast milk infection. In breast milk infection there is often very little diarrhoea.

Here in Virginia infectious diarrhoea begins about the middle of May and is prevalent until September. A smaller number of cases are seen in the colder months. It is a very safe plan to have all milk boiled for an infant under eighteen months of age from May 15th to September 15th. During this period anti-scorbutics can be given, and heliotherapy used, as an anti-rachitic.

Probably the most common cause of diarrhoea in infants is intestinal fermentation caused by excess of sugar. The products of fermentation irritate the intestinal mucosa but the mucous membrane is not attacked by the bacteria. (Practical Infant Feeding by Hill page 296.)

Under normal conditions the small intestine

is fairly sterile. The child can only absorb a certain amount of sugar and, when an excess is given, it passes into the intestine and ferments. Overheating of the body from hot weather or too much clothing are important causes of fermentation.

Infected milk is also a cause of sugar fermentation. The fermentation of sugar produces acids which irritate the mucosa and cause diarrhoea. Acetic acid is a common product of sugar fermentation in the intestine by bacteria. Other acids such as formic and butyric are also formed. Acetic acid is very irritating and the mucosa is injured, this injury reduces the anti-bacterial function, permitting harmful bacteria to pass into the circulation. It will be remembered that acetic acid is used to remove warts and corns.

There are various degrees of this condition; season may or may not be a factor.

In mild cases omission or reduction of sugar will cure the case. A purgative is not necessary. If the case has fever and there is no diarrhoea, a purgative is necessary. No food is given but barley gruel for twelve or twenty-four hours. One grain of saccharin to the pint of barley gruel will make it palatable. Sugar should be omitted for one day and sometimes longer, rarely over three days.

For the past six or seven years I have used protein milk in fermentation cases of diarrhoea. The high protein tends to make the intestine alkaline. Two purposes are thus obtained, the intestine is rendered alkaline or the acidity reduced, and the alkali reserve of the body which has been heavily drawn upon is restored. Thus acidosis which is usually present is checked and the irritating acid in the intestine neutralized. Protein milk can be used with breast milk, with barley gruel or skimmed milk. Finkelstein's formula was made with lactic acid milk. Some pediatricians have adopted the lactic acid milk and use little protein milk in the lactic acid milk. Protein milk can be bought on the market and it is quite easily made at home. A very serviceable preparation can be made in two hours. I have had it made in the homes of rich and poor, and in hospitals, for years. It is prepared as follows: Three junket tablets or three teaspoonfuls of essence of pepsin are added to one quart of milk; keep at a temperature of 100° F. for 30 minutes; break up the clot and strain in cheese cloth or fine wire sieve.

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia, in Roanoke, October 16-19, 1923

It is best to let it strain for an hour and safer to let it strain in a refrigerator. The curd is rubbed through the sieve several times in order to insure fine division of the casein. This casein powder can be used in barley gruel or skimmed milk; it is more commonly used in fat free lactic acid milk. The amount of protein milk or casein obtained from one quart is 5 or 6 ounces. To this is added one pint of fat free lactic acid milk and enough water to make one quart. This will give low sugar 1.5 per cent, high protein 3.5 per cent, fat 2.5 per cent.

Unless some sugar is used acidosis may result. For the first day of treatment, saccharine may be used to make the protein palatable, the second day enough sugar to make a 3 per cent sugar, gradually increasing to 6 per cent. As the case improves, protein milk is not needed longer than one week or ten days.

Lactic acid milk suits a large number of these cases. If lactic milk cannot be obtained, skimmed milk can be used. It is worth while making the lactic acid milk as it is superior to any other milk product in the gas bacillus cases. It is made in twenty-four hours by inoculation with lactic acid bacillus. The milk should be previously boiled to kill other bacteria. Marriott, of St. Louis, has had marked success with lactic acid milk and Karo syrup.

Colonic irrigation is used in many cases more than is desirable. One irrigation may be used early in the disease but rarely later in the disease.

Owing to great loss of fluid in diarrhoea, water has to be given in large amounts. In many cases of extreme dehydration, intraperitoneal saline solution is a valuable means of restoring fluid. Physiologic saline solution is used at a temperature of 100° F. One teaspoonful of salt to one pint of water gives the normal solution; 100 to 300 c.c. can be given at a time, according to the size of the baby. It can be repeated in twelve or twenty-four hours. Rarely is it necessary to give more than three injections. As an alkali, precipitated chalk is more valuable than the soluble soda which is largely absorbed in the stomach. I rarely use either bismuth or opium in diarrhoea.

Infectious diarrhoea presents a different problem. Here we have protein putrefaction which is more dangerous than sugar fermentation. The dysentery bacillus is the usual cause though other bacteria are found. Un-

clean milk is the common cause. Failure to wash the breast before and after nursing is a cause in cases occurring while breast fed.

Infectious diarrhoea can be started by fermentative diarrhoea. This disease is infectious and can be transferred by soiled napkins, "fingers, food and flies."

The stools are usually alkaline and are not especially offensive in odor. Blood is common in the stools of infectious diarrhoea, while more pus is seen than in fermentative diarrhoea. The treatment of this form of diarrhoea is different from the diarrhoea caused by infections. An initial purgative is usually required. This should be a smooth purgative such as castor oil. It is rare to have to repeat the purgative. Constant purgation is not safe. One dose of castor oil will often produce blood seen by microscope, and calomel will produce mucus and blood in the stool of a healthy child.

All food is to be withdrawn for twelve or eighteen hours. Water is given every hour. After the starvation, an eight per cent sugar solution in barley gruel is given for one or two days. Dextri-Maltose is a good sugar to use. Milk is then given in diluted form. Skimmed milk or fat free lactic acid milk is used, the protein and fat kept low. Barley gruel is a good diluent, beginning with 1/3 or 1/4 milk.

The gas bacillus type of infection presents a problem of feeding different from the infectious type. In this type the treatment is more like the treatment of fermentative diarrhoea; a low sugar and high protein is used. The gas bacillus will thrive on a high sugar but does not thrive on protein. The lactic acid milk is excellent for gas bacillus diarrhoea cases. In this class the protein lactic acid milk excels. Saccharine can be used for the first one or two days, then lactose not over 4 per cent, gradually increasing as the patient improves. During the first day of starvation a simple test will determine whether the case is infectious or gas bacillus. If a small quantity of milk is boiled and put into a glass tube with some of the bowel movement, the milk will coagulate and have holes in it like cheese and smell rancid. For vomiting I have found stomach washing with a solution of bicarbonate of soda superior to any other treatment. Mechanical diarrhoea is usually in the older child and is due to eating heavy coarse food, especially fruit. Vomiting is usually severe.

Purgation is necessary; no food except water should be given. If acidosis occurs from excessive vomiting, soda bicarbonate can be given by bowel, 6 per cent solution, a pinch of starch being used to prevent irritation. Lactose solution can soon be given in these cases.

I have tried to point out the necessity of classifying diarrhoea in infants as the treatment depends entirely on the cause of the diarrhoea.

#### DISCUSSION.

DR. SAMUEL NEWMAN, Danville, Va.: I wish to ask if Dr. Grinnan uses seventeen per cent (17%) sugar solution with new-born babies, as Schick recommends, to prevent loss of weight.

DR. GRINNAN, closing: Fifteen per cent is often used in cases of dehydrated children; three times the caloric value is sometimes essential.

925 West Grace Street.

### THE USE OF GLUCOSE PER RECTUM IN THE FIRST STAGE OF LABOR.\*

By M. PIERCE RUCKER, M. D., Richmond, Va.

Glucose therapy has recently had a prominent place in the treatment of eclampsia and the toxemias of pregnancy. Titus<sup>1</sup> has shown that the liver cells are quickly depleted of glycogen in toxemia and that a depleted liver cell is inactive so far as its detoxicating function is concerned. This is in accord with the previous experimental work of Opie,<sup>2</sup> Whipple<sup>3</sup> and others, upon animals. The St. Louis investigators used phosphorus and chloroform as poisons and rats as laboratory animals. The California workers used chloroform and dogs. It was found that a carbohydrate diet not only had a marked effect in protecting the liver against the toxic effect of the drugs, but also hastened the repair of the liver necrosis in a very remarkable manner. We know that, whatever the nature and origin of the toxin or toxins of eclampsia may be, the action upon the liver is the same as that of chloroform. Titus' work would indicate that glucose has the same power of protection against the action of the toxins of pregnancy as it does in the case of chloroform poisoning. He recommends either intravenous, rectal, or oral administration, according to the severity and the acuteness of the toxemia.

Following Titus' work, I have used glucose as he suggested, in a number of toxic cases at or near term, in which induction of labor

was deemed advisable. I was impressed with the shortness of the first stage of labor as compared with previous similar cases in which glucose was not used. I therefore extended the use of proctoclysis with glucose solution to my non-toxic cases with gratifying results. The first stage was greatly shortened and the patients finished their labors strong and refreshed. This was especially noticeable in several patients seen in consultation, who had become worn out by a long tedious dilating stage.

Impressions, however, are very poor material for a medical paper. In order to have something to back up my impressions, and to be able to give you some tangible facts, I have gone over all my normal cases in which I have induced labor with bags and used glucose per rectum. The use of bags at term gives a more uniform result, especially in regard to the length of the dilating stage, than is the case with spontaneous labor. Both precipitous and long tedious labors are eliminated. In the language of the statistician, the coefficient of deviation is smaller. In a previous paper<sup>4</sup> before this society, I presented my results with bags and version at term. At that time, I found the average duration of labor, estimated from the time the bag was placed until the expulsion of the afterbirth, to be 13.68 hours for primiparas and 7.88 hours for multiparas. In the present series, the cases were handled in the same manner except that the patients were given a proctoclysis with five per cent glucose solution as soon as the bag was placed and the proctoclysis was kept up until the dilatation of the cervix was complete. Nothing was given by mouth during this time. The amount of hyoscin used was approximately the same in the two series. Usually, as in the former series, the bag was weighted until the patient began to have pains. However in a number of cases, especially in the multiparas, the dilatation was so rapid, that there was danger of having the delivery too close to the initial dose of morphin. In many of these cases where the softness of the cervix led me to believe that the dilatation would be rapid, the weighting of the bag was left off entirely.

I have used glucose in this manner with bags and version at term in fifty-four non-toxic cases. There were twenty-seven primiparas and twenty-seven multiparas. One of the multiparas had a funnel pelvis and her previous

\*Read at fifty-fourth annual meeting of Medical Society of Virginia, in Roanoke, October 16-19, 1923.

labor was unusually long and tedious on account of inefficient uterine contractions. Another was so nervous and rebellious that she got practically no glucose. Her labor lasted 11 hours and 55 minutes. Two of the primiparas belonged to the funnel pelvis class, and their labors lasted just the same time, i. e. 15 hours and 15 minutes. The average duration for the primiparas was 7 hours and 52 minutes, the extremes being 3 hours and 30 minutes and 15 hours and 15 minutes. The average duration for the multiparas was 6 hours and 18 minutes, the extremes being 2 hours and 20 minutes and 12 hours and 15 minutes (the funnel pelvis case).

If the patient is in a hospital, the glucose is administered in a five per cent solution by the drop method. If I have not the facilities of a hospital, I vary the technic somewhat. When glucose is not at hand, a satisfactory solution can be made by dissolving a teaspoonful of Karo syrup in a pint of hot water. A gill of this can be given per rectum every hour, the patient being instructed to retain it.

#### MODE OF ACTION

To what are we to ascribe these very definite clinical results? At first I was of the opinion that the action of moisture and heat upon the uterus, causing the cervix to relax and the fundus to contract more vigorously, was the chief factor. Murray<sup>5</sup> as far back as 1886 demonstrated that both heat (115° F.) and cold (60° F.) had a marked and immediate effect on the uterus, causing it to contract vigorously. The beneficial effect of hot enemas upon a lagging uterus has long been a common clinical observation. Recently there has appeared a very interesting book upon obstetric physiology by Vignes.<sup>6</sup> This author classifies sugar as an oxytocic. He is of the opinion that its ecobolic action is seen only after labor is well advanced and intimates that it is due to its energy supplying effect. Bossi<sup>7</sup> in 1893 described the ecobolic action of sugar in cases of inertia, and reported eleven cases. He used 30 grams of glucose in 200 c.c. of water.

It would be interesting to determine just how much benefit is due to heat, how much to fluid, and how much to the glucose. Perhaps at some future time I will be able to properly evaluate these three factors. At this time, however, I am presenting a practical paper

and such theoretical considerations do not now concern us. The practical point is that, in the administration of glucose per rectum, we have a means of shortening the first stage of labor and of supplying the patient with much needed energy.

### CHRONIC OCCLUSION OF THE DUODENUM IN VISCEROPTOSIS; BASED ON A STUDY OF TWENTY-EIGHT CASES.\*

By DOUGLAS VANDERHOOF, M. D.,  
and  
T. DEWEY DAVIS, M. D.,  
Richmond, Va.

The possibility of chronic obstruction to the duodenum where it is crossed by the root of the mesentery has been recognized for many years. Glenard,<sup>1</sup> in 1889, and Kundrat,<sup>2</sup> in 1891, called attention to the fact that persistent, partial constriction of the duodenum at

\*Read before the fifty-fourth annual meeting of the Medical Society of Virginia, in Roanoke, October 16-19, 1923.

this point was not an infrequent occurrence. In 1907, Conner<sup>3</sup> suggested this obstruction as an etiological factor in acute dilatation of the stomach. VanderHoof,<sup>4</sup> in 1917, reviewed the literature on the subject of dilated duodenum secondary to chronic arteriomesenteric occlusion and reported six typical cases. Since that time articles and case reports dealing with this condition have been published by a number of observers, among them Crouse<sup>5</sup> and E. L. and W. A. Kellogg<sup>6,7</sup> in this country, and Hartmann,<sup>8</sup> Romme,<sup>9</sup> Ranzel<sup>10</sup> and Hurst<sup>11</sup> in the foreign literature. Chronic occlusion of the duodenum has become recognized as a clinical entity and its treatment has been placed on a sound anatomical and physiological basis.

The duodenum is normally slightly constricted where it is crossed by the root of the mesentery and its accompanying vessels. This was shown by Albrecht,<sup>12</sup> in the cadaver, and has since been confirmed by a number of investigators. The aorta and vertebral column just posterior to this point form an unyielding surface which acts like one lever of a nut-cracker. Anteriorly, the firm mesenteric vessels supply the other lever. Between these jaws passes the soft, compressible duodenum. It is obvious that any unprotected downward drag on the mesentery and its contained vessels will tend to close these levers. This is exactly what happens in the viscerototic patient. But if there are deposits of fat in the mesentery and behind the parietal peritoneum, these bear the brunt of the pressure, and the closure of the jaws will be prevented. However, in the thin individual, these pads are lacking, leaving nothing to prevent the duodenum from being compressed. In addition, if the posterior lever of the nut-cracker is thrown forward, as is the case in increased lordosis of the lumbar spine, the chances of obstruction are necessarily much increased. This fact was brought out by Schnitzler,<sup>13</sup> and further emphasized by VanderHoof, one of whose patients showed the condition to a marked degree. The latter also called attention to the fact that in extreme visceroptosis where the intestinal coils rest on the pelvic floor there is less chance of dragging on the mesentery with its accompanying duodenal compression.

Bloodgood<sup>14</sup> and Jordan<sup>15</sup> suggested that in ileal stasis and constipation the increased weight of the terminal ileum and proximal

colon tends to enhance the downward pull. The Kelloggs<sup>7</sup> advance this theory as the explanation of certain so-called bilious attacks in which the patient complains of severe constipation with nausea and the vomiting of bile, relieved by a laxative.

Another etiological factor in the condition is the perpendicular course of the jejunum in visceroptosis rather than the normal outward curve into the left renal fossa (Crouse<sup>5</sup>). This would increase the duodeno-jejunal angle, making the obstruction more complete.

Since VanderHoof's article appeared in 1917, twenty-two additional cases of dilated duodenum have come under our observation, and the whole series of twenty-eight cases of chronic duodenal occlusion has been studied with regard to the symptomatology and diagnosis of this affection. The result of treatment has been followed in a number of these patients with striking relief of troublesome, often serious, symptoms.

The clinical features of chronic duodenal occlusion are conveniently grouped under the following heads:

1. **VOMITING.** Persistent, or recurring vomiting is present in the majority of cases. This is generally associated with nausea, but in other cases there is simple regurgitation of food or actual rumination. Owing to the fact that the duodenal obstruction is infrapapillary, that is, below the entrance of the common bile duct, the vomited material is often tinged with bile. The regurgitation or the vomiting begins very soon after the meal is eaten. It is differentiated from the vomiting due to occlusion at the cardiac or pyloric ends of the stomach by the fact that in cardiospasm there is apt to be a definite difficulty in swallowing, while in pylorospasm vomiting is most apt to occur at the height of digestion, two to four hours after the meal.

Persistent vomiting may result in acidosis and death of the patient. Finney<sup>16</sup> and Bloodgood<sup>14</sup> have each reported fatal cases of dilated duodenum with a patent condition of the pylorus, and one of VanderHoof's early cases came to necropsy with typical arteriomesenteric occlusion and greatly dilated duodenum.

In other instances, rather frequent vomiting may occur without giving rise to any serious results over a period of some months. Under such circumstances the condition is often misinterpreted and thought to be a functional dis-

turbance or a neurosis. Many such cases of supposed "hysterical vomiting" have been completely relieved by rest-cures and forced feeding by physicians who attributed the splendid results to psychotherapy, and who failed to recognize the relief of the mechanical obstruction brought about by the posture and the increase of body fat.

2. PAIN. Epigastric distress or pain is a common complaint, and is often associated with flatulence and a sense of fulness. It is often described as an aching or dragging pain. In quite a few instances, however, the pain may be acute and referred to the lower right costal border. In such instances the condition is often mistaken for gall-bladder disease. Occasionally the pain simulates that occurring in peptic ulcer. It has been stated by a few authors that chronic duodenal obstruction favors the occurrence of duodenal ulcer. This complication did appear in one of our twenty-eight cases.

3. CONSTIPATION. Obstinate constipation occurs in the majority of cases, while in a few instances the bowels are entirely regular. The stools show nothing abnormal.

4. UNDERNUTRITION. Patients with chronic duodenal obstruction are always below weight for their height. Many of them have lost weight, others have always been thin. The "habitus enteroptoticus" is indelibly stamped upon these cases, and this may be associated with exaggerated lordosis of the lumbar spine.

5. SEX AND AGE. The majority of cases occur in young women. In our twenty-eight cases there were twenty females and eight males. The youngest patient was a girl of 15 years, the oldest patient was a woman of 62 years. Sixteen of our cases were between the ages of 15 and 35 when they came under observation. It should be noted, however, that the condition is essentially chronic and in many instances the symptoms date back over a period of several years.

6. GENERAL SYMPTOMS. Vague toxic symptoms are very common. The patients generally complain of weakness and exhibit signs of an unstable nervous make-up. Headache is frequent.

Physical examination in these cases reveals but little. The thin, visceroptotic type of individual with an acute costal angle and relaxed abdominal walls is observed. Occasionally there is some tenderness in the epigastrium, and

at times a sense of resistance is felt above and to the right of the umbilicus.

Careful gastro-intestinal X-ray studies with good technique and vigorous manipulation in the attempt to completely fill the dilated duodenum confirms the diagnosis in practically every case. Occasionally a very extraordinary fluoroscopic appearance is observed, as was described by Jordan<sup>15</sup> in one of his patients with hugely dilated duodenum. It should be remembered, however, that the condition is often periodic, and examination when the patient is free from symptoms may fail to disclose any abnormality. This point has been recently emphasized by Hurst.<sup>11</sup>

The treatment of the condition is preferably medical but, if this is unsuccessful or inadvisable, resort to surgery is indicated. The medical treatment is chiefly mechanical and directed toward opening the "levers" to which reference has been made above. Since little can be done to change the posterior lever, our attention is naturally centered on the more mobile anterior one. Could we actually reverse the normal position of the body for sometime after each meal, the compression would obviously be relieved, but this is impracticable. Therefore, we resort to a modification of this posture.

In the beginning, until the patient falls into the routine, hospital treatment is advisable. The first essential is bed rest and the value of the prone posture is further enhanced by elevating the foot of the bed eight to twelve inches, and by instructing the patient to lie on his face as much of the time as possible. One hour after each meal the patient assumes the knee-chest posture for a period of twenty minutes. Immediately after this the patient goes through a set of two exercises. The patient lies flat on his back and comes to the sitting posture without the aid of the arms an increasing number of times. Alternating with this he raises the legs up to a right angle with the prone body. These exercises are gradually increased in number until each is done fifty times after each meal. In addition, the patient receives daily general massage with special attention to the abdominal muscles.

A vigorous attempt should be made to control the constipation which has been shown to be a possible etiological factor. Strong purgatives should be avoided as they only increase the difficulty in the end. The intelligent use of bran and mineral oil with plenty of water,

drinking a pint of water before breakfast and between meals, will usually prove efficacious.

At the same time every effort should be made to increase the deposit of mesenteric fat, else little will be accomplished. A general diet is given of good nutritious food especially rich in fats and carbohydrates. In addition, nourishment between meals and at bedtime is ordered. If the appetite is not satisfactory, simple tonics may be prescribed. For some months after the period of active treatment it is best that the patient sleep with the foot of the bed elevated, lie down one hour after meals, and continue the forced feeding.

The postural treatment of arteriomesenteric occlusion of the duodenum, with exercises and massage to strengthen the abdominal walls, supplemented by forced feeding and increase of body weight, will bring about complete relief of the condition in the vast majority of cases. So satisfactory have been our results that we look upon the above procedure as a therapeutic test and, if the response to medical treatment is not prompt and progressive, we are apt to feel that we are not dealing with an uncomplicated instance of this affection. In an occasional case, however, after the attempt at medical treatment has failed, surgical relief may be indicated. It should be recognized that gastro-enterostomy does not relieve these patients. The operation of duodeno-jejunosomy was first done for this condition by Stavely,<sup>17</sup> in 1910, with complete success, and similarly good results from this procedure have been since reported by the Kelloggs.<sup>7</sup>

#### CONCLUSIONS.

Duodenal occlusion from compression of the third portion of the duodenum by the mesentery and its contained vessels is a definite clinical entity.

This condition is not infrequent in instances of visceroptosis, owing to increased drag on the mesentery.

Arteriomesenteric occlusion of the duodenum brings about a dilatation of the duodenum proximal to the compressed point, and is followed by a train of characteristic symptoms, the most prominent being persistent or recurring vomiting and epigastric pain.

The probability of chronic duodenal occlusion should be suspected in every thin, visceroptotic individual complaining of chronic "indigestion" with nausea and vomiting. The

diagnosis is confirmed by competent X-ray examination after a barium meal, with appreciation of the fact that the degree of occlusion and dilatation of the duodenum may vary in the same individual at different times.

Postural treatment with increase of body weight (deposition of fat in the peritoneal tissues) brings about complete relief of this malady in almost all cases. In an occasional instance a properly performed duodeno-jejunosomy is indicated and is also followed by most satisfactory results.

#### METABOLIC EMBOLISM, REPORT OF A CASE.\*

By J. N. UPSHUR, M. D., Richmond, Va.

Mrs. B. age 46. Previous history: Reared in an orphan asylum, which she left at 18 years of age. No serious disease prior to fatal illness. Was attended by the writer while in the asylum. Was lost sight of for two or three years after leaving the asylum. When called to see her, she had been several months in bed, examination revealed a large abscess in the left side of the pelvis. Went to hospital for operation, but under the influence of hot douches and tampons of ichthyol and glycerine, the abscess ruptured, and she made a complete recovery. For several years she only had transient indispositions. At rare intervals had slight endometritis. Was married at twenty,

\*Read by title at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

but continued the immoral life which she had previously led. The abscess previously mentioned was from gonorrhoeal infection. With one of her paramours she continued her association up to the time of her death. For several years, he was the subject of locomotor ataxia. She was a large woman, weighing 245 lbs. She consulted the writer April 19th. She had slight menorrhagia, which was controlled after five applications of a twenty-five per cent solution of argyrol. On the morning of April 24th, at 2 A. M., she was awakened by an acute abdominal pain; the writer was called at 9 A. M. and saw her an hour later. She was lying on her back, abdomen distended, tender and tympanitic, persistent nausea, and bowels relaxed. Gave a hypodermic of morphia gr.  $\frac{1}{4}$  and atropine  $\frac{1}{150}$ . Was seen at 2 P. M. at which time pain had centered in the lower right quadrant of the abdomen and all of the cardinal symptoms of appendicitis were present. Was seen at 3 P. M. by Dr. Bryan in consultation, who agreed with the writer as to diagnosis and the immediately critical condition demanding prompt surgical interference. She was removed to Grace Hospital, and at operation the following condition found as reported by Dr. Bryan. "The leucocytes were 13,000, no urinalysis was made. The abdomen was tender and rigid throughout, particularly in the lower quadrants, temperature 103, pulse 90. General anaesthetic, ether, drop method, administered by Dr. Willis, assisted by Dr. Creekmur. We decided upon the right rectus, which was generously made on account of the large amount of subcutaneous fat. The peritoneal cavity was cautiously entered and there was an immediate flow of serous bearing flakes of lymph, almost purulent but with no odour. Those intestines presenting proved to be on evisceration the loops of the small intestine, some four or five feet above the ileocecal valve. They were intensely red, strawberry colored, with innumerable small patchial hemorrhagic spots so closely put together that the whole presented red color, and congestion extended likewise in the mesentery which was elongated, thickened and greatly edematous, almost brawny, with bluish-grayish spots here and there which would indicate a possible breaking down. The condition stopped rather abruptly at about five feet from the caput proximally and likewise only a few inches from the caput distally; the omentum had

apparently become attached to this large distended edematous loop and was violently red and inflamed, there being here and there hemorrhagic cysts, one or two of which were the size of a robin's egg each. There were likewise multiple subperitoneal fibroids over the fundus of the uterus, probably fifteen or more, none of them larger than a malaga grape and many the size of a small hazel nut. The appendix was located with considerable difficulty due to the short colonic mesentery and was found to be bound down by adhesions. It was fibrous, atrophic, hard and small and we did not attempt to remove it. Investigation of the upper abdominal cavity showed the gall bladder and liver to be normal and there were no evidences of a duodenal ulcer. The right and left kidneys were not palpated, but there was a distinct thickness and heaviness of the head of the pancreas, but I do not know that this has any particular bearing on the case. A large rubber catheter was placed in the pelvis about Douglas' cul-de-sac and twenty ounces of saline solution injected with a large syringe into the peritoneal cavity for attenuation of the peritoneal fluid and a spiral cut rubber tube bearing a strip of iodoform gauze was placed deep in the pelvis and brought out at the lower angle of the wound. Tissues were brought together in layers with catgut No. 2, silkworm gut, through the skin. Duration of the operation 50 minutes.

*Remarks:* I believe the case to be one of thrombosis of the mesenteric vessels and more pronounced evidences of the terminal stage would have been gangrene of the loop to which we above referred. It may be that our operation was of some benefit as gangrene is not always a sequel of hemorrhagic infarct. We did not consider the pathology sufficient for resection. She took up three quarts of water that night by proctoclysis, her temperature next morning was 101, her kidneys acting well and her condition more favorable than during the operation."

April 27, 1923. Her condition was so grave that a secondary operation was deemed necessary, as giving her the only chance for life. "The old silkworm gut sutures were cut and removed, tissues were easily broken through with the finger, the peritoneal cavity readily entered. There was a considerable amount of seropurulent exudate which by gravity found its way to the pelvis, also considerable plastic

lymph, organized exudate binding the intestines together. The small intestines are greatly ballooned, their walls thickened and red, no attempt was made for an extensive investigation of the peritoneal cavity and organs, and one of the large distended loops of the small intestine was brought into the wound, catgut approximating the peritoneum and deeper layers, the skin was then sewn together with silkworm gut with this large loop hanging well out from the abdomen; purse string suture was then put about the free border of the gut, puncture made, considerable gas and fluid escaping, and a large fenestrated rubber tube shoved into the proximal loop some four or five inches, purse string suture pulled together to hold the tube in place, vaseline put over the intestine and about the wound, copious dressings. It is evidently a paresis throughout, the character of the peritoneal exudate indicates a severe state of septic peritonitis, and the prognosis, of course, is most grave."

She died early the morning of April 28th.

*Remarks.*—It is very singular that, with the extensive pathologic condition in her abdomen, she had no symptom of digestive disturbance and, on the morning prior to her seizure, she was at my office and expressed herself as "feeling fine." There was never any reason in this case for a Wassermann, but her well known immoral life and the locomotor ataxia of her paramour (who has since her death also died) and conditions found at operation give strong suggestion that syphilitic infection was causative of her trouble.

In the VIRGINIA MEDICAL MONTHLY for April, 1923, Dr. Stuart McGuire reports two cases in a paper read at the fifty-third meeting of the Medical Society of Virginia. In neither of his cases was a diagnosis made prior to operation; in one of his cases seven feet, four inches of the bowel was removed, in the other case four feet, six inches; both of these cases recovered. The success in these cases is a tribute to Dr. McGuire's good surgical judgment and operative skill. In the discussion, Dr. Horsley emphasized the importance of the removal of a sufficient amount of bowel, saying that he had lost a case he thought from failure to do this. It was emphasized that agonizing abdominal pain with symptoms of shock are very significant symptoms. In the case reported in this paper, there was intense pain, temperature 103 F., but no evidence of shock.

Dr. McGuire emphasizes the fact that the mortality in these cases (92.5 per cent) should be largely reduced by early recognition and prompt operation. But the symptoms so closely resemble those of fulminant appendicitis, that a differential diagnosis is rendered difficult. The urgency of a prompt operation is emphasized in either case. At the same meeting of the State Medical Society Dr. Tankersley, of Greensboro, N. C., reported three cases. His cases occurred following operation. The first case, five days after operation for appendicitis, the second, "somewhat similar," six days after operation for appendicitis developed acute pain in the right iliac, profound shock, subnormal temperature, pulse rapid and weak, breathing fast and shallow, and died promptly. The third case developed after operation for subacute appendicitis, from which she had suffered for a year. She developed nine days after operation hiccough, rise in temperature, severe pain in abdomen, general, fecal vomiting. Twenty c.m. of intestine was resected; patient died twelve hours later. These papers referred to may be read with profit, as to discussion of pathology and treatment. Some five hundred cases have been reported, and these undoubtedly represent but a small proportion of the actual number. (James F. Mitchell, article March 1923, *Loose Leaf Medicine*, vol. V. pgs. 597-8). C. B. Parker, of Toronto, says in an article, 1922. "When considering the etiology of this condition in the main, the causes of the obstruction of the mesenteric obstruction are embolism, thrombosis, sclerosis of the arterial wall, or a combination of the two, while venous obstruction is more complicated, and occurs almost invariably as thrombosis, although retrograde embolism has been described." He also says, "that thrombosis occurs in the liver or gall bladder, or pancreas, as a result of inflammation," and then he adds, "intravascular clotting may occur apart from sepsis and is apt to occur after operations in which veins are transfixed, as for example, suturing the omentum. In addition to these more common causes, there are many others recorded, such as thrombosis commencing in strangulated hernia, ulcers of the intestine, intussusception, abscess of the mesenteric glands, breaking down carcinoma, phlebitis of the lower extremities, prostatic abscesses, cirrhosis of the liver." Parker also says, "the prognosis depends on the length of intestine implicated

as the primary consideration; the length of time since the onset, and condition of the patient are of less importance. Nine cases of spontaneous recovery, well authenticated, are on record, twenty-five cases of successful resection, one of these being his own case. Treatment should include operation as promptly as possible, delivery of the affected bowel outside the abdominal wall, shock combated by all known means, interstitial infusion of salines, warm applications to the abdomen; if intestine be markedly distended, it should be emptied. Enough intestine must be removed to insure sufficient blood supply to the remaining intestine. If the upper part of the small intestine is required, axial union is the best."

Leo Brady of Baltimore says, writing in January, 1923, "Of five hundred cases reported, there were only thirty-five recoveries." He reports fourteen cases from the Johns Hopkins Hospital records, in three of which there were no infarctions and thrombosis was only discovered on autopsy. The bibliography listed gives further discussion on this subject.

## HEART BLOCK.\*

By J. MORRISON HUTCHESON, M. D., Richmond, Virginia.

Clinical heart block was first described in 1875 by Galabin, who reported a case in which the auricle and ventricle contracted at different rates. This conclusion was drawn from auscultatory findings and tracings from the heart's apex. In 1899, His published poly-graphic curves showing the same condition and suggested that it was due to a lesion of the auriculo-ventricular bundle. Hay, in 1905, recorded finding changes in the auriculo-ventricular bundle postmortem in a case that showed block during life. Thus the condition known as heart block became associated exclusively with diseases affecting the bundle of His.

Since the advent of more exact methods of tracing the contraction impulse, our knowledge of disorders of conduction has advanced rapidly, and the term heart block must now include not only the various grades of block in the bundle, but also certain disturbances which arise elsewhere in the course of the excitation wave as it passes through the heart chambers.

—The conduction system of the heart showing in shadow diagram the approximate relation of the more recently discovered structures to familiar anatomic divisions of the heart (after Smith).

Plate 1.

It will be remembered that the contraction wave starts in the sino-auricular node, spreads through the walls of the auricle and reaches the auriculo-ventricular bundle by which it is transmitted to the ventricles. The bundle divides into two main branches which supply the right and left ventricles and these in turn subdivide and spread or arborize through the ventricular walls (Plate 1). Any interference, therefore, with the orderly passage of the impulse from its origin to its destination may be properly termed heart block. It is to be remembered, however, that the whole conduction system is under the influence of the vagus

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

and that vagal stimulation may at times cause varieties of block which closely resemble those produced by the structural changes of disease.

By special methods of investigation several varieties of block may be readily recognized, and these have been classified according to the location in the conduction system at which they occur. Thus we may distinguish sino-auricular block of varying degree due to poor

small branches of the arborization system. The last two types are included under the term intra-ventricular block. Experimentally, these disorders may be produced in healthy hearts by injury to the conduction pathways at certain points and at times by stimulation of the vagus. Heart disease, however, rarely attacks isolated areas, so, when defective conduction is found in the human subject, it is usually

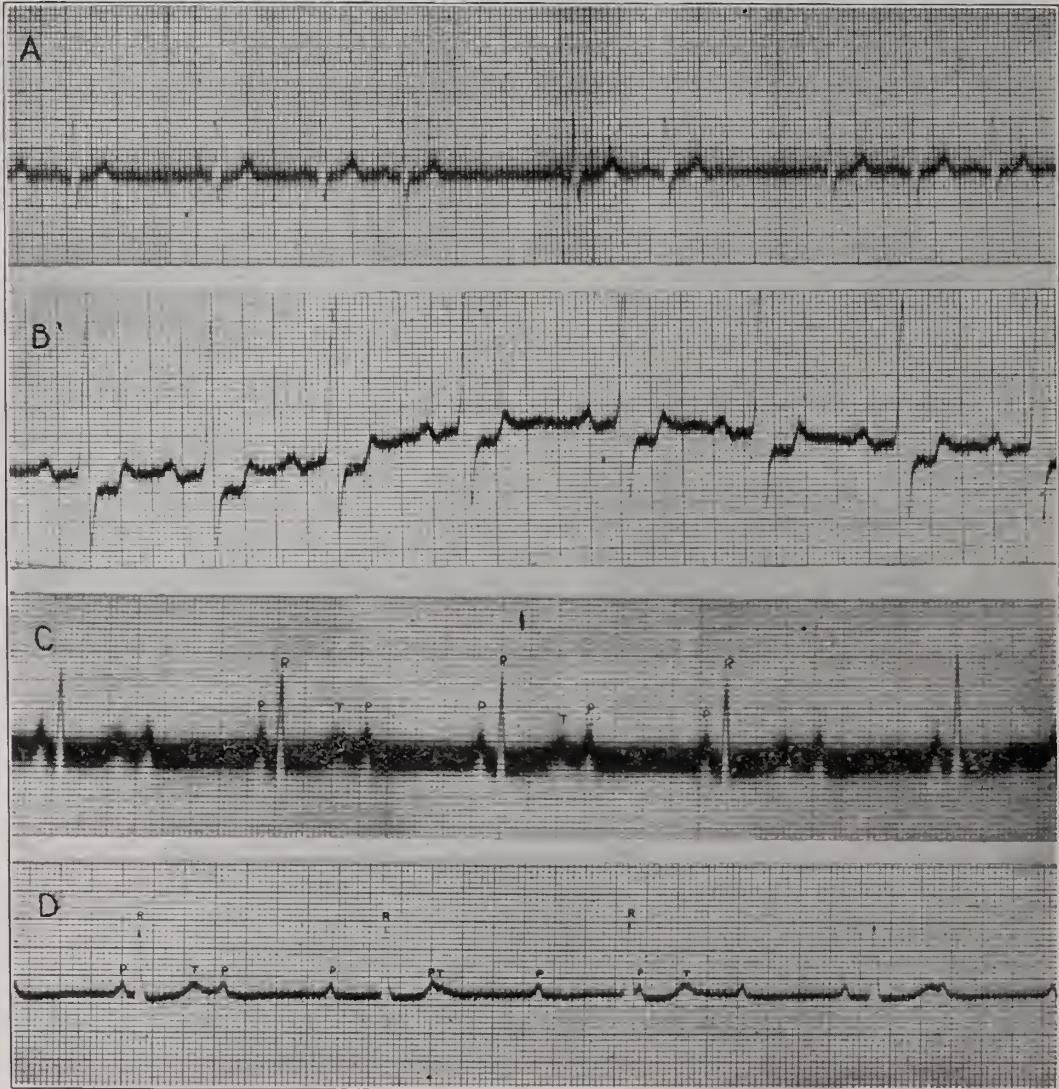

Plate 2.

Fig. A: Sino-auricular block. Irregularity of the whole heart with pauses equal approximately to two normal intervals. Fig. B: Prolonged conduction time resulting from Digitalis. P-R interval exceeds .2 second. Fig. C: Partial (2:1) block. The ventricle responds to every other auricular contraction. Fig. D: Complete block. Auricles and ventricles contracting at regular independent rates.

transmission in the bundle of His; bundle branch block where conduction is faulty in the right or left branch; and arborization block in which the defect lies in one or more

to be looked upon as one manifestation of widespread cardiac disease involving other structures besides the conduction system. Investigation, therefore, of the several types of block

yields information of value not only as to what the heart is doing but also as to the nature and extent of the disease with which it is affected.

Sino-auricular block is a rare disorder probably always due to extra-cardiac causes acting through the vagus. It often occurs in neurotic individuals, and may be produced by digitalis and caused to disappear by atropine. It manifests itself by sudden changes in the contraction rate of the whole heart producing intervals between beats equal approximately to two normal intervals. So far as cardiac efficiency is concerned, sino-auricular block is of no significance. Its recognition is, however, important at times, for it may easily be confused with partial block of the bundle, a condition of different significance. The record shown here (Plate 2, Fig. A) is from a neurotic individual of thirty-four who complained of palpitation and showed an irregular pulse but in whom no other sign of cardiac derangement was demonstrable.

Auriculo-ventricular block, or A-V block, as it is commonly called, is due to impaired conduction in the bundle of His. It may be the result of syphilitic or rheumatic infection or other chronic degenerative processes where actual tissue change is demonstrable in the bundle, or it may occur as a temporary affair in acute infections or from digitalis. There is a prevalent idea that syphilis is the chief cause, but this is not borne out by the facts. White found syphilis in sixteen of 156 cases, while Willius, in an analysis of twenty-two cases of complete auriculo-ventricular dissociation found none syphilitic.

Auriculo-ventricular block may be partial or complete. Experimentally, the several grades may be produced by exerting varying degrees of pressure on the bundle grasped in a forcep. The mildest form is that in which there is delay in impulse transmission from auricle to ventricle. This defect can rarely be made out by clinical means, yet it is suggested when the first sound is reduplicated or, in cases of mitral stenosis, when the murmur or thrill or both occur in early diastole (Plate 2, Fig. B). When the block in the auriculo-ventricular bundle is more pronounced the ventricle fails to respond to certain impulses, causing either an occasional dropped beat or a succession of them. Commonly there is a ventricular response to every other auricular beat giving rise to what is known as two to one

block. The latter condition usually shows a pulse rate of from forty to fifty per minute, and upon exercise this rate at times doubles abruptly. Plate 2, Fig. C, showing a two to one block was taken from an elderly patient with arteriosclerosis, who later showed a complete block.

When conduction from auricle to ventricle is completely obstructed the ventricle assumes its own rate which is as a rule abnormally slow (Plate 2, Fig. D). Nearly all patients who show a ventricular rate of thirty-five or less have complete block. On auscultation the first and second sounds are heard as usual, but often there is a third sound, the auricular contraction, which may occur at any point during diastole or fall with the first or second sound altering their character somewhat. In cases of mitral stenosis, this third sound may be accompanied by a murmur. Pulsations may also be seen in the jugulars corresponding to auricular beats and exceeding the ventricular rate.

Auriculo-ventricular block, by reason of the abnormal slowing of the heart rate, is at times accompanied by attacks of unconsciousness known as the Stokes-Adams syndrome. These occur, however, in the minority of cases, and as a rule the block itself and the resulting slow rate produce no symptoms. The illustration, Plate 2, Fig. D, was taken from a case of rheumatic heart disease with mitral stenosis, complete A-V block and Stokes-Adams attacks. Auricular contractions were plainly heard between ventricular beats and were followed by a distinct murmur.

Except in the transient forms due to toxic agents or to acute infections, auriculo-ventricular block is of grave significance. When persistent, it is always to be regarded as evidence of disease, not limited to the bundle, but affecting the entire myocardium. The recognition of A-V block is therefore of vast importance, as it may be the only sign of severe myocardial damage. Notable exceptions have been recorded, but as a rule chronic high-grade block of the bundle means death in a few years from general heart failure.

In the treatment of patients who show incomplete A-V block, digitalis is theoretically contraindicated on the ground that it may cause complete dissociation. Digitalis does usually increase the grade of block, but this effect is in itself comparatively harmless and cannot be weighed against the good to be derived from the use of the drug to improve

cardiac efficiency. Where the block is already complete, digitalis cannot affect it further and may be given when heart failure demands it. In cases due to toxic agents, atropine will often cause the block to disappear. For the relief of attacks of Stokes-Adams syndrome, adrenalin has proved of value. Where syphilis is a possible factor, antiluetic treatment is indicated, but instances in which the block has disappeared as a result of antiluetic therapy are rare indeed.

Intraventricular block or defective conduction beyond the bundle has been the subject of considerable discussion in the past few years. It appears to be more frequent than auriculo-ventricular block and, according to several observers, is of graver prognostic import, indicating severe myocardial damage with extremely high mortality. In those cases in which autopsies have been made, advanced

are involved. Patients with this condition usually show symptoms and obvious signs of heart failure, but occasionally the electrocardiogram furnishes the only evidence available. Even in the absence of symptoms, an electrocardiogram of this character should demand the greatest caution, especially as regards physical or mental strain. It is probable that many of the unexpected deaths following surgical operations occur in patients having this type of heart. Plate three illustrates the electrocardiographic findings in a case of right bundle branch block. This patient had survived what seemed to be a coronary thrombosis, and when seen showed an enlarged heart with broken compensation. On digitalis, compensation was restored, but the bundle branch block persists. Plate four shows arborization block in an individual with no symptoms except vague precordial pains; no cardiac enlarge-

sclerosis of the coronary arteries and extensive myocardial fibrosis have usually been found. Willius, in an analysis of 112 patients, in whom intraventricular block was found, reported a mortality of 69.6%, the average duration of life from the time of examination being 8½ months.

The electrocardiograph distinguishes two types of intraventricular block: bundle branch block where one of the main branches is affected, and arborization block where one or more small branches in the arborization system

ment, murmurs, or signs of vascular degeneration were made out. Sudden death occurred two months after the record was taken.

Unfortunately, not all types of heart block can be identified by ordinary clinical methods of examination, but a familiarity with what has been learned from electrocardiographic and other studies is an invaluable aid to those who seek to know all that can be known about a possibly diseased heart. With a clear understanding of normal cardiac conduction and of the defects known to occur in disease, one may,

by diligent application of the unaided senses, detect or at least suspect the several types of block with a surprising degree of accuracy.

## CRANIAL INJURIES.

### Hemorrhage and Economic Prognosis.\*

By GEORGE TULLY VAUGHAN, M. D., LL. D., F. A. C. S.,  
 Washington, D. C.

A great surgeon has said that no injury to the head is so slight as to be ignored or so serious as to be regarded as hopeless.

For example, a boy 18 years old was struck a light blow on the head with a broom-stick. In less than an hour unconsciousness and spasms of the extremities came on. At the operation no injury to the skull was found, but extensive intracranial hemorrhage, which caused the death of the patient in a few hours.

On the other hand, a workman blasting had

a tamping iron about one inch in diameter at the large end and tapering to about one-fourth of an inch at the small end and over four feet in length, driven entirely through his brain and survived the injury fifteen years. The specimens, tamping iron and patient's skull, can be seen in the Harvard Medical Museum.

The injury may be an abrasion, a contusion, or open wound affecting the scalp alone, or it may go further and involve the bone or the brain itself.

Just as in the abdominal or thoracic cavities the viscera may be ruptured without damage of the containing walls, so in the cranium, the brain and its blood-vessels may be ruptured without fracture of the skull. Conversely, fractures of the skull may occur without brain

\*Read at the meeting of the Association of Surgeons of the Norfolk and Western Railway, Cincinnati, O., September 12, 1923.

injury, but as a rule fractures of the skull mean injury to the cranial contents.

The varieties are as to region, those of the vault and those of the base. As to exposure to the air, shape, size, etc., simple or closed, compound or open, linear, stellate, depressed, complete and incomplete, local or limited; as general or bursting.

Fractures of the base are recognized also according to the fossa affected—each being characterized by a superlative: Fractures of the anterior fossa are least fatal; of the middle fossa, most frequent; of the posterior fossa, most fatal.

Naturally the importance of fracture depends on the injury to the brain, blood-vessels and nerves, and one of the commonest of these conditions is hemorrhage.

Traumatic intracranial hemorrhage comes from the blood-vessels between the skull and dura mater, from those on the surface of the brain, or from those within the brain substance. Usually the cause is a fracture or diastasis of one or more of the cranial bones, but sometimes vessels are lacerated and at the same time the skull escapes fracture. The symptoms are caused chiefly by compression from the effused blood or clot and come on rapidly according to the size and situation of the clot, in the form of unconsciousness, spasms, paralysis, vomiting, headache, somnolence, slow pulse, special eye symptoms, and changes in blood and cerebrospinal fluid pressure and contents. In many cases there is a *silent* or *free interval*, a name given to that period of time which elapses between the receipt of the injury and the onset of serious symptoms from pressure by the effused blood.

The blow on the head may stun the patient and cause headache and nausea, but he may go on about his business apparently normal for hours, days, or weeks, before the collection of blood which is gradually increasing reaches sufficient size to produce marked symptoms of compression. It is during this silent interval that many sad mistakes in diagnosis have been made: as the patient feeling nauseated and dizzy may have taken an alcoholic stimulant and, walking with uncertain gait, is taken up and put to bed in a station house or elsewhere without medical attention, charged with intoxication, and some hours later he is found dead from intracranial hemorrhage. According to Connell, the silent interval varies from a few

minutes to six or eight weeks—the average seems to be about 24 hours.

When the signs of compression, headache, vomiting, spasms, or paralysis, slow pulse, somnolence, perhaps unconsciousness, come on, the skull should be opened where the focal symptoms indicate the lesion, preferably by an osteoplastic flap of large size. The flap is replaced after the operation and leaves no defect in the skull.

For bleeding from the bone, sometimes a troublesome complication, I have been using for many years a piece of soft tissue, muscle or fascia, cut from any convenient part of the wound, and pressed or rubbed on the bleeding surface until it sticks.

From an economic standpoint, the prognosis in wounds of the head (cranium) is important, as the earning capacity is diminished in many on account of headache, paralysis, or epilepsy. T. Crisp English (*London Lancet*, Feb. 20, 1904), as a result of the investigation of 300 cases of head injuries from one to twelve years after the injuries had been inflicted, concluded that from 20 to 40 per cent had their wage-earning capacity reduced or destroyed, especially if their work were intellectual in character.

L. B. Rawling, (*Br. Journal of Surgery*, July, 1922) wrote letters to 1,000 patients who had received gunshot wounds of the head during the World War. Of 452 replies up to 1920, 30 per cent claimed complete disability, 26 per cent doing a little work, and only 43 per cent doing ordinary work. The conditions causing disability were headache 89 per cent, giddiness 77 per cent, nerves 68 per cent, paralysis 29 per cent, and fits 25 per cent.

The following history of a patient with intracranial hemorrhage is selected from a number of such cases as illustrating many points of interest.

A. J. H.: white; 51 years old; salesman; was hurt in an automobile accident July 25, 1922, receiving a scalp wound about three inches long in the *left* occipital region. He was not unconscious but had symptoms of concussion—vomiting, dizziness, and headache. He continued going about attending to his business for five weeks, taking long trips by rail or automobile, suffering somewhat at times with headache and weakness, but otherwise seemed normal. At the end of five weeks the headache and weakness had increased. There

was mental dullness and somnolence so that he took to his bed. During the next three weeks these symptoms continued to increase, except the headache of which he no longer complained, to a condition of complete apathy. There had been no fever but a subnormal temperature (97-98), pulse had been slow (60 or less), no change in eye grounds on ophthalmoscopic examination and spinal puncture and X-ray of skull were negative.

I first saw him September 28, lying in bed apparently asleep. Shaking him caused him to open his eyes, but he would not speak and at once dropped back into somnolence. Pulse 60, involuntary and unnoticed evacuations from bowels and bladder, reflexes exaggerated and leucocytes, 14,000. Pupils slightly dilated but reacted to light.

The diagnosis was compression of the brain from abscess, blood, cyst, or tumor. Owing to the long time, eight weeks, which had elapsed and the subnormal temperature since the injury, it was thought probable an abscess existed. The location of the lesion was impossible and, as there were no focal symptoms, it was decided that it must be in a silent area of the brain, and as these areas are more numerous on the right side of the brain, it was thought best to expose as large a portion as possible of the *right* hemisphere, although the injury received had been on the *left* side of the skull.

Seen at twelve o'clock that night after transfer to hospital, the patient was comatose, pulse 110, temperature 101, and he was in a profuse sweat.

Next morning, September 29, 1922, the pulse was less rapid, the coma not so deep, and the nurse reported having observed slight twitching of the *left* foot. This was encouraging to the decision already made to expose the *right* side of the brain, so a large osteoplastic flap, 5½ by 4½ inches, was turned down on the right side of the skull exposing the larger part of the right hemisphere covered by a blue and pulseless dura mater. On turning down the dura, a large clot of blood was found beneath the arachnoid, extending from the extreme front of the frontal lobe back to the occipital lobe and down to the base, causing a deep indentation into the cerebral tissue, like the bed of a large tumor. On removal of the clot no pulsation at first was seen in the brain, but in a short time feeble pulsation was noticed. No bleeding point was found. The dura and the

osteoplastic flap were sutured in place without drainage.

On awaking from the anesthetic, the patient talked rationally, recognized persons and called for a urinal when needed. There was no complication attending the patient's recovery and he was discharged from the hospital October 26, 1922. When last heard from in July, 1923, he was apparently perfectly well and attending to his business as usual.

The following points in this history may be emphasized:

1. Hemorrhage without fracture.
2. Hemorrhage on the opposite side to that receiving the blow.
3. The long silent interval, five weeks, during which the blood was escaping and accumulating on the surface of the brain.
4. The difficulty in locating the lesion in the brain as there were no focal symptoms such as spasm, paralysis, choked disk or aphasia.
5. Effect on earning capacity. There seems to be no deterioration in this respect and no complication so far.

1718 I Street, Northwest.

### THE RELATION OF FOCAL INFECTION IN THE PRODUCTION OF OCULAR DISEASE.\*

By H. MAXWELL LANGDON, M. D., Philadelphia, Pa.

This paper is written not to bring forth anything that is original nor to refute anything which has been written. Its sole purpose is to set forth the facts concerning a group of cases of various ocular conditions, all of which have had as their cause some focal infection which could not be located except by careful examination and in two of which, numbers nine and thirteen, the signs were so misleading that it was only the insistence of the ophthalmologist which led to operation and the preservation of vision.

As will be seen, the ocular conditions are variable in type and have no definite connection with the site of the underlying cause, very similar changes resulting from sinus, tooth and tonsillar infections.

If any one thing is impressed upon us by the facts here related, it would seem to be that the human body is an entity and not a group of independent parts, and that trouble in one organ is frequently the result of disease elsewhere in the individual, and can be found only

\*Read at the meeting of the Virginia Society of Otolaryngology and Ophthalmology in Richmond, April 18, 1923.

after painstaking search, and that the physician must not become so highly specialized that he regards the organ of his particular interest as isolated.

So recent is our knowledge of the relation of sinuses and teeth to the ocular structures that it seems probable that in several of these cases the cause would not have been discovered had they occurred fifteen years ago and the vision, if not the eyes, would probably have been lost. Several would have been attributed to syphilis, as many to tuberculosis, and the rest distributed among the mysterious causes then assigned for such happenings.

CASE 1. Miss E. B. S., age twenty-one, was seen on March 4, 1922, complaining of blurred vision of each eye. Examination showed no changes in any structure of either eye. O. D. V. was 5/10, the best corrected vision being 5/9 plus; O. S. V. 5/8 partly, capable of correction to 5/6. Examination of the visual fields showed normal peripheral limits with a relative central color scotoma, the diagnosis being retro-bulbar neuritis. Physical examination showed a rather low blood pressure, 100—65, hemoglobin sixty-eight per cent, reds 2,250,000 and whites 5,000. Wassermann weakly positive, but no other findings. Examination of the teeth showed them in good condition. The tonsils had been removed and the sinuses were reported as healthy. Vision not improving under iodids, another rhinologist, Dr. Ross Hall Skillern, was asked to see the patient and he felt that there was enough sphenoidal infection to account for the trouble. The sphenoids were drained and in six weeks vision was 5/5 plus in each eye.

CASE 2. Mrs. W. L. H., age forty-two, first seen in 1906 and at intervals since then for refraction. On December 1, 1922, came complaining of a blur before O. D. Central and peripheral vision were normal and there were no fundus changes. Three days later central vision had fallen to 5/8 and there was a central relative scotoma for red and green. A diagnosis of retro-bulbar neuritis was made. Examination showed a hyperplastic sphenoiditis of the right side, treatment of which caused a disappearance of the ocular symptoms. At no time were there fundus changes.

CASE 3. Mrs. P. E. D., age thirty-five, first seen in October, 1914, for refraction. On July 13, 1922, came complaining of blurring of vision of O. S. for the preceding ten days, during which time she had had a cold. The right

eye was normal in all respects; the left eye showed no changes save for a central vision of 5/15 with a central relative scotoma for red and green. A diagnosis of retro-bulbar neuritis was made and examination showed involvement of the right sphenoid, which was opened. By August 9, 1922, the scotoma had disappeared and central vision was 5/5 plus.

CASE 4. Mr. A. H., age thirty-nine, seen first December 27, 1915, for refraction. On April 26, 1921, he reported complaining of blurred vision of O. S. Examination showed O. D. normal in all respects. O. S. V. was 5/15 with a crescentic patch of retinal edema at the macula. Wassermann was negative as were the nasal passages and throat. Three teeth were found to have apical abscesses, extraction on May 10, 1921, resulted in a subsidence of the retinal edema with a return to normal vision by June 10, 1921.

CASE 5. Mrs. E. T. L., age sixty, reported on July 19, 1920, with a history that O. S. had been sore since the preceding day. Examination showed O. D. normal with a vision of 6/10. O. S. slight ciliary injection with two posterior synechia and a vision of 6/15. Examination showed normal urine, negative Wassermann, two teeth with apical abscesses and an involvement of the ethmoid cells. The teeth were extracted and the ethmoiditis treated by suction, the patient however not objecting to more radical procedure. This attack cleared up but two months later O. D. was involved. In January, 1921, the left eye was again involved which lasted, with short intermissions, until August of that year when the left antrum and the ethmoid were cleaned out, with an almost immediate improvement in the ocular condition, and without return up to the present. Corrected vision is normal and, except for a few pigment spots on the anterior capsule of the lens, the eye is undamaged. One of the interesting things about this case was a sensitization to atropin after a long period of use and the necessity of using scopolamine; also interesting was the long dilatation of the pupil without increase in ocular tension in a woman of sixty.

CASE 6. Mr. B. H., age twenty-five, first seen March 13, 1917, with a history that O. D. had been inflamed four years previously, with some recurrence at times. O. S. had been sore the previous week. O. D. was normal in all respects with a vision of 6/5. O. S. showed intense ciliary injection, with a cloudy cornea,

the pupil filled with exudate and a slight hypopyon; vision being perception of hand motions at one foot. The eye had been under indifferent treatment. Under suitable local and general measures, conditions improved so that in four days the exudate in the pupil was absorbed and vision was 6/25. The Wassermann was negative, the teeth were in good condition but the sphenoids were infected. On April 27, 1917, a hemorrhagic retinitis developed in O. S. which treatment quieted, the nasal treatment consisting in the use of the suction apparatus. In June the right iris became inflamed, but the attack was light. In August, 1918, O. S. was again involved, the iris being so congested that there was hemorrhage from it, into the anterior chamber, leeches being required to lessen the iritic hyperemia; a similar attack occurred three months later. In December, 1919, a retro-bulbar neuritis with central scotoma and some edema of the disc appeared in O. D., vision falling to 6/30 to return to 6/5. Radical operation has been refused though he has had several ocular inflammatory attacks, each aborted by nasal treatment.

CASE 7. Mrs. E. S. S., age thirty, seen first June 30, 1921, with a severe irido-cyclitis of O. S., O. D. being normal in all respects with a vision of 5/5. O. S. had a vision of 5/60. Local treatment was prescribed and nasal examination by Dr. Seth A. Brumm showed the left nasal cavity in bad condition, with the ethmoid probably involved, and X-ray examination by Dr. George E. Pfahler showed a cloudy ethmoid. Operation confirmed these findings with almost immediate improvement. By July 15, 1921, two weeks after the first visit, the eye was white and vision normal.

CASE 8. Mrs. A. H. C., age thirty, was first seen February 15, 1915, for refraction. On December 7, 1915, she again reported, this time with an inflamed right eye, which went on to a severe irido-cyclitis with much K. P. and iris engorgement. Physical examination including a Wassermann was negative, but nasal examination showed a septum deflected to the right with acute infection of the ethmoid and sphenoid cells. They were treated and by December 27, 1915, the eye was white. On August 1, 1919, there was another outbreak in the same eye and again intra-nasal interference was required, with prompt relief, the eye being clear in two weeks. A third attack started December 19, 1922, with much congestion of

the iris and chemosis of the conjunctiva. Pus was obtained on opening the ethmoids and by January 2 the eye was again almost white, with normal vision.

CASE 9. Mrs. C. C., age thirty-three, was first seen on February 3, 1923, with a right eye which had been sore for about twelve hours. There was considerable corneal haze, and ciliary and iritic congestion, the vision being 5/10. O. S. was quiet with a vision of 5/5. Teeth, Wassermann and general physical examination were negative. She was seen by three rhinolaryngologists all of whom said the sinuses were negative but the tonsils were badly infected. Following an expression of infectious material from the tonsils, the eye greatly improved, seeming positively to point to the source of infection. The tonsils were removed February 9, 1923, and the eye became worse, the pupil filled with exudate, cornea densely hazed and the conjunctiva so greatly chemosed that it over-hung the limbus; vision at this time was scant light perception. In addition to the other local remedies, leeches were applied to the temples with no great relief. On February 14 there was a small hypopyon. Consultation was again held with the laryngologist, Dr. Ross Hall Skillern, who could still find nothing to suggest sinus involvement. The eye continued in its severely inflamed state and on February 18 the writer insisted on amputation of the right middle turbinate, which was done by Dr. Skillern the following day, when there was found in the sphenoid a thin blood-tinged serous fluid. In forty-eight hours the improvement in the eye was most remarkable, the cornea being clear enough to see that the vitreous was quite hazy; in three days more the vitreous was clear enough to see that the disc and retina were quite edematous. Improvement however continued and in four weeks from the nasal operation, corrected central vision was normal.

CASE 10. Mr. N. W. B., age twenty-six, first reported on August 1, 1922, complaining of blurred vision of O. S. for the preceding twelve days, without pain or other symptoms. O. D. V. was 5/5 and this eye was normal. O. S. V. was 5/25 without external changes. The vitreous was quite hazy and there was a large patch of exudative choroiditis to the nasal side of the disc and about twice its size. It was believed to be either syphilitic or tubercular. Specific infection was denied and a blood Wassermann was negative, physical examination

was negative and tuberculin injections gave no reaction; the teeth were in good condition. Nasal examination showed that the sphenoids and posterior ethmoids were the site of a low grade inflammatory process and they were drained on August 24, 1922. By September 5, 1922, vision was 5/10 and by September 29 the vitreous was quite clear, vision was 5/5 and the choroidal patch quiet.

CASE 11. Dr. E. B. K., age twenty-seven, had been refracted first ten years ago. On January 30, 1923, he reported that O. S. was tender and that there had been some photophobia. Examination showed some slowness of pupil activity but no other changes. On February 2 there was some congestion and the following day some K. P. as well as a linear infiltrate into the lower portion of the cornea. Blood and urine were negative, Von Pirquet negative, Wassermann negative, sinuses negative, one apical abscess at root of lower left second molar tooth, cultures from tonsils showed streptococcus viridans and staphylococcus aureus. The tooth was extracted and the tonsils treated, cultures from the tooth showing streptococcus viridans. On February 12 the eye was distinctly better and went on to complete recovery by February 28.

CASE 12. Miss E. B. V., age seventeen, was first seen on October 27, 1922, with blurred vision of O. D., which had then lasted for two weeks. No other symptoms. O. D. V. was 5/35 with a large central scotoma, the disc was hyperemic with some blurring of the temporal margin. O. S. V. 5/5, the eye being normal. Wassermann and Von Pirquet tests negative. sinuses, blood, urine and teeth negative, but the tonsils were badly infected, and were immediately removed. On November 4, O. D. V. was 5/15, the disc still being swollen with a complete macular wheel. By November 24, O. D. V. was 5/5 and the fundus was normal except for slight hyperemia of the disc and one or two "spokes" remaining of the macular change; central color vision was normal.

CASE 13. Mrs. M. B. W., age fifty-two, seen on January 3, 1917, complaining of blurred vision of O. D. with pain in the right frontal region following influenza. O. D. V. was limited to counting fingers at two feet, the direct pupil response was abolished but consensual reaction was good, a condition which was reversed in the left eye. The right disc was hyperemic with blurring of the margins. The left eye had normal vision, full field and

no changes except the loss of consensual pupil activity. Dr. George B. Wood could find no signs of sinus involvement and X-ray examination by Dr. H. K. Pancoast was negative, but so plain did the underlying cause seem to be that the sphenoids were opened on the writer's insistence on January 28, 1917. Almost at once an improvement in vision was noticed and, by February 2, 1917, vision of O. D. was 6/20 and one week later corrected vision of this eye was 6/6.

These cases may be divided into three groups according to the site of the original focus, or into types of ocular involvement in which case four groups will result, and it has seemed well to select this second classification. We then have group one where there was an acute uveitis of greater or less intensity to which six of the cases belong; five resulting from sphenoidal or ethmoidal involvement and one from a tooth root abscess; group two, of retrobulbar neuritis with four cases all due to sphenoidal involvement; group three, with two cases of retino-choroiditis, one due to sphenoidal hyperplasia and the other to a tooth root abscess, and one case of neuro-retinitis with tonsillar infection as the cause.

From this analysis we see that there is no definite connection between the site of the original infection and the type of the ocular inflammation and that a diagnosis of the ocular disease will not *per se* enable us to locate the original infection, but a complete physical examination is the only reliable method of procedure. It will be realized from a study of the cases in group two that at times this type closely simulates the result of tobacco-alcohol amblyopia and may be very difficult to differentiate from that condition. It seems quite probable that some of the tobacco cases, in which in spite of the cessation of the use of the toxic agents the visual defect persisted, were also affected by unrecognized sinus involvement and therefore naturally were not cured by the removal of the influence of the tobacco and alcohol.

As to the method of the production of this type of neuritis by sinus disease, two views are held, one that it is an actual neuritis due to the seeping through the thin bony wall of the sphenoids of toxic material from the sinuses, and the other that it results mechanically from pressure on the nerve. Of these theories the former seems to the writer to be the more probable.

The course of transmission is either by continuity of tissue involvement, through the lymphatic or through the blood stream.

Retro-bulbar neuritis from sphenoid or ethmoid involvement is an example of the first method, uveitis from sphenoidal infection of the second, and neuro-retinitis from infected tonsils of the third.

The most important item of the treatment after the source of the infection has been localized is its radical removal. Palliative treatment by vacuum or suction apparatus is, in the writer's experience, useless and to be avoided unless there is a very definite contra-indication to more radical proceedings. Nothing but good has followed the opening of the sinuses in any case which the writer has seen and he believes that in case of doubt this should be done.

When we come to consider the proportion of these various groups which are caused by focal infection we find no reliable figures. Formerly we believed that the greater number of cases of irido-cyclitis were due to syphilis, tuberculosis, gonorrhoea or rheumatism, now it seems that at least one-half of the cases of this condition or of uveitis are due to localized infection, and this estimate is probably too low, and we now know that there is no such entity as "rheumatism."

Retro-bulbar neuritis was "tobacco-alcohol amblyopia" or from some similar toxemia; of this condition it would seem that at least two-thirds the cases are from sinus disease, and many of the remainder are complications of disseminated sclerosis.

Retino-choroiditis is still probably most frequently due to syphilis or tuberculosis and only in an occasional instance does it result from focal infection as in Case No. 10 of this series.

The two needs which it is hoped this paper has shown are first a prompt and complete physical examination, and second as thorough a removal of the cause as is possible.

### FACTORS IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.\*

By O. O. ASHWORTH, M. D., Richmond, Va.  
Assistant Attending Physician, St. Elizabeth's Hospital, Richmond; Formerly Assistant Physician, Catawba Sanatorium, Virginia.

Clinical tuberculosis may develop in only two ways. These are, once infection takes

place, through the renewal of activity of latent foci which have existed for variable lengths of time, or through the uninterrupted progression of foci from the time of infection to the cropping out of symptoms.

While there is no tuberculosis without tubercle bacilli, these cannot do harm unless one is predisposed to the disease. Naegli in 1900 published a report of five hundred autopsies. Seventy-one per cent showed pathological changes due to tuberculosis. Among individuals under eighteen, only twenty-five per cent showed lesions, but in persons above eighteen years of age the proportion that showed traces of infection reached ninety-eight per cent. Other pathologists have since confirmed Naegli's findings. It is rare to find an adult who does not show some skin reaction to tuberculin, irrespective of his economic or social condition. While it is known that where there is most poverty, tuberculosis is more often found, it must not be assumed that it is confined to those of the poorer class. An investigation of the number of patients in private sanatoria who can pay more than \$50.00 per week for treatment is convincing. The nature of predisposition is a complex affair, and may be due to physiological and anatomical factors, but it is most certain that environment, a wrong living plan, whether adopted by the poor or rich, plays the greatest role.

What is chiefly aimed at in practice is discovering tuberculous disease. The patient is interested in the results of tuberculous infection and whether any special line of treatment is necessary to improve his health. This information can only be given after a careful inquiry into the patient's history and symptoms and a consideration of the physical signs elicited by an examination of his chest and other parts of his body, with routine laboratory examinations, and the X-ray when necessary and available. A hasty diagnosis of a suspected lesion is as hazardous as neglect to recognize active disease.

While tuberculosis is not hereditary, it is a fact that several members of a family are often affected, either because they all have been subject to similar environmental influences, or from massive infection during infancy and childhood. It rarely occurs in consorts or those exposed to the disease in later life. While tuberculosis itself is not hereditary, a weakened re-

\*Read before the Southside Virginia Medical Association at Emporia, September 11, 1923.

sistance to this disease may be transmitted hereditarily.

General symptomatology in doubtful cases is of more significance than indefinite physical signs. There is no active tuberculosis without constitutional symptoms. Pottenger has classified the symptoms of tuberculosis into three groups: (1) Those due to toxemia (malaise, lack of endurance, lack of strength, nerve instability, diminished digestive activity, increased metabolic rate, loss of weight, tachycardia, night sweats, fever, leukocytosis); (2) Reflex causes (hoarseness, tickling in larynx, cough, digestive disturbances, loss of weight, chest and shoulder pains, flushing of face); and (3) Those due to the process *per se* (hemoptysis, sputum, frequent and protracted "colds," and pleurisy). It is evident that, if there are multiple symptoms from the toxemia, a rather extensive or virulent early process exists. Symptoms from reflex causes and the process *per se* may occur in an early or a late process. From all symptoms mentioned in general, lack of endurance, loss of weight, nerve instability, lack of appetite, rapid pulse, and fever are the most constant manifestations. These are the physiological effects of tuberculin when injected.

The signs of early tuberculosis are not those of consolidation or increased density, but of irritation and toxemia. Cabot states, "In the earlier stages of incipient tuberculosis there may be no recognizable physical signs. The earliest physical signs are fine crackling rales." Osler says, "Feeble breath sounds are the most frequent characteristic early signs. The expiration is usually prolonged." If the numerous foci of miliary tuberculosis cannot be discovered in their early stages by auscultation, percussion, or radiography, it is not logical to believe that it is possible to detect the incipient lesion by auscultation and percussion before granular breathing or rales have made their appearance.

Inspection may lead to a strong suspicion of tuberculosis, but an opinion should never be given by simply looking at a patient, for many who appear strong are suffering from tuberculosis. A dilated pupil, flushed cheeks, lagging or limited movement of one side of the thorax, unilateral atrophy of breasts or muscles of thorax, axillary sweating, displaced apex heart beat, supra- and infra-clavicular depressions, drooping shoulder, prominent scapula,

deformity of spine, curved finger nails, and clubbing of fingers must be observed, but the absence of all these is not conclusive of the absence of tuberculosis. Palpation may detect rigidity of the muscles of the neck and thorax, apex impulse of heart, thrill, or increase and decrease in tactile fremitus, enlarged cervical, supra-clavicular and axillary glands. In percussion a light stroke should first be used, beginning at the base of one side and percussing upward to detect small degrees of variation from the normal pitch. The interspaces of the two sides should be compared, bearing in mind the normal anatomical differences in the note. The diaphragmatic excursion and Kronig's isthmus may be obtained by tidal percussion and compared on the two sides. An increase in retrosternal dullness at the borders of the heart may be approximated. Resistance offered to the pleximeter finger is often of more value than an attempt to hear an impaired note. The axilla should never be omitted. It must be remembered that hyperresonance is often present over extensive pathology.

As in percussion, auscultation should begin at the pulmonary bases and go upward. With quiet breathing, variations from the normal should be noted, comparing the two sides. Feebleness or roughness of respiratory murmur, granular breathing, rales, pleural friction, prolongation of expiration, tubular breathing, increased whispered voice, cogwheel or wavy breathing, cardiorespiratory murmur, should be charted with the blood pressure reading and the character of heart sounds.

Each patient should be taught how to expire and cough and, if rales were present with breathing before cough, it should be noted whether they disappear or are provoked by cough. Rales which disappear during examination are usually of no significance. To be of significance, rales must be strictly localized over a limited area and persistent but, when present, whether basal or apical, their existence should be explained. In minimal cases, not over one per cent show rales except after cough. In moderately advanced cases from fifty per cent to seventy-five per cent, and in far advanced cases from forty per cent to fifty per cent show rales only after cough. Therefore, the value of the expiratory cough in diagnosis cannot be over-estimated.

Pottenger has given the most logical expla-

nation of the small heart in tuberculosis—that it results from defective filling of the chambers of the heart on account of impaired breathing. During a year's experience in routine repeated blood pressure readings in incipient cases of tuberculosis at Catawba Sanatorium, I did not find hypotension a feature of diagnostic value.

Laboratory examination of the sputum, if there is any, using concentrated methods, is of inestimable value. However, in the average sanatorium where repeated examinations are made, tubercle bacilli are not found in more than sixty per cent of the cases (far advanced, moderately advanced, and minimal cases). Routine blood examination may show a mild leukocytosis or a leukopenia with diminished hemoglobin, and often relative increase of lymphocytes.

Even where pulmonary lesions are definite, radiography by a skilled radiologist in conjunction with a thorough clinical examination will give a much more comprehensive and complete idea of the case, both as to diagnosis and prognosis, than is possible from physical examination alone.

That too little effort is being made by the medical profession to make an early diagnosis of pulmonary lesions is realized by a study of the annual reports of the Virginia State Tuberculosis Sanatoria. These reports show that more than fifty-five per cent of the cases admitted for treatment are suffering from far advanced disease—and this does not include cases rejected because too far advanced for admittance.

### **SPASMUS NUTANS.\***

By ALEX. F. ROBERTSON, Jr., Staunton, Va.

We have chosen spasmus nutans as our subject on account of its rarity and good prognosis. While this is a well recognized condition among pediatricians, it is not often encountered or generally known by the internist. Not uncommonly these little patients are carried from clinic to clinic, and run the gamut of a complete neurologic examination including lumbar puncture and spinal fluid examination before a diagnosis is made.

Spasmus nutans or nodding spasm is a functional nervous affection seen in infants usually

between the sixth and twelfth months of age, and limited to the first two years of life. It is slightly more common in boys.

The onset is always in the winter months between November and March. There seems to be a definite relation to dentition, although some authorities think this merely coincidental.

**ETIOLOGY.** A slight rickets is nearly always present. Most authorities claim that it is invariably associated with rickets. The theory that it is due to poor lighting of the nursery is not generally considered tenable. The hypothesis has been advanced that this affection is brought about by slow myelization of the nerve fibers of the central nervous system. There have been no autopsy findings to prove or disprove this theory.

**PROGNOSIS.** The prognosis is conceded by all to be good. Still, from whose work we have obtained the best description which we have been able to find of this condition, says the prognosis is 100% good. Epilepsy and idiocy do not follow. A few of these children later in life are nervous and eccentric, but this is not the rule. It has occurred to us that their attacks of spasmus nutans in infancy are merely early manifestations of a nervous or neurotic tendency. Recovery may occur in two or three months, and is usually complete by the end of the second year. After apparent recovery, this condition may temporarily recur in moments of excitement.

**SYMPTOMS.** *First:* rhythmic movements of the head, which may be anteroposterior, lateral rotation, or a combination of the two. These movements vary from twenty to one hundred and twenty a minute, and come in cycles, with widely varying intervals of quiet between, and are usually absent when the child's attention is fixed. They occur only when the head is held erect. *Second:* nystagmus. Nystagmus usually accompanies the nodding, and often has a unilateral predominance, or may appear only in one eye. Its appearance in infants, in the absence of other neurological signs, and without impairment of vision, is sufficient evidence upon which to base our diagnosis. The nystagmus may precede the head-shaking by weeks or months; rarely it may be absent.

**DIFFERENTIAL DIAGNOSIS.** This condition must be distinguished from congenital nystagmus, reflex nystagmus, voluntary head-rolling of infants, and infantile epilepsy.

Congenital nystagmus may be due to blind-

\*Read at the meeting of the Medical Association of the Valley of Virginia in Winchester, May 31, 1923.

ness from any cause, to errors of refraction, or to organic disease of the central nervous system, especially hydrocephalus. These conditions may be ruled out by careful neurological and ophthalmoscopic examinations.

Reflex nystagmus is usually associated with intestinal disturbances or acute infectious diseases, which are not present in true spasmus nutans. Proper treatment of these conditions causes prompt disappearance of the eye symptoms.

Voluntary head-rolling of infants is a coarser movement, usually taking the form of deep bowing, and is easily differentiated.

Infantile epilepsy is usually associated with spasms of the trunk as well, and these movements are present only during attacks.

**TREATMENT.** When associated with malnutrition or rickets, proper measures should be taken to improve the nutrition of the infant, this being accomplished chiefly by proper adaptation of the food and improvement of hygiene, if this is defective. Codliver oil is useful in combating a rachitic tendency.

#### REPORT OF CASE.

P. C., six and one-half months old, was the third child of healthy parents. He was born at full term after normal delivery, and weighed nine and one-half pounds. He was circumcised under ether anaesthesia when ten days old. He was breast fed entirely for several weeks, after which time complemental feeding with modified cow's milk was instituted. A few weeks later he was weaned on account of failure of the mother's milk. The food always agreed with him well, and he gained regularly in weight without suffering from any intestinal disorder or disease of any kind. At the age of six and one-half months, on March 8th, the mother noticed nystagmus of the left eye, which was followed several days later by a less intense nystagmus of the right eye. On March 22, a rotary movement of the head developed. All of this took place without any digestive upset or other symptoms.

**PHYSICAL EXAMINATION.** The infant was quite large, well nourished and developed, and appeared bright and happy. He seemed to be interested in his surroundings, grasped for objects and appeared mentally normal. The fontanelles were neither bulging nor depressed, and the head-chest ratio was normal. Pupils were equal and reacted to light. There was a rapid lateral nystagmus of both eyes, more pronounced in the left, and of a rate of about

eighty to the minute. This sign disappeared when a finger or bright object was brought within a few inches of the infant's eyes, fixing his attention. There was a rotary movement of the head of rather wide excursion and varying in rate from forty to eighty to the minute. This movement was suspended when the child reached for a toy or concentrated on a near object. There was no rigidity of the neck. The tongue was clean: the throat normal. The heart and lungs were normal. There was no rosary. Abdominal examination was negative. There was a slight bowing of the legs. Reflexes were not increased. Temperature and pulse were normal, and the weight was 22 lbs. 4 oz. Examination of the eyes was made by Doctors Fisher and Henkel, March 15, with the following findings: The child had nystagmus. Examination of the fundus showed no pathology. Apparently the muscle balance of the eye was normal as far as could be ascertained. No measurement of the refraction was made.

**TREATMENT.** The infant was being fed on a proper diet consisting of modified cow's milk, cereal, vegetable soup, and orange juice. As this food was well assimilated and there had been no symptoms of indigestion and the increase in weight had been steady, it was considered entirely suitable, and no change was made in the diet. Although it was our impression that this case was not associated with rickets, yet, on account of the bowing of the legs, codliver oil has been given. No bromides or other drugs have been used.

**PROGRESS.** Examination May 19th showed no change in the infant's condition, except that the rotary movements of the head were much less extensive in their excursion, and the rate of movements was about sixty to the minute.

#### CONCLUSIONS.

1. Spasmus nutans is a condition which is easily recognized if the cardinal signs, nodding and nystagmus (together with the absence of all other signs and symptoms) are borne in mind.

2. A prompt recognition of this condition will save much unnecessary anxiety on the part of the parents, and embarrassment on the part of the internist.

#### DISCUSSION.

DR. CHAS. E. CONRAD, Harrisonburg: I agree with Dr. Robertson that the diagnosis of this condition is a great relief to the parents. I recently had a case which I saw first when the child was three months of age. It was then a feeding case. The weight was nine pounds. I saw it again at eight months,

when it weighed eighteen pounds. At eight months it showed decided rotary movements, nystagmus, and strabismus. Another interesting thing is that I found she showed some very marked indications of spasmophilia, well defined Chvostek and Trousseau signs. I gave her calcium bromide. I saw her again in two months and she showed no improvement. Since then I saw her about a month ago, eighteen months after the onset, and as far as could be seen the child was entirely well except for slight internal strabismus. The people, on account of another child in the family having a severe nervous condition, were very much disturbed. There was complete recovery except for slight internal strabismus as stated above. I gave calcium bromide and the child got along all right, but I do not know if it had any effect except on the spasmophilia. In this case there was no question of darkness as a cause, the rooms being well lighted.

### FURTHER REPORT ON SPINAL ANESTHESIA\*

By W. CALHOUN STIRLING, M. D.,  
Genito-Urinary Surgeon.

and  
CHAS. S. LAWRENCE, M. D., F. A. C. S.,  
Winston-Salem, N. C.

There are certain requirements which an anesthetic solution must fulfill in order to satisfy conservative surgical judgment, some of the most important of which are: 1. Complete loss of pain sense; 2. Relaxation of the abdominal muscles; 3. Reduction of shock to a minimum; 4. Disturbance of the cardio-renal organs as little as possible; 5. Allowance of sufficient time for careful operation; 6. Lessening of the post-operative morbidity; 7. Maintenance of the acid-base equilibrium of the blood as near normal as possible.

In advocating the use of spinal anesthesia, it is not claimed that it is a panacea for all anesthetic ills, but realizing the limitations of any form of anesthesia, it is claimed that it fulfills a very definite field in surgery. It is the purpose of this discussion to take up these seven factors, and as briefly as possible, to compare the results produced by the three most commonly used anesthetics; i. e., ether, gas-oxygen and spinal.

At the Lawrence Clinic, we have given one hundred and forty spinal anesthetics, with no mortality and with less than five per cent untoward reactions during operations, and none following them. Based on our own observation, as well as the literature, and seeing the results obtained by others, we believe it is as safe as either gas-oxygen or ether, if used judiciously. Unfortunately in the past, the reports of the surgical literature have given it

an unsavory name, due not to the principle *per se*, but to the failure to acquaint oneself with the anatomy of the area to be anesthetized, together with the pharmacological action of the injected drug; also the various drugs used in the past have had a higher degree of toxicity than the solutions used at the present time. It is only on the reports of skilled operators, using it in a large series of cases, that an unbiased opinion can be formed as to its merits. Babcock reports over 6,000 successful anesthetics, Yount reports 7,000, Jonnesco has given 5,016, Chute something over 328, Labat reports over 200, and Smith of Boston has given 100. Including this and other reports there are over 18,000 spinal anesthetics reported, with only one death, that being before the solution was injected. What further corroborative evidence do we need to satisfy ourselves as to its non-toxicity? More careful study of the technique of giving it, as well as the desired action required, i. e., just where anesthesia is wanted, will in the future make this method of anesthesia more popular, with less reactions reported. There are many factors involved in the successful administration of a powerful drug in such a vital area, so its use should be confined to those who have carefully studied the method and can recognize any untoward reactions promptly, otherwise the literature will continue to report unsatisfactory results and condemn it without justification.

In this series, five per cent of the cases required a small amount of ether to divert their attention, so called "psychic ether," as other signs pointed to good anesthesia. In six cases, it was necessary to completely narcotize the patient, as the loss of pain was not obviated. This was in the first few given and we are glad to say that in the last fifty anesthetics given, there has been no complaint, showing that it is necessary to thoroughly acquaint oneself with the procedure before condemning it. There has not been any severe reactions in any case, such as is reported by certain authors. As a rule we give it and go on with the operation; rarely has it been necessary to administer any stimulant to offset an undue reaction. Some writers have criticized this procedure on the ground that the patient was made more nervous at being present at his own operation. This has been overemphasized, as it has been found that a hypodermic of morphine and scopolamine given one hour before the operation will relieve this anxiety and the patient

\*Read before the North Carolina Medical, Pharmaceutical and Dental Association in Winston-Salem, N. C., June 19-21, 1923.

is usually indifferent to any manipulation that he may receive.

Muscular relaxation with spinal anesthesia is all that one could desire, if the anesthetic is successfully administered, rarely requiring any retraction of the abdominal muscles, the abdominal wall can be literally lifted up and inspection made of the entire abdominal contents, lying quietly in a state of tonus, called by the French the "silent abdomen." This relaxation obviates trauma from retraction, which is an important factor in promoting rapid and uneventful healing. The intestines are in a state of tonus, rarely requiring packing off and extensive handling, with its resulting train of symptoms later recognized as ileus, tympanites, etc. Many prominent surgeons have said that they had never been able to get good relaxation with gas-oxygen, without giving ether with it; this has been the experience of the writer. Surgeons accustomed to spinal anesthesia, in the removal of adenomatous prostates, all declare that the relaxation and other features are much superior to gas-oxygen, its nearest rival in this particular work; with gas the anesthetist is urging the operator to get out, whereas with intra-dural anesthesia the operator can feel sure of an hour in which to do a careful dissection and leave the field dry. With the former the breathing is labored, the muscles are in a state of partial rigidity and the time element plays an important part in the operation. A very interesting point in this connection is the marked physiological action that pituitrin exhibits on the involuntary muscles of the gut, combined with spinal anesthesia. Recently, in a case of peritonitis resulting from ruptured appendix, operated on by one of us, the bowels had not moved in three days previous to entry in the hospital; on examination, no peristaltic movements were detected, the abdominal walls were tense and badly distended with gas. After the abdomen was opened, the patient was given one ampoule of pituitrin; in less than two minutes there were active peristaltic waves along the intestines, the patient passed much gas and fecal matter and, after being given another ampoule, more gas and fecal matter was passed and a large amount subsequent to operation. Patient left the table with the abdomen flat, and there was no vomiting later. It is a common occurrence for the patient to pass feces on the table and after returning to the room; this is a definite aid in

these cases of ileus and other paralytic conditions of the bowels. It is to be recommended in cases of intestinal obstruction where no definite cause can be ascertained.

Crile, in his excellent work on "Shock" has shown that spinal anesthesia will prevent shock. He attributes shock to two conditions, where hemorrhage and other causes that do not ordinarily enter into the cause can be ruled out. It is a bombardment of the brain with nervous impulses, coming from two sources, the first a result of over-stimulation of the brain due to operative injury, the second a result of psychic disturbances coming from fear and other psychic influences. With ether the psychic factor can be obviated, but the operative injury is even more the cause of shock, while with nerve block, i. e., spinal anesthesia, all impulses from the field of operation are prevented from reaching the brain, and the psychic phase is controlled with morphine and scopolamine; this is "anoci-association par excellence." In this report it has frequently been observed that a patient will go through a major operation with no shock, shown by the pulse rate and other signs, even in procedures like a panhysterectomy, or a prostatectomy on a very aged man.

The urine is examined before, as well as after, operation to see what influence the anesthetic plays on the renal tissue, and it has been noted that in no case has any toxicity been noted following the operation, evidenced by casts, albumen, etc. McNider has shown the depressing influence that ether has on the renal tubules, with an increase in the stainable lipoid material in the collecting tubules, with a diminution in the phenolsulphthalein output, and an increase in the blood urea and creatinine. Cabot and others say that the toxic influence that novocaine exerts on the kidneys can be disregarded; this has been our experience. There is no class of patients whose cardio-renal organs needs as much rest, as the prostatic, so, if we can devise a method of giving the prostatic drainage, without undue work being thrown on the already diseased organs, it behooves us to do so, if the patient is to receive the best management. Uremia is one of the chief causes of death following this operation, due in a large measure to the added work thrown on the kidneys, so, if we can spare the patient this strain, it rests on the operator to do so.

Pneumonia following a general anesthetic is a complication in two per cent of all cases, quite a factor in increasing the death rate in post-operative conditions. With spinal anesthesia, there is here, just as there is with the kidneys, no extra strain on the lungs and, if the septic factor be eliminated, we should not have any complications in the lungs.

The duration of this method of anesthesia varies, depending on the weight of the patient, age, and disease, usually lasting from fifty to ninety minutes; as a rule, an hour can be safely relied on for complete anesthesia as high as the abdomen, and an extra ten or fifteen minutes in perineal work. The anesthesia resembles the tide somewhat, slowly diffusing upward to the highest point of the subarachnoid space, with less concentration at that point, then gradually receding, so that the upper level of anesthesia is of the shortest duration and the lower level has the longest duration, as well as the deepest anesthesia. In doing a major and minor operation, the perineal work can be done without discomfort, after the patient begins to complain of pain in the upper incision. Using spinal anesthesia for its nerve blocking value, it has been combined with ether in cases where it is not feasible to depend on it alone, to obtund the pain sense, in extensive traumatizing accidents.

The morbidity following the operation has been greatly lessened in our series; there have been very few cases with nausea or vomiting, very few cases having any unusual accumulation of gas requiring measures to relieve it. The patient can take fluids before, during and immediately after the operation, making it unnecessary to give fluids by the rectum, and under the breasts, where the body fluids are depleted. Only one case has had a severe enough headache to cause comment, lasting two days and requiring nothing but slight elevation of the head to relieve it. No other untoward symptom such as meningeal irritation, etc., has been seen in any case.

It has been shown that the hydrogen-ion concentration of the blood is seriously disarranged in ether narcosis, due doubtless to the toxic effect it exerts on the kidneys—a most important factor in maintaining the equilibrium of the blood plasma at a constant physiological level, necessary to insure a prompt and uneventful recovery. This is not disturbed in spinal anesthesia.

The oldest patient was eighty-one and the youngest six years old. As a rule children stand spinal anesthesia well, if not too neurotic in temperament. The toxicity of the injected solution is, in our opinion, the result of direct absorption and not the result of upward diffusion of the novocaine, as claimed by some writers for, if the latter were true, we would expect to get more paralyses, especially that of respiration, which has not been seen in any case. Smith of Boston, has shown that the sharp drop in arterial tension is a result of the splanchnic centers being paralyzed; the higher the drug diffuses, the more the blood pressure drops, so that this must be kept in mind in trying to get anesthesia above the costal margin; if the area of anesthesia reaches above this point, there is usually a sharp drop in blood pressure. Blood pressure readings are made every ten minutes throughout the operation and, as long as the patient breathes regularly and deeply, no significance is attached to a moderate drop in the tension. If there is any sign of air hunger or marked restlessness, the patient is promptly given ten minims of adrenalin subcutaneously, which usually causes a prompt reaction; good results have also been obtained with caffeine in four grain doses for this condition, though it is rarely seen. Just after the spinal puncture is made, the patient is given one c.c. of pituitrin, as it is believed to aid in stabilizing the arterial tension. Re-breathing, using a closed inhaler, is valuable in cases with respiratory distress, supplying additional carbon dioxide, which will stimulate the medullary center. The patient must be closely watched by some one to see that he breathes regularly, as at times he forgets to breathe. This point must be watched very closely.

The contra-indications to this method of anesthesia are: 1. Patients with marked hypotension in shock where the pulse is very weak; 2. In cases of general septicemia; 3. In neurotic prejudiced patients; 4. In marked deformed spinal column disease; 5. In fevers of indefinite origin; 6. In diseases interfering with respiration, such as tumors, etc.; 7. In very obese patients with short diaphragmatic breathing space; 8. The aged and debilitated should be given small doses.

The indications for this over other forms of anesthesia include: Diabetics requiring operations, in patients with renal impairment, in

lung complications such as tuberculosis, and in acute coryza, requiring emergency operations. It is well tolerated in cardiac cases with compensation, and is indicated in all amputations on the lower extremities. As has been said, all genito-urinary operative cases stand it well with the possible exception of kidney cases; experience shows that traction on the renal pedicle will as a rule cause pain, though I recently operated on a patient with nephroptosis under local anesthesia, with very little discomfort.

The extent of the upward diffusion of the drug, when injected into the subarachnoid space, depends on several factors, some of which are under our control, these being, first the space through which the solution is injected, second, the amount of pressure used to inject it, third the position of the patient after receiving the drug, fourth, the amount of spinal fluid withdrawn, and last, the dilution of the anesthetic. The factors which cannot be controlled are, the natural diffusibility of the anesthetic solution, and the normal circulation of the spinal fluid, which is toward the periphery. These six things must be kept in mind in doing a spinal puncture as they are the controlling factors in keeping the blood pressure from dropping too much, as well as protecting the bulbar centers from the anesthetizing solution.

Various drugs have been used from time to time in this work, such as cocaine, tropococaine, apothesine, stovaine and novocaine. Our experience has been limited to the latter drug, as we believe it to be the least toxic. Novocaine hydrochlorid in minute crystal form is the drug of choice, and is put up in sealed ampoules in sterile crystals, of certain dosage; it has been found that ten and twelve centigram doses will satisfy all demands. Following the technique of Labat, somewhat, the dosage depends on the age and weight of the patient, a safe rule being to give one centigram for each ten pounds body weight. Adrenalin has not been used in conjunction with novocaine, as it causes a more marked drop in the blood pressure.

Briefly, the technique is as follows: One hour before the operation, the patient is given a quarter grain of morphine and one one-hundredth grain of scopolamine hypodermically and, by the time the patient enters the operating room, all nervousness is usually gone, and the patient is resting quietly. The patient

is placed in a sitting position with the back bowed well forward, the head resting on the chest, the lower spinal region is sterilized with iodine, and the iliac crests are located. A line drawn between these points crosses the fourth lumbar process. From this landmark the space to be injected can be located and, using a flexible twenty gauge needle, the spinal puncture is made, after anesthetizing the skin with one per cent novocaine. The needle is introduced in a slightly upward direction; a slight give can be felt when it penetrates the dura. The obturator is now withdrawn, so that when the needle enters the canal, clear fluid will drop from the needle; enough fluid is collected to dissolve the novocaine crystals. Then from ten to twenty c.c. of fluid is collected and discarded, the amount depending on the height of anesthesia desired, as well as the spinal fluid pressure. The dissolved novocaine is drawn into a five c.c. glass syringe and, after connecting it to the needle, the drug is gently introduced into the subarachnoid space, injecting a small quantity, aspirating more fluid in the syringe, and in this manner gradually emptying the syringe. An important point in the technique at this juncture is to make sure the needle is properly placed in the canal, for, as has been said, in connecting the syringe, the position of the needle may be altered, and thus cause a failure to get anesthesia (by aspirating fluid into the syringe several times the proper position of the needle may be insured). After withdrawing the needle, the patient is placed in the recumbent position (or any position desired), and the head well supported on pillows. The Trendelenburg position may be used if desired, or the patient turned over, if an operation is to be done on the back. Anesthesia above the costal margin is less satisfactory, the danger increasing in proportion to the height desired above that point. It is the refinements of technique in administering spinal anesthesia that give the most satisfactory results and, to attempt to give it without acquainting oneself with the above enumerated factors is to spell disaster and condemn it without justification. It is not our intention to leave the impression that a particular anesthetist is necessary, as any surgeon can give it, if careful study is made of it and the fact kept in mind that a powerful drug is introduced into a vital area. If the *modus operandi* is not thoroughly understood, the patient is subjected to an un-

necessary danger and an otherwise valuable method of anesthesia is discredited.

#### RESUME.

1. Spinal anesthesia, while not a panacea for all anesthetic ills, is a valuable adjunct in surgery below the costal margin.

2. Careful study of the pharmacological action of the injected drug, as well as of the anatomy of the area where anesthesia is desired, will lessen the number of failures and prevent any unnecessary reactions.

3. It is the anesthetic of choice in genito-urinary surgery, with the possible exception of the kidney.

4. The morbidity is greatly lessened: very few patients have complained even of a headache following the operation and there is less distention and vomiting.

5. Patients who have taken spinal anesthesia are with one accord very enthusiastic over it.

6. It is easy to inject and, if carefully watched, one accustomed to give it rarely has any trouble at all.

### A CASE OF ACUTE MASTOIDITIS COMPLICATED BY FACIAL PARALYSIS. OPERATION. RECOVERY.\*

By E. U. WALLERSTEIN, M D., Richmond, Va.

Mrs. Mary L., white, widow, age 53, was first seen on July 12, complaining of a discharging ear.

The past history is unimportant except that her general health was good and there had been no previous ear trouble.

The present illness began with a coryza five

days ago. The right ear became painful, and increasingly so, until the drum spontaneously ruptured, producing a small amount of bloody discharge. This increased in amount and became purulent. Three days later the patient was first seen. At this time she had a discharging ear, tinnitus and impaired hearing. There was an absence of pain.

Examination revealed a medium sized, stellate perforation at the umbo and a moderate amount of discharge. The case was apparently one of simple otitis media. As there was sufficient drainage, no incision was made. The patient was instructed to irrigate the ear and instill mercurochrome 4%. Within a few days the drum picture began to clear and discharge diminished. However, slight purulent discharge continued and, two weeks after the first examination, the patient complained, that within the last two days her face had felt "stiff" and had become paralyzed on the right side.

There was now a complete right facial paralysis. All branches of the nerve supplying the facial musculature were involved. Neurologic examination of the other cranial nerves was negative. The patient had no pain, the mastoid was not tender to pressure and the drum picture was not that usually found in mastoiditis. The drum was incised at this time, in the attempt to provide freer drainage. X-ray examination showed a cloudy mastoid but no breaking down of the cells.

Within a few days sagging of the posterior-superior canal wall developed and the discharge increased in amount. The temperature remained constantly around 99.5 and the facial paralysis continued.

On July 30th, eighteen days after first examined, the patient was prepared for operation.

The laboratory findings at this time were: Wassermann, negative; Hemoglobin, 85%; W. B. C., 11,000; P. M. N., 83%; urinalysis, trace of albumin.

Operation was done under ether anesthesia. On opening the cortex, a pneumatic mastoid was found. The cell-lining mucosa was thickened, but there was no bone necrosis until a number of cells were reached about one-half inch from the mastoid tip along the posterior canal wall in close proximity to the course of the facial nerve. These cells were broken down and about one-fourth drachm of pus was

\*Read before the Richmond Academy of Medicine and Surgery, October 9, 1923.

obtained. No direct connection could be demonstrated by the probe between these cells and the facial canal.

The antrum was located and freely exposed. On careful inspection of the antrum floor, no dehiscence or necrosis of the facial canal could be found. Culture of the pus from the mastoid cavity, obtained at operation, showed a pure culture of pneumococcus—type not determined.

The recovery from the paralysis was rapid. Within three days the patient could partially close the eye on the affected side. On smiling, the face was still pulled to the healthy side. Within ten days after operation the only evidence of a facial paralysis was a slight difference in the naso-labial folds of the two sides. This gradually disappeared, the hearing returned to normal, and the patient was discharged as cured thirty-four days after operation.

As to the underlying pathology: Due to the fact that recovery from the paralysis was so rapid and that there was no demonstrable dehiscence or necrosis of the facial canal wall, the paralysis was probably due to edema within the canal, which quickly subsided as soon as all infectious material was removed.

The case did not offer difficulty in diagnosis since the middle ear disease was present. However, at times there is difficulty in distinguishing Bell's palsy from facial paralysis of otitic origin. Cases are on record of paralysis due to ear involvement in which the drum picture was normal. The apoplectiform character of Bell's palsy usually serves to differentiate it from paralysis complicating otitis media. In the latter condition the onset is gradual.

Facial paralysis complicating acute otitis media is more common in children than in adults since a dehiscence of the facial canal is more frequently found in children.

The occurrence of facial paralysis in chronic otitis media is of dire significance as it points to such conditions as necrosis of the canal wall, cholesteatoma, involvement of the internal ear, brain abscess, or meningitis.

In acute otitis media, facial paralysis is a relative indication for operation; in chronic otitis media it is an absolute indication.

## THE SIGNIFICANCE OF THE EARLY UROLOGICAL LESIONS.\*

By W. T. GAY, M. D., Suffolk, Va.  
Junior Surgeon and Urologist to Lakeview Hospital, Suffolk.

In this brief paper I will not attempt to give any new or heretofore unknown facts. Prompted by the frequency with which we see urological lesions that have progressed to an incurable or dangerous condition because these early symptoms appeared to be so trivial or transient that the true condition was overlooked, even though our improved laboratory methods and instruments of diagnosis probably enable us to make a more correct, positive and localized diagnosis than in any other branch of medicine or surgery of the internal organs; and because these far advanced urological lesions often present such a pitiful and hopeless condition, accompanied by such untold suffering, I will attempt to briefly consider a few of the more important early symptoms.

In studying for the cause of any urological symptom, the matter of first importance is to get a complete history and make a thorough and complete physical examination, especially looking for evidence of tuberculosis, syphilis and focal infection. Probably the most common symptom with which we have to deal is some derangement in the act of urination. Difficulty in the act may vary from a diminution in the size of the stream to a complete obstruction, either of which may come on gradually or suddenly, depending upon its cause, which is variable. We should first determine the presence or absence of stricture, and of a foreign body such as stone, then a rectal examination of the prostate noting any abnormality of its size, shape and consistency. Here it is well to remember that the encroachment on the sphincter is not always in direct proportion to the size of the gland and we may have a very definite prostatic obstruction without any marked palpable enlargement of the gland as determined rectally.

If we are unable to determine the cause thus far, then a cystoscopic examination is necessary to confirm or eliminate some inflammatory condition or polypus in the posterior urethra, or the presence of a vesical stone acting as a ball valve obstruction, or the enlargement of the prostate which could not be detected rectally.

\*Read before the Southside Virginia Medical Association at Suffolk, March 14, 1922.

The cause for painful, burning urination may be local or from some constitutional condition which may cause some change in the chemical composition of the urine, such as the fevers and diabetes. Of the local causes may be mentioned obstruction, urethral or vesical calculi, inflammations of the urethra and bladder. Cystitis, except traumatic from instrumentation, catheterization, etc., is probably always secondary to infection elsewhere, and we should not be contented until we have found its origin either in the lower tract, the kidneys, or some focus outside.

Frequency may be due to an increased output as in diabetes, to nervous excitability or spinal lesions, to prostatic enlargement or new growth in the bladder, or it may be due to purely local conditions, such as urethral and vesical irritation. It is to be remembered that in the young adult frequency, first by day and later nocturnal, is often the first and only symptom of renal tuberculosis. For this reason we should always give the symptom of frequency a careful consideration and not be satisfied until we have utilized all known means to locate the cause early, when treatment can offer the best hope of relief.

Pyuria is probably one of the most frequent urological symptoms and at the same time one of most vital importance. We will exclude pyuria of acute urethritis, which with the other symptoms of acute inflammation is self-evident, and consider the more chronic types. When pus is found in the urine, much information can be had by the three glass tests which tells us whether the pus is coming from the anterior urethra, or from the prostate, or whether it comes from the posterior urethra and beyond. When this method fails to locate the source, a cystoscopic examination is called for. We may find the pus due to some obstruction in the urethra, causing back pressure with a secondary cystitis. It is not uncommon to find that a vesical calculus or diverticulum is present to cause a more or less permanent pyuria. Not being satisfied with the findings in the bladder, we must next investigate the ureters and kidneys. When pus or pus and blood is found coming from the ureters, we have just begun the examination and work from now on is to determine its cause. This we must do by examination of the pus to determine the type of infection, and by func-

tional test to determine the degree of damage to the renal structures. When indicated there should be an X-ray examination of the kidneys and ureters, both before and after the injection of some opaque media, such as the silver preparation, or preferably sodium bromide solution, to determine the presence of a stone, a dilated or kinked ureter, a dilated pelvis, renal destruction, or new growth.

Hematuria, however slight or transient it may be, is a symptom that demands a thorough investigation to determine its source and cause. It arises from a great variety of causes and may come from any part of the genito-urinary tract. Clinically, hematuria may vary from microscopic blood to the proportion of a severe hemorrhage. If due to an inflammatory condition, it is characterized by pain and pus will be found in the urine. But often hematurias are unaccompanied by any degree of pain and these cases constitute a very important group because, being free from pain or having perhaps very slight and transient pain, they are not investigated as they should be. For example, the bleeding from a papilloma or a malignant disease of the bladder is often the first and only symptom of these lesions and intervals of months or even years may elapse between bleedings. The patient in the meantime has acquired a false sense of security, believing that he has been entirely relieved, only to find on the recurrence of hemorrhage that his disease has progressed from one which could have been relieved to that of an incurable condition.

By the two or three glass test we can tell whether the blood comes from the anterior urethra or beyond. When it is uniformly mixed with the urine, its source can only be detected by cystoscopic examination. Symptomless hematuria of either vesical or renal origin may be continuous or intermittent and, if on cystoscopic examination the source cannot be localized in the bladder, ureteral catheterization is called for and it must be remembered that renal hematuria can only be detected when it is active. If not bleeding at the time of the examination, then it is necessary to re-examine during its active stage.

In conclusion, always consider hematuria, however slight or transient, a serious condition until proven otherwise.

Remember that a symptomless pyuria may mean a chronic pyelitis which, if unrecog-

nized and untreated, may lead to a more serious condition—pyonephrosis—with complete destruction of the kidney and even, perhaps, its fellow of the opposite side.

### REPORT OF CASE OF FRACTURE OF ELBOW FROM THROWING BALL.\*

By CHAS. M. HAZEN, M. D., Richmond, Va.

The Academy may recall some radiograms of elbows previously shown in which satisfactory results of treatment eventuated in difficult cases.

In the present report the interesting feature is not so much the corrective procedure, but the etiology, which is somewhat unusual.

We are told in the text-books that "The humerus may be broken by direct or indirect violence, like the other long bones; but also the humerus is more frequently fractured by muscular action than any other bone of this class. It is usually the shaft, just below the insertion of the deltoid, which is broken."

I find in the *Journal of the American Medical Association*, May 23, 1918, reference to the *Progres Medical of Paris*, in which Dr. Senleq reports a "Fracture of the Humerus from Throwing Hand-grenade," and the comment, "Since Phelip reported in 1916 a case of this kind, five similar ones have been encountered. The fracture is in healthy men as they throw the grenade by hand. The bone breaks obliquely into three overlapping pieces, as Senleq shows by a radiogram. Vautrin's patient was an American soldier and the fracture occurred while he was playing ball. Consolidation was not complete until the end of the fourth month. In the other cases one month generally sufficed."

Nothing is said of the exact location of these fractures—of the shaft, of course—whether near elbow, or higher. It is remarkable if in all six cases there were three pieces.

In the case which I am reporting it is the internal condyle of the humerus which has suffered and we are dealing with an *elbow* injury, so classified for study and treatment. The damage is slight compared with that previously described, but not unlike what commonly happens from falling on the arm. The lateral radiogram reveals practically nothing, the anteroposterior shows fragmentation with

some displacement. (The mechanism of the Jones' position will reduce this perfectly).

The points in the diagnosis, without the X-ray, of separation of the internal condyle are (Cotton): "Intact (passive) mechanism of the joint; lack of lateral play in the joint; local tenderness and swelling; thickening at a point near, usually below, the proper site of the epicondyle; sometimes a loose fragment can be made out; pain on active use or on passive stretching of the superficial flexors."

A word here as to the nomenclature and exact anatomy, quoting from Gray: "By some writers the external condyle is called the *external epicondyle* and the internal condyle the *internal epicondyle*." "The external epicondyle (*epicondylus lateralis*) is a small, tubercular eminence, less prominent than the internal, curved a little forward, and giving attachment to the external lateral ligament of the elbow-joint, and to a tendon common to the origin of some of the extensor and supinator muscles."

"The internal epicondyle (*epitrochlea* or *epicondylus medialis*), larger and more prominent, and therefore more liable to injury than the external, is directed a little backward; it gives attachment to the internal lateral ligament, to the *pronator radii teres*, and to a tendon common to the origin of some of the *flexors* of the forearm. The *ulnar nerve* runs in a groove at the back of the internal condyle."

The muscles which pull on the internal condyle produce flexion and pronation. The pronator radii teres arises chiefly from the tendon common to it and the flexors and the intervening fascia, as well as from the humerus just above the condyle and by a lesser head from the coronoid process of the ulna. The action of the pronator is to turn the forearm and palmar surface down.

The flexors arising from the internal condyle are the flexor carpi radialis, ulnaris, sublimis digitorum, and palmaris longus; the deeper muscles with the same functions arise from the bones and fascia below the elbow; they are the flexor profundus, longus pollicis and pronator quadratus.

Referring again to Cotton, "As a rule, the diagnosis is based upon the change in shape of the portion of bone left behind, with the disappearance of the 'hook,' and the changed relation of the ulnar nerve."

\*Read before the Richmond Academy of Medicine and Surgery, June 5, 1923.

This author also concludes that, "The best guide to the success of reposition is palpation. Remember that the external condyle should lie a little higher than the internal and the olecranon only slightly behind the condyles. We may, while holding the fragments firmly, partly extend the arm to test the axis."

He also refers to the marked atrophy (presumably a late result) in the muscles arising from the internal condyle.

The patient in this case is an overgrown boy of 12 years and one would expect his rapid development of bone to favor such an injury. The ossification of the internal condyle begins at the fifth year, considerably earlier than the external, but union with the shaft is not so rapid and is affected at about the age of 18. These facts, and a study of the bodily movements involved in throwing, help to explain why this point should be the one to give way.

All of us have played baseball and a little reminiscence and experiment in the act of throwing, especially with the jerk used in pitching, will recall the strain which comes on the muscles attached to the internal condyle.

An analysis of the act discovers a series and

combination of muscular activities, beginning in the legs and extending to body, shoulder, arm, fore-arm, hand and fingers. A similar aggregation occurs in boxing, in batting, and in the "follow-through" of golf.

The body swings forward on the feet, bends at hips with shoulders moving forward; body twists to side throwing shoulder across, arm swings from shoulder, elbow bends in flexion, forearm pronates, wrist bends flexing hand, fingers flex; ball is delivered.

It is apparent that this maneuver of the body as a whole is in essence flexion and pronation of all the parts which co-operate; it is also evident that the greatest strain, the result of the accumulated momentum of all the combined muscular action, will be felt by the snapper of the whip, which is the forearm and hand. Therefore, the point of greatest strain is the shaft and internal condyle of the humerus, from which arise flexors and pronators.

It may be noted in passing that most pitchers exhibit exaggerated movement, raising the foot high in front before throwing, "winding-up" with shoulders and arms, a lot of "body-English"; most of this is intended to deceive and disconcert the batter, to mask the direction and point of delivery, the rate of speed—like the ancient mask of the Japanese warrior, the stamp of the fencer's foot, the insulting jabber of the pugilist, the wearing remarks of the baseball coach.

The many pictures which are published of our national heroes will demonstrate the points of the argument that the internal condyle is a point which might be expected to be damaged by the muscular act of throwing.

#### SUMMARY.

Radiogram shows fracture—fragmentation of internal condyle of humerus due to throwing ball.

The mechanism of injury is explained as due to the pull on the attachments of flexors and pronator, not only by their own contraction but also as subjected to the whip-like effect of the whole movement of foot, knee, hip, the side-twist of body, the swing of shoulder, the bend of elbow, wrist, fingers.

*Professional Building.*

### NASAL GANGLION NEURALGIA.\*

By M. H. HOOD, M. D., Portsmouth, Va.

A deep feeling of profound regret, though born of a brief and local experience, that in the past, and to some extent at the present, patients with a neurosis of the nasal ganglion have been grossly neglected, and the wish to minimize this number of sufferers, prompts the presentation of this subject.

The patients who suffer either the few or the many and varied symptoms of nasal ganglion neuralgia are not so numerous as are those who present themselves with the more common complaints or diseases, as errors in refraction, tonsillitis, etc., and yet it should be just as humanely important, as scientifically so, that these rather unusual conditions, when presented, should be recognized, diagnosed and the proper therapy applied or administered, as should be in the ones of more frequent occurrence. For several reasons these patients should be, by far, more interesting: (1) Because they are more or less unusual. (2) Because they bear, and plainly present, in a striking manner, the unmistakable ear marks, signs and evidences of uncompromising pain and suffering in their faces and countenances. (3) Because a great number of them are cases of long standing, some of which still endure their torture, without any imbalance of their nervous mechanism, while others who have suffered more intensely have apparently experienced at least a partial imbalance of their nerve forces and, as a result, are frequently referred to us with a so-called nervous breakdown, or as neurotics, neurasthenics, or as those who have been "hipped," etc. Often the patient will inform you that he has consulted every available physician and specialist, and in some cases even the chiropractors, with no result or relief whatever, and they are conscious of the fact that they are the bugbears, meddlers, triflers, pests and naggers of the medical profession. (4) Because when you make an accurate diagnosis in these cases, you must relieve the symptoms at least temporarily and, if treated properly, a favorable prognosis can usually be rendered.

Prior to 1908 the knowledge of rhinologists concerning the nasal ganglion might have been perfect to the letter, according to Gray, Piersol and other recognized texts on anatomy. But

their interests and efforts to simplify and bring together both the anatomical facts and the principles of their physiology to the extent of identifying a singular or separate syndrome (a neurosis) of this ganglion, which might be amenable to treatment, other than excision of the ganglion itself, was utterly lacking. So far as I am informed, it was truly a branch of our speciality, the development of which was practically untouched. To those who grasped the possible idea, it was indeed a ripe and promising field for an unlimited amount of work, by all available talent. Since 1908 there has been more than a considerable amount of work done in this particular field; numerous articles have been written. It has been presented at the various medical societies and associations including city, county, state and national. It occupies a chapter in at least one book and the writer predicts that it will, in the near future, occupy its rightful place in the leading texts of our speciality. The author who has done more work and accomplished most in this special field is unquestionably Dr. Greenfield Shuder, Washington University Medical School, St. Louis, Mo., under whom it was my pleasure and privilege to take my post-graduate work in laryngology and rhinology and whose views I shall follow more or less closely in this paper.

#### ANATOMY.

The sphenopalatine, sphenomaxillary Meckel's, or the nasal ganglion, is one of the four small ganglia associated with the extra-cranial portion of the fifth nerve. Each of these ganglia is a recipient of three roots: motor, sensory and sympathetic. Investigation by various authorities apparently justifies the conclusion that these ganglia are properly recorded as belonging to the sympathetic group. The nasal ganglion consists of an interlacement of nerve fibres; in each are embedded numerous stellate sympathetic neurons. It is a triangular reddish gray body about 5 mm. in length and situated high up in the sphenomaxillary fossa in close proximity with the sphenopalatine foramen, just beneath the maxillary branch of the trigeminal nerve, but for practical purposes, just posterior to, and immediately above the posterior tip of the middle turbinate, from one or two mm. to nine mm. beneath the surface of the nasal mucous membrane.

\*Read at the meeting of the Virginia Society of Oto-Laryngology and Ophthalmology in Richmond, April 18, 1923.

*Roots:* The sensory root consists of the sphenopalatine nerves, also axons of the sympathetic ganglion cells, and dendrites of the cells of the gasserian ganglion. The motor root is the great superficial petrossal nerve, a branch from the facial, and may also carry sensory fibres. The sympathetic root, the great deep petrossal nerve, is a branch from the carotid plexus. The two great petrossal nerves fuse at the middle lacerated foramen to form the vidian nerve. The vidian nerve joins the nasal ganglion, beside giving off nasal branches, and a branch to the pharyngeal ostium of the eustachian orifice receives a filament from the otic ganglion.

*Branches:* The ascending or orbital branches supply the sphenoidal and posterior ethmoidal air cells and the periosteum of the orbit. The descending branches supply the mucous membrane of all but the anterior part of the inferior portion of the inferior turbinate bone, and adjoining portions of the middle and inferior meatuses, the hard palate and its mucous membrane, the inner side of the gum, and the mucous membrane of the soft palate and tonsil, motor filaments to the levator palati, and azygos uvulae muscles. The internal branches supply the mucous membrane of the posterior superior portion of the outer wall of the nasal fossa, the roof and septum of the nose and that portion of the hard palate which lies posterior to the incisor teeth. The posterior branches or pterygopalatine supplies the mucous membrane of the nasopharynx in the region of the fossa of Rösenmuller.

*Anatomical Relations:* Practically all authorities seem to agree that the nasal ganglion is situated high up in the sphenomaxillary fossa and a great many agree that it is in close proximity to, or close to the plane of the sphenopalatine foramen. It is also in close relation to the walls of the sphenoidal sinus, regardless of the variations in the boundaries of the sphenomaxillary fossa, or the irregularities of the sphenoidal air cells whether divided into one or more compartments, or prolonged downward and forward, or downward into the pterygoid process, and in some variations it is as closely associated to the walls of the posterior ethmoidal cell.

In its relation to the lateral wall of the nose the nasal ganglion may be found as superficially as one to two mm. or as deeply seated

as nine mm. from the surface of the mucous membrane.

The nerves and ganglia which are and may be associated with the nasal ganglion should be the basis of possible explanation of referred pain in nasal ganglion neuralgia.

It is directly connected with the nerves in the greater portion of the mucous membrane of the nasal fossa, hard and soft palates and a great portion of the nasopharynx; also the mucous membrane of the post-ethmoidal and sphenoidal air cells, as well as the periosteum of the orbit through its descending internal and ascending branches, respectively. Hence, there is a possibility of pain referred through the ganglion to the root of the nose, hard and soft palates, nasopharynx, parietal eminence, occiput and orbit; also, the possibility of sympathetic manifestations or vasomotor secretory phenomenon in the nose, as in hay fever. It is directly connected with the maxillary nerve since its sensory roots are formed by the palatine branches from the maxillary. Hence, there is the possibility of referred pain being directed along the course of the second division of the fifth. It is directly connected with the vidian nerve through the fusion of its motor and sympathetic roots, the great superficial and deep petrossal nerves, which are branches of the facial nerve and carotid plexus, respectively. And in this manner it is also connected with the facial nerve and carotid plexus. The great deep petrossal nerve represents the association cord between the superior cervical sympathetic and the nasal ganglion. Anatomically, the fibres of the cervical sympathetic from the nasal ganglion pass downward by way of the vidian nerve and carotid plexus to the cervical sympathetic and give branches to the cervical nerves, and proceed finally to the lower cervical ganglion, which is in intimate connection and often fused with the first thoracic. These ganglia are in association, with, or often fused with the nerves, which in addition to supplying the neck, also make up the brachial plexus and supply the upper extremity.

From the evidence at hand, both anatomical and clinical, the following assumptions would seem possible and probably justifiable: (1) That neuralgic pain referred to the root of the nose, to the parietal eminence, to the orbit (deep seated) or along the upper jaw, is of nasal ganglion origin. (2) That the apparent

sympathetic syndrome or vasomotor secretory phenomenon of the nose, as occurs in hay fever, regardless of the season of the year, with the accompanying eye symptoms, originates in the sympathetic elements of the nasal ganglion. (3) That persistent itching of the hard palate, throat, or along the course of any nerve or ganglion with which the nasal ganglion may be associated, could originate in the nasal ganglion. (4) That neuralgic pain referred to the occiput, the neck, shoulders, upper extremities, breast, axilla or shoulder blade, is a vidian neuralgia originating in the sympathetic elements of the nasal ganglion, and that the path of the impulses is from the nasal ganglion through the vidian nerve, upper, middle and lower cervical, and first thoracic ganglia, through the last two of which pass the heart and lung fibres.

From a clinical and therapeutic standpoint we know that we can control many of the neuralgic pains about the eye where no pathology can be demonstrated, as blepharospasm, photophobia, and the like, by cocainization of the nasal ganglion and by means of the same procedure we also know that the symptoms which accompany many pathological processes of the eye, as iritis, corneal ulcer, keratitis, etc., can be controlled. Since the ophthalmic symptoms with or without demonstrable pathology, in reference to the nasal ganglion, are only clinical and therapeutic facts, there is no positive anatomical explanation, so far as I am aware, but a reasonable assumption seems to be that these are referred pains or vaso-motor secretory manifestations from the nasal ganglion, but by way of what branches these impulses travel, no one has thus far been able to determine. A more complete knowledge of the anatomy and physiology of this apparent nerve mechanism is wanting.

#### SYMPTOMATOLOGY.

The symptoms occur in the form of syndromes, namely: The neuralgic, the sympathetic, or a combination of the two.

*The Neuralgic Syndrome:* Frequently the neuralgic symptoms appear following a mild, moderate or dreadful head cold or coryza. The pain begins usually at the root of the nose, in and about the eye, upper jaw and teeth, and sometimes the lower jaw and teeth are involved, and extends posteriorly along the temple, zygoma, about the ear including the mas-

toid process, with special emphasis of a tender spot just behind the mastoid process. Then it extends backward to the occiput, down the neck into the shoulder, and may continue throughout the upper extremity; or it may be directed to the shoulder, axilla or breast. The pain in the neuralgic syndrome seems to vary as to location, occurrence and severity. As to location, it may be present at any one or more, or even in all the anatomical regions, as mentioned above. As to occurrence, the attacks may occur day or night, without warning, and may last from a few minutes to hours, days, weeks, and in some cases it remains more or less constant. As to severity, in mild cases there may only be a sensation of tightness or drawing, or a sensation of the teeth being too long on the affected side, stuffy ears, aching throat, itching of the hard palate, stiffness or rheumatism of the neck and shoulders. In the more severe cases, the pain is described by patients as a ball of fire, a knife cutting, or a drill, drilling into some nerve; or like an electric current turned loose in the nose, eyes or head. This pain is excruciating and unbearable.

*The Sympathetic Syndrome:* This type apparently occurs with less frequency than the neuralgic syndrome. A history of the sympathetic syndrome coming on with, or following a coryza may or may not be obtainable. The most striking thing occurring in this syndrome is the vasomotor secretory phenomenon, which usually occurs in the following manner: During any season of the year, without any warning whatsoever, the patient is suddenly seized with sneezing spells which give rise to simultaneous congestion of the nasal mucous membrane and with an unlimited quantity of thin, hot, watery and irritating nasal discharge. The entire nose becomes red and congested. The ophthalmic disturbances appear immediately after the onset of sneezing. The conjunctivae become noticeably red and congested. The eyes may itch and burn. Lacrimation has already begun. Pupils become dilated, lids wide open, and the patient presents the appearance of staring. Photophobia may be marked even with the patient in a well darkened room. Near work becomes very difficult, if attempted. If these patients are properly treated, the symptoms usually subside immediately, not to return. If these cases go on and establish themselves into morning sneezing (rhinitis

nervosa, vasomotor rhinitis or hay fever), it appears to be a purely sympathetic syndrome. Often these patients who have sympathetic symptoms also suffer some of the neuralgic manifestations, but they will not consent to have their so-called rheumatism, stiffness of the muscles and neuritis of the neck and shoulders, or even any part of a lower half neuralgic headache connected in any way whatsoever with their morning sneezing. Following these cases further, Dr. Sluder says, "It appears that the syndrome becomes subdivided and betrays itself as single symptoms, namely: eye ache, ear ache, tooth ache, neck ache, etc., so it happens that the sympathetic symptom-complex may present a single symptom, sneezing, or eye disturbances which simulate low-grade conjunctivitis, with asthenopia." Dr. Sluder also says he has seen asthmatics of nasal ganglion origin, and proved it by cocainizing and injecting the ganglion, which relieved the asthmatic attacks immediately, and a few times he has seen a red external nose (rosacea) that was of nasal ganglion origin. Why in a neurosis of the nasal ganglion one group of patients will suffer only the neuralgic syndrome in its entirety or in part, another group will be victims of only the sympathetic syndrome, and still another or third group will be subjected to the symptoms of both the neuralgic and sympathetic syndromes, to any extent and degree, no clear statement has as yet been made.

#### DIAGNOSIS.

With the symptomatology as given above, present in part or as a whole, the diagnosis is practically completed or confirmed by the immediate cessation of all symptoms, as the result of cocainization of the nasal ganglion. This procedure should be repeated two or three times at separate sittings, when symptoms are at their height, to avoid error in diagnosis. In doubtful cases it should be repeated on several occasions and with constant findings only, as relief of all symptoms should be construed as evidence of nasal ganglion neuralgia.

It must be differentiated from sphenoidal and post-ethmoidal infections as suppurative and hyperplastic, which Dr. Sluder forcefully emphasizes is easily done by the results and effects obtained through cocainization of the ganglion. In a neurosis of the ganglion, all the symptoms are relieved in ten minutes, while in

sphenoidal and posterior ethmoidal infections it has no effect whatever, because the lesion is central to the ganglion, in which case intrasphenoidal applications of cocaine will relieve.

In the sympathetic syndrome, where the vasomotor secretory phenomenon predominates, as in hay fever, it has been the custom of Dr. Sluder and his associates first to have the patient desensitized to any given pollen or protein to which the patient may be sensitive. If he is permanently relieved, no other procedure is necessary. If it is found that the patient is not sensitive to any pollen or foreign protein, or if sensitive and the administration of the given pollen or protein does not relieve the symptoms, then the nasal ganglion is cocainized repeatedly, and, if relieved of the sneezing attacks by this procedure, the diagnosis of nasal ganglion neuralgia, sympathetic type, is rendered.

The recognition and diagnosis of the cause of a neurosis of the nasal ganglion would seem to appear as mechanical and as an extension of infection or toxins from infection: mechanical, as nasal obstruction or deflection of the nasal septum; extension of infection or toxins from infection, as coryza, especially in the region of the ganglion, or from sinusitis, as sphenoidal and post-ethmoidal.

#### PROGNOSIS.

The prognosis seems to be very favorable when an accurate diagnosis has been made, and treatment administered with equally as much accuracy and skill.

#### TREATMENT.

In a few of the mild cases, cocainization of the ganglion and the application of 2% solution of silver nitrate, or a 4/10% gaseous solution of formaldehyd to the sphenopalatine district one or two times weekly, for from two to four weeks, is of great value; and in some cases it seems to give permanent relief for both the neuralgic and sympathetic syndromes. For the more severe cases, Dr. Sluder injects, and recommends the injection of the nasal ganglion with  $\frac{1}{2}$  c.c. of 5% phenol in 95% grain alcohol, after complete cocainization of the ganglion has been obtained. This procedure may give relief for years and it may be permanent; or in some cases the injection of the ganglion may be required as often as once a year.

In our small series of cases, eleven in all

who submitted to treatment and one who would not submit to treatment—neuralgic 7, mixed 1, sympathetic 3—we have not found it necessary to inject the nasal ganglion. While we are aware that such a neuralgia may be present without nasal obstruction, yet in the few cases under our observation and treatment, whether mild or severe, neuralgic or sympathetic in type, we observed a moderately or markedly deflected septum and always present only, or more marked on, the side of the deflection.

*Treatment:* Regardless of type or severity, with the exception of only the 12th case, our treatment has been the same. In this case cocaineization of the nasal ganglion and application of silver nitrate, 2%, to the sphenopalatine district was given on two occasions. This patient has a deflected septum but refuses operative procedure. She still suffers moderate attacks of nasal ganglion neuralgia. The treatment of our other cases has consisted of submucous resection.

*Results:* Six of the seven cases with the neuralgic syndrome have been completely relieved. The other case is 90% cured according to her statement. Two of the three with the sympathetic syndrome have been entirely relieved. The mixed case also has complete relief. The post-operative period in these cases varies from two months to two years and three months.

Only two and a half years having elapsed since my partner, Dr. L. Leroy Jones, and I have become interested in and worked on nasal ganglion neurosis, so we deem it unwise to draw conclusions. From our experience, however, we believe it as worthy of the conscientious efforts, further scientific investigation and professional skill of the ablest men in our speciality, as any subject within its scope.

*Professional Building.*

### THE CIRCULATION IN THE INFECTIONS OTHER THAN ENDOCARDITIS, RHEUMATIC FEVER, AND SYPHILIS.\*

By FREDERICK R. TAYLOR, B. S., M. D., High Point, N. C.

I was originally asked to write a paper for this heart symposium on myocarditis in the infections, but I have changed this title to the present one for two reasons—first, the exact meaning of the term myocarditis is somewhat uncertain, as some would include cloudy swell-

ing and other degenerative processes while others would stick to the etymology of the word and include only strictly inflammatory processes; and second, because many serious circulatory conditions during and after infections, even sudden death, are often quite as much vasomotor in origin as they are myocardial, though the myocardium is usually blamed for the situation. It seems unwise, then, to attempt to limit our discussion to the myocardium, and I believe it will be more profitable to consider the entire circulation as a functioning unit, and to speak of circulatory weakness or circulatory failure, rather than of pure myocardial disease.

I have excluded endocarditis because I understand that this large subject is to be handled in a separate paper, as it should be; and rheumatic fever, that great destroyer of the heart, though it usually produces a carditis, so frequently leaves its indelible marks in the endocardium, that we naturally associate the two conditions. Syphilis has been excluded because this society has so recently discussed it in a special symposium.

We will begin with the statement that from symptoms and physical signs it is often impossible to distinguish between a weak myocardium and an unstable vasomotor mechanism, though this should be done when possible. The electrocardiograph may help us in this matter, but I am not competent to discuss that, and most patients suffering from infections do not have access to that instrument.

One of the simplest evidences of the effect of the infections on the circulation is the character of the pulse in fever. We speak of the pulse frequency being in proportion to the temperature, but in the very next breath we begin to recite a list of exceptions to this rule, such as typhoid fever, smallpox, influenza, etc. This relation between pulse and temperature curves is a very useful observation, by no means to be cast aside, but it would probably be more correct, if we wish to generalize, to state, as Ivy Mackenzie does, that the pulse varies in fever, not according to the temperature, but according to the specific properties and affinities of the poisons which are generated, directly or indirectly, in the course of the infection. It has been observed that the slow pulse of typhoid fever is not accelerated by atropin, thus differentiating it from the pulse in many

\*Read before the High Point meeting of the Guilford County Medical Society.

other diseases and in health. This is highly suggestive of the importance in certain infections of a toxic effect on the regulatory mechanism of the circulation as well as on the heart and vessels.

It has been well said that pathological anatomy is the groundwork of modern medicine, but there are many important circulatory conditions which it does not explain, especially certain transitory toxic symptoms. The best pathologists sometimes fail at post mortem to find an anatomic explanation of a death. Many well known chemical poisons, such as strychnin, morphin, nicotin, pilocarpin, etc., may kill quickly without leaving recognizable anatomic changes, and it is just as reasonable that toxic conditions resulting from infections often leave no anatomic trace.

Albuminous degeneration or cloudy swelling of the myocardium is very frequent in the infections, but we know little of its clinical significance.

We used to hear much of fatty degeneration and fatty infiltration, but again hear what Ivy Mackenzie has to say in his chapter on "The Circulation in Infectious and Toxic Processes" in Volume II of *Oxford Medicine*. He states that the clinical importance of fatty *degeneration* has been much overestimated in infectious and toxic states, and that it does not exercise a determining influence on the course of events. He further states that fatty *infiltration* has no association with infectious or toxic processes, though by its presence it may render the heart more liable to premature exhaustion in toxic states.

Waxy and hyalin degeneration of the myocardium are sometimes seen in special diseases, notably typhoid fever and diphtheria, where they may also occur in the skeletal muscles.

Necrosis may occur with septic infarction in pyemia, but this is of no special importance, as the whole body is then overwhelmed with a necessarily fatal condition. Brown atrophy, seen in advanced pulmonary tuberculosis, is also of no clinical importance.

In the strictest sense of the term, myocarditis is rare in the infections as a whole. It is the rule in acute rheumatic fever as part of a carditis, it is fairly frequent in diphtheria, especially when treatment is not given early, and it is occasionally seen in typhoid fever. Ivy Mackenzie describes an acute idiopathic myocarditis which runs a rapidly fatal course

typical of a general infection, with the only gross evidence of disease at autopsy in the myocardium. The condition does not seem to be widely recognized as a clinical entity, and I know nothing of it from personal observation.

Apart from chronic rheumatic infection of the heart and cardiac syphilis, chronic myocarditis in the strict sense of the word does not exist, though a fibrosis of the heart is common.

We must confess that we often cannot make any accurate estimate of the state of the myocardium in many acute infections such as pneumonia, scarlet fever, measles, smallpox, influenza, etc. In many of these the heart may be rapid or slow. The sounds may be feeble, but this is not necessarily evidence of myocardial disease. The heart sounds may be feeble in a syncopal attack, but syncopal attacks, with the exception of Stokes-Adams disease, are vasomotor in origin rather than myocardial. So the weak sounds in infectious diseases may be in part due to a disorder of the nervous mechanism regulating the circulation.

Certain cases of sudden death without dyspnea, cyanosis, or edema, during or soon after an acute infection, are commonly attributed to "acute dilatation of the heart." Acute dilatation of the heart without dyspnea or cyanosis is a difficult thing to explain and, when at autopsy we find a tremendous engorgement of the splanchnic vessels, and recall that during the fatal attack pallor and general collapse were the cardinal elements of the picture—in short, that the condition was absolutely typical of shock—it makes us pause to inquire if our long cherished views concerning heart failure in the infections are adequate. We dare not say that the heart was in no degree responsible, but surely the picture implicates the vasomotor mechanism, and we should really speak of death from *acute circulatory failure*, rather than call the whole process acute dilatation of the heart. The one is stating something that we know to be a fact, the other is assuming something we do not know and cannot prove to be true.

I will not say much about the arrhythmias in the infections, as the paper on graphic cardiologic methods will no doubt deal exhaustively with them. However, many types of arrhythmia should be recognized on physical examination. Sinus arrhythmia is of no importance,

and is usually easily recognized by the fact that the pulse becomes faster during inspiration, especially towards the end thereof, and slows during expiration, and especially during the pause following expiration. Extrasystoles are characterized by premature heart beats which often do not reach the radial pulse, followed by a compensatory pause which brings the pulse back into the dominant rhythm. A series of several extrasystoles in succession may be confusing, and require graphic methods to demonstrate their true nature. Extrasystoles *per se* mean nothing, but, taken in connection with other circulatory abnormalities such as valvular disease, arteriosclerosis, high blood pressure, etc., or in the presence of nephritis, may be of ill omen. Auricular fibrillation, characterized by a total irregularity of the pulse, absolutely without any dominant rhythm is common in a failing circulation, and is usually evidence of a damaged or badly fatigued heart muscle. Auricular flutter is hard to diagnose without graphic methods. John Hay gives the following criteria for the suspicion of it: a persistent steady pulse rate of 120 and over, not materially modified by rest, movement, or emotion, which, on the administration of digitalis, either shows a sudden marked slowing or develops an arhythmia. A peculiar arhythmia sometimes occurs in flutter that is highly suggestive, and that is, an alternating series of rapid and slow pulse beats, the fast ones being about double the frequency of the slow ones, without any relation to the respiratory phases, and without any compensatory pauses. I recently saw Dr. Henry A. Christian make a provisional diagnosis of flutter on the strength of this arhythmia, and confirm it with an electrocardiogram, in a patient desperately ill with pneumonia.

Sir James Mackenzie has done us a great service in diverting our attention from the minutiae of murmurs to the vital question of the state of the myocardium, and the presence or absence of the phenomena of decompensation, but let us not be too insistent on focusing our attention exclusively on the myocardium. We must consider the whole circulation as a functioning unit, and ask not simply "What is the state of the heart muscle?", but "What is the state of the circulation?"

There is a syndrome common after any severe prolonged strain, frequently seen after the

acute infections, known under various names such as neurocirculatory asthenia, disordered action of the heart, irritable heart of soldiers, etc. Just what it is we do not know, but it is certainly not exclusively myocardial, it does have pronounced vasomotor features, and the nervous system may be affected in various other ways. The prognosis is good in the long run, but the condition is often an obstinate one.

Rest is the one prime essential in the treatment of the circulation during an acute infection. Little other treatment is indicated unless there is definite evidence of circulatory weakness. Someone will at this point no doubt raise the question of routine early digitalization of pneumonia patients. I do not have the slightest objection to it, and, indeed, commonly practice it, for it at least has the definite advantage of giving one time to find out whether one has an active preparation of digitalis or not. Other than this, with modern methods of rapid digitalization, the value of the method may be open to question. This may sound like heresy and, until recently, I should have stoutly supported the routine digitalization of pneumonia patients as essential, but let me quote from a letter received from Dr. Henry A. Christian dated June 28, 1921. He writes, "As to digitalization in pneumonia, I myself doubt its value. In my judgment it is not at all necessary now that with large doses we can get a quick digitalis effect. Herein is one of those curious happenings which we often see. In Cohn's work on pneumonia he found a considerable number of cases of fibrillation, etc., in his first 100 cases of pneumonia, and preached digitalis as a result. In his subsequent studies he found very few cases in which cardiac conditions arose likely to be benefited by digitalis. The latter has certainly been my experience." Again Dr. Christian writes on July 16, 1921, "Except for those cases of pneumonia developing auricular fibrillation or some other similar cardiac disturbance, or in those cases already having a cardiac insufficiency before the pneumonia, I personally do not think that digitalis will accomplish anything."

When definite evidence of circulatory weakness appears in an acute infection, we must try to consider so far as possible the type of disturbance confronting us, in order to give the most effective treatment. There are three types commonly met with.

1. Typical cardiac decompensation, with dyspnea, cyanosis, edema, etc. It is in this type that morphin and atropin given at the onset exhibit their happiest effects. This must be supplemented with digitalis, given until re-results are obtained. The initial dose of digitalis should be rather large though I confess I have never yet resorted to a single dose of a half an ounce of the tincture intravenously. Half a dram to a dram of the tincture, or 3 to 5 grains of the powdered leaves has seemed to me sufficient in most of my patients as an initial dose, and subsequent doses will be calculated according to the effect of the first one, being reduced as soon as a digitalis effect becomes apparent.

2. The second type of circulatory weakness encountered in the infections is that type above mentioned which presents a picture of shock, and the treatment is the treatment of shock—warmth, stimulation, intravenous saline containing adrenalin, bandaging the extremities, etc. However, as stated above, we cannot completely separate cardiac failure from vasomotor failure or other disturbance of the regulatory mechanism of the circulation such as vagal disturbances, etc., and during and ever since my service as resident physician in the Germantown Hospital, Philadelphia, it has been my practice in severe circulatory failure to give a variety of drugs in sequence, with the idea of working on various parts of the circulatory apparatus in succession, and avoiding over-stimulation of any one part. My usual scheme of treatment, which seems to have been justified, at least in some cases, by results, is to use four drugs in sequence, giving each drug every eight hours, so that the patient gets one or another every two hours. These drugs are digitalis, atropin, camphor, and caffeine. They may be given in any order, though it is well to have a dose of atropin due early in the night, and to combine morphin with it if the patient is restless. All except the digitalis are given hypodermically, and that is so given if the patient cannot take it by mouth. I have for years believed that better results can be obtained in this way in acute circulatory failure than by using a single drug, and this is in accord with the theory that the whole circulation fails rather than the heart alone. In addition to the drugs mentioned, if the patient is given to “sinking spells” which alarm the family,

there is no harm in giving aromatic ammonia at any time if he can take it, as its action is very fleeting. I follow Crile in believing that strychnin is harmful in shock or in acute circulatory failure of any kind.

3. Neurocirculatory asthenia persisting after convalescence from an infection is well established, requires different treatment than other forms of circulatory weakness. Here absolute rest is usually inadvisable. Judicious exercise, especially exercise enjoyable to the patient, such as that obtained from games requiring only moderate effort, is beneficial from both its physical and psychic effects. However, care must be taken to avoid over-exertion.

There is a possibility that the general asthenia so characteristically following influenza may be due to adrenal insufficiency, but in this endocrinomaniac age we must adopt the scientific attitude of the gentleman from Missouri. Again let me quote from a personal communication from Dr. Christian, dated October 17, 1921. “Finally, in regard to adrenal insufficiency in influenza, I do not think you will find anything about it in my chapter on influenza, (i. e., in *Oxford Medicine*) and I doubt whether there is any association. However, one of my associates brought up the point as, in studying some of the cases, he felt that there was a considerable number of patients who showed hemorrhages into the adrenal in cases of influenza. I do not know whether he ever went over enough cases and checked up these lesions to justify any final statement. The adrenal is an organ which lends itself rather easily to artefacts, and one has to be very careful in drawing conclusions from what you find in the adrenals at death. I pointed this out to him at the time. I will find out whether he did any more about it, and will keep my eye opened for descriptions of lesions in this organ.”

Since receiving this letter from Dr. Christian I have not seen anything further on this subject, so suppose it is still at least very doubtful whether adrenal insufficiency exists in these cases.

In closing, let me emphasize that I do not believe any routine scheme of treatment is applicable to all cases, and it is always necessary to meet individual needs as they arise. The best of care will not always prevent the Grim Reaper from harvesting in childhood, youth,

and maturity, by means of circulatory failure in the infections, but there is no greater joy than the realization that in an occasional case one has been privileged to stay his hand and restore to health a patient in the morning or the high noon of life, whose presence can for years to come be a blessing to his family and community.

## PLEURISY—ITS ETIOLOGY AND SIGNIFICANCE.\*

By L. F. COSBY, M. D., Abingdon, Va.

In making the above selection for a subject of this paper, I had several topics in mind when this idea came to me as being one of the best and most difficult subjects that I might have selected, so if I make many grave errors or misstatements, please be kind hearted and overlook them. As all of you gentlemen know, this is one disease that is most overlooked by the men in general practice, and the one that receives the least attention of physicians. How many of us pass up a case of pleurisy by not even examining the chest and by telling the patient that he or she has "intercostal neuralgia, nervous indigestion, or that it might be a touch of muscular rheumatism." The above facts, to which I plead guilty, proved the incentive that made me take the above subject for discussion.

Pleurisy or pleuritis is an inflammation of the pleural membranes that may involve their parietal, visceral or diaphragmatic coverings.

*Etiology*—The inflammatory signs may be confined to the pleura, in which case it may be spoken of as primary. The simplest form follows exposure to cold. In all probability the majority of these pleurisies are not primary but represent the localized flaring up of an old inflammatory process in the neighboring tissues of lung and glands. Photographs of the X-ray reveal the presence of old tubercular areas in the region of many pleurisies, wherein the ordinary methods of diagnosis present only the evidence of the pleural involvement. The tubercular pleurisy is always secondary to an older focus of infection.

Secondary pleurisy has its origin in (1) extension of inflammation from the lungs, especially in pneumonia, tuberculosis, pulmonary abscess and lung infarcts; (2) extension of inflammation from adjacent organs and struc-

tures, notably in pericarditis, mediastinitis, bronchial lymphadenitis, and following perforation of the diaphragm from liver abscess or cancer of the stomach; (3) metastatic infection from tonsillitis, articular rheumatism or general septicemia; (4) association with chronic diseases such as nephritis, leukaemia and gout.

The lung, enveloped as it is by the visceral pleura, is responsible for the greatest number of pleurisies. Nearly every form of inflammation of the lung involves the pleura sooner or later, whether it be pneumonia, tuberculosis abscess or infarct. Frequently the pleuritis is obscured by the overshadowing signs of lung inflammation, though the presence of pain is always indicative of pleurisy or pleural involvement.

*Bacteriology*—The exact determination of bacteria responsible for pleurisy is not always possible. The sputum and pleural exudate offer the best material for examination. But in both media secondary invaders may dominate over the original organisms. The bacteria commonly found are the tubercle bacillus, pneumococcus and streptococcus. Other organisms occasionally obtained from pleural exudates are Friedlander's bacillus, influenza bacillus, diphtheria bacillus, and typhoid bacillus. It is interesting to note that pleurisy is relatively rare in three diseases in which pulmonary complications are often present, influenza, typhoid and measles. The leukopenic characteristic of these infections may offer an explanation of this fact. Mixed infections of pyogenic organisms with tubercle bacillus are common and often, when cocci only can be found in the exudate, a primary tuberculous inflammation may be diagnosed by the general physical findings.

The morbid anatomy we will not discuss as all of you are familiar with the pathological findings in this disease.

Before going further, I would like to make a few remarks concerning the "Absorptive power of the pleura." The channels through which the products of absorption flow are the endothelial cells, lining the pleura, the lymphatics and the blood vessels. Fibrin is reduced to a state of liquefaction preliminary to absorption. Fluids are taken up under certain conditions by the blood and disseminated through various parts of the body. Experiments have shown that a hypertonic salt solu-

\*Read at meeting of Sullivan, Johnson and Carter County, (Tenn.) Medical Society at Bristol, Va.-Tenn., June 1923.

tion introduced into the pleural cavity is followed by increase in the fluid content within a few hours. *Per contra* a hypotonic salt solution is rapidly absorbed.

*Clinical Types of Pleurisy*—The clinical course of pleurisy may end after the fibrinous stage, it may go onto the stage of effusion, or it may terminate in the formation of pus. There are usually three types of pleurisy recognized for descriptive and diagnostic purposes and these types are dry or fibrinous pleurisy, pleurisy with effusion, and empyema. In addition, there are a number of atypical forms which we will not discuss, being of lesser importance than the ones mentioned above.

*Dry Fibrinous Pleurisy—Etiology:* This condition is an inflammation of the pleura associated with an exudate of fibrin. The cause of fibrinous pleurisy in order of their frequency are the tubercle bacillus, pneumococcus and streptococcus. Nearly all of the dry pleurisies are of tubercular origin, a point that all practitioners should remember and bear in mind when treating a case of this kind.

*Pleurisy with Effusion*—This is an inflammation of the pleura associated with an exudate that may be serous, serofibrinous or hemorrhagic. *Etiology:* It is well to keep in mind that all the clinical types of pleurisy are arbitrarily classified. A dry pleurisy more often than not will yield a few drops of fluid, mostly serum to the exploring trocar. The terms employed are derived from the predominating elements found in the exudate, fibrin, serum, blood and pus. The factors determining the proportion of these elements are unknown or only partially understood. For lack of specific information we assume that the quality and virulence of the germ on the one hand and the individual reaction of the tissues on the other hand are chiefly concerned. But the type of inflammation that will be excited by a germ organism cannot be predicted. Thus the tubercle bacillus may cause a simple fibrinous, serous, hemorrhagic or purulent exudate. A pneumococcus pleurisy may terminate in the fibrinous, serofibrinous or purulent stage. The same variety of exudate prevails in pleurisies accompanying pneumonia and cancer.

The serous or serofibrinous effusion with an amount of fluid sufficient to give physical signs is generally of tuberculous origin. It is estimated that between seventy and eighty per cent of all cases are tuberculous. Only rarely

can the tubercle bacillus be recovered on a cover glass preparation or in the cultures, but the inoculation of guinea pigs with the fluid causes death from tuberculosis in a high percentage of the cases. Frequently too, an effusion occurs in association with tuberculous lesions in the lungs and bronchial glands. Serous exudates of the pneumococcus origin are less common than the fibrinous. They have a greater tendency to become purulent than the tuberculous forms and are usually more localized. Occasionally streptococcus effusions remain serous but all the pyogenic cocci show a disposition to pus formation.

It might be well at this part of the paper to take a little time and discuss the diagnosis of pleurisy with effusion.

The recognition of a primary serous pleurisy ordinarily presents little difficulty, because the physical signs are characteristic. The secondary cases need to be differentiated from pneumonia. Both effusion and consolidation give dullness and may exhibit bronchophony, but in the latter the viscera are not displaced. A thickened pleura is not always easy to distinguish from pleural effusion, and the two conditions may both be present. Exploratory puncture will clear up the diagnosis. Puncture is also necessary to definitely diagnose a small or circumscribed exudate. A tumor mass may give rise to flatness on percussion and its presence is often suspected for the first time after a dry tapping, a point well to be remembered.

*Empyema* is a pleurisy with purulent effusion. *Etiology:* The exudate may be purulent from the beginning, but usually it starts from a seropurulent effusion and gradually acquires a thicker consistency as the pus cells increase. The pneumococcus and streptococcus are the common etiological germs found in the exudate. According to most observers, the pneumococcus is the causative organism in about half of all cases in hospital practice. Lord, in his series of empyemas, found streptococcus in 39.4 per cent, pneumococcus in 20.4 per cent, staphylococcus in 3.6 per cent, and mixed infections in 16 per cent. The pus was sterile in 18 per cent, and many of this group were tuberculous. But during the war period the statistics show a predominance of the streptococcus. The great epidemics of measles, influenza and streptococcus pneumonia were associated with an overwhelming proportion of

streptococcic empyemas. Empyema is generally a complication of some lung inflammation. In military practice, penetrating wounds of the chest contribute a fair share of the cases.

Having outlined and discussed the various etiological factors of pleurisy in the foregoing statements, I wish to lay stress on one or two points which I think will be of interest to all. During my student days in medicine, I remember well the statement that our professor in medicine made, "that an idiopathic pleurisy" was always tubercular in origin, and in after years in practice I had a case which was very interesting, of which I will give a brief outline.

Female, white, age twenty-four, of good social and moral standing, married, complained of anorexia, mental torpor, and a general down and out feeling which had been going on for several weeks, accompanied by a slight feeling of discomfort and occasional pain in right chest. She had always been a strong and healthy girl, had the usual diseases of childhood, no serious illness of any kind, and, since marriage, had given birth to one strong and healthy girl baby.

Upon physical examination I could not make out anything in the chest except a slight pleural rub in right lower chest, which was not accompanied by pain on deep inspiration or expiration. Thinking possibly that there might be some pulmonary involvement, I made several examinations of the chest, but always found it negative. Abdomen was negative at all times, while she was under my care. Urine and blood normal, as well as temperature and pulse. Bearing in mind that there might be a possible focus of infection that I had overlooked, I advised her to go to a T. B. specialist, which she did, and he reported negative findings in her chest. About three months after this illness she was taken suddenly ill with a severe colicky pain in right lower abdomen and elevation of temperature, slight nausea, but no vomiting. She was immediately taken to a hospital, where the regular routine examination was made and the only thing of interest was rigid right rectus, and elevated temperature, blood and urine being normal. The surgeon advised operation under local anesthesia and, upon opening up the abdomen, he found a badly inflamed appendix with a localized peritonitis with quite an exudate which proved to be tubercular.

I simply mention this case to show you that while the main initial symptoms in the chest were pleuritic in character, it developed later on that the appendix was the seat of trouble. After convalescing from the operation, this patient again went to a chest specialist and he reported negative findings, and today she is a strong and robust woman.

Before closing this paper I would like to impress the importance of making a thorough physical examination in all cases which come to you complaining of a pain in the chest. The average physician, I am sorry to say, does not make a thorough examination of all patients, but I am sure, if he should do so, he would find that he would be able to clear up a good many obscure cases and that he would make a better impression on his clientele.

#### OCULAR INTERPRETATIONS IN THE DIAGNOSIS OF SYSTEMIC DISEASE.\*

By HUNTER H. McGUIRE, M. D., Winchester, Va.

First, I desire to express my appreciation for the honor conferred upon me at your last meeting, when you saw fit to elevate me to the presidency of an association which, though young in years, is already assuming a prominent position in developing scientific medicine in this great old Commonwealth. I liked to feel, however, that your action has been the result more of a desire, on the part of this Association, to give public recognition to the specialty I represent, than to honor me personally, and I sincerely hope that such has been the case.

It is with this thought in mind that I feel constrained to point out very briefly some of the great developments in the science of ophthalmology in recent years and to emphasize what these developments have meant to internal medicine. That ophthalmology has more than kept pace with the other branches of medicine is without question, and that it has become to be recognized as one of the most important specialties of medicine can be asserted with equal emphasis.

It is a significant fact that the policies of a great medical organization, the American Medical Association, are, this year, being guided and directed by an able representative of ophthalmic science, Dr. George E. de Schweinitz, of Philadelphia. This one fact, it seems to me, indicates that the medical pro-

\*Address of president before the Medical Association of the Valley of Virginia in Winchester, May 31, 1923.

fession of this country has been impressed by the contributions ophthalmologists have made concerning ocular interpretations in the diagnosis and treatment of constitutional disease. It is, therefore, with the view of enlisting your sympathy and interest in this phase of the work that I wish to direct your attention to a few ophthalmoscopic conditions which in themselves point to certain pathologic processes in distant organs, and to make some comments upon visual field changes in the diagnosis of certain diseases of central origin.

The ocular changes in the various forms of nephritis, manifesting themselves in exudative types of retinitis with retinal hemorrhages and occasionally optic neuritis, are always discussed in textbook articles pertaining to this subject, and yet how often are these patients first seen by the ophthalmologist, after a destructive pathologic process in the kidney has practically doomed its victim.

We hear much these days of arteriosclerosis. In fact, it might be said that it has become to be a fashionable disease, and the man who can boast of hardened vessels and a high blood pressure at once assumes an air of distinction, which his less fortunate fellowmen are unable to obtain. In general arteriosclerosis, the retinal vessels of course share and, while it is not possible in all cases to detect any evidence of the disease with the ophthalmoscope, in the great majority it is possible to do so: consequently, arteriosclerosis is one of the diseases often first discovered by the ophthalmologist.

It is a well known fact that the retinal vessels can be examined during life with a minuteness that is not possible with any other vessel of the body, for they are seen with great distinctness and under a magnification of about 15 diameters: thus, changes in their structure are readily detected, and the progress of the changes can be traced. It would be interesting, if time permitted, to describe these changes from the incipient stage of the disease to the stage where we are able to observe almost complete obliteration of the vessel.

The uveal tract, because of a generous blood supply, is a favorite location for evidences of constitutional disease. The great vascularity of this structure with frequent anastomoses of the large sized vessels appears to furnish a particularly fertile soil for the elimination of bacteria or their toxins, and we not infrequently find here manifestations of disease before it

is discovered in other parts of the body. As examples of such instances may be mentioned syphilis, tuberculosis, dental disease and gastro-intestinal disturbances.

The various changes we find in the optic nerve, originating from new growths in the brain or toxins in the blood stream, ranging from a slight hyperemia to choked disc, the slowly progressive optic atrophy of luetic origin, the picture indicative of pituitary body disease, are manifestations which deserve the attention of the internist and neurologist, in the study of their cases, and should not be overlooked in reaching logical conclusions in the diagnosis of disease.

It is not possible even to mention many important ophthalmoscopic changes which should concern the internist in his analysis of an individual case and my sole desire in bringing this subject to your attention is to emphasize the importance of complete ophthalmoscopic investigation in the diagnosis of those diseases in which we know ocular changes occur.

In the present state of our knowledge and in the rapidly developing methods of accuracy in diagnosis, we are frequently overlooking very important symptoms if we fail to study the eye-ground.

The ophthalmoscope should be as universally employed as the stethoscope. I do not mean to intimate that the general medical practitioner, or even the specialist in internal medicine, will be able to interpret eye-ground changes with the same degree of accuracy as the trained ophthalmologist but I do feel that, with the new type of electric ophthalmoscope and a reasonable degree of practice, he will be able to recognize departures from the normal. He certainly should be in a position to determine whether he is dealing with a healthy or diseased fundus and can, if necessary, call to his assistance an eye man for the interpretation of the clinical picture.

The ophthalmoscope of Hemholtz, which has in the process of development attained a greater degree of efficiency in the present electric instrument, has opened up a field of investigation, the value of which cannot be estimated, but ophthalmology is now in a position to assure the medical world that an even greater field of investigation is shortly to be developed. The advent of the slit lamp of Gullstrand, an instrument with which it has become possible to study the microscopical

structure of the living eye and thereby recognize pathological changes in the cellular tissues, promises to revolutionize ocular pathology. While yet in its infancy, both American and European investigators, in their researches, have convinced the ophthalmological world that slit-lamp microscopy is destined to become of far reaching value in the study of pathological conditions of the eye. It would seem, therefore, that this method of investigation should establish an even closer relation between ocular lesions and systemic disease than has been obtained up to this period.

Perimetry, or the study of visual field changes, has undergone rapid developments in recent years and has added much to our knowledge of diseases of the optic tracts. The characteristic changes in simple glaucoma, in the various types of optic atrophy, in retrobulbar optic neuritis, and in diseases of the chiasm and pituitary body, have been of untold value in enabling the ophthalmologist to correctly interpret lesions behind the eye and in aiding the neurologist in the diagnosis of functional nervous diseases.

This brief and very imperfect presentation of a subject which needs more elaboration will, I trust, at least help to stimulate an interest on the part of this Association in establishing a more intimate relationship between ocular pathology and general systemic involvement.

### NEGLECTED HYGIENIC MEASURES IN THE TREATMENT OF ACUTE INFECTIOUS DISEASES.\*

By S. B. NICKELS, M. D., Clinchport, Va.

In choosing this subject for my paper today, it is not my intention to bore you with something that you already know but its purpose is briefly to call your attention to a few measures—hygienic and therapeutic—which are very frequently neglected by many physicians, especially by those practicing in rural districts who do not have access to a hospital, and to a lesser degree those practicing in large towns and cities.

One of the first commonly neglected measures to which I wish to call your attention is *care of the mouth* in acute infectious diseases, or especially acute illness accompanied by a temperature. To my mind this is one of the most frequently neglected points by the majority of physicians today. The mouth should be

kept scrupulously clean by a cotton swab applicator two or three times daily. Saline solution, sodium bicarbonate, euthymol, borax solution, or a combination of these, with ten or twenty per cent. glycerine or other mild cleansing solution such as Dobell's, may be used. Keeping the mucous membrane of the mouth clean and the teeth properly cared for will shorten many an hour of suffering due to stomatitis, infections, and abscess of the salivary glands which frequently takes place, especially in pneumonia. The patient rests more comfortably, takes nourishment better, and digestion is not altered by the bacteria which would otherwise be swallowed. How can a patient with a heavy coat of sordes on the teeth and ulcerated patches over the mucous membrane of the mouth take nourishment with any degree of comfort? The writer on his first visit to a patient having an acute infectious disease prescribes the following simple mouth wash to be used as directed previously:

Euthymol 3 ounces.

Aqua qs 6 ounces.

Protection of mucous membranes from trauma, etc., with albolene and similar petroleum oils, is of value following cleansing of mouth, especially in mouth breathers and where there is mucous membrane infection. Carious teeth, old roots, tartar deposits, etc., should be seen to. Antiseptics such as phenol, eucalyptus, argyrol, silver nitrate, iodine, etc., are of doubtful value. Their use may cause injuries to mucous membranes. If used they should be in dilution too weak to cause irritation.

Second, *Nasal Infection* and nasal vault infection are frequently neglected as well as accessory sinus disease. These may be sources of danger but are difficult to treat effectually by the general practitioner. Mechanical cleaning by swabs is allowable; syringing is liable to cause injury or spread infection. Patient may clean nose by blowing, if old enough; application of ointment and medicated oils for protection and mild antiseptic action is of value.

Third, *Care of Skin*: The patient should have at least one bath daily and be sponged oftener in case of a high temperature. The patient should be sponged or bathed first with warm water followed by a mixture of equal parts of alcohol and two per cent boric acid in water at the required temperature. The following complications can generally be prevented by an experienced nurse:

\*Read at the meeting of the Southwestern Virginia Medical Society in Christiansburg, May 17 and 18, 1923.

1. Bed sores;
2. Corneal ulceration;
3. Middle ear infection;
4. Parotitis;
5. Boils;
6. Cracked lips;
7. Tender toes;
8. Hypostatic congestion.

(1) To prevent bed sores: (a) Keep sheets clean, dry and smooth. (b) Clean the skin promptly, dry it, rub in zinc oxide ointment and powder with starch or talcum. (c) Do not allow prolonged pressure on bony prominences. If a red spot appears where there has been pressure, keep off that part by rings or pads and paint the spot with picric acid, one per cent.

(2) To prevent corneal ulceration, keep cornea clean by bathing the eyes every four hours with a two per cent watery solution of boric acid.

(3) Boils in crops are generally due to the use of dirty sponges. If a boil appears, care must be taken to avoid spreading of the infection.

(4) Cracked lips can be prevented by the use of cold cream.

(5) Middle ear infection or parotitis, as mentioned before, may result from improper care of the mouth. The mouth may be cleansed as directed before and the throat sprayed every four hours with a non-irritating antiseptic as Dobell's solution, or alkaline antiseptic or an oily spray as chloretone inhalant (P. & D.) will serve, diluted if necessary, to avoid irritation of the mucous membranes. Excessive dryness of the tongue from mouth breathing can be prevented by the use of vaseline or liquid alboline.

(6) Hypostatic congestion of the bases of the lungs is due in part to protracted lying in one position. It can be combated, if not prevented, by rolling the patient on one side and supporting him in position for an hour or more by means of a pillow. The patient should then be rolled on to the other side for another period of time, and these maneuvers should be practiced at least once daily.

Fourth, *Isolation* is of great value and should be as early as possible. Finding of missed cases, such as scarlet fever, etc., in a family or neighborhood or school are often possible by investigation at the time of the first recognized case. Isolation should be carried on for four weeks in case of scarlet fever and until

there are no abnormal discharges according to the discretion of the attending physician. Technique of isolation is that of surgical asepsis reversed, that is, to keep infection in a small zone instead of a small area free from infection. Avoid infecting clothing or utensils from careless touching of patients or putting infected hands or things into pockets, etc. Wash hands carefully on leaving zone of infection. Do not handle face or uninfected objects until hands are thoroughly cleansed. Be careful of door-knobs. Boil dishes, utensils, etc., as they leave patient. Do not put down infected dishes, etc., in an uninfected zone. Use care to prevent discharges from nose, throat and ear, especially in scarlet fever, from being spread about sick room.

The foregoing measures are briefly those most frequently neglected by the general practitioner and, when given proper attention, our patients escape many hours of suffering which would otherwise happen.

#### COMMUNITY SYPHILIS WITH OBSERVATIONS ON TYPE INFECTION.\*

By JOHN J. GIESEN, M. D., Radford, Va.

The prevailing idea is that syphilis, as a health factor, belongs to the larger cities. This is to a certain extent true. However, there can be and there frequently are small communities in which the occurrence of the disease is alarmingly frequent. This is probably the result of conditions peculiar to the particular community. One syphilitic in a village or town can quickly infect, directly or indirectly, a large percentage of the population. Various factors and conditions may aid or retard infection, where there happens to be a focus or foci.

During the last four years, I have had the opportunity of treating and seeing in consultation about 100 cases of syphilis in all of its stages, the majority of the cases originating in small towns in West Virginia, Tennessee and southwestern Virginia. All of these cases have been carefully studied and the source of infection determined when possible. In a resume of this series of cases, I have noted a striking fact that fourteen out of the 100 cases came from two small communities, both of which have populations less than 400. Another fact of interest is that the conditions and factors which would ordinarily tend to retard

\*Read at the meeting of the Southwestern Virginia Medical Society at Abingdon, September 6-7, 1923.

or favor spread of the disease were markedly different in these two communities. Still another fact of interest is that in the cases from one of the communities we found one type of syphilis predominating, while another type predominated in the cases from the other community.

The names of these two little towns, for obvious reasons, will not be mentioned. One of them is a coal-mining community in southwestern Virginia; the other is a rural community in east Tennessee. The Virginia community furnished eight cases and the Tennessee community six cases to the series. From what we have been able to learn by inquiry and investigation, the morals and standards of living in the Virginia coal-mining community are of low order, while those in the Tennessee rural village are of the highest type. All of the patients from the Virginia community were illiterates or near-illiterates, those from the Tennessee community were all well educated and of a high order of intelligence. However, the majority of the cases from both communities were unaware of the fact that they had syphilis and sought medical advice for relief from some other condition or from some symptom of the unrecognized syphilis. In the Virginia community, where the morals are poor, where marriage is not a stable institution, and where illegitimacy is prominent, we can readily understand how one infected person could, directly or indirectly, infect a large percentage of the population. In the Tennessee community, where conditions are just the reverse, it is not so readily understood, particularly when it is noted that none of our six cases from this community are in any way related, either by blood or marriage. In the Virginia community, the disease seemed to be more of a family affair, all of the eight cases being closely related, either by blood or marriage.

All of the eight cases from the Virginia community exhibited lesions of the skin and bone, one presenting also a cardio-vascular complication, while none were of the neurological type. The Tennessee community's six cases were all of the so-called neurological or "nervous" type: one was a psycho-neurotic with syphilitic background, one had syphilitic epilepsy (congenital), two had general paresis, one had tabes dorsalis, and one had a brain gumma. All of the Virginia cases responded well to therapy and all except two, who did

not complete treatment, made apparently entire recovery. None died. Three of the Tennessee cases subsequently died, the two paretics and one with gumma of the brain, the other three responded poorly to therapy and none made complete recoveries or even satisfactory improvement.

None of the fourteen cases from the two communities were in the acute stage of the disease when seen. All of them had had their trouble for several years or longer. Ten of the cases were previously undiagnosed, although all of them had consulted physicians from time to time for various ailments. None of them had received any anti-luetic treatment prior to coming under our care.

These facts have been enumerated to demonstrate that syphilis can and does infest small communities, even where local morals and standards of living are good, and that the small town or rural physician lets too many of these cases slip through his fingers undiagnosed. By checking up suspicious lesions or symptoms and keeping his eyes open, he can often recognize these cases early instead of allowing them to progress undiagnosed to a stage where therapy is not curative. By an early diagnosis and the prompt institution of treatment, the patient's chances for cure are greatly increased and at the same time the chances for spread of the disease in the community are correspondingly decreased.

It can reasonably be presumed and probably actually demonstrated that all of the six cases of so-called "nervous" syphilis, originating in the Tennessee rural community, developed from some one focus, and that the eight cases from the Virginia coal mining community with predominating skin and bone lesions also developed from some one original focus. All of the fourteen cases, of course presuming our diagnoses to have been 100 per cent correct, were due to the specific organism—the *treponema pallidum*. In the one instance, however, the organism seems to have had a selective affinity for the skin and bone with entire freedom from cerebral or spinal manifestations, while in the other instance the organism seems to have affected principally the nervous system. This is an illustration of the accepted theory that in syphilis there are true type infections or different strains of the organism at fault.

## NON-PULMONARY FORMS OF TUBERCULOSIS AND TUBERCULOUS COMPLICATIONS.\*

### Their Symptoms and Treatment.

By H. R. EDWARDS, M. D., Richmond, Va.

Under this heading we may discuss the more frequent non-pulmonary forms of tuberculosis, also some of the more common complications usually associated with pulmonary tuberculosis.

In general we may say that the symptomatology of all forms of tuberculosis is more or less similar, especially in the toxemic symptoms manifest, that is, fever in the afternoon, loss of appetite and weight, fatigue, etc., with more or less specific symptoms relative to the particular organ involved, as loss of voice in laryngeal tuberculosis and hematuria in the renal form. For convenience of discussion we will mention the various groups; lymphatic, serous membranes, and special organs.

Tuberculosis of the lymphatics is most often observed in early childhood. Though it is present to some extent in the glandular structure of the majority of adults, as a rule the infection is traceable to early childhood. In the majority of cases it is only slight in extent. The glands usually affected are the cervical, tracheo-bronchial, and mesenteric, the last receiving their infection both from the human and bovine bacilli. Tissue destruction may progress to suppuration with the usual scrofulous conditions, which may or may not heal, but are amenable to the usual methods of treatment. The cervical glands show the largest amount of suppuration.

The symptoms are those of toxæmia, loss of weight, fever, and the phenomena associated with the enlargement of the glands. There is often pain over them and along their course; a child cannot seem to gain weight; he is backward in his classes and listless. The treatment consists of rest, correction of sleeping and living habits and proper diet. The violet ray has perhaps its greatest usefulness in tuberculosis in this particular field; exposure to sunlight in graduated dosage is very effectual. Surgery is a method of last resort and should be abandoned if possible. Tracheo-bronchial and mesenteric forms are given the usual systemic treatment.

The serous membranes most often affected

are the pleura and peritoneum. The pericardium is occasionally affected, but that is not common. There is a latent form with symptoms of cardiac insufficiency, an acute form with the usual general symptoms, quite often a miliary form associated occasionally with cerebro-spinal manifestations. There may still be an exudative form with associated tuberculous and pericardial symptoms.

The pleural form is perhaps the most common form of tuberculosis of the serous membranes. It has been found that nearly all pleurisies with effusion are of tuberculous origin and occur before, with, or following disease of the parenchyma of the lung. The pleural form may be insidious or acute in onset. Usually there are adhesions formed. It may be hemorrhagic in type or there may be serous effusion or purulent effusion resulting in empyematous conditions. Often it is a terminal condition.

Included are the usual symptoms of acute or insidious tuberculosis, and nearly always a variable amount of acute pain noticed most on deep respiration. There is cough which is often very distressing and painful. It tends to chronicity, and is often re-activated by a cold or other acute respiratory infection. In the wet forms aspiration of a small amount of fluid will often reveal bacilli on microscopical examination.

In dry pleurisy we notice an acute onset, usually with chills, fever, dyspnoea, and pains in the side of the chest. There is diminution of motility; percussion is often negative; auscultation, especially in the axillary region, will elicit a "pleural rub," the pain is sharp and lancinating, and there is invariably a non-productive cough. The pain is felt only superficially but often there are distinct tender points. In diaphragmatic forms there are no auscultatory signs as a rule, but the pain, due to the nerve connections, is referred to the neck and the crest of the shoulder. If the infection is along the border of the diaphragmatic pleura, the pain is found in the lower thorax and the upper abdomen. Much depends upon the associated history of onset.

"Interlobar pleurisies" are not usually diagnosed by a friction rub, but there is a definite lessening of breath sounds in the region of the area of involvement, and there seems to be an immobilization of the lung above their point.

"Apical pleurisies" are far more common

\*One of a series of lectures and demonstrations to a class of physicians in tuberculosis, held under auspices of the Health Bureau, Department of Public Welfare, Richmond, Va., February 15 to April 15, 1923.

than we have considered them previous to the use of the X-ray; almost always affected in lesions involving the upper lobes. The symptoms are the same as those of dry pleurisy, viz: mild fever, unproductive cough, pain, and loss of weight. On physical examination we find a friction rub, diminished breathing, cog-wheel breathing, and crepitations. Apical pleurisies are practically always associated with a parenchymatous involvement.

Pleurisy with effusion may be insidious, or acute, the symptoms are more or less those found in other forms with the exception of more dyspnoea, depending upon the amount of effusion. Physical examination shows enlargement of the affected side to bulging of the intercostal spaces, rigidity of the erector spinae muscles. There is a flat note on percussion, with a tympanitic note above the fluid line. The presence of adhesions may prevent the flat note appearing anteriorly and, if in sufficient amount, there is displacement of the viscera. Unless prevented by adhesions, the mediastinal contents will be displaced before the lung will become compressed. The course of pleurisies with effusion, if non-tuberculous, is of short duration, reabsorption being the rule. If tuberculous, they tend to chronicity. Tapping is of questionable value, for as Fishberg says: "While the effusion is in the diseased chest, the diseased lung, the tuberculous lesion is compressed; toxemia is thus prevented as in artificial pneumothorax." Often the effusion will absorb, but may go on for months or years. The patient improves rapidly upon absorption. The prognosis is more favorable in children than adults.

The treatment of pleurisies consists of rest in bed as long as there is an elevated temperature, avoidance of exposure, etc. Pleurisy jackets or adhesive strapping often helps. Belladonna plasters, painting with iodine, or some such local counter-irritant is efficacious. In the very acute forms morphia may be required to control the pain. The wet forms are subject to the same course of treatment. Aspiration should not be practiced, if possible to get relief otherwise. Autoserotherapy has been advocated, but is of doubtful value.

Tuberculosis of the peritoneum occurs more often than we have expected before, and is most commonly associated with disease in the intestines. It may be acute and miliary in form or chronic with fibrotic changes, and in some instances hemorrhagic or exudative.

Many times it pursues its course without pain or particular symptoms. It is a fact that many abdomens are opened for exploration or specific surgery and the presence of tuberculous peritonitis found. On the exposure to air and again closing up the peritoneum the condition seems to clear up entirely. Numerous cases have given all the typical findings of an acute appendicitis, when on operation the appendix was found absolutely normal.

The symptomatology consists of abdominal pain, vomiting, diarrhoea, mild fever, loss of weight. There may be ascites and, if in sufficient amount, percussion may give its signs. Adhesions may account for apparent tumor masses. The treatment is that of general tuberculosis; pneumo-peritoneum may have some value, but surgical procedures are best let alone.

#### COMPLICATIONS OF TUBERCULOSIS

It is a more or less well established fact at the present time that tuberculosis is present in the parenchyma of the lung before it is evident in other organs, as the meninges, kidney, and larynx, any one of which may at any time take the ascendancy. Though it is possible for it to be primary in other locations than the lung, it is usually, however, a complicating factor.

Lobar pneumonia and so-called tuberculous pneumonias often complicate phthisis. The symptoms are those of an acute pneumonia which does not clear up as rapidly as an uncomplicated one is expected to. Occasionally they are terminal.

Considering the alimentary tract, our attention is chiefly concerned with the intestines. Tuberculosis of the tonsils has been noted. It is rare, however, notwithstanding the fact that in most diseased tonsils removed, we find tubercle bacilli present.

Intestinal tuberculosis is most frequent in children. Infection probably takes place by the swallowing of sputum or through extension from the glandular or lung condition. In some it is traceable to the bovine variety of infection. It may be acute or insidious in form. The lesions are located chiefly in the ileum, caecum, or colon, and are characterized by ulceration, which may be slight or extensive. This may proceed to perforation, or heal with a variable amount of stenosis. Its symptoms are: emaciation, rise in temperature, persistent diarrhoea, which is amenable to active treatment but on discontinuing immediately reappears; it may be intermittent but persists over long periods. The stools are variable in

number, often as high as twenty a day, they are fetid, dark colored, at times containing sloughing from the bowel. There may be streaks of blood, but copious hemorrhage is not the rule. The emaciation proceeds rapidly with the diarrhoea. The X-ray in efficient hands often will reveal the ulcerations as filling defects and is a valuable adjunct to our diagnostic methods.

Treatment is doubtful; for most cases appear for treatment only after the disease has been allowed to progress to an advanced stage. Medical treatment consists of rest in bed, a very nutritious diet, easily digestible with little roughage that may irritate the mucosa. Intestinal antiseptics are of doubtful value, though combined with sedatives they are capable of relieving many of the disagreeable symptoms. In a certain type of case, resection of the bowel has been used with good results. The best results in this form as in all others are gained by early diagnosis and treatment. The violet ray has been of distinct advantage in many cases and real cures have been effected.

There is tenderness over the abdomen, colicky pains, and general gastro-intestinal upset, the diarrhoea may alternate with constipation. Occasionally there are tumor-like masses palpable in the abdomen, and always associated with the above symptoms are the other symptoms of pulmonary tuberculosis. There is nearly always a more or less extensive pulmonary involvement which is often active.

Tuberculosis of the brain and cord is most common in the young and as a terminal complication. The brain itself is not frequently affected, the most common point being the meninges. It may be insidious over several weeks' time, or may be acute and take on a miliary type. Occasionally in the chronic form a meningo-encephalitis results with a hydro-cephalic onset. In those cases not in extremis, meningeal involvement should be considered when headaches—an uncommon tuberculous symptom—and vomiting of solids and liquids with nervousness and irritability are present. Various phenomena particularly referable to the brain and cord are noted in the course of the disease as; aphasia, photophobia, drowsiness, and even hemiplegia. Breathing is slowed and may become Cheyne-Stokes in type; the patient finally becomes involuntary and passes into coma and convulsions. In the very early stages of involvement the first symptoms may be the patient's

loss of hopefulness. He takes no more interest in things about him and loses his usual optimism. Lumbar puncture may reveal a cloudy fluid, with an increased lymphocytosis and a high pressure. Repeated tapping relieves some of the symptoms but it is usually a terminal affair, the patient lasting only a few days to a few weeks.

Tuberculosis of the genito-urinary tract occurs rather infrequently, in females usually, between the ages of twenty to thirty years. It spreads by the blood stream, peritoneum, direct extension, coitus, and instrumentation. It may involve the parenchyma of the kidney only or extend to the ureter, bladder, or any of the connected organs, as the seminal vesicles, vas deferens, and epididymis.

The symptoms in the early stages are difficult to diagnose. The urinary findings most constant are pus cells, epithelium, albumin, and an acid reaction. The presence of tubercle bacilli may not be demonstrable on concentration of a catheterized specimen under the microscope, but injection into the guinea pig may prove a diagnosis. Hematuria is not a constant finding but occurs fairly often. There is impaired function of the affected kidney as demonstrated by the phenolsulphonphthalein test.

The usual symptoms are dull pains in the lumbar region, irregular fever, chills, loss of weight and appetite, the kidney may even be palpable. In the advanced stages we often have the conditions present in an advanced nephritis as oedema, anasarca, or even uraemia.

The treatment of this form of tuberculosis consists largely of the treatment in other forms in the earlier stages. A bland diet requiring the minimum of elimination on the part of the kidneys is essential; absolute rest in bed while there is an elevated temperature is important. Violet ray has been used. In the more advanced forms of renal tuberculosis surgical interference is often resorted to. It is stubborn at best and the sooner a diagnosis is made the better, for it is the earlier treatment that is most efficacious.

Laryngeal tuberculosis may be primary but is usually preceded by pulmonary disease. It occurs in from ten to fifty per cent of cases but is a serious factor in only a small number of cases. Males are the most often affected. Their occupational surroundings, abuse of tobacco and alcohol, likely being accountable for it. It consists in an infiltration of the vocal chords

with ulceration and sloughing. The aryepiglottidean folds and interarytenoid space is often involved.

The symptoms are often varied as to the location; those showing a lesion at the entrance to the larynx are more severe than those showing one inside the larynx. Hoarseness is present in varying degrees, from mild tiring of the voice to complete aphonia. There is a variable amount of pain which may be paroxysmal and severe. Dysphagia exists in variable degrees. Warm foods and solids are the hardest to pass. Loss of weight, elevated temperature, and the usual symptoms are present. Though some cases show no loss of weight, its course either acute or chronic, if it goes into ulceration and fibrous aphonia, may be permanent.

Treatment consists first in putting the larynx at rest: in the mild cases whispering may be allowed, but, if the oedema is marked and the hoarseness persistent, much better results are obtained with complete cessation of speech and the observance of the usual regimen for tuberculosis. The local treatment consists in cauterization and application of escharotics both of which are doubtful in value and only advisable in experienced hands. Lactic acid in solutions of fifty per cent strength is used by some but its use also is questionable. Solutions of twenty to twenty-five per cent argyrol are sometimes soothing and, in my experience, I have felt they have a psychic effect on the patient; their healing value is doubtful. Sprays of orthoform combined with menthol and chloroform often help, as do solutions of cocaine. Alcoholic injection into the superior laryngeal nerve in cases of severe dysphagia has been practised.

Appendicitis is a possible complication though the men doing the largest amount of tuberculosis work have had no particular success with surgical intervention; it usually occurs in the terminal stages and operation would not mean much to the patient. It is a fact that many appendices removed show the presence of tubercle bacilli. Its diagnosis is often difficult as there are numerous conditions simulating it.

Phlebitis and thrombosis occur usually in the terminal stages and usually in the femoral vein, though they are known in the jugular. The diagnosis is easy as the edema starts in one extremity and the usual signs of phlebitis are present. Purpura is observed most often

in the terminal stages; superficial cold abscesses are rare.

Empyema occurs usually following a pneumonia and, if it is not infected with the tubercle bacilli, the prognosis is much better, but in the presence of the bacilli its eradication is long and tedious. Much has been done in recent years with rib resection to get dependent drainage and irrigation with Dakin's solution and weak solutions of iodine. In those cases supposed to be of a tuberculous nature, Beck's paste has been used to advantage, but it is a slow process. In the absence of adhesions much can be expected of the final expansion of the lung. Adhesions almost always complicate, and various methods have been advised for their destruction. Radical operations are to be avoided if possible. Permanent fistulas are the rule.

Spontaneous pneumothorax occurs in the healthy as well as in the tuberculous; however, the consensus of opinion is that the phenomenon is due to a tuberculous lesion of the pleura which ruptures, causing a rent in the pleura. It occurs most often in males. Sometimes there is no apparent exciting cause; in other cases, overexertion, coughing, and the like precipitate it; in some cases it is terminal. It may be complete or partial in the case of adhesions. Tuberculous disease of the lung is either present at the time or very often follows the spontaneous collapse. Cases have been known to go for years with a collapsed lung without serious symptoms at its onset or during its course.

The symptoms are acute distressing dyspnoea, cyanosis, rapid and very feeble pulse, coldness, perspiration; the expression is that of agony, prominent eyes and cyanotic lips, lowered temperature. Some cases terminate with this condition in profound shock, others gradually recover. There may be effusion of fluid in the pleural cavity. Physical signs show an immobilized side, percussion gives a hyperresonant note, shifting dulness is evidence of air and fluid in the pleural cavity. Metallic and amphoric notes are elicited, breath sounds are absent. The diagnosis is often difficult, depending usually upon the degree of collapse but, in the course of pulmonary tuberculosis, the sudden onset of dyspnoea, pain in the chest, and physical signs of pulmonary collapse, the diagnosis is comparatively easy. The tympanitic note depends upon the tension

of the air in the cavity, thus low tension may not give a tympanitic note at all.

In treating this condition, if it is mild, usually all that is needed is a hyperdermic injection of morphia, keep the patient quiet for several days and gradually allow him to go back to light exercise. In the very acute forms the treatment is urgent, a heart stimulant is necessary, and the usual procedures for shock. Thoracentesis is next to be performed; this may be repeated at intervals through the day when it becomes necessary. A cannula may be inserted and rubber tubing connected and immersed in water to form a water valve arrangement to prevent the return of air into the lung. In some cases even an increased pressure in the pleura may facilitate the healing process.

If the cases are not in danger, it may be advisable to allow the compression to remain and to institute artificial pneumothorax.

Influenza is a complication and some authors claim that they have seen few cases with symptoms of re-activation that were not due to the tuberculous process directly rather than to influenza. In the past epidemic there were without doubt many cases of influenza in tuberculous cases, but it is also true that without a doubt many of the deaths attributed to influenza were likely due to tuberculosis.

1110 *Capitol Street.*

### THE PHYSICIAN'S SYMPATHY IS A PSYCHOLOGICAL REMEDY OF GREAT VALUE IN THE TREATMENT OF DISEASE.

By WILLIAM JOSEPH JONES, M. D., Crozet, Va.

In order to elucidate my subject, I shall briefly refer to two nerve trunks which originate in the brain, and are located one on either side of the spinal column. These two are one nerve, called the great sympathetic nerve. Within the sheath of this nerve are situated numerous enlargements which are named ganglia. These are composed of gray matter and are centers of nervous influences. The great sympathetic sends branches or filaments each to its fellow, above and below, to the spinal cord, which is an extension of the brain, and by plexal connections establishes communication with all the organs of the body. It is the greatest factor in motion as well as sensation, and without its mysterious influence there would be no harmony in the varied functions of organic life. When one organ is dis-

eased or injured, the whole physical economy is in sympathy. In the healthful processes of the body there is sympathy everywhere, without which thinking, tasting, smelling, hearing, seeing, feeling, digestion, assimilation, and elimination could not go on in harmonious accord without disturbing elements. It might be that a traumatic or pathologic condition would cut off sympathy from the brain and produce a psychological disturbance causing hypochondria, dementia, or insanity. It might be that the fibers of the sympathetic which supply the heart would be injured or diseased so that accumulating toxins would clog the wheels of life, when abnormal circulation of the blood current with indescribable distress and fearful apprehensions would lead on slowly but surely to the cold, dark chambers where sleep the countless dead. All physical functions must have sympathy in order to perform without pain or friction the work that nature has assigned.

If the great sympathetic nerve, which contributes an influence as unknown and mysterious as spirit with spirit, becomes diseased or in any way disturbed, one can readily understand that there will be confusion in every organ and through organic disturbances inharmonious conditions would affect bone, sinew, and muscle.

These physical facts convey to our minds some sort of conception of the relations of human beings to one another. The physician in his special relation is pre-eminently one who must take into consideration not simply physical conditions but also mental and spiritual entities as matters of profound study, embracing the domains of psychology and religion in order to treat intelligently the varied aspects of personalities that will come under his observation; without such knowledge he would often find perplexities to obscure his intelligence and hinder his medical skill. The physician must be all things to all of his clientele. Of necessity he enters largely into the peculiar conditions and, indeed, the secrets of every family who claim him as physician and on whom they rely for psychological as well as physical healing. The soul of a man or a woman is often in greater need of treatment than the body and frequently the bodily ailment must be treated, if treated at all, through the mental and moral susceptibilities of the patient. The man who writes M. D. after

his name may have won the right to do so by hard mental work and may truly deserve the diploma which hangs on the wall of his office, yet he may be a professional failure at the bedside of the sick because he aims to practice only the science and art of medicine and does not put genuine humanity into his conduct.

There has been only one *Great* Physician since the world was inhabited. He combined the moral and physical. He touched the heart whenever he healed the pathological flesh. Hippocrates reached upward and forward when he founded in scientific truth and moral equity our great profession, which, since his time, has progressed to the wonderful skill and amazing success of this day and generation.

It may be that the large majority of medical men are not ready to acknowledge allegiance to the supremacy of spirituality or to psychological evolution rather than the product of a plasma passing through a tadpole existence to a state of apeism, through a missing link to that mysterious humanity which none of us comprehends. Nevertheless, there are some who forsake the comforts of christian civilization and bend every act of life in a sympathetic devotion to the uplift of humanity in the far-away territory of foreign superstition and ignorance. The scalpel and the hypodermic are means that often lead to the fountain of life from which flows the civilization of the Great Teacher and the truth that spans the ages of eternity. Our profession has reached not only high standards in skill and science but has also won an enviable place among the great and good who have devoted sacrificial labor with intensity of thought in investigation and experimentation along the lines of sympathy for suffering human beings, searching in the field of psychology as well as in the territory of science.

About forty years ago, I had a hurried morning call to visit a baby six or eight months old, said to be dangerously ill. It was the first child of one who had arrived at the mile post a few years after young maidenhood, when she married a widower of age and experience. On my arrival she met me at the door with the baby in her arms. Her first words were "Doctor, I fear that you cannot properly examine my baby." It was screaming and writhing as if in great pain. I said "I think I can. You sit down and calm your-

self." She said that the baby would not leave her a minute and that it had suffered since midnight. I talked quietly and sympathetically to the mother. The baby watched me and listened. In ten minutes it had ceased screaming and writhing and, after permitting it to inspect me until I thought it was satisfied, I held out my hands. It came to me and nestled in my arms, the arms of a loving father. It was soon asleep and I delivered it to its mother. I held out my hand to say good-bye. The other words were, "Your baby is not sick and therefore does not require medicine. It is now well. Do not forget what you have learned."

A young lady, past her teens, was suffering intensely. Her parents were considerate and did not call me until after the breakfast hour. I was ushered into her room and saw at once that this was a case of hysteria. I sat on a chair placed by her bedside for me. I did not ask to see her tongue, nor did I place my fingers on her wrist where the pulse was beating away her young but unhappy life. I preferred to talk to her and with her. I spent an hour or less with her. When I bade her goodbye, she thanked me for my visit, and said, "Doctor, I feel much better now. I am free from pain and think I can sleep. Come to see me again." I did go occasionally and had the pleasure of seeing her a useful and happy personality in her home and community.

Let us be careful to hold to the good things of the past. Sympathy helps the giver and the receiver and elucidates both the predicate and the subject.

It is good, by the use of your hypodermic, to relieve the intense pain of a boy who induced a colic by eating a cabbage stalk or a raw turnip. That case demands action rather than sympathy. In the practice of medicine there is as much use for sympathy as for the hypodermic syringe or the judicious application of mustard and hot water. Psychology has a place as important as drugs and instruments. Even the ignorant and wicked sometimes learn a lesson of wisdom and reform the conduct of life to conform to the standards of propriety and righteousness, and the good and skillful physician has credit in records of eternal justice. The highest ideals of physicians are not found in material values, but in psychological entities.

### Let's Get Together on the Roads.

The Plains, Va.,  
November 9, 1923.

TO THE EDITOR:

Now that the Pay-as-you-go Plan has been adopted by a decisive majority of the voters, it behooves every one of us who loves Old Virginia to "bury the hatchet" and put his or her shoulder to the wheel and do our best to make a success of the adopted plan. *For it is the roads after all that we want*, much more than the success or failure of any particular plan.

And above all, let's discard at once the argument, all too frequently heard in the recent campaign, that "the good roads would not benefit anybody but tourists and joy riders."

In the first place, this is not an argument for the Pay-as-you-go Plan, or for any other plan of building roads; on the contrary it is an argument directly against building roads by any plan. In the second place, it isn't true and, as long as any considerable percentage of Virginians maintain this attitude toward roads, just so long will Virginia have to remain in the mud.

A recent copy of the *Southern Planter* contained a letter from a farmer in Louisa County, in which he complained that down there, there was a road being built that paralleled the C. & O. R. R. for most of its length. Then he asks the question, "How can a road that parallels a railroad possibly help the farmers?" and answers his own question by saying, "If we farmers need good roads at all, we need only a few miles on which to haul our produce to the railroad for shipment and not great stretches of road for tourists to joy-ride over."

Now if this gentleman would go up into Maryland or Pennsylvania and drive over some of the great highways leading west from Baltimore or Philadelphia to the far western borders of those States, the first thing with which he would probably be struck would be the large number of enormous trucks going into Baltimore or Philadelphia, some of them probably from 100 to 150 miles away, loaded down with corn and wheat, hogs, sheep and cattle, some with as many as five fat cattle aboard; in fact, transporting everything the farmer produces or consumes into or out of the Balti-

more and Philadelphia markets. Then he would realize at once that these farmers are not "joy-riding" their hogs and cattle to market but are transporting them this way, over roads paralleling the railroads mind you, because it is cheaper transportation than the railroad has been giving them.

What are the railroads going to do about this? Are they going to let their engines and rolling-stock lie idly on the siding and watch this business go by them? Not a bit of it! They are going to reduce their freight rates and get their share of the business, and *the farmer gets the benefit of the reduction*. Nor will the railroads be injured by it any more than have the Express Companies been injured by the Parcel Post. Honest competition injures nobody.

This is but one illustration of the many ways that the improved highways are benefiting the farmers in the states that have them.

Another argument too frequently heard is that "having always gotten along without the improved roads, we can continue to get along without them." So we can, but any of us who might be unfortunate enough to have a member of his family very ill, or to be suffering with a severe pain himself, and the doctor had to come horseback over miles of mud roads, or perhaps spend several hours prying his automobile out of a mud-hole with fence rails—I say, any one in this position would probably think that it was indeed a slow way to get along.

And so I might go on almost indefinitely multiplying arguments to illustrate how improved roads benefit not only the farmer, but the merchant, the doctor, "the butcher, the baker and the candlestick-maker," in short, every business man and woman, whoever or of whatever profession they may be. Yes, we need the through highways as well as the short by-ways and we need them for business transportation much more than for pleasure and comfort.

Furthermore, unless and until Virginia gets her farmers connected up with her markets by improved roads, her farmers will have to compete at a disadvantage with those of our neighboring states where they are already connected up.

And though many of us thought the Bond Issue Plan better than the Pay-as-you-go Plan, now that the latter has been adopted,

let's get together on it, stop talking so much, and go to work with all our might to get the roads built as rapidly as possible.

RICHARD MASON, M. D.

## The Truth About Medicine

In addition to the articles enumerated in our letter of September 29th, the following have been accepted:

- Cheplin's Biological Laboratories
- Cheplin's B. Acidophilus Milk
- Lederle Antitoxin Laboratories
- Diphtheria Toxin Antitoxin Mixture (0.1 L+)—Lederle, 30 c.c. vials
- H. K. Mulford Company
- Diphtheria Antitoxin Standard—Mulford
- Diphtheria Antitoxin Superconcentrated—Mulford
- Parke, Davis & Company
- Antidysenteric Serum—P. D. & Co.
- Protein Extracts Diagnostic—P. D. & Co.
- Colon Bacillus Protein Extract Diagnostic—P. D. & Co.
- Gonococcus Protein Extract Diagnostic—P. D. & Co.; Micrococcus Catarrhalis Protein Extract Diagnostic—P. D. & Co.; Pneumococcus, Type I, Protein Extract Diagnostic—P. D. & Co.; Pneumococcus, Type II, Protein Extract Diagnostic—P. D. & Co.; Pneumococcus, Type III, Protein Extract Diagnostic—P. D. & Co.; Pseudodiphtheria Bacillus Protein Extract Diagnostic—P. D. & Co.; Staphylococcus Albus Protein Extract Diagnostic—P. D. & Co.; Staphylococcus Aureus Protein Extract Diagnostic—P. D. & Co.; Staphylococcus Citreus Protein Extract Diagnostic—P. D. & Co.; Typhoid Bacillus Protein Extract Diagnostic—P. D. & Co.
- Silver Nitrate in Capsules—P. D. & Co.

### NEW AND NONOFFICIAL REMEDIES.

New Tuberculin B. E. Dried.—To obtain this product, tubercle bacilli are dried, ground for several months in a ball mill, the finely disintegrated bacillary bodies are mixed with a suitable base and made into tablets. Each tablet represents a definite amount of New Tuberculin B. E. Dried.

Tablets Tuberculin B. E.—P. D. & Co.—New Tuberculin B. E. Dried, marketed in vials No. 1 of ten tablets, each tablet containing 0.0001 mg.; in vials No. 2 of ten tablets, each tablet containing 0.001 mg.; in vials No. 3 of ten tablets, each tablet containing 0.01 mg.; in vials No. 4 of ten tablets, each tablet containing 0.1 mg.; in vials No. 5 of ten tablets, each tablet containing 1 mg.; also marketed in packages of 5 vials, Nos. 1, 2, 3, 4 and 5 inclusive. Parke, Davis & Co., Detroit.

New Tuberculin T. R. Dried.—The mass culture of tubercle bacteria is washed repeatedly, agitated again in water, washed, ground to complete disintegration, extracted repeatedly with water, and the water insoluble material, instead of being ground to form a suspension in water as in New Tuberculin T. R. Liquid, is dried. The dried material is thoroughly mixed with a suitable diluent. Each tablet represents a definite amount of dried tubercle bacilli.

Tablets Tuberculin T. R.—P. D. & Co.—New Tuberculin T. R. Dried, marketed in vials No. 1 of ten tablets, each tablet containing 0.0001 mg.; in vials No. 2 of ten tablets, each tablet containing 0.001

mg.; in vials No. 3 of ten tablets, each tablet containing 0.01 mg.; in vials No. 4 of ten tablets, each containing 0.1 mg.; in vials No. 5 of ten tablets, each tablet containing 1 mg.; also marketed in packages of five vials, Nos. 1, 2, 3, 4 and 5, inclusive. Parke, Davis & Co., Detroit. (Jour. A. M. A., Oct. 6, 1923, p. 1207).

Sal-Ethyl.—A brand of ethyl salicylate—N. N. R. For a discussion of the actions, uses and dosage of ethyl salicylate, see New and Nonofficial Remedies, 1923, p. 272. Sal-Ethyl is supplied in the form of Sal-Ethyl Capsules, 5 minims. Parke, Davis & Co., Detroit. (Jour. A. M. A., Oct. 13, 1923, p. 1285).

Antidysenteric Serum—P. D. & Co.—An antidysenteric serum (see New and Nonofficial Remedies, 1923, p. 287), obtained from horses immunized against several strains of Shiga and Flexner Types of dysentery bacilli. It is marketed in packages of one syringe containing 10 c.c.; in packages of one vial containing 10 c.c.; in packages of one vial containing 20 c.c. Parke, Davis & Co., Detroit. (Jour. A. M. A., Oct. 20, 1923, p. 1363).

Cheplin's B. Acidophilus Milk.—A milk culture of bacillus acidophilus, containing not less than fifty million of viable B. acidophilus per c.c. at the time of sale. For a discussion of the actions and uses of bacillus acidophilus milk, see Lactic Acid-Producing Organisms and Preparations (Jour. A. M. A., Sept. 8, 1923, p. 831). For adults the dose is from 500 c.c. to 1,000 c.c. Cheplin's B. Acidophilus Milk is marketed in bottles containing respectively 200 c.c. and 400 c.c. Cheplin Biological Laboratories, Inc., Syracuse, N. Y.

Diphtheria Antitoxin Standard (Purified and Concentrated Globulin).—Formerly marketed as diphtheria antitoxin concentrated (globulin). (See New and Nonofficial Remedies, 1923, p. 283). This brand of diphtheria antitoxin concentrated is also marketed in packages of one syringe containing 20,000 units. H. K. Mulford Company, Philadelphia.

Diphtheria Antitoxin Superconcentrated.—The product resembles serum antidiphthericum purificatum U. S. P. It differs in that the volume per thousand units is smaller, and the protein content is claimed to be lower. It is marketed in packages of one syringe containing respectively 1,000 units, 3,000 units, 5,000 units, 10,000 units and 20,000 units. H. K. Mulford Co., Philadelphia.

### PROPAGANDA FOR REFORM.

Colorless Iodin Preparations.—The so-called colorless iodine preparations do not contain iodine in the free state, but some form of combined iodine, chiefly iodid. For instance, Tinctura Iodi Decolorata, N. F., is a solution of sodium iodid and ammonium iodid obtained by mixing iodine and sodium thiosulphate, stronger ammonia water and alcohol. When tincture of iodine is used externally, it is with the view of obtaining the therapeutic action of free iodine. Since the colorless iodine preparations do not contain free iodine, their external use as a substitute for tincture of iodine is irrational. When tincture of iodine is given internally, the free iodine contained in it is converted into iodid before absorption. Therefore, tincture of iodine and the so-called colorless iodine preparations given internally have essentially the same therapeutic effect. However, if a colorless iodine preparation is to be administered, it would be simpler and more rational to administer sodium iodid. (Jour. A. M. A., Oct. 20, 1923, p. 1383).

The Action of Arsenicals in the Body.—Voegtlin and his associates, in the Hygienic Laboratory of the U. S. Public Health Service, have observed that certain compounds containing sulphur groups in the SH form are able to counteract the toxic effects

produced by arsenoxid on trypanosomes and a representative mammal. They advance the theory that arsenic in certain trivalent forms is a specific poison for the SH group in the trypanosome organism, and that arsenic causes death of the cells by interfering with the oxidative processes. Voegtlin and his associates concluded that the failures reported in the treatment of the later stages of syphilis are due to the fact that arsphenamin, neoarsphenamin and silver arsphenamin lack the essential penetrative power for the infected tissues, and for this reason, they do not reach the last parasites in sufficient amounts to cause their death. In the effort to secure a more complete sterilization of syphilitic patients in the more advanced stages of the disease, sulpharsphenamin, tryparsamid and 3-amino-4 oxyphenol arsonic acid are suggested for trial as remedies of superior penetrative power. (Jour. A. M. A. Oct. 27, 1923, p. 1442).

Van Ess.—The Van Ess Laboratories, Inc., Chicago, put out "Van Ess Special Dandruff Massage" and "Van Ess Liquid Scalp Massage." "Van Ess" is sold with the claims that it will make hair grow and that it will stop falling hair in two weeks. The A. M. A. Chemical Laboratory reports that Van Ess Special Dandruff Massage is a perfumed liquid which separates into two layers on standing. The upper layer consists essentially of a petroleum oil which appears to be kerosene. The lower layer appears to be composed of water and alcohol containing small amounts of quinin sulphate, coloring matter and perfume. The laboratory concludes that it is probable that a mixture of 35 parts of kerosene, 15 parts of alcohol denatured by the addition of 2 grains of quinin sulphate per fluid ounce and 50 parts of water would have whatever therapeutic properties the Van Ess Special Dandruff Massage possesses. (Jour. A. M. A., Oct. 27, 1923, p. 1461).

## Book Announcements

**A Practical Text-Book of Infection, Immunity and Biologic Therapy.** With Special Reference to Immunologic Technic. By JOHN A. KOLMER, M. D., Dr. P.H., D.Sc (Hon.) Professor of Pathology and Bacteriology in the Graduate School of Medicine, University of Pennsylvania; Member of the Research Institute of Cutaneous Medicine, Philadelphia. With an introduction by ALLEN J. SMITH, M. D., Sc.D., LL.D., Professor of Pathology in School of Medicine, University of Pennsylvania. Third Edition, Thoroughly Revised and Mostly Rewritten. 8vo. of 1210 pages containing 202 original illustrations, 51 in colors. Philadelphia and London. W. B. Saunders Company. 1923. Cloth, price \$12.00 net.

**The Care of the Baby.** A Manual for Mothers and Nurses, containing Practical Directions for the Management of Infancy and Childhood in Health and Disease. By J. P. CROZER GRIFFITH, M. D., Professor of Pediatrics, University of Pennsylvania; Physician to the Children's Hospital, etc. Seventh Edition, Thoroughly Revised. Philadelphia and London. W. B. Saunders Company. 1923. Cloth, \$2.50 net.

**Diseases of the Skin.** By RICHARD L. SUTTON, M. D., LL.D., Professor of Diseases of the Skin, University of Kansas School of Medicine; Former

Chairman of the Dermatological Section of the American Medical Association; etc. Fifth Edition, Revised and Enlarged. C. V. Mosby Company. St. Louis. 1923. 8vo. 1214 pages with 1069 illustrations and 11 colored plates. Cloth, \$10.00.

**An Introduction to the Study of Mental Disorders.** By FRANCIS M. BARNES, JR., M. A., M. D., Associate Professor of Nervous and Mental Diseases, St. Louis University Medical School; Consultant Neuropsychiatrist to U. S. Veterans' Bureau Ninth District, St. Louis, etc. Second Edition. St. Louis. C. V. Mosby Company. 1923. 8vo. 295 pages. Cloth, price \$3.75.

**Diagnostic Methods.** A Guide for History Taking, Making Routine Physical Examinations and the Usual Laboratory Tests Necessary for Students in Clinical Pathology, Hospital Internes, and Practicing Physicians. By HERBERT THOMAS BROOKS, A. B., M. D., F. A. C. P., Professor of Clinical Medicine, College of Medical Evangelists, Los Angeles, Cal.; Formerly Professor of Pathology, College of Medicine, University of Tennessee, Memphis. Fourth Edition. St. Louis. C. V. Mosby Company. 1923. 8vo. 109 pages with fifty-two illustrations. Cloth, price \$1.75.

**Alcohol and Prohibition in Their Relation to Civilization and the Art of Living.** By VICTOR G. VECKI, M. D., San Francisco, California. Philadelphia and London. J. B. Lippincott Company. 12mo. 165 pages. Cloth, price \$2.00.

**Rhus Dermatitis.** From Rhus Toxicodendron, Radicans and Diversiloba. (**Poison Ivy**). Its Pathology and Chemotherapy. By JAMES B. McNAIR. The University of Chicago Press, Chicago, Illinois. 8vo. 298 pages. Cloth.

### Public Health Exhibit in New York.

Early in November there was held in New York City a public health exhibit, demonstrating the facilities available at marine hospitals and other relief stations for the medical and hospital care and treatment of beneficiaries of the Public Health Service. The exhibit occupied eight booths and covered about 800 square feet of floor space. It showed a complete surgical operating suite; a dental operating suite; a modern X-ray machine which was operated for the benefit of visitors; a suite showing modern equipment for physio- and hydrotherapy; an ambulance; a model ship's medicine chest and the operation of the medical-advice-by-radio service. The exhibit was given by the U. S. Public Health Service in co-operation with the American Marine Association.

Have you looked over the advertisements this month? If not, please do so before putting down your journal. Mention this journal in writing them.

## Editorial

### Heart Disease In Early Life.

This is a national question. It is closely related to public health of young citizens. It is a companion problem of rheumatic infection of youth. Can we not agree that rheumatic infection is due to a specific organism, streptococcus? For the past twenty years the bacterial origin of rheumatic fever has been under question, but now it seems quite clear, after widespread investigation and after proceeding to the conclusion with proper scientific caution, that we may conclude that the bacterial cause of rheumatic infection, as shown in articulations of bones, is also the cause of acute heart disease, and that the crippled heart results therefrom. Primary attacks of endocarditis can usually be traced to tonsil infection, and chronic heart lesions follow.

Allen, at Glasgow, emphasizes the magnitude of the problem by citing the following facts: "in 1921, 53,710, or 11.7 per cent of deaths at all ages and from all causes in England and Wales were due to heart disease, and this did not include disease of blood vessels." Rheumatism accounted for about one-half to one-third of the deaths due to heart disease in the wards of a general hospital. He cites America on this point and says that 11 per cent of the total deaths were due to heart disease. An examination of 198,304 children

in eight schools of Glasgow showed that about .6 per cent had organic heart disease. Taking Great Britain, Allen estimates that there are from 40,000 to 50,000 children of school age who have organic heart disease.

### THE SATURDAY MORNING CHILD'S CLINIC BY FAMILY DOCTOR.

In view of the well known widespread prevalence of rheumatic infection among children at the school age and in view of the great necessity for the early discovery of the causative factor, it would seem wise, in addition to the routine examinations made at the schools by the school physicians, that children be sent periodically on Saturday mornings to the office of the family physician for careful inspection and study as to possible infection of the nose, throat and teeth, or the possible presence of evidences in the body of rheumatic infection or the determination of cardiac lesions. As a result of such diagnostic inquiry, should positive signs be found, at once, by a sympathetic agent, the family doctor, proper measures might be undertaken for the correction of infections and for careful instructions in the case of the crippled heart.

#### The Bacteria.

- |                  |                                   |
|------------------|-----------------------------------|
| 1. Streptococci  | 3. Staphylococci                  |
| S. hemolyticus   | Aureus and albus                  |
| S. viridans      | 4. Meningococci                   |
| S. rheumaticus   | 5. Tubercle bacilli               |
| S. mucosus, etc. | 6. Colon bacilli                  |
| 2. Pneumococci   | 7. Diphtheria bacilli and others. |

BACTERIAL VICTIM.

#### The Result.

|                 | Death often results.     |

### THE FAMILY PHYSICIAN'S TRAINING.

For this service, probably a brief course of study on the part of the family doctor may be in order. He may need just a little brushing

\*Copy of photo in Hare's Practical Diagnosis.

up for his child's clinic in the matter of examination of the child's nose and throat. He will need a winning smile, an air of friendliness, a presence of gentleness. He will need a head mirror and a tongue depressor. He will require, it may be, a retractor or some instrument to make some pressure on the tonsils. He will need a hand mirror to reflect light, and a nose speculum. He will need a stethoscope. He will need a clinical thermometer. He should weigh his patient: he should examine the heart carefully, before and after exercise. He should examine the lungs and also the urine. Were such a simple clinical study of children followed by intelligent family physicians at Saturday clinics, much sickness and suffering might be prevented, and particularly in the field of rheumatic infections.

Such a plan, of course, can only be useful if the general practitioner takes seriously the examinations of such children. Surely it is easy of operation; on every country side, in every town and city throughout the land, an office clinic for school children could be held at a Saturday morning hour when children are free from school duties and transportation by automobile easily obtainable. This could be agreed upon by the doctor, the parents and the children. Such a method of periodic study of children would do much to ward off impending systemic infections and to prevent chronic heart maladies of later life.

#### **Early Symptoms and the General Practitioner.**

Sir James Mackenzie is emphasizing a newer and finer insight into the primary manifestations of disease. Under this system of approach in the study of ill health, the recognition of dysfunction in its initial forms is demanded. The interpretation of the full significance of beginning symptomatology is needed in modern medicine. The old habits of mental analysis must be reformed and a keener sense of the real meaning of apparently insignificant physical disturbances is needed by general practitioners as well as specialists. The time-worn descriptions of diseases, useful and important as these have been and are, must be given a less important place in medical literature. Text books and much current literature have dealt with descriptions of disease, as displayed in the late, terminal, and often irremediable and fatal stages. This is illustrated in the

description of the signs and symptoms of chronic tuberculosis in the human body; in the all but moribund state of Bright's disease; and in the gross and late signs of heart disease, as shown in such phenomena as cough, dyspnoea, hemorrhage, oedema, dropsy, *et cetera*.

The new movement, championed by Mackenzie, would bestir the general practitioner to an understanding and study of disease in its very beginnings; to cultivate a mental acumen for a more accurate sensing of the oncoming malady by a true interpretation of the earliest disturbances. Every disease must display or give evidence of its presence in the initial stage. In this great threshold of disease, knowledge of vast importance awaits alert medical appreciation. The general practitioner of medicine may find most satisfying efforts here. For it must be granted, that much of the present day abundant surgical pathology in man is, or may be, explained by the failure of the medicine of the past to early understand the significance of beginning ill health. For instance the understanding of focal infections may serve to prevent the gastric ulcers, the infected gall bladders, the pyelitis, and other pathological states that the drainage and removal procedure of modern surgery so excellently handles. The same may be said of beginning gastric disturbances as has been said so well by surgeons, themselves, of early cancer.

But this is not alone a problem for the physician. The layman necessarily must participate largely as a factor in this stage of medical progress. Simultaneously with improvement in the acumen of the physician for the beginnings of disease must come an education of the public in the fundamentals of ill health and its early manifestations. Many laymen live the "dyspeptic life" and do not believe the distress from indigestion to be anything but "normal" to man. So insidious and stealthy have been the onward movements of symptomatology in such cases, such persons have not felt the significance of the dysfunctioning stomach nor thought of these signs as harbingers of gross pathological processes which may finally require surgical intervention.

Again, many a layman does not understand the significance of the periodic headache, the dimness of the vision, sense of bodily tension, the forceful heart beats, the slight

dyspnoea on slight exertion, often felt in the fifth decade; these individuals feel that these slight disturbances are "natural" at the age. Again, many women have signs of incipient and beginning hyperthyroidism which may escape notice in the remedial stage.

So it is easy to see that while the profession needs and must acquire a rather keener sense for the understanding of the symptoms of ill health in its earliest stages, the more essential and more fundamental movement in this direction must be made in the minds of the people themselves. This reduces the matter to that well understood, but rather poorly accomplished public need of a nation-wide publicity as to the nature and early manifestations of diseases as we find them in this country.

While organized medicine and public health bodies may back such a movement, it would seem that the public press under skilled and intelligent direction, both by governmental agencies and professional organizations, would be more potent in propagating an understanding of this public need.

From the standpoint of Sir James Mackenzie's principles of symptomatology, the problem relates to physicians and the following quotations may be given to indicate the points he endeavors to sustain:\*

"A great deal of time and labor is spent on getting records, and an enormous mass has been accumulated. Everyone recognizes that they should be of inestimable value, but somehow or other the good results are never commensurate either with expectations or with the labor spent. If one asks a physician or surgeon what use he makes of the records of his predecessors, who it may be, for a quarter of a century, had been piling them up, he will reply that nobody ever looks at them! This fact has been recognized, and strenuous attempts are being made to remedy this state of affairs. But there is little prospect of success so long as we remain ignorant of the phenomena of ill-health. The most favored method today is to have each patient examined by a great many specialists. Each specialist may find something wrong, and all their findings are carefully recorded. But such records are of little help, as they do not tell us the outcome of the complaint. This is recognized in some quarters, and the patients are to be 'followed up.' But what is it that should be watched in the following up, and which of the specialists is to do it? The object is to note the modification in the symptoms with the progress of the disease, but in the present state of knowledge of the nature of symptoms, only a very imperfect or useless record can be kept."

\* \* \*

"Large numbers of perfectly healthy people are rejected for life insurance, and for entrance into the Services, have their lives restricted, and are subjected to various forms of treatment, because some sign as a murmur or an irregularity of the heart

is detected. Modern medicine is developing along new lines, in which numbers of specialists are combining to make a more thorough examination of each patient. That each specialist may frequently find symptoms belonging to his special department is to be expected, seeing that in a sick man every organ may be disturbed. But if each or all of them is asked what is the nature of the ill-health which is provoked by the disturbance, no clear information can be obtained. That does not mean that each specialist may not do good by his treatment, or that such a combination may not be successful, but the point is that there is not that knowledge which enables the specialist to understand the relation of the disturbance which he detects with ill-health, and in consequence of the absence of this knowledge he is forced to treat patients whose sufferings cannot be relieved on the same lines as those who can be relieved."

\* \* \*

"Many examples of the evil effects of specialism in the practice of medicine could be cited, and the following may be taken as an example. A problem which is ever cropping up in general practice is how to deal with patients with affections of the heart who become pregnant. A perusal of recent obstetric books shows that the writers have so imperfect a knowledge of this subject that their opinions are of little value. The heart specialist has never had the opportunity of studying the effect of pregnancy in either the normal or diseased heart. The absence of this kind of knowledge often has calamitous results."

\* \* \*

"The recognition that there is an urgent need for a new outlook in medicine is not the result of a superficial view or of a hasty survey. It is forty-four years since I entered upon the practice of medicine as a general practitioner. After a few years it gradually dawned upon me that I was profoundly ignorant of the nature of the complaints for which I was consulted. If a patient had a pain I might be able to give relief, but when I asked myself how was the pain produced and how my remedy acted, I had to admit I did not know. When I detected in a patient a murmur in the heart, or an irregularity in its action, I looked upon these as signs of serious significance and proceeded to treat them according to the fashion of the day. But when I asked myself in what way they indicated danger, I could not tell. The same blank ignorance faced me when I looked closely into nearly every form of complaint—whether trivial or serious. At first I thought my ignorance was peculiar to myself, but I soon found that neither the consultants to whom I brought my patients, nor the books I read, could give me the kind of knowledge I wanted.

"I therefore resolved forty years ago to improve my own knowledge, and for that purpose I set myself two objects—(1) to find out the nature and mechanism of individual symptoms, and (2) to find the bearing the cause of the symptom had on the patient's health in the present and in the future. From that time onward I have steadily pursued this inquiry. Needless to say, progress has been slow and difficult. One great obstacle was my profound ignorance of the manner in which the functions of the body were carried on. In striving to remove this ignorance, I discovered that the knowledge essential to the attainment of my object in many instances did not exist, and I had to devise measures to get this knowledge. Many were the failures, but gradually a measure of success was achieved. I kept reviewing the steps I had taken, and studied the reasons of success to find the reason for the failures, till

\*Sir J. Mackenzie, *Lancet*, November 3, 1923, pages 964-5.

I finally was able to understand the reason for the slow progress of medicine in dealing with the ill-health common among the people, and recognized a great field of investigation which had been neglected, but which is absolutely essential for the progress of medicine and its intelligent practice."

### Surgery and Physiology, or the Surgeon as a Physiologist.

No longer does surgery lean alone upon anatomy as its main support. The saying that anatomy is the sole basis of surgery must, in present times, be modified. An accurate knowledge of anatomy is no less essential to the art of surgery than heretofore; the manual work of the surgeon, the technique of the operation, as applied to the anatomy of the patient, is just as important as ever. Modern surgery is no longer considered a mere mechanical art, although the mechanical and physical alterations of the anatomical structures, incident to operative procedures, as well as the dangers involved in such, have a fundamentally important place in the surgeon's work. In the work of Dr. Crile, at Cleveland, and in his splendid contributions to the science of surgery we have an illustration of the point under comment. A skilful manipulation and readjustment of anatomical structures, during the process of surgical operations, call for a special knowledge of anatomy. But the more advanced improvements in surgical problems and surgical methods are found in the adjustment of the body, subjected to changes resulting from surgical interventions to a newer consideration for function or physiology.

So today, surgeons are thinking more in terms of physiology. Many modern surgeons, both in this country and abroad, having accomplished a high standard of skill in technique of operative procedures, are turning from problems of dissection to problems of physiology. Many are becoming earnest physiologists. In this way physiology is becoming an aid to better surgery.

The Clock of Life is wound but once  
 And no man has the power  
 To tell just when the hands will stop—  
 At late or early hour.  
 Now is the only time you own;  
 Live, Love, Toil, with a will;  
 Place no faith in "Tomorrow," for  
 The Clock may then be still.

## News Notes

**Christmas Greetings  
 and Best Wishes for a Happy and Prosperous  
 1924 to all our Readers**

### Medical Activities In Wise County, Virginia.

*The Daily Progress*, of Norton, Va., in a recent issue featuring the Appalachian National Park, tells much of the progress in all lines of work in the southwestern section of the State. It is pleasure to note that the medical profession is no laggard in successes being attained there. It is stated that Wise County "has grown in thirty years from the poorest and one of the least known, in the State, to the richest and one of the most progressive."

A Health Department was established in Wise County in 1917, which employed a health officer for his whole time, until his activities were terminated by his entering the World War. Later, the full work of the Department was resumed and a venereal disease clinic was also established. Dr. W. R. Culbertson is now health officer of Wise County and, under his administration, a great deal of excellent health work is being done in this county.

Norton has also one of the best hospitals of the southwestern section. It was established about three years ago and is a 30-room hospital with X-ray and all other modern apparatus. The staff includes Dr. J. A. McGuire and Dr. G. B. Setzler, of Norton, and Dr. J. Francke Fox and Dr. W. H. St. Clair, of Bluefield, W. Va.

### Richmond Academy of Medicine and Surgery.

At the meeting of the Academy, held November 27th, a new Constitution and By-Laws were unanimously adopted. The essential features in these were that the Richmond Academy of Medicine and Surgery should hereafter be designated as the Richmond Academy of Medicine and that the business and scientific work of the Academy would be divorced, the business activities being put under charge of a body of trustees consisting of the incumbent president and the four former latest presidents of the Academy, and that the scientific program should be delegated to a committee of three who, with the president and the board of trustees, would formulate the scientific work of the Academy during each year. This departure is considered a conser-

vative one and for the best interests of the Academy as a whole. Final action on all important measures affecting the interests of the Academy will be left to the membership for ultimate action. This reorganization of the Academy and its methods and activities is in line with the progressiveness of the profession, will be constructive, and of great benefit in furthering the scientific interests of the members, and will give them a better opportunity for serious minded scientific work. The offices of secretary and treasurer are to be combined.

During the past year, the work of the Academy has been of an unusually high character and there has been a personal enthusiasm and unity of action that has been most helpful.

#### **Another Virginia Member, American College of Surgeons.**

In our November issue, in giving names of Virginia surgeons elected to fellowship in the American College of Surgeons, at its recent meeting in Chicago, we failed to include the name of Dr. George W. McAllister, of Hampton. We regret the omission, which was brought to our attention by a friend of Dr. McAllister's. This makes a total of six from Virginia elected to fellowship in the College this year.

#### **The Johnston-Willis Hospital**

Has moved into their handsome and thoroughly modern new building at Kensington and Colonial Avenues, Richmond. The formal opening was held on December 10th.

The hospital had outgrown its old quarters on Franklin at Sixth Street, where it has been operating since its foundation in 1909 by Drs. George Ben Johnston and A. Murat Willis, and their associates, for the accomodation of their private patients.

The new location is particularly attractive, overlooking as it does the grounds of Battle Abbey and having spacious grounds of its own. The building is 165 feet by 40 feet, is six stories with a tiled roof garden. There are accommodations for 125 patients, with telephone service in each private room. The construction is strictly fire-proof, being reinforced concrete frame, brick and stone exterior, partitions of hollow tile and terrazza floors. The hospital is complete in every respect; each department has been carefully arranged for convenience of patients, doctors and nurses, and the most modern equipment is installed

throughout. The operating suite contains three operating rooms and other rooms for special surgical examinations and treatments. The X-ray laboratory has spacious quarters and is equipped with the most modern and approved apparatus for diagnostic and therapeutic work, including a powerful, high voltage machine for deep therapy administration. Portable apparatus is also provided for bedside work and study of special cases during operation. The hospital possesses an amount of radium adequate for any purpose for which this element is indicated as a therapeutic agent. The provisions for the care of maternity cases includes a modern delivery-room and nursery; the facilities for the care of new-born infants have been worked out and completed in detail.

The clinical laboratory is complete and includes electro-cardiographic and basal metabolic units. It is possible to take electrocardiographs on any floor or room in the hospital. Ample quarters are provided for hydrotherapy. A special feature of the culinary department is a complete cafeteria system for the nurses and doctors. This is an innovation in this city, but has proved highly satisfactory in some of the other more modern hospitals elsewhere. There is a complete refrigerating plant which, besides cold storage, provides ice and cold water throughout the building.

There are a number of rooms with private baths and each floor has a sun-parlor. In addition, a spacious sun-parlor on the roof opens on the tiled roof garden, which commands a beautiful view of the city. This feature is particularly attractive for convalescent patients. Here they can enjoy the open air and sunshine and can see their friends in home-like surroundings. Visiting physicians are invited to inspect the hospital at any time.

#### **The McGuire Clinic.**

The McGuire Clinic in conjunction with St. Luke's Hospital opened its doors December the first. The Clinic Building, which is connected with every floor of the hospital, has practically been rebuilt from basement to roof and supplied with all the facilities of a large modern professional office building.

The Department of Surgery, Gynecology and Urology will be under Dr. Stuart McGuire, Dr. W. Lowndes Peple, Dr. R. C. Fravel and Dr. Beverly F. Eckles. The Department of Orthopedic Surgery will be under Dr. W. T.

Graham. The Department of Internal Medicine will be under Dr. Garnett Nelson and Dr. Hunter H. McGuire. The Department of Pathology and Radium Therapy will be under Dr. S. W. Budd. The Department of Roentgenology will be under Dr. A. L. Gray and Dr. J. L. Tabb. The Department of Ophthalmology, Otolaryngology and Rhinology will be under Dr. W. R. Weisiger. The Department of Dentistry will be under Dr. John Bell Williams and Dr. Guy R. Harrison. The Department of Obstetrics will be under Dr. Virginius Harrison. The Business Manager will be Mr. G. H. Winfrey, former Secretary and Treasurer of the Medical Society of Virginia.

The Department of Roentgenology under Dr. Gray and Dr. Tabb will be equipped with the latest improved X-ray apparatus for X-ray diagnosis and the latest model machine for administering the high voltage X-ray treatment. This deep therapy apparatus promises much in reaching the more deeply seated malignant conditions hitherto inaccessible.

The Radium Laboratory under Dr. Budd has an adequate supply of radium to meet all needs. It will be used in connection with Surgery and Roentgenology in the treatment of many of the cases of malignancy as well as other pathological conditions.

The Department of Medicine, under Dr. Nelson and Dr. Hunter McGuire, is equipped with a new electro-cardiographic apparatus, an alpine light, an apparatus for estimating basal metabolism, and all other equipment needed in the diagnosis and treatment of medical diseases.

With a virtually new office building in intimate connection with an established hospital, with new equipment and a staff of men experienced in their several specialties, the organization should be a great success.

#### **New Superintendent at Stuart Circle Hospital.**

Miss Charlotte Pfeiffer has been elected by the Board of Directors as Superintendent of the Stuart Circle Hospital, Richmond, to succeed Miss R. Z. Van Vort. Miss Pfeiffer arrived in Richmond December 1st and will assume charge of the Hospital on December 16th. She comes on the recommendation of Dr. A. R. Warner, Executive Secretary of the American Hospital Association. The Stuart Circle Hospital has always enjoyed a high rating with the American Hospital Association and with

the American College of Surgeons and, when the necessity for finding a successor to Miss Van Vort arose, Dr. Warner was consulted and as a result of this correspondence Miss Pfeiffer was recommended. She has visited Richmond for conference and is enthusiastic about her new work.

Miss Pfeiffer's first connection with hospital work was as Deaconess in the Lutheran Church. She thus entered on her work as a life of service, and has served in all capacities in hospital work. She has taken courses in home economics, has done social service work, especially in organization, and did field work under the direction of United Charities in Chicago. She took the post-graduate executive course in the Illinois Training School in 1920 and a post graduate course in practical hospital administration at the Bridgeport Hospital, Connecticut. For the past four years she has been principal of the school of nursing at the Deaconess Hospital in Milwaukee, where she made notable success. She enters on her work in Richmond with a broad training and a successful practical experience, and with ideals and a vision that peculiarly fit her to carry on the work at Stuart Circle Hospital.

#### **Married.**

Dr. Joseph Thompson McKinney and Miss Ruth Markley, both of Roanoke, Va., November 14.

Dr. William Percy Jones and Miss Eliza Palmer, both of Urbanna, Va., the latter part of October.

Dr. R. L. Hudnall, Beverlyville, Va., and Miss Mary E. Robertson, Heathsville, Va., November 7, in Baltimore, Md.

Dr. Harry B. Sanford and Miss Alice Smith, both of Richmond, Va., November 14.

Dr. Powell Garland Dillard, Lynchburg, Va., and Miss Nannie Sue Hoge, of Pembroke, Va., November 20.

Dr. John W. Turman, Richmond, Va., and Mrs. Dell Williams Peoples, Warrenton, N. C., October 27.

#### **The Petersburg Medical Faculty,**

At its annual meeting on November 22, elected Dr. D. D. Willcox president; Drs. J. R. Beckwith and E. W. Young vice-presidents; Dr. C. M. McCuiston corresponding secretary; and re-elected Dr. J. M. Harwood secretary-treasurer. All are of Petersburg. Drs. J. Bolling Jones and Fletcher J. Wright were appointed to arrange for the annual meeting

of the Southside Virginia Medical Association, which was held in that city on December 11th.

#### **Arlington County Medical Society.**

At the regular meeting of this Society, held November 7th, Dr. Stacy T. Noland, Clarendon, was elected president, and Dr. B. H. Swain, Ballston, was re-elected secretary-treasurer. The Society decided that, instead of meeting quarterly as heretofore, they would hold meetings only twice a year—on the first Wednesdays in May and November.

#### **The Augusta County Medical Association**

Held its regular tri-monthly meeting in Staunton, November 7. Present officers of the Association are: President, Dr. Alex. F. Robertson, Jr., Staunton; vice-presidents, Drs. F. E. Hamlin, Staunton (at present in Philadelphia taking post-graduate work), T. W. Hankins, Fordwick, and H. F. White, Fishersville; secretary, Dr. H. G. Middlekauff, Weyers Cave; treasurer, Dr. J. L. Alexander, Staunton. Meetings are held quarterly.

#### **Clinic for Crippled Children.**

Dr. William Tate Graham, orthopedic specialist of Richmond, held a clinic at Courtland, Va., November 24, by special request of the Red Cross Chapter and Board of Public Welfare of Southampton County. He examined about twenty-five children and suggested that hospital treatment should be helpful to several. He was assisted in the work at the clinic by Dr. W. T. McLemore, chairman of the Red Cross Nursing Committee, Miss Mary L. Babb, Red Cross secretary and Welfare superintendent, and Dr. and Mrs. R. L. Raiford.

#### **Dr. B. L. Carter's Daughters,**

Misses Mary Lee and Raeburn Carter, of Blue Spring Run, Va., spent the Thanksgiving holidays in Richmond.

#### **The American Association for the Study of Goiter,**

Composed of goiter surgeons, pathologists, anaesthetists, internists, and radiologists, will hold its annual meeting in Bloomington, Ill., January 23, 24, and 25, 1924. The program, to be issued in a few days, will list a number of excellent papers, demonstrations, and diagnostic and operative clinics. Dr. E. P. Sloan, of Bloomington, is president, and Dr. J. D. Moschelle, of Indianapolis, secretary.

#### **Dr. Edgar W. Robertson,**

Onancock, Va., who was very ill for several

weeks, is much improved and hopes soon to be at work again.

#### **Dr. Charles R. Robins,**

Richmond, acted as toastmaster at the banquet given by the local chapter of the Omega Upsilon Phi fraternity in Richmond, on November 24.

#### **Dr. J. B. Tuttle,**

Of Craigsville, Va., is spending the winter in Florida, having made the trip there in his car. He will return to his home in Virginia in the Spring.

#### **Dr. D. Lane Elder**

Was elected one of the directors of the DuPont Club of Hopewell, at its annual meeting held last month.

#### **Offer to Endow Chair of Music.**

A proposal has been made by Drs. Wm. J. and Chas. H. Mayo to endow a chair of music in the Rochester, Minn., public schools, by annually placing the sum of \$2,000 in the hands of the schools' board of trustees.

#### **Elected Members of Board of Country Club.**

Drs. Robert C. Bryan and Robert S. Preston, both of Richmond, were among the five new members of the board of governors of the Country Club of Virginia, elected at the annual meeting in November.

#### **Dr. E. M. Magruder,**

Charlottesville, Va., was re-elected chieftan of the American Clan Gregor Society at their annual meeting in Washington, recently.

#### **Dr. Alfred B. Claytor,**

Bedford, Va., has been elected surgeon of the Watts-Graves Camp, Sons of Confederate Veterans, of that city, for the coming year.

#### **Dr. Edward Latane Flanagan**

Announces the opening of his offices in Medical Arts Building, Franklin at Second Streets, Richmond. His practice will be limited to X-ray diagnosis and treatment.

#### **Two Newport News Doctors Have Narrow Escape.**

Drs. R. A. Davis and Morris P. Beecroft, of Newport News, Va., narrowly escaped serious injuries on Thanksgiving Day when, with a party of friends, they were on their way to the foot ball game in Richmond. A short distance from this city, the car turned turtle and all of its occupants, except the driver, were thrown clear of the car. All of the men received only slight injuries.

### Some Good Hunters Among the Doctors.

Drs. J. W. Abbitt and L. J. Roper, Portsmouth, Va., Dr. H. M. DeJarnette, Fredericksburg, Va., Drs. James Morrison and J. R. Gormen, Lynchburg, and Dr. Thos G. Hardy, Farmville, Va., are among the Virginia doctors who have had some good luck hunting this Fall.

### New Dean of Johns Hopkins Medical School.

Dr. Lewis Hill Weed, professor of anatomy at Johns Hopkins University Medical School since 1919, has been elected dean of the Medical School to succeed Dr. J. Whitridge Williams. Dr. Williams, who has been dean of this school for the past thirteen years, recently resigned that he might more fully devote his time to the new women's clinic of Johns Hopkins Hospital, of which he is director.

### The Virginia Public Health Nurses' Association

Met in Richmond the last week in November. Practically every section of the State was represented by those interested in health work and reports showed that much good work was being accomplished by the work of these nurses in co-operation with the State Board of Health. Dr. Ennon G. Williams, State Health Commissioner, and Dr. Roy K. Flannagan, assistant State Health Commissioner, addressed the Association at the opening meeting. Dr. Mary E. Brydon, head of the child welfare division of the board of health, presided at a round table discussion of matters pertaining to her department. Several others interested in public health work in Virginia also addressed the meetings.

### Rex Hospital Has Addition.

An addition including thirty-five beds for children was recently opened at Rex Hospital, Raleigh, N. C. The money for this addition was given by Mr. W. H. Williamson, of Raleigh, as a memorial to his wife.

### Pine Camp Enlarged.

Pine Camp, Richmond's municipal tuberculosis hospital, has been much enlarged and improved and had its formal opening November 17. Appropriate exercises marked the opening of the additions, following which the buildings were inspected by the visitors, and refreshments were served. Great credit is due Dr. E. C. Levy, Director of Public Welfare of Richmond, and his able assistants for their

untiring efforts in behalf of the enlargement of this hospital.

Pine Camp was founded by the Richmond Tuberculosis Association in November, 1910 and was taken over by the city in 1916. Former capacity of the camp has been thirty-six patients; with the additions, it is now able to care for eighty-four. It is expected later to increase the capacity to ninety-two beds.

### Rear Admiral Cary T. Grayson,

Washington, D. C., delivered an address in Danville, Va., December 5, under the auspices of the Wednesday Afternoon Club. His subject was "Heredity and Training."

### Dr. S. Josephine Baker,

Of New York, has been appointed consulting director in Maternity and Infancy and Child Hygiene of the Children's Bureau of the U. S. Department of Labor. Until last Spring, Dr. Baker was for twenty years director of the Bureau of Child Hygiene of the New York City Department of Health.

### The Association of Surgeons of the Chesapeake and Ohio Railway

Held their seventh annual meeting at White Sulphur Springs, W. Va., November 16 and 17, under the presidency of Dr. S. W. Hobson, of Newport News, Va. There was an attendance of over 200 and the sessions were interesting and pleasant throughout. On the first afternoon, the members of the Association presented Dr. W. T. Oppenheimer, of Richmond, Va., chief surgeon of the road, with a motor car, as an expression of their esteem and affection, the presentation speech being made by Dr. J. M. Salmon, of Ashland, Ky. Officers elected for the ensuing year are: President, Dr. C. C. Coleman, Richmond, Va.; vice-presidents, Drs. L. L. Bigelow, Columbus, O., J. E. Cannaday, Charleston, W. Va., H. W. Porter, Louisa, Va.; secretary-treasurer, Mr. George E. Meanley, Richmond, Va. Members of the executive committee are: Drs. W. E. Vest, Huntington, W. Va., H. U. Stephenson, Richmond, Va., C. C. Garr, Lexington, Ky., E. H. Griswold, Peru, Ind., Eric Twachtman, Cincinnati, O., and W. R. Laird, Montgomery, W. Va.

### Xmas T. B. Seals.

Funds from this sale are used to support free tuberculosis clinics, public health nurses, indigent patients at sanatoria, and for preventive work among children, such as fresh air

classes, nutrition classes, summer camps and the Modern Health Crusade. Last year, Virginia raised \$55,568.30, the major portion of which was used for health work in the counties and cities in which it was raised. Virginia raised 2.3 cents per capita for population. A per capita rate as high as 8.5 for the population was raised in one state. Can we not better the amount raised in Virginia? Buy your allotment promptly.

#### **Dr. J. Hampton Hare,**

Of Newland, Va., was a recent visitor in Washington, D. C.

#### **Physicians' Scholarships Awarded.**

The American Child Health Association announces that its resident and travel scholarships for physicians have been awarded to the following: Dr. Charles Armstrong, Salisbury, N. C.; Dr. William W. Bauer, Milwaukee, Wis.; Dr. R. L. Carlton, Winston-Salem, N. C.; Dr. Eugene C. Chimene, Minneapolis, Kan.; Dr. William De Kleine, Saginaw, Mich.; Dr. Seymour Fiske, New York, N. Y.; Dr. Arthur M. Kimberly, Bristol, Conn.; Dr. George A. Lamont, Vancouver, B. C.; Dr. George N. Leonard, Albany, N. Y.; Dr. Marie M. Long, Memphis, Tenn.; Dr. George C. Marlette, Bay Minette, Ala.; Dr. Walter R. Moore, St. Joseph, Mo.; Dr. Russell B. Sprague, Yarmouth Port, Mass.; Dr. Thomas D. Walker, Macon, Ga.; Dr. Ruth Weismann, Dorchester, Mass. The purpose of these scholarships is, broadly, to stimulate interest in child health work and to provide means for better training of physicians along this line. One hundred and one applications were received from thirty-six states.

#### **On Democratic Committee of Richmond County.**

Drs. H. L. Segar, Warsaw, Va., and B. A. Middleton, Emmerton, Va., have been elected members of the recently reorganized Democratic Committee of Richmond County, Va.

#### **Dr. and Mrs. J. Alfred Riffe,**

Covington, Va., were recent visitors in Richmond.

#### **Dr. D. Hunter Marrow,**

After spending the summer months at his old home at Union Level, Va., has returned to Daytona, Fla., for the winter.

#### **Sanatorium Destroyed by Fire.**

Much credit is due the nurses for their

heroism in saving the patients when Gaston Sanatorium, Gastonia, N. C., was almost completely destroyed by fire on the afternoon of November 16. The loss, estimated at \$50,000, is only partially covered by insurance.

#### **Dr. William S. Thayer,**

Emeritus professor of medicine in Johns Hopkins University, Baltimore, recently addressed the senior medical class of the Medical College of Virginia, his subject being "Bacterial Endocarditis."

#### **Dr. and Mrs. B. L. Phillips,**

Richmond, are now much improved after being in a local hospital for sometime for injuries suffered in an automobile accident.

#### **Mary Washington Hospital Awards Diplomas.**

Eight nurses were awarded diplomas of graduation from the Mary Washington Hospital, Fredericksburg, Va., November the 9th. Dr. J. N. Barney presided, Dr. Frank C. Pratt presented the diplomas and Dr. C. Mason Smith made the presentation of the hospital pins.

#### **Dr. W. L. Davenport,**

Amelia, Va., was among those to make speeches at the opening of the Co-operative Warehouse in Amelia C. H., in November.

#### **Dr. H. Orlando Bell**

Has been appointed medical inspector of the Richmond Bureau of Health, to succeed Dr. Henry E. Davis, resigned. Dr. Bell entered upon his duties December 1, and will work with Dr. G. R. Maloney in the control of contagious diseases.

Dr. Bell is a member of the class of '20, Medical College of Virginia and since graduation has been connected with the New York Nursery and Childs' Hospital, and with the Willard Parker Hospital in New York City.

#### **How About Your Magazine Subscriptions for 1924?**

Have you placed orders for your magazines for 1924? If not, you can place all of these, new and renewals, through the office of the Medical Society of Virginia. It saves you trouble; it helps your Society. How about sending them in now? State when you wish subscriptions to begin.

#### **Automobile Fatalities for 1922,**

Just announced, show an increase of one per 100,000 in fatalities from automobile ac-

cidents in the registration area of the United States, during 1922. Virginia as a whole showed a very slight decrease from six to 5.8 per 100,000. This decrease was marked in Norfolk City, where the rate fell from 18.1 to 8.8 per 100,000. We regret to note, however, that Richmond did not participate in this improvement, her rate showing an increase of four-tenths of one per 100,000. Can't we lower this next year?

#### **Impaired Hearing Helped by X-Rays.**

Exceedingly apropos is the publication of a paper on "X-Ray as an Advance in the Treatment of Impaired Hearing" by J. J. Richardson, M. D., F. A. C. S., Washington, D. C., in the wake of a clinic held in Richmond recently during the National Osteopathic meeting. At this time, one of the members of the Osteopathic Association held clinics in this city at which it was stated that deaf people had their hearing completely restored. Dr. Richardson reports improvement varying from a slight degree to a complete cure in not less than 60 per cent of about 600 cases. The X-ray was used by him as an adjuvant, as he states that "Any discernible and corrigible anatomic or pathologic defect should, of course, receive all possible clinical aid" prior to the use of the X-ray.

#### **National Board Bulletin,**

Commencing October 1923, is to be published bi-monthly by the National Board of Medical Examiners, from Philadelphia, at the subscription price of 50 cents a year. This periodical has been started for the purpose of keeping the Board's candidates and others interested more fully informed of its program and progress.

In this connection, we might state that Part I only of the examinations will be held in February 1924, the exact date to be named later. Dr. J. S. Rodman, Philadelphia, is secretary-treasurer of the Board, and Mr. E. S. Elwood, 1310 Medical Arts Building, that city, managing director of the Bulletin.

#### **Foreign Health Officers Entertained.**

On December 4, the Rockefeller Foundation gave a dinner at Commodore Hotel, New York City, in honor of the foreign health officers representing eighteen foreign governments. These officers have been in the United States for the past three months under the auspices of the Health Section of the League of Nations, for the study and observation of

various types of public health organization. Dr. George E. Vincent, president of the Foundation, presided.

The visit of these health officials to the United States represents the third general interchange of public health personnel arranged by the Health Section of the League of Nations. The first was in Belgium and Italy in 1922, and the second in England and Poland in the Spring of 1923. A contribution from the International Health Board of the Rockefeller Foundation, amounting to \$60,080 a year, for a period of three years, made possible this international interchange of public health personnel.

#### **American Academy of Ophthalmology and Otolaryngology.**

At the annual meeting of this association, held recently in Washington, D. C., Dr. Walter B. Lancaster, Boston, was elected president, and Dr. Luther C. Peter, Philadelphia, secretary.

#### **Number of German Hospitals Close.**

According to the *Journal of the A. M. A.*, during 1922, forty-five hospitals were forced to close in Prussia owing to financial stress. This included nine private hospitals with 1,049 beds in Berlin alone.

#### **The Atlanta Graduate School of Physicians and Surgeons,**

Atlanta, Ga., will have their formal opening on April 9, 1924. Dr. William Perrin Nicolson is dean, and Dr. Michael Hoke president of the faculty.

#### **Centenary of the Lancet.**

In October, the *London Lancet* issued a special number commemorating its one hundredth anniversary. Established in 1823 as a medical weekly, the *Lancet* has weathered full many a storm, but has come through them all as one of the leading medical journals of this day. This journal was established by a London practitioner named Thomas Wakely, and it is interesting to note that in its whole career it has had but five editors, all of them, with the exception of the present one. Sir Squire Sprigge, having been Wakelys. We wish this journal a continuance of its great popularity and influence.

#### **The American Journal of Roentgenology and Radium Therapy,**

The official organ of The American Roentgen Ray Society and the American Radium Society will appear in enlarged form in 1924.,

the increased pages being given to more illustrations, more abstracts and more original articles. Dr. A. C. Christie who was Colonel in charge of roentgenology in the U. S. Army during the war will be the editor. Dr. James T. Case, Dr. H. K. Pancoast and Dr. W. Duane will be the associate editors with a large collaborating staff of the leading roentgenologists in the country. The subscription price is \$10.00 and Journal will be published as formerly by Paul B. Hoeber, Inc., New York.

#### **Burroughs Wellcome and Company**

Extend a cordial invitation to the medical profession to visit the exhibition rooms in their new building at 9-11 East Forty-First Street, New York City, just off Fifth Avenue, opposite the Public Library. This firm's general offices for the United States are now installed in this building. Doctors visiting New York at any time will be welcomed to inspect the fine products put out by this Company.

#### **The Southern Medical Association,**

At its annual meeting in Washington, D. C., the middle of November, selected New Orleans, La., as the 1924 convention city, and elected the following officers: President, Dr. Charles L. Minor, Asheville, N. C.; vice-presidents, Dr. Robert C. Lynch, New Orleans and Dr. Thomas A. Groover, Washington, D. C.; secretary-manager, C. P. Loranz, and editor of the Association's journal, Dr. M. Y. Dabney. Both of the latter of Birmingham, Ala., were re-elected.

#### **Leprosarium to be Enlarged.**

Construction is to be undertaken at once of the new buildings for the Carville, La., leprosarium. As cost of building has advanced since the appropriation was made by Congress, building of the infirmary will be delayed, but accommodations will be added to care for 204 additional lepers. There are at present 174 patients at this institution—some of them blind and much mutilated from the disease. There is already a waiting list of more than 100 and it is estimated that there are many more throughout the United States who should be segregated.

#### **Wanted—**

Experienced interne for 35-bed hospital; one capable of assisting in operations, giving anesthetics, doing laboratory work (no Wassermanns), and would prefer one who could do X-ray work. Address Box 359, Martinsville, Va. (Adv.)

## Obituary

### **Dr. Charles Wesley Astrop,**

A prominent physician and citizen of Surry, Va., died in Richmond, November 20, having been in failing health for several years. He was born in Brunswick, Va., August 18, 1858, and studied medicine at the Medical College of Virginia, from which he graduated in 1884. Several years later, he took a post-graduate course in New York. He had made his home in Surry since 1897, and practiced there until several years ago when he retired on account of his health. Dr. Astrop was a member of the Medical Society of Virginia and an ex-president of the Southside Virginia Medical Association. He is survived by his wife and a son, who is connected with the faculty of the University of Richmond. The burial was held at Fork Union, Va.

### **Dr. John Clancy Parish,**

Smithfield, Va., died in his home at that place November 30, after a lingering illness. He was the only child of Mr. and Mrs. Thomas P. Parish, of that place, and was 34 years of age. He graduated in pharmacy from the Medical College of Virginia in 1910 and later returned there and studied medicine, taking his M. D. degree in 1914. At this time he was appointed to an internship at Memorial Hospital, Richmond. Upon completion of this service he returned to Smithfield, where he practised his profession and made for himself a large circle of friends and admirers. His parents and his wife, formerly Miss Allene Moore, of Richmond, survive him. The funeral was held with Masonic honors.

### **Dr. James Harvey Bogle,**

Formerly of Roanoke, Va., died at Sebring, Fla., November 10, after a brief illness. Dr. Bogle was born in Bland County, Va., 55 years ago and, after graduating from the College of Physicians and Surgeons of Baltimore in 1893, located in his native county for several years. While there, he was a member of the Bland County Board of Health. Later, he moved to Roanoke, in which place he practiced until his removal to Florida several years ago. He had been a member of the Medical Society of Virginia since 1896. Dr. Bogle is survived by his wife and several children.

# For Infants Deprived of Breast Milk

1. Infants fed on S. M. A. look and act and grow like breast-fed infants.
2. Their flesh is firm, and they develop normally.
3. They are normally free from rickets and spasmophilia.
4. S. M. A. may be fed to infants of all ages without modification or change.
5. It requires only the addition of boiled water to prepare.

## WHAT'S IN A NAME?

Whose name is signed to infant feeding instructions in your community—the manufacturer's or yours? You are the doctor.

Does the family physician instruct the mother of a baby to go to a drug store and follow the druggist's advice as to the selection of a food for the infant's requirements? Hardly ever.

Generally the doctor writes his feeding formula just as he does any other prescription and changes it from time to time to suit the requirements of the individual infant. His name and reputation are at stake. The baby's nutrition must be considered and possibly its life may be saved by proper food.

First thought

**Breast Milk**

Second thought

**Cow's Milk, Mead's Dextri-Maltose  
and Water.**

The physician who uses Mead's Dextri-Maltose when artificial feeding is necessary controls his case. There is no outside interference and his creative talent has full scope because Mead's Dextri-Maltose is supplied without directions on the packages and no advertising to the laity.

An ethical product offered exclusively to the medical profession must have merit. Will you investigate?

Pamphlet describing methods for prolonging breast milk, and samples of Mead's Dextri-Maltose, will be sent to physicians on request.

### THE PHYSIOLOGY OF THE PANCREAS, WITH SPECIAL REFERENCE TO THE PANCREATIC FUNCTION IN GENERAL METABOLISM.\*

By THEODORE HOUGH, Ph. D., University, Virginia.

In view of the time which can reasonably be allowed for this paper, I have decided to limit myself to the physiology of the pancreas in the utilization of glucose in metabolism; and even in this field to attempt only to emphasize the more important points, with the special purpose in view of giving the setting of the discovery of insulin in the development of our knowledge of the general physiology of metabolism.

The discovery of insulin has not come upon us like a bolt out of the blue, as did that of the Roentgen rays or radio-activity. It is not even the crowning gift of a long line of physiological research; it is on the contrary, to change the figure, merely a milestone in the advance of knowledge; and, if I mistake not, its greatest ultimate benefit to the race lies, not in the introduction of a new therapeutic agent, but in that it gives us a new starting point for future investigation of some of the most obscure but most important problems of the metabolism of living cells.

#### THE DISCOVERY OF THE RELATION OF THE PANCREAS TO CARBOHYDRATE METABOLISM.

The memory of men of my own age goes back to the days when diabetes was simply a name given to a disease syndrome, one feature of which was the presence of glycosuria. It was known that this glycosuria is not of renal origin; also that the glycogenic function of the liver is impaired. Obviously carbohydrate metabolism was deranged but in what way it was deranged was not known—indeed on this subject there was the greatest variety of conflicting and irreconcilable opinion.

Important steps had been taken, however, in unravelling the tangle. The distinction was clearly recognized between the alimentary glycosuria following a candy spree and the glycosuria of diabetes which persists at times despite the complete exclusions of carbohydrates from the diet. Hyperglycemia was generally held to be the cause of glycosuria in both cases, although the existing methods of blood sugar analysis still excused, if they did not justify skepticism on this point.

Claude Bernard had not only demonstrated the glycogenic function of the liver but had also shown that acupuncture of a certain region of the bulb resulted in discharge of glycogen from the liver and glycosuria. These and other facts had been established but their synthesis into a satisfactory picture of carbohydrate metabolism awaited new discoveries.

Diabetes was suspected to be primarily a disease of the liver, or of the tissues generally. No suspicion was prevalent that deficient pancreatic function had anything to do with the trouble. After some preliminary announcements,\* von Mering and Minkowski in 1890 and Minkowski in 1893 gave to the world the full account of their well-known experiments, showing that extirpation of the pancreas led to a severe and fatal diabetic condition; and that this was not due to the withdrawal of the digestive action of the pancreatic juice, since, on the one hand, it does not follow ligation of the pancreatic ducts and, on the other, does not occur so long as a comparatively small remnant of the pancreas with no ducts connecting with the intestine is left, but immediately develops upon the removal of this remnant.

Von Mering and Minkowski's results were immediately fully confirmed and Hedon added the important experiment of first transplanting in the subcutaneous tissue a lobe of the gland absolutely separated even from connective tissue connection with the intestine, but

\*Read as part of the symposium on The Pancreas, at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

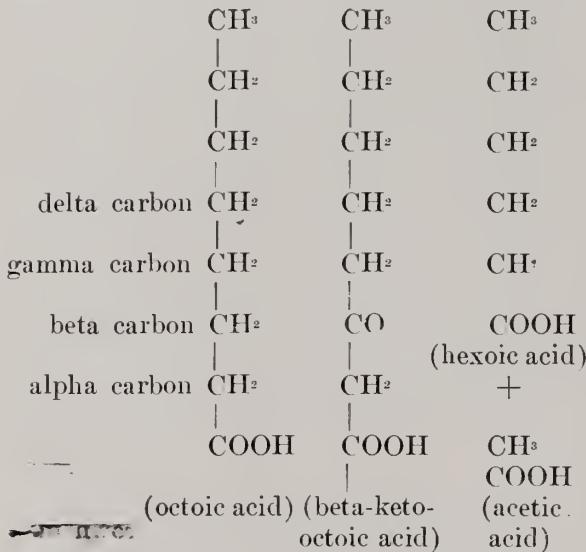

\*It shows how little the medical world of 1887-89 was prepared for this epoch-making discovery that the first announcement in the *Centralblatt f. Klin. Medizin*, 1889, x, p. 393 commands only a title reference with no abstract in the *Centralbl. f. Physiologie* for 1889.

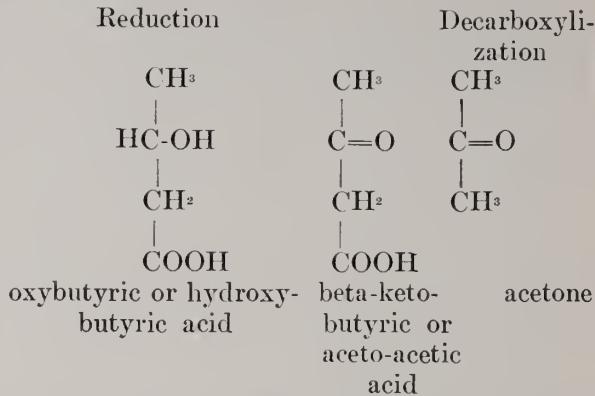

amino-acids whose combination makes the protein molecule are substituted fats of an odd number of carbon atoms; but the natural fats are practically without exception esters of fatty acids of an even number of carbons.

This interesting "find" of the "pure scientist" has a most important bearing upon the occurrence of acetonuria and acidosis in all conditions (including diabetes) when sugar is not burned properly in the body. When oxygen attacks a fatty acid, it usually if not always unites with what we call the beta-carbon atom, i. e., the second carbon atom from the COOH, or carboxyl group, thus:

In the chemical laboratory oxygen may attack other carbons, and probably it may do so at times in the body; but generally it attacks the beta-carbon. The long carbon chain then breaks at the point of oxygen attack with the formation of acetic acid and an acid with two less carbons than the one we started with. The acetic acid is readily oxidized to carbon dioxide and water. The hexoic acid, in the above case, would next be attacked in the same manner on its beta-carbon, giving us the 4 carbon acid, namely butyric acid. This is likewise attacked, giving beta-keto-butyric acid (or aceto-acetic acid). We should expect this to break up into two molecules of acetic acid; but for some reason this last step is taken only in the presence of "active" glucose; i. e., that isomeric form of glucose which enters into the oxidative metabolism. Instead thereof in the diabetic body the aceto-acetic acid may undergo two changes, as follows:

It is for these reasons that these three compounds are associated in the urine of diabetics.

#### ACIDOSIS A CONCOMITANT OF KETONURIA.

The body, therefore, with impaired power of oxidizing sugar, is also unable to complete the oxidation of fats. Apparently it carries through the process of beta-oxidation quite successfully until the final stages are reached. Considerable energy is furnished the body in this process, but at the expense of the production and accumulation of enough of the relatively strong oxy-butyric and beta-keto-butyric (aceto-acetic) acids to draw too heavily on the alkali reserve and thus produce the condition of acidosis.

Insulin clears up both glycosuria and ketonuria (acetonuria) primarily by making it possible for sugar to burn and, in consequence of this burning, making it possible for these products of fat oxidation to "burn in the fire of the carbohydrates" just as they do in the normal body. The end products of this final normal step in the oxidation of fats, carbon dioxide and water, are promptly excreted, thus avoiding acidosis.

#### THE SUBSTITUTION OF ODD CARBON SYNTHETIC FAT FOR EVEN CARBON NATURAL FAT IN DIABETIC FEEDING.

Mention should be made in this connection of another promising attempt to facilitate the feeding of diabetics so as to avoid acidosis. If we could feed fats whose fatty acids contain an *odd* number of carbon atoms, beta-oxidation would occur; but this would bring us to the three-carbon acid, propionic acid, which is readily cared for by oxidation or by synthesis into sugar. We thus escape the pitfall of aceto-acetic acid. As already pointed out, the natural fatty acids of our fatty food all contain an even number of carbons. Chemists have pre-

pared the odd-carbon acids, but until recently only at prohibitive expense as a source of food. Recently Prof. R. H. McKee of Columbia University has succeeded in preparing on a commercial scale a fat whose fatty acid contains an odd number of carbon atoms. The cost of this fat at present is \$8.00—\$9.00 a pound; it is palatable and seems to serve in metabolism the same purpose as the naturally occurring fats. A manufacturing plant has been erected at Long Island City to make this product, known as Intarvin, for use in diabetic feeding.

When one remembers that the chief problem of diabetic feeding is to supply enough energy to the body after the usual chief source—the oxidation of glucose—is impaired or destroyed and, in consequence, fats cannot be used abundantly because of the danger of acidosis, the importance of having an odd carbon fatty acid in diabetic feeding is obvious.

#### THE PHYSIOLOGICAL SETTING OF INSULIN.

This paper makes no pretence of summarizing the literature of the physiology of insulin or of diabetes. This literature has accumulated with feverish rapidity during the past year. Fortunately, journals like the *Journal of the American Medical Association* keep the medical profession so well informed of progress that even "he who runs may read." I shall merely conclude with a brief glance at several points which will perhaps assist the general practitioner to get the physiological setting of these discoveries.

1. *What is insulin from the standpoint of chemical structure?* We recall the light thrown on adrenal function by Abel's demonstration of the structure of epinephrin and the light thrown on thyroid function and therapy by Kendall's demonstration of the structure of thyroxin, both these discoveries holding out the prospect of synthetic preparation of these internal secretions. Have we any similar knowledge of the chemical structure of insulin? We have not. We do not even know that it is a single compound. It is known to be destroyed by pepsin and trypsin (and hence cannot be administered *per os*) and this strongly suggests that it is a protein or peptide combination, or combinations, probably of considerable complexity. If this surmise should be confirmed, the prospect of synthetic preparation is not hopeful.

2. *Widespread occurrence of insulin-like substances in plants and animals.*—On the other hand, glucose is a food of all animals and of most plants. The green plant makes it with the aid of sunlight from carbon dioxide and water; the mold grows actively upon material containing it; the action of yeast on it is well known; and the occurrence of dextrose and glycogen is all but universal in the animal kingdom. If the mammalian body requires a special agent to make the glucose of its food available, we should expect to find it or some similar substance in plants and animals generally. This expectation is being realized in that Willaman has prepared from green plants and Collip from yeast an extract which lowers the blood sugar in diabetic animals. This suggests that insulin, or something performing the same general function as insulin, is widely distributed, a part of the mechanism, as it were, of most and possibly of all living organisms; and that in the higher animals this function has been segregated in the islet cells.

3. *Seat of action of insulin.*—Where does insulin act? In the blood, or in the cell?—for it would seem clear that it acts in the one or the other or both. Its addition to drawn blood has not, in the experiments made to test this point, increased the rate of disappearance of sugar (glycolysis) from the blood; on the other hand, it causes sugar to disappear much more rapidly from the fluid used in perfusing an isolated beating heart. These experiments strongly suggest that the seat of action of insulin is the cell itself, but they do not disprove the possibility that insulin may play its role in part or in whole in the blood. Glycolysis merely means that sugar has disappeared in the form which will give the reaction upon which the quantitative test is based. Its non-occurrence does not prove that the sugar has not been changed in internal structure, perhaps into a more reactive isomer, which still gives the reducing test; and it may be—for all the conclusive experimental evidence that I know to the contrary—that insulin acts upon the sugar in the blood, making it more reactive, and that this more reactive form of glucose enters the cell, there to be immediately oxidized.

4. *Regulation of the pancreatic manufacture and secretion of insulin.*—The extraction of insulin and the rough estimates we are al-

ready able to make of its amount in different organs, or in the same organ at different times, would also seem to give us a method of attacking the problem of the physiological adjustments of the pancreatic functions to the varying needs of carbohydrate metabolism in the organism as a whole. Virtually nothing is known on this subject today. Does the normal pancreas maintain a steady secretion of insulin into the blood or is its rate of manufacture or secretion or both adjusted to the existing needs of the organism? Here again we recall the history of adrenalin,—at first thought to be steadily secreted at a more or less uniform rate into the blood until shown to be under the control of the nervous system and secreted when occasion demands the more vigorous action of the reaction organs of the sympathetic fibers. With regard to this part of the physiology of the pancreas we are in the same stage of knowledge as we were with regard to the adrenals in 1895 and doubtless it will take long and careful investigation to answer the important physiological questions which crowd upon us. I merely desire to show you that the discovery of insulin gives us a new point of attack upon this field of physiology.

5. *The hypoglycemic reaction.* — To the physiologist and the student of metabolism probably the most important new revelation which has come to us as the result of the work with insulin is the hypoglycemic reaction consequent upon an overdose. So far as I know, this is a new discovery in the field of carbohydrate metabolism and a fact of deep significance, which demands immediate and intensive study. Going back to the days when Liebig dominated thought on metabolism, we recall his classification of foods into "plastic" and "respiratory," the former (proteins) providing material for tissue building and the energy for muscular work; the latter (fats and carbohydrates) serving no other function than the liberation of heat through oxidation. We recall the classical experiment of Fick and Wislicenus, which overthrew this theory of the (Czar of chemistry as effectively as Pasteur overthrew his theory of fermentation and showed that the oxidation of fats and carbohydrates yields energy for muscular work as well as heat to maintain the constant body temperature. Later it was shown that the energy for muscular work could come ultimately from protein or fat or carbohydrate;

but vestigial survivals of the old Liebig classification remain today in a very generally held point of view that the only function of fats and carbohydrates is to be burned either to do work or produce heat and it is largely immaterial whether fat or carbohydrate is used for this purpose. In other words, the fats and the carbohydrates play essentially the same role in metabolism.

Biochemistry has meanwhile accumulated facts which raise doubts as to the correctness of this point of view. For example, it is known that the cerebrins—a group of lipoid constituents of many cells—contain galactose in the molecule; also that the nucleic acids contain pentose or hexose radicles and that probably the hexose radicle is glucose. Obviously galactose and glucose are building stones of important chemical compounds. The development of lipoid chemistry has pointed to a similar function of fatty acid in the synthesis of other compounds.

Now comes the physiological and clinical observation that reduction of the blood sugar below a certain level is fatal; that, as this level is approached, certain important symptoms make their appearance, among them being a "rapid pulse rate (but a slow rate when the reaction is severe), pallor, sweating, stupor, peculiar feelings of impending danger, incoherence in speech, tremulousness, and finally coma and convulsions" (Seale Harris). Finally, all these symptoms are relieved promptly by increasing the blood sugar.

I can only make the wildest guesses at the physiological genesis of these symptoms; but I can see that they open up a new field of extensive investigation into many of the fundamental problems of metabolism. It would seem that the combination of insulin and odd-carbon fat in feeding normal and depancreatized animals gives us the means of studying the role of carbohydrates without the complication of ketonuria and acidosis. Hitherto, by the use of insulin, we could reduce the blood sugar to very low figures (0.03—0.04 per cent) but the picture of the effects of sugar deficiency in metabolism was blurred or completely obliterated by the resulting acidosis. It would seem that we should now be able to meet the energy needs of the body for comparatively long periods of time with odd-carbon fat and thus be in a position to see how metabolism in particular and the bodily functions in general are

influenced by deprivation of one of the usual foods. The combination of odd-carbon fat and phlorhizin poisoning holds out similar alluring prospects, which only actual research, and I doubt not an immense amount of most painstaking; critical research, can make our own; but it is one of the most important problems for immediate attack.

Physiologists have long suspected that the two sole sources of energy for muscular work may be glucose and fat. Protein food, it is true, may also serve as the ultimate source of energy for muscular work; but this may be only in virtue of the amino-acids of which it is composed and into which it is broken down in the alimentary canal; these amino-acids, after absorption into the body and deamination (removal of their ammonia radicle), give us sugar and fatty acids; and it may be that it is only this part of the protein molecule which serves as the source of energy for muscle work. Insulin may yet reveal to us the real chemistry of muscular contraction.

But these are more dreams of an enthusiastic physiologist, at least for the present. May I close this paper with a plea for the importance, the fundamental importance, the all-importance of pure science in the progress of medicine and the unstinted recognition of this in the form of public and professional support? It is certainly with no desire to detract one iota from the justly earned recognition of men like Banting, Macleod, Collip, and their co-workers that I remark that an almost painful lack of appreciation of true relative values is shown in the fact that the isolation of insulin and the working out of its therapeutic application has brought to the men who have done this work—and done it so well—far more public recognition than ever fell to the lot of von Mering and Minkowski, of Opie, of Graham Lusk, of Dakin, or even to that prince of pioneer investigators, Claude Bernard, who have made contributions of equal merit and some of greater importance to the physiology of carbohydrate metabolism but whose great discoveries did not at once find application in the practice of medicine. I do not begrudge the recognition which has come to Banting and Macleod. They richly deserve it. Nor do I find fault with the lack of popular recognition of the pure scientists whose work has helped to lay the foundations of our knowledge and our practice. This is inevitable in the

nature of the case. One hundred years from now all this will matter nothing whatever. I do insist, however, that the work of von Mering and Minkowski, of Lusk, and the rest is as important to us today as that of the Canadian investigators; and that without the former we should not only not have the latter, but we would not know what to do with insulin if it came to us as a gift by some sort of direct inspiration; and I insist upon this, not for a moment to plead for similar popular, personal recognition of the results of purely scientific investigation in the field of medicine—for this I do not “care a fig;”—I do it to emphasize the all important character of “pure science” in medicine and to urge that you do all in your power to increase public support of this work in our medical schools and research institutes. Every great advance in practice has come from the increase of insight, through patient, accurate, truth-seeking and generally long continued investigation into the pure science of the phenomena of living things with which we deal.

### THE PATHOLOGY OF THE PANCREAS.\*

By K. D. GRAVES, M. D., Roanoke, Va.

The pancreas is subject to a number of pathological changes, such as abscess, calculi in ducts, carcinoma, adenoma, sarcoma, inflammation, hemorrhage, syphilis and tuberculosis; but, owing to the limited scope of this symposium, I shall limit myself to a discussion of the changes which take place in it incident to the disease known as diabetes mellitus.

A great deal of work has been done, and many theories advanced as to the function and importance of the internal secretion of the pancreas. Mering and Minkowski in 1889 showed that extirpation of the entire pancreas led to the familiar train of symptoms of diabetes mellitus. Opie in 1900, and later Schaefer and Ssobolew, called attention to the islands of Langerhans in connection with diabetes, and maintained that the active portion of the pancreas in preventing diabetes was to be found in them; and MacCallum in 1909 and Kirkbride in 1912 performed a most interesting experiment which was as follows: Half the pancreas of a living animal was ligated, and the animal survived; a year later the animal

\*Read as a part of the symposium on The Pancreas, at the fifty-fourth annual meeting of the Medical Society of Virginia, in Roanoke, October 16-19, 1923.

showed the transformation of the ligated portion into a thin transparent film in the mesentery. Extirpation of the normal half of the pancreas was followed by a transient glycosuria, from which the animal survived and recovered; but after the extirpation of the thin film which represented the other half of the pancreas, the animal developed severe diabetes; this film contained only islands of Langerhans.

Surprisingly few cases of diabetes have been found which show gross changes in the pancreas; but, as has been mentioned above, the majority show microscopic changes of one sort or another, either in the number of islands or their microscopic appearance. Weichselbaum and Heiberg emphasized the importance of the islands, the former the qualitative, and the latter the quantitative; Allen lays stress on hydropic degeneration as an end result, and fibrosis and chronic pancreatitis as evidence of functional impairment; Conroy considers that both quantitative and qualitative changes are operative, laying emphasis on hyalinization and fibrosis of the insular tissue. Cecil found pathological changes in the pancreas in 87% of his diabetetic cases.

I have cited the above opinions and conclusions chiefly to show their divergence. It is, in the light of our present knowledge, manifestly impossible to say didactically by gross or microscopic examination, that a certain patient had diabetes; we may say that we find certain conditions which strongly suggest the disease, but here our report must end. If, after such exhaustive efforts as have been made to correlate the visible picture of the organ with diabetes, we must confess our inability definitely to diagnose the disease by a study of the pancreas, we must feel fairly safe in assuming that further light on the characteristic changes which take place in the pancreas will probably come, not through further microscopic study, but by some other avenue of approach, such as possibly a biochemical reaction, as we have with adrenalin; or a biophysical reaction, as we have with the electrocardiograph; or some other equally remote, but equally possible means of detecting deviation from normal.

In conclusion, may I reiterate that, although years of exhaustive study have been spent by the leaders in pathological thought, in their effort to correlate microscopic changes in the pancreas with symptoms of the disease in the

human organism, there is still a wide divergence of opinion, apparently indicating that they have not yet solved the problem; but that, with the momentous and epoch-making discovery of Banting and his associates, a new era has been ushered in, which promises hope to the diabetic patient, and encouragement to the student of the subject.

*Lewis-Gale Hospital.*

## DIAGNOSIS AND MEDICAL ASPECTS OF DISEASES OF THE PANCREAS.\*

By JAMES H. SMITH, M. D., Richmond, Va.

How can we recognize disease of the pancreas? What is the lesion? What are the broader indications as to treatment? These I conceive to be the questions embraced in my subject.

An anatomical and functional isolation of the isles of Langerhans tends to hold in disease as in the normal. When advanced stages have been reached in acinar or interacinar lesions, carbohydrate metabolism may be impaired—sometimes, indeed, early; but we do well not to rely upon these two parts of the gland for evidence incriminating each other. Disease affecting the external secretion will be first considered.

Because the external secretion splits fats, proteins and carbohydrates, diagnostic evidence may be furnished by failure of either of these classes of foods to be digested, or by a lessened content of the respective enzymes in the faeces. Steatorrhea is the name given to the passage of stools containing liquid fat, solidifying on cooling. While it points directly at the pancreas, its occurrence is rare. Significance almost as great is attached to the chemical determination of more than fifty per cent of fat unsplit. Lesser percentages may be due to other causes. The not uncommon clay or putty colored stool may be due to pancreatic deficiency, or, as the term "acholic" indicates, to biliary obstruction, or to some process such as peritoneal or mesenteric tuberculosis, which interferes with intestinal absorption.

The presence in the faeces of undigested striped muscle is indicative of pancreatic rather than hepatic disease. But it may result from any condition in which the intestinal contents pass rapidly through the bowel. It has been termed creatorrhea.

\*Read as part of the symposium on The Pancreas, at the fifty-fourth annual meeting of the Medical Society of Virginia, at Roanoke, Va., October 16-19, 1923.

Failure of the starch-splitting ferment to reach the intestine is evidenced by a shortage of diastase in the fæces, and an excess in the blood and urine. The two latter are of value when the kidney function is not impaired. I will not quote the technical details of this and other special tests; I have had no experience with them except through pathologists. The Cammidge reaction has never come into general use, and its value is doubtful. There is a series of so-called "messenger" tests, consisting of passing various substances through the bowel to see what happens to them. Einhorn's method of obtaining duodenal contents for examination of its tryptic activity was a forerunner of Lyon's method for study of the biliary secretion. Beyond question, we need something that will furnish direct evidence of disease of the pancreas, but it can hardly be said that any one of these tests has, so far, proved uniformly reliable.

To return to the data to be had at the bedside; the typical stool in disease of the pancreas is bulky, pale, soft, gaseous, offensive, high in fat content, and may contain indigested muscle fibres. This will be recognized as quite the same description applying to the stools in sprue, though it does not constitute the diagnosis of sprue. Glandular insufficiency involving the pancreas, liver, intestinal glands, and often the stomach may develop in sprue or other wasting constitutional disease, such as pernicious anaemia or pellagra. The tongue is often a good index of such a deficiency. Ashford<sup>1</sup> claims that true tropical sprue results only when there is superimposed upon glandular insufficiency, colonization in the digestive tract of a specific organism, *monilia psilosis*. Others have attempted to treat sprue specifically with vaccines made from this organism.<sup>2</sup> Probably the etiology of sprue should be regarded as unsettled.

In conditions in which pancreatic secretion is deficient, beneficial effects have been reported from the administration of fresh pancreatic substance. Several careful investigators have testified to a potency of commercially prepared pancreatic extracts. Such products from reputable makers are useful remedies, and it is preferable to get a clean preparation from a drug store rather than something to be eaten raw from a butcher. Se-

lection should be made with a view to the ferment or ferments most needed. In a case of severe, prolonged secondary anaemia due to hemorrhoids, with stools of the character described, I attributed much benefit to pancreatic extracts. An American physician, returned from Korea, stated that sprue is common in that country, that he had treated many cases, and was convinced that he himself was suffering from that disease. He improved under pancreatic extract along with diet and the chance to recuperate from fatigue and worry in a difficult environment. Thomas Brown<sup>3</sup> reports five cases of sprue in which he established the fact of pancreatic insufficiency. Four showed remarkable improvement from the administration of pancreatin, which is a preparation of trypsin. A large number of minor illnesses, and a symptom-group arising in various diseases, situations in which we often prescribe calomel, flatulent indigestion and the like may be contributed to by a pancreatic fault, as much as by biliary derangement. This is the state referred to by Garrod<sup>4</sup>, in which the pancreas is only "worried," rather than diseased. In my experience, pancreatic preparations are more effectual in relieving such complaints than are the bile salts. After all, the bile salts are adjuvant only to the pancreatic lipase.

The intimate relationships, both anatomical and functional, between the liver and the pancreas at times make differential diagnosis almost impossible. The pancreatic duct comes into direct relation with the common bile duct at the diverticulum of Vater, and the head of the pancreas lies in close apposition. Thus, the fat-splitting function of both secretions may be interfered with by a single calculus; progressive jaundice and enlarged gall-bladder—Courvoisier's law—are as characteristic of cancer of the head of the pancreas as of the bile-ducts; and inflammation traveling along the ducts may result in acute or chronic pancreatitis as a complication or sequel of bile-tract infection. Most of us keep pretty well in mind the liver as a source of abdominal trouble. Whenever we suspect the liver, we should consider the pancreas; roentgen-ray study may help to locate the lesion. As the same measures of treatment, chiefly surgical, are applied to both in the present state of our

knowledge, no very vital issues usually are at stake. As between drainage and removal of the gall-bladder, perhaps the pancreatitis at times associated with cholecystitis deserves special consideration. This, however, is a surgical question. When we think of these two extensive systems of ducts, and the organs to which they lead, it is not difficult to understand why gall-bladder operations often fail to give the permanent relief hoped for.

When the pancreas becomes the seat of acute hemorrhagic inflammation, the clinical picture most nearly approaches that of intestinal obstruction. Suppurative inflammation, necrosis or gangrene may follow. From obstruction, acute inflammation of the pancreas is distinguished by an even more sudden and overwhelming onset. The localization of pain is more apt to be epigastric, and the increased peristaltic action of the bowel when obstructed would not be expected. A perforated peptic ulcer would likewise come to mind, and here the history would be helpful. If the abdomen is opened, a characteristic fat necrosis may declare the pancreatic origin of the trouble, due to the digestive powers of the secretion.

Because of the location of the pancreas, tumors of this organ are usually to be found in the epigastrium or left hypochondrium. If a rounded mass presents itself in this area, a pancreatic cyst would be suggested. The pulsation transmitted to such a cyst by the abdominal aorta, suggesting aneurysm, may usually be eliminated by causing the patient to assume the knee-chest position.<sup>5</sup> Roentgen-ray study of the stomach should exclude cancer of that organ.

Certain pathologists, notably Warthin, have endeavored to show that syphilitic pancreatitis is a frequent cause of diabetes mellitus. There is little corroborative evidence. Williams, Mitchell, Rosenbloom, Joslin and Lemann, have all presented data to the contrary. In seventy-eight cases of diabetes reviewed by the writer a year ago,<sup>6</sup> syphilis had been recognized in three only. Clinical recognition of syphilis of the pancreas is hardly possible without evidence of a luetic affection elsewhere or a positive Wassermann reaction. Tuberculous pancreatitis likewise would require a more or less general background of tuberculosis for its recognition.

Briefly to review the diagnostic considerations up to this point, disease affecting the external secretion of the pancreas is to be inferred from disturbance of digestion with its attendant pain, discomfort, wasting and anaemia; from the gross and microscopic character of the stools; from a study of the enzymatic activity of the fæces, the tryptic activity of the duodenal contents, and the starch-splitting power of the blood and urine. These data suggest faulty pancreatic function. Naturally they are more pronounced in the conditions resulting in obstruction of the pancreatic duct—calculi, cancer and cysts. Jaundice, the outward sign of a deranged liver, is also the only color in which the pancreas with its colorless secretion can signal its distress. Acute hemorrhagic pancreatitis gives the picture of an upper abdominal catastrophe of the gravest kind. In a pancreatic cyst, the tumor would have the common physical characteristics of a cyst, would usually tend toward the left of the upper abdomen, and often transmits pulsations from the abdominal aorta. If, now, carbohydrate metabolism is impaired, as shown by glycosuria or abnormally high blood sugar under normal dietetic conditions, any suspicions held as to a parenchymatous lesion of the pancreas are strengthened. Carbohydrate tolerance tests, experimentally conducted, are as yet having widely different interpretations put upon them. Some would assign them value in the study of thyroid function, and others plot a blood sugar curve for cancer anywhere from the tongue to the anus.

It is seen, then, that the pancreas, as regards its external secretion, is still a subject that lies tucked away behind the stomach, duodenum and the liver, both in the patient's abdomen and in the purview of the diagnostician. That we know more about a fractional part of the gland, the Islands of Langerhans, than we do about the major part, is due to the highly specialized function of the former. Until very recently, there was a question in the minds of some, whether diabetes mellitus was essentially a disease of the internal secretion of the pancreas. That may be considered as settled, and this weird and fascinating subject has become one of the things of which we may speak with comparative confidence. Endocrinology has got itself labeled as a pseudoscience and the nest of theorists. The enthusi-

6. Smith, James H., Va. Med. Monthly, February, 1923.

asm of its followers may lead them often to venture into the speculative, but solid achievement in the realm of the thyroid and pancreas, to mention none other, may well account for their faith and hope.

The diagnosis of frank diabetes mellitus is familiar to every medical student. Sugar in the urine should be regarded as due to diabetes until proved otherwise. Unless urinary sugar can be shown to be some form other than dextrose, potential or early diabetes is a safer working diagnosis than alimentary glycosuria. Carbohydrate tolerance tests are useful but, after all, the best test is a knowledge of the way the patient metabolizes a normal average diet. Renal diabetes is a rather rare condition in which the blood sugar remains normal on an average diet, though sugar appears in the urine. A low renal threshold for sugar is inferred. The symptoms of diabetes mellitus are lacking and it should not be treated as such. Diabetes insipidus is not a disease of carbohydrate metabolism. Loewi's phenomenon, the pupil dilating under the influence of adrenalin, seems to apply about equally well to exophthalmic goiter, diabetes and grosser pancreatic lesions (Garrod). It is an interesting observation, doubtless indicative of a relation between these conditions through the sympathetic nervous system, but it can hardly be considered necessary or valuable in the diagnosis of diabetes.

A discussion of the treatment of diabetes and its complications would carry us far beyond the limits of this paper. As it was a hundred years ago, so now, the treatment is primarily dietetic. Until 1922 the problem was to find out the patient's tolerance, to induce him to live within it, and to teach him how to do it. With the introduction of insulin, the situation has changed. A great tactical advantage is won, but the strategic principles are not altered. Insulin does one specific thing: given hypodermically or intravenously, it metabolizes sugar. We have no ground, as yet, to believe that the pancreatic lesion is healed, nor is it certain how far carbohydrate tolerance can be restored. In other words, it is substitution therapy, not a cure. The diabetic is not enabled to return to a normal diet; but his own inadequate tolerance can be added to in grams by the use of insulin, unit by unit, till the diet is brought to a rea-

sonable and comfortable level. Acidosis is controlled even, sometimes, when the patient is in coma. The dangers of hypoglycemia are not great if intelligent care is used.

To my mind this one achievement of honest medical effort offsets all the offenses of a generation of quacks. The foundation was laid by years of work by faithful scientists from von Merring to Allen. To few has it been given to serve their country in war and their fellowmen in the ways of peace, in the measure that has come to Banting, the youthful Canadian.

It now remains for the public health authorities, hospitals and philanthropic individuals to provide adequate clinics for these sufferers. This necessity does not arise out of any enormous cost of insulin, reports to the contrary notwithstanding. The factors involved are unique. The disease is chronic, requiring, under the best conditions, about a month of close observation of the patient, preferably in a hospital. This in itself, is no great stumbling block. It has been overcome with reference to tuberculosis, insanity, orthopedic and other diseases. Diabetes, however, is exceptional in that its management demands unusually close co-operation between three separate hospital departments—the ward, the laboratory and the diet kitchen. Above all, and surpassing the requirements in any other disease, there is the need to educate the patient in food values. People of all grades of intelligence and all sorts of home conditions, must be dealt with. The painstaking, conscientious efforts of a competent teacher are here essential. Usually a specially trained nurse or dietitian is best suited to the job. Manual training has been introduced into our public schools to provide our youth with a trade. Educational diabetic clinics must be organized in our hospitals to restore to economic efficiency and to save the lives of those who cannot follow the trade they have learned.

#### THE SURGERY OF THE PANCREAS.\*

By ARTHUR D. OWNBEY, M. D., Newport News, Va.  
Associate Surgeon, Elizabeth Buxton Hospital.

The pancreas is situated behind the peritoneum and lies across the posterior abdominal

\*Read as part of symposium on The Pancreas, at the fifty-fourth annual meeting of the Medical Society of Virginia, at Roanoke, October 16-19, 1923.

Dr. Ownbey substituted for Dr. J. T. Buxton, the original appointee, who was prevented by illness from taking part in the symposium.

wall at the level of the first and second lumbar vertebrae. It is five to six inches in length, one and one-half inches in breadth, and from one-half to one inch in thickness. The broad right extremity or head rests in the hollow of the duodenal curve. The body lies behind the stomach, and the tapered extremity or tail comes into contact with the spleen, and has the left kidney lying behind it.

The pancreatic duct or the canal of Wirsung is the principal excretory duct of the pancreas and extends through the substance of the gland from left to right. Commencing small by the junction of the little ducts of the lobules situated in the tail of the pancreas, it gradually grows in size as it constantly receives the ducts of the lobules composing the gland. Upon reaching the neck the duct turns obliquely downward, backward, and to the right. It comes into relation with the common bile duct, lying to its left side. After leaving the head of the gland it passes very obliquely through the mucous and muscular coats of the duodenum, and usually terminates by an orifice common to it and the common bile duct upon the summit of an elevated papilla, situated at the inner side of the descending portion of the duodenum, three or four inches below the pylorus. Occasionally the common bile duct and the pancreatic duct open separately into the duodenum. The duct of Santorini is frequently seen as an accessory duct of the canal of Wirsung given off in the neck of the gland. It passes horizontally to the right and opens into the duodenum about an inch above the orifice of the main duct. The pancreas resembles the salivary glands in that each lobule consists of one of the ultimate ramifications of the main duct, terminating in a number of cecal pouches or alveoli which are almost completely filled with the secreting cells, so that the lumen is barely visible. In certain parts, chiefly in the tail, there are found in the connective tissue among the gland tubules and alveoli, collections of cells, known as the islands of Langerhans, being named after the author who first described them in 1869.

The pancreas has two chief functions, that of an organ of internal secretion and of external secretion. The islands of Langerhans furnish the internal secretion and are not connected in any way with the duct system of the pancreas. The internal secretion controls the assimilation of sugars and a lack of this secre-

tion produces the well-known condition of diabetes mellitus. The external secretion is the most active and most important of all the digestive juices.

Diseases of the pancreas may be divided as follows:

1. Solid tumors:
  - Cancer
  - Sarcoma
2. Fluid tumors:
  - True cysts
    - a. Retention cysts
    - b. Proliferative cysts
    - c. Congenital cysts
  - Pseudocysts
  - Hydatid cysts
3. Pancreatic lithiasis.
4. Wounds of the pancreas.
5. Pancreatitis (as classified by Mayo Robson):
  - Acute
    - a. Hemorrhagic
      - a. Ultra-acute, in which the hemorrhage precedes the inflammation, the bleeding being profuse and both within and outside the gland.
      - b. Acute, in which inflammation precedes the hemorrhage, which is less profuse and is distributed in patches throughout the gland.
    - b. Gangrenous
    - c. Suppurative (diffuse)
  - Subacute
    - a. Abscess of the pancreas
  - Chronic. Intestinal
    - a. interlobular
    - b. interacinar

#### CARCINOMA OF THE PANCREAS

Carcinoma is the most common neoplasm of the pancreas and, while it may be primary, it is usually not, being more frequently secondary to lesions of the stomach, duodenum, gall-bladder and bile ducts. When primary it involves the head of the gland in most all cases. Patients suffering with cancer of the pancreas are usually past middle age of life and give a history of vague digestive disturbances, accompanied by general weakness and rather rapid emaciation. Obstruction of the bile ducts may occur with a resulting jaundice which develops gradually, painlessly, and never lessens in its intensity. Should the lesion extend backward so as to involve the vena cava and portal vein, ascites will develop. Should the islands of Langerhans be involved to a very great extent there will develop a glycosuria. The association of chronic jaundice with distention of the gall-bladder is generally considered as an almost pathognomonic sign of cancer of the head of the pancreas (law of

Courvoisier). Surgical treatment in cancer of the pancreas carries with it an almost prohibitive mortality. It is doubtful if even an exploratory operation is justifiable if one is reasonably certain that the condition being dealt with is cancer. However, in some instances much relief has been obtained by an anastomosis being made between the gall-bladder and a convenient portion of the intestinal tract. This will afford a somewhat satisfactory drainage of the bile with a lessening and perhaps complete relief from the itching and ill-feeling produced by a deep jaundice.

#### SARCOMA OF THE PANCREAS

Sarcoma of the pancreas is found infrequently as a primary growth and only very occasionally is it observed as a secondary growth. A few cases have been reported where a sarcoma has been removed with gratifying results.

#### CYSTS OF THE PANCREAS

Cysts of the pancreas may be classified as true pancreatic cysts, pseudocysts and hydatid cysts.

Among the true cysts we have (1) retention cysts, due to the obstruction of the outflow of the pancreatic secretion, with the resulting dilatation of the ducts of the acini; (2) proliferative cysts or cystic neoplasm. These are cystic tumors, due to spontaneous proliferation of the epithelial elements of the gland, with accumulation of the fluid in the cavities which are so formed. They may be simple such as cyst-adenomata; or malignant, cystic epitheliomata or carcinomata; (3) congenital cystic disease of the pancreas which is exceedingly rare. Pseudocysts constitute a large porportion of cases reported as pancreatic cysts. While they may be found within the substance of the pancreas, the greatest number of pseudocysts are formed in contact with the gland, particularly in the lesser peritoneal cavity, usually as a result of some traumatic injury to the pancreas in which there has resulted some hemorrhage in or around the pancreas.

In the early stages the symptoms of cysts of the pancreas are vague. Pain in the epigastrium or just above the umbilicus may be present and may occur even when the cyst is not palpable. Epigastric distress with a feeling of fullness and vomiting may be the chief complaints. Should there be adhesions to the stomach, certain gastric disturbances will probably be present. Emaciation and weakness

have often been recorded and in not a few cases will be very striking. In some instances pressure symptoms may be observed, pressure on the portal vein producing ascites and compression of the vena cava causing edema of the legs. Nothing is found upon physical examination unless the tumor mass be large enough to palpate, in which instance, fluctuation can usually be made out though at times the sac is so tense that it appears to be a solid growth. The tumor is situated in the epigastrium and may be to the right or left of the median line. Cysts of the pancreas are usually most difficult to diagnose.

Cysts of the pancreas are amenable to surgical treatment and may be treated in one of the following ways: (1) aspiration; (2) evacuation and drainage; (3) extirpation, partial or complete.

Aspiration was used in some of the earlier cases but has now been abandoned.

Evacuation and drainage is the operation most generally applicable.

The abdomen may be opened on one or the other side of the median line above the umbilicus. The cyst is exposed by dividing its peritoneal coverings which vary according as to whether the cyst is above or below the stomach. Usually it is most easily reached by going through the greater omentum just below the stomach. Upon exposing the cyst it should be well walled off by means of gauze sponges to minimize the possibility of the contents of the cyst, which are very irritating, coming into contact with the intestines and abdominal viscera. The greater part of the contents may be withdrawn by introducing a large aspirating needle into the sac. The puncture is enlarged and the cavity temporarily packed with gauze to soak up the remaining fluid, while the edges of the opening are sutured to the parietal peritoneum. One or more drainage tubes are then introduced and are gradually removed as the cavity obliterates itself. In some instances fistulae through which pancreatic juice discharges may remain for months after this operation.

Extirpation is applicable only in those cases where the pedicle is small and there are few or no adhesions. However, should the cyst appear malignant in character, a serious effort should be made to remove it. Malignancy is indicated when little intra-cystic growths can be felt.

### PANCREATIC LITHIASIS

Pancreatic lithiasis is a condition that is not often found but is probably more commonly present than is suspected. The stones are usually found lodged in the ducts though there may be cases in which they are found in a cystic diverticulum. The smaller stones may be expelled into the intestines without any symptoms. They are composed chiefly of the carbonate or phosphate of lime and possibly some cholesterin. They are usually irregular in shape, firm and white or grayish-white in color.

There may or may not be any symptoms of stones in the pancreas. Pain which is generally localized in the epigastrium is the most common symptom and may be slight or severe and paroxysmal. Nausea and vomiting often accompany the attacks. Jaundice is only occasionally seen and is most often due to gallstones occurring simultaneously though it has been produced by a large pancreatic stone pressing upon the common bile duct sufficiently to produce obstruction to the flow of bile. Chills and fever may occur according to the amount of infection present. Glycosuria is a late manifestation of the disease and is present only after an involvement of the islets by an intra-lobular pancreatitis. Alimentary glycosuria is a significant and frequent finding. Most pancreatic calculi are discovered accidentally while operating for some other upper abdominal condition.

The treatment is surgical and consists of the removal of the stones. The situation of the calculi determines the method of procedure. Stones in the ampulla of Vater or in the right extremity of the duct of Wirsung may be removed by opening the duodenum and incising or stretching the papilla common to bile and pancreatic ducts, so that forceps or a probe may be introduced into the duct of Wirsung. Should the calculi be situated some distance from the papilla, it will be necessary to expose the pancreas through the gastro-hepatic omentum or through the transverse mesocolon. The gland is incised over the stone, the stone removed and the incision closed by deep sutures of catgut. In some instances the stone can be more easily reached by severing the reflection of peritoneum from the duodenum to the abdominal wall and retracting the duodenum anteriorly and to the left. Whenever the gland

has been cut, it is safest to insert a cigarette drain down to site of incision.

### WOUNDS OF THE PANCREAS

The pancreas is very infrequently wounded because of its depth within the abdomen, its protection by other viscera and the partial shelter afforded by the costal arch.

Gunshot and stab wounds constitute the most frequent injuries and next to these are such injuries as would result from a violent blow upon the epigastrium, as by the kick of a horse or from being crushed, such as would occur when a heavy vehicle passes over the body.

The pancreas is practically never injured unless there occur simultaneous wounds of some other abdominal viscus and symptoms of injury to the pancreas are usually masked by the symptoms of the lesions of other organs such as the liver, stomach or spleen.

In any case where there is a stab or gunshot wound or severe contusion of the abdomen with evident signs of intra-abdominal injury, it is not so important that a diagnosis be made before operation but that an exploratory operation be done and it is imperative that the pancreas receive a thorough inspection. The chief dangers from injury to the pancreas are hemorrhage, infection and fat necrosis. In favorable cases of punctured or incised wounds, the torn edges may be brought accurately together by strong catgut sutures, passing through the capsule and parenchyma, care being taken to avoid catching up the duct of Wirsung. If there has been much hemorrhage, it must be thoroughly controlled and provision made for drainage. Fat necrosis necessitates the free drainage of the secretion and probably leaving the wound open with tamponing of the abdominal cavity. In all operations on the pancreas one should be careful to produce as little trauma as possible.

### PANCREATITIS

Of the two chief forms of pancreatitis, catarrhal and parenchymatous, the latter is the more frequent and the most common.

There are three principal theories to explain the cause of pancreatitis but as yet the cause and the way in which it works is still somewhat unclear. The first theory is that pancreatitis is produced by the effect of bile entering the duct, or by reason of an obstruction due to a stone or mucus or by a spasm of the duct sphincter at the outlet of the common duct.

The second is that duodenal contents are forced into the common duct at a time when it is temporarily relaxed and thence into the pancreatic duct. The third explains it by a lymph-borne infection from the gall-bladder, bile ducts and duodenum. And then there are those who believe that the infection may be hematogenous in origin.

As regards the obstruction of the flow of the bile through the sphincter, two explanations have been offered. In the first place, as can be easily understood, it is possible for a stone to block the ampulla of Vater in such a way as to make the common bile duct and the pancreatic duct into one. Second, it is believed that acid in the duodenum will produce a spasm of the sphincter and this theory is borne out clinically by the fact that chronic pancreatitis is often present in patients with ulcer of the duodenum and in alcoholics. In these persons it is thought that the acid injected into the duodenum remains longer before it is neutralized than in normal individuals.

It has been shown experimentally that normal bile introduced into the ducts of the pancreas produces inflammation and necrosis of the parenchyma with which it comes into contact. Others claim that, when normal bile enters the pancreas, no particular harm is done. However, when infected bile enters the pancreas, there occurs extensive and massive destruction with edema, congestion, hemorrhage and an inflammatory response on the part of the fixed connective tissue.

It has been shown experimentally that mucin modifies the irritant action of bile and, therefore, any condition such as an obstruction of the cystic duct by a stone, which would tend to lessen the normal amount of mucin, furnished by the wall of the gall-bladder, would render the occurrence of pancreatitis more likely.

According to Deaver, infection carried by way of the lymphatics plays the most important role and supports his view by the statement that in most instances chronic pancreatitis is associated with the inflammation of some abdominal viscus and that the most often diseased part of the gland—the head (the part furthest removed from the duct)—is that which has a free lymphatic relationship with the affected viscus. He has designated that part of the head of the pancreas which is most often found diseased as the triangle of infec-

tion, that is, the area between the ducts of Wirsung and Santorini.

As to the pancreatitis being produced by the entrance of the duodenal contents into the pancreatic duct, it may be said that this is a possibility that seldom occurs. It has never been proven by animal experimentation but the possibility is evident by the fact that in a few instances post mortem dissection has shown the pancreatic duct opening directly into the lumen of the intestine and, in one or two cases, a localized pancreatitis has been demonstrated around the duct of Santorini.

According to the conclusions drawn by Mann and Giordano from their experimental work, we must look elsewhere for the explanation of the cause of most cases of pancreatitis than the passing of bile into the pancreatic duct, but to the greater number of clinicians and surgeons the most plausible explanation for the cause of pancreatitis is the one attributing the condition to a reflux of bile into the pancreatic duct.

#### ACUTE PANCREATITIS

In this paper the term acute pancreatitis covers the acute hemorrhagic, acute gangrenous, and acute suppurative forms, since they are all phases of the same condition and are not distinct pathological entities, though as a rule the latter two follow the first named condition.

As to the relation between hemorrhage into the pancreas in acute pancreatitis and inflammation there has been considerable controversy. There are those who hold that hemorrhage occurs altogether apart from inflammation, not caused by it, not causing it; that such hemorrhage may be fatal and at post mortem examination not the smallest trace of an inflammatory process found. This condition is known as "pancreatic apoplexy." There are others who hold that an acute inflammation is the primary factor and the hemorrhage, slight or severe, is secondary. And still there are others who contend that the hemorrhage occurs first and is followed speedily by an acute inflammatory outbreak.

#### SYMPTOMS—ACUTE

The patients are usually of middle age and obese. The onset is sudden with intense pain in upper abdomen. The severity of the pain is the most significant thing. The location of the pain is most often in the epigastrium and may be on the left but is more commonly felt

on the right of the midline near the gall-bladder region. However, the location is so variable that it is of little importance. Vomiting occurs and is repeated again and again without bringing relief. The skin is pale and moist, the pulse rapid and of poor quality, temperature normal or subnormal. There may be cyanosis, shallow breathing and dyspnea. Tenderness is usually marked, not localized, but extends across the epigastrium. Distinct rigidity of the muscles is rare though some resistance may be felt on deep palpation. Should the patient survive the acute onset for twenty-four to forty-eight hours, the hyperacute symptoms will subside and in two or three days signs of acute upper abdominal peritonitis may appear. Suppuration is characterized by fever, chills, weakness, emaciation, high leucocyte count, marked tenderness and rigidity. Acute pancreatitis must be differentiated chiefly from perforation of a duodenal or gastric ulcer and gall-stone and kidney stone colic. However, the pain in acute pancreatitis is much more severe than in other of conditions named. Exercise increases the pain of acute pancreatitis and this fact tends to differentiate it from kidney colic. Constipation is marked as the result of a toxic ileus, and the condition is often mistaken for intestinal obstruction but vomiting lessens in acute pancreatitis while in obstruction it is usually progressive. William Linder states that tenderness in the left costo-vertebral angle is of extreme diagnostic importance and invariably means involvement of the tail of the pancreas. In all cases of suspected acute biliary disease an associated pancreatitis should be considered.

Treatment consists in immediate operation. The earlier the operation, the greater the chance of recovery, although we now know that mild cases often get well spontaneously. It is not advisable to delay operation hoping that the signs of shock may lessen. The collapse is due to absorption of toxic products of the pancreatic necrosis and delay will allow a steady increase, lessening chance of recovery. A longitudinal incision of sufficient length is made through the middle or to the inner side of the right rectus to give a good exposure of the pancreas. There are three routes by which the pancreas may be exposed and the omental bursa opened: (1) above the stomach, through the gastro-hepatic omentum; (2) below the stomach, through the upper part of the gastro-

colic omentum; (3) through the transverse mesocolon. The second route is the usual method of approach. Should there be marked necrosis and hemorrhage, more than one route may be opened and gauze drains inserted in order to drain thoroughly and prevent the spread and absorption of the toxic products. Upon opening the peritoneum a blood stained fluid or a peculiar odorless beef-broil fluid may escape and the pancreas is found to be greatly swollen, dark in color and engorged in blood. Yellowish white spots of fat necrosis may be seen in the mesentery or the omentum or the pancreas. It should be punctured lightly in several places and free drainage afforded. This is accomplished by means of pieces of rubber dam tucked into the slits in the pancreas and also gauze which are brought out together through the original wound or through a posterior stab wound in the left loin, or even in both directions. The gall-bladder and bile ducts are rapidly inspected and, if the patient's condition be satisfactory, such treatment of them adopted as seems proper. However, in the severe cases it will be better to establish free drainage as quickly as possible and leave the biliary tract pathology for a later operation.

#### SUBACUTE

Subacute pancreatitis is similar to acute pancreatitis except to a slighter degree. In this condition we have single or multiple abscesses of varying sizes in or around the pancreas which have formed usually following an acute pancreatitis. The condition may begin with the sudden onset of pain, acute, but not overwhelming, in the epigastrium. Vomiting often occurs but faintness and collapse are not so marked. The pulse is not so rapid and the patient does not look so ill. Instead of hastening to his end he lingers on and in a few days, as an abscess begins to form and enlarge, the temperature rises, often reaching 103° to 104°, and there may be a succession of rigors. The loss of flesh and strength is most striking. Epigastric tenderness is rather marked and in some instances a swelling may be made out.

The subacute variety is much more amenable to surgical treatment than the acute. Upon opening the peritoneal cavity, fat necrosis is usually observed and is a pathognomonic sign of the condition you are dealing with. Drainage here is the chief factor in the treatment.

The abscess may be evacuated through the

anterior abdominal wall or through incision in the lumbar region as has been described under treatment of acute pancreatitis.

#### CHRONIC PANCREATITIS

Chronic pancreatitis is of the two forms: (1) chronic interlobular pancreatitis, characterized by an overgrowth of connective tissue between the lobules; (2) chronic interacinar pancreatitis with an atrophy of the acini and a growth of connective tissue between the acini with slight involvement of the interlobular septa. In the latter type the islands of Langerhans are often degenerated and sclerosed.

The chief symptoms of chronic pancreatitis are emaciation; creatorrhea; steatorrhea; glycosuria and pain which is present in half or less than half of the cases and, when it does occur, is difficult or impossible to distinguish from that of duodenal ulcer or gall-stone. The pain is deep seated and radiates posteriorly into the left shoulder. Should colic be present, it is usually due to calculi. Occasionally some resistance is felt in the epigastrium which does not move with respiration thus differentiating it from tumors of the stomach. However, an enlargement sufficient to be palpable is rare.

The diagnosis of chronic pancreatitis by the surgeon at operation is open to criticism because he bases it upon the palpation of an enlarged and hard pancreas. A hard pancreas is not necessarily a diseased pancreas and no organ varies more in size than the pancreas. It is also extremely difficult to differentiate chronic pancreatitis from cancer of the pancreas. Deaver thinks it can practically never be done.

Since chronic pancreatitis is most often associated with diseases of the biliary tract, the best results from surgical treatment will come by the proper management of the pathology of the biliary tract encountered at operation. Drainage of the bile is the most important thing and may be effected in one of three ways: (1) choledocotomy; (2) cholecysenterostomy; (3) cholecystostomy. Robson and Moynihan believe that tube drainage direct to the skin is much more efficient and satisfactory. It is best to keep the external fistula open until the bile appears healthy, which requires from a few weeks to more than a year. The close etiologic relationship of pancreatitis and dis-

eases of the adjacent viscera should always be borne in mind when operating in the upper abdomen and the proper handling of a beginning cholecystitis or bile tract infection will prevent most of the cases of pancreatitis. Medical men should be aware of this fact and not hold cases of bile tract infection under medical treatment too long before referring the patient to a surgeon.

## THE ETIOLOGY AND PREVENTION OF DIABETES.\*

By SEALE HARRIS, M. D., Birmingham, Ala.

Diabetes is essentially a deficiency of the secretion of insulin by the Islands of Langerhans in the pancreas. According to modern nomenclature the word "hypoinsulinism" would better describe the condition characterized by an excess of sugar in the blood than does diabetes mellitus, which the ancients gave it because of the presence of sugar in the urine. Hypoinsulinism is also a better name for the condition than glycosuria because the latter condition may be transient and result from the use of phlorizin, or adrenalin, and it also may be a sequence of emotional disturbances and a condition of the kidneys known as low renal threshold, in which there is no deficiency in the secretion of insulin and a normal amount of sugar in the blood.

### HYPERINSULINISM.

From recent observations, I am convinced that there is a definite syndrome, perhaps a distinct disease entity, which should be called hyperinsulinism, the symptoms of which are those as described as resulting from hypoglycemia. While not strictly relevant to the subject assigned me, I mention this in order for it to be a matter of record when published, because I have seen no mention of it in medical literature. Every physician who has had much experience in treating digestive diseases sees patients who, when their stomachs are empty, complain of extreme hunger, weakness, nervousness, tremulousness, sometimes dyspnoea, subnormal temperature and low blood pressure. We have examined the blood sugar in two such patients at the time when they were having the symptoms described above and their blood sugars were .065 and .070, respectively. The symptoms disappear after eating or after taking a soft drink. In one of these cases the blood sugar went up to .130 after a meal of high carbohydrate content. It is possible that hyperinsulinism may precede hypoinsulinism as hyperthyroidism is sometimes followed by hypothyroidism. We are beginning some observations (which we hope to publish in a few months) on patients who have nervous symptoms associated with hunger that we believe to be the result of hyperinsulinism.

### PANCREATITIS PRECEDES DIABETES.

But to get back to the discussion of the etiology of diabetes, anything that can inhibit or destroy the function of the insulin-producing cells may cause the disease. It is therefore obvious that the causes of diabetes, like the sins of men, are many. It seems probable, however, that the most important underlying factor in the production of diabetes is a preceding, or a concurrent, pancreatitis; and in discussing the etiology of diabetes, the causes for infection of the pancreas should receive prime consideration.

The theory that a damaged pancreas precedes hyperglycemia does not in the least disprove the theory that over-eating or improper eating is a predisposing or an exciting cause of diabetes. In the first place, a crippled pancreas may be able to metabolize the glucose producing foods in the normal diet, but would fail to take care of the carbohydrate in the debauches of the gourmand; secondly, the point that I desire to stress particularly is, that pancreatitis is often the result of the vitamin deficiency in a diet in which there may be an excess of proteins, carbohydrates and fats.

### SOURCES OF INFECTION IN PANCREATITIS.

Since a pancreatitis resulting in permanent damage to the pancreas is the most important predisposing cause of diabetes, it is necessary to consider the sources of the original infection in pancreatic inflammations.

On account of its protected position, primary infection of the pancreas must be rare. Trauma of the pancreas, however, associated with other internal injuries, does occur. We recently have had two cases of severe diabetes which developed so soon after railway accidents that there can be but little doubt that the internal injury involving the pancreas was the direct cause of the glycosuria. These cases were reported at the recent meeting of the American Medical Association.\*

Secondary infection of the pancreas may take place in a number of ways but, on account of its anatomical relations, its blood supply and its lymphatic connections, it would seem that the most frequent sources of infection come from lesions in the gall-bladder, stomach, duodenum, and other portions of the small intestines and the colon. Indeed, when the

\*Read by invitation as part of the Symposium on the Pancreas at the fifty-fourth annual meeting of the Medical Society of Virginia, in Roanoke, October 16-19, 1923.

\*Journal of the American Medical Association.

anatomical relations and the collateral circulation of the pancreas are considered, it is difficult to understand how it escapes infection, when there is an inflammatory lesion of any viscus in the abdomen or of any part of the peritoneal cavity.

#### THE ROLE OF GALL-BLADDER INFECTIONS.

Infections of the gall-bladder would seem to be, and often are associated with a pancreatitis. The opening of the common bile duct in the duodenum is very close to the openings of the ducts of Wirsung and Santorini, when the latter does not empty into the main duct. The common bile duct is always in contact with, and often embedded in, the head of the pancreas; therefore it would seem that, both by continuity and contiguity of structure, a cholangitis or a cholecystitis would be associated frequently with an inflammation of the pancreatic duct, (sialo-angitis and sialodochitis) and a generalized pancreatitis.

The fact that surgeons, in operating for gall-bladder disease, so frequently find an enlarged and inflamed pancreas, which subsides with the removal of the gall-bladder infection by drainage, seems to favor the theory that pancreatitis is often secondary to gall-bladder disease. I have observed several such cases, in two of which the surgeons, after opening the abdomen, made the erroneous diagnosis of cancer, because of the enlarged hard pancreas with extensive adhesions to surrounding structures. In both cases, drainage of the gall-bladder gave relief of symptoms, with restoration to health and no evidence of pancreatic disease over a period of two and four years.

A number of cases have been reported of glycosuria patients whose urine became sugar free after gall-bladder drainage. We have had one such case; therefore, it would seem advisable to suspect gall-bladder infections in diabetes and, if such exist, a gall-bladder drainage may cure the pancreatitis and at the same time remove the primary or associated lesion. In gall-bladder infections associated with diabetes, or with known pancreatic lesions, drainage would seem to be indicated rather than a cholecystectomy. I would not be understood as advising an operation as a cure for diabetes but, in cases in which there is known gall-bladder disease, it seems likely that there is associated an active pancreatitis and the operation for the gall-bladder condition, which

may be the focus of infection for the pancreatitis, may save the pancreas from further damage, and in that way be helpful to the diabetic.

#### STOMACH AND INTESTINAL INFECTIONS.

Since the pancreatic duct, or ducts, open in the descending portion of the duodenum, and the head of the pancreas is almost entirely surrounded by the coil of the duodenum, it would seem that a duodenitis, which we know to be a frequent condition, may be followed by pancreatic disease. Ulcers of the duodenum may result in adhesions to the pancreas with subsequent pancreatitis. The jejunum is also in relation to the inferior surface of the body of the pancreas.

The concavity of the lesser curvature of the stomach corresponds approximately to the convexity of the anterior surface of the pancreas; and ulcer and carcinoma of the stomach result in adhesions to, and secondary infection or metastasis of, the pancreas.

The anterior surface of the pancreas is separated from the transverse colon by the lesser peritoneal sac, and the colon itself may actually be in contact with the inferior surface of the pancreas. A colitis may be followed by pancreatitis, and in my opinion lesions of the colon are perhaps the most frequent sources of infection of the pancreas.

Since the spleen, the left kidney and the left suprarenal body are in contact with the tail of the pancreas, the primary infection in pancreatitis may be in one of those organs.

#### HEMATOGENOUS INFECTIONS.

Pancreatitis undoubtedly may be of hematogenous origin, and the removal of focal infections from the tonsils and teeth should receive the same consideration as in the inflammatory diseases of other organs of the body.

Pneumonia, measles, scarlet fever, influenza and other general infections may also cause pancreatitis. Many diabetics assert that a few months after an illness from some of the acute communicable infections, sugar was first found in their urine. It is possible that the recent severe epidemics of influenza or "flu" may account partly for the apparent increase in diabetes in the last few years.

Syphilis, while not playing the important part that some have thought, no doubt does affect the pancreas. We have had one case recently in which we thought syphilis was the

cause of diabetes. The story of the negro who, after a positive Wassermann, was told that he had syphilis, replied: "Yassir boss, I knows dat but I's sick too," illustrates the fact that the syphilitic may have diabetes without luetic involvement of the pancreas. It may also be a fact that a person has had diabetes for months or years and contracts syphilis and sugar is found in his urine when undergoing treatment for the latter condition. Clinicians of large experience generally agree that syphilis is not a frequent cause of diabetes.

It would seem, since the blood supply of the pancreas comes from the superior and inferior pancreatic-duodenal branches of the hepatic and superior mesenteric arteries, and from the splenic artery, that infections of the intestinal tract would be carried in the blood stream to the pancreas; and that intra-abdominal lesions are the most frequent sources of pancreatitis. McCarrison made sections of the intestines of pigeons in which he had produced an enteritis by feeding them exclusively pure carbohydrates. These sections, on microscopic examinations, showed eroded villi with the blood tract therefrom leading to distended subperitoneal vessels, constituting a direct passage for intestinal organisms to the blood stream. The intestines harbor the various streptococci, the colon bacillus and other pathogenic organisms, and there then can be no question but that enteritis and colitis in human beings are the foci of infection for the pancreas and even the remote organs of the body.

Since the pancreas is rich in its lymphatic relations with the intestines and other abdominal viscera, its afferent lymph channels no doubt often bring to it pathogenic organisms from adjacent diseased tissues.

#### GASTRO-INTESTINAL INFECTIONS AS PRIMARY FOCI IN THE PRODUCTION OF PANCREATITIS AND DIABETES.

We know that infections of the gastro-intestinal tract are among the most frequent diseases of both infant and adult life; and in my opinion that is the source to which many of the infections of the pancreas with the resulting impairment of the insulin forming glands must be finally traced. I have not seen any statistics on the incidence of gastro-intestinal diseases in the United States, but I am convinced that they are increasing. Recent re-

ports from various clinics in England show that 25 per cent of all patients admitted have abdominal lesions. When we consider the large number of abdominal operations for appendicitis, gastric and duodenal ulcer, and gall-bladder infections, as well as the frequency of the medical diseases of the gastro-intestinal tract, such as acute and chronic gastritis, enteritis and the colitis associated with both diarrhea and constipation, it surely seems that gastro-intestinal diseases are among the most frequent of the present time.

The causes for the increase in diseases of the digestive organs have been ascribed by McCarrison to faulty food. In his book "Studies in Deficiency Disease," and in his Mellon lectures before the Society of Biological Research, University of Pittsburgh, November 18, 1921, and published in the *Journal of the American Medical Association*, Vol. 78, No. 1, pp. 1-8, McCarrison describes his experiments on animals, and his observations among the natives of the Himalaya Mountains, which seem to prove that infections of the intestinal tract, particularly colitis, result largely from the present day diet of an excess of carbohydrates, fats and meat proteins, with a deficiency of the anti-neuritic and the anti-scorbutic vitamins, in addition to the lack of other requisite constituents of human food, particularly iodine, calcium and phosphorus.

McCarrison fed healthy monkeys on pure carbohydrates, fats and proteins—a diet similar to that of white bread, polished rice, potatoes, sugars and sweets of all kinds, lean meats, animal and vegetable fats, upon which most civilized peoples live—with a constantly resulting enterocolitis. He fed control monkeys on a diet containing the same amounts of carbohydrates, fats and proteins, but with the proper vitamins and mineral substances, and the control animals remained normal. He fed pigeons on autoclaved polished rice with the result that they not only developed enteritis and colitis, but a polyneuritis.

#### MCCARRISON'S CONCLUSIONS.

McCarrison thinks that our present day diet of an excess of carbohydrates, fats and lean meats, with a deficiency of vitamins and mineral content, by lowering resistance of the tissues of the gastro-intestinal tract, deprives them of their protective power to prevent invasion of pathogenic organisms. He found

that properly nourished monkeys, when given quantities of the entameba hystolitica, did not develop dysentery, while those fed on a deficiency diet promptly developed diarrhea and the characteristic lesions of amebic dysentery.

McCarrison also called attention to the fact that in his nine years' practice among the inhabitants of a remote part of the Himalayas, during which time he performed an average of 400 major operations a year, he did not see a case of asthenic dyspepsia, gastric or duodenal ulcer, appendicitis, mucous colitis, or other digestive diseases, this in spite of the fact that the general hygienic conditions were bad. He thought this freedom from the abdominal infections so prevalent among civilized people was due to the fact that all infants were fed upon mother's milk, or they died; and that the adults among these remote tribes of the Himalayas lived on natural foods, i. e., milk, eggs, fresh fruits, leafy vegetables. They had no sugar or alcohol. McCarrison came to the same conclusion as Hinhide that "the two chief causes of death among civilized people are food and drink."

#### INTESTINAL STASIS A CAUSE OF COLITIS.

Applying to human beings the deductions drawn from animal experiments, McCarrison called attention to the similarity of the conditions observed in the intestines of animals fed on an exclusive pure carbohydrate diet and the anatomical factors seen in chronic intestinal stasis. Intestinal stasis, in my opinion, exists in a large majority of adult Americans. X-ray studies of the gastro-intestinal tract is a routine procedure in the examination of our patients. We find that in more than 75 per cent of cases the barium meal is still in the cecum and ascending and transverse portions of the colon 24 hours after ingestion. Examination of the feces is another routine laboratory procedure in our work and a large proportion of cases show mucus present in the specimens. Intestinal mucus means a lesion somewhere in the small intestines, or colon—we think usually in the colon. We have found intestinal stasis and mucus in the feces in many of our diabetics, and it seems to me that a chronic colitis is often the source of infection in the pancreatitis which impairs the function of the islet glands to the extent that diabetes develops.

#### DIABETES THE VESTIGIUM OF A BURNT-OUT CONFLAGRATION.

Allen speaks of diabetes as "the vestigium of a burnt-out conflagration." He made investigations on animals in which he produced experimental pancreatitis followed by hyperglycemia, thus proving to his satisfaction that a damaged pancreas is an essential factor in the etiology of diabetes.

It may be that the pancreatitis occurred years before the glycosuria is discovered and that the anamnesis does not elicit a history of a previous pancreatitis; but I believe that we may assume a previous or a present pancreatic infection in the majority of cases of diabetes and that we should endeavor to find the cause of the pancreatitis and remove it if possible. It seems probable, though it is not possible to prove it, that in many cases the pancreatitis was associated with the intestinal infections of infancy and that, though the pancreas be permanently damaged, the Islands of Langerhans are able to secrete enough insulin for normal carbohydrate metabolism in a person of average weight; but that in obesity, the overworked, crippled pancreas rebels against the load that has been placed upon it by the individual who over-eats.

Those who believe that over-eating is the sole cause of diabetes in many cases, and that the obese individual is potentially a diabetic, point to the fact that even in severe diabetics sometimes no lesions of the Islands of Langerhans can be demonstrated either macroscopically or microscopically. Allen meets this objection to the theory of a preceding pancreatitis as an important underlying factor in the production of diabetes, by stating the fact that he has produced pancreatitis in animals and that after their recovery autopsies have revealed no evidence whatever of the pancreatic infection which he knew had existed.

Banting is of the opinion that a pancreatitis is an important though not the only etiological factor in diabetes and, in support of this opinion, he cited instances in the Children's Hospital in Toronto in which the removal of infected tonsils was followed by a return to the normal, or a marked reduction in the blood sugar of infant diabetics.

#### THE ROLE OF OVER-EATING IN THE ETIOLOGY OF DIABETES.

The theory of a previous pancreatitis in

diabetes should not make us underestimate over-eating as a large factor in the production of diabetes. The statistics of Joslin\* show clearly that the majority of diabetics, 60 per cent, are, or have been, overweight. Most of our diabetics give a similar history. Paulin† showed that the blood sugar was high in obese individuals who did not have glycosuria, and his conclusion was that they were potentially diabetics; but the normal pancreas can stand a heavy load and the great majority of obese individuals do not develop diabetes. Over-eating and a diet deficient in vitamins plus a damaged pancreas seem to me to be the important etiological factors in diabetes.

#### THE IMPORTANCE OF VITAMINS IN THE DIABETIC'S DIET.

In the treatment of diabetes it is as necessary to consider the vitamin content and the proper mineral constituents of food as to know that the starches and sugars and proteins and other glucose-forming foods are reduced to the patient's tolerance. Therefore, in making up the diabetic's menu, the fats should consist largely of butter and cream, which are rich in vitamin A; the carbohydrates should come principally from the green vegetables, which contain not only vitamins A, B and C, but are rich in iron calcium, phosphorus and other essential minerals, and from raw fruits and uncooked vegetables which contain the anti-scorbutic vitamin. The diabetic should be taught the vitamin and mineral values of his daily diet as well as the arithmetic of carbohydrates, fats and proteins.

I have recently had a case which illustrates the necessity of considering the vitamin content of the diabetic's diet. A young diabetic who had learned to weigh and measure his food in grams and who could estimate accurately the number of calories of proteins, carbohydrates and fats he could eat to keep his urine free from sugar and diacetic acid, had not learned anything of vitamins. He did not like milk and butter and had omitted them from his diet for years. On a daily diet of about 1250 calories, low in quantity and deficient in vitamins, he developed tuberculosis which with him was more serious than the diabetes. He undoubtedly had diabetes because it was pronounced so by one of the greatest diabetic clinicians in the country, and while the low

diet allowed tuberculosis to develop, the function of the insulin-forming glands seems to have been restored. He is now in San Antonio, Texas, taking 3500 calories of a diet rich in vitamins and his urine remains sugar free. He has gained 25 lbs. in weight and seems to be recovering from the tuberculosis and apparently his diabetes has also been at least temporarily relieved.

#### HEREDITARY AND RACIAL SUSCEPTIBILITY.

There are many other factors in the etiology of diabetes beside infections of the pancreas: because autopsies have shown extensive lesions of the pancreas with degeneration or destruction of a large part of the islet bearing tissue in persons who had no symptoms of diabetes during life. Heredity and racial characteristics are said to play a part and it may be true that one may, by inheritance or racial tendency, have a lowered resistance to infections of the pancreas. It seems likely, however, that what are often considered hereditary and racial tendencies are acquired conditions from habit and environment. For instance, it is no doubt true that the incidence of diabetes is greater among Hebrews than any other race. They also in my opinion suffer more from digestive disturbances than the individuals of other races. The Hebrews live in the cities. They are prosperous, they have plenty of food and are usually large eaters. They eat meats, fats, bread and sweets, but they are not vegetable eaters and their diet may be deficient in vitamins B and C. They also lead sedentary lives which predispose to intestinal stasis and colitis which, in my judgment, is the primary source of a large part of the infections of all the abdominal organs including the appendix, gall-bladder, liver and pancreas. So it may be that prosperity and city life have more to do with the incidence of diabetes among the Hebrews than has heredity and racial tendencies.

The Jews are known to have less tuberculosis than any other race in America. That too probably is not due to racial insusceptibility but to the fact that from the time of Moses, who described the "promised land" as flowing with milk and honey," to the present day, milk and butter, which are rich in vitamin A, the great protector against tuberculosis, have been an important part of the Jew's daily diet. The problem, therefore, in decreasing the in-

\*Joslin: "Diabetic Manual," page 19, Lea & Febiger, 1919.  
†Paulin: Southern Medical Journal, Vol. XV, 1922, p. 249.

idence of diabetes among the Jews is to teach the sins of eating an excess of meats, bread, sweets and fats, and their need for eating more green vegetables and fruits that are rich in vitamins B and C, the protectors against infection of the alimentary canal.

The negro race is said to be less susceptible to diabetes than the whites. That too is probably not due to racial resistance to infections of the pancreas but to the negro's love for the green vegetables, fruits, milk and butter which are cheaper than meats and which contain the vitamins and mineral constituents which go to make up sound teeth and a healthy alimentary tract. For the same reason the negro is less susceptible to all abdominal diseases, including appendicitis and gall-bladder infections. It is likely that the deficiency of vitamin A in the negro's daily diet, more than any other factor, renders him less resistant to the ravages of tuberculosis instead of his having any racial susceptibility to the disease.

Emotional disturbances undoubtedly may bring on hyperglycemia as has been observed in many cases, but in these a damaged pancreas is probably the preceding cause. I recently had a patient who had shown sugar in his urine and had a high blood sugar while he was at work, about which he worried a great deal. After a few days' rest in bed in the infirmary, his urine became sugar free and his blood sugar normal and remained so for a month, even though he was allowed breads and other carbohydrates in large quantities; but on his return home to the worries incident to his business, the sugar in his urine returned. When he cut his work to six hours a day and ceased worrying, the sugar again disappeared from his urine.

Worry, overwork, grief and psychic shock of any kind that disturbs the sympathetic nervous system, may bring on transient glycosuria, but it is unlikely that permanent hypoin-sulinism results from nervous influences in the individual with a pancreas that has not been crippled by previous disease.

#### THE DEFICIENCY DIET OF THE AMERICAN PEOPLE.

McCollum's observations on the diet of the American people as a factor in mouth infections apply equally to infections of all the organs of digestion, including the pancreas. He points out the fact that a diet of white

bread, potatoes, refined cereal breakfast foods, polished rice, and sweets, the muscle cuts of meat and fat meat, lard and butter substitutes, is deficient in vitamins B and C, and lacking in calcium, iodine, phosphorus and other essential minerals. He is urging the American people to go back to the diet of our parents and grandparents, who lived on bread made from whole wheat flour, or whole corn bread, unpolished rice, milk and its derivatives, butter and cheese; the green vegetables and raw fruits, with a moderate amount of meats. McCollum has announced a formula of the perfect daily diet, i. e., "one raw fruit, one uncooked vegetable, two green vegetables and one quart of milk a day," to which should be added enough bread, butter and meat to meet the nutritional needs of the body. This diet, if carried out by the American people, would result in an enormous decrease in diabetics, along with a lessened number of cases of intestinal infections.

In my opinion, McCollum, Sherman, Funk and many others, in their studies in nutrition, have made discoveries which can be made of as far reaching good to mankind as the work of Pasteur and Lister. If what physicians now know of diet and nutrition were known and the knowledge applied by the public, diabetes would become a rare disease. The problem, therefore, is to teach all classes that can and will learn the simple principles of diet and nutrition.

#### EDUCATION IN THE PREVENTION OF DIABETES.

Thomas Jefferson said: "The present generation is already lost; teach the youth of the country" and he founded as his life's greatest work the University of Virginia. Jefferson was only partly right, because some adults can learn and apply new knowledge, though the great majority, even though they know it, will shorten their lives, will continue the eating habits they learn in their youth. Calories and vitamins will continue to be a joke with most obese men or women until nephritis or diabetes over takes them; and the hope of the future, in so far as preventing the diabetes and other degenerative diseases is concerned, lies in teaching the children the simple facts regarding the quantity and quality of the food needed for perfect nutrition. Something is already being done in teaching personal hygiene, including diet and nutrition, in the schools and colleges, but we should not stop

until every boy and girl in the land, even before they enter the high school, shall have a working knowledge of the nutritional needs of their bodies.

Diabetes is as much of a public health problem as typhoid fever, but the death rates of the former have increased while the latter is being reduced everywhere. From the viewpoint of prevention, diabetes is largely a matter of diet, or personal hygiene, while typhoid prevention is largely a question of public hygiene. Our public health authorities and the medical societies should take up the fight against diabetes. They should confer with the educators and the school boards in their communities to the end that every private and public school and college everywhere shall give instruction in personal hygiene, particularly in diet and nutrition.

The organized medical profession can also help in the fight by giving the public the facts regarding the alarming increase in diabetes, while at the same time stressing the fact that it can be prevented by eating more green vegetables and more raw fruits and less meats, less white bread and less sweets. Since the public has learned of the use of insulin, people generally are interested in the subject of diabetes; and now is the psychological time to begin the campaign for its prevention. Will the medical profession live up to its opportunities in preventing diabetes, as it has done so nobly in the fight against communicable diseases?

*Empire Building.*

## THE TREATMENT OF DIABETES WITH DIET AND INSULIN.\*

By ELLIOTT P. JOSLIN, M. D., Boston, Mass.

The necessity for the treatment of diabetes by physicians generally rather than by specialists is apparent when one considers that one death out of fifty in Boston and New York is from diabetes. Exactly how common the disease is in the country, it is difficult to determine. It is probably safe to say that there exist today at least one million individuals who either have diabetes or will develop it before they die.

The cardinal causes of death of my diabetics have been four: diabetic coma, cardio-renal with vascular disease, infections, and tubercu-

losis. Coma has been responsible for the death of fifty-one per cent of 887 of my fatal cases, cardio-renal with vascular disease seventeen per cent, infections sixteen per cent, and tuberculosis six per cent. During the last four years thirty-three deaths have occurred in hospitals, and the reasons for a fatal issue in this hospital group are so different that they challenge attention. Coma and infections have changed places. The mortality from coma has dropped to twenty-one per cent and the mortality from infections has risen to forty-five per cent. The reduction in the percentage of deaths from coma is attributable to (1) a diet low rather than high in calories and qualitatively regulated, (2) prompt inauguration of certain prophylactic and preventive measures in patients liable to coma, and (3) insulin. On the other hand, the proportionate increase in the percentage of deaths from infections is explained chiefly by the deaths from gangrene of the lower extremities and secondarily from other infections, both general and local.

The diet in diabetes should be moderate in quantity. Excess in food is the most common precursor of diabetes, and it is therefore irrational to continue what has already proved harmful. For this reason the first step taken with patients beginning treatment should be to curtail the amount of food. Examination of Table I shows that upon the first day of the test diets (T. D. 1) the calories have been reduced to 1,304 calories, which are about two-thirds of the average calories taken by an adult weighing 154 pounds (70 kilograms). As a matter of fact, in practice I usually begin with test diet two (T. D. 2), which amounts to 931 calories. If this reduction in calories does not result in making the patient sugar free, advance is made to lower calories, which are found in test diet three and test diet four. As will later be shown, with the use of insulin one seldom needs to employ test diet four with its few calories or the next diet below it, and also below the line, with a still smaller number.

Reduction in carbohydrates accompanies the lowering of calories in the test diets employed to get the urine of the diabetic sugar free. If the patient is passing very large quantities of sugar in the urine, one can begin with test diet one, though usually one commences with test diet two, which contains about 100 grams carbohydrate. After one day of this diet, one can proceed to test diet three, with 66 grams

carbohydrate, and so on to test diet four upon the next day unless the Benedict test is negative. In former days still lower carbohydrates and less calories were frequently required to banish the urine sugar and even a day of fasting would occasionally be interpolated, and thereafter one would progress day by day, C<sup>2</sup>PF<sup>2</sup>, C<sup>3</sup>PF<sup>3</sup>, etc., increasing the diet in both calories and carbohydrate until sugar reappeared. Then one would drop back a line or two (10 to 20 grams) in carbohydrate and adjust protein and fat by increasing the protein fat (PF) number. Today insulin shortens the stay, and one often jumps from T. D. 3 to C<sup>6</sup>PF<sup>6</sup>, which contains nearly the same amount of carbohydrate, but distinctly more protein and fat.

The above system of gradually reducing the total calories and the carbohydrate until the urine of the patient becomes sugar free, and thereupon gradually raising the carbohydrate until the carbohydrate tolerance is obtained and then making any necessary adjustments of protein and fat, accounts for the lessened prevalence of coma in hospital patients.

Under-nutrition is the keynote of all modern diabetic diets. I have laid emphasis on lowering of fat, Newburgh and Marsh on lowering of carbohydrate, and Petrén especially on lowering of protein, but all are indebted to Allen for a preliminary lowering of total calories.

The protein requirement is fundamental. For a young child 2 or 3 grams per kilogram are desirable, for a youth 1.5 grams, for an adult 1 gram, and after sixty it may be lowered to 0.66 gram per kilogram body weight. Not alone for maintenance of body tissue is the protein requirement fundamental, it is even more fundamental in severe cases to prevent acidosis. Protein underlies the proper balancing of fat and carbohydrate, the ketogenic-antiketogenic ratio. If the protein is 1 gram per kilogram body weight and only that amount of carbohydrate given which enables the patient to be sugar free, the fat may be raised to thrice the grams of carbohydrate. If necessary calories are not secured, the protein must be lowered to 0.66 gram per kilogram body weight and then the fat can be four or even five times the carbohydrate, provided the carbohydrate is so low as to eliminate glycosuria. Under either of these conditions there is no danger of acidosis, or, in other words, the ketogenic-antiketogenic ratio is not exceeded. The calories required for a patient depend first of all on maintenance of strength and weight. They seldom vary far from 30 per kilogram body weight in adults, but children may require twice as many. The foods which make up the diet of the diabetic should not be too varied. Otherwise they are confusing for both doctor and patient to estimate in carbohydrate, protein, and fat values. After demon-

strating ability to keep sugar free on standard foods, the patient may experiment with them. My patients usually confine their dietetic reck-

onings to the foods shown in Table II. My aim is to make the routine diet as simple as possible.

TABLE II.

Thomas Groom & Co., Inc., 105 State St., Boston.

Education of the patient in the prevention of coma is the second factor which has reduced my coma mortality. Patients have been taught for some years, whenever they feel "sick," I seldom say "ill," (1) to go to bed, (2) to take

a cupful of hot liquid every hour, hot water, coffee, tea, broth, water-oatmeal gruel, or, instead of the gruel, orange juice, (3) to get a nurse in order to conserve strength and save burning body calories, (4) to keep warm, (5)

to take an enema, and (6) to call the doctor. In other words, they are taught to regard any indisposition as premonitory of coma. They are not to diagnose their cases.

The first function of the doctor when he arrives is to diagnose the coma. A diabetic can have coma from acid poisoning, but his coma may be due to apoplexy, uremia, morphine, septicemia, meningitis, trauma, or hypoglycemia. Indeed, the doctor who is called to a case of coma in a diabetic must use every scrap of medical knowledge and skill with which books and experience have endowed him. Insulin is useless in all comas save those due to acidosis, and the physician must beware.

If the diagnosis of diabetic coma is established, the second function of the doctor is to give insulin, and the technic will be described shortly. His third duty is to provide by subcutaneous injection of salt solution a sufficient amount of liquid for the patient by which acid bodies can be excreted. A quart of salt solution given subpectorally ensures a supply of liquid in contrast to its precarious administration by mouth or rectum, whereby it is often expelled. Support of the heart is a fourth requirement, and this is accomplished with digitalis and caffeine. Frequently, and especially in children, there is a fifth indication: namely, gastric lavage. Dilated stomachs are by no means infrequent and such are dangerous, not alone because they deprive the tissues of needed fluid, but also because of reflex action upon the heart. A sixth demand upon the doctor arises only in the event of a fatal issue. Then an autopsy is essential, first to establish the diagnosis and second to afford an opportunity to secure information which will help in the treatment of another case.

It is fitting thus to discuss the dietetic treatment of diabetes which has been built up through the ages with laborious effort, and the prevention of coma which the last generation has developed, because without this knowledge insulin therapy would be not only futile, but often fatal.

Insulin has allowed forty-six out of forty-eight children coming under my care August 7, 1922, or later, to be alive at the end of twelve months. I need say no more for its efficacy. One of the two deaths resulted from the omission of the insulin by a child who kept on eating the enlarged diet which its use had afforded. After five days he chanced to develop an in-

fection, which always makes any diabetes more intense, and he shortly went into coma and died within seven hours of admission to the hospital. Such a death should be preventable. This is one danger connected with insulin therapy. The other death was that of a child reported to be in coma about 100 miles from Boston whose transfer to the hospital did not begin until some twenty-four hours after permission was given for admission. She also lived about six hours following arrival. Such a case would far better have been treated at home. The insulin should be taken to the patient rather than the patient to the insulin.

An overdose is the second danger one encounters from insulin. This is known as a reaction and is associated with a lowering of the percentage of blood sugar below the normal level, 0.10 per cent. So soon as the blood sugar falls below 0.08 per cent, certain definite symptoms appear, and perhaps the first notable symptom is extreme hunger. As the blood sugar falls to this figure, perspiration, which is often apparent upon the forehead, and tremor develop. If the blood sugar reaches 0.045 per cent or below, unconsciousness usually develops and may be accompanied by convulsions.

Perhaps not over two of the less than 100 reactions, which have occurred in the course of more than a year with my patients, have been accompanied by unconsciousness. This I ascribe to the use of small doses of insulin.

The antidote to a reaction from insulin is the administration of glucose. Commonly this is taken by the patient in the form of orange juice. It may be taken as corn syrup or actual sugar, because most sugars turn to glucose immediately upon ingestion. With children the syrup or honey may be given when it is difficult to administer more liquid foods. Ten to fifteen grams of glucose suffice as a rule to banish the symptoms of a reaction and the antidote may work within five minutes. Adrenalin acts similarly, and 10 minims of a 1-1000 solution injected subcutaneously act promptly. One should be somewhat cautious, however, in the administration of adrenalin to be sure that there is enough available carbohydrate in the body to allow it to be mobilized.

The first dose of insulin administered to a patient at the New England Deaconess Hospital is usually 1 unit, and this is increased by 1 unit before each meal until by the fifth meal the patient is taking 5 units before a meal.

Thereafter 5 units are given about twenty minutes before each meal. At the same time the changes in diet take place which have been outlined above, because treatment with insulin should work hand in hand with treatment with diet. If the urine of the patient does not promptly become sugar free, the dose is changed to 6 units before a meal or even 7, 8, 9, 10, or more units. So soon as the urine becomes sugar free, then the noon dose is usually omitted and the total dose divided into two doses, that before breakfast being somewhat larger than that before supper.

If the patient remains persistently sugar free upon a maintenance diet, the attempt is made to omit the evening insulin by gradually decreasing the dose by 1 unit every one or two days, and in a good many cases this is possible. Then one attempts to lower gradually the morning dose. As a matter of fact, about ten per cent of my cases treated with insulin have been able to omit it entirely.

Small doses have characterized my method of treatment. In fact, at the close of the first year of insulin medication there were but about 20 out of 300 diabetics taking insulin who were receiving 20 or more units of insulin daily. Insulin is in its infancy, and it has seemed advisable to proceed slowly with it. As a rule it has been necessary to increase the dose somewhat as time has elapsed.

The morning dose of insulin should usually be the largest administered during the day, and, conversely, the quantity of carbohydrate at breakfast should usually be the lowest. These rules, however, are not invariable. Before changing the dose of insulin it is always desirable to determine whether the carbohydrate is properly divided at the different meals. For this purpose single specimens of urine throughout the day should be tested qualitatively and the results balanced against the dosage of insulin and the intake of food. Patience and study often will obviate the necessity for an increase in insulin.

The test of single urinary specimens during the twenty-four hours is of the greatest value in the treatment of diabetes, and its importance has been especially urged by my associate, Horace Gray. By this method general practitioners can treat satisfactorily many cases of diabetes without blood sugar determinations, and the advantage of this is obvious. In fact, it is because of the possibility of watching the

effect of insulin in this manner that I have felt it safe to urge the use of insulin by doctors throughout the country.

Diabetic coma requires larger doses of insulin, but before insulin is given to any patient with coma, the doctor must assure himself that the type of coma is really that due to acidosis and not due to apoplexy, uremia, meningitis, septicemia, morphine, or trauma. When the diagnosis of diabetic coma is assured, then insulin should be administered immediately and best intravenously for the first dose, though that is unessential. It is safe to give 10 units every hour and usually safe to give 15 units hourly for the first three hours. Fifteen units of the new insulin equal 21 units of the old, so dosage creeps up rapidly. One continues to give insulin in hourly doses until the hourly specimen of urine becomes sugar free or, if available, the blood sugar drops to nearly normal. It is essential each hour, before administering the insulin, to test the urine. Otherwise, severe reactions may be encountered. Following the commencement of recovery, insulin should be continued at less frequent intervals. It should not be permanently omitted. If this is done, a relapse may occur. Each case is a rule unto itself.

Gangrene, directly or indirectly, led to the death of twenty-three per cent of Boston's diabetics between 1895 and 1913 and is the next important preventable diabetic cause of death. Any diabetic above the age of fifty years should be cautioned against the possibility of developing gangrene. He should be warned of its dangers and should be told to protect his feet against injury by new shoes, hot water bags, trauma, and from careless treatment of toenails and corns, and of the necessity of reporting the slightest injury to his physician. Each physician should take pride in freedom from gangrene among the diabetic patients who consult him. He should be as zealous to protect all his patients from gangrene as from typhoid fever.

The surgical treatment of gangrene brings up the question of preparing diabetic patients for operation. With the advent of insulin, it is now safe to say to the surgeon that so soon as the lesion in question should be treated surgically, it is possible to have the patient ready for the operation. Food should be given in simple form, such as oatmeal gruel or orange juice, up to within three or four hours of operation, be-

cause so often patients do not eat for some hours after they leave the operating table, and consequently they are in a position to develop acidosis of greater or lesser extent. Water-oatmeal gruel and orange juice are the foods generally advised, because these are well borne by the stomach, and furthermore patients seldom will get in these two forms of food more than 50 grams of carbohydrate in the twenty-four hours after an operative procedure. Along with the food, insulin may be continued as heretofore with that particular case, although slight changes in the dosage may be necessary. Formerly none of my patients were operated upon with ether, but with insulin the surgeons are beginning to employ it again. However, all the amputations in the gangrene cases and all the prostatic operations for many months have been conducted under spinal anesthesia.†

#### A SYSTEM FOR THE USE OF INSULIN WITH THE DIABETIC DIET IN GENERAL PRACTICE.\*

By WARREN T. VAUGHAN, M. D., Richmond, Va.

There can be no doubt that the more satisfactory plan of treatment for the diabetic is with hospitalization, and instruction by a qualified internist, or better a specialist in diabetes. Those who can afford this will obtain maximum therapeutic success, but we must at the same time consider how best to provide for that large number of individuals who for financial or other reasons cannot obtain hospital treatment and instruction. Those best qualified to discuss diabetes, while stressing the obvious advantages of carefully controlled scientific therapy, recognize the necessity of aiding the greater number who must do as well as they may under the guidance of the family physician.

It is undoubtedly for this reason that Joslin has spent years simplifying the technic of therapy, in the elaboration of his diet cards for the use of the general practitioner. That such efforts have met with success is shown by his observation that in Boston, for example, the average life of diabetics treated at home has been increased and the incidence of com-

plications, such as coma, decreased quite in proportion to similar improvements noted under the best hospital or class instruction. We may state with assurance that the treatment of diabetes by the medical profession in general has improved greatly with under-nutrition therapy. We may state with equal assurance that, except where the family physician has become especially interested in this disease or has received some post-graduate instruction, many of his patients are not treated as thoroughly or as systematically as they should be.

With the advent of insulin, the question arises whether treatment can be carried on at home with such a degree of success as to compare favorably with the results at the hands of the specialist. This much is certain, that for successful dietary or insulin therapy the patient or his physician, or preferably both must receive thorough preliminary instruction. This having been obtained the further treatment must be so systematized and simplified that it can be continued with a minimum of doubt or misunderstanding. Insulin has to a great extent rendered starvation treatment unnecessary but it has at the same time made accurate dietary regulation even more important. For this reason a new series of charts and tables must be evolved. The present paper deals with a system which the writer has found satisfactory for his own use, and which the patient, after discharge, carries out at home under the guidance of his physician.

A brief recapitulation of the general principles of insulin treatment is necessary, before we pass on to consideration of routine therapeutic measures. Because of limited time we must content ourselves with discussion of the average uncomplicated case.

*Optimal Diet.* The diet even under insulin should be no more than sufficient for the patient's metabolic needs. No attempt should be made to fatten patients needlessly. Theoretically the diet may be increased to any desired amount, provided sufficient insulin be administered and provided the proper balance between protein, fat and carbohydrate be maintained. It should not, however, be increased beyond such levels as will satisfy reasonable normal demands for energy. There are several reasons for this. Increased caloric intake causes increase of metabolic rate. This in turn calls for more food. There develops a more pronounced tendency towards hyperglycemia.

†A demonstration was given of a simple and accurate method for the quantitative determination of sugar in the urine. The apparatus is quite inexpensive and can be purchased of Emil Greiner & Son, 55 Fulton St., New York City.

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia at Roanoke, October 16-19, 1923.

Increased intake necessitates more insulin and more frequent injections with consequent greater liability towards hypoglycemic reactions. Furthermore, if the patient who has attained a certain degree of obesity suddenly finds himself unable to procure his insulin, there is real danger of resultant acidosis. Extreme under-nutrition is no longer necessary, but moderate under-nutrition still appears preferable to hypernutrition.

In general a food intake of about 2,000 to 2,600 calories may be allowed in the average adult case. One man may attend to his daily duties with 2,000 calories while a larger man doing heavier work may require more. From the economic viewpoint a certain individual may do more efficient work with larger doses, thereby increasing his earning capacity. In such a case, the increased amount spent on insulin may even be a good investment. Accuracy of control is another factor. Thus Allen and Sherrill point out that a child of wealthy parents who will always be attended by a specially trained, highly intelligent nurse, may be fed more abundantly than another child treated on a charity basis who will ultimately have to carry the responsibility of his own treatment at home.

*Insulin Dosage.* The average unit is considered as metabolizing 1 — 1.5 grams of glucose. Occasionally one unit will reduce glycosuria by as much as three grams.\* The ratio varies in practical work with the individual patient and particularly with the extent of glucose retention. When at the beginning of treatment the blood sugar is high and there is consequent greater concentration in the tissues, larger quantities of insulin are required to render the patient sugar free than is later necessary to keep him so. Thus in one case on a steady diet we have reduced the daily insulin dosage from fifty to twenty-five units.

In acidosis or coma, or with superimposed infections, the dose required is greater than without such complications. Most observers have found that in the average case from ten to thirty units are necessary to maintain the patient in equilibrium. As much as seventy units have been given daily.

My own dosages have varied between two and fifty-five units per day. An adult requiring but five units daily, whose blood sugar is not materially elevated, will often do as well

with slightly increased dietary restriction and the omission of insulin. In the case of growing children, on the other hand, it appears better to provide sufficient food to meet normal growth requirements, and to supplement with the insulin. I have also been giving small dosages of five units to a group of very mild diabetics in an attempt to permanently raise the sugar tolerance in the extremely early cases.

Woodyatt has developed a relatively simple system of dosage determination. On a basal diet he establishes a daily excretion of sugar. Thus if the individual excretes steadily twenty-five grams of glucose, twenty units will about render him sugar free. He then receives one-half of this calculated dose. This dose is increased by five units daily, and later the caloric intake is gradually increased to the desired amount.

*Frequency of Administration.* Opinion differs quite remarkably as to the number of injections that should be given each day. Allen and Sherrill advocate three injections, and even four in case the blood sugar rises at night. Joslin, Gray and Root as well as Banting, Campbell and Fletcher report satisfactory results from two doses. In mild cases the latter give a single daily dose before one meal in which most of the carbohydrate has been concentrated. Wilder and his associates obtained best results with single injections of the entire amount thirty minutes before breakfast, and with food distributed equally between the three meals. This was particularly so when the dosage did not exceed thirty insulin units. As a rule, the second meal comes early enough to neutralize any severe late effect on the blood sugar level. Woodyatt has practically eliminated multiple daily doses and in ninety per cent of all cases administers a single morning injection. Rarely he gives two doses a day. This of course does not apply to complications such as acidosis or coma.

Wherever possible I have used a single morning administration with food divided evenly between the three meals. In this way I have given as high as fifty-five units in a single dose without hypoglycemic reaction. This was in an individual exhibiting an unusually slow fall in glycemie level after injection. However, she did better and required less insulin when the insulin was divided into two doses. My experience also has been that where the

\*On October 15, 1923, the strength of the standard unit was increased 40 per cent.

daily dosage exceeds twenty units, it is better given in divided doses. I give the major proportion before breakfast and a smaller amount before the noon meal, occasionally before the evening meal. Theoretically, it may be better to give three or even four injections daily, but in actual practice few patients will submit indefinitely to this number of needlings each day.

*Must the Patient be Maintained "Sugar Free?"* With few exceptions the urine should be maintained sugar free. Blood sugar well above normal provides some protection against the occurrence of hypoglycemia and also allows greater economy in the use of insulin. On the other hand, hyperlycemia may be a factor in the degenerative processes such as arteriosclerosis, optic neuritis and so on, and probably throws a greater load upon the islet tissue of the pancreas. Joslin, Gray and Root brought an average fasting blood sugar of 0.24 per cent down to 0.19 per cent at the end of treatment.

*Hypoglycemia.* The reaction of greatest importance following insulin results from too rapid or too great fall in blood sugar level, with resulting hypoglycemia. The symptoms are well known to all who have used insulin. Symptoms may develop with a sugar level as high as 80 milligrams per 100 c.c. The level at which symptoms appear varies in different individuals and at different times. Symptoms usually become pronounced at 60 to 50 milligrams. A glycemic level of 35 mg. per 100 c.c. is usually accompanied by unconsciousness. Reaction usually occurs two hours after administration but may be delayed. Joslin observed hypoglycemic symptoms after one insulin unit in a man with tolerance for 114 grams of carbohydrate, but who was weakened by diarrhoea. Allen has observed a reaction after one-half unit in an individual extremely weakened and emaciated, on a low diet. Heavy exercise increases the tendency to hypoglycemia.

Treatment consists in the administration of glucose, usually by mouth. Orange juice is very successful. Other sugars than glucose are not as highly recommended. If necessary, glucose may be administered intravenously. Hot tea or coffee and beef extracts produce temporary relief but no increase in blood sugar concentration and are followed by relapse. As a rule there is no recurrence after the administration of glucose. Often five grams will tide a pa-

tient along till the next meal. Twenty grams are frequently administered. Epinephrin is recommended in unconsciousness. This apparently causes a mobilization of tissue sugars into the blood. Such treatment must be followed by the giving of orange juice or some preparation containing a moderate quantity of dextrose.

*Does Insulin Produce a Permanent Increase of Tolerance?* Uppermost in the minds of all since the advent of insulin has been the question—"will its administration produce permanent cure?" It is still too early to prognosticate remote results, but the studies in general do not indicate permanent improvement in sugar tolerance. Although several cases have acquired some increased ability to metabolize glucose, the vast majority cannot cut down the amount of insulin as time goes on.

The foregoing principles cover only the more important phases of treatment. They serve, however, as the ground work for a routine plan of treatment. Complications, including acidosis, have not been considered, since they require highly individualized treatment and accurate laboratory control. In the absence of tables such as Joslin has prepared for under-nutrition therapy I have found that Wilder, Foley and Ellithorpe's Diabetic Primer satisfactorily fills the patient's requirements. Two editions have appeared and the daily diet lists appearing in the second are quite different from those of the first. The chief variance is in their higher fat content. It has been my experience that a mild diabetic does better on the relatively lower fat diets in the first edition, while some of the more severe cases, during the period of observation at least, do better on the higher fat diets. It is to be regretted that both series of diets were not incorporated in the second edition. To be sure the ketogenic-antiketogenic ratio of the high fat diets is within safe limits, but the large fat content often becomes distasteful to the patient. This is not the case with those diets found in the first edition of the book.

It is absolutely essential for success that the patient weigh his food and examine twenty-four hour urine collections, daily at first and at frequent intervals later.

Blood sugar determination is not indispensable in the treatment of a diabetic. However, a knowledge of the glycemic level at the beginning of treatment is most valuable and les-

sens the risk of hypoglycemia. It is also more satisfactory to know the glucose content of the blood after the urine has become sugar free.

The following program of treatment has proven satisfactory in my hands:

1. The patient procures and studies the Diabetic Primer, purchases scales, and learns to test his twenty-four urine collections qualitatively for sugar.

2. He is weighed and a general examination is made together with the necessary laboratory studies, including alveolar carbon dioxide tension determination. The results of this study may modify the plan of treatment.

3. After the twenty-four hour output of sugar has been quantitated, the patient is placed upon that diet in the Primer which should keep him in metabolic equilibrium without providing an excess of nourishment.

4. After two or three days on such a diet with daily sugar determinations, insulin administration is started, following very much the plan recommended by Woodyatt. Approximately one-half the calculated quantity of insulin necessary to render the patient sugar free is given on the first day and the amount is increased steadily each day, usually by five units, until sugar no longer appears in the urine. The drug is given in a single morning dose, preferably before breakfast.

5. Careful watch is maintained for acidosis or other complications, throughout the treatment by frequent physical examinations, regular urine studies, and, when necessary, repeated alveolar carbon dioxide tension determinations.

6. After the patient has become sugar free, and unless he be overweight, the diet and insulin dosage are adjusted so that he may maintain his weight.

7. A blood sugar determination at the end of the period of standardization will show the influence of treatment on the glycemie level and will indicate whether the amount of insulin should be further increased.

It has been my experience that if more than twenty units of insulin are to be administered, better results are obtained in broken doses. I customarily give the major portion before breakfast and a smaller amount before the noon or evening meal.

With the use of the special recipes and the food tables in the back of the Diabetic Primer, substitutions in the proper amount can be made

for practically any of the foods in the regular diet lists, so that the patient may eat those foods which are in season, or in fact nearly whatever he desires, provided the quantity thereof is properly regulated.

Contrary to the opinion of many, I find that in the absence of complications, instruction and treatment are more satisfactory if the patient is not placed in the hospital. From the beginning he works out his routine at home, where he will eventually have to be under any circumstances, and his results are discussed and his problems clarified in daily consultations at the office.

DISCUSSION OF PAPERS BY DRs. HOUGH, GRAVES, SMITH, OWNBEY, HARRIS, JOSLIN AND VAUGHAN.

DR. L. G. PEDIGO, Roanoke: I am very much interested in this subject, and want to ask one or two questions for information. I notice that the discussion is one confined to diet and insulin treatment. I want to know if this treatment is found to be incompatible with anything that has been found advantageous in the treatment of diabetes. At one time appendicitis, then gall-bladder condition, occupied the footlight, then high blood pressure; now everything from headache to a revolution is attributed to the teeth. What I want to know is whether insulin treatment is incompatible with anything else, the salicylates, for instance. The insulin is not new in so far as I can discover, as some twenty-five years ago it was used in hospitals in Europe, being used in the form of liquid extracts from the pancreas of healthy animals. Brown and Sequard wrote excerpts in the lower '90's that glycosuria could be checked down by the liquid extracts used hypodermically. Is insulin incompatible with the salicylates von Luren used with such success?

DR. STUART MCGUIRE, Richmond: I can add nothing of value to the discussion of the papers just read, but I rise to say how much I have been interested and instructed by this symposium. I could not help but think how fortunate it was that it was scheduled for the general meeting of the Society. If it had been put in the medical section then I and other surgeons would not have heard it. I think the subdivision of our Society into sections has been a great mistake. Surgical men should hear medical papers and medical men should hear surgical papers. If I had the authority, I would limit the number of papers on the program of our annual meeting and go back to the old plan of having all papers read in one general session. If this plan is not practical I would advocate requiring the surgeons to attend the medical section and medical men attend the surgical section, then we would all learn something instead of hearing as we do now the same old things over and over again.

I was very much amused at Dr. Harris' story of the Jew drummer he had lunch with on the dining car on his trip to Roanoke and his expert analysis of the food he ate. Jews as a rule are abstemious in the use of alcohol but consume large quantities of rich food, which explains why so many of them have diabetes. If the drummer in question had known Dr. Harris' identity, he might have been as much embarrassed as I was when, coming back from France on an Army transport, I sat next to Dr. Joslin at table. The trip took three weeks and I enjoyed his

companionship very much but I never got over the feeling that he was calculating the value in calories of all the food I consumed.

I want to take advantage of this opportunity to say that both Dr. Harris and Dr. Joslin did splendid work in the Army and that they made as good military officers in time of war as they now make medical experts in time of peace.

Dr. R. B. JAMES, Danville: Dr. Pedigo made a very good point for the average practitioner who cannot carry out the insulin treatment, which is not possible for the poor patient. Dr. Pedigo speaks of the pancreatic extract. Twenty-five years ago these were used extensively and with good results but we do not hear so much of them today. There are certain cases, however, that cannot be controlled by diet and pancreatic extract and these heretofore have been hopeless cases but insulin seems to offer them relief. Most cases can be kept comfortable by diet alone, others by diet and the pancreatic extract. I have three cases now that are doing well under this treatment. Salol, the salicylates and other intestinal antiseptics helped in many cases, but I have found none so good as the pancreatic extract.

Dr. EDWARD SANDIDGE, Amherst: At what stage should diabetics be given this insulin? If you have a patient in good health apparently, with no symptoms of diabetes—no nausea, no dryness of skin—except glycosuria which is generally worse before menstrual period, would you give insulin when she shows no symptoms of diabetes, otherwise?

Dr. E. E. WALKER, Phenix: Can sugar occur in the blood without showing a trace in the urine? Suppose a man is to have some sugar today, then would have more by eating a certain food, will insulin get that out?

Dr. THEODORE HOUGH, University: Just one point I should like to clear up in closing—the point referred to by Drs. Pedigo and James, that in times past pancreatic extracts have been used, and possibly at times with beneficial effects. It is equally true that they have much more frequently been used without any effect and we know why this is so.

Both gastric juice and pancreatic juice have been shown to destroy insulin, the active agents in each case being the proteolytic ferments. Ordinary extracts of pancreas usually contain active trypsin; sometimes they do not. Some of these extracts may, therefore, possibly have been effective; but usually the insulin had been destroyed by the trypsin.

Dr. SEALE HARRIS, Birmingham, Ala.: Aside from the great honor of an invitation to address you, it is worth the trip from Birmingham to have heard this symposium on diabetes. All of the papers and discussions have been greatly enjoyed, particularly the one by Dr. Hough which is a classic, and of course, Dr. Joslin's address is the great feature of the occasion.

In the diet of diabetes it is not only important that the patient should understand diabetic arithmetic thoroughly, that is, he should know the exact amount of proteins, fats and carbohydrates that he should have for each of his three meals, he should also be taught the facts regarding vitamins. We recently had a patient who came to us for insulin and on examining him we found that he was well advanced in tuberculosis which undoubtedly had developed since he had been placed on a low diet for diabetes. He knew exactly the number of grams and calories of carbohydrates, fats and proteins that he should take and had kept himself sugar free for more than two years but he did not like butter and milk, the principal source of vitamin A. I think it is quite definitely proved that vitamin A is the great

protector against tuberculosis and other respiratory infections, and I believe had this patient been taught that milk, cream, and butter are the principal sources of vitamin A, he would not have developed tuberculosis.

Dr. Hough spoke of the credit which has been given the discoverer of insulin but not enough credit had been given to many others who have made great scientific discoveries. I agree with him that physicians who have made great discoveries have not received the praise which they deserve but I do not think that Dr. Banting has received more than the credit which is due him for what I believe to be the greatest discovery in medicine for this century. Indeed, I have never seen anything finer in my life than Dr. Banting's attitude regarding his discovery and I know that he has not been responsible for the publicity that has been given the discovery of insulin. He has given up the opportunity of great riches to accept the position as professor in the University of Toronto at \$7,500 a year. He will not receive one cent for the manufacture or sale of his great discovery. In giving credit for the wonderful advance in the treatment of diabetes, I think we should not forget that it was the work of Lusk, Attawater, Sherman, Allen, Joslin, Woodyatt and others who made it possible for insulin to be of value in the treatment of diabetes. Indeed, if we did not know food values and the amount of glucose-forming foods that the patient is taking, insulin would be too dangerous to use. With the adjustment of diet to the patient's need and to the amount of insulin that is used, there is no danger in insulin.

One of the physicians spoke of the use of pancreatic extracts by mouth. I think it cannot be stated too emphatically that no pancreatic extract that has ever been manufactured, or that ever will be manufactured, will have any effect whatever when given by mouth; because insulin, the only pancreatic extract that affects carbohydrate metabolism, is destroyed by the gastric and intestinal juices. Banting told me that in the Toronto Clinic they had tried to use insulin by mouth, by enteric capsules, through a duodenal tube into the intestines, and by rectum, and with absolutely no effect whatever on the blood sugar level. He is absolutely sure that the insulin can never be used any other way than hypodermatically or intravenously.

Dr. E. P. JOSLIN, Boston, Mass.: *Pancreatic extracts*: I have tried, besides insulin, two others and found that they did not work by mouth. Suppose you are giving insulin every day, then omit insulin and substitute an oral preparation. Perhaps no sugar will appear in the urine next day but, within five days after leaving off the insulin, the full form of the disease becomes manifest. Consequently, in testing any extract, one must wait at least five days.

I know of nothing which is incompatible with insulin.

I would not call a case of diabetes cured until a patient had lived at least twenty years. A woman in the hospital had a blood sugar of .09 per cent before a meal, 0.13 after meal. She appeared as if cured. When I increased her diet by twenty grams carbohydrate, the blood sugar went up to 0.19 per cent.

The cost of insulin is not great. Insulin is dropping in price and can be sold at a profit at two cents a unit, December, 1923. The average case does not take more than sixteen units. At the old price, buying wholesale for the hospital, it would cost forty-eight cents; by the new price, thirty-two cents, and even less, because now the unit is stronger. Is that too much? I have observed that the patient who

was too poor to pay for the treatment could smoke a couple of cigars daily. If a patient is doing well without insulin, do not give it. If a patient has no pain, one would not give morphine.

### OPINIONS ON VARIOUS QUESTIONS IN GALL-BLADDER SURGERY, BASED ON ONE THOUSAND OPERATIONS.\*

By STUART MCGUIRE, M. D., Richmond, Va.  
Surgeon to the McGuire Clinic.

During the past twenty years I have operated on more than one thousand patients for disease of the gall-bladder. Recently I have had the cases tabulated and studied with the hope of securing data which would enable me to prepare a paper that would be interesting and instructive. I thought my files contained satisfactory case histories, laboratory reports and operative findings of these cases, but I am mortified to confess that when the records were put to the crucial test of furnishing accurate statistics, they proved woefully deficient. A case report, which on casual reading appeared most excellent, would almost invariably be found to lack some essential detail when it came to tabulating facts in parallel columns, and I have completed my labors "a sadder and wiser man." I recognize now more fully than I ever did before the necessity of the campaign being carried on by the American College of Surgeons to standardize hospitals and to emphasize the importance of keeping full, accurate and systematic case records.

The following are some of the facts I have been able to learn from the study of my gall-bladder cases. The youngest patient in the series was thirteen, the oldest seventy-nine, the average age being forty-five. This confirms the accepted belief that no age is immune but the disease is more frequent about middle life. Seventy-one per cent of my patients were women and twenty-nine per cent were men. This confirms the statement that gall-bladder disease is about three times more frequent in women than in men. It is recognized that infection through the blood stream is probably the essential cause of cholecystitis, but stagnation of bile is an important predisposing factor and this condition is more common in women because of pregnancy, tight clothing, constipation, obesity and lack of fresh air and exercise.

All the cases in my series were white patients. I have done a great deal of surgery on negroes in thirty years of clinical teaching and, while I have operated on two or three mulattoes for gall-bladder disease, as far as I can recall I have never had a case of cholecystitis in a full blooded negro. Dr. Liek, of Dantzig, has recently written to find the relative frequency of gall-stones in the white and colored races in America and stated that the Germans have found practically no gall-bladder disease in the negroes in Africa. Dr. Phemister, of Chicago, referred the question to me among other Southern surgeons and in a second letter told me that the replies received showed that the disease was very rare in the colored race.

Some years ago I discussed the question of the frequency of cholecystitis and appendicitis in negroes with Dr. Wm. J. Mayo and I stated to him I had never seen a case of gall-bladder disease in a black patient. Dr. Mayo laughed and said that practically the only operations he had ever done on negroes had been for gall-bladder trouble. The explanation of the difference in our experiences may be the fact that Dr. Mayo's negro patients probably came from Chicago, while mine came largely from rural communities. I believe the Southern negro's fine teeth and immunity to diseases of the gall-bladder and the appendix are due to his good digestion. With changing conditions this will pass, and he will eventually acquire all the susceptibilities of our so-called modern civilization.

In the series of cases I now report gall-stones were present in seventy-four per cent of cases and absent in twenty-six per cent of cases. For some reason it is always gratifying to a patient and the family to learn after an operation that gall-stones had been found and removed. The larger the stone or the greater the number, the more the satisfaction. The surgeon, however, knows that the formation of gall-stones is merely an incident associated with gall-bladder infection. It is a fact that some of the most obviously diseased gall-bladders I have ever removed or drained contained no stones.

No one questions the propriety of removing a diseased gall-bladder although it contains no stones but what should be done if in operating on a supposed case of gall-bladder disease the surgeons finds, in the words of Willy

\*Read at fifty-fourth annual meeting of Medical Society of Virginia held in Roanoke, October, 16-19, 1923.

Myers, "a seemingly normal, soft, bluish and glistening organ not harboring stones or presenting any adhesions whatever?" All of us have had such embarrassing experiences. In my early work I frequently contented myself in such cases with removing the appendix if it was present and closing the abdomen. Most of these patients did not get permanently better, thus justifying my diagnostic ability while condemning my surgical judgment. With increasing experience, and, fortified by the practice of my surgical friends, I now unhesitatingly remove these apparently innocent gall-bladders, provided the patient's clinical history points to gall-bladder disease, the search of the abdomen reveals no other cause for the symptoms, and the preliminary examination of the patient has excluded the possibility of stones in the urinary tract or other extra-abdominal conditions which might lead to error. As previously stated, in certain cases I have had cause to regret not removing an apparently normal gall-bladder and, since I have become more radical, whatever compunctions of conscience I may have felt at the operation table have been relieved by examination of the specimen in the laboratory, where small stones that could not be palpated were found or unquestioned evidences of infection were demonstrated.

My records in the series of cases reported do not show what percentage of patients were classed as acute and what per cent were classed as chronic at the time of admission to the hospital. They do show that only five per cent were acute at the time of operation. Many cases that were acute on admission were treated medically and classed as chronic at the time of operation. These figures bring up the very important question of when to operate in acute cases. This question has been settled for appendicitis, but not for cholecystitis. Will it be safer in an acute case to treat the patient medically until the virulency of the infection subsides and an operation can be done under more favorable conditions, or will it be better to operate at once and relieve pain, stop septic absorption and remove the danger of gangrene and perforation? Unfortunately, I have no figures that will help to settle this question. I can remember scores of acute cases that were kept in the hospital under medical treatment for one or two weeks and then safely operated on when the disease was quiescent.

I can remember others whose symptoms were so urgent that an immediate operation was done and whose lives were undoubtedly saved by prompt intervention. On the other hand, I recall patients who apparently died because of delay who might have recovered if they had been promptly operated on, and others who apparently died because of undue haste who might have recovered if they had been first treated medically. There ought to be some general rule to guide us in these cases, but at present there is none, and the best a surgeon can do is to settle the question to the best of his ability in each individual case. Personally, I do not believe that infection of the gall-bladder presents an emergency at all comparable to infection of the appendix and, unless a case of cholecystitis is attended by symptoms that cause alarm, I am in favor of waiting until the acuteness of the infection subsides.

An analysis of the operations reported in this paper shows that the gall-bladder was drained in sixty-three per cent and removed in thirty-seven per cent of the cases. The series covers the work of twenty years, and in the first part of this period practically all the gall-bladders were drained, while in the last few years practically all of them were removed. The change from an almost routine cholecystostomy to an almost routine cholecystectomy was based not only on the altered opinion of the surgical profession but on personal experience as well. Cholecystectomy is certainly a more difficult operation to perform than cholecystostomy and at first it was hard to believe that it could be done with less risk to life, and that the patient would suffer no bad results from the sacrifice of the organ. With a little experience, however, I found the operation comparatively simple and safe. Convalescence was quicker and freer from complication and, most important of all, the patients remained well. My figures showed that eight per cent of the cases whose gall-bladder had been drained came back to the hospital for a second operation, owing to persistent fistulae, recurrence of gall-stones or symptoms due to adhesions, while practically all of the patients whose gall-bladders had been removed remained permanently well. I now do a cholecystectomy on all patients except those in which I drain for secondary pancreatitis, those whose general condition is so

bal from sepsis, cholemia or other causes that they will only bear the gentlest and quickest procedure, and those in which the gall-bladder and adjacent structures are so acutely infected that it seems safer to drain as a preliminary operation. Patients who are drained are warned that they may have further trouble and many of them are operated on a second time and the gall bladder removed before they leave the hospital.

Much has been written by the advocates and opponents of cholecystectomy with reference to the functions of the gall-bladder and the results of its removal. Few believe that the gall-bladder is important as a reservoir for bile as the amount it is capable of storing is small compared with the total secretion of the liver. Some attach importance to the fact that the composition of the bile in the gall-bladder varies from that secreted by the liver, in as much as it is more concentrated and contains a larger amount of mucus. Other writers believe the gall-bladder acts as a tension bulb, like the air chamber to a fire engine, to regulate the flow of the stream. It has been observed that after the removal of the gall-bladder there is a dilatation of the hepatic, the common and the stump of the cystic ducts, and this is thought to be an effort of nature to compensate for the loss of the gall-bladder. Bile pressure is dependent on the force of the secretion of bile by the liver and the resistance to the escape of bile by the sphincter muscle at the ampulla. The gall-bladder may act as a tension bulb to regulate the inequalities of bile pressure but, even if this is the case, its function is not a vital one, as proved by the large army of people who are well and happy despite the removal of the organ.

The average mortality of all the operations on which this report is based was 6.7 per cent. This is not high considering the fact that many of the patients were operated on during a period when surgery was not resorted to except as a last resort and at a time when present methods of technique were as yet undeveloped. The group of cases that showed the highest mortality were those with stones in the common duct where the death rate was ten per cent. The group showing the lowest mortality were the more recent cholecystectomies whose death rate was 2.7 per cent. As I look back over my results I am impressed by the fact, so often stated by so many men

with reference to operations for so many diseases and conditions, namely, that early surgery is easy and safe and that late surgery is difficult and dangerous. This is especially true in gall-bladder disease. There is no such thing as innocent gall-stones. They all in time will give trouble and if the patient lives long enough will require operation. If an operation has to be done sooner or later, then the sooner the better. Every conscientious practitioner, when called on to consider whether or not to send a patient with gall-bladder disease to a hospital, should answer the question made familiar by a popular advertisement, "If eventually, why not now?"

The symptoms of gall stones are familiar to all of you and I will not weary you by dwelling upon them. The most important are the following:

*Indigestion*, not produced by imprudence in eating, coming on without definite relation to taking food and usually relieved by eructation or vomiting; *pain*, located in the epigastrium and radiating to the back or right shoulder blade; *tenderness* over the gall-bladder elicited by deep pressure; *colic*, abrupt in its onset, sudden in its relief; *jaundice*, occurring on an average of once in seven cases and more often due to cancer than to gall-stones; fever seen during acute exacerbations of infection and characterized by rapid rise and fall of temperature.

At one time it was thought that the irritation of gall stones almost invariably increased the acid contents of the stomach. It has been learned, however, that hypochlorhydria is as frequently found accompanying the condition as hyperchlorhydria and I now no longer place any confidence in the result of gastric analysis, except in excluding other conditions.

The value of X-ray findings is still a question under discussion. Gall-stones are not calcareous substance but are composed chiefly of fat, as can be proved by subjecting one to the heat of an open flame when it will soften and burn much like sealing wax. They do not cast a clear shadow as do urinary stones but are only visualized on the X-ray plate when they contain lime salts. Conscientious radiologists only claim to be able to show gall-stones in from thirty to fifty per cent of the cases where they are actually present. While a positive report is conclusive, a negative report in the words of Goldberg, "Don't mean anything."

Some X-ray men claim that a healthy gall-bladder does not show on the plate under ordinary conditions. Therefore, if a distinct shadow can be outlined, such gall-bladder should be considered diseased as its walls are thickened or its cavity filled with pathologic material. It is possible that the technique of pumping air into the peritoneal cavity will increase the value of the X-ray as a diagnostic help.

After the examinations have been completed to establish a diagnosis of cholecystitis, then an examination similar to that for life insurance should be made to see whether the patient is in condition for the operation. In addition to the usual test, the coagulation time of the blood should be taken, especially if jaundice is present. If the coagulation time is delayed, the patient should be given 5 c.c. of a ten per cent solution of calcium chloride intravenously for three successive days after the plan suggested by Walters of the Mayo Clinic.

If there are any evidences of myocardial weakness, a preliminary course of digitalis should be given. The evil of the old practice of purgation and starvation is now generally recognized by abdominal surgeons and should especially be avoided in these cases. This type of patients have usually had their intestinal tract thoroughly emptied by a dose of castor oil given before the X-ray examination, and all they need is a simple soap suds enema administered the morning of the operation. Food, especially of the carbohydrate type, should be given in as large quantities as the stomach will tolerate up to twelve hours before the operation and water should be forced up to the last moment. In debilitated cases it is often well to give a solution of glucose and soda before as well as after operation, by the Murphy drip method.

The patients are placed on the table in the simple horizontal position. I have tried various methods of angulation and many forms of pads or cushions under the back, but have given them up as they embarrass respiration and do not give better exposure.

The anesthetic I employ is gas-oxygen followed by ether. The use of the latter agent is necessary to produce the degree of relaxation required to examine viscera thoroughly without traumatism.

The incision I use is an upper right rectus

beginning at the margin of the ribs and extending down far enough to give an ample field for operation. In a case of doubt as to whether a patient has cholecystitis or appendicitis, I do not make an incision over the appendix and palpate the gall-bladder, but make the incision over the gall-bladder and hook up the appendix, thus being able to inspect both. After the abdomen is opened, before I palpate or inspect the gall-bladder, I make a complete examination of the other abdominal organs unless there is some strong contraindication for doing so. If the patient is a woman, I first carry my hand down to the pelvis and determine the condition of the uterus, tubes and ovaries. I next bring the cecum up into the incision and as a rule remove the appendix. After the cecum is returned, I draw out and inspect the stomach and duodenum. I then examine the head of the pancreas and finally palpate the common duct with my thumb above and two fingers below, noting the size of its caliber, the thickness of its walls, the presence or absence of stones and whether there is evidence of infection as shown by the enlargement of adjacent lymph nodes. Only after this general survey of the abdomen is completed do I yield to the temptation to examine the gall-bladder itself. When the gall-bladder is exposed, its size, color, thickness of its wall, amount of distention and character of adhesions should be noted. Pressure should be made to see if it will empty and careful palpation carried out to find whether or not it contains stones. If these facts are all accurately recorded and afterwards compared with the patient's clinical history and laboratory reports, much useful information will be learned. In a good many recent cases where patients gave history of having had their gall-bladder drained medically by the Lyons method and who had reports of the character of the fluid removed, I found gall-bladders that could not be emptied by mechanical pressure and whose contents were totally different from that the so-called test would lead one to expect.

I usually remove the gall-bladder by clamping, cutting and ligating the cystic duct and artery and dissecting it free from above downward. The raw surface resulting is covered by sewing the divided edges of peritoneum together and a drain of soft rubber tissue is placed in position. I drain all my cases be-

cause if the drain does no good, it does no harm and I believe it is safer for the patient. It certainly saves me anxiety and makes me sleep better.

1000 West Grace Street.

### SOME PRACTICAL POINTS IN THE DIAGNOSIS AND TREATMENT OF GALL-BLADDER DISEASE.\*

By W. LOWNDES PEPLE, M. D., Richmond, Va.  
Surgeon to McGuire Clinic.

It is an interesting thing to watch the emergence of any particular disease out of doubt and obscurity, and see its position established with assurance and certainty.

Many of us remember the position of the diseased appendix twenty or twenty-five years ago; how good men waited for days and pondered over a diagnosis which the patient himself often makes today. And so it is with the gall-bladder. Free discussion and interchange of thoughts and observations is making this subject clearer and clearer to us all, as time goes on and opinion crystallizes.

I think, however, we are still far less accurate in our diagnoses in the upper abdomen than in the lower, but we are getting more and more accurate as each year goes by.

In my work as a clinical teacher in the Medical College of Virginia, it has been my custom to go over and over the points of the differential diagnosis of the diseases of the abdomen in an extremely elementary manner, and I still find this routine of self-questioning to be a very good way of approaching any case of right-sided abdominal disease.

If the thumb of the right hand is placed along the lower right costal margin, the palm and extended fingers will cover an area of turbulence and trouble which I have called the "Balkans of Surgery." In this small area covered by the breadth of a hand we have some of the most perplexing problems with which the physician and surgeon are called upon to deal. Here lie, from above downward, the pylorus, the duodenum, the gall-bladder, the right kidney, the appendix, and the right ovary and tube in the female.

I know of no better way of arriving at a correct diagnosis in an acute condition of the right abdomen than to have these five or six points always in mind, and to narrow them

down by a process of elimination until we are reasonably sure of indicting the one that is left.

First, let us remember that nothing is absolute in disease; people do not get sick according to the rules laid down by text-books; there are a myriad variations. It is, after all, the personal element, the alertness of the observer, that counts for accuracy and success in diagnosis. Let's forget books and causes and theories for a while, and take a case just as the country doctor sees him. We will say he has been curing tobacco and has been seized with a severe pain in his abdomen. We reach him some six hours later. What has he got? How are we to find out? What are we to do? Let's follow our plan.

Is it his *stomach*? What had he eaten? Has he vomited? Was there any blood in the vomitus? When did his bowels move last? Was there blood in his stool? Did the stool look black or tarry? Has he ever had an attack like this before? Did emptying his stomach relieve his pain? Did emptying his bowels relieve his pain? How old is he? Remember that ulcer of the stomach is far less frequent than ulcer of the duodenum and occurs in older people.

What is his temperature? What is his pulse rate? Is he shocked, or was he shocked when the attack came on? What is the character of his pain? Is it terrific, agonizing, so that two or more hypodermics of morphine are required to ease him? Is there a marked board-like rigidity that never relaxes?

What is it that happens to an ulcer to produce such a picture? It is perforation. How could one tell a perforation of the stomach or duodenum from a perforation of the gall bladder? You can't tell—unless you had determined beforehand from previous knowledge of the case that the patient already had gallstones or an ulcer. It would make no difference anyway, for a hole in one hollow organ is as bad as a hole in another. Nature is about as apt to seal one as the other, and she does it far oftener than we have any right to ask it of her.

Before dismissing the stomach: Examine his lungs. Are both clear, front and back, and from top to bottom? Has he a diaphragmatic pleurisy? Always think of this and pneumonia.

*The gall-bladder.*—Practically speaking,

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

there are two acute conditions of the gall-bladder which we must always bear in mind in such a case as we have outlined—inflammation of the gall-bladder, and stones in the gall-bladder. They may exist separately or together.

In cases of severe repeated attacks of pain without fever, if we can fix it on the gall-bladder, it is fair to reason that the condition is a mechanical one and is due to stone. If accompanied by fever, we know that inflammation is present, whether accompanied by stones or not. Gall-bladder pain and ulcer pain, gall-bladder tenderness and ulcer tenderness are so much alike that it is the patient's history that will be the determining factor in making a differential diagnosis.

*The right kidney.*—Always palpate the kidney with one hand in front and one over the kidney region in the back, and see if it is tender. A big, distended gall-bladder, or a high, post-cecal appendicular abscess may fool us to death, but not every time, so let's try every time.

Let's make a microscopic examination of the urine, always catheterized in the female, and in the absence of pus and blood we feel reasonably safe in excluding pyelitis and stone.

*The appendix.*—Any of the symptoms of appendicitis may be lacking in a given case. Every surgeon has operated for acute appendicitis when the trouble was in the gall-bladder or when an ulcer of the duodenum had perforated. We will doubtless make other similar mistakes. But, when we have fixed the responsibility on the appendix and turn over our symptoms; nausea, vomiting, pain, localized tenderness, fever, rapid pulse, rigidity—of all the symptoms enumerated, be over-careful in the absence of nausea or vomiting. If he has not been nauseated nor vomited, go over him a second or third time.

*The right ovary and tube.*—Always make a careful vaginal examination where there is any question at all. We can usually demonstrate an inflamed ovary or swollen tender adherent tube, or we can exclude it definitely from further consideration.

I have not stressed the laboratory side of our diagnostic work; but there are two invaluable aids which can be done so quickly that they should be in reach of all. They are a differential white blood count and a microscopic study of the urine. A high poly count

would exclude typhoid fever from our consideration; if very high, with a board-like rigidity, we might clinch a diagnosis of perforation and hasten surgical intervention. If a microscopic analysis will eliminate the kidney, it is well worth any time and trouble that may have been taken to make it; for, if we mistake an appendix for a gall-bladder, we remove the appendix and no harm is done, but we do not operate for pyelitis. It is most important to exclude or confirm it.

I have not taken up the question of X-ray. We would not resort to it, of course, in acute cases, if we had it at hand. But it is invaluable in chronic or interval cases. In skilled hands about eighty per cent of ulcer cases can be demonstrated by it. A negative X-ray for gall-stones means nothing, for shadows are gotten in a very small proportion of cases when stones of even considerable size exist.

In all cases great care should be used in getting an accurate history, and nothing so conduces to accuracy as writing the history down. One gets the dates, facts, and the logical sequence of events then clearly fixed in the mind and, if memory fails us later, it is all there on paper. The history of indigestion and flatulence is important; the effect of taking of food on the attacks.

Many people with gall-stones have eliminated one article of diet after another, until they scarcely have enough to sustain them. Ulcer people, and especially duodenal ulcer, will usually tell us that food relieves their pain, or that the pain is worse just before meals when the stomach is empty. Some have formed the milk and cracker lunch habit, to stop these hunger pains. Ulcer people almost all take soda, because it gives them relief. So much is this true that soda-taking should be regarded as a symptom. Gall-bladder people are not soda eaters, though some use it to help get the gas from their stomachs, getting a measure of relief in this way.

Gall-bladder pain goes through to the shoulder; but ulcer pain may do this also. It is the relation of pain to eating that gives us the differential clue. The tenderness and pain is about in the same locality for both. And remember the gall-bladder and pylorus are not at fixed points up under the margin of the ribs, but are often on a level with the umbilicus.

Jaundice is found in so small a proportion of cases that we do not lay stress upon it. If

present, it points very definitely to the gall tract, and means mechanical, inflammatory, or malignant obstruction.

When we have decided that the case in hand is not one of simple indigestion, what is the best and safest thing to do, pending operation? Avoid the use of purgatives. Purgatives promote peristalsis, and peristalsis promotes perforation and tends to spread inflammation. Empty both ends of the gastro-intestinal canal and splint the middle segment. The stomach tube above; the enema tip below; splint the middle with small doses of morphine at regular intervals. If one-eighth grain is given every four hours, it will give better results than a larger dose given only after suffering has become acute, and in the end less of the drug will have been given.

To continue with our patient: let us say we have made out our case and opened the abdomen and found our diagnosis is correct. We have gall-stones and cholecystitis. What shall we do?

Of course, we assume that a man who would open the abdomen is prepared to do anything that may be called for by conditions as they present themselves. There is in my judgment too great a tendency now-a-days to "follow the leader;" to go in pre-determined to follow this or that particular plan. It is a question that requires sane judgment in the individual case. I have seen gall-bladders removed, with which I could see nothing wrong. I have left in gall-bladders that I know ought to have come out. I have done so deliberately, because I believed that in the case in question removal was a far more hazardous operation than simple drainage. No one should be ashamed to do a second operation for the removal of a gall-bladder that he has previously drained.

To briefly summarize: a gall-bladder with thin walls, not diseased but containing stones, may be opened, the stones removed, and the opening sutured and the gall-bladder dropped back without drainage, as emphasized in a paper by Dr. Willis.

The gall-bladder, if containing pus but with walls but little affected, may be drained with the assurance of a very fair proportion of permanently good results: and, by this, I mean cured patients.

The gall-bladder, if greatly thickened and atrophied, or tremendously distended, or if gangrenous, should be removed. If, however,

the technical difficulties are very great and a prolonged operation would prove dangerous, if there is profuse capillary hemorrhage when adhesions are separated, one should drain and quit; and be no more ashamed of it than of the first step in a two-stage prostatectomy.

The best operator is not always the best surgeon. A good surgeon should have the courage to do as much or as little as is necessary, to get his patient well.

1000 West Grace Street.

#### DISCUSSIONS OF PAPERS BY DRs. McGUIRE AND PEPLÉ.

DR. A. MURAT WILLIS, Richmond: The relative proportion of the cases of calculous and non-calculous cholecystitis is of much importance. If Dr. McGuire has removed one thousand gall-bladders in twenty years and twenty-six per cent of these were instances of non-calculous cholecystitis, it would be interesting to learn what percentage of non-calculous cases has occurred in the past five years, since he has come to direct more attention to the condition. From one of the great clinics of this country, there was recently reported a series of 500 cases of cholecystectomy, ten per cent of this number being instances of non-calculous cholecystitis. Of the gall-bladders removed from the patients suffering from "non-calculous cholecystitis," thirty-three per cent were found to be normal on histological examination, and the subsequent history of the patients showed that no relief was obtained by the operation. From another great American clinic, a report came a few years ago, stating that forty per cent of all cholecystectomies were performed on patients suffering from non-calculous cholecystitis; and histological examination revealed that *all of these gall-bladders were diseased*. Such diverse reports as these suggest that there is something radically wrong somewhere.

Another point is whether it is safe to close the abdomen without drainage after cholecystectomy. If we *must*, on the basis of obscure digestive disturbances for which we can find no other clear cause remove a gall-bladder, is it necessary to introduce a drain? We may be reasonably sure of furnishing the patient with an adequate cause for his subsequent symptoms, for our drain will inevitably introduce infection and lead to formation of adhesions. Naturally, there are instances where one should hesitate to omit drainage after cholecystectomy, but, as I pointed out years ago, in many cases, its omission results in a more rapid and less uncomfortable convalescence with less likelihood of post-operative complications. My attitude receives support from the experience of operators at the Mayo Clinic; two thousand cholecystectomies without drainage have been performed there recently. Dr. McGuire sleeps better when he employs drainage; he will find that his patients will sleep better if he omits it in suitable cases; they will have a smoother convalescence; and the dangers of post-operative adhesions and hernia are lessened.

DR. McGUIRE, in closing: The paper I read discussed many unsettled questions and contained the expression of many positive opinions; therefore, I expected more criticisms than I received.

DR. WILLIS speaks as if there were two distinct forms of gall-bladder disease, cholecystitis with stone and cholecystitis without stone. I think there is but one form. If infection of the gall-bladder occurs, then cholecystitis results and a stone may or

may not form. A gall stone is not the cause of cholecystitis, but a result of the disease. It is purely an incident in the pathologic process. In operating for gall bladder disease, I am not influenced by the presence or absence of gall-stones; I am interested in the condition of the gall-bladder itself. As I stated in my paper the worst gall-bladders I have ever removed or drained contained no stones.

I do not advocate removing innocent gall-bladders, but some gall-bladders look innocent when they are really diseased and cause symptoms. When a patient has symptoms which clearly point to the gall-bladder and when the preliminary examination and the exploration at operation fail to show any other cause for the symptoms, then I would remove an apparently innocent gall-bladder on suspicion. This suspicion will be confirmed nine times out of ten by the laboratory examination of the specimen.

Finally, with reference to drainage: I do not drain cases because it makes me sleep better, but it makes me sleep better to drain cases, because I am sure it is safer for the patient.

Despite the greatest care in ligating the duct and controlling bleeding, I continue to have biliary drainage in a certain proportion of the cases I operate on. Although I have studied these cases carefully, I am unable to explain the cause or to predict under what conditions it is most likely to occur. I therefore drain all cases in order to protect the few who need it. I use a strip of soft rubber tissue, which does no harm if it does no good.

DR. PEPLÉ, in closing: I have nothing to add except that I think we should not fall into a routine. We should consider each case on its own merits. The gall-bladder is there for a very definite purpose, and it should not be removed without definite indications for so doing.

The easier, quicker convalescence of the cholecystectomy over the cholecystostomy cases probably tempts us to do the latter too often.

As for drainage, I have not yet gotten to the point of feeling safe in closing a cholecystectomy without drainage.

### GONORRHEAL ARTHRITIS.\*

By WILLIAM A. SHEPHERD, M. D.,

Associate in Medicine, Medical College of Virginia,

and

BERNHARD STEINBERG, M. D.,

Resident Physician, St. Philip Hospital,  
Richmond, Va.

A comparatively short time ago, Rosenau called attention to focal infection as a potent factor in disease. Since then, we have come to realize that teeth and tonsils are responsible for a great many ills, but in the general onslaught on these members, the genital tract has been to some extent overlooked. Consequently, in many instances the true focus remained undiscovered and untreated. Arthritis as a sequel to gonorrheal infection of the genital tract is a rather common occurrence. Its prevalence and gravity justify a more careful consideration. This communication is intended to present a general resumé of the subject of

gonorrheal arthritis, its various manifestations, methods of diagnosis, and treatment.

There is evidence that the gonococcus was considered a possible cause of arthritis long before Lindermann<sup>1</sup> in 1892 demonstrated its presence in diseased joints. However, his demonstration does not seem to have been very convincing since Sternberg<sup>2</sup> writing in 1896 discredits the claim and Strümpell<sup>3</sup> in 1897 dismisses the subject with scant attention. In 1896, Thayer and Blumer<sup>4</sup> found the gonococcus in blood culture, thus indicating a possible route of joint infection. In recent years, many investigators have demonstrated the gonococcus in joints, establishing its position as the etiological factor in the disease. However, very little interest has been shown in gonorrheal arthritis and very slight progress made in its diagnosis and treatment, as evidenced by the meagre literature on the subject, especially in this country.

*Etiology.*—Arthritis is the most serious complication of gonorrhea. It destroys tissue and produces ankylosis. It shows a marked tendency to recur and commonly results in endocarditis. Approximately five per cent of all cases of genital gonorrhea are complicated by obvious arthritis. Many more cases presenting less striking symptoms are either neglected or entirely overlooked. It is interesting to note that typical cases of arthritis may result from infection of the eye<sup>5</sup> and even of the finger.

Metastasis to the joints usually occurs in the acute stage of the primary infection, although it may occur in any stage.<sup>6</sup> During an acute urethritis, the patient may altogether escape arthritis, only to have an attack in the chronic or latent stages. Recurrent attacks are prone to be of increasing severity. Frequently, especially in women, there is no concurrent evidence, clinical or otherwise, of uro-genital infection. In such instances the diagnosis rests upon the demonstration of the organism in the joints.

Young adults show the greatest susceptibility to gonorrheal arthritis, although practically no age is exempt. It has been observed in children under ten.<sup>7</sup> Certain observers (Northrup<sup>8</sup>, Norris<sup>9</sup>) claim a greater incidence in males, but in dispensary and hospital where both sexes are represented, we have observed practically an equal proportion in females. The colored race in this country is especially susceptible to the disease. No joint is immune

\*Read at fifty-fourth annual meeting of Medical Society of Virginia in Roanoke, October 16-19, 1923.

to the infection but the most commonly involved is the knee. The order of incidence in other joints is as follows: ankle, wrist, digits, elbow, shoulder, hip, tempormaxillary, metatarsal, sacroiliac, sternoclavicular, chondrocostal, intervertebral, cricoarytenoid, tibiofibular.<sup>10</sup> The condition is usually monoarticular, but two or more joints may be affected simultaneously or in rapid succession.

*Pathology.*—Except for the peculiar tendency to production of osteoporosis<sup>11</sup> and greater disposition to ankylosis, the pathology of gonococcal arthritis does not differ materially from that produced by other organisms. The inflammation is not confined to the articular surfaces but spreads along the tendon sheaths and adjacent periosteum, giving to the joint a fusiform appearance. Instead of affecting the articular surfaces, the inflammation may be confined to the soft tissues around the joint; in which event the capsule contains an accumulation of cloudy, serous or sero-fibrinous fluid with few leucocytes and gonococci may or may not be present. Infection of the articular surfaces and synovial membrane results more commonly in a thick, cloudy fluid, showing many leucocytes and usually the gonococcus in pure culture or associated with other pyogenic organisms, especially staphylococcus and streptococcus. Roughening of the articular surfaces with calcareous deposits may result. Adhesions may form between the surfaces, producing ankylosis. A less marked limitation of motion follows fibrous overgrowth when the infection is confined to the soft tissues around the joint.

*Symptomatology.*—Gonorrheal arthritis presents itself in various forms, and it is difficult to differentiate them sharply. A subacute or chronic case of uro-genital gonorrhea may be attended by lightning-like pains with only slight joint inflammation or no clinical evidence at all. Osler has called these attacks arthralgic. Except for these fleeting pains, the patient is free from symptoms. This form of arthritis is as commonly met with as it is commonly unrecognized. Occasionally, the patient experiences sharp pains along the course of a tendon or over a bursa but presents no evident pathological changes or constitutional disturbance. In the chronic form of arthritis, when exostoses occur on the os calcis, what is known as "painful heel" results.

The type next in severity is the single joint,

usually the knee, distended with a serous effusion. The joint is inflamed, painful, and motion is limited. There is a tendency to chronicity in so far as the fluid is apt to remain for a prolonged period of time. In this type there may be a slight elevation of temperature, but generally there are no constitutional symptoms.

The most virulent type of gonorrheal arthritis resembles an acute attack of rheumatic fever. It usually attacks several joints in rapid succession. Its sudden onset with a rise of temperature to 103° F. and prostration is suggestive of a septicemia. The joint is hot, swollen, distended with fluid, extremely tender and has a fusiform appearance. The slightest motion produces excruciating pain. While the joint is at rest, there is only slight discomfort. The effusion is in the joint as well as in the surrounding tissues. Occasionally, the periosteum and the bursae are involved. Ankylosis may follow one of these acute attacks. Usually as soon as one joint subsides, another flares up.

During or closely following the joint attack a cardiac murmur may appear. With the progress of the disease, the murmur becomes more pronounced until it can be heard all over the precordia, indicating the presence of an acute endocarditis. Septicemia may set in with a sudden rise of temperature to 105° F. accompanied by chills, sweating, and extreme prostration. The prognosis is grave, such cases usually terminating fatally. However, neither the onset or the entire attack may be so severe. Although the acute joint may be present, neither symptoms of valvular lesion nor septicemia may follow, yet recurrent attacks always predispose the patient to these dangers.

*Diagnosis.*—Definite diagnosis rests upon the finding of the gonococcus in the aspirated fluid. This procedure first employed by Lindermann (loc. cit.) has not been generally adopted by the profession. Apparently, there is a manifest hesitancy to puncture the joint for diagnostic purposes, due, perhaps, to a fear of producing a mixed infection. Under ordinary precautions this danger is negligible, and the procedure should be more commonly employed. The technique offers no special difficulties, produces but slight discomfort, and is not apt to result in any complication. After preparing the part with iodine, a sterile No.

20 needle attached to a glass syringe is thrust vertically through the most dependent part of the joint into the space between the articular surfaces. If no fluid is obtained at first, the direction of the needle may be changed or reinserted at another point. Novocain, one per cent, may or may not be used depending upon the patient.

It is evident that the history of a previous infection must be elicited. The uro-genital tract should be investigated with great care for presence of gonococci and gonorrheal lesions. In the presence of a positive history or of definite lesions, suspicion of joint involvement is aroused if the patient has shooting pains in the joints or along the tendons, or stiffness with or without pain, even though there is no inflammatory reaction. The purulent joint gives a leucocyte blood count of 12,000 to 20,000. There is no record of any observation bearing on the occurrence of leucocytosis in the other forms of gonorrheal arthritis. The complement fixation test is a great aid in diagnosis. Kolmer<sup>12</sup> states that the reaction is positive in eighty per cent to 100 per cent of all cases, when using a polyvalent antigen.

X-ray offers but little aid in diagnosis. A. L. Gray (personal communication) states that in acute cases there is nothing characteristic except for the evidence of a diffuse arthritis. If, in a chronic case, there is ankylosis of the patella to the femur, the case is very apt to be of gonorrheal origin, particularly if there are at the same time spurs on the os calcis.

*Differential Diagnosis.*—It is evident that gonorrheal arthritis closely simulates other common conditions. In absence of definite findings, the differentiation is often difficult. In acute articular rheumatism the fever is higher, sweating and prostration are more pronounced. The joints are apt to be more sensitive and usually several are attacked simultaneously. Puncture of the joint commonly shows the streptococcus. Gout, in this country, is relatively uncommon; it shows evidences elsewhere such as tophi and arterioscleroses, and usually affects one joint. Arthritis deformans shows peculiar deformities as a result of osteophytic processes. Polyarthritis chronica villosa occurs in women at menopause and in children; the disease is of long duration, pain is severe and independent of motion. What is known

as "chronic rheumatism" is characterized by absence of acute manifestations, its slow progress and its occurrence in middle and old age. This condition is probably infrequently of gonorrheal origin. Tubercular joints are common in children. The symptoms and X-ray clear the diagnosis promptly. In Charcot's joint, absence of pain, symptoms of tabes dorsalis and X-ray serve to differentiate. In neuritis the nerve trunk itself is sensitive to pressure, the pain is boring, follows the course of a nerve, and usually the attack can be traced to some etiological factor, such as infectious disease, or organic poisons.

*Treatment*—In an acute case, the patient should be put to bed, given a light, nourishing diet and plenty of water. The affected joint should be immobilized. Pain may be alleviated by local application of ice and full doses of salicylates. A tonic of iron and arsenic is advantageous later on. When the acute stage subsides, moderate exercise of the joint should be employed. If a coincident urogenital infection exists, it should be vigorously treated and, if necessary, surgery resorted to. Cunningham<sup>13</sup> advises removal of seminal vesicles. Little can be done locally for the arthralgic pains; eradication of the urogenital focus and systemic treatment are the only methods of use. Hot air treatment of the painful bursae and tendons may be tried. In the painful heel the surgical removal of the exostoses is recommended. In the joint with serous effusion without acute symptoms, aspiration of the fluid, tight bandaging and systemic treatment with attention to the genital focus is a logical procedure. Incision and irrigation of the purulent joint has been practiced but this procedure seems needlessly radical. Potassium iodide, salicylates, hot air, thermocautery, blistering are of little avail except for alleviation of symptoms.

*Antigonococcic Serum*—The first attempt at specific therapy of gonorrheal arthritis seems to have been made in 1907 by J. C. Torrey, working in the Loomis Research Laboratory; Torrey injected intramuscularly 2 cc. of the serum for 3 or 4 days and a complete cure was apparently obtained; later he increased the dosage from 36 to 45 cc., giving 12 to 15 cc. daily for 3 days with good results. In 1919, Debre and Paraf<sup>14</sup> punctured joints in 15 patients with different types of gonorrheal arthritis and injected the serum in place of the

evacuated effusion; in six cases the cure was complete in less than 8 days, while eight cases were cured within 15 days. Later, others reported success with serum injection. Results with the gonococcus serum are not uniform; nevertheless, it is a valuable remedy and should be more commonly employed. This serum has been available for some time in 5 cc. ampules; it should be given in acute cases in doses of 15 cc. intramuscularly on 3 consecutive days. Injection of foreign proteins is of doubtful value in acute cases and of no value at all in chronic cases.

Sensitized vaccine was employed first by Besredka in 1902 and proved to be of some benefit. Howorth<sup>15</sup>, Cole and Meakens<sup>16</sup>, Rogers and Torrey<sup>17</sup> find vaccine therapy of value and this has proved true in our experience. Vaccine may be given in acute or chronic stages, small doses of 10 million cocci in acute and 50 million in subacute, every five days. It is advantageous to increase the dosage gradually, beginning with 25 million cocci, increasing by 5 million daily or every other day up to 550 million. In diabetes, carcinoma, advanced nephritis, and other debilitating diseases the use of vaccines is contraindicated.

Defour and Debre<sup>18</sup> aspirated joints and, without heating or sterilizing the fluid, injected it subcutaneously and report good results from this procedure. Ballenger and Elder<sup>19</sup> state that in order to obtain satisfactory results the synovial fluid must be infected and purulent. They used 15 to 20 cc. of the fluid every 2 to 7 days.

Ross<sup>20</sup> employed 10 to 20 cc. of electrargol intravenously every second day and reported very striking results. In one case herewith reported we aspirated 20 cc. of fluid from the joint and replaced it with 25 cc. of 5% argyrol, with the result that other affected joints subsided and there were other evidences of systemic action.

#### CASE REPORTS.

On account of its typical character and especially interesting features, the following case is reported in detail.

Case 1. F. C., colored, female, age 18. Three years ago the patient had an attack of gonorrhoea attended by acute symptoms in right knee and metatarsal joints. At intervals, since then, she has had 4 early joint attacks involving hip, intervertebral, temporo-mandibular,

wrist, and metacarpal joints. The present attack began four days ago with swelling of right shoulder and left elbow joints. They became distended with fluid, extremely painful, and motion was limited. The metatarsal and lumbar intervertebral joints are painful but not swollen. She has a sore throat. There is a faint systolic murmur at the apex transmitted to axilla; cryptic, hypertrophic tonsils; fever of 102° F. She gives a history of dysmenorrhoea and leucorrhoea. Her Wassermann, blood culture, urine, cervical, urethral and vaginal smears are negative. On day of admission, leucocytes—13,500; 6 days later the leucocytes increased to 24,800. Six days after admission, 20 cc. of a cloudy, straw-colored fluid was withdrawn by puncture from the right shoulder. Microscopic examination revealed abundant pus cells and intracellular diplococci. The pain in the shoulder was relieved by the puncture. On the following day, 1125 million cocci of polyvalent gonorrhoeal vaccine was administered intravenously with increased doses every other day. A week later, another 30 cc. of cloudy fluid was withdrawn from the shoulder and 25 cc. of 5% argyrol was injected. In 4 hours the temperature rose from 101° F. to 105.6° F. She had been running a fever between 101° F. and 104.6° F. On the following day the temperature came down to 100.6° F.; on the second day to 98.8° F. and gradually returned to normal. Three days after the argyrol injection, the left elbow was absolutely normal and the pain in the intervertebral and metatarsal joints gone. The shoulder joint remained distended for 14 days, at the end of which time the joint returned to normal; by that time the cardiac murmur was very faint and confined to the apex. In the meantime, the genital infection was treated. She was discharged as cured.

Case 2. M. J., colored female, 36. Two weeks before the right knee began to swell, the joint was red, painful and limited in motion. On admission, the joint is distended with effusion, slightly tender, no inflammation. She gives a history of pain in the lower abdomen, leucorrhoea, dysmenorrhoea, and shooting pains in other joints. Tonsils atrophic, teeth in good condition. Cervical, vaginal and urethral smear negative. Twenty-five cc. of clear yellowish fluid was withdrawn from joint; no organisms found. The knee was tightly bandaged and she was given increasing doses

of vaccine. In a week she was discharged as improved and referred to the gynecological dispensary for treatment of the genital infection.

Case 3. M. F., colored female, 19. Married 3 years ago; since then had pain in lower abdomen, dysmenorrhea, menorrhagia, leucorrhoea and, within the last month, she had pain in knee, elbow and ankle joints with slight swelling. Wassermann 3 plus, no gonococci in smears. A double salpingectomy was performed on her. Previous to the operation she was given vaccine treatment. She made an uneventful recovery and was discharged as cured.

Case 4. J. H., colored male, 22. Four weeks ago the patient had an acute attack of gonorrheal urethritis which subsided in two weeks. Immediately after the cessation of the urethral discharge, the right elbow joint became swollen, painful and motion was limited. The patient was seen two weeks after the elbow was involved. The joint had a fusiform appearance, swollen, flexed at an angle of 35° and extremely painful to slightest motion. Temperature 99.8°. Patient complained of headache and malaise. Physical examination otherwise negative. X-ray showed no bone lesion. A joint puncture was done and a small amount of cloudy fluid withdrawn: a smear demonstrated intracellular diplococci. Ten cc. of 5% argyrol was injected into the joint. In two days, the patient's physical condition was improved, the joint pain subsided and, within one week after injection, the swelling almost entirely subsided, motion returned to normal and pain was entirely gone. He was referred to the genito-urinary department for treatment of the urethral condition.

#### DISCUSSION

DR. H. S. HEDGES, Charlottesville: Just one word about eye complications which are by no means uncommon in chronic sub-acute gonorrhoea. In all cases very much violent pain is suffered, which is sometimes so severe that it is hardly controlled by morphine. Sensitized and autogenous vaccines have been used and have given some of the most brilliant results.

DR. M. PIERCE RUCKER, Richmond: This is a very important subject. No age is immune. Dr. Royston has recently reported one case in the new born which showed no evidence of surface infection. He thinks that it was undoubtedly transmitted through the placenta. The infant had involvement of the knees and elbows and, later, ankylosis of the jaw. In the fluid that was aspirated, gonococci were demonstrated—a very interesting observation.

I have never seen a case in a new born, but have seen several mothers with gonorrhoeal infection in the puerperium.

#### THE CONCURRENT OCCURRENCE OF TUBERCULOSIS AND ASTHMA.\*

By GERALD A. EZEKIEL, M. D., Richmond, Va.  
Member of Richmond Tuberculosis Dispensary Staff; Associate Visiting Physician to Pine Camp Hospital.

We were taught in the medical colleges fifteen years ago that a patient with asthma never had tuberculosis. This belief is still held to be true by some physicians of today, and the effect of this teaching of the physicians of ten or more years ago is still fresh in the minds of the laity. I have asked a good many tuberculosis specialists, whom I have met, their views on this point, and they all tell me that they have seen the two conditions present at the same time, but that this common erroneous idea that they do not occur in conjunction does exist. The object of this paper is to com-

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

but this fallacy and to try to establish the truth on this point. The need of this was forcibly presented to me by a patient of mine, an asthmatic, absolutely refusing X-ray examination, because a specialist in Philadelphia ten years ago told him that asthmatics never had tuberculosis.

The diagnosis of tuberculosis in conjunction with asthma is at times rather difficult, due to the alteration in breath sounds by the asthmatic breathing. The sibilant and sonorous rales of asthma render obscure and almost, if not entirely, inaudible the fine crepitant rales of an early or slight tubercular infection of the lungs.

In my experience, the diagnosis of the concurrent existence of these two conditions can be made most often by aid of the history, X-ray examination and bacteriological examination. I am giving a few case histories to illustrate the application of these points. In several of these cases the physical findings were either altogether negative, or else typical of bronchial asthma but, on account of a suggestive history, X-ray examination was ordered and gave definite positive results. To speak of the bacteriological examination in tuberculosis may seem trite. We all know a positive finding means tuberculosis without question and that a negative report does not necessarily rule out tuberculosis. I want to emphasize the need of repeated examinations before regarding a sputum as negative. I have received as many as eight negative reports and then on the ninth examination obtained a positive report.

Case No. 1158, November 6, 1919. E. P., white, male, age 8. Present illness began with bronchial trouble three years ago, now has fever, loss of weight, weakness, shortness of breath, dull pain in chest, cough, good deal of expectoration. Physical examination: Diminished expansion of chest, percussion note increased, few coarse rales left base. November 12, 1919, weight 48 $\frac{1}{4}$  pounds. Sputum: Negative. Provisional diagnosis was made of asthma and probable pulmonary tuberculosis. November, 1920, patient was placed in hospital for further observation. Weight 47 $\frac{1}{4}$  pounds (one year later.) Physical examination: Emphysematous breathing, sibilant rales throughout the chest. X-ray examination November 6, 1920, as follows: "Patient has a slight bronchial type of tuberculosis, involv-

ing both lungs. A good deal of this is well calcified but there are uncalcified tubercles seen in both lungs, chiefly the upper and lower right lobes and outward from the hilum in the left lung. There is a slight pleural thickening between the upper and middle lobes of the right lung. Each hilum contains a dilated bronchus." Sputum: Positive. Protein sensitization test: Reacted to egg and cabbage. Final diagnosis: Pulmonary tuberculosis and asthma.

Case No. 1299, October 25, 1922. Mrs. F. D., white, female, age 29. Present illness began with bronchitis ten years ago, now has night sweats, loss of weight, weakness, indigestion, shortness of breath, dull pain in chest, expectorates thick yellow mucus. Normal weight 190 pounds, present weight 161 $\frac{3}{4}$  pounds. Physical examination: Squeaking rales throughout the chest. Sputum: Negative. Wassermann: Negative. Provisional diagnosis: Asthma and pulmonary tuberculosis. X-ray examination November 24, 1920 as follows: "Patient has apparently a slight bronchial type of tuberculosis, chiefly in the middle lobe of the right lung. The bronchial branches in this lung and the structure in the right hilum are much thickened. Emphysematous areas are seen outward from right hilum." Final diagnosis: Pulmonary tuberculosis and asthma.

Case No. 1442, May 17, 1921. A. S., white, male, age 40. Present illness began four years ago with pain in chest, now has loss of weight, fever, weakness, indigestion, shortness of breath, cough, hemoptysis, and has had several hemorrhages. Physical examination: Lungs emphysematous and full of sibilant rales and rhonchi. Sputum: Negative. Wassermann: Negative. Provisional diagnosis: Bronchial asthma and tuberculosis. This patient was finally successfully X-rayed in July, 1921 with the following report: "Patient has a general fibrosis of all bronchial branches particularly on the right side. Numerous calcified tubercles are seen in both lungs. There is a group of uncalcified tubercles behind the second right interspace. There is a mass of scar tissue to the right of the heart extending from hilum to the diaphragm. The mediastinal pleura is thickened. Patient has a hypertension type of aortic arch. The top of the aorta reaches well below the sterno-clavicular joint. The heart and aorta are small. Conclusion: Patient has a fibroid phthisis. The marked scar tissue de-

posit to the right of the heart, extending outward from right hilum, is suggestive of a specific infection." Final diagnosis: Pulmonary tuberculosis, fibroid type, and asthma.

Case No. 1918, August 17, 1922. Mrs. V. C., white, female, age 26. Gave history of having had asthma the last twenty-one years. Present illness, asthma for last two months, tires easily, loss of weight, night sweats, cough, expectorates a great deal of greenish yellow sputum. Normal weight 102 pounds, present weight 91 pounds. Physical examination: Few rales in right upper lobe, hypertrophied tonsils. Sputum: Negative. X-ray report September 2, 1922, as follows: "General thickening of all bronchial branches. A few well calcified tubercles are seen in each lung. Patient has had pleurisy on the left side resulting in a pleural adhesion at the left costophrenic angle. There is no evidence of recent unhealed, clinical tuberculosis." Provisional diagnosis: Asthma and pulmonary tuberculosis. This patient's tonsils were removed and she was given sanatorium treatment. Final diagnosis, April 26, 1923: Chronic pulmonary tuberculosis arrested, and asthma. At this time she weighed 124 pounds, a gain of 33 pounds and was doing nicely.

I might at this point explain that the provisional diagnosis is made at the time of the first examination of the patient. An attempt is made to form an opinion of the case, so as to have a working diagnosis. In the first case cited, provisional diagnosis was made and one year later confirmed by X-ray and sputum examination. Up to this time the sputum had been negative. In the second, third, and fourth cases the diagnosis was confirmed by X-ray examination. Positive sputum was never obtained in these three cases but the X-ray findings, with the history and physical findings of these cases and the outcome, bear out the diagnosis as made. I could give some additional similar case histories, but these few are typical of the point I wish to make, that is, X-ray and sputum examinations will enable you to properly interpret and confirm an otherwise obscure or questionable diagnosis of tuberculosis and asthma occurring concurrently.

In making the provisional diagnosis, asthma was placed first. This was usually the disease condition that caused the patient to seek medical advice. In making the final diagnosis, pulmonary tuberculosis was placed first, because

this seemed to be the main condition to be treated and certainly the more important. It is possible the asthma is super-imposed upon a tuberculosis due to a protein sensitization to tubercle bacilli. I have not had the opportunity to study this point sufficiently to make any definite statements at this time, but merely mention this as a possibility and a point that I hope to be able to investigate later.

1652 West Grace Street.

## THE BLOOD CULTURE AS A DIAGNOSTIC AID.\*

By AUBREY H. STRAUS, M. A., Richmond, Va.

We have all heard of people who claim to have had typhoid fever more than once. We have also probably met physicians who claim to have treated typhoid fever two, or even three, times in the same person. I have never heard of a case, however, in which there has been laboratory proof of typhoid fever occurring more than once in the same person.

I cannot, of course, undertake to say that such a thing is impossible, but I do regard it as most unusual. The true explanation of these occurrences, in all probability, is the fact that there are quite a variety of bacteria which may occur in cases of enteric fever. Clinically, the infection caused by many of these organisms is identical with true typhoid fever.

Many such organisms are known and there are doubtless others not yet described. In Table I we have summed up all our blood culture work, showing a large variety of findings. Yet there are many organisms described by others which we have never encountered.

The figures in Table I are of considerable interest in showing how great the variety of such infections may be. The rapidly increasing use of the blood culture has made this table possible and will, in future, doubtless disclose a still greater range of infections than those so far found.

While the physicians of Richmond have made use of the blood culture for many years, it is only during the last year that it has begun to come into general use in the rural sections. With the further simplification set forth in this paper we hope to see its use extended.

\*From the Laboratories of the State Board of Health and the Richmond Health Bureau.  
Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

TABLE I.

## SUMMARY OF BLOOD CULTURES EXAMINED.

Result	Number	Per Cent
Positive -----	249	22
Negative -----	881	78
Total -----	1,130	100

The positive results were as follows:

## FIRST GROUP.

*Organisms Causing Infection Clinically Resembling Typhoid<sup>A</sup> Fever.*

B. Typhosus -----	217
B. Para-typhosus B. -----	6
B. Coli -----	6
Unidentified Bacilli Resembling Para-typhoid--	2
B. Fecalis Alkaligenes -----	1
Bacillus resembling B. Asiaticus -----	1
Friedlander's Bacillus -----	1
Unidentified, hemolytic bacillus -----	1
	235

## SECOND GROUP.

*Organisms Causing Infection, Not Usually Resembling Typhoid Fever.*

Streptococcus -----	8
Pneumococcus -----	3
Meningococcus -----	1
Influenza Bacillus -----	1
Unidentified Bacillus resembling the Influenza bacillus -----	1
	14

In the first group of the above table, it may be noted that there are seven organisms, other than *B. typhosus*, causing eighteen cases which the attending physicians stated could not be distinguished from true typhoid fever. In most of these cases, however, the course of the disease was mild. The variety of these infections is far greater than anticipated. Paratyphoid fever in Virginia appears to be rare, especially para-typhoid A. Because of this fact, we advocate the use of the straight typhoid vaccine rather than the "triple vaccine," which contains also the two para-typhoid bacilli.

The cases in the second group, for the most part, developed symptoms corresponding to the blood culture findings. In one case, however, a death certificate had already been signed for typhoid fever before our report of the "pneumococcus present" was rendered.

In view of these results we are convinced more than ever that the blood culture is a most valuable diagnostic test. Without a blood culture, cases will be diagnosed as typhoid fever that are not, and some will *not* be diagnosed as typhoid fever that are. For a physician to diagnose "para-typhoid fever" without cultural confirmation, or specific agglutination, is inaccurate.

While there is no specific treatment for any of these infections a physician should, nevertheless, be interested in knowing what he is treating. Unquestionably, some of the unsuccessful protection reported from typhoid vaccine has been in cases where the infection was of some other nature.

From a public health standpoint, the type of infection is very important. The precautions necessary in a case of typhoid fever are hardly necessary in a *B. coli* infection. Likewise, it would probably be useless in this case to search for the source of the infection.

The Widal reaction or agglutination test, in suspected typhoid fever, should always be used in conjunction with the blood culture. By this I mean a real agglutination test made from whole blood, and not the obsolete and unreliable test made from a drop of dried blood.

In a general way the agglutination test is of most value after the disease has been in progress for ten days or more, and the blood culture of the greatest value during the first week or ten days. No definite limits can be set, however, and we find great variation. Therefore, the only dependable way is to get a specimen of whole blood and have both tests made.

Formerly we have supplied special outfits, containing bile medium, for blood cultures and other outfits for agglutination, but we now find this to be unnecessary. In Table II we have compared regular blood cultures with cultures made from the clotted blood, and obtained results as satisfactory by the one method as by the other, so far as typhoid fever is concerned.

TABLE II.

## COMPARING BLOOD CULTURES AND CULTURES MADE FROM CLOTTED BLOOD.

Blood Culture Direct into Bile	Cultures from Clots		Total
	Positive	Negative	
Positive -----	19	3	22
Negative -----	3	65	68
Total -----	22	68	90

As shown above each cultural method disclosed three positive cultures not found by the other method. Nineteen bloods were positive by both types of culture and sixty-five were negative by both. It seems probable that the role of chance, due to the small amount of blood used, might account for this; that is, it appears that the clot-culture is about as reliable as the regular blood culture, but where

both are used, and consequently more blood examined, the chances of positive results are increased.

In the above discussion we refer only to organisms in the first group in Table I. Organisms of the second group in Table I do not grow in bile culture medium, yet we find this the most satisfactory medium for organisms of the first group. As it is not practicable to handle several different containers, where specimens must be mailed, and, as ninety-four per cent of all positive findings fall into group one, we have used only bile medium in our statewide work.

Where organisms such as the streptococcus, pneumococcus, and the influenza bacillus are suspected, bile culture medium is not satisfactory. In these cases suitable medium must be obtained from the laboratory, and the blood inoculated directly into this medium.

Since cultures made from the clotted blood have shown results as satisfactory as inoculating the blood directly into bile medium, a single tube of whole blood may be used for the two specimens. This simplifies matters greatly for the practitioner, as all that is necessary is to draw 3 to 5 c.c. of blood aseptically and put it into a test tube, just as is done for a Wassermann test. From the serum in this tube an agglutination test is made in the laboratory and from the clotted blood a culture. Negative results on both of these tests will rarely occur in true typhoid fever.

The laboratory methods used in all of this work have been described elsewhere\* and will not be repeated here.

In conclusion I wish to point out:

First. Not all enteric fevers with certain clinical manifestations are typhoid fever.

Second. The blood culture is the only method of determining the nature of these other infections.

Third. For a reliable diagnosis in typhoid fever both a blood culture and an agglutination test must be made. A tube of whole blood, aseptically collected, will serve satisfactorily for both tests.

Fourth. In cases of suspected endocarditis, septicaemia, etc., special culture medium must be used in order to obtain satisfactory results.

## SYMPTOMATOLOGY AND DIAGNOSIS OF EXOPHTHALMIC GOITRE.\*

By Wm. B. PORTER, M. D., Roanoke, Va.

A study of the symptoms of a disease involves an analysis of those disturbances produced by the structural, metabolic and psychoneurotic changes incident to the perverted physiology in the affected being.

The diagnosis of a disease must involve a careful weighing of the evidence afforded by a study of the symptoms, the abnormal physical phenomena, the collected laboratory data, and lastly, a broad and common-sense amalgamation of all these into a composite picture of the clinical status of that human being.

During the last few years much has been accomplished in the study of the endocrine system, yet in no class of patients is one so liable to be tripped by symptoms or does one encounter such bizarre and uncertain physical phenomena as in the suspected case of exophthalmic goitre.

The perverted physiology and bio-chemical changes occurring in hyperthyroidism involve the entire somatic system; consequently, in no disease is it so important that the diagnosis carry with it a broad and complete understanding of all the immediate and collateral evidence of disturbed function, for it is only upon this complete inventory that a rational and sane therapy can be based.

In this discussion we are not interested in those patients who have a "lump" in the neck, and who have none of the primary or secondary manifestations of exophthalmic goitre and no elevation of basal metabolism. We are interested in those patients who, with or without thyroid enlargement, present symptoms and signs best grouped under the single term of "sympatho mimetic," the term of Barger and Dale to denote "manifestations that are tantamount to electrical stimulation of the thoraco-lumbar division of the involuntary nervous system, or to stimulation of this same system by adrenalin." Such signs include the cardinal symptoms of tachycardia, exophthalmus, goitre and tumor, and the minor symptoms of exophthalmic goitre, such as diarrhoea, sweating and palpitation.

The work of Lieb, Kessel, Hyman, and Lande has shown that this symptom-complex

\*Read in the symposium on "Disease of the Thyroid" at the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

can and does exist in patients who have no elevation of basal metabolic rate or who never have had such a disturbance of catabolic function. These observers have coined the term "autonomic imbalance" to denote that group who have all or most of the primary and secondary manifestations of exophthalmic goitre, but who do not or have not had an elevated basal metabolism, a group undoubtedly representing a much larger percentage than has been generally appreciated.

Recently, a woman thirty-six years old consulted me, complaining of nervousness, palpitation, tachycardia and dyspnoea with exertion. She stated that eighteen months previously she was operated on in another city, at which time a partial thyroidectomy was done. Her symptoms now were the same as they had been prior to her operation. At this time she was getting radiation over her thyroid which had been begun seven months previously. She felt that her symptoms were exaggerated rather than improved.

Examination disclosed most of the orthodox signs of exophthalmic goitre, i. e., slight exophthalmus, tachycardia, tremor and pronounced sweating of the hands and axillae. The basal metabolic rate was 36, -40, -38. This patient was given thyroid extracts and a tonsillectomy was done and in six weeks' time she reported feeling practically normal.

This case well illustrates one of the main points I wish to make in the consideration of the diagnosis of exophthalmic goitre. The diagnosis is complete and accurate in so far as it carries with it the information necessary for a sane and logical therapy. The patient was undoubtedly one suffering from "autonomic imbalance," who incidentally had a goitre. This disturbance of her involuntary nervous system had been activated by a focal infection in her tonsils and accentuated by the psychic insult of frequent abortions. The hyperthyroidism was no doubt the result of the thyroidectomy and prolonged radiation. The basis upon which treatment was begun and resulted in cure was not the disturbance of her involuntary nervous system but the knowledge derived from a study of her basal metabolism which showed a markedly depressed rate.

In a study of patients who present the manifestations of a Graves' syndrome, I believe it to be absolutely incumbent upon us to deter-

mine whether there is or has been an elevation of the basal metabolic rate before any positive therapeutic procedures are instituted. The work of Benedict, Means, Aub, Roth, Carpenter, Boothby, and a host of other observers has repeatedly shown that increased basal metabolic rate is the most reliable single sign in exophthalmic goitre.

In the routine study of patients, one encounters a large group whose symptoms are sufficiently suggestive to place them in the category of hyperthyroid suspects. These patients include those suffering from the neurasthenic states, disturbances of the autonomic nervous system, and functional derangement of the neuro-circulatory apparatus. If there should exist a coincidental goitre, the picture may be most confusing.

Means and Burgess have recently studied a group of border-line cases with particular reference to differential diagnosis. They found that the majority of the type with incomplete evidence of abnormal thyroid function had a normal metabolism. If a basal rate is secured, an increased basal metabolic rate is strong presumptive evidence of hyperthyroidism. They conclude that the metabolism test is distinctly useful in differential diagnosis.

I do not believe that these patients can be differentiated by any one laboratory test. It is usually possible to place them in their proper category by a clinical analysis of the individual, using the laboratory finding as confirmatory evidence, with due regard for its limitations and pitfalls.

The study of the endocrine system is in its infancy. The advances made are too frequently based upon speculation and hypotheses, hence conclusions are uncertain. The diagnosis of thyroid disease has not been simplified by any of the newer methods of study; rather it has become more complex, but this is not regrettable if we are able to more accurately define the type of patients demanding selective therapy.

The determination of this fact may be accomplished by a careful analysis of the existing symptoms and abnormal physical phenomena, yet there are few of us who would be willing to treat a case of typhoid fever without a clinical thermometer. Then why subject a patient to a major operative procedure or radiation until it has been determined with

some degree of accuracy whether such drastic measures are indicated? They may be, but there is a fair chance that they are not.

Various laboratory procedures have been introduced as an aid in determining hyperactivity in thyroid disease, the Goetsch test, Kettman's reaction, the Glucose Mobilization Rate, and many others, but undoubtedly the use of the closed calorimeter is the simplest and most consistent method at our command. The value of this method is in direct proportion to the appreciation of the necessity of careful and repeated tests. It is a laboratory procedure and is, therefore, not devoid of possible error, but when one properly balances it with a careful history, an analytical analysis of the symptoms, and a painstaking survey of the physical phenomena, one then has that data necessary for a logical diagnosis.

### THE MEDICAL TREATMENT OF GOITRE.\*

By W. W. CHAFFIN, M. D., Pulaski, Va.

The medical treatment of goitre was assigned to me and I have no choice in the matter, and must tell you not only what I believe about it, but also what is believed about it by medical men of note.

I believe all the authorities agree that the drug which has promised more for the relief of the symptoms of goitre, if not the cure, is iodine in some form.

Crile has shown that iodine is taken up by the thyroid gland when given by the mouth, by inhalation, or by external application, and it makes very little difference, from a scientific point of view, what form of iodine is used, as the thyroid will take it up from the most stable compounds, even mercuric iodide.

Wyeth even went so far as to report favorable results from the inhalation of iodine which were secured by the suspension in the patient's room of a wide-mouthed bottle containing a ten per cent solution of tincture of iodine.

The early Greeks treated goitre by the internal administration of the ash obtained by burning sea sponges, not knowing that the substance was rich in iodine.

In 1907, Marine emphasized the fact that iodine is necessary for the proper function of

the thyroid, and also that in active hyperplasia of the thyroid, the iodine store is reduced. Consequently, the administration of iodine should theoretically control this active condition. However, this is not the case practically, at least not to any extent. How many of us have seen the fruitless painting of the neck with iodine for this condition? About all we have seen is a tremendously sore condition of the neck added to the other discomforts of the patient. So much then for the iodine treatment.

The glandular treatment has been much exploited and as heartily condemned. Theoretically it promised much, but practically, it proved to be a "will of the wisp."

Personally, I have treated a good many cases with the different forms of medication and rest in bed. I have tried the iodine thyroidecine, sodium cacodylate, sedatives, etc., and I honestly believe that, aside from the rest the patient gets, the results from the treatments were nil; and the only good my treatment did was to rest the patient and get her in better condition for a surgical operation. So you see where I stand on the treatment of these cases.

### SURGICAL TREATMENT OF DISEASES OF THE THYROID.\*

By T. J. HUGHES, M. D., Roanoke, Va.

Doubt and inexactness add much to the problems of the thyroid. This fact is emphasized by the preceding papers in this symposium. The ground has been thoroughly covered as regards the pathology, etiology, diagnosis and therapeutic treatment of this important gland, which has been termed the "balance wheel of nutrition."

The etiology has been doubtfully accepted, therapeutic treatment is speculative in its results, and in most cases is varied and uncertain and, until we know more exactly the amount of thyroid tissue to remove to correct thyrotoxicosis, and yet avoid the ultimate results of excision of too much of the gland, we should avoid extreme radical thyroid surgery, bearing in mind the tendency in every field of modern surgery for the pendulum of radicalism to swing too far.

The differences of opinions of leading clinicians and surgeons upon thyroid problems,

\*Read in the symposium on "Disease of the Thyroid" at the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

\*Read in the symposium on "Disease of the Thyroid" at the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

which should have long ago been definitely settled and generally accepted, should make both the therapist and the surgeon accept, with solemn duty and responsibility, the management of diseased conditions of the thyroid gland.

Too much and too long treatment may stimulate the growth, increase thyrotoxicosis and bring disaster to the heart and nervous system; while removing too much or too little gland tissue, without proper preparation and analysis of the case in hand, may make a worse wreck of the patient or subject it to a recurrence of the devastating condition.

There is, probably, no subject more generally discussed, more indefinitely settled, and less generally accepted than are the problems of thyroid surgery. There are, however, a few facts which have been established by clinical observation, pathological and histological study and practical experience which should be emphasized, and should serve to strengthen our endeavor to avoid the pitfalls which beset the pathway of both physician and surgeon.

From the surgical standpoint, I would call attention to the fact that tumors of the thyroid are more often malignant than is generally supposed, that malignancy occurs earlier in life than is the case with perhaps any other organ of the body. Of 290 patients with malignant tumors of the thyroid gland, examined at Mayo Clinic from 1901 to 1921, more than fifty per cent developed goitre before they were thirty years of age, and about twenty-five per cent of this series had not noticed any thyroid enlargement previous to one year before the diagnosis of malignancy was made; hence the importance of avoiding prolonged stimulating treatment, and referring these cases early for surgical treatment before the gland or tumor undergoes malignant degeneration. Louis B. Wilson, from a careful study of the pathology of tumors of the thyroid, believes that they all have their origin in proliferating "fetal adenomas." It is most important that all nodular tumors of the thyroid be examined and, if markedly proliferating adenomatous tissue is found, the tumor should be considered potentially malignant and the thyroidectomy followed by X-ray treatment, and the patient kept under observation for a long period of time.

Eminent surgeons differ in their opinions as to the diagnostic value of the reading of the

metabolic rate, some relying to a very great extent on this index as an aid in diagnosis and relative safety in operative procedure, while others almost wholly disregard it. It does seem, however, that, if nothing more, the metabolic rate is of great importance in differentiating between psycho-neurosis and true thyrotoxicosis, especially when the thyroid is not appreciably enlarged. The writer believes, perhaps contrary to the general opinion, that exophthalmic goitre and all toxic adenomata are purely surgical conditions, and that the health of the patient would be better conserved if all tumors of the thyroid, in adults, were removed as early as possible after recognition. Both the psycho-neurotic cases, with little or no thyroid enlargement, and the non-toxic cases with thyroid enlargement, are dangerous pitfalls and may lead to disastrous delay.

The diagnosis should be definitely made; the degree of damage from thyrotoxicosis determined and remedied as far as possible by appropriate preparatory treatment; then bear in mind that any plan of surgical procedure we may decide upon is dangerous. No operation should be attempted, not even a preliminary ligation, until the probability of an approaching crisis has been reckoned with.

The question of "When and How" to operate is another problem afflicted with divergent opinions. The relative safety in primary ligation, multiple stage operation, and operation in one stage, is by no means settled. Mayo and Crile ligate frequently, with confidence in its safety and benefit, while Finney, McGuire, and others apparently consider it an unnecessary ordeal. I am not convinced that, after the preliminary rest and preparatory treatment, primary ligation has any advantage in safety over multiple stage excision, provided care is taken not to do more than our patient can stand; and whether the gland is removed in one or multiple stages, in extreme toxic cases, the incision should be left open, packed and closed on the following or second day after operation. If death is going to result from hyperthyroidism, it will usually occur within a few hours after operation; therefore, the surgeon and all assistants should remain on the job and employ every means to sustain the patient and to combat reaction of the temporary hyperthyroidism. Ice bags to the head, heart and groins, saline and glucose solutions by proctoclysis, hypodermoclysis, and intra-

venously, if necessary, should be employed.

The most popular incision is the ordinary Kocher collar, made in such a way that a string of beads will cover the scar, the flap dissected up, the muscles retracted without division, if the size of the tumor will admit of its removal without difficulty. If, however, dexterity is enhanced, the muscles may be divided and sutured without appreciable loss of function or deformity. From four-fifths to seven-eighths of the gland is excised, leaving a floor of thyroid tissue and the posterior surface of the capsule overlying the trachea, and protecting the parathyroids and recurrent laryngeal nerve from damage during the operation.

#### ANESTHESIA

In my opinion, one of the most important questions the surgeon is called upon to decide in thyroid surgery is the proper anesthetic to use. Gas-oxygen, local analgesia and general narcosis, all have their advocates. The writer is convinced that local, or a combination of local and gas-oxygen anesthesia, should always be used in exophthalmic goitre and other forms of toxic adenomata.

1st. The condition leading to surgical shock, such as position of the patient's head, producing dyspnoea, undue pressure from instruments, and the afferent stimulation of the sensory nerves, are greatly lessened by the use of local anesthesia. The patient is a welcome assistant in avoiding injury to the recurrent laryngeal nerve by being able to cough or talk at the suggestion of the operator.

2nd. Post operative nausea and vomiting rarely occur and consequently the tendency to hemorrhage is lessened.

3rd. Liquid nourishment may be given immediately after operation, and the employment of hypodermoclysis, proctoclysis and intravenous methods of supplying needed fluids are often found unnecessary.

4th. The danger of post-operative pneumonia is eliminated and, in our experience, post-operative reactions of hyperthyroidism are fewer and less severe, under local anesthesia.

Satisfactory anesthesia may be obtained either by infiltration or nerve-blocking methods. A half per cent solution of novocain, which has been boiled, is used. If the infiltration method, or combination of both, is used, the dissection of the flap is facilitated by thick-

ening of the subcutaneous tissues of the neck by the inhibition of the solution injected.

With the proper preparation of the solution, healing should be by first intention. The patient is allowed to sit up on the second day, and leave the hospital at the end of the week, or ten days.

The post-operative treatment consists in sustaining the heart and quieting the nervous system, as suggested above, in avoiding or combating surgical shock and the temporary hyperthyroidism which often follow thyroidectomy. To this end, in addition to the measures already mentioned, we give large doses of digitalis, which is begun a day or so before operation, and continued until the heart's action is quieted to within normal limits after the operation. The patient is kept quiet and the nervousness controlled for the first twenty-four hours by morphia hypodermically, bromides and chloral, and such other quieting and sustaining remedies as may be indicated.

The following is a brief report of a case operated on yesterday. Mrs. P., age 43, entered the Shenandoah Hospital, September 1, 1923, complaining with pelvic and bladder discomfort, generally run-down condition, very nervous, loss of flesh, rapid pulse, foul breath and extreme weakness. A goiter about the size of a lemon, which to her mind was not giving her trouble, was observed. Further examination revealed metabolic-rate plus 38, blood pressure S. 140, D. 105, pulse rate 130, urine negative, except there was a large quantity of bladder epithelial cells. Except for the rapid pulse and slight irregularity, the heart showed no abnormal condition.

*Family History:* Married, has seven children, all living and healthy, except three have goiters. The patient has had her goiter for the past twenty-three years, has enjoyed good health up to the past few months, when the symptoms given above began and have gradually grown worse; she has marked tremor but no bruit and no exophthalmus. Blood examination negative.

*Diagnosis:* Toxic adenoma of the thyroid. Operation performed September 5, 1923, under local anesthesia, employing the combined block and infiltration methods; pulse at beginning of operation was 110, at the close 88. As the patient's condition was good, we closed the incision.

A letter from this patient about three months after this article was written states that she is now enjoying perfect health.

*American National Bank Building.*

### THE THYROID PEDIATRICS.\*

By ROGER H. DUBOSE, M. D., Roanoke, Va.

It is my sole object in this paper to discuss briefly the most common types of thyroid disease in infancy and childhood.

In the last five years there has been a great advancement in the field of "Ductless Glands." The possibilities of further advancement in this field are perhaps greater than in any other branch in medicine. We still know very little about the function of these glands. We do know that the thyroid secretion has something to do with the development of the young, both mentally and physically.

The most common forms of thyroid disease are cretinism and myxedema. These are merely different expressions of a hypo-functioning thyroid gland. The clinical signs of the cretin are characteristic, yet the diagnosis is not always simple in the very young, for we are apt to be confused with a mongolian idiot and achondroplasia. Some authorities believe that cretinism is often due to psychical disturbances during pregnancy. We now accept the fact that cretinism is due to the absence of the internal secretion of the thyroid gland. The same condition holds true where the gland is removed by surgical means. Congenital absence of the gland is often times noted in post-mortem findings. It is spoken of as congenital myxedema.

The clinical signs of the cretin are not so evident in the very young, yet an early diagnosis is most essential, if we expect to obtain our very best results by the administration of thyroid extract.

Physically, cretins are short in stature, usually under weight as compared to the normal infant. The hands and feet are small. The thumbs are especially short. The skin is very dry, rough, wrinkled and often times copper colored. The neck is short and thick. The nose is broad and flat. The tongue is thick and protrudes. The fontanelles are late in closing, likewise dentition is delayed. The cretins are habitually constipated. The ma-

majority of them have umbilical hernia. The temperature is sub-normal. The hair is coarse, dry and straight. Talbot, in measuring these infants found the length of the arm from the acromion process to the tip of the second finger to be shorter than in the normal infant, likewise the length of the leg from the pubic bone to the sole of the foot to be much shorter than in the normal. The head of the cretin appears to be much larger as compared to the normal child but, if measured, it will be found to be approximately the same.

Mentally, these infants have a stupid facial expression. They are as stupid as they appear to be. They do not sit, walk or talk as early as the normal child.

Fisher, as well as Talbot, found the basic metabolism in cretins to be much lower than in the normal. The same is true in some cases of mongolian idiocy. It is exceedingly difficult to obtain the basic metabolism in the very young. That being the case, it occurs to me that the most practical method to pursue, when we suspect a mental retardation, is to put these infants on thyroid extract. The earlier the administration of thyroid extract is begun, the greater the improvement will be, both mentally and physically. The longer the treatment is delayed, the greater the chances are for the cretinoid condition to become fixed.

No hard fast rule can be laid down as to the quantity of thyroid extract to be given to the unfortunate ones. Some will tolerate larger doses than others. Talbot says the maximum dose of thyroid is that which would bring the basic metabolism up to the basic metabolism of a normal child, of the same age. I usually begin with a small dose, and gradually increase it until my patient shows signs of some nervous manifestations. They often times will tolerate 1 to 3 grains a day. When the pulse becomes quickened, it is advisable to reduce the dose to one-half, and gradually increase it again.

Achondroplasia is a rare disease in children because of the fact that very few infants having the disease survive infancy. They are usually prematurely born, or develop hydrocephalus soon after birth and die. When these infants do develop into childhood, their mental powers are normal and the physical condition is usually good. Teeth usually appear at a normal age. The most notable feature is the shortness of their limbs, while their bodies are

\*Read in the symposium on "Disease of the Thyroid" at the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

of normal length. The parts affected are those portions where cartilage is replaced by bone.

I do not know just what the basic metabolism would be in these infants. The rarity of the disease probably prevents much research work in these cases. So far as I know, there is no treatment that will produce growth.

The mongolians differ from the cretins in having a comparatively thin neck, normal temperature, soft smooth skin, and slanting eyes. They are not as short and chubby as the cretins. The similarity of a mongolian and cretin in the old is not so evident as in the young.

As stated above, in some cases of mongolian idiocy the basic metabolism is low. In these cases, thyroid extract is of therapeutic value. Evidently there is some close connection between these diseases. This is also true in some cases of a mental defective.

I have a boy, now four years of age, who came under my observation one year ago. At the age of two and one-half years he could say three or four words. He was seven months of age before he sat up. His first teeth appeared at nine months of age. He stood alone at fifteen months of age. He was three pounds under weight. He appeared to be nervous, restless and irritable. Family history negative. No history of birth trauma whatever. The tonsils and adenoids were removed at two years of age. A diagnosis of mental defective was made, and he was put on mixed glands.

In less than six months there was a decided change in the child's mental condition, and today you would not suspect him to be mentally defective, yet his physical powers are slightly below normal. His disposition has changed to that of the cheerful, playful child. He appreciates his toys and is much more obedient.

Hyperthyroidism is said to be due to the hyper-secretion of the thyroid gland. The disease is rarely seen in children. The ratio is about one to fifty as compared to adult cases. When it does occur, they have a protrusion of the eyes (exophthalmus), muscular tremor, palpitation of the heart (tachycardia) and usually bilateral enlargement of the glands. They often have hemorrhage from the nose because of the increased blood tension. The symptoms are practically the same as those seen in adult cases. It is well to remember that in the young you are dealing with the growing organism, and in the adult that fact

may be disregarded. The basic metabolism is increased in these cases and acts as a good guide for a definite diagnosis.

X-ray therapy in the hands of an experienced operator, and surgery are the most important methods of treatment I know. Various drugs have been advocated, such as belladonna combined with iodide of sodium, strophanthus, digitalis, and spartein sulphate have also been used with very good results.

In conclusion I want to emphasize:

It is most important for us to differentiate between mongolian idiocy, achondroplasia and cretinism in the very young. I would suggest that we place every suspected mentally defective case on mixed glands. In this ray we are most likely to derive some benefit. We cannot do any harm if we keep these patients under close observation and do not push the drug too rapidly.

When a definite diagnosis of cretinism is made, the administration of thyroid extract should be continued indefinitely. The same is true in other mentally defective cases where improvement is seen.

### ROENTGEN RAY TREATMENT OF HYPERTHYROIDISM.\*

By JOSEPH T. MCKINNEY, M. D., Roanoke, Va.

In the preceding papers of this symposium, the diseases of the thyroid gland have been so fully covered that we shall deal only with the X-ray treatment of hyperthyroidism. The colloidal, cystic, simple goiters, non-toxic adenomata, and those with normal or reduced function causing deformity and pressure symptoms, should never be treated with the X-ray, but treated surgically. Malignant goiters should first be operated upon (if not inoperable) and later followed by an intensive course of X-ray therapy.

The two types of goiter in which X-ray therapy offers good results are the exophthalmic goiter, and toxic adenomata with hyperthyroidism, the later condition having been first and completely described as a definite clinical entity by Plummer. The X-ray then is not a treatment for goiter, but for hyperthyroidism, manifested by constitutional disturbances due to toxemia caused by an excessive secretion of thyroxin, which markedly

\*Read in the symposium on "Disease of the Thyroid" at the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

stimulates the oxidative process throughout the body.

Increased basal metabolism and estimation of the basal metabolism rate, gives us the most accurate determining factor of the increased secretion of the gland, enabling us to follow the course and results of treatment. No case should ever be subjected to X-ray therapy without careful basal metabolism studies before, during, and after treatment. This one point cannot be too strongly emphasized.

Brilliant as have been the results achieved by surgery in the treatment of toxic adenomata with hyperthyroidism and exophthalmic goiter, the fact still remains that the results even in the most skilled hands are not all to be desired. Development of surgical technique and surgical management of these cases in such master hands as the Mayos and Crile has been one of the outstanding achievements of surgery during the past decade. However, modern surgery has accomplished about all that can be hoped for from surgical measures. For further advances in the handling of these cases we must confidently look to radiation in some form or other. That much remains to be learned in this comparatively new field, all roentgenologists admit, but that brilliant results can be obtained in a number of these cases has been proven beyond doubt in the hands of numerous roentgenologists all over the country.

Surgery in the final analysis aims to remove a proper portion of a hyper-excited gland, but in this we are not then affecting a cure of the hypersecretion. The amount of gland to leave must be based purely upon the judgment of the operator. The X-ray on the other hand not only helps to destroy the gland, but to inhibit the function of the cells composing the glandular structure. According to Holmes and Means "These cells atrophy and disappear and are replaced by connective tissue, which later contracts and interferes with the blood supply to such an extent as to further inhibit glandular function."

Before X-ray treatment is begun, a careful physical examination by a competent internist should be made, all foci of infection looked for and corrected, if found, basal metabolism tests made, and the type of goiter determined. It is absolutely essential that the roentgenologist have the closest co-operation of the internist in the handling of these cases. The

great importance of rest, diet, proper daily regime, and co-operation of the patient must not be overlooked.

Treatments are usually administered at three week intervals, from three to five treatments being given. If a patient does not improve after three months from the time of beginning the X-ray treatment, further treatment should not be given in the light of our present knowledge. Usually three areas over the thyroid are treated, using 5MA. 6MM. of aluminum filter, 9 inch spark gap, 8 inch distance and 5 minutes time over each area.

Dr. Richardson in speaking of the Roentgen ray treatment at the Massachusetts General Hospital, under the direction of Dr. Holmes, states "X-ray therapy will accomplish the cure of a percentage of cases, in others bring about improvement. In some cases the results of treatment are as brilliant as any I have seen by any therapeutic agent."

My own experience bears out that of other workers, some cases showing splendid results and, so far as we can determine to date, permanent cures. It is only fair to state, however, that in some few instances patients have not improved. Only recently a case which had not responded satisfactorily after three treatments was advised to seek surgical relief, which she did, and so far as we can judge seems to be doing well. Many other cases have improved, though of course cases which have developed permanent myocardial damage cannot be cured either by surgery, or X-ray therapy, though they may be relieved of their symptoms.

A brief report of the following two cases may be of interest.

Case 1. Mrs. C. P., married, age 46, referred by Dr. George B. Lawson, April 31, 1922. Patient presented a typical history for the past six months of the usual classical symptoms of toxic adenomata, complicated by myocarditis. She had lost fifteen pounds of weight in that time, was exceedingly nervous, and was running a pulse rate of 120 to 140. Her metabolic readings, as reported by Dr. Lawson, were as follows: April 31, 1922, (63-56-53) average 56, July 22, 1922, (36-35-39) average 36, August 9, 1922, 30-30, January 8, 1923, 42, March 21, 1923, 35, May 21, 1923, minus 4, plus 2.

Patient was given four X-ray treatments on the following dates, April 31, 1922, June 28, 1922, September 22, 1922, and January 8,

1923. She showed definite signs of improvement after the second treatment and has steadily improved in every way. About ten days ago patient saw Dr. Lawson, and he reports that she was relieved of her symptoms, and that her progress had been entirely satisfactory.

Case 2. Miss S. H. McC., age 35, seamstress, referred by Dr. J. W. Preston, April 8, 1921. He reports that he has had patient under observation for a little over one year, during which time she has been running a pulse rate of 100 to 114, weight 114, blood pressure 140/80, temperature normal. Patient complains of nervousness, loss of sleep, trembly sensations, and general debility. The thyroid showed all three lobes to be slightly increased in size. Slight tremor of the fingers was noted, knee kicks increased, and disturbed heart action present. Tonsils were reported to be diseased and were removed July 14, 1920, though little change was noted in her general condition following tonsillectomy. Chest was negative at all examinations.

Although we were unable at this time to have basal metabolism tests made, X-ray therapy was advised, patient being given treatments on the following dates, April 8, 1921, May 7, 1921, July 2, 1921, and December 2<sup>d</sup>, 1921. She began to show marked improvement after the third treatment and continued to improve steadily. Her condition at present is good, she is relieved of all her symptoms, has gained over twenty pounds in weight, and has been able to resume her occupation as a seamstress.

The results in the above two cases have been duplicated in a number of others. Only recently a young woman, who had been under observation for over a year and was given four X-ray treatments, recovered to such an extent that she was able to get married this summer.

#### CONCLUSIONS:

Let me again emphasize that all cases of colloidal cystic, simple goiters, non-toxic adenomata, and those causing deformity and pressure symptoms, should never be treated with the X-ray, but treated with surgery when the occasion demands intervention.

Many cases of exophthalmic goiter and toxic adenomata with hyperthyroidism can be offered permanent cures, and others greatly improved by X-ray therapy. However, should improvement not be noted in three months,

further X-ray therapy should be abandoned and an operation advised.

The closest co-operation between the internist, surgeon, and roentgenologist should be maintained in handling these cases. Repeated and careful basal metabolism tests should be made before, during, and after X-ray treatment.

### SHOULD VIRGINIA HAVE A DEPARTMENT OF PSYCHIATRY?\*

By L. S. FOSTER, M. D., Williamsburg, Va.

To give an affirmative answer to the question, we must show the need of a psychiatrist from the standpoint of public welfare and mental hygiene and whether or not such a department will be a liability or an asset to the State.

We go on from day to day feeling that all is well and conditions satisfactory, because, if a person is insane and a menace to society, he or she is committed to an institution, and we overlook the fact that there are as many if not more persons of the moron type, borderland cases, who compose the large majority of delinquents and defectives dealt with in our Juvenile and Police Courts every day and who are passed on to jail, to the great detriment of the offender. We endeavor to wreak vengeance on certain persons for committing offences and in order to accomplish this we lock them up for a while behind steel bars, at much expense, but we make no effort to find out what are the actual causes of their criminal conduct and how best we can eliminate such causes and prevent future crime. We concern ourselves with the deeds of the criminal and overlook his needs. We assume that all men, except those obviously insane are equally responsible and if they commit crime, should be punished, feeling in a vague way that this will compensate for the evil acts they have committed and for the outrages they have wrought on society. Somehow, we hope this will deter them from future criminal conduct. The newer and growing conception is, that the offender rather than the offence is the thing to be studied and understood and that the treatment be regulated more by the moral and mental make-up of the offender than by the nature of the offence,

Certain causes for human failure and anti-

\*Read at the meeting of the Seaboard Medical Association of Virginia and North Carolina in Newport News, Va., December 4-6, 1923.

social conduct are readily discoverable by scientific methods. Studies have been made in courts and penal institutions in this and other countries, which show, as far as crime is concerned, that the most important element in the whole situation is the criminal himself and conditions which are found within him and within the environment which influences him. From sixty-five to seventy-five per cent of the inmates of our penal and correctional institutions show physical and mental conditions which have every thing to do with their criminal conduct. You would no doubt find, if diligent inquiry should be made, that two out of every three persons sentenced to your correctional institutions and almost every other person passing through your police court is a recidivist (a repeated offender). If this be so, then we have failed in that which we set out to accomplish in these cases, the prevention of crime; nor have we protected society from them, if they promptly return to the same criminal conduct they exhibited before their arrest. What would you think of an hospital that, after a fixed period of time, returned to the community two-thirds of its cases in no better condition than they were the day they entered the hospital?

This is a plain matter of common sense and public welfare. It is a matter of criticism of our entire system of dealing with offenders. The solution of this evil is a psychiatrist, who can carefully study each offender, as to his physical, neurological, psychiatric and social status; in other words, to find the underlying cause for his conduct, to know his constitutional make-up, his physical and mental condition, and the many and varied causes from within which have every thing to do with his criminal conduct. The most important thing we can bring to this entire problem, is the organization of diagnostic machinery for the careful study of the causes of delinquent conduct and the wise mapping out in the light of this study, of intelligent and far-reaching medical, social and educational treatment.

We believe this problem can be approached and dealt with in the same scientific spirit, with which we have attacked other human evils, such as tuberculosis, yellow fever, malaria, typhoid and other diseases. To do this most effectually, we must investigate the cause of the juvenile offender. It is of the most profound significance to our country that

crime has its roots deeply planted in childhood. We think of the greatest woes of childhood as destitution and disease, but delinquency of a degree requiring the attention of courts and officers of the peace, shadows the lives of more children than do some of the most prevalent and serious diseases and the danger of entering upon criminal careers is a more threatening one than is hunger or bodily neglect. The adult is what the child was; so, if we can control the mental, physical and moral life of a child, we can more efficiently direct its future action as an adult. This is the keynote to the program for attacking crime. Childhood is the golden period for this prevention program. In the Juvenile Court, the public school and at home will we find the criminals of the future. What we do or fail to do for these maladjusted children today, will show itself in their criminal or non-criminal conduct in later life.

The need of a psychiatrist to aid the court in recognizing the presence of feeble-mindedness, insanity and other conditions, and giving to persons so afflicted the type of care and treatment they in all justice have a right to demand, can not be doubted. The service of the psychiatrist in such cases will and should have no relation to the question of guilt or innocence of the offender. These are legal matters and are based on facts of evidence, which indicate whether or not the individual did or did not commit the offence in question. The service of the psychiatrist will be after the legal question of guilt or innocence has already been determined; then it is he can afford the court most important aid in the way of information, that will assist in determining what sort of disposition is in the best interest of public welfare and will do the most good for the offender.

The National Committee for Mental Hygiene, New York City, in 1922, made a survey of delinquency and dependency problems in St. Louis, and a part of their report shows that sixty-nine per cent of 178 prisoners studied at the workhouse, after thorough psychiatric examinations, were found to be classified in terms of deviation from average normal mental health; were handicapped by nervous and mental conditions, which are important factors in their delinquent conduct. Thirty-seven per cent was found among those diagnosed, psychopathic personality. This is

in keeping with findings in courts and penal institutions throughout the country. It is the psychopathic individual who furnishes us with our delinquent problem, the unstable, neurotic, poorly balanced individual with marked character defects and personality handicaps, but apparently with good intelligence, is the most difficult problem we have to meet in handling criminals.

Time will not permit me to go further into this phase of the subject. Suffice it to say, that every intelligent, broad-minded man and woman who has studied the subject will agree that, from the standpoint of public welfare and mental health, the State should have a psychiatrist. As to the question of liability or an asset to the State, permit me to say, that it should be remembered that expense is no excuse; we are already shouldering the burden of our failure to early recognize and prevent conditions that have caused despondency. It is not a question of whether we want to pay, that we are doing already. It is a question of whether we want to pay intelligently in treatment, social adjustment and prevention, or unintelligently in relief, financial aid and custodial care. The cost of such a department for the State will be nominal as compared to the saving in its criminal expenses; but it is the aid to the courts and the duty we owe to the offender to give him the best chance to make a useful citizen. These are matters of vital importance to every citizen of this Commonwealth. As has been said, every life is either an asset or liability to society and industry and it should be the aim of the State to aid the unfortunate defective and delinquent in every way, lest we fall short of our duty.

I doubt very much if any of you have carefully examined the State Auditor's report for the year 1922. That report shows that the total expense of the criminals in the counties and cities amounted to the sum of \$742,448.40. The astounding part of these figures is the fact that it cost the State for maintenance of prisoners in county jails, that is for board, clothing, medicine and medical attention, \$210,728.92 and for the cities the sum of \$167,552.08. Just remember this, that for the misdemeanor cases only, it cost the State \$89,171.48. You may ask, what we can do about it? I answer, in the first place, have the misdemeanor cases examined to ascertain the cause of their delinquency; you would be surprised

to know how many of them are repeaters, mentally deficient, of the moron type.

We should have a State law empowering the judges to give an indeterminate sentence, which beyond question is the most intelligent method to be employed in the sentencing of prisoners, especially the misdemeanants. The indeterminate sentence is based on the theory that, while an offender should be withdrawn from the community for a season in the interest of public safety, he is to be released when he is thought ready to become a useful citizen. This will be decided by the judge, when in possession of all the facts as to the prisoner's mental and physical condition, presented for his consideration by the psychiatrist; then if he is to be returned to the community, he should be placed under the kindly supervision of a well-trained parole officer. The period of release from the penal institution is one fraught with great danger to society as well as the prisoner himself. It is most important that he be tided over this risky period and assisted in every way to readjust himself to normal living.

The obligation of the State to fit prisoners, so far as possible, for that honest work, the lack of which brought most of them into prison seems clear. They go into the jail without a vocation, trade or calling of any kind and they go out in the same condition. The main object of the prison administration should be to fit a man to lead an honest and useful life after his discharge; otherwise, with the best intentions, finding himself incapable of earning an honest livelihood, he will, when discharged, if not supervised, almost invariably turn back to evil ways, and thus you have the recidivist. The psychiatrist can save the State much expense by locating the cause of the repeater, which is most frequently mental and, by proper treatment and management, relieve the courts of their annoying and incessant reappearance. All the misdemeanor cases and addicts should be placed where they can be made self-sustaining and treated as defectives, instead of being made to languish without employment in our jails, at great expense to the State and often in a more pitiable condition when released than when committed.

The problem of the prisoner is educational and mainly one of industrial training. In order that this industrial training shall be effective, there must not only be vocational schools, but industries into which men may be drafted

and in which they may develop their proficiency for the benefit of the State instead of being a charge and there can be no better or healthier place for them than on a farm. Those who for the past twenty years have obtained practical results in the handling of offenders and have passed the experimental stage, feel that the district farm can be made the greatest factor in the reformation of the misdemeanant.

We have in this State three prison farms, one at Occoquan, operated by the District of Columbia, one for the city of Lynchburg, and the other for Newport News. Richmond has been talking about a city farm for some years, but up to this time has done nothing more. Norfolk a few years ago purchased a large farm but has progressed no further. The Occoquan farm is a wonderful institution and doing splendid work for its prisoners. The Lynchburg City farm for the year 1922, with only 77 city prisoners and 81 State prisoners, was operated at an expense of only \$351.30 to the city. It is a very great pleasure for me to state that the city farm of Newport News, with 151 city prisoners and 56 State prisoners for ten months of this year, that is from January 1st to October 31st inclusive, with an expenditure of \$12,668.59, in which amount is included \$3,000 for improvements, had receipts of \$23,146.68, including a balance of \$2,569.18 from last year—a splendid showing. The citizens of this city have every reason to be proud of their fine farm and their industrious and intelligent manager. If we had an indeterminate sentence law, the number of prisoners sent to the farm would be at least four times as many as are now sent, with profits in proportion. If this city farm can feed her prisoners at an expense of seven cents a day, why should the State pay sixty cents for the first twenty-five prisoners, fifty cents for the next twenty-five, and twenty-five cents for all over fifty, to the county and city jails, besides denying them the sunshine, fresh air and healthy surroundings, which God intended that every man and woman should have?

Isolation, created by a distant and impersonal supervision, such as we find in most of our jails, is the greatest barrier to reformation that could be built around the first offender. His errors are often the consequence of bad environment and lack of will power and he can not be corrected by indifference and disci-

pline, but by kindness and encouragement.

These thoughts are not advocated from merely sentimental considerations, but from a sincere belief, that the ends of justice are best served by palliatives, rather than by vindictive methods. I believe in the people, but unfortunately the great mass of our citizens are not informed as to the conditions existing in some of the jails of this State. If they were, they would use every effort and every spark of humanity to alleviate the trouble. It is a blight upon our civilization and a reflection upon our intelligence to stand mute in the face of the crowded condition of some of our city jails and do nothing.

### PRESENT DAY ATTITUDE TO APPENDICITIS.\*

By CHARLES R. ROBINS, M. D., Richmond, Va.

The history of appendicitis and its treatment occupies an important position in the history of surgery. The discovery of the nature of this trouble, the debate as to whether its treatment should be medical or surgical, and the decision that it was purely a surgical condition, were more or less coincident with the development of modern surgery, and in a way was one of the active causes of the movement which resulted in the modern standardized hospital. Previous to the advent of appendectomy, the abdomen was a forbidden city; gynecology was largely a matter of pessaries and office treatment; and abdominal operations were comparatively rare and the subject of intense interest and doubtful outcome. When operation became the recognized treatment, operations began to be more frequent; technique became a matter of supreme importance and intense study, and the necessity of providing a place where proper technique could be efficiently carried out and operative care and treatment supplied called for more and better hospital accommodation.

Appendicitis soon became a vogue, both with the patient and the surgeon, and the ability of the surgeon was indexed by the number of appendectomies he had performed and the number of recoveries. As a result of this a number of discoveries were made. The most important was that the success of the operation depended on early intervention. Even the worst types of appendicitis, those with gan-

\*Read at a meeting of the Richmond Academy of Medicine and Surgery, November 27, 1923.

grene and rupture, were followed by prompt and easy recovery if the operation were undertaken early enough, and it became quite common for long series of cases to be reported without a death. Mortality was reduced to a point of often one to one-half per cent. The profession became alive to the possibilities of prompt surgery, and an abdominal pain became synonymous with a ride to the hospital at any hour of the day or night and an immediate operation. It was discovered, also, that many of the symptoms ascribed to other pathological conditions were really dependent on pathology in the appendix. Cases of indigestion, recurring nausea, pelvic disturbances and various other symptoms too numerous to mention, were found to be relieved by the removal of the appendix, and so chronic appendicitis developed its vogue also.

The safety and confidence inspired as a result of the experience in this line of surgery and the results attained, led to the invasion of other fields, and it was then discovered that there was rather more or less common pathology affecting other portions of the gastrointestinal tract, particularly the gall-bladder and duodenum, together with various kinks and ptoses. Then we had the general abdominal exploration and the development of various slogans, as for instance, "There is no such thing as indigestion," and "pain means pathology."

It is needless to say that as a result of such a wholesale onslaught, it did not take such a great while to develop a negative side; and cases began to crop up with rather disconcerting frequency which had been operated on for this, that and the other, and which had either not been benefited or had been made worse. Cases of acute appendicitis continued to have attacks of pain until they passed the gravel, and so forth.

It was then that the surgeon began to feel the need of an internist. The feeling that every one could be cured by a surgical operation began to be followed by doubts as to whether in any given case cure would certainly follow: and we are now in the stage of the complete study of the case. The pessimism that arises from failures is a very healthy thing. It should lead us to avoid errors and to approach more nearly the unattainable 100 per cent cures. The necessity for exact diagnosis so insistently demanded at the present time and the analysis of results are among

the most gratifying developments of the medicine of today; but notwithstanding this, I have noticed in the last few years what appears to be a more or less general change in the attitude toward appendicitis, and it is to several of these points that I wish to call attention now.

The general impression is that the mortality from appendicitis is very small, usually spoken of as one-half or one per cent or less. Now this is a mistake. It is an ideal which can and should be attained, but is not. If every case of acute appendicitis were operated on at the right time, in the incipiency of the attack, there would be practically no mortality. But in a delayed case, whatever the treatment followed, there is and always will be, a definite more or less large mortality. As easy and as certain as is the early operation, the delayed operation presents complications and difficulties that make them as serious as any that we are called upon to perform, and call for the exercise of the best judgment based on a thorough experience. We are, therefore, wrong if we think of appendicitis as a slight operation easily performed at any stage and followed by a certain recovery. Such results can only be attained by early and prompt intervention. I think I find, however, that the difference between the two types of early and late cases is not as clearly defined as it should be, and there is a rather apparent tendency among practitioners to reserve operation for those cases which, as they say, really need it, expecting the same favorable results when the operation is finally performed. I have observed that the number of delayed cases is apparently increasing.

It is often extremely difficult to determine the seriousness of the case in the incipiency of the attack. This is particularly true of gangrenous appendicitis. These cases not infrequently present comparatively few evidences of the serious nature of the case until the onset of peritonitis; and it happens frequently with me, and with others, that a patient apparently in very good condition and presenting few signs of a serious malady, will walk into the hospital and at operation be found to have an appendix that is gangrenous in part or throughout. Delay in such cases must inevitably result in serious complications and doubtful outcome.

The differential diagnosis between appendi-

citis and other conditions is often difficult. Infection of the kidney, stone in the kidney and ureter, strictures of the ureter and many other conditions not related to the gastrointestinal tract, will produce symptoms quite closely resembling appendicitis. In the past it often happened that a case would be operated upon, few if any evidences of appendicitis found, and the subsequent history would later reveal the true nature of the trouble. These errors of diagnosis have made the surgeon more cautious, and it is the general practice now to review every case carefully, particularly with reference to these pitfalls in diagnosis. As a consequence, cases brought to the hospital for immediate operation are often held up until the doubtful points can be eliminated.

The routine examination of the blood and urine has proved to be very helpful and, where necessary, the roentgenological examination has been used to clear the urinary tract of suspicion. Even with these aids, confusing points may still remain, and the treatment of the case must become a question of judgment. These aids can be applied without serious loss of time or hazard to the patient, but the inevitable result is that in a fair percentage the operation will be very properly postponed or found to be unnecessary or a different operation or treatment instituted.

This doubtless is sometimes embarrassing to the attending physician who may have rushed the patient to the hospital having impressed the necessity of immediate operation to save life or dire consequences. However, I think that the question of diagnosis must always be left to the surgeon who must of necessity be a diagnostician as well as operator, and the case should be referred for review as well as operation. The properly equipped hospital has means for perfecting a diagnosis that are not possible outside in their entirety, and these, added to the larger experience of the surgeon in his particular field of work, must be recognized as making his final opinion of the case paramount. However, these procedures and this delay has created an uncertainty and indefiniteness in diagnosis on the part of the attending physician and he hesitates to refer the case until his diagnosis is more complete. One of the greatest aids to diagnosis is at this point used, namely observation, which requires delay. This is quite scientific in a way but

may also prove to be dangerous. Every case of appendicitis should have the chance of an early operation, and there can be no question but that doubts are more safely cleared up in the hospital than elsewhere.

The reason for this paper lies in the fact that I have observed recently a growing disposition to react against some of the tenets previously held in reference to appendicitis and to unlearn some of the fundamental lessons that we have learned, we thought, rather thoroughly. I have been impressed with the fact that I am called on more frequently than formerly to treat serious and delayed cases; and in talking to physicians I have been impressed with a growing spirit of indifference to the dangers of appendicitis and an attempt to do the impossible, and that is to tell whether the case of appendicitis is one that should be operated upon or not.

The facts are I believe,

(1) That every diseased appendix should be removed. This does not mean that any good will come from removing an appendix that is not diseased; and our diagnosis must be complete and searching enough to fix the responsibility squarely on the appendix.

(2) That every acute case of appendicitis should be operated upon early, before grave complications develop, and the earlier the better.

(3) That the favorable results from operation refer to the early, not to the late cases. Safety is in direct ratio to the promptness with which the operation is undertaken.

(4) That it is not always possible to determine the gravity of a case in its early stages. We can never say that any patient with appendicitis is safe when the appendix is allowed to remain in. Many cases of gangrenous appendicitis have mild symptoms and obscure signs in the commencement of the attack.

(5) That in case of doubt, as at times there must inevitably be such cases, it is safer to operate than not.

(6) That these deductions form the basis on which appendicitis must be treated, if successfully, and that a departure from them will mean an inevitable increase in mortality.

*Stuart Circle Hospital.*

#### DISCUSSION.

DR. G. P. LAROCHE emphasized the importance of withholding food and cathartics from patients with any kind of abdominal pain unless accompanied with

diarrhea. In a series of 100 of his cases, there was not a single patient who had not taken a cathartic.

Twenty years ago, Ochsner stated that, whenever possible, operation should be done within the first twenty-four hours. When this was not possible, operation should be delayed. Occasionally, patients with an abscessed appendix are comparatively free of pain. On the other hand, little inflammation is found frequently in cases of much pain. Therefore, we cannot consider the clock.

In another series of 100 cases, Dr. LaRoque was able to carry patients through with morphine and plenty of water, but no food or cathartics.

DR. GARNETT NELSON does not believe that any one can foretell the condition of the appendix from the outside. If it can be proven that some other condition exists, it might be well to postpone operation; but if not, it is best to operate. He cited a gangrenous case, wherein he thought that rupture was certain. He thinks that Dr. LaRoque is in error.

DR. J. N. UPSHUR believes in the promptest operation possible. All of the trouble he has seen in this disease has been due to delayed operation. He cited the case of a boy who had all the symptoms of appendicitis, and a consultant called to see the boy was confident the diagnosis was correct, but, the symptoms having abated somewhat, operation was delayed and calomel given. The next day, the patient had improved, and has never had another attack.

Another case was that of a woman, six months' pregnant, who had had pain for two weeks, her attending physicians making a diagnosis of appendicitis. Dr. Upshur, doubting the diagnosis, ordered a purgative and an enema, whereupon there was an enormous evacuation, and the patient made an uneventful recovery. Ten days later, she had premature labor, but has never had recurrence of the pain. He thinks that in these two cases the symptoms were due to pressure of large fecal accumulations on the cecum.

DR. ST. GEO. T. GRINNAN asked Dr. Robins if he is always able to distinguish between acidosis and appendicitis in children. He has seen several cases in which diagnosis was doubtful.

DR. ROBINS, closing the discussion, stated that he had made no attempt to cover the whole subject of appendicitis. His reason for writing the paper was that many wrong ideas were apparently beginning to be held on the subject. It had been established by abundant clinical experience that prompt operation in the beginning of the attack is followed by almost universal recovery. This has removed the fear of death but it will be found that, when this principle of immediate operation is abandoned, there will be a mortality rate that is quite different. The tendency to delay is dangerous and favorable statistics cannot be secured in delayed cases. Waiting a day or two to see if the patient had not improved allows the favorable opportunity for operation to be lost. The object of the paper therefore was to impress the gravity of delay.

*Times* of December 3. *The Times* has been such a consistent friend of the regular medical profession that it seems to me it might be wise to reproduce in the *VIRGINIA MEDICAL MONTHLY* this editorial comment. The last paragraph of the editorial comment is particularly striking.

If the public could only understand that there is no such thing as "allopathic" doctors, and that the regular doctor has a perfect right to use any remedy he sees fit, we would go a long way toward establishing scientific medicine on a satisfactory basis. When, however, an overwhelming majority of both houses of our legislature, under pressure of lobbyists representing all the imaginable cults, is willing to override our State Board and put through such measures as a special bill to exempt men like De Collard from the jurisdiction of the State Medical Examining Board, and to establish a "School of Propathy," the task of trying to uphold a standard of scientific medicine is most discouraging.

Is it not time that each doctor should act upon what he or she professes to believe—that the profession of medicine is the noblest possible calling—and resent the contemptuous treatment that is heaped upon the medical profession by many politicians and business men? Elections will be coming on before long. Let each doctor interview the prospective candidate for office and find his attitude about regular medicine and public health measures. It is a strange inconsistency and a straddling of both sides of the issue when a legislator votes for a sentimental appeal for an appropriation for the crippled children's hospital on the one hand, and on the other hand supports a measure to establish some of the cults.

If the doctors themselves would take more interest in such measures, the politicians would not be so contemptuous of the work of the regular medical profession after the election is over.

Sooner or later public sentiment will be aroused by such miserable occurrences as happened in Connecticut and elsewhere, when incompetent and untrained eclectic doctors have been the cause of suffering and death. If the public press would only take the attitude of *The New York Times*, what an enormous help it would be to the people of this State!

J. SHELTON HORSLEY, M. D.

## Correspondence.

### Topics of the Times.

Richmond, Va.,  
December 6, 1923.

TO THE EDITOR:

I enclose a clipping, "Topics of the Times," from the editorial page of *The New York*

This excellent newspaper states:

HERE IS A CHANCE FOR REFORM

Connecticut's highly commendable campaign against quack doctors, and its reverberations in other States, almost warrant the hope that success might attend an immediate and earnest attempt to change the medical practice laws all through the country. And no laws need changing more. Thanks to the abysmal ignorance in medical matters which characterizes a majority in our legislative bodies, statute books show how well the quacks have been able to win confidence in the two delusions on the acceptance of which their legal right to do business must rest. The first of these is that nothing is "medical practice" except the administration of drugs, and the second is that there are and must be "schools" of medicine, each equally efficient and each entitled to bestow upon its representatives the title of doctor.

Not all who believe those two propositions are insane, and not all who uphold one or the other of them is a conscious swindler. But both are grotesquely false, and the legislators who have treated them as true are responsible for the scandals just revealed in Connecticut. They are to blame for the absurd fact that in most of the States there are several boards, each empowered to examine candidates and grant licenses.

This means that several quackish cults can send "graduates" of their so-called colleges and diploma mills before men of like mind who will turn them loose on the public to minister to the sufferers from all kinds of diseases, and in almost every instance to use in dealing with conditions widely different the single expedient—usually some form of suggestion or massage—with which alone they have been equipped.

ONLY ONE BOARD IS NEEDED

In no State should there be more than one medical examining board, and that one alone should issue licenses to practice medicine. Its members would not belong to any "school." They would be men of real medical education themselves, able to distinguish between a real medical college and a diploma mill—between a real doctor and a quack. They would know that a real doctor is one who has acquired a decent knowledge of all the many means by which disease, by himself or others, can be prevented and cured if curable. They will be ready to use suggestion or the manipulation of bones or viscera in cases demanding it—as ready as they are to administer drugs when drugs are needed or to trust wholly to diet and outdoor life in the not infrequent instances when nothing more is required or can be done with any expectation of benefit.

Not one of the men licensed by such a board would claim universal efficacy for any form of treatment. Whoever does that is instantly revealed as a quack, either ignorant or dishonest, and he is not any the less a quack because he can produce "testimonials" from grateful patients, including the familiar legislator whose close relative was saved from fast-approaching death by an "irregular" after he, or more often she, had been given up by anywhere from one to a dozen "regular" doctors.

The number of people, otherwise intelligent, who thus can be deceived and with the best of intentions can deceive others as gullible as themselves is disgracefully and humiliatingly large.

—N. Y. Times.

Why Put Higher Tax Levy on Railroads?

Warrenton, Va.,  
December 17, 1923.

TO THE EDITOR:

I am reliably informed that our Congress is trying to put a higher tax levy on the railroads. This in my opinion is a grave mistake of judgment. It is plainly unwise to further tax a utility already bearing a bit too much tax. Mr. Mellon tells us that a lowered taxation on every thing will not only meet all the requirements of the Government but leave a surplus of millions. And it is my impression that Mr. McAdoo expresses the same opinion.

The railroads are now crowded with carriers, giving us reasonable rates and quick and safe service. Why make them pay more tax when the revenue now exceeds the running expense of the Government? It would be far better to lower their taxes and through leniency induce them to put new lines in undeveloped territory, and thereby encourage increased thrift and prosperity. The increased prosperity would tend to lower, not raise, our taxes.

All physicians should be interested in this matter. They should feel it their duty to write our representatives in Congress and try to prevail upon them to vote against all bills offered to place more taxes on the railroads. The people at large should do the same.

STEPHEN HARNSBERGER, M. D.

## Proceedings of Societies

### Virginia State Board of Medical Examiners.

At the meeting of the State Board of Examiners held in Richmond, December 11-14, 1923, the following doctors were granted licenses to practice medicine in Virginia:

- Dr. W. J. C. Agnew, Washington, D. C.
- Dr. E. G. Bauersfeld, Frederick Junction, Md.
- Dr. F. J. Clements, Fork Union, Va.
- Dr. A. A. Creecy, Norfolk, Va.
- Dr. Ernest Flehme, Philadelphia, Pa.
- Dr. Geza Frank, Brooklyn, N. Y.
- Dr. Emily Gardner, Richmond, Va.
- Dr. J. M. Gaines, Alexandria, Va.
- Dr. C. E. Hawks, Brook Hill, Va.
- Dr. P. L. Hill, Gaffney, S. C.
- Dr. S. P. Hileman, Richmond, Va.

Dr. C. E. Houston, Virgilina, Va.  
 Dr. T. D. Jones, Charlottesville, Va.  
 Dr. J. W. Kirk, Philadelphia, Pa.  
 Dr. C. A. Luck, Danville, Va.  
 Dr. W. B. Meares, Jr., Richmond, Va.  
 Dr. J. J. Olinsky, Norfolk, Va.  
 Dr. R. J. Neff, Charlottesville, Va.  
 Dr. C. W. Scott, Charlottesville, Va.  
 Dr. R. G. Waterhouse, Jr., Richmond, Va.

#### **Richmond Academy of Medicine and Surgery.**

At a meeting held on November 27th, the President, Dr. J. Allison Hodges, in the chair, Dr. Mark W. Peyser, Secretary, a new constitution and by-laws was adopted to go into effect at the first meeting in December.

The name of the organization is changed to the Richmond Academy of Medicine, the offices being a presidency, two vice-presidencies and a secretary-treasurership. A Board of Trustees, composed of the five most recent past-presidents, names the secretary-treasurer and the Committee on Discussions, which is the only permanent committee, and considers all the business, bringing to the attention of the Academy only those matters it deems of sufficient importance. This will permit the Academy to devote its time to consideration of scientific matters, doing away with audiences for outside matters.

Dr. Carrington Williams read a paper on and reported a case of, *Diverticula of the Large Bowel Complicated with Carcinoma*.

Dr. Chas. R. Robins read a paper entitled *Present Day Attitude Toward Appendicitis*, which was discussed by Drs. G. P. LaRoque, Garnett Nelson, J. N. Upshur, St. Geo. T. Grinnan and Robins (see paper and discussions on page 714.)

Dr. W. H. Higgins read a paper entitled *Clinical Significance of Hunger Pains*, which was discussed by Drs. J. Shelton Horsley and Higgins.

At the meeting held on December 11th, election of officers was held and Dr. Fred M. Hodges was elected president, Drs. Arthur S. Brinkley and William H. Higgins vice-presidents. The secretary-treasurer is to be chosen by the board of directors. In accordance with the plan to divorce business from the scientific meetings, standing committees were dissolved and all business will hereafter be handled by the board of trustees. This is com-

posed of Dr. Virginius Harrison, Dr. James K. Hall, Dr. Garnett Nelson, Dr. Thos. D. Jones, and Dr. J. Allison Hodges. Upon installation of Dr. Fred Hodges as president at the January meeting, he automatically succeeds Dr. Virginius Harrison as a member of the board.

The year just completed has been one of the most successful in the history of the Academy, due largely to the hard work of the retiring president, Dr. J. A. Hodges, and the interest displayed by members.

MARK W. PEYSER, *Secretary*.

#### **The Southside Virginia Medical Association**

Held its eightieth session in Petersburg, December 11, with a splendid attendance. Many excellent papers were read and freely discussed, perhaps the most interesting being that of Dr. Guy R. Harrison, of Richmond, whose subject was "The Borderline of Medicine and Dentistry." The active interest shown by the members of the Southside in the problems of the allied profession of dentistry marks a new and very important step forward in the progress of the medical and dental professions of Southside Virginia.

The following officers were elected for 1924: President, Dr. George H. Reese, Petersburg; vice-presidents, Dr. W. E. Anderson, Farmville, Dr. R. H. Manson, McKenney, Dr. Cora Z. Corpening, Suffolk, and Dr. M. H. Tredway, Emporia; secretary-treasurer, Dr. R. L. Raiford (re-elected), Sedley. Members of the Executive Committee are Drs. E. L. Kendig, Victoria, J. E. Rawls, Suffolk, and C. S. Dodd, Petersburg; members of the Nominating Committee are Drs. J. B. Jones, Petersburg, W. C. Harmon, Dolphin, and D. C. Mayes, Church Road. Drs. D. D. Talley, Frank S. Johns, and Guy R. Harrison, Richmond, were elected to honorary membership in the Association.

The Association adjourned to meet in Suffolk, in March, 1924.

R. L. RAIFORD, *Secretary*.

#### **The Southampton County (Va.) Medical Society**

Held its annual meeting in Courtland, on the afternoon of December 14. The following officers were elected for the coming year: President, Dr. S. J. Railey, Handsom; vice-presidents, Dr. J. C. Rawls, Franklin, and Dr. J. N. Applewhite, Capron; secretary-treasurer, Dr. R. L. Raiford (re-elected), Sedley. The next meeting is to be held in April.

The Society adopted resolutions unanimously endorsing a Health Unit for Southampton County, such as is being operated in other counties of the State.

#### The Warwick County (Va.) Medical Society,

At its annual meeting on December 11, elected Dr. C. B. Courtney, Newport News, president, and Dr. A. D. Ownbey, also of Newport News, secretary-treasurer. Resolutions were passed endorsing the Lye Legislation Bill of the Medical Society of Virginia. Other County Societies are urged to do likewise and to send such resolutions or letters to Hon. E. W. Milstead, of Newport News, who will be the patron of this bill in the State Legislature.

#### The Dinwiddie County (Va.) Medical Society,

At a recent meeting, elected the following officers for the ensuing year: President, Dr. C. S. Dodd, Petersburg; vice-president, Dr. D. C. Mayes, Church Road; secretary-treasurer, Dr. William C. Powell (re-elected), Petersburg. Dr. F. J. Wright, Petersburg, was elected delegate and Dr. J. M. Harwood, also of Petersburg, alternate, to the House of Delegates for the Staunton meeting of the Medical Society of Virginia.

WILLIAM C. POWELL, *Secretary.*

## The Truth About Medicine

In addition to the articles enumerated in our letter of October 27th, the following have been accepted:

- Abbott Laboratories
- Butesin
- E. Bilhuber, Inc.,
- Afenil
- Ampules Afenil
- Cutter Laboratories
- Diphtheria Antitoxin Globulin
- Glycerinated Vaccine Virus
- Gonococcus Vaccine
- Hoffmann-LaRoche Chemical Works
- Iodostarin
- Chocolate Tablets Iodostarin-Roche,
- Chocolate Tablets Iodostarin-Roche 0.25 Gm.
- Parke, Davis and Co.
- Carbon Tetrachlorid (Human Use)—P. D. & Co.

#### NEW AND NONOFFICIAL REMEDIES.

**Butesin.**—*n-butyl-para-aminobenzoate*. Butesin is the normal butyl ester of 4-aminobenzoic acid. The actions and uses of butesin are similar to those of benzocaine (anesthesin), which is the ethyl ester of 4-aminobenzoic acid (see New and Nonofficial Remedies, 1923, p. 41, Anesthetics, Local, Difficultly, Soluble). Butesin is used as a dusting powder, either pure or diluted. It may be used in the form of troches, ointment, suppositories or dissolved in a

fatty oil. Butesin is a white, crystalline powder, odorless, tasteless, almost insoluble in water, but soluble in alcohol, chloroform, ether and in fatty oils. The Abbott Laboratories, Chicago. (Jour. A. M. A., Nov. 3, 1923, p. 1523).

**Diphtheria Antitoxin Globulin.** This product (see New and Nonofficial Remedies, 1923, p. 283), is also marketed in syringes containing 20,000 units. Cutter Laboratory, Berkeley, Calif.

**Glycerinated Vaccine Virus.** This product (see New and Nonofficial Remedies, 1923, p. 293), is also marketed in packages containing one capillary tube. Cutter Laboratory, Berkeley, Calif.

**Gonococcus Vaccine.** A gonococcus vaccine (see New and Nonofficial Remedies, 1923, p. 304), marketed in vials of 5 c.c. and 20 c.c., each cubic centimeter containing 500 million cocci. Cutter Laboratory, Berkeley, Calif. (Jour. A. M. A., Nov. 17, 1923, p. 1693).

**Afenil.**—Calcium chloride urea. A molecular compound of calcium chloride and urea. Afenil has the actions of calcium chloride. It is claimed that when afenil solutions are administered intramuscularly or intravenously, the drug is better tolerated and less irritating than calcium chloride. It is claimed that the intravenous administration of afenil is indicated in hay fever, asthma and other diseases of the respiratory tract in anaphylactic conditions, skin rashes, urticarias and as a means of preventing severe arsphenamine reactions. Afenil is marketed in ampules containing 10 c.c. of a 10 per cent. solution of afenil. E. Bilhuber, Inc., New York.

**Silver nitrate solution in capsules.** P. D. and Co. An aqueous solution of silver nitrate contained in capsules composed of beeswax with an inner lining of a hard paraffin. The solution is intended for the prophylaxis of ophthalmia neonatorum in the newborn. The solution is marketed in two forms: capsules containing 6 minims of a 1 per cent. solution, capsules containing 6 minims of a 2 per cent. solution. Parke, Davis and Co., Detroit. (Jour. A. M. A., Nov. 24, 1923, p. 1789).

#### PROPAGANDA FOR REFORM.

**The Menace of "Moonshine" Whisky.** The untoward results of overindulgence in whisky have usually been ascribed to its alcoholic content, although now and then ill-defined "by-products" of fermentation present in the distillate have been charged with a toxicity out of all proportion to the quantities ordinarily present. The indefinite "fusel oil" and furfural were often designated as the pernicious ingredients. In properly made and suitably aged whiskies, such constituents could at most play only a minor part in the intoxication produced. While alcoholism is less prevalent today than it was a few years ago, its attendant and after effects on its victims are more serious. The impression is broadcast that this is due to the "moonshine" liquor which is being distributed. The danger from the presence of methyl alcohol in "moonshine" whisky is well-known. Its presence is explained by the use of denatured alcohol (which may contain methyl alcohol) in the preparation of "moonshine" whisky. However, the investigation of the federal authorities indicates that ordinarily methyl alcohol is not the pernicious constituent of illicit whisky, but instead the product has been found often to contain a high proportion of acetaldehyd. The "ranker" the liquor, the higher the aldehyd content. (Jour. A. M. A., Nov. 10, 1923, p. 1611).

**Pregl's Solution.** It has been stated that Pregl's (isotonic) iodine solution is probably prepared by

treating a solution of sodium carbonate with finely powdered iodine. When the iodine has dissolved, sodium chlorid is added and the solution diluted to a definite volume. The product is stated to contain sodium ions, free iodine, iodid ions, hypoiodite and iodate ions—this in addition to the carbonate and chlorid. A proprietary brand of this solution is sold in Germany as "Presoid." All favorable reports of the therapeutic use of Pregl's solution have had their genesis from apparently biased sources. (Jour. A. M. A., Nov. 10, 1923, p. 1628).

*Iridinol.*—The Council on Pharmacy and Chemistry reports that about fifteen years ago "Iridium (Medicinal)" was put on the market by the Platinum Co. of America, and the same company manufactured "Iridinol" which was marketed by the P. H. Potter Chemical Co. (now P. H. Potter and Sons, Inc.), New York. Both products were, at that time, claimed to contain iridium and were marketed for a high price with grossly misleading claims for the efficacy of iridium as a therapeutic agent. Iridium (Medicinal) seems to have been abandoned, but Iridinol, advertised by P. H. Potter and Sons, Inc., as an "ethical preparation" continues to be sold. In the earliest advertising Iridinol was claimed to be a "nontoxic preparation of iridium." At that time the A. M. A. Chemical Laboratory was unable to detect the presence of iridium, and it was concluded that no very large amounts of iridium could have been present. Regardless of the presence or absence of iridium, there is not the slightest evidence for the therapeutic value of this metal in the conditions for which it is recommended by the exploiters of Iridinol. In the present advertising for Iridinol no definite claim is made for the presence of iridium. Instead, the agents merely imply its presence. Iridinol is recommended by the exploiters in anemia, rheumatism, specific blood diseases, diseases of the nose and throat, of stomach organs, liver and kidneys, of the nervous system, diseases of children and as a systemic alterative. In view of the long-continued activities of P. H. Potter and Sons, Inc., for the use of Iridinol, the Council authorized publication of a report for the information of physicians who may be importuned to use it. (Jour. A. M. A., Nov. 24, 1923, p. 1807).

*Whooping Cough Vaccine.* In a series of articles on biologic therapy prepared under the auspices of the Council on Pharmacy and Chemistry, W. C. Davison (The Journal, Jan. 22, 1921, p. 242), concluded a review of the use of pertussis bacillus vaccine thus: "In summing up the prolific and somewhat contradictory literature on this subject, it may be concluded that injections of Bordet-Gengou bacillus vaccines may have a slight though unreliable prophylactic effect, and that therapeutic inoculations are of practically no value. Further experiments are necessary to raise this procedure from the limbo of non-specific therapy." The Council on Pharmacy and Chemistry has accepted pertussis bacillus vaccine for New and Nonofficial Remedies, but states in regard to the usefulness of the product: "The evidence indicating that it is of value for either prevention or treatment is very questionable, and the reports are conflicting." (Jour. A. M. A., Nov. 24, 1923, p. 1809).

## Public Health Students to Visit Richmond Bureau of Health.

Dr. Allen W. Freeman, a former Richmonder and head of the School of Public Health Administration at Johns Hopkins University, Baltimore, has announced that a number of the students of the school of hygiene and public health will be sent to Richmond this winter to study the operations of the local bureau of health, records of this department being considered especially good.

## To Improve Quality of Carbonated Beverages.

The American Bottlers of Carbonated Beverages have established a research fellowship at Iowa State College, Ames, Iowa, to train scientific workers who may have access to a well equipped laboratory, the object being to improve the quality of carbonated beverages, commonly known as soda water. This is receiving the hearty approval and commendation of experts on food production, including U. S. Government officials engaged in advisory and regulatory work in connection with Pure Food Laws.

## Annual Report of the U. S. Public Health Service,

For the fiscal year ending June 30, 1923, covering the one hundred and twenty-fifth year of the existence of the Public Health Service, indicates that general health conditions throughout the United States have continued as satisfactory as in recent years. Also, an increasing interest in Public Health improvement has been noted. The need for new marine hospitals and the difficulty of securing medical officers for the regular corps of the Service are stressed. Twenty-five hospitals are now operated by the Service, including the National Leprosarium at Carville, La.

A novel feature of this report deals with the use of the radio for dissemination of popular health information and the stimulation of greater interest in general health matters. The U. S. Service was the first national health agency to make use of the radio for this purpose, having inaugurated this service July 13, 1921. Its actual cost has been insignificant.

## Editorial

### Diseases of Gall Bladder and Bile Ducts.

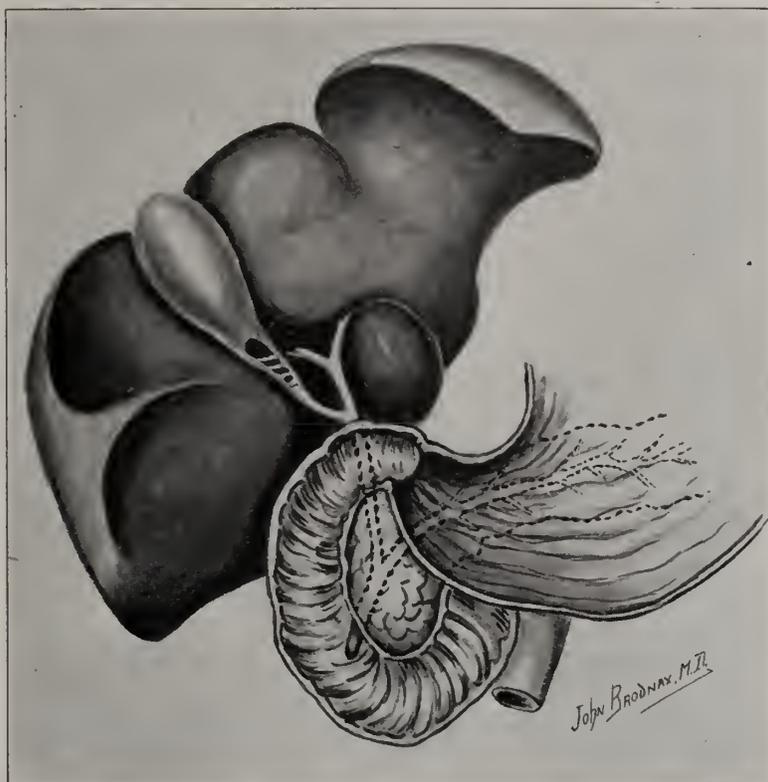

The occurrence of symptoms originating in dysfunction disease of the gall-bladder and bile ducts is very common. Much of this symptomatology has been covered, in its initial forms, by the terms "biliousness" and "torpid liver," and the like. For such conditions our forefathers in medicine prescribed massive doses of calomel and, in more recent times, "broken doses of calomel" have been widely prescribed. These disturbances of digestive processes, resulting from a dysfunction of the stomach, duodenal, biliary or pancreatic action which culminate in the state called biliousness or torpid liver, may or may not be related to the disease of the gall-bladder and biliary ducts. No doubt, liver cells receiving blood laden with food products from the portal vein and with blood from the hepatic artery, to say nothing of the lymphatic fluids, are continuously secreting bile, at a more or less normal rate, during the period of so-called torpidity. The flow of bile is probably only obstructed when ejection is to occur from the gall-bladder and common ducts into the duodenum as the acid chyme passes over the mucosa at the site of the ampulla of Vater. The more or less persistent introduction of food products into a tract which is dysfunctioning results in this "bilious" state.

Patients, who are fat and forty, with the history of years of periodic headaches, with recurrent "stomach attacks" characterized by

pain in epigastrium, gas eructations after taking food, "heart-burn," "sour stomach," probably are well along in an established pathology of the gall tract, or some other viscus in upper alimentary tube. These patients are numerous. They have many disquieting symptoms. They have mild and severe pains; they have gas eructations; "sour stomach;" nausea; loss of appetite; attacks of "biliousness;" sometimes jaundice; constipation; flatulence. The more severe grades of bile tract infection and dysfunction are characterized by chills and fever, and more active symptoms of a systemic nature. It is with a view to the brief consideration of these types of bile tract infection that our readers are asked to consider these comments.

The quantity of bile secreted daily varies from one to two pints. It is secreted continuously by the liver cells and flows through the biliary ducts to the common duct where the flow is obstructed by the sphincter. The gall-bladder is filled probably between periods of digestion. Ejection of bile into the duodenum takes place during the time of digestion. It is yellow to golden yellow in color. It is darker in color at times and sometimes is greenish. It is stimulated in quantity by any agent that causes hemolysis of the red corpuscles; it is increased in amount by bile itself; its flow is increased also by "secretion" or by the pancreatic "hormone."

Inflammation of the gall tract, including gall-bladder, cystic duct, common duct and biliary ducts, is very common, as above stated, and it is rather difficult to make a hard and fast differentiation between cholecystitis and cholangitis. Cholecystitis is usually accompanied by cholangitis. The inflammatory process in the mucosa results from the implantation and proliferation of bacteria. These microorganisms may reach the gall tract by two general routes. They may enter from the blood in such acute conditions as pyemia, septicemia, pneumococcus-emia, influenza, and from such chronic foci as tonsil and teeth infections. They may enter, also, by the alimentary route in such conditions as appendicitis, ulcerations in the intestines, typhoid fever and such like. The question whether the migrating organisms travel by the portal blood stream or by the hepatic artery is not settled; but it is probable that infection may reach the gall-

Drawing by Dr. John Brodnax, Department of Anatomy, Medical College of Virginia.

bladder and bile ducts by both avenues. Once there is an infection, there is set up a disturbance in the flow of bile, its ejection and retention in the bile ducts and gall-bladder. For many years in this infection the typhoid bacillus and colon bacillus were recognized as the most common and frequent offenders.

More recently, Rosenow's work in this connection is very interesting and should be considered as a noteworthy contribution to the etiology of cholecystitis. Rosenow has shown that the non-hemolytic streptococcus is a frequent cause of cholecystitis. Strains of this streptococcus from the tonsils appear to have a selective action for gall-bladder. The pneumococci may produce cholecystitis, seen not infrequently in pneumonitis, but sometimes without it. To these we may add the following organisms: *Streptococcus haemolyticus*, *staphylococcus*, *Bacillus influenzae*, and others. Implantations of bacteria set up forms of cholecystitis of various degrees of severity and pathology. But all forms, whether acute or chronic, have a beginning stage of more or less mildness, giving rise to quite mild disturbance of function or systemic symptoms.

*Catarrhal Cholecystitis:* In this initial gall-bladder disease one might note only microscopic leukocytic and lymphocytic changes while macroscopically the structures appear normal. But such microscopic change in the mucous membrane of gall-bladder and ducts is quite sufficient to set up disturbance in the flow of bile and in its constituents. As the mucous membrane assumes grosser pathology, the perversion of bile becomes more marked and deposition of cholesterol may be the beginning of the formation of stone. This acute non-suppurative cholecystitis causes thickening of mucosa and swelling of it, blocking the cystic duct, frequently. In acute non-suppurative cholecystitis, the onset may be sudden, entering the clinical picture as a part of a systemic disease. Such symptoms as pain, tenderness, rigidity of right rectus, are common. If obstruction occurs, the gall-bladder may be outlined by palpation. The patient usually exhibits jaundice, vomiting, rapid heart action, fever and leukocytosis.

*Suppurative Cholecystitis:* Acute suppurative cholecystitis is an advanced and progressive stage of what has just been briefly out-

lined. This type is usually associated with that degree of aggravation and chronicity as is found in gall-stones. The general symptoms are much the same, only more violent. The only treatment of this condition is surgical, unless the case is a poor surgical risk. In this case some advantage may be gotten for the patient by medical measures. One may readily recall the local clinical signs. They are much the same, while the constitutional symptoms are more marked. The facies of the patient is more significant of severe pathology; the pulse and fever increase in rate and degree; the spleen enlarges; the kidneys show signs of acute inflammation. The pancreas may, also, give evidence of associated pathology, with deep body pain, loose bowel movements, possibly with free fat. There may be glycosuria.

*Chronic Cholecystitis:* This form of gall tract infection is slow, insidious, and often is difficult to unearth—unless brought to the fore by an acute exacerbation. It is a progressive development of established catarrhal cholecystitis. In such cases the gall-bladder is often adherent to surrounding viscera and the mucous membrane is destroyed, being supplanted by cicatricial tissue, in the most aggravated forms. The infection and inflammatory processes are found to invade lymphatic system and involve the pancreas at its head. In such gall-bladder cases, the symptoms are characterized by recurrent attacks of pain. This pain of biliary colic is usually caused by the presence of gall-stones. Gall-bladder attacks of pain may occur without gall-stones, however. Adhesions and chronic changes in the gall-bladder set up a gastric syndrome in which pain is no inconsiderable feature, although other symptoms of stomach disorder are found, such as gas eructation, pyrosis, epigastric oppression, nausea, and constipation. The gastric secretory function as well as the gastric motor function are decidedly at fault in this form of gall-bladder disease. In addition one may expect associated systemic disturbances, such as multiple arthritis, neuritis, myocarditis, nephritis, and high blood pressure signs.

*Pericholecystitis:* The peritoneum covering the gall may become involved in the pathology.

Acute inflammation of peritoneum results from extension of virulent infection within the viscus. It may occur also from perforating gastric ulcer. The chronic adhesions in this region result from recurrent cholecystitis with

or without gall-stones. This condition may set up complications in the intestines by formation of a kink or constriction. The gall-bladder area of pain at the right of the spinal column, between seventh and tenth ribs, is thought to bespeak pericholecystitis with adhesions.

*Catarrhal Jaundice:* This may result from gastro-intestinal disturbances, such as occur from indigestion of food, acute poisons, acute infections, acute duodenitis. The swelling of the mucosa of duodenum, in the region of the biliary papilla, may produce some occlusion of the bile duct; jaundice results. Acute pancreatitis may also produce catarrhal jaundice by compression on common duct. This and other conditions may produce catarrhal jaundice. One would feel that all such cases are due to a microbial infection, although no specific organism has been found.

This condition is more often met with in the young. Its onset is gradual, usually following some definite gastro-intestinal disturbance. There occurs icterus in the sclera; jaundice of face, extremities and trunk follow. The temperature is moderate and the pulse is slow. There are the dry, clay-color-stools. The urine shows bile pigment. In severe forms, pancreatitis, nephritis, hepatitis may occur, with clinical evidence.

*Suppurative Cholangitis:* This is also of microbial origin. The bacillus coli, bacillus typhosus and paratyphosus, streptococcus, staphylococcus, pneumococcus are the common causes of cholangitis. One must not forget Rosenow's work on the selective action of organisms, found in chronic disease of tonsils and teeth, for the gall tract.

The gall tract, composed of the common duct, intrahepatic and cystic ducts, is affected. The gall-bladder may be and usually is involved. The ducts are dilated, their walls are infiltrated. The liver is enlarged; hepatitis exists; abscess formation may follow. Infection, traveling by lymphatics, or by continuity, may involve the duct of Wirsung and other adjacent structures. The symptoms are consonant with the pathology. Rigors, sweats, septic range of temperature, prostration, nausea, vomiting, diarrhea, jaundice, pain, enlarged liver, enlarged spleen, distended abdomen, make up a partial list of symptoms found.\*

## News Notes

### The Seaboard Medical Association of Virginia and North Carolina

Held its twenty-eighth annual meeting in Newport News, Va., December 4, 5 and 6, under the presidency of Dr. Joseph T. Buxton, of that city. The attendance was large. This with the discussion of each and every paper, and two well attended public meetings—one on Medical Education and Health Officers' Training and the other on Child Welfare—made the meeting a phenomenal success.

A resolution was passed memorializing the Legislatures of Virginia and North Carolina to be as liberal to the Departments of Health, as the funds of the respective states will permit, especially continuing venereal disease control, which is distinctly constructive work in the Health Departments of both States. A committee was appointed to co-operate with the Walter Reed Medical Society and the Medical Society of Virginia in the matter of the "Walter Reed Memorial."

Rocky Mount, N. C., was selected as the place of meeting in December, 1924, and the following officers were elected: President, Dr. William E. Warren, Williamston, N. C.; vice-presidents, Dr. James W. Hunter, Norfolk, Va., Dr. George A. Caton, New Bern, N. C., Dr. Robert A. Davis, Newport News, Va., and Dr. B. C. Willis, Rocky Mount, N. C.; secretary, Dr. Clarence Porter Jones, Newport News, Va., and treasurer, Dr. George A. Caton, New Bern, N. C., both of the latter being re-elected.

CLARENCE PORTER JONES, *Secretary*.

### The Tri-State Medical Association of the Carolinas and Virginia

Will hold its twenty-sixth annual session in Greenville, South Carolina, on Wednesday and Thursday, February 20-21, 1924. The Imperial Hotel will be headquarters of the Association. A session will be held morning and afternoon and also on the evening of the twentieth. Only forty titles may be placed on the program and the five sessions will give ample time for each paper to be read and discussed. The Association will meet in a single section.

It is hoped that the usual preliminary exercises may be entirely dispensed with and that immediately after the Association has been

called to order the reading of the pages may begin.

The physicians of Greenville have been requested not to attempt to provide entertainments of any kind. The real business of this organization is the diffusion of medical knowledge and the entire time of the meeting will be devoted to that purpose. The Association is not interested as a body in medical or other policies, but its purpose is to make better doctors of its members.

The program is being rapidly formulated and every indication points to a splendid meeting. Four or five invited guests will address the Association.

Dr. Chas. O'H. Laughinghouse, Greenville, N. C., is president; Dr. W. L. Peple, Richmond, Dr. D. A. Stanton, High Point, N. C., and Dr. S. B. Sherard, Gaffney, S. C., vice-presidents; and Dr. James K. Hall, Richmond, secretary-treasurer. Dr. L. O. Mauldin, Greenville, S. C., is chairman of the local committee of arrangements.

### Dr. William F. Drewry,

For the past twenty-five years superintendent of Central State Hospital, Petersburg, Va., and one of the best known psychiatrists in the country, has resigned his connection with the State Hospital and accepted the position of city manager of Petersburg, at a salary of \$10,000 a year. He entered upon his new duties on January 8.

It was with a feeling of regret that we first learned of the fact that Dr. Drewry was severing his connection with a work in which he has excelled. However, in his new position, he has undoubtedly entered a field in which he will have broader scope for his excellent talents and it is a pleasure to learn from him personally that he expects to maintain his interest in all things medical—and especially in this his native State. Editorials in our leading dailies have paid high tribute to Dr. Drewry and the great service he has rendered Virginia.

Petersburg is to be congratulated upon her selection of city manager and this Journal extends Dr. Drewry its best wishes for his continued success in his new work.

### The Seaboard Air Line Railway Surgeons

Held their annual meeting on board steamship Governor Cobb, en route to Cuba, December 4, Dr. H. H. Bass, Henderson, N. C., sec-

ond vice-president, presiding. At the annual banquet held on the following evening on the roof garden of Plaza Hotel, Habana, the chief surgeon, Dr. Jos. M. Burke, Petersburg, Va., presided as toastmaster. On December 8, on board the steamship Cuba, returning home, the last session of the convention was held. Special resolutions were passed on the death of Dr. R. B. Epting, Greenwood, S. C., who died February 18, 1923, shortly after his election to the presidency of the Association. Dr. Joseph M. Burke, chief surgeon, was presented a handsome 23 jewel Harvard watch and gold chain as a token of affection from the members.

Sarasota, Fla., was selected as the next place of meeting. The following officers were elected for the ensuing year: President, Dr. H. H. Bass, Henderson, N. C.; vice-presidents, Dr. Jack Halton, Sarasota, Fla., Dr. B. J. Wither- spoon, Charlotte, N. C., and Dr. T. M. McDuffee, Manatee, Fla.; member of executive council, Dr. Edward T. O'Connell, Birmingham, Ala. Dr. J. W. Palmer, Ailey, Ga., was re-elected secretary-treasurer.

#### **Dr. Turner S. Shelton**

Has been elected a member of the executive committee of the South Richmond Post, No. 187, American Legion.

#### **Members of Nottoway Red Cross Board.**

Dr. W. W. Bennett, Blackstone, and Dr. H. G. Carter, Burkeville, have been elected members of the executive committee of the Red Cross Chapter of Nottoway County, Va.

#### **Major Alfred P. Upshur, M. C.,**

Of Fort Sam Houston, Texas, spent the holidays with his parents, Dr. and Mrs. J. N. Upshur in Richmond.

#### **Dr. Charles M. Caravati,**

Of the class of '22, Medical College of Virginia, returned to Richmond, January 1, after having served as resident interne at Providence Hospital, Washington, D. C., for eighteen months. He is engaged in the general practice of medicine, with offices at 917 Park Ave.

#### **Dr. Dean B. Cole**

Announces the opening of offices in Suite 503, Medical Arts Building, Richmond, Va. His practice will be limited to diseases of the chest.

#### **Dr. M. L. Dalton,**

Formerly of Floyd, Va., but who is now living in Hinton, W. Va., has just returned from New York City, where he spent several weeks

in post-graduate work at the N. Y. Post-Graduate Medical School and Hospital.

It is interesting to note that Dr Herbert C. Chase, of the class of '10, former University College of Medicine, Richmond, Va., is director in charge of the Medical Department of this school.

#### **Dr. G. R. Faircloth,**

Williamsville, Va., is taking up special work in urology at Brady Urological Institute, Johns Hopkins Hospital, Baltimore, Md.

#### **Dr. D. M. Thomasson**

Returned to his home in Lynchburg, Va., the first of December, after taking a special course at the New York Post-Graduate Hospital.

#### **The American Congress on Internal Medicine**

Will hold its eighth annual clinical session in the amphitheatres, wards and laboratories of the various institutions concerned with medical teaching, at St. Louis, Mo., beginning Monday, February 18, 1924.

Practitioners and laboratory workers interested in the progress of scientific, clinical and research medicine are invited to take advantage of the opportunities afforded by this session.

Address inquiries to the secretary-general, Dr. Frank Smithies, 1002 North Dearborn Street, Chicago, Ill. Dr. Elsworth S. Smith, St. Louis, Mo., is president of the Congress.

#### **Officers in American Legion.**

Dr. E. C. Levy has been elected vice-commander, and Dr. J. B. Bullard a member of the executive committee of the Richmond (Va.) Post No. 1, American Legion, for the coming year.

#### **Dr. W. J. Crittenden,**

Orange, Va., is spending some time in New York.

#### **Dr. and Mrs. S. M. Yancey,**

Harrisonburg, Va., have gone to Lakeland, Fla., where they expect to spend the winter with their children.

#### **Dr. B. M. Rosebro,**

Richmond, recently visited Dr. H. B. Melvin, who has been sick at his home in Halifax, Va.

#### **Dr. R. L. Kern,**

Of this city, who has been quite ill from blood poisoning, is now much better.

#### **Married.**

Dr. George Blight Harrison, Fredericksburg, Va., and Miss Florence Kimbrough Jackson, Lynchburg, Va., December 15.

Dr. Archer A. Wilson, Oxford, N. C., and Miss Amorette E. Barker, Richmond, Va., December. Dr. Wilson was a member of the class of '23, Medical College of Virginia.

Dr. Cyrus E. Hawks and Miss Dorthy Ellen Arnold, both of Richmond, December 7. Dr. Hawks was formerly connected with Catawba Sanatorium, Va., but is now located at Pine Camp, Richmond.

**Dr. Hugh C. Henry,**

Since 1911 first assistant superintendent at Central State Hospital, Petersburg, Va., has been appointed superintendent of that institution to succeed Dr. William F. Drewry, resigned. Dr. Henry is a native of Charlotte County, Virginia, and a graduate of the Medical College of Virginia. He has been connected with the hospital since 1903 and is recognized as one of the leading alienists of the South.

**Dr. Charles M. Edwards,**

Richmond, Va., who served in the medical corps of the Army, in the World War, as director of physio-therapy at several army posts, has received an appointment as major in the Officers' Reserve Corps.

**A National Conference on Civilian Vocational Rehabilitation**

Will be held in Washington, D. C., February 4-8, 1924. Speakers of national prominence from the fields of social work, industrial management, organized labor, and officials actually in charge of rehabilitation in the States, are to address this conference.

The vocational rehabilitation of disabled civilians represents one of the outstanding accomplishments in social, educational, and labor progress of recent years. For over three years, thirty-six states, co-operating with the Federal Government, have maintained an organization for the rehabilitation of those who are vocationally handicapped from accident or disease.

**Dr. S. W. Budd,**

Richmond, has been elected president of the Virginia Kennel Club, for the ensuing year.

**Dr. R. F. Thornhill,**

Of Pulaski, recently visited his old home in Culpeper, Va.

**Dr. and Mrs. S. W. Brewer**

Have returned to their home at Singer Glen, Va., after a visit to Richmond.

**"Swat the Quack."**

In consequence of the unpleasant publicity which has recently come to some states from improper licensing of doctors, "swat the quack" crusades are being commenced. Texas and New York, it is announced, have both entered upon campaigns to weed out the fakirs and undesirables. Medical Practice Acts have been sufficiently stringent in some states, to keep out many physicians with bogus diplomas and those in other ways unfit for the high calling of medicine. However, this will be a good time for "house cleaning" everywhere.

**Dr. Robert S. Carroll,**

Medical director of Highland Hospital, Asheville, N. C., is spending a year traveling and studying in Europe and the Orient.

**Dr. R. L. Raiford,**

Sedley, Va., is spending the winter in New York City, taking a course in eye, ear, nose and throat work.

**Dr. George T. Divers**

Has recently moved into his new hospital at Stuart, Va. This hospital, which will accommodate about fifty patients, has been unmade modern in every respect.

**Dr. Florence E. Kraker,**

Philadelphia, who has just returned from a year in China where she was on the teaching staff of the Margaret Williamson Hospital, at Shanghai, has been appointed specialist in maternal hygiene in the Children's Bureau of the U. S. Department of Labor. Dr. Kraker was for sixteen years a member of the teaching staff of the maternity department of the Woman's Medical College of Philadelphia, during the latter years of her work there being professor of clinical obstetrics.

**Dr. A. R. Gray,**

Bentonville, Va., who has been quite sick for the past four months is now able to be out again.

**1922 Death Rates.**

The Department of Commerce, through compilations made by the Bureau of the Census, announces that the mortality rate for the registration area in 1922 was 11.8 per 100,000 population against 11.6 in 1921. Virginia was

one of the six States showing a lower rate for 1922 than for 1921.

In the registration area of the United States, it was shown that there was a decrease in number of deaths from tuberculosis, in deaths of mothers from childbirth or puerperal causes, and in deaths from typhoid fever. In fact, the rate for deaths from typhoid fever was the lowest ever shown for the registration area. There was an increase in the number of deaths from diabetes and cancer.

#### **Staunton Kiwanians Honor Doctors.**

The committee of tellers of the Staunton, Va., Kiwanis Club, although not required to do so by the constitution and by-laws, in the recent election of officers declared among others, the election of Dr. T. M. Parkins as poet and Dr. Guy R. Fisher as artist.

#### **Sir Auckland Geddes Resigns.**

Sir Auckland Geddes, British ambassador at Washington, has resigned his post, due to bad health, and will not return to America. As a physician and a man interested in scientific research, he has made many friends among American physicians who will regret to note his retirement.

#### **Fire at Insane Hospital in Chicago.**

On the night of December 26, fire destroyed a frame structure used for tubercular patients at the Chicago State Hospital, at Dunning, and seventeen patients were burned to death or suffocated. The financial loss was estimated to be \$100,000.

#### **The Southern Surgical Association**

Held its annual meeting at White Sulphur Springs, W. Va., the middle of December, under the presidency of Dr. James F. Mitchell, of Washington, D. C. It was decided to hold the next meeting in Charleston, S. C., December 9, 10 and 11, 1924. The following officers were elected: President, Dr. Le Grand Guerry, Columbia, S. C.; vice-presidents, Dr. J. M. Mason, Birmingham, Ala., and Dr. John T. Moore, Houston, Tex.; secretary, Dr. H. A. Royster, Raleigh, N. C., and treasurer, Dr. Urban Maes, New Orleans, La. Both of the latter held over on unexpired terms.

#### **Virginia Doctor Honored.**

We are much interested to note that, at the recent meeting of the Southern Medical Association in Washington, D. C., Dr. A. I. Dodson, of St. Elizabeth's Hospital, Richmond, received one of the three awards made for scien-

tific exhibits. It is especially notable that Dr. Dodson was the only individual to whom an award was given, the other two recipients of awards being the Department of Pathology of the Medical School of Vanderbilt University, Nashville, Tenn., and the Medical Department of the U. S. Army, through the Army Medical Museum.

Dr. Dodson is to be congratulated on his achievement, and especially in view of the fact that there were a number of scientific exhibits, many of them of a very high character.

#### **The American Association for the Study of Goiter**

Is to hold its annual meeting January 22, 24 and 25, at Bloomington, Ill., under the presidency of Dr. E. P. Sloan, of that city. Dr. J. D. Moschelle, Odd Fellows Building, Indianapolis, Ind., is secretary of the Association. Operative clinics will be held in connection with the meeting.

The primary object of this Association is to bring together each year men who will present the best that has been "thought, said and done" about goiter and its associated problems. Members of all State medical societies are invited to attend this meeting.

#### **Dr. Swanson Loses Home by Fire.**

The home of Dr. W. T. Swanson, in Pittsylvania County, Virginia, was destroyed by fire on the night of December 16, practically everything in it being lost.

#### **Dr. Frederick Gochnauer,**

Upperville, Va., was elected adjutant of the Dr. Thomas Lee Settle Camp, C. S. V., at their annual meeting held in Upperville, the last of December.

#### **Dr. Chas. J. Terrell,**

Hewlett, Va., left in December for Orlando, Fla., in which place he expects to spend several months.

#### **Dr. Wyatt S. Beazley, Jr.,**

A member of the class of '23, Medical College of Virginia, who is now one of the resident internes at St. Francis Hospital, Jersey City, N. J., spent the Christmas holidays with his parents, Dr. and Mrs. W. S. Beazley, in Richmond.

#### **Dr. Sidney L. Scott,**

Fredericksburg, Va., was recently elected president of the Kiwanis Club of that place, for the ensuing year.

**Dr. and Mrs. T. N. Davis,**

Lynchburg, Va., were among the Christmas visitors in Richmond, having come to visit Mrs. Davis' parents.

**Dr. R. W. Paul,**

Richmond, who has been taking post-graduate work in New York City, returned home for the holidays and later left for Rochester, Minn., where he will take up further work in surgery.

**Officers in American Legion at Warrenton.**

Dr. Howard Fletcher, Warrenton, has been elected vice-post commander and Dr. W. G. Trow, also of Warrenton, a member of the executive committee of the John D. Sudduth Post, American Legion, for the coming year.

**Wise County Active Against Rabies.**

As there have been an unusually large number of rabid dogs in Wise County, Virginia, this year, the board of health of that county has decided to end the "mad dog" danger in that county, by not permitting any dog to run at large in the county unless a reputable physician will certify that he has given canine vaccine to the animal. Any dog found running at large shall be killed or confined at the discretion of the county health officer; every rabid dog shall be killed, and every dog suspected of being rabid shall be killed or confined for observation, at the discretion of the health officer.

**Dr. and Mrs. Vaden L. McCullers,**

Of Locust Dale, Va., were recent visitors in Charlottesville, Va.

**Richmond Dental Society.**

At the annual meeting of this Society in December, Dr. C. Browne Pearson was elected president and Dr. John C. Tyree, secretary-treasurer, for the coming year.

**The Church Hill Medical Society,**

Richmond, Va., at their regular meeting in December, elected the following officers for the ensuing year: President, Dr. A. S. Lilly; vice-president, Dr. S. M. Cottrell; secretary-treasurer, Dr. R. S. Faris; librarian, Dr. B. L. Phillips; reporter, Dr. Ramon D. Garcin. Of these officers, Drs. Lilly, Faris and Garcin were re-elected. The Society met at the home of Dr. F. P. Fletcher. After the business session and the reading of a paper by Dr. Marshall L. Boyle on "Malnutrition in Children," supper was served those present.

**Dr. William A. Smith,**

Haywood, Va., has been named sub-chairman

to have charge of the \$3,000,000 Harding memorial campaign in Madison County, Virginia.

**Dr. Carrington Williams,**

Richmond, first vice-president of the Civitan Club of this city, has been made president, succeeding Alexander Forward, resigned.

**Dr. William T. Green, Jr.,**

A member of the class of '20, Medical College of Virginia and recently house surgeon at Bellevue Hospital, New York City, announces opening of his office at 337 New Monroe Building, Norfolk, Va. His practice will be limited to diseases of the ear, nose and throat.

**Dr. and Mrs. Powhatan Moncure,**

Bealeton, Va., are spending some time visiting a daughter at Chevy Chase, D. C.

**The Blue Slip**

In this issue of the journal should have your attention, as it means a saving to the Society, of which you are part owner. Look for it and give it your attention, won't you?

The new year starts with this issue of the journal. Let's make it a good one.

**Corrected Dates for A. M. A. Meeting.**

Since it has been found that the Republican National Convention will not be held in Chicago, the Board of Trustees of the American Medical Association has rearranged the dates for the Chicago meeting, and states that they will be June 9-13, inclusive, instead of in May, as previously announced.

**Dr. Gordon Wilson,**

Baltimore, Md., at the December 7th meeting of the Baltimore City Medical Society, was elected president of the Society for the ensuing year.

**Sir Frederick Treves,**

The celebrated English surgeon, died at Lausanne, Switzerland, December 9, at the age of 70 years.

**Income Tax Time Again.**

All of our readers are now so familiar with the "Who, When, Where, How, and What" of this tax, that all necessary should be the reminder that March 15, 1924, is the last date for filing this return and making at least a first payment. Secure your tax form from collector of internal revenue for district in which you live. You are liable to penalty for failure to make a return within the specified time.

### **The Annual Report of the Surgeon General of the U. S. Navy**

Covers the fiscal year ending June 30, 1923. The various activities of the Medical Department show that the professional work has been of a high standard and the naval hospitals are in excellent condition. At the close of the year, the strength of the medical corps was 757. Health conditions in general were better than the average, compared with figures of the preceding five years. The death rate was the lowest in the history of the Navy.

As in the past, the Medical Department of the Navy reports difficulty in securing desirable acquisitions to the commissioned personnel, as well as to the Nurse Corps and Hospital Corps.

## **Obituary**

---

### **Dr. Edgar Waples Robertson,**

One of the best known and most beloved physicians of the Eastern Shore, died at his home in Onancock, Va., December 11, after an illness of several weeks. He was born in Kingston, Md., October 2, 1845, but had lived in Onancock since a young child. Upon completion of his academic education, he studied medicine at the University of Maryland, from which he graduated in 1866, and at once took up the practice of medicine at Onancock, continuing active in his work until his illness this Fall. Dr. Robertson had endeared himself to the people in that section as only an old-time family physician can do and worked for all that pertained to the progress of his community. He was a member of the Medical Society of Virginia, a fellow of the American Medical Association, and a member and ex-president of the Accomac County Medical Society. In addition to his interest in his profession, Dr. Robertson was an active and enthusiastic member of the Baptist Church.

Surviving him are three sons, one of them being Dr. John W. Robertson, of Onancock.

### **Dr. Albert Chapman Lancaster,**

Of Martinsville, Va., for many years a prominent physician of Henry County, died in a

Roanoke hospital, December 30. He had been suffering for some time from a complication of diseases. Dr. Lancaster was born in Floyd County, Virginia, 48 years ago, and studied medicine at the University of the South, Sewanee, Tenn., from which he graduated in 1900. He practiced in Patrick County, Virginia before moving to Martinsville, and also served in the medical corps of the army in the World War. Dr. Lancaster was a member of the Medical Society of Virginia and a fellow of the American Medical Association. Interment was made in Roanoke. He is survived by a brother.

### **Dr. Frank Waters Hains,**

Formerly of Petersburg, Va., and for many years a member of the Medical Society of Virginia, died in Key West, Fla., December 30, at the age of fifty-nine years. He was on his way to Petersburg from Sebring, Fla., where he had been for his health, when he became ill and was taken to a Key West hospital where he later died. He had suffered for many years with heart trouble. Dr. Haines was a graduate in medicine from the University of Maryland in 1888 and had been a member of the Medical Society of Virginia since 1894.

### **Dr. George Torian,**

Of Brookneal, Va., died December 15, in Lynchburg, death being due to blood poisoning. He was sixty-three years of age. Dr. Torian graduated from the Medical College of Virginia in 1881 and had practiced medicine for many years in Campbell County, Virginia. He is survived by his wife and six children.

### **Dr. Fielding Lewis Ashton.**

News was received December 19 of Dr. Ashton's death in Seattle, Wash., where he had made his home for ten or twelve years and was specializing in urology. Dr. Ashton was a native of King George County, Virginia, and forty-two years of age. He studied medicine at the University College of Medicine, Richmond, from which he graduated in 1905. He is survived by his wife, formerly of Fredericksburg, Va., and two sisters.

### **Dr. Elijah Brodie Meadows,**

Of Oxford, N. C., died December 2, following a long illness. Dr. Meadows was forty-eight years of age and had studied medicine at University College of Medicine, Richmond, from which he graduated in 1901.

Thousands of physicians have found S. M. A. helpful in their problem of feeding infants deprived of breast milk, since *most infants do exceedingly well on it.*

Literature and samples to physicians on request.

## CALCREOSE

### PULMONARY TUBERCULOSIS

Tablets

Powder

Solution

In many cases cough is indispensable and is best treated by promoting expectoration. For this purpose, creosote is a reliable remedy.

—(Stevens Manual of Practice of Medicine, p. 384)

CALCREOSE (calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium, which possesses the pharmacologic activity of creosote but apparently does not cause gastro-intestinal disturbances. To secure the best results from the use of CALCREOSE it is important to give it in proper dosage. CALCREOSE may be given in the form of the solution or tablets.

### THE UNDERLYING PRINCIPLES OF SURGERY OF THE INTESTINES AND STOMACH.\*

By J. SHELTON HORSLEY, M. D., Richmond, Va.

The underlying principles of most surgical procedures depend upon physiology, and physiology occurs only in living tissue. Surgery of the intestines and the stomach should be based upon physiologic principles, though satisfactory mechanical technic is also essential. It is doubtless better for an operation to be performed bunglingly, if founded upon correct principles, than to have a skillfully executed surgical technic that ignores physiologic principles; but a combination of principles and good technic would be ideal.

The basis for the underlying principles of surgery of the intestines and stomach can be found in recent works on physiology. It is important to emphasize that the books must be recent, for even in the last few years the American and English physiologists, Cannon, Bayliss, Starling, Carlson, Luckhardt, Dragstedt, Alvarez and others have revised many of our former ideas about the function of the stomach and intestines. These new views concerning peristalsis and secretion have an important bearing on surgery of the gastro-intestinal tract.

In surgery of the bowel, after removing or correcting the pathology, efforts should be made to restore function, and there must be a knowledge of the function in order to restore it satisfactorily. Because a certain surgical technic may be successful in the upper intestinal tract, it does not by any means follow that it will be equally useful in the lower ileum or the colon.

The two most important factors in the function of the intestinal tract which affect surgical operation in the upper and in the lower bowel are peristalsis and the bacterial content. Alvarez has called attention to what he

terms the "gradient" theory of peristalsis, and claims that, in general, peristalsis is more rapid in the upper part of the jejunum, and decreases in rapidity down to the cecum. He says the upper part of the small intestine is named jejunum because it is "hungry" or empty, as it quickly transmits its contents to the ileum. The absorption of products from the upper portion of the intestine when obstructed is for some reason very much more serious than the absorption of products of obstruction lower down. Various theories attempt to explain this difference, but the clinical and experimental fact of the rapidity in the fatal course of obstruction in the upper small intestine as compared with obstruction in the lower bowel is accepted by every one. Dragstedt, of the University of Chicago, has shown that if in a dog the upper jejunum is divided and brought into the incision in the abdominal wall, the animal will die from obstruction due to the slight pressure of the margins of the abdominal incision; though if the lower ileum or colon is similarly treated the animal will survive. If a tube is placed in the severed jejunum to prevent the open intestine being compressed by the abdominal wall, the animal does not die from obstruction. He has demonstrated that pressure by a delicate rubber band which would prove fatal in the upper jejunum, would be successfully overcome in the lower ileum or colon. In view of the rapid peristaltic action of the upper small intestine these findings seem paradoxical. The rapid peristalsis, however, seems to have comparatively little force, and a slight obstruction that cannot be overcome quickly deranges the vital mechanism of the upper small intestine.

The clinical deductions to be made from this are, first, that it is exceedingly important in resections of the upper jejunum to provide an ample lumen at the sutured union. In an end-to-end anastomosis, but little diaphragm must be turned in, and if a continuous mattress suture is used the stitches should be merely snugly approximated and not drawn together.

\*Read before the fifty-fourth annual meeting of the Medical Society of Virginia, in Roanoke, Va., October 16-19, 1923.

too tightly. A backstitch should be taken at frequent intervals. Preferably only one row of sutures should be used. After the anastomosis is completed the bowel on each side of the union should be invaginated with the finger and thumb to demonstrate whether the lumen at the site of the union is ample. If there is any doubt about this, or particularly if the intestine is dilated from obstruction, an enterostomy should be done. If the anastomotic opening seems too small the suturing must be revised.

In performing an enterostomy anywhere in the small intestine, it is not necessary to use a large tube. The contents are liquid and gas, so a soft rubber catheter, about a No. 14, with one or two additional perforations, is all that is necessary. Elsewhere (*Operative Surgery*, C. V. Mosby Co., St. Louis, 1921, pp. 592-597, and *Clinics and Collected Papers of St. Elizabeth's Hospital*, C. V. Mosby Co., St. Louis, 1922, pp. 227-230), I have described a technic based upon the principle of Coffey, in which an incision is made down to the mucosa of the bowel for a distance of about two inches. The mucosa is perforated at one end of the incision and a catheter is introduced through the perforation and fastened by a pursestring suture, which also transfixes the catheter. The catheter is laid on the exposed mucosa and buried with a continuous suture. The mucosa acts as a valve so that when the enterostomy is to be discontinued the tube can be withdrawn, and usually there is no discharge of fecal matter after the catheter has been removed. In this way but few adhesions are left, rest for the sutured bowel is provided during the period of healing of the anastomosis, and, particularly in the upper part of the intestine, any tendency toward obstruction with its serious consequences is eliminated. In surgery of the large intestine where an accumulation of gas may tend to stretch the sutures, where the bacterial content is high, and healing may be poor, the rest given by this enterostomy aids greatly.

In surgery of the upper jejunum and of the duodenum the intestinal contents have very few bacteria, and extreme precautions for preventing contamination with bowel contents are not essential, though it is always wise to be as careful as possible to prevent infection. The importance of clamping and tying all raw surfaces before opening the lumen of the

bowel, and particularly of closing the triangular area at the mesenteric border of the small intestine, has been fully emphasized in previous communications. In the upper small intestine, however, it is even more important to provide an ample lumen.

In chronic obstruction of the terminal duodenum, caused by a kink or stenosis where the duodenum becomes the jejunum in the transverse mesocolon, the symptoms frequently resemble those of ulcer or particularly of ulcer with stenosis. In such an obstruction, the duodenum is always dilated. The proper regulation of diet can frequently mitigate this condition, and in mild cases may be practically curative. When the obstruction is persistent however, it should be relieved by surgical procedures. As the duodenum is greatly dilated it can be easily anastomosed by the lateral method to the upper jejunum. I have done this procedure five times without mortality, and with complete relief in the majority of instances.

It has been well established by Cannon, Blake and others that lateral anastomosis is unwise if an end-to-end union can be done. A lateral anastomosis frequently leaves blind pockets which may cause trouble later, and the destruction of the function of circular fibers by the incision for a lateral anastomosis is a very serious objection. However, in certain instances, when the lumen of the intestine is small and the mesentery is fat, it is impracticable to do an end-to-end union, and a lateral anastomosis is indicated.

In the lower part of the small intestines, conditions are quite different. The bacterial content increases, and the activity of the peristalsis is diminished. Fatality from obstruction is delayed in this region and, if there is time for the swelling or congestion to subside, a narrow anastomotic lumen is more consistent with recovery than in the upper intestinal tract. One of the main operative considerations here is the avoidance of fecal contamination. In resection of the lower ileum and the colon, it was formerly my practice to use practically the same technic as was employed in the upper small intestine. About six months ago, however, I lost from infection a patient in whom I had done a resection of the lower ileum, cecum and ascending colon for cancer. The technic was carried out by closing all raw surfaces before opening the

bowel, and by severing the bowel from the mesentery outward. The lumen of the bowel was then disinfected as well as possible with moist bichloride sponges. This is the weak part of the technic, when bacterial contents are great as in this region. It is not possible to disinfect the mucosa of the colon and lower ileum by gentle cleaning with bichloride sponges. Stronger antiseptics will of course injure the delicate mucosa. With the bichloride sponging bacterial virulence can be lessened, but not sufficiently to make the procedure

entirely safe. Though I have had a series of ten successful resections of the cecum and ascending colon with this same technic, I cast about for a method of avoiding contamination in such operations.

The problem was quite different from that in the upper small intestine. It is not necessary to establish a wide lumen or to do such accurate suturing, but it is essential to avoid contamination and to provide as far as possible rest for the intestine while healing. The article of Dr. H. H. Kerr, of Washington,

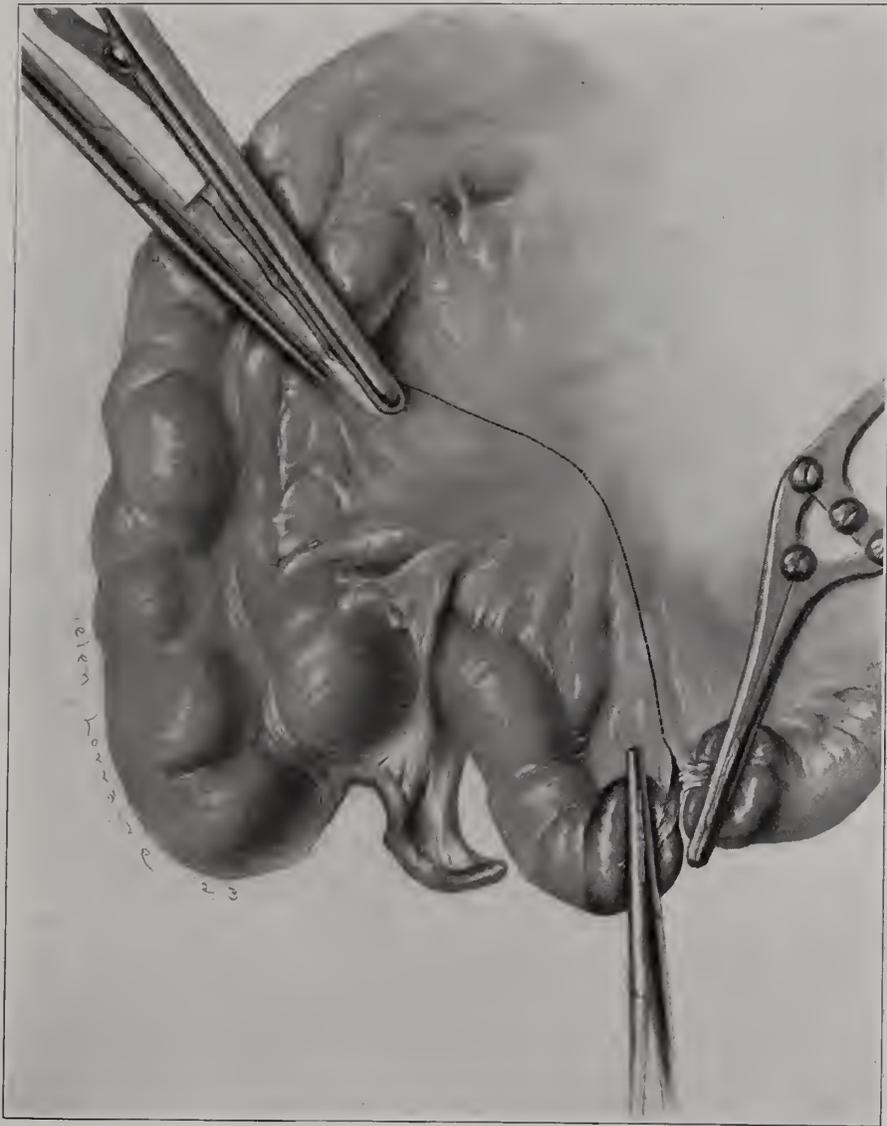

Fig. 1.—Drawing shows the resection of the terminal ileum, cecum and part of the ascending colon, according to the technic of Kerr. The black line in the mesentery is point of section. The mesentery along this line should be divided, clamped and tied before the bowel is opened. Note that the clamp on the small bowel is placed at right angles to the mesentery, and on the large bowel parallel to it. The ileum has been divided and cauterized with the electric cautery; the colon is about to be cauterized.

D. C., "Intestinal Surgery," *Journal A. M. A.*, August 25, 1923, pp. 641-647), which was read before the Section on General and Abdominal Surgery of the American Medical Association in June, 1923, seemed to have solved this problem. The technic suggested by Kerr consists essentially of first dividing the mesentery, closing of the raw surfaces, and ligating the blood vessels. Then after packing off the rest of the intestines, the bowel is clamped at the point of proposed resection with two stout clamps placed closely together.

ried over the clamp and a right-angle suture is taken close to the clamp, preferably not entering the lumen of the bowel. This right-angle suture is continued, taking a bite first on one side of the clamp and then on the other. At the end the suture is finished similarly to the way in which it was begun by a bite in the longitudinal axis of the bowel. (Fig. 2). The two ends of this suture, which is a basting stitch, are seized with hemostats and pulled upon as the clamp is gradually released. In this way the charred end of the bowel is automatically infolded. Hemostats grasp the basting stitch close to the bowel. The other end is treated in a similar manner and the two ends of the bowel are brought together while making traction on the ends of the basting stitch. The bowel is sutured

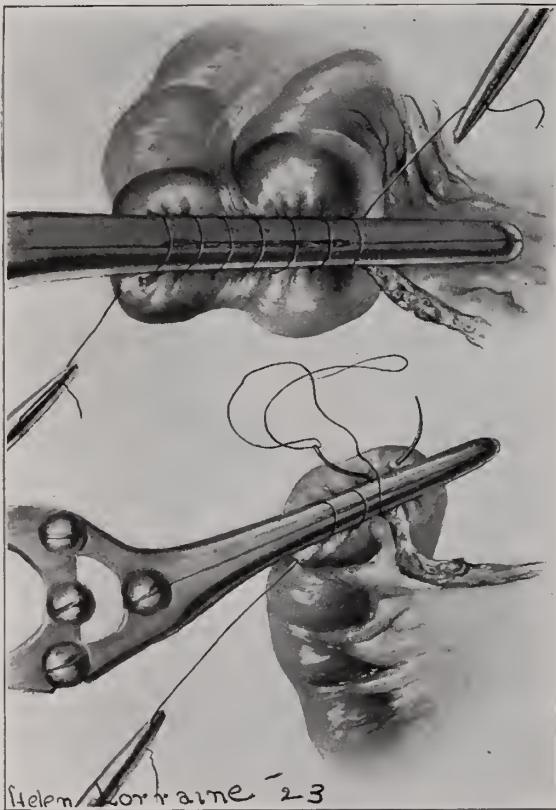

Fig. 2—Both ends of the loop to be resected have been divided, and the basting stitch has been applied on the colon and is being inserted on the ileum. After this is applied the clamps are gradually loosened and removed while the ends of the basting suture are being pulled on in the axis of the blades of the clamp. This automatically inverts the charred stump.

It is divided with the cautery, and the healthy end of the bowel is cauterized down to the clamp as in the clamp and cautery operation for hemorrhoids. Both ends of the loop to be resected are treated in a similar manner (Fig. 1). A basting suture of catgut in a round needle is begun. The first stitch is taken parallel with the axis of the bowel at one side of the clamped bowel. It is then car-

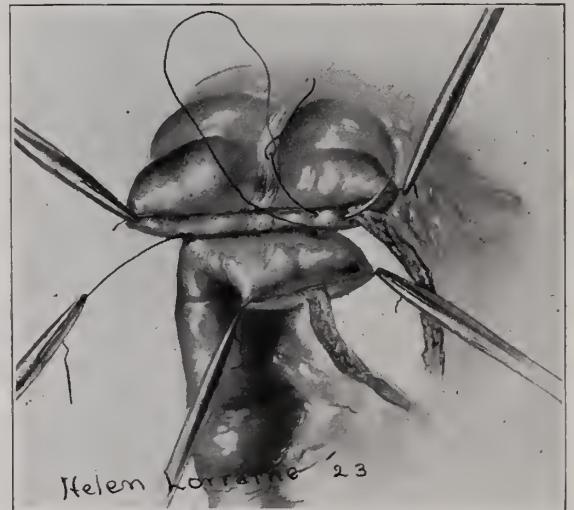

Fig. 3—The ends of the bowel are brought together, keeping traction on the basting stitch. The ileum is fastened to the colon with a continuous suture of linen or silk. This is applied in such a manner as to have a redundancy of about an inch of the ileum in order to produce a slight intussusception and so simulate an ileocecal valve.

bringing the posterior surfaces together with a continuous mattress suture of silk or linen taken close to the basting stitch and using a backstitch at frequent intervals (Fig. 3). The wall of the bowel is snugly approximated, and the suture is terminated by tying it to the end left where the first knot in the suture was tied (Fig. 4). In the large bowel it is well to reinforce this by interrupted mattress sutures of fine tanned catgut. The basting suture is then withdrawn, and the lumen of the bowel is fully established by invaginating the bowel on both sides of the anastomosis with the finger and thumb.

Fig. 4—The suture has been completed, and one basting stitch is being withdrawn, after which the other will be withdrawn. Note that the mesentery of the ileum is not apposed to the mesentery of the colon.

The disadvantage of this operation is that considerable diaphragm is turned in. This would make its use in the upper small intestine, where the bacterial content is low and where the bowel is peculiarly sensitive to even a slight obstruction, rather unwise. In the lower small intestine and in all the colon, however, this objection does not hold, particularly if a catheter enterostomy is done at the time of the resection. Additional advantages are that the diaphragm does not bleed, because it is both crushed by a clamp and sterilized by the cautery, and that no raw surface is left free to absorb the septic material so abundant in the ileum and colon. Methods which involve turning in the raw margin of the bowel of necessity expose to the septic fecal contents this cut surface, which may be capable of immediate absorption of infection. With clamping and cauterization, however, the healing doubtless occurs in the same manner as with the clamp and cautery in a hemorrhoidal operation, the eschar protecting the raw surface until granulations are formed which are competent to resist infection.

There are numerous slight modifications of this technic established by Kerr which would be applicable under varying conditions. For instance, in clamping the resected bowel it is best to place the clamp on one end so that it is not entirely parallel with the mesentery. (Figs. 1 and 4). In this way the mesenteric borders are not approximated, so that the raw surface of the mesentery on one side is apposed by the peritoneum of the bowel on the other. It is well known that it is only necessary to

have peritoneum on one side in order to obtain satisfactory union, but it is essential to have peritoneum on one side. Consequently, when the mesenteric borders are accurately apposed, the lack of peritoneum on either side may delay union.

After the anastomosis has been completed, the mesentery is united with a continuous suture of catgut.

Usually an enterostomy along the lines already mentioned is made in the oral end of the bowel about four or five inches from the anastomosis. By using this technic, contamination is practically prevented, especially if the bowel at the site of the enterostomy has been stripped and then clamped with intestinal forceps. The catheter should first be introduced through a stab wound in the abdominal wall, and its outer end clamped in order to prevent fecal matter flowing through the catheter before the tube has been fixed in position.

Since September 1, 1923, I have done two resections of the large bowel with this technic, one for cancer around the ileocecal valve, in which the terminal ileum, cecum and ascending colon were excised. In the other there was a rather advanced cancer of the transverse colon with enlarged lymph nodes, which were probably mostly inflammatory. However, an extensive resection was done, leaving only the sigmoid and cecum and a small stump of the ascending colon (Fig. 5). Both patients have made a satisfactory recovery, though in the latter case much of the gastropiploic artery was excised and this interfered sufficiently with the nutrition of the stomach to cause some gastric symptoms. The patient is now doing well.

In surgery of the stomach I have elsewhere called attention to the underlying principles that should govern operations in this region. No one surgical procedure can be made to fit all conditions that may demand operations on the stomach or duodenum. In extensive infiltrating ulcer of the duodenum the most satisfactory procedure is to occlude the pylorus by the simple method of ligating it with a large kangaroo tendon, and then a posterior gastroenterostomy should be done. It is probably better not to use clamps in a gastroenterostomy, and to employ absorbable sutures, though with occlusion of the pylorus, nonabsorbable sutures would doubtless give no trouble. In

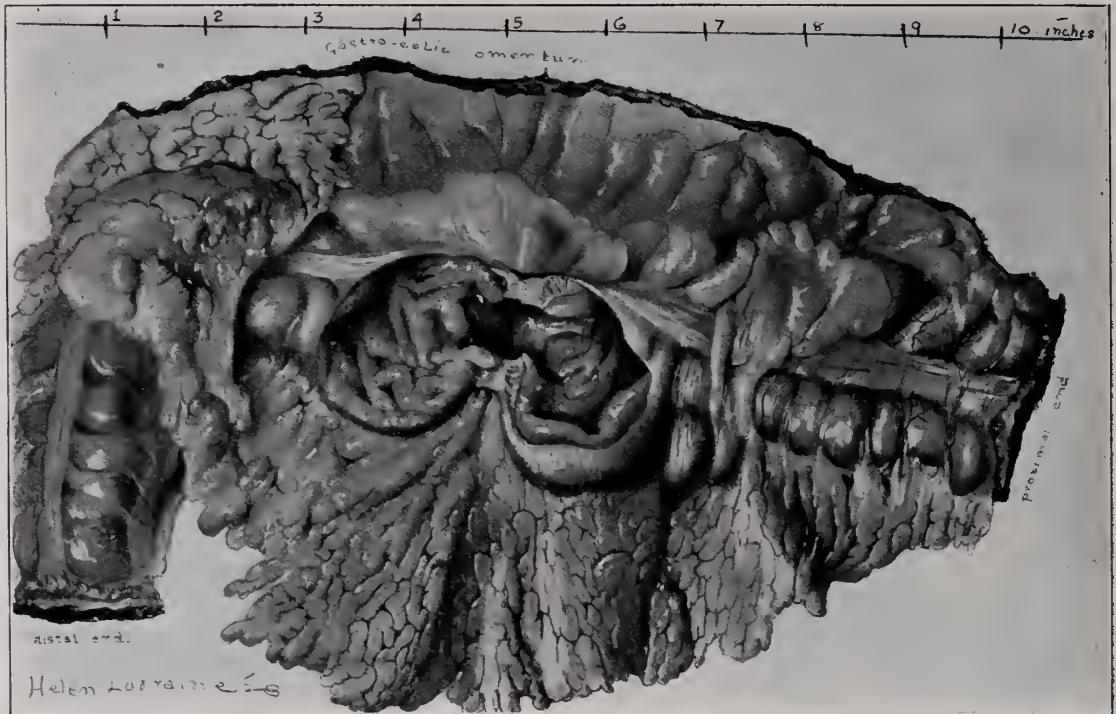

Fig. 5—Drawing of specimen removed according to the technic of Kerr. It consists of most of the ascending colon, the transverse colon, and the descending colon. The specimen is opened from behind. There is a cancer which has produced marked constriction and has everted edges. The specimen contains all of the great omentum and most of the gastrocolic omentum which was removed very close to the stomach. An enterostomy according to the technic described was done in the lower ileum. The patient made a satisfactory recovery.

four cases that I have had, gastro-enterostomy with occlusion of the pylorus was done, following unsuccessful results after pyloroplasty. It seems that occlusion in this simple manner in the presence of adhesions or an ulcer is much more satisfactory than would be such an occlusion performed in normal tissues. It is well known that when a ligature is placed on the normal pyloric end of the normal stomach it eventually cuts through and the lumen is soon re-established. This is the tendency also when there is pathology in this region, but with a large infiltrating ulcer or extensive adhesions the occlusion is more efficient.

When the ulcer is on the stomach side of the pylorus and is large, a resection should be done. If it can be satisfactorily accomplished without too much tension, the Billroth I method, uniting the duodenum to the lesser curvature of the stomach instead of to the greater curvature, is a satisfactory procedure. Where a more extensive operation is necessary, the Polya-Balfour anterior method, joining a loop of jejunum to the stump of the stomach

after a pylorotomy, gives satisfactory results. A small ulcer in the stomach may be resected locally, taking care to excise no more tissue than necessary, and uniting the wound in three layers with absorbable sutures so as to avoid turning in a great amount of tissue. The only inversion of the peritoneum is in the last row of sutures. The first is merely an approximation of the mucosa, the second uniting the incised muscular and peritoneal coat edge-to-edge, and the third row inverting the second row. It is wise to prevent contamination, but if the tissues are well packed off, the spilling of a small amount of gastric contents is not a matter of great concern.

When the ulcer in the duodenum is well circumscribed or if there is a narrow band of constriction or when a gastric ulcer is excised at any point, the pyloroplasty which I have described elsewhere is a very satisfactory procedure. In a paper published in the *Journal of the American Medical Association*, September 15, 1923, I reported the late results of fifty-six such pyloroplasties. There were three deaths following operation, all of which oc-

curred in the first twelve cases, and were due to errors that now can be avoided. In the last forty-four consecutive cases there was satisfactory operative recovery and no subsequent deaths. Of these cases thirty-two are complaint-free, and fourteen were improved. Two could not be traced, though they were complaint-free when last heard from, a few months after operation. Five were unimproved, and were subsequently operated upon again, in one case a pylorotomy being done, and in four a gastro-enterostomy. They are now complaint-free so far as gastric symptoms are concerned. All of the unimproved patients and many of those who are slightly improved were in the earlier series of cases, so that not only has there been no fatality in the last forty-four cases of this series, but there has been a much smaller proportion of unsatisfactory results in the last two-thirds of the series than in the first third.

In conclusion, I wish to emphasize that while it is a fundamental essential to understand the technic of the application of intestinal sutures, it is no less important to view surgery of the gastro-intestinal tract from the standpoint of physiologic function, and to make the operative technic in any particular region conform to these principles.

### THE REHABILITATION OF YOUNG WOMEN.\*

By TOM A. WILLIAMS, M. B., C. M., Washington, D. C.

As applied to soldiers, rehabilitation is a familiar word. Many look upon it as a novelty of the war and attribute the need for it to army life. Long before the war, however, one of the chief functions of neurologists was the rehabilitation of ill-adjusted persons. The majority of these were women labeled hysterical, so much so, that at one time that disorder was looked upon as exclusively feminine. Mobilization of an army having focused attention upon disadapted men long enough, it seems timely to bring into the limelight once more the fact that the emancipation of women has not absolved them altogether from former weaknesses which, after all, are merely human. It will be instructive, therefore, to consider some kinds of situations in which young women sometimes fail in adaptation and the kind of measures to be adopted for their rehabilitation.

Environmental mal-adjustments show curious expression at times. For instance, it would not be suspected at first that an alimentary disturbance so extreme as the invariable vomiting of food could be attributable to an ethical viewpoint, yet so it frequently is. For nausea is not only an expression of distaste of food but of moral disgust as well.

In one young woman who had been long treated vainly by gastroenterologists, proper psychological exploration showed that she vomited not because food was disgusting in itself but that it reminded her of an episode which made her mouth loathsome. This was having allowed herself in a weak moment to be kissed by a man of evil repute. The uncovering of this incident and its resetting into its proper proportions and relationships caused the association of the incident with the taking of food to cease besides rehabilitating the girl in other respects.

In another patient the mere acquaintance with those of a freer morality than the very narrow one in which she had been brought up led to a disgust of life so great as to lead to hysterical attacks in the office where she worked. In addition to this a severe resentment dominated the girl's relations with others. It took a considerable time to give this patient a proper prospective in these matters and enable her to carry on with any comfort, so deeply rooted were her misconceptions.

In this patient a part was also played by the acute disappointment of a dawning affection unreciprocated by a young man whose alert mind had captivated her slower and more modest intelligence. Very much of a Lothario however, his want of seriousness was quickly found out, to her acute disappointment, even before she had realized under my guidance the depth of her affection.

Situations of this kind, which are very frequent, are among the hardest to adjust in the early stages but, as everyone knows, time works wonders, especially if new impressions of like kind are furnished. When these are lacking the rehabilitation is often tedious.

In one young woman the physical attraction was very intense, although she was fully aware of the unworthiness of its object as a possible husband. The struggle of motives caused great anxiety in a girl already over impressionable to outside opinion, as was shown by a previous laryngeal cramp which prevented her singing

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

solos. The love situation not only exhausted her, but the fruit of this was a most obstinate Scrivener's palsy which it took me six months to get rid of. Complications of a physical nature and the method of dealing with the patient were set forth at length in a monograph on "Writer's and other Occupational Cramps" (*Jour. de Neurol. and Psychol.* Leipsic, 1912.) The case itself was also published in *N. Y. Medical Journal* under the title "Multiple Professional Cramp in a Psychasthenic."

In another instance attacks of apparent unconsciousness were traced to a conflict between a love for the family and the desire for freedom of choice where her affections were concerned. In this case physical fatigue was a factor also, and had to be counteracted long after the psychogenetic situation had been dealt with.

#### DEEPSEATEDNESS OF CAUSES.

Dissatisfactions are often deeply hidden, and are scarcely explicit to the patient until she is led to delve into her own motives in an honest fashion. There is so often a mistaken attempt to conceal from herself what looks like a disloyalty to the family or early traditions, which often conflict with the changed circumstances in which the patient finds herself. The reconciliation can, however, be effected by the patient if she is given to understand the proper philosophy. Very often the traditional ethics has been misconceived in too literal a manner, and the conflict disappears upon a proper analysis. Sometimes, however, there is a real conflict between the true aspiration of the patient and the conservative motives of elders between whom an antagonism has arisen which is irreconcilable without extraneous explanation. It is the duty of the psychiatrist to shed this light on these situations. It is usually more difficult to deal with the friends than the patient herself, when these former are obstructing the patient's proper function. But even that can be done when they are convinced of the wisdom and sincerity of the physician for they are often willing to suspend their own judgments in his favour. The result quickly justifies the psychiatrist, and he has then no more loyal supporters than his former antagonists. A case in point is the following:

*Awkwardness and shame, paralyzing initiative in work and society, due to environment repression.*—A woman, aged 26, was referred by a physician who had unsuccessfully treated

her several months. She was very reticent, disclosing her complete story with much difficulty and trepidation. She was eating her heart out in routine work in which she was neither using her college education nor satisfying her craving for contact with other human beings. Nor did her leisure afford her the kind of companionship she longed for. She did not know how to reach away from the safe monotony of a sheltered life into the adventurous variety of the constructive idealism which she worshipped. She was immensely handicapped by a lack of ease of manner and charm, which she envied in others: she was ashamed of her awkwardness.

This situation might only too readily have been attributed to the humiliation she felt at the intense and facile stimulability of her physical sexuality, and a prolonged analytic search might have proved too strong a temptation to those psychopathologists who can think only conventionally.

But as insistent as were the physical discomforts of the patient, I considered that the psychological problem was even more important and that to slough this, a change of environment was imperative. It should not need to be said that explanations as to the significance of reproductive physiology were given, and that these were of great comfort to the patient. Although they scarcely affected the phenomena themselves, they altered many of the psychologic consequences. The patient was assisted to take steps to prepare for an occupation which would favor human contact in constructive work, in which she is now, a year and a half later, happily engaged without supervision.

Thus, even when the aspect of the case is highly sexual, and when physical ebullitions are perhaps the most painful of the discordant elements of a scarcely tolerable situation, yet they may not be the main factor of the maladjustment at all, for adjustment may be effected without any success in mitigating these difficulties. The real issue may be a psychosocial one, and affective satisfaction is then (see some neglected *Psychopathic Factors*, J. A., M. A., 1922) gained by the provision of opportunity for the kind of intellectual activity craved.

The contrary was the family attitude in the notorious Bowles case about which I was consulted on one occasion. This girl at thirteen had eloped with a lad not much older but was

arrested before reaching Baltimore. Placed in a House of Detention, she escaped again, only to be reincarcerated swearing that she would never submit to imprisonment, so she jumped from a third story window, breaking both legs. Before the second arrest the father had been advised by me how to proceed, but he obstinately refused to deviate from his oppressive methods, hence the tragic result.

This case may be contrasted with a very similar one where the adopted father was an intelligent physician and himself brought his girl of fifteen and a half to me. The situation was really much more difficult than the former, for the girl was antagonistic at first, and later admitted a sexual impulsion so strong that she would lock herself in her room for days in order to safeguard herself. Here the family cooperated in freeing the patient and helping her through her difficulties, so that in six months she was happily married.

#### TEMPORARY MODIFICATION OF SURROUNDINGS.

Sometimes the emotive habit is so firmly fixed that a special environment is required for a time to recondition it. As for instance where intense dread of a stormy father paralyzed the initiative of a child whose mother was unduly solicitous, so that, never able to attend school regularly, she eventually took to bed full of hysterical fancies and terrified at a late budding sexuality. After the discovery of the mechanism, which this girl's reticence made very difficult, the special environment was not in this case provided, so that the rehabilitation has not yet taken place in this instance.

However, in another patient it was two years before the essential measure recommended was adopted. This was a young married woman, the victim of intense terror which was traced to a fear of assault which she feared she might really desire. (See *Jour. Abnor. Psy.*, 1911, for full account of the case.) The disclosure of the mechanism produced no improvement in this patient, and she only recovered when the fostering of distrust of herself by an aunt who lived with her, was removed only two years after the reconditioning.

Deformations of character are sometimes very strongly fixed and retraining may be required. This is especially so concerning motor habits which have necessarily to be considerably automatized. In the case of speech for example, stammering is very often traceable to

undue stressing at school or at home in a child whose psychomotor processes are naturally slow, or are retarded in development. The anxiety created by fussy supervision and correction further impedes this smooth co-ordination of the complex speech co-ordination. Once the stammer becomes established, fear of it increases the difficulty. The greater the concentration and determination of the patient, the more likely she is to stammer unless her efforts are directed intelligently which is not often unless she receives some sound information and guidance. The most helpful preliminary to this is a careful analysis of the situation along with a penetrating neurologist.

The same is true of the various tics, the expression of dissatisfaction or uneasiness usually of psychological nature. Space forbids further mention than a reference to an extended presentation in the *J. A. M. A.*, 1922.

However, even though the tic may not in itself be felt as an incumbrance by the patient, yet it is an indication of the need for rehabilitation through an attack upon its sources, of which many of the products may be latent, but are likely to lead to inconvenient mal-adjustments unless dealt with.

#### PECULIARITIES AS INDICATORS OF NEED FOR HELP.

Eccentricity, mendacity, kleptomania, undue immersion in pleasure, work or religious exercises are all indicators of the need for rehabilitation. The principles underlying these aberrations do not differ from those already indicated. They are only the more striking and dramatic manifestations of states that more often show themselves as timidity, undue reticence, unsociability, lack of enterprise, or in quarrelsomeness, despondency, or a pessimistic view of life. All of these are indicators of need of adjustment to life, which is most quickly, completely and economically effected by the medium of the psychiatrist of sound training and judgment.

For instance, a girl, aged 16, athletic and of exuberant nature, was brought to me by a physician relative who looked upon her as in some way different from other girls. He described her as being unreceptive to the exhortations of her mother as regards behaviour, unequal in her collegiate studies and temperamental in her affiliations.

I found a strongly built girl with active cir-

culcation, exuberant mentality and facile affectivity. She was exceedingly frank but could not quite analyze the particular difficulty she felt the most, viz., an inability to abstract and generalize to the satisfaction of her teacher of literature. Although her memory for detail was very good, she thought she lacked the power to grasp what were looked upon as the essentials by others. She was unable to give an example of this, however, so the issue could not be decided out of hand. But I set forth how very frequently the same literary work may receive very different appraisement at the hands of various critics, and what is significant in literature depends upon the aspect selected. I analyzed a paragraph to illustrate how different persons would vary in their estimation of the various facts contained therein. I prescribed the daily practice of abstracting a historical work, such as Gibbon or Motley, and asked her to send me some examples of the kind of faults to which she felt herself prone.

But there were other difficulties in this girl's life induced by a strong motive to do right and the conflict between a spontaneity of expression which seemed to her harmless and the inculcations of her elders towards repression of this. By nature a tomboy, she was constantly urged to be ladylike, frowned upon and nagged so that she often wept at her own short comings. And yet underneath it all she felt urged to activity which seemed in itself harmless enough. Long strides, running and leaping, expressions of liking for others did not seem so wicked. Worst of all, upon the establishment of menstruation, the idea was implanted that she must be very guarded in her behaviour towards men, who were depicted as lions in the path seeking to devour her. She related this with bated breath, and the effect of such pernicious advice might have been disastrous but for an innate simplicity and beauty of character in the girl.

It was explained to the patient that it was better to grow up into a strong woman through exercise of her body than to vitiate herself by false ideals of ladylikeness, that all people were not constituted alike and that what might be easy for a more indolent nature would be a penance for her. Nor would ingenuousness of behaviour even with men be misunderstood for long. ("To thine own self be true.")

Another of her troubles was that she was told that her desire to serve put her in a posi-

tion of inferiority and yet she had been taught that to serve was christian. Being full of energy and quickly sympathetic, she made a practice of running errands for other girls and even doing some of their work. For this she was scolded on the ground that she was being taken advantage of. I could not disapprove of this provided she did not overburden herself and did not encourage indolence in those she helped.

As in this girl the motives are animated by a high moral standard, and as there is great temperamental energy, repressive methods should not be attempted, but scope for her activities should be provided in the fullest measure. Only in this way will the exuberance be balanced and adapted to the exigencies of contact with others. Unskilful guidance may easily mar a promising life whereas the patient's own aspirations are likely to lead her in beneficent directions.

A psychoneurosis is after all only the expression of want of harmony. In the foregoing instances it has been traceable to active positive factors of hurt. But quite often the factors are negative, i. e., the absence of the proper avenue of self-expression, the circumscribing of the personality by an unsuitable environment such as jail. The home may be a prison. One patient characterized it as a "House of Hate." The vacuity of the patient's mind may be the important factor. Here must not only the way be pointed out but pabulum may have to be provided for the constructive impulses which every healthy human being has.

The rapidity with which rehabilitation can be effected is sometimes astonishing, as for instance, in a girl of twenty-one whose psychological development had become arrested at the twelve year old stage because of complete preoccupation by a series of obsessions, of which the most insistent were those concerning urination, but in which the comparison of the ages of associates was also most intensely preoccupying. These were traced to the impulse to transcend a sense of inferiority which had been imposed upon her by parents whose oversolicitude regarding the child's health had reflected upon her behaviour. It was a striking illustration of care killing the cat. From being a girl unable to concentrate upon the least matter extraneous to her obsessions, she has become able not only to discard these completely, but to show a most remarkable capacity to as-

simulate scholastic instruction, and to adapt herself to external interest. Besides this, distinct change in her physical appearance is occurring, abstracted looks being replaced by an alert mien.

#### PHYSICAL FACTORS.

So far allusions have been made only to situations where the source is purely psychological, and usually of social, ethical or moral significance. Quite often, however, the source of disadaptation is a physical inadequacy or defect. For instance in a physician's daughter who showed intense timidity besides being deprived of legitimate satisfactions of social life, the sources of the difficulty lay in an undue fatigability since an infection in childhood, an endocrine inadequacy which impaired activity, and an intense acne of the face of which she was much ashamed and which was the cause of much embarrassment, greatly interfering with her social adjustability. Here not only had psychotherapy to be employed, but the improvement of physical condition was an even more important factor in the rehabilitation of this girl, for her good sense had counteracted much of the environmental distresses.

There is no need to insist upon the need for tracing out and getting rid of chronic infections. There is perhaps more need to urge due attention to metabolic and endocrine factors when a young woman finds herself inadequate. But it does not follow that a latent infection, or a faulty metabolism even when present, is the cause of a disadaptation. Many a surgical disappointment would be saved if this were remembered. On the contrary, dissatisfactions are sometimes expressed as visceral perturbations. Always this must be kept in mind in adjudicating a case which superficially looks medical or surgical.

Thus in a case of claustrophobia and agoraphobia, which I have often related, an enlarged thyroid and rapid pulse were present. Some clinicians might have been tempted to treat these latter without exploring the mechanism of the patient's fears, in the hope that these would disappear as thyroid hyperactivity ceased, for we know that hyperthyroidism is itself panic-bringing. In this instance, this would have been to put the cart before the horse, for the fears were traceable to external situations clothed with dread by the imagination of the patient. The method of finding and removing this was discussed in detail in

Chapter VII in my book on "Dreads and Be-setting Fears." (Little, Brown & Co. 1923).

Suffice it to say that in a week the fears were completely removed from a girl who in fear had been unable to enter a meeting place, or cross the street without a circulatory reaction so intense as to cause her to tenaciously believe that her heart was diseased. She has remained well for six years.

Many a gastro-intestinal disorder too should be sought not in the gall-bladder or the appendix but in an anxious mind. The same is true of functional cardiac disturbance. The way to rehabilitate cases of this kind is not through hospitalization, but by a psychotherapy based upon the mechanism of the disturbance.

The peculiarities of the period of gestation are well-known; but the puerperium is also a period of difficulty in many young women. Metabolic and endocrine factors however are not the only ones at work in the troubles subsequent to child bearing and during lactation. Too little attention is paid to the very profound psychological adjustments often necessitated by the marriage state. Economic situation, temperamental differences and a new mode of life may all come to a head during the inactive period following the birth of a child. Hence, a so-called post-puerperal psychosis may merely be the expression of maladjustment and require a psychological exploration which may provide the stepping stone to setting the patient upon her moral feet once more. For example, in a patient sent from Norfolk eighteen months ago, it was attention to this factor which led to the rehabilitation.

In another particularly complex case in a patient sent from West Virginia last summer, only by sedulous attention to her psychology was suicide prevented and recovery effected.

These contentions, so true, have unfortunately often been misapplied even by skillful physicians and surgeons. And therapeutics based upon them has been attempted *without adequate exploration* to ascertain whether the patient's affection is psychogenetic or not. We should think poorly of the gynecologist who suspended the uterus because of a pain in the back unless he had both incriminated the uterus and excluded bones, joints and nervous system as factors. Very inadequate would be the diagnosis of a neurologist who gave arsphe-namin to an ataxic patient unless he both ex-

cluded polyneuritis, pernicious anemia and spinal tumor, as well as found definite signs of syphilis.

And yet much of the psychotherapy attempted is based upon a diagnosis of the situation even less adequate than the foregoing. This is exactly what the charlatans do who are at present riding to wealth on the wave of interest in applied psychology.

So that correct psycho-diagnosis is an essential preliminary to all efforts at rehabilitation, and long and intelligent training is required by those who may hope to succeed in the task.

1746 K Street.

#### DISCUSSION

DR. L. G. PEDIGO, Roanoke: Dr. Williams has been a guest at intervals and we feel that we can take personal liberties in discussing his papers. We can hold up his papers as models for facts. Considering that the author of this paper was born of Scotch and Welsh parents and located in Washington, his treatment of a difficult subject is very edifying. These cases are so difficult that the average practitioner finds great difficulty in dealing with them at all and, if we could unload all our cases of this sort on a man like Dr. Williams, it would be a great comfort. The trouble with this type of case is the lack of the faculty of decision—there is indecision of some kind. It is difficult to bring them to decision on any subject at all. Another feature, and it is a suggestion in regard to the treatment—get the cases away from the family. Of course the family is not always at fault, but the patient thinks so. Her mental attitude is such that the morbid environment must be gotten away from. She impresses upon the new candidate for her affections that there is a diabolical conspiracy against her.

DR. WILLIAMS, (closing): I am very proud to say to Dr. Pedigo that I am not a stranger and you may say anything you like; also, I am a member of the Medical Society of Virginia. Washington is Virginia after all, and a great many patients come to me from Virginia physicians.

About indecision—indecision is usually due to want of understanding on the patient's part. Not knowing her own psychology, she feels that such and such is right. Understanding, for the most part, is being capable of proper judgment. Sometimes, when a patient does not develop the habit of decision, although understanding herself, it is necessary to have training just as in school. One patient now being trained by the wife of a clergyman had been kept childish by her parents during her whole life and, although of good mind, had to be trained just as a child.

A woman from South Carolina, whom I observed, required three months' training in canteen work before she acquired the power of decision. After her training, she managed a canteen in South Carolina, showing great decision of character, after practicing the ideas of her own psychology which she had gained. I think that only when the family influence is very bad should the patient be removed from home, or if you cannot show the family their mistakes and help them overcome the bad influences. As a matter of fact, if you do change the environment, do not put the patient in a general hospital; that's all right physically, but she will do better in some

place more like the normal. Only when the personnel is trained for it can harm fail to accrue to neurotics in hospitals. (See "Management of Psychoneurotics in General Hospitals," *Southern Medical Journal*, 1921).

### THE SCOPE AND LIMITATIONS OF SUBTEMPORAL DECOMPRESSION IN ACUTE BRAIN INJURIES.\*

By J. G. LYERLY, M. D., Richmond, Va.

The studies in this paper are based on a series of ninety-six cases of acute head injuries with unconsciousness, or signs of intracranial injury, who were admitted to the service of Dr. C. C. Coleman of the Hospital Division of the Medical College of Virginia, over a period of one year, from July 1, 1922, to July 1, 1923. This does not include the cases that were seen in other hospitals or in consultation which, if included in this series, would increase the number considerably. Of these cases there were thirteen deaths, making a mortality of 13.5 per cent. This includes all of the fatal cases, some of which died within several hours after admission.

There were forty-one cases which had fractures of the skull, thirty-two of which were compound, eight depressed, and five of the latter were compound as well as depressed. All of the cases of depressed fractures were operated upon to remove the depressed fragments from the brain for local pressure. This does not mean that they had a subtemporal decompression which is done to relieve general intracranial pressure. It may become necessary later to do a subtemporal decompression in these cases if the intracranial pressure becomes excessive.

Of the thirteen cases that died, eleven had fractures, and two showed no fracture of the skull. In these two cases that showed no fracture, one was proved by autopsy, and in the other no autopsy could be obtained, but the X-ray, together with an extensive laceration of the scalp exposing the skull, did not reveal a fracture, although the spinal fluid was very bloody and under increased pressure at spinal puncture. This indicates that it is not necessary for a patient to have a fracture of the skull in order to receive a fatal intracranial injury.

As to the cause of these injuries, there were

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

thirty-three injured by automobiles, twenty-eight by falls, and the others by miscellaneous causes, showing the predominance of the automobile as an etiological factor.

There were forty-six cases with lacerations of the scalp. Regardless of whether or not the patient has a fracture underneath the laceration, it is our practice always to excise these lacerations under local anaesthesia within the first twelve or sixteen hours, or as soon after shock as possible, in order to convert a potentially infected wound into a clean incised wound. For compound depressed fractures or gun-shot wounds of the brain, we follow the plan of Cushing in his war experience of debridement of the scalp and removal of contaminated bone, with irrigation of the wound in the brain with normal saline solution to free it of blood clots and other foreign material.

In this series there were nine subtemporal decompressions with four deaths. Two of the deaths were due to meningitis as proved by autopsy, the source of the infection in one case apparently coming from a fracture into the sphenoid sinus, and in the other from a fracture through the middle ear with rupture of the ear drum on the same side. The third and fourth deaths occurred in patients who developed pneumonia, as proved by autopsy in one case, and clinically in the other.

As the brain is the most important structure involved in a severe head injury, it and its surrounding membranes and fluid will be given the most consideration. Unless there is some depression of fragments causing pressure on the brain or a compound fracture of the vault, fractures of the skull will be given the same importance as laceration of the scalp, bleeding from the ear or nose, ecchymosis around the eyes, or ecchymosis around the mastoid. These are all evidences of a possible injury to a more vital structure within the cranium. Other signs than the above must be looked for, because they do not reveal to us the damage done to the brain, and any of the above signs may be present without evidence of brain pathology.

Intracranial pressure is undoubtedly the most important effect of the average brain injury. It may be due to edema of the brain, intracranial hemorrhage, increased secretion of the cerebro-spinal fluid, transudation of serum from the traumatized tissues into the fluid spaces, or the lack of absorption of the cerebro-

spinal fluid.

The most logical way of classifying these cases from the therapeutic standpoint would be: (1) Those which do not have intracranial pressure; and (2) those which do have intracranial pressure. Under the class of cases which do have intracranial pressure it may be due to: (a) edema of the brain; (b) hemorrhage; (c) edema plus hemorrhage; (d) meningeal hemorrhage; (e) infections, meaning meningitis, encephalitis, or abscess; and (f) localized pressure as in depressed fractures.

When a patient is admitted to the hospital in an unconscious condition, or with a history of transient unconsciousness, every effort should be made to determine whether or not he has a dangerous pressure. The signs upon which we rely chiefly to determine this are: drowsiness or unconsciousness, pulse rate, systolic and diastolic blood pressures, eye-ground findings, and spinal fluid pressure measured with a manometer at spinal puncture; and of less importance signs such as vomiting, condition of the pupils, X-ray examinations, focal signs, temperature, convulsions, and respiration. If there is a rapid increase in the intracranial pressure, as from hemorrhage, during the first three to twelve hours, there will be first a slowing of the pulse rate and a rise in the systolic and pulse blood pressures. Later, if the pressure is not relieved, a rise in the pulse rate and a fall in the systolic with a high pulse pressure will result from a fatal pressure transmitted to the medulla. If the life of the patient is to be saved, before the pulse rate begins to rise or the systolic blood pressure drops, quick and efficient measures will have to be instituted to relieve the pressure, employing a subtemporal exposure to evacuate the clot and stop the bleeding, as in meningeal hemorrhage. It would be useless to temporize with a spinal puncture to relieve the pressure in such a case. Should the pressure come on more slowly over a period of days, as from cerebral edema, we have not found any great rise in the systolic blood pressure, but there does seem to occur a rise in the pulse pressure and a slowing of the pulse rate. Here haste in radical measures to relieve the intracranial pressure may not be necessary, and resort to more moderate procedures is advisable. There may be given a thirty per cent solution of sodium chloride in one to two ounce doses every three hours, or a saturated solution of

magnesium sulphate given in half ounce quantities every three hours, as advised by Dowman, with daily spinal punctures to estimate the spinal fluid pressure with the manometer and to reduce the pressure by withdrawal of the fluid as advised by Jackson and others.

Some brief reports are given herewith as an illustration of acute brain injuries, some of which may or may not be aided by a subtemporal decompression.

The following case illustrates the great benefit that may be derived from spinal punctures alone, in a case of rather severe intracranial injury with subarachnoid hemorrhage and pressure:

Case 40, J. H., white, male, age 60 years, admitted on March 12, 1923, with history of being knocked down by an automobile. Was unconscious and had hematoma in right posterior parietal region. Had ecchymosis around right eye, vomiting, and had bleeding from nose. Reflexes were normal, and had no paralysis. Pupils were equal and reacted to light. Eye-grounds showed engorgement of retinal veins. Pulse 72, blood pressure systolic 180, diastolic 90. Spinal fluid very bloody, pressure 30 mm. hg. Battle's sign developed behind both ears. X-ray did not show a fracture. Patient was very restless and semi-conscious for a week. General condition was very poor with serious chest injuries and associated complications. Intracranial pressure was relieved by repeated spinal punctures and hypertonic fluids by mouth. Patient made an excellent recovery.

This patient's general condition was not good. The intracranial pressure was readily controlled by repeated withdrawal of the bloody subarachnoid fluid. Free blood in the subarachnoid spaces can be removed most easily by lumbar drainage, and it alone should not be an indication for a subtemporal decompression, because all of the free blood is not removed in this way.

We have never seen any danger result from spinal punctures in the early stages of acute brain injuries even when the intracranial pressure was high. A careful eye-ground examination is always made before every spinal puncture, to rule out a choked disc which, in our opinion, should exclude a spinal puncture in any case because of the well known fatal tendencies of a spinal puncture in a brain

tumor with choked disc. We have never seen a choked disc in acute brain injury even when the spinal fluid pressure was high as registered by the manometer.

The following case is an example of almost immediate relief of symptoms following a subtemporal decompression:

Case 9, J. C., white, male, age 64 years, admitted November 9, 1922, with history of falling from wagon. Was temporarily unconscious. Examination showed contusion of scalp in left parietal region. Battle's sign was marked behind left ear. Was conscious and rational, but had marked aphasia. He could understand what was said and could write his name very well, but could not name objects nor say what he wanted to say. No paralysis was present except for little weakness in right lower face. Pupils were equal and normal. Eye-grounds showed engorgement of retinal veins and hyperemia of left disc. Reflexes did not show anything abnormal except for a few beats of ankle clonus on right side. Pulse was 56, and blood pressure was systolic 140, diastolic 78. X-ray showed fracture of skull starting in left parietal region running down into base of left middle fossa. Under local anaesthesia a left subtemporal decompression was done. The dura was very tight and, upon nicking same, a stream of bloody fluid escaped under high pressure. The brain was found to be contused and plum colored. On the following day the aphasia was improved. The patient was discharged three weeks later without headache or any signs of aphasia.

Attention has been called to the fact by Naffziger that in a certain proportion of cases there seems to be imprisoned a large collection of fluid in the subdural space and, when the dura is nicked at subtemporal decompression, the fluid spurts under great pressure. This fluid which is between the dura and arachnoid cannot be removed by spinal puncture, which only drains the subarachnoid space. A subtemporal decompression here gives a prompt and satisfactory relief of symptoms.

The following case is an example of a rather severe brain injury with increased intracranial pressure, in which a subtemporal decompression does not prevent a fatal issue:

Case 5, W. B., colored, male, age 50 years, admitted on July 8, 1922, with history of being knocked down by an automobile and rendered unconscious. Since then has been in a stupor

and extremely restless, scarcely ever using right arm or leg. Pupils were equal and sluggish. Right biceps and knee jerks greater than left. Umbilicals absent on right. Positive Oppenheim and Gordon on right. Pulse 64, and blood pressure systolic 124, diastolic 85. X-ray showed a fine linear crack in the frontal bone. Eye-grounds were negative except for fullness of veins. Spinal puncture showed extremely bloody fluid, hemoglobin estimation on fluid fifty per cent, pressure 18 mm. hg. Under local anaesthesia a left subtemporal decompression was done finding subdural hemorrhage and contusion and laceration of brain on left side. The brain was under high pressure, was very dry, and no fluid was present in the subarachnoid spaces. On the following day spinal puncture showed pressure of 16 mm. hg., and fluid less bloody. Blood pressure systolic 134, diastolic 88, pulse 70, extremely restless. Temperature, pulse, and respirations gradually went up and patient died of pneumonia on sixth day. Autopsy revealed fracture of the skull, laceration and contusion of the brain, subdural hemorrhage, and hypostatic pneumonia.

It cannot always be predicted as to whether or not a subtemporal decompression will adequately offset the pressure. There seems to be a class of cases in which the brain is under tremendous pressure and, when it is exposed by a subtemporal decompression, it is found to herniate rapidly upon opening the dura, and to be extremely dry and without any free subdural fluid. When this condition exists, the subarachnoid spaces over the cerebral cortex are probably obliterated and the cerebrospinal fluid cannot be absorbed. Then it is necessary, along with a subtemporal decompression, to resort to spinal drainage to remove the dammed up fluid in the basal cisterna and ventricular system. Dr. C. C. Coleman is of the opinion that unless a subtemporal decompression removes something, whether it be free fluid, blood clot, or some other foreign substance, it generally fails to relieve the pressure.

The following case is another example of great benefit derived from a subtemporal decompression:

Case 79, E. F., white, male, admitted on August 4, 1922, with history of a fall by which he was rendered unconscious. Had a laceration in the occipital region, which was excised under local anaesthesia and the wound sutured. Had bleeding from left ear, and eye-grounds

showed retinal veins engorged. X-ray was not conclusive of fracture. Pulse was 52, blood pressure systolic 136, diastolic 84, on admission. Three hours later blood pressure systolic 122, diastolic 62, pulse 60. Four hours later blood pressure systolic 114, diastolic 60, pulse 56. Thirteen hours later blood pressure systolic 128, diastolic 28, pulse 60. Twenty-one hours later blood pressure systolic 114, diastolic 20, pulse 56. Spinal puncture showed bloody fluid under pressure of 30 mm. hg. Under local anaesthesia a right subtemporal decompression was done. Upon opening the dura a large amount of free fluid escaped under great pressure. The brain was contused and edematous. The patient made a rapid recovery and was discharged from the hospital in two and a half weeks.

This case also indicates the wonderful improvements following a subtemporal decompression upon finding a large amount of subdural fluid and a wet edematous brain. It also exhibits beautifully the falling diastolic and rising pulse pressures with a slowing of the pulse rate in a progressive rise in the intracranial pressure from cerebral edema and subarachnoid bleeding. We do not believe that spinal punctures here alone would be sufficient to take care of the intracranial pressure which probably would continue for several months following such an injury.

The following case shows how hopeless some patients are from the first, usually dying within several hours after admission, regardless of what is done for them:

Case 93, J. F., white, male, age 11 years, admitted on April 30, 1923, with history of falling four stories from a building. Was unconscious and had extensor rigidity of neck, back, arms and legs, resembling decerebrate rigidity. This was more marked on the right side. Pupils were dilated and equal and did not react to light. There was an inexhaustible ankle clonus on the right side, and exhaustible on left. Had double Babinski. Vomited some blood. At 7:30 P. M. pulse was 100, blood pressure systolic 122, diastolic 78. One hour later, pulse was 90, blood pressure systolic 144, diastolic 76, temperature 101.4. Two hours later pulse was 112, blood pressure systolic 130, diastolic 46, temperature 104. At 11:30 P. M., four hours later, pulse was 160, blood pressure systolic 120, diastolic 20, temperature 107.4. Patient died eight hours after admis-

sion. X-ray showed fracture of first cervical vertebra.

This patient had a direct injury to the medulla. The rapid rise in temperature, the pulse, and blood pressure findings were especially of interest. The systolic blood pressure remained up until the end, while the diastolic pressure was falling, giving a progressive rise in the pulse pressure, accompanied by an increase in the pulse rate and a hyperthermia, which meant disturbance of the medullary centers.

There does not appear in this series a typical case of extradural hemorrhage, such as we very much look for but rarely ever see. There does appear a case of extradural hemorrhage with which was associated grave injuries to the intracranial structures but to which death could not be attributed alone.

Case 7, R. H., colored, male, age 25 years, admitted February 2, 1923, with history of having fallen a considerable distance. Entered hospital deeply unconscious and in shock, with bleeding from nose and left ear. Few hours later, right pupil was larger than left and did not respond to light. Had double Babinski and vomited. Had laceration of scalp over right parietal region. Pulse was 60, and blood pressure systolic 130, diastolic 90. Two hours later pulse was 70, blood pressure systolic 144, diastolic 32. With diagnosis of probable extradural hemorrhage, it was decided to operate at once, but the patient died of respiratory failure before the operation could be done. Autopsy revealed fractures of the skull radiating into all three fossae on both sides of the skull, with part of the rim of the foramen magnum split off and depressed, extradural hemorrhage one inch thick on right side, and thick layer of subdural hemorrhage all over the surface of the brain and around the medulla.

There is probably no other condition which the surgeon must recognize and meet more promptly than a case of extradural hemorrhage. The history of a relatively mild head injury, with or without temporary unconsciousness, followed by the so-called "lucid interval" of consciousness, and then followed by unconsciousness, should always put us on our guard against extradural hemorrhage. The condition must be recognized early, relying on the patient's history and condition before he be-

comes unconscious, also the unequal pupils, the slow pulse, and the high systolic and pulse pressures. When it is recognized, a prompt operation must be done through the subtemporal route, with removal of the blood clot and ligation of the bleeding vessel, even before the systolic blood pressure falls or the pulse rate increases, if the life of the patient is to be saved.

### 503 Professional Building.

#### DISCUSSION.

DR. JULIAN RAWLS, Norfolk: I would like to call your attention to some apparently very severe brain injuries which have entirely cleared up on only symptomatic treatment. Of course there are times when an operation is an absolute necessity either to save life or to prevent bad sequelae.

Recently we had six cases in a period of three months, all of which were treated symptomatically, all of which recovered and, up to date, none of which have developed bad symptoms.

One of these patients was a negro man brought in the hospital by the patrol. He had a bullet wound between his eyes from which brain tissue was oozing. The next morning he had some little disturbance in mentality, he answered questions rather slowly, but that was about all. An X-ray showed the bullet to be in the mid-line about one-half an inch from the occipital bone. It had missed both his optic nerve and his longitudinal sinus. He stayed in the hospital for two weeks with no rise of temperature and practically no mental disturbance. I saw him two months after leaving the hospital, when he appeared to be perfectly normal in every way. No attempt was made to remove the bullet.

Another case was a child who fell from a second story window and landed on her head on a concrete pavement. She had a fracture completely across the vault with a fluctuation all over her head. She probably did her own decompression beneath her scalp. Within a week her symptoms had entirely disappeared and she left the hospital.

In another case a child was brought in who had been run over by an automobile. She had two convulsions in the ambulance coming in. She was in coma all night, but by morning her symptoms began to clear up and in a few days she was all straight. This child had a discharge of serum from her ear.

In another case, a young school teacher was run over by an automobile. She had both a fracture of the base and a fracture of one lamina of the third cervical vertebra. She developed a facial paralysis and was unconscious for three weeks. Under expectant treatment her paralysis has cleared up, her physical symptoms have disappeared and her mental condition, except for a slight instability, is normal. She was injured in April and she expects to resume her school teaching in February.

Now don't misunderstand me. I do not believe in sitting by and letting a patient drift on until a falling blood pressure and a rising pulse rate indicate that we have waited too late to save his life or until we doom him to a life of mental instability or possibly epilepsy, but I do believe that a good many cases of severe brain injury are best treated expectantly.

## SOME POINTS IN THE DIAGNOSIS OF EXTRA-UTERINE PREGNANCY.\*

By W. DENNIS KENDIG, M. D., Kenbridge, Virginia.

Our whole knowledge of a proper conception of the subject of extra-uterine pregnancy dates back since 1863 when Lawson Tait operated his first case. Since that time much advance has been made with the diagnosis and treatment of this condition, yet within the last few years very little that is new has developed. However, because mistakes in diagnosis seem to be relatively more frequent than would be expected, because it is a condition of frequent occurrence, and because early operative measures are of such great importance, this paper would seem to be justified. My attention was called to this difficulty in diagnosis from the fact that our records show that less than 50% of cases of extra-uterine pregnancy admitted to the hospital were diagnosed before admittance.

Brady, in the *Johns Hopkins Hospital Bulletin* last May, states that in a series of fifty cases from 1917 to 1922, their diagnosis, after admittance to the Hospital was correct in 72% of all cases taken together, 75% in tubal abortion and rupture, and 60% in unruptured cases. At first glance, extra-uterine pregnancy may not seem to be so frequent, yet Fancher states that it is estimated that about 1% of all pregnancies are extra-uterine. The necessity of early operation is well stated by Montgomery of Philadelphia, who "believes it better to operate at once even though the patient may be profoundly shocked, and then employ measures for restoring circulation as the operation proceeds." De Lee quotes Schauta as saying that in 241 cases of extra-uterine pregnancies treated expectantly, he found 75 recoveries and 166 deaths.

Pathologically, extra-uterine pregnancy is divided into ovarian, tubal and abdominal pregnancy. This condition is also divided into three definite stages, exhibiting different symptoms and presenting different problems to the physician, viz: Before rupture, after the time of rupture, and those cases which survive rupture without operation. Yet, on account of the fact that a majority of the cases mark this stage, on account of the necessity for an early recognition of such cases and on account

of the demand for prompt operative interference in the ruptured stage, I shall confine my remarks to the discussion of this, the tragic stage of extra-uterine pregnancy. Nearly all cases of extra-uterine pregnancy rupture before the twelfth week. Polak found that 299 cases out of 307 reported ruptured before this time. A ruptured extra-uterine pregnancy is seen usually first by the general practitioner. The recognition of the condition, except in the text book cases, requires a careful history, a thorough physical and laboratory examination, and even then a large percentage of cases are not recognized until a laparotomy is performed.

It is considered that the history is of first importance in the diagnosis of extra-uterine pregnancy. Change in menstruation constitutes the most important point in the history. You will find a missed or irregular period and, if the period is present, the quantity is small. Usually the patient has given birth previously, followed by a long period of sterility, and then has a delayed, missed, or irregular menstruation. Absolute sterility is not definitely associated with ectopic pregnancy, but relative sterility, especially the one child type, is a very significant point. A history of previous pelvic disease, such as congenital anomaly, inflammation of the tube, intra-uterine instrumentation, intra-abdominal operation, especially some procedure for the cure of sterility, are of great importance, but a lack of such history should not influence a diagnosis against it.

Although it cannot be proven definitely and although I know of no authority supporting it, I am of the opinion, from the history of our cases, that many extra-uterine pregnancies are caused by the use of contraceptive measures. I mean that contraceptive measures are used during the first ten days after menstruation, and not used for the ten days or two weeks previous to the period. This violation of the physiologic laws of copulation, I believe, would render the lining mucous membrane of the uterus less receptive to normal gestation, and inhibit the usual activity of the cilia, occasionally causing the impregnated ovum to take the wrong course or remain stationary in the tube.

Pain is the chief and most constant symptom. It is sudden, intense and of a cramp-like or colicky character, usually localized in the lower abdomen to one side, although at times the pain may be higher up in the region of the

\*Read by title at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

gall-bladder. In extra-peritoneal rupture, the pain varies according to the amount of blood lost. At times when the pain strikes a patient the shock is so profound that there is a complete collapse, so much so that patients have been known to fall on the street. A decidua is expelled upon the death of the ovum after rupture. The decidua is expelled in piece meal or in a whole decidual mass or cast, with the characteristic bloody discharge that does not readily clot. This is also one of the chief diagnostic points. The pulse is small, frequent or hardly palpable, its degree depending upon the amount of blood lost and upon the extent of shock. There is a decided drop in blood pressure, the patient becomes anemic, the red blood count comes down, a leukocytosis develops, the hemoglobin index falls, there is mental disturbance, inability to arise and assume the erect posture, the patient is pale, has fainting spells, dyspnea and cold sweats. There is usually subnormal temperature early during shock and later a slight temperature elevation. The lower part of the abdomen is rigid and very sensitive to palpation. We may find the cervix is sensitive to motion, pain upon defecation, lower abdominal dullness on percussion, the usual breast phenomena and other symptoms common to early pregnancy.

The above picture should lead to a careful investigation. Upon pelvic examination the parts are found blue, congested, and the uterus, due to the absence of the growing ovum, is not much changed in consistency or shape, although it is enlarged and there is usually a slight softening of the cervix. There is great pain on movement of the cervix, due to the peritoneal irritation, caused by the blood which gravitates into the cul-de-sac. A vaginal examination will sometimes reveal a soft boggy enlargement or blood crepitus in the abdomen, or a hematoma in the fold of the broad ligament.

Cullen pointed out that the dark color of the umbilicus is at times a sign of ectopic pregnancy. Since that time Novak says that several writers have noted this sign, and found it of great help in making a diagnosis. Dr. Jackson has made a suggestion for the determination of Cullen's sign when it is apparently absent, that of placing the patient in a dark room, and throwing the light of an ordinary flash light on the umbilicus, which he claims will bring out the greenish blue color.

Schuman describes another class of symp-

toms, which he calls the stenic variety, and is concurred in by Cresler and others, who call them silent cases of extra-uterine pregnancy. Here we do not have collapse, pallor, weak pulse or other signs of hemorrhage: but the diagnosis has to be determined on the history, tenderness, distention of abdomen, especially on bimanual examination.

It must not be forgotten that tubal pregnancy may be double, recurrent or bilateral. A tubal pregnancy may co-exist with a uterine pregnancy. Of these Heineck says that the recurrent type is by far the most frequent, and that the recurrence is nearly always in the opposite tube.

Dr. Stuart McGuire, in a paper before the Southern Medical Association a few years ago, states that in a series of fifty cases there were six who had a recurrence in the opposite tube and were operated on by him the second time. He estimates that there were six other recurrences, who went elsewhere for treatment.

Shock with abdominal symptoms, in a woman capable of bearing children, should always create a suspicion of ectopic pregnancy. As soon as a diagnosis is made, the treatment is invariably surgical. The operation should be performed with as little anesthetic as possible. Always withhold stimulation until the bleeding points are tied off.

I would like to emphasize the following points:

1. Where there is any possibility of an extra-uterine pregnancy, obtain an accurate and complete history of the case.
2. There is usually a subnormal or no temperature during shock of the tragic stage, although temperature will develop later.
3. Discharge of the decidua without villi is a pathognomonic diagnostic point.
4. Never give stimulants until after ligature is secure around the bleeding points.
5. Extra-uterine pregnancy is more frequent than is generally believed.
6. Extra-uterine pregnancy is more probable, it appears, in women who for a week or so after menstruation, and for this period only, use contraceptive measures to prevent conception.
7. Immediate operation as soon as diagnosis is made. These cases usually recover if operated on early. These cases are usually fatal if left to nature.

## TUBERCULOUS AND NON-TUBERCULOUS COMPLICATIONS AT PINE CAMP SANATORIUM DURING THE YEAR 1922.\*

By W. NELSON MERCER, M. D., Richmond, Va.  
Director, Tuberculosis Division, Richmond Health Bureau.

The correct evaluation of statistics lies in a thorough understanding of the conditions pertaining to the subject under consideration. Therefore, I will describe briefly the sources and the types of patients admitted to and under treatment in Pine Camp Sanatorium of Richmond, Va., during the year 1922.

Pine Camp Sanatorium is the municipal tuberculosis hospital operated by the Department of Public Welfare of Richmond for resident white tuberculous patients who are unable to afford the expense of sanatorium treatment in other institutions. However, Richmonders who have been to various sanatoria and are unable to further pay their way in them are frequently admitted to Pine Camp, if proven to be worthy cases still in need of hospitalization.

The chief sources of admission are (1) from the free City Tuberculosis Clinic, (2) from consultations by the Director of the Tuberculous Division with practitioners in the city, and (3) by direct applications of tuberculous patients who reside in the city or for the time are under treatment in other sanatoria. No discrimination is made regarding the clinical classification of applicants, provided they are eligible socially and financially and are in need of sanatorium treatment. Due to this fact the percentage of far advanced cases admitted to Pine Camp is higher than prevails in other Virginia sanatoria, which fact should be remembered when comparing the tables of complications.

With a capacity of thirty-six, ninety-two patients were treated at Pine Camp during the year 1922, their stay ranging from two days to twelve months and, although this number is comparatively small, we may derive some-

\*Read at fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

thing of benefit from the results obtained.

Upon comparison of the three tables, it is evident that the vast majority of deaths occurred among those patients who had tuberculous complications of an extreme nature. Six of the total of twelve fatal cases had laryngeal involvement in an advanced stage. Most of the laryngeal cases were admitted with this complication and had advanced pulmonary tuberculosis as well. Some came to Pine Camp as a last resort—in extremis.

An entirely different picture is presented by the non-tuberculous complications, the only death among these being due to a post-operative carcinoma of the stomach, resulting in inanition.

It will be noticed that the proportion of improvement is greater among the tuberculous than among the non-tuberculous complications, which may be accounted for by their yielding more readily to treatment, if this is begun when they first appear. Ten of the twenty-six tuberculous complications which improved were benefited by surgical intervention. Five of the eleven non-tuberculous complications which improved were likewise helped by prompt surgical treatment.

Those complications which remained unimproved yielded to no treatment whatever, although they were not progressive in every instance but were chronic in character.

TABLE No. 1.  
PINE CAMP SANATORIUM.  
*Tuberculous Complications, 1922.*

Complication	Total	Improved	Unimproved	Died
Tuberculosis of Larynx*-----	13	5	2	6
Pulmonary Hemorrhage*-----	12	10	0	2
Ischio-rectal Abscess (Post-op. 2)*	4	3	1	0
Hydropneumothorax (Op.)*-----	3	3	0	0
Pyopneumothorax (Op.)*-----	2	1	1	0
Peritonitis (Op.)-----	1	1	0	0
Tuberculosis of Metatarsal Bones (Op.)-----	1	1	0	0
Tuberculosis of Hip Joint (Post- Op. 1)-----	2	2	0	0
Enteritis-----	2	0	2	0
Meningitis-----	2	0	0	2
Total-----	42	26	6	10

\*Multiple Complications.

Table 1 gives the tuberculous complications which manifested themselves in such a manner as to render them worthy of special care and treatment. Those marked with a \* oc-

curred as multiple complications in individual patients, occasionally two or three in the same case. When a fatal termination resulted, the principal causative factor is noted in that column.

Five of the thirteen cases of laryngeal tuberculosis were benefited by treatment, some of which were entirely cured, while two showed no improvement, and six died.

Ten of the twelve pulmonary hemorrhage cases improved or entirely healed. Two bilateral far advanced patients died with terminal bleeding.

Two of the ischio-rectal abscesses had been previously operated upon, and three of the four improved with routine treatment. One was unimproved.

Hydropneumothorax complicating artificial pneumothorax treatment required repeated aspiration in three cases, the fluid entirely disappearing.

Pyopneumothorax complicated two artificial pneumothorax patients in one of whom the pus disappeared after repeated aspirations, but in the other a small amount remained.

The two cases of enteritis were not benefited by several methods of treatment, probably due to their long standing and the far advanced condition of the lungs.

Meningitis developed rapidly in one patient, the first symptom being diplopia, while in the other the usual headache preceded other symptoms of a terminal nature. In both cases the lung pathology was far advanced.

Acute tuberculosis of the metatarsal bones occurred in one case of moderately advanced pulmonary disease and, after prompt removal of the two bones involved under gas-oxygen anesthesia, the patient made an uneventful recovery and has worked steadily since discharge as an arrested case.

Both cases of hip joint disease deserve comment as one patient is 26 years old and had been in a cast and brace for years, only within the past year being allowed to leave off the cast and use crutches. He now walks well without crutches or cane. The other case gave a history of pulmonary tuberculosis and traumatism in a street car accident ten years ago, which necessitated resection of the head of the femur involved and fixation of the joint. The sinus which developed after operation has been closed for several years, and the patient gets around remarkably well with a cane. The pul-

monary condition of both cases is apparently arrested, one having resumed his former occupation of clerk, and the other will soon be discharged.

Tuberculous peritonitis developed in one patient with typical symptoms and signs of acute appendicitis but, due to the advanced condition of the lungs, operation was considered a bad risk. However, the nausea and vomiting progressed with excessive abdominal pain localized in the right lower quadrant which necessitated surgical intervention. An exploratory laparotomy was done under local and gas-oxygen anesthesia. Some free fluid, enlarged glands, and small tubercles lining the peritoneum were found but the appendix was normal. The fluid was removed and the wound closed, the patient's temperature came to normal, his indigestion disappeared, and since then he has had no symptoms of abdominal pathology. He was discharged to his home in the suburbs of Richmond much improved.

TABLE No. 2.

PINE CAMP SANATORIUM,  
Non-Tuberculous Complications, 1922.

Complication	Total	Improved	Unimproved	Died
Nephritis Chronic (Op. 1) -----	6	3	3	0
Interstitial (Op. 3) -----	4	4	0	0
Diabetes Mellitus -----	2	2	0	0
Carcinoma of Stomach (Post-op.) -----	1	0	0	1
Valvular Heart Disease -----	1	0	1	0
Tabes Dorsalis -----	1	0	1	0
Psychosis -----	1	0	1	0
Renal Calculus -----	1	1	0	0
Hemiplegia (Old) -----	1	0	1	0
Hypopituitarism -----	1	0	1	0
Intestinal Obstruction Partial (Post-op.) -----	1	0	1	0
Cataract, One Eye -----	1	0	1	0
Pterygium (Op.) -----	1	1	0	0
Total -----	22	11	10	1

Among the non-tuberculous complications (Table 2) which required operative intervention, three were women in which the signs and symptoms of pelvic inflammation demanded correction. The stage of disease in the lungs varied from early to moderately advanced and in all three cases gas-oxygen anesthesia was employed with good results.

The one case of renal calculus was cured by dislodging and passing the stone during catheterization.

The pterygium of one eye was removed under local anesthesia.

In the fatal case of carcinoma of the stomach (pylorus), this was discovered during a previous operation for suspected gastric ulcer, after which the patient became gradually worse and finally died due to inability to retain any nourishment. His pulmonary condition was far advanced.

The one case of partial intestinal obstruction following a former appendectomy presented symptoms of chronic constipation and periodic attacks of vomiting with abdominal pain. Due to her refusal to allow a laparotomy, the cause was not removed.

The treatment of the nephritic and diabetic patients was dietetic with the usual routine for all tuberculous cases. All of these improved except three of the nephritic cases which remained stationary. One of the nephritics required numerous abdominal aspirations of large amounts of ascitic fluid which finally disappeared and has not returned after six months.

TABLE No. 3.

PINE CAMP SANATORIUM,  
Summary of Pulmonary Tuberculosis Cases With and Without Complications, 1922.

Complication	Total	Improved	Unimproved	Died
Tuberculous -----	42	26	6	10
Non-tuberculous -----	22	11	10	1
No Complication -----	36	34	1	1
Total -----	100	71	17	12

Of the thirty-six patients who apparently had no complications (Table 3), thirty-four improved under routine sanatorium treatment, and of these nine suitable cases were benefited or arrested by artificial pneumothorax treatment.

Only one uncomplicated case remained unimproved, and one died.

CONCLUSIONS

1. Tuberculous complications are usually of more serious prognostic significance than non-tuberculous.

2. Early recognition of both tuberculous and non-tuberculous complications with prompt medical treatment or surgical intervention offers the greatest prospect of cure or improvement.

3. The presence of pulmonary tuberculosis in any stage should not prevent surgical intervention under local or gas-oxygen anesthesia for the correction of a grave complication.

4. Complications of any nature should not be regarded as hopeless until every known method of treatment has failed.

*Room 409, City Hall.*

#### DISCUSSION.

DR. WYNDHAM B. BLANTON, Richmond: Dr. Mercer's paper is very interesting. The complications of tuberculosis are very important, and I believe clinically are often overlooked. In connection with this, will say that four or five years ago I saw a thousand or more cases of pulmonary tuberculosis. Of the seven hundred (700) autopsies studied, 37% presented intestinal infection, 24% glandular tuberculosis; 15% tuberculosis of the spleen and liver; the peritoneum and pericardium come next with something like 5%.

DR. W. NELSON MERCER, Richmond: The complications noted in this paper were clinically demonstrable in living patients and do not include post-mortem findings. Dr. Blanton's autopsy statistics serve to prove the frequency and seriousness of tuberculous complications, which should be recognized early and treated accordingly.

### TWO SHORT PUBLIC HEALTH COURSES AT THE UNIVERSITY OF VIRGINIA.\*

By HARRY T. MARSHALL, M. D., University, Va.  
Professor of Pathology, and Member of State Board of Health.

During the last twenty or thirty years, the number of people engaged in caring for the public health has increased from a handful to the proportions of a small army. Within the same period, the responsibilities of public health officials have become more diversified. In the public health department of a large modern city or of a state, there may be twenty or more different lines of work carried by the department force. Some officials will be engrossed in matters of organization and administration, others in educational matters and publicity, others in problems of engineering, others in highly specialized bacteriological, or statistical, or nutritional fields. In addition, there will be subdivisions devoted to the special public health problems of tuberculosis; of venereal diseases; of infant welfare; of school inspector; of water; milk; foods; of sewage disposal. This incomplete list serves to indicate that there is considerable diversity of occupation to be found on a public health force. Within the subdivisions there will be still fur-

ther differentiation. As a rule, a large, well developed public health staff will include one, or several, highly trained officials; a number of officers expertly trained along one or more highly technical lines; a number of doctors who have picked up some practical working knowledge of public health matters, and who are chiefly engaged in field work; public health nurses, sanitary inspectors, etc. In this state, the chiefs of the three great tuberculosis hospitals and their staffs are also public health officials.

Where do public health officials come from? Where and how are men and women trained to become public health officials? Several of the large universities have given at least a partial answer to this question, by offering courses which prepare the graduate for leadership in the public health movement. Another partial answer has been worked out in the health departments themselves, where medical graduates, and non-medical laymen are received, given intensive practical training, like apprentices, and taken over as public health agents.

In the construction of the university courses, the directors have been guided by those ideals of scholarly thoroughness which underlie the arrangement of university courses for students of engineering, or of medicine. The students are carried through courses extending, usually, over several years, designed to give a solid grounding in the sciences relating to their chosen profession. They must acquire specific knowledge of at least the outlines of those great fields into which their professional work will carry them. They must develop a reasonable degree of technical proficiency through laboratory or field work.

It seems only reasonable to assume that graduates in public health who have spent several years in preparation, will be qualified to work into commanding positions in the various public health services of cities, states and the nation, but only in rare cases will they be content to accept humble and poorly paid positions in small towns and country districts. Now the question may be asked, "What part can a state university play in training students for these humbler positions?" A consideration of the development of public health in Virginia may be of value in answering this question.

It is only some fifteen years ago that Vir-

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

ginia began to apply modern public health methods to the State on a wide scale. At the time the State Board of Health was reorganized in 1908, there was practically no functioning health department either in the State or in the counties and, though Richmond and Norfolk had, already, young and active health offices, the other cities and towns had moved little or not at all along this line. In the fifteen years which have elapsed since the inauguration of the new State Board of Health, nearly one-half (forty or more), of Virginia's one hundred counties, and several of the cities and towns have established local health work on a whole time basis, some in an elementary way, others more elaborately. In some communities there may be only a sanitary inspector, or only a nurse, and from this minimum there will be found more and more complete organizations up to those of the large cities. Fortunately, the State law vests with the State Board of Health control over the smaller, undeveloped local health units, and the State Health Board, through professional and financial backing and direct supervision, exercises, in fact, a very real directorship over the local health work.

The establishment of health units by counties is a relatively new development, hardly any of the modern health units being over six or eight years old. They have been started as a rule through the efforts of the Commissioner of Health and his assistants acting in conjunction with groups of citizens in the locality to be developed. It is usually not easy to secure a large amount of money for such an undertaking, and in not a few rural communities there may be active opposition to, or at least distrust of the proposed innovation. It, therefore, happens that most of the county health units have humble beginnings, the idea of the State authorities being that any work accomplished will carry its own story to the county, and lead to expansion of the local unit. This theory is proving true in practice, and, in addition, the success of the county health units is proving to be a distinct incentive to some of the more tardy counties to follow the example of their neighbors. All in all, the development of local health units in counties and towns is a movement which is advancing with increasing momentum.

The progress of this movement for the building up of small local health units carries with

it an increasing demand for public health agents who will know at least how to care for the most urgent public health needs of the community, but who can be obtained for a modest salary. The position will not appeal to the highly trained public health graduate. Officers for these positions have been found hitherto largely by chance; at times when an officer is needed, an untrained man is drilled by the State health authorities until he learns enough to look after rural sanitation and a few other fundamental matters. He is then placed at work,—it may be, actually in charge of a rural unit, if he is a doctor,—and is encouraged to push forward, learning as he goes, under the scrutinizing supervision of the State health authorities. He is kept in close touch, through telephone, letters and visits, with the expert staff of the State Board of Health, so that he can secure advice or assistance from the sanitarians, engineers, bacteriologists or others in the central office. While this method of training has sufficed to meet most of the needs, up to the present, the demand for health officers is increasing at a rate that makes it advisable to plan for a stabilized training for officers of the types most needed at present in Virginia,—especially in the counties and small towns. It seems that the public health development in Virginia, with a central consulting staff supervising and advising the field workers in charge of small rural units, at the same time encourages counties and towns to engage in local public health work, and, on the other hand, creates a special question in regard to the education of public health workers to meet this demand.

A little over a year ago an opportunity arose for the University of Virginia to take a share in the training of health workers for the State. An active rural health unit, functioning successfully for two years in Albemarle County was enlarged so as to have control in public health matters over Charlottesville and the University as well as the county. The director of this unit is a member of the University of Virginia teaching staff and, in addition to lecturing, he can send his pupils to gain first hand knowledge of health problems in field work in city and county. With this organization as a foundation, the authorities at the University, after advising with the Commissioner of Health, Dr. Williams,\* and his assistant, Dr. Flannagan, decided that the training

most needed to meet the present State needs includes, first, the practical, intensive training of medical graduates in the fundamentals of rural public health: and, second, the training of sanitary inspectors.

Two courses have, accordingly, been designed: a twelve weeks' course for medical graduates, and a ten weeks' course for inspectors. From our experience last session, we are inclined to believe that this course meets a growing need in the State, and that training of this type will be necessary for ten or twenty years, or until public opinion is ready for more highly organized, and more expensive rural units. In our courses, the student learns to look after rural sanitation: water supplies: school inspection, with follow-up work and clinics: maternity and infant welfare work; and public health office work.

The courses given last year covered, essentially, the subjects outlined above. We expect to mould the course in the future to meet new needs as they may develop. At present we consider it advisable to include some lectures on medical, public health and laboratory subjects, and to lay more stress on contact with the hospital and dispensary.

While we are aware that these courses are, educationally, far from ideal, we believe that organized training of this kind under university direction will ensure a more evenly trained product, and a greater supply of trained health agents, and we believe that in offering these courses we are fulfilling one of the obligations of a State university in meeting an educational need of the State. We recognize that the new courses are in the nature of an educational experiment, but it is our hope that, through control of these new courses, the University and the State Health authorities will be able to mould the education of public health agents, so as to meet the expanding needs of the State.

#### DISCUSSION.

DR. WM. S. KEISTER, Charlottesville: Just one word, especially as being Health Officer of Albemarle County and Charlottesville. The plan of the University is primarily to meet the State's needs, as Dr. Marshall expressed it, for trained health workers. It was with some timidity that we faced the public health proposition and started at the other end. The need is not for theoretical health officers, but rather for men who can meet the local needs. Some communities are not prepared for higher trained theoretical men; they do not want men trained in theory without practice. It is with this idea in view that

they are trying to organize in the University, a course which provides more practice instead of so much theory. There is nothing against theory, but we need practical artisans in public health rather than higher trained experts. We trust that this course will be the means of meeting the needs of the State and possibly of the South. We feel that there is a great need and some agency should be developed to meet this need.

## HANDICAPS TO PUBLIC HEALTH ADMINISTRATION.\*

By ROY K. FLANNAGAN, M. D., Richmond, Va.  
Assistant Health Commissioner  
and  
Director Rural Health Work for Virginia.

### INTRODUCTION.

#### A LARGE OPPORTUNITY.

At the outset I would like to challenge the thought and interest of the medical profession in the public health field as a career. I would particularly direct attention to the tremendous need for health service in the rural districts of the South and to the large opportunity furnished by this need for the use and development of all the qualities that make for leadership.

While the administration of a city health department is by no means a sinecure, I am in position to know that every qualification desirable in a city health officer must be more or less intensified in order to win distinguished success in the country districts. For, while principles are the same, to achieve results every method of disease control must be simplified and adapted to widely varying geographical, cultural and social conditions.

The handicaps of temperament, training or lack of experience that tend to hinder the work in town will be found to be even more of a hindrance in the country. If, therefore, what I have to say to you seems to unduly exalt country work, please be informed that it is to the most needed, and, in many respects, the most attractive public health task that my mind reverts. I even confess to a lively hope that some of you who hear me will feel impelled to accept the challenge to take up rural public health work, involving as it does the lives and well being of the most worth while folks on the American continent. I have heard of medical missionaries for foreign shores: no more devoted service to God or to man

\*It is a pleasure to acknowledge our indebtedness to Dr. Williams and Dr. Flannagan for their advice and assistance.

\*Read by title at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

(synonymous terms as we all know) is possible than bringing to malaria ridden, hook-worm infested, typhoid fever and dysentery infected sections of our own Anglo-Saxon southern land the gospel of good health and the knowledge of how to secure it. For a sick body rarely houses a healthy soul.

#### KNOWLEDGE, VISION AND PURPOSE.

The chief factor in success in any business or profession is a knowledge of it. The more knowledge of what you are doing and where you are endeavoring to go, the better initial equipment you have. This is axiomatic. But with the highest equipment in knowledge of public health principles and practice and with the keenest appreciation of all of the implications wrapped up in the preventive idea, there have been conspicuous failures in the administration of public health departments—failures, not total perhaps, because no well planned work based on knowledge and vision is ever a total failure, but disastrous defeat and at least temporary retirement from the field with all the discouragement and loss of prestige that goes with being licked. There is an even worse aspect to it than this; a defeat in the public health field of activity, as in battle, actually means unnecessary loss of life.

It is to the causes that go to make up such defeat and the means of avoidance of them that I address myself at this time, for, to my mind, the pursuit and practice of "Preventive Medicine" offers the opportunity, and successful public health administration a goal worthy of any man's aspiration.

#### HANDICAPS.

Given then knowledge, vision, purpose, and a fair measure of honesty and industry, what are the things to be overcome, avoided or guarded against in the administration of the public health? I would name four as perhaps the most important:

1. Lack of sympathy with people,
2. Over confidence,
3. Stubbornness,
4. Impatience.

Over against these, on the principle of overcoming evil with good, I would place these four:

1. Love for man as man independent of his creed or condition,

2. Humility,
3. A spirit of give and take (teachableness),
4. Patience, and a faith that tomorrow will bring the fruit of today's planting.

*Lack of Sympathy.*—If there is one thing that might be said to absolutely inhibit success in public health work at its present stage, it is *Lack of Sympathy* with and for people as they are, which carries with it the inability to put oneself in the place of the other fellow. The quality of sympathetic understanding, which may be translated as *love* of your fellowman applied, is, I fancy, largely a matter of temperament in many cases, but it is more often a matter of training. In this connection I would like to quote a few verses from one of the later poems of Kipling—*A Pilgrim's Way*:

1. I do not look for holy saints to help me on my way,  
Nor male or female devilkins to lead my steps astray,  
If these be added I rejoice, if not I shall not mind  
So long as I have leave and choice to meet my fellow kind,  
For as we come, and as we go—and deadly soon go we—  
The people, Lord—Thy people, are good enough for me!
2. Then I will honor pious men whose virtue shines so bright—  
(Tho' none are more amazed than I when I by chance do right).  
And I will pity foolish men for woe their sins have bred—  
(Tho' ninety-nine per cent of mine I brought on my own head)  
And, Amorite or Eremite or General Averagee  
The people, Lord—Thy people, are good enough for me!
3. And when men bore me overmuch, I will not shake mine ears  
Recalling many thousand such whom I have bored to tears.  
And when they labor to impress, I will not doubt nor scoff;  
Since I, myself, have done no less and sometimes pulled it off.  
For, as we are, and we are not, and we pretend to be,  
The people, Lord—Thy people, are good enough for me!
4. And when men do me random wrong, as oftentimes hath been,  
I will not cherish hate too long (my hands are none too clean).  
And when they do me random good, I will not feign surprise,

No more than those whom I have cheered by  
wayside charities.  
But as we give and as we take, whate'er our  
takings be,  
The people, Lord—Thy people, are good enough  
for me!

5. \* \* \* \* \*

6. Deliver me from every pride—the Middle, High  
and Low—  
That bars me from a brother's side, whatever  
state he show.  
And purge me from all heresies of thought and  
speech and pen  
That bid me judge him otherwise than I am  
judged, Amen.  
That I may sing of Crowd and King and road-  
borne Company,  
That I may labor in my day, vocation and de-  
gree  
To prove the same in deed and name and hold  
unshakenly  
(Where'er I go, whate'er I know, who'er my  
neighbor be),  
This single faith in Life and Death and all  
Eternity,  
The people, Lord—Thy people, are good enough  
for me!

A man may be cold natured and yet by cultivating gentlemanly instincts and practicing courtesy to all and the discipline of listening to the other fellow and dexterity in trying to find a point of contact (even though it sometimes stretches the imagination beyond belief), or if this is impossible, the grace of silence—he may overcome and win success in the face of this natural handicap. Sympathy is a heart quality and may not be successfully simulated for long, but careful cultivation in this field, as in all others, brings fruit. Lack of sympathy is due to selfishness and the incurably selfish man or woman has no place in public health work, or in the practice of medicine for that matter.

Wordsworth says:

He whose eye is ever on himself doth look on *one*  
*the least of nature's works,*  
One, who might move the wise man to that scorn  
that wisdom deems unlawful ever,  
Be wiser, thou! Instructed that true knowledge  
leads to love,  
True dignity abides with him alone who in the  
silent hour of inward thought  
Can still suspect and still revere himself in lowli-  
ness of heart.

Small men are not needed in the field of public health. The naturally sympathetic more easily succeed, but a large souled man will overcome handicaps of personality as he does those of knowledge by study and practice.

*Over Confidence.*—Another important thing

to avoid is *Over Confidence*. A lack of confidence in oneself is a serious fault in an administrator, but to be *too cock-sure* and overweening in asserting one's superior knowledge is without doubt fatal to popularity, and few people weigh enough mentally to carry such an attitude successfully. I use the word popularity advisedly for the most important single thing that a health officer must do is to establish himself and his work in the public confidence, and a lack of humility at times will undo the effect of much conscientious work. Nobody ever personally likes a conceited man. His habitual attitude towards others thrusts them into the background and injures their self-esteem. He will be tolerated if he has ability, but will be gradually shut out from the social intercourse that gives the human contacts so necessary to sympathetic co-operation on the part of the public.

Teachableness, adaptability, and deference to age, custom, experience, and perhaps, prejudice, are traits that will go a long way towards smoothing the pathway which, under the most favorable conditions now existing, will still be thorny and rough. Get a clear view of the way to go and move steadily and with confidence forward, but remember always that "pride goeth before destruction and the haughty spirit before a fall," and—watch your step.

*Stubbornness.*—Another stumbling block in the way of successful public health administration is *Stubbornness* in the administrator. In every community there are so many unmistakable public health needs, so many flagrant departures from proper sanitary practice, and often so many actual disease breeding conditions in evidence, that the new health officer in a crusading spirit is greatly tempted to make his program for relief on the basis of these needs and then stubbornly "hew to the line, without fear or favor." I grant that on the face of it, pursuing such a course would seem to have much to commend it, but in most instances to do so means that the health officer will have to play a lone hand and thus rarely "gets by" with it.

A city or county government that appoints him and the organizations that have probably forced the government to act in health matters will loudly vociferate when he takes office that this hewing to the line is the thing to do, but they do not mean it for when

criticisms of the health department come by reason of what seem iconoclastic tendencies, neither of these groups can be depended upon to uphold the health officer. If he has consulted with them beforehand and adjusted his activities to the possible rather than to the eminently desirable, and has gained their approval, either tacit or expressed, to a course of action, he has cleared the decks and may then proceed with reasonable assurance of support. To some men such consultation with non-professional and untrained men and women is repugnant and it is very difficult for them to admit that the compromises often suggested have any merit whatsoever, and so they avoid embarrassing themselves with conferences and in their pride of opinion forge ahead. Few health officers with such a stubborn and unyielding spirit survive their first term in office. Far be it from me to suggest that having once decided upon a desirable course the health officer should give in when criticism develops: he would never get anywhere in that case. Having made his plans after due consideration, he should be firm in purpose and bold in action without truculence. The study of each large procedure contemplated and the gaining of it as complete a knowledge as possible of the elements of the problem from all angles, especially from that of the public (which presumably has become more or less adjusted to present conditions), is absolutely essential. If a board of health made up of people such as compose our town councils, our boards of supervisors, and our welfare committees, definitely oppose a contemplated course of action, it is seriously to be questioned whether the health officer can force the procedure, however desirable it may be, on the public at large. It may be wise to wait for a more propitious time, and turn his attention to the multifarious health activities that will command support. Many splendidly conceived programs are wrecked because it has not been possible to consummate them in the short term of a headstrong and stubborn health officer.

*Impatience.*—And this brings me to the fourth common obstacle to successful administration—*Impatience*. Each administrator of health should realize that he has entered upon a campaign, not simply a battle; he must fully appreciate that there will be many advances and many retreats, many sieges, much sapping and mining and propaganda work. The enemy

is entrenched behind custom and prejudice and careful planning is necessary to dislodge him. Before attacking, all available forces should be at hand, and the heaviest artillery in place. An ill-advised battle involving a frontal attack may mean the loss of the commander-in-chief, perhaps, a very heavy price to pay for impatience. The preventive principle can afford to wait. It clearly commands the future, so impatience and anger or ridicule directed at people who believe differently and who defend the sacredness of the ancestral dunghill or are sentimental over a fragrant draught from the old oaken bucket are unnecessary from a man who has already taught the children of the community to know the birthplace and the dangers of the housefly and has illustrated the handwashing possibilities of a wet well-rope. This teaching, like chickens, will come home to roost; just give it time, for education and time are on the side of prevention and Johnny and Mary grown up will take care of the manure pile and put a tight pump in the well if the old folks do not.

I would not have you get the idea that I advocate a waiting game exclusively, the health officer who is worth his salt is working all the time, for there is always plenty to do, but I would sound a warning against impatience and the execution of hastily conceived plans for reaching important objectives. Prepare for your fight and then go in to win with every ounce that is in you.

*Medical Self-Consciousness.*—In addition to the foregoing handicaps to successful administration of public health work, I would call attention to another which is a little difficult to describe in a word, but which may be defined as *Medical Self-Consciousness*. The whole trend of the training of a doctor and of his experience in the practice of his profession is toward developing this self-consciousness. The ethics of the profession forbid advertisement of his wares or work and the right-thinking doctor is, therefore, the more acutely sensitive to lapses on the part of others less scrupulous or less careful than he. This reacts on him and is apt to beget in him a species of self-righteousness.

The sense of his own importance is constantly enhanced by the reception without question on the part of his patients of his dicta and his orders in respect to their ailments. He is flattered by them and the doctor whom he

supersedes is damned, and all the littlenesses of human nature are in parade before him. It is not to be wondered at that he often becomes puffed up, self-centered and non-co-operative with his fellows and goes to the extreme in his demands upon them. This attitude along with the fundamental medical aim, the healing of the individual sick, is at the opposite end of the pole from the aims and practice of public health, and, however admirable it may be in part, it stands in the way of progress in public health administration.

#### DISTINCTIONS

The public health is paramount: private aims, personal feelings, dignity, tradition, and custom must retire in the face of public peril: i. e., pestilence or the threat of pestilence. The practicing physician is distinctly a private personage and his function is private. The well-being of the individual is his concern and the ills of his patrons are the business of no one but himself and them, except, in so far as the law and the public weal impose duties upon him in relation to certain of his cases. He is in fact the better doctor by reason of this personal attitude. It is the other way about with the public health officer. His business is public in every sense of the word, the individual counts for little with him, and he has nothing personally to do with treatment, though he does indeed at times bring to doctors and specialists the opportunity for great health service. His concern is not with the individual sick except as that individual is a menace to others. He will at times shut the sick one away from contact with his fellows without regard to what the ill person's feelings or his family's feelings may be in relation to the action. It is the protection of the public that engages his attention and no private viewpoint, whether of self or of the sick one, has any proper standing with him in his official capacity. (Even in this, however, he should not neglect to be human). Medical self-consciousness, therefore, must go to the scrap heap when the doctor becomes a public health officer.

#### PUBLICITY

The public must be fully informed as to what he proposes to do and be systematically apprised in detail of the successive steps taken in reaching the goal. The aid of everyone must be invoked in carrying out his purposes.

the department of which he is the head must, if possible, be made a household word, and the health officer must not fear to see his name paraded in the public prints. So long as the work for which he stands progresses and the rate of sickness and of death is steadily decreasing, considerations of dignity or of sensitiveness must be put aside.

#### SINGLE MINDEDNESS

And this brings me to the last point I wish to make. Successful public health administration demands a whole-hearted service. Either be a doctor or be a health officer. Do not try to be both at one and the same time. It cannot successfully be done; such an attempt will only lower the public health standard in your community, bring you into conflict with your professional brethren and in the end injure both interests for which you are attempting to stand. The profession of medicine offers a wide and enormously important field for the highest sort of service to humanity. The men who have won the heights in this, as in all other departments of human endeavor where social values are the measure of progress, are those who by their painstaking efforts and epoch-making discoveries freely given to mankind have brought millions within the circle of their benefactions.

The profession of Public Health offers, in my judgment, an even wider field for helpfulness to mankind. It takes the discoveries of science and translates them to the people at large in terms of health and life. Scientific truth shut within laboratory walls or within the comparatively small circle of even a great physician's contact means little for humanity. The public health officer with the service he creates and administers puts meaning and force into facts which otherwise would never, however important they are, find common application.

These two professions must go hand in hand: one is complementary to the other. If they ever seem to be antagonistic, if ever the physician observing the encroachments made by public health practice upon the formerly enlarging boundaries of his field of endeavor is tempted to place obstruction in the way, let him remember that he is but observing the growth of his own offspring and, as a father, his duty is to guide him, but also to speed him on. Then as disease diminishes and the dream

of the founders of modern medicine becomes an actuality, he can take this unction to his soul that to him and to him alone in the last analysis is due the consummation—a cleaner, healthier, and a happier world.

### THE VALUE OF DIPHTHERIA TOXIN-ANTITOXIN IN RURAL COMMUNITIES.\*

By WILLIAM S. KEISTER, M. D., Charlottesville, Va.

Director, Joint Health Department of Charlottesville, Albemarle County and the University of Virginia; Health Officer of Charlottesville.

I wish to thank you for the honor of being permitted to appear before you and discuss with you briefly some of the aspects of the value of diphtheria toxin-antitoxin in rural communities.

Although we now know the cause of diphtheria, its method of transmission, and its means of treatment and prevention, and have a test to determine one's susceptibility to it, yet much remains to be done before it is properly controlled. The general public must learn the importance of calling in the doctor as soon as suspicious symptoms appear, and cases of "sore throat" must not be regarded too lightly. The physicians, on the other hand, should give antitoxin promptly and when in doubt. The use of toxin-antitoxin, especially for children under school age, will be the means of producing a diphtheria-immune population in a few years, if taken advantage of by the general public.

This disease has been known since early times as accounts of it seem to have been mentioned in the Babylonian Talmud, and the Greeks believed it came from Egypt long before the time of Hippocrates. It was not until the years 1883 and 1884, however, that Klebs and Loeffler discovered the causative organism. The next great discovery in this disease came when Von Behring gave to the world diphtheria antitoxin. Although it was discovered in 1890, it did not come into active use until 1895. The influence of this discovery upon the death rate may be shown by the following results. The death rate in 1879-80 was 112.6 per 100,000; 1889-90, 97.8; and in 1899 it dropped to 45.2 and in 1918 to 13.8. In 1911 Schick published the results of his intracutaneous test and in 1913 demonstrated its

application as a practical test for immunity in the presence of exposure and gave simple means of testing for antitoxic immunity before and at intervals after injections of antitoxin.

"Von Behring on May 8, 1923, reported the early results of the injections of neutralized toxin in a small number of persons," but "he did not originate the mixture nor establish the fact that those who had no antitoxin, develop it." It remained for Park and his associates of the Bureau of Laboratories of the New York City Health Department late in 1913 to demonstrate the practical use of toxin-antitoxin injections controlled by the Schick test for the immunizing of children against diphtheria, and they "established the facts that the procedure was harmless and that after three injections about eighty per cent of those individuals possessing no antitoxin or insufficient antitoxin to protect from diphtheria, developed immunity."

In an article on "The Control of Diphtheria," by Drs. Wm. H. Park, M. C. Schroder and Abraham Zingher, of the New York City Health Department, which was read at a meeting of the American Public Health Association in Cleveland in 1922, the following very significant statement was made, which shows the need for some agent other than antitoxin to confer an active immunity upon the general population: "The fact that the improvement which continued for many years after the introduction of antitoxin has ceased and that in fact a few years ago diphtheria began to increase slowly in the United States made us appreciate that we had reached about the limit of what we could do with the old measures. It made us think seriously of using active immunization. This was with the hope of rendering the population permanently immune rather than of waiting for cases to develop and then trying to cure them and to prevent the further spread of the contagion." "Owing to the fact that diphtheria antitoxin is not a product of human cells but is made by the cells of the horse, it disappears gradually after injection from the human body, so that at sometime between two and four weeks, the antitoxin is dissipated and the immunity disappears." "Antitoxin has been most successfully used as a preventive in those who are in direct contact with cases of diphtheria, such as children in a family in which diphtheria has developed, or in institutions in which an out-

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

break of diphtheria has occurred. The only precaution necessary is not to give antitoxin as a preventive to children showing physical characteristics of status lymphaticus or giving a history of having had attacks of asthma."

According to the above observers, eighty to eighty-five per cent of deaths from diphtheria occur in children under five years of age. The United States census reports for the registration area for the years 1910 to 1914 show that 62.2 per cent of deaths from diphtheria, 95.2 per cent whooping cough, 80.6 per cent measles and 53.9 per cent scarlet fever occur under five years of age. Are not the above figures sufficient evidence to cause us to use every means to protect the dear little ones from these diseases? Unfortunately we have no adequate means of protecting them from the last three diseases but, by using diphtheria toxin-antitoxin during this early age period, many lives can be saved and a diphtheria-immune population produced. Park and his associates found in a large number of persons who were given three injections of toxin-antitoxin that "about eighty per cent of those individuals possessing no antitoxin or insufficient antitoxin to protect from diphtheria developed immunity." They also found that, with few exceptions, they retained the immunity over a period of six and one-half years. Many observers are inclined to feel that the immunity produced is permanent, at least observations of a large number of persons inoculated would indicate it. During two years in New York City since the use of toxin-antitoxin, the number of cases of diphtheria diminished twenty per cent and the death rate decreased from twenty to sixteen per 100,000. No doubt all the credit cannot be given to toxin-antitoxin but must be shared with the plain antitoxin which is now more generally used. In a comparison of 90,000 children inoculated with toxin-antitoxin and subsequently Schick tested, with 90,000 children who received no protection, it was found by Park that four times as many children developed diphtheria among the control cases as among the tested cases, although there were only fourteen cases of diphtheria among the tested children and some of these did not take the full series of three inoculations. It would seem that all Schick positive cases may become negative if a sufficient number of series of inoculations are taken. There are very few positive after one complete series of inoculations,

and it is rare to have a positive after the second series. Before six months of age the child usually has an immunity received from its mother, but Park considers it advisable to immunize all children between six months and six years of age with three injections of toxin-antitoxin, irrespective of the results of the Schick test. After six years of age (or even before), most workers give the preliminary Schick test (especially in urban communities), and later immunize the positive cases. It is advisable, where possible, to do a Schick test on all immunized persons in three months to a year or more after the toxin-antitoxin injections to see if the immunity is present. If the test is positive, another series of injections should be given. The toxin-antitoxin injections are given in a series of three inoculations a week apart, though it is permissible to give the first inoculation along with the Schick test.

In carrying out this work in rural communities, the problems met with are somewhat different from those of cities. Some of the difficulties met with in the country are: 1. Difficulties of transportation over poor road frequently and for long distances and often in bad weather, which make it necessary to make as few trips to a single school as possible. 2. Indifference of the public toward all public health measures, especially something new, and lack of sufficient co-operation, particularly when there is no imminent danger of contracting diphtheria. 3. Ignorance regarding disease and the use of sera, etc., and the difficulty in explaining the value of the Schick test and the use of toxin-antitoxin, and 4. The fear of local reactions as a result of the treatment. It is largely because of the above difficulties that we do not feel justified in Albemarle County in insisting upon a preliminary Schick test, even though such a procedure may be desirable and more scientific. Yet we feel that there is no contraindication to the use of toxin-antitoxin for everyone and can see no real reason why everyone desiring it should not receive it, even though some may already be immune. The writer has advocated its use by the physicians of the county since 1920, but it is only in the past year or so that it has been used extensively. Our own experience with it covers a period of nearly two years. During 1922 we gave 2,476 injections and in 1923 to date 294 injections making a total of 2,770 injections,

and without a single serious complication. At first the preparation used frequently gave some rather strong local reactions, which were temporary, especially in older children, but in the case of the new, less toxic preparation, the reaction has been practically nil. The latter result has aided greatly in securing the confidence of the children and carrying on the work. Each c.c. of the original preparation contained 3L + doses (120 lethal doses) of toxin and 3.5 units of antitoxin. The new preparation is made by adding  $\frac{3}{4}$  of a unit of antitoxin to 1L + dose (40 lethal doses) of toxin, and each c.c. contains  $1/10$ L + dose of toxin. In the case of either preparation, the dose is 1 c.c. for all persons over one year of age and  $\frac{1}{2}$  c.c. for those under a year. The local reactions when present are due to the autolyzed bacillus substance (protein), and the new preparation eliminates most of this. As a public health measure, the writer feels that the use of diphtheria toxin-antitoxin at the present time is even more valuable as a life saver and in the prevention of disease than the vaccination against smallpox, notwithstanding the increase in recent years in the prevalence of the latter.

To summarize briefly: 1. Diphtheria is a disease about which we know the cause, method of transmission, means of treatment and prevention and have a test to determine individual susceptibility, and yet the morbidity and mortality rates are entirely too high, largely due to (a) the ignorance of the public, and delay in sending for the doctor, (b) delay on the part of the physician in using antitoxin and in sufficient amounts and (c) serious complications and sequelae.

2. Antitoxin should always be used as a therapeutic measure when in doubt. It lowered the death rate from 112.6 per 100,000 in 1879-80 to 13.8 in 1918.

3. The death rate from diphtheria under five years, in 1910-1914, was 62.2 per cent of the total deaths from this cause in the United States. This is the period of election for the use of toxin-antitoxin, although the schools are more accessible for this work.

4. There are no contraindications to the use of toxin-antitoxin, and the protection derived from it appears to be permanent. It is now possible to bring up a diphtheria-immune population.

5. The writer considers it inadvisable to give the preliminary Schick test in rural com-

munities, as he does not feel that the advantages to be gained overcome the disadvantages.

6. The local reaction has largely been eliminated by the use of the new preparation.

#### DISCUSSION.

DR. P. K. GRAYBILL, Fincastle: I would like to ask Dr. Keister a few questions. I understand it takes from eight to twelve weeks to produce immunity. Suppose in that interval a child develops diphtheria, would toxin-antitoxin tend to lighten the case and prevent complications?

If a teacher in a primary grade develops diphtheria during school, should the pupils in that grade be given immunizing doses of antitoxin or toxin-antitoxin?

DR. M. PIERCE RUCKER, Richmond: Dr. Keister's statistics about mortality in young children confirm my opinion that obstetrics is the most important branch of medicine. The only way you can better these figures is for the obstetrician to take a hand. I have been in the habit of giving my patients weight cards. On the bottom of these cards I have printed: "Vaccinate child against smallpox at three months. Immunize against diphtheria at eight months."

DR. R. L. PAGE, Batesville: In connection with Dr. Keister's paper, I wish to report the results of the use of toxin-antitoxin in Miller School. Assisting Dr. Keister, we gave three hundred injections. I am glad to report that there has not been a single case of diphtheria in that institution in the older children—no signs at all. Usually before this, we had several cases in the Fall and Winter, but since then we have had none. I am very much pleased with results.

DR. W. H. RIBBLE, Wytheville: Something like fifteen days ago I had a case of diphtheria. A sister slept in the bed with the patient, the night before. I gave the sister prophylactic dose of antitoxin, and the patient 10,000 units. Ten days after this I sent swabs from both to Health Department for examination—the sister's was positive—the child who had diphtheria, negative.

DR. WM. S. KEISTER, Charlottesville: I am glad that I have stirred up some questions. However, some are right hard to answer. As I understand it, one of the chief drawbacks is that it takes from six to twelve weeks to develop immunity with toxin-antitoxin. We inoculated most of the children in Albemarle County at the time of a diphtheria outbreak. We have to ride a horse when he is ready. We urged the people to be protected before the school term opened. I wrote to the different teachers to please let me know if any would like to be inoculated before the Fall session. I received one letter in reply. It is very difficult to get the fullest cooperation from the school authorities and parents. The opportune time is when no diphtheria is present, but we feel, from a Public Health standpoint, that the time to do the work is when we can get the people to take advantage of it.

Out of twenty-seven hundred inoculations, one child developed diphtheria about ten days after the third inoculation. We do not guarantee that immunity will develop in that time. I believe that where children have been closely associated with cases of diphtheria, antitoxin is worth more. I do not think it advisable to inoculate a whole school because of the danger of anaphylaxis. It seems that when there is no diphtheria, people are not interested. I personally feel that it often takes some little time to develop immunity, but I believe that quite a few get

protection in less than the average six weeks. I have not had enough experience to tell whether toxin-antitoxin makes the case any milder, but I should think it would be milder. It does no harm to give toxin-antitoxin to those directly exposed to diphtheria.

In regard to the question of whether to give toxin-antitoxin or straight antitoxin, it is hard to say. We did a rather peculiar thing in Nelson County. Some of our Albemarle children were in school across the line in Nelson, and we considered that an excuse to go over.

Dr. Sizer, of Schuyler, had had experience with some sixty odd cases of diphtheria. These had run on for several weeks and the people were very anxious to open school. It was a question what should be done. We decided to "strain a point." We gave every child a prophylactic dose of one thousand (1,000) units of antitoxin. On account of the danger of anaphylaxis many of the physicians in Albemarle have hesitated to give it in this way. It is sometimes permissible, however, where physicians see the case every day and observe closely the other members of the family to wait to give them antitoxin until symptoms occur. In regard to anaphylaxis, some feel that desensitization is one way to get around it—giving about one-half c.c., waiting about fifteen minutes, giving another one-half c.c. and waiting fifteen minutes, then another, and waiting fifteen minutes, etc.

I am very glad Dr. Page said a word about Miller School. When a case of smallpox broke out we vaccinated every living soul, the laborers, pupils and others. Although there were marked symptoms of smallpox, not another case occurred and there has been none since. Every pupil was also inoculated with diphtheria toxin-antitoxin.

Throat cultures are examined by the Laboratory of the State Board of Health. A negative culture does not mean anything in diphtheria. If the physician has any idea there is a case of diphtheria, he should not wait for laboratory diagnosis. He should give antitoxin, then if the laboratory diagnosis confirms his opinion, he can pat himself on the back. I think the thing to do is to give antitoxin in five, ten, or twenty thousand units. Do not wait until the Board of Health confirms your clinical diagnosis.

### THE ROENTGEN RAY TREATMENT OF CERTAIN NON-MALIGNANT CONDITIONS OF THE UTERUS.\*

By A. L. GRAY, M. D., Richmond, Va.

Radiotherapy, including both roentgen and radium therapy, for deep-seated malignancy, whether of the uterus or other of the less superficial viscera, has been followed by some measure of success. While the newer methods of measurement of dosage and means of obtaining the desired depth dose are giving increasingly encouraging results, these results are still far from uniform and can not be predicted with even a fair degree of certainty.

There are, however, other conditions of the uterus which, though they may not present so hopeless an outlook for their victims, nevertheless may cause as complete disability, as intense pain and, unless subjected to the dangers and suffering of a major surgical operation, as definite a fatality as is usual in uterine carcinoma. In these conditions it can be safely stated that radiotherapy has proceeded beyond the experimental stage and may be classed as practically a specific.

The conditions referred to in the foregoing statement comprise uterine fibroids, uterine hyperplasia, as fibrosis of the myometrium, hypertrophy with or without hemorrhage; certain menstrual disorders accompanied by alarming systemic or nervous manifestations and idiopathic menorrhagia or metrorrhagia.

Shortly after the advent of the Coolidge tube I was called upon by Dr. Stuart McGuire to treat a lady with a uterine fibroid approximately the size of an adult head. This lady had been referred to him for hysterectomy, but the hemorrhage had been so profuse and of so long duration that her hemoglobin was too low and the blood volume so reduced that he declined to operate and resorted to various means to ameliorate her condition, but without material benefit. The tumor was irradiated through twelve portals by the intensive cross-fire method. Following the second series, an interval of four weeks having elapsed between the first and second, all bleeding ceased and the patient rapidly regained her blood supply. A third series was given, after which the operation was done successfully and an uneventful recovery ensued. The size of the tumor was also materially reduced.

Since this beginning it has been my privilege to administer deep roentgen therapy for fibroids of all sizes from the smallest palpable nodule to the size of a six months' pregnant uterus. In no case where the treatment was not interrupted by an over anxious patient or physician, has the result been other than the complete disappearance of the growth or its shrinkage to such an extent that it ceased to produce inconvenience and patient failed to return for further treatment.

As compared with surgery, I may summarize the advantages and disadvantages in the average case as follows:

\*Read at fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

## SURGERY.

1. Results obtained after total disability in a hospital and at home from 6 to 8 weeks.
2. Mortality risks and suffering incident to a severe major operation.
3. Results after complete recovery definitely permanent.
4. The usual nervous manifestations of the menopause may often be delayed by leaving a portion of a healthy ovary. This may, however, be followed by cyst formation and a subsequent operation may be necessary.
5. Opportunity afforded to examine tumor for malignancy.

## RADIOTHERAPY.

1. Results obtained gradually in 12 to 24 weeks, with no disability that did not previously exist.
2. No mortality risk nor suffering, except a transient nausea and slight malaise in 50% of cases.
3. Recurrences may arise in a small percentage of cases requiring further irradiation.
4. In large fibroids it is difficult or impossible to cause a disappearance of the tumor without destroying the ovarian internal secretion.
5. No such opportunity except in sub-mucous fibroids.
6. The economic advantages are markedly on the side of radiotherapy.

In the second class of cases in which there is no definite tumor present, but where a hyperplastic condition exists, often attended by severe menorrhagia or a persistent metrorrhagia, unless there be some other accompanying lesions, as ulceration, polyps or malignancy, a definite cure may be expected in two to four series of treatments. A case illustrative of this class is as follows:

Mrs. S., w. f., age 49, multipara, referred by Dr. W. L. Peple, had been having severe menorrhagia for the last several periods. Hemorrhage profuse and continuing with only a few days' cessation between the periods. Weak, anemic and nervous.

Pelvic examination by Dr. Peple revealed a uterus three times its normal size, hard and fibrotic. Roentgen radiation was administered through four ports of entry, cross-firing on the uterus. Bleeding ceased and did not return after first treatment, but, with a view to producing a complete menopause, two additional series were given at four weeks' intervals. Following her third treatment she was returned to Dr. Peple for another examination. He reported that the uterus was then about normal in size, possibly slightly smaller than the average, was freely movable and showed

no abnormality. There has been no recurrence since her discharge one year ago.

Illustrative of the third class: Mrs. Y., w. f., age 42, nullipara, was referred by Dr. Stuart Michaux, on account of menorrhagia, dysmenorrhea and a reflex or nervous vomiting that seriously threatened her life from emaciation and exhaustion. Her menstruation continued at regular intervals with slight improvement, until three series of treatments had been given, after which it ceased. A fourth series was administered in order to insure a permanent menopause.

Patient has continued to improve, but has always been of a neurotic type. There has been no return of the former trouble since the last treatment, five months ago.

In women, during the child bearing period it is possible in many instances to re-establish a normal menstruation rather than produce a complete cessation. That this may be accomplished even in the presence of a fibroid is shown in the following case:

Miss W., age 22, had abandoned her employment as a secretary, on account of severe menorrhagia, which had caused confinement to her room and bed for a considerable portion of the preceding six months.

She was referred by Dr. Stuart Michaux with a diagnosis of a small uterine fibroid. Four series of roentgen ray treatments were given before menstruation ceased, but none was given thereafter. Menstruation was stopped for two months only, after which it returned and has since been entirely normal. Examination by Dr. Michaux showed a complete disappearance of the fibroid.

As to the after effects on patients in whom a premature menopause has been produced, the results as compared with surgery are about the same. In my own experience I have observed that there are as a rule fewer and less intense reactions the nearer the patient's age approaches the normal climacteric and in younger women I have thought that the manifestations were of a lesser degree when stoppage was more gradual. Authorities agree that the treatment in no way affects sexual desire or gratification.

In conclusion, it seems that there are distinct fields for both surgery and radiotherapy in the treatment of these non-malignant conditions. Surely it would be unwise to await

the slow action of radiotherapy in any case in which the delay would be detrimental to the patient: as for example in alarming hemorrhage, possible early malignancy where a cure might be effected by a surgical removal, or where a total disability already exists in a patient who is a good surgical risk. Perhaps it is better to remove by myomectomy small subperitoneal fibroids in women during the earlier child bearing period, but in other cases falling in the three groups before mentioned there seems to be abundant evidence to prove that radiotherapy is the preferable procedure.

Since the effects of radium and the roentgen rays are so nearly identical the choice will depend upon the physical factors. Radium introduced into the uterus produces its effects more promptly, but control of the dosage is probably more difficult with radium than with the roentgen rays, and there is also added the risk of the surgical procedure required for its introduction.

The importance of a correct diagnosis can not be too strongly stressed. Where failure has resulted it will perhaps usually be found that some unrecognized complication has existed.

300 *Medical Arts Building.*

### MESENTERIC TUMORS.\*

By JULIAN L. RAWLS, M. D., F. A. C. S., Norfolk, Va.

I am lead to report these two cases of mesenteric tumors because of the apparent rarity of this class of tumors. The latest reports that I can find record about two hundred cystic tumors of the mesentery and only one hundred solid tumors. I am inclined to think that there are a good many isolated instances of mesenteric tumors that are not on record, either because the operator did not think them of sufficient importance to justify reporting them or else because of unfortunate results.

However, Dr. Edmund L. Bartlett, of the University of California Hospital, reporting cases of mesenteric cysts, states that for over a period of five years in one thousand five hundred and seventy-two (1572) laparotomies only two cases of mesenteric cysts have been seen at the University Hospital. He also states that "In none of the instances reported was the clinical diagnosis correct and for the

most part the true condition was not even suspected."

Carter, writing in *Surgery, Gynecology and Obstetrics* in November 1921, reports a case of mesenteric cyst in a young Indian girl operated on for appendiceal abscess. He also states that no reported case has been diagnosed previous to operation.

Keen's *Surgery* states that mesenteric cysts belong to the rarities of surgical observation, though they seem to be four times as common as solid tumors of the mesentery.

The cysts may be serous, chylous, hemorrhagic, dermoid and echinococcic. The solid tumors may be lipoma, sarcoma, carcinoma and fibroma, fibroma being the least common.

Ewing states that chyle-angioma of the mesentery is a cavernous lymph-angioma containing milky fluid which arises from congenital or acquired obstruction of the lacteal vessels.

As we have seen, the accurate diagnosis is almost impossible before operation. If seen early, before they have reached a large size and before inflammatory changes have fixed them, we should have a movable tumor without very severe pain. Wilensky states that the free mobility of the tumor is the most important single symptom and that, if in addition it can be demonstrated that the intestine maintains a fixed position to the tumor and is movable with it through several examinations, a presumptive diagnosis of mesenteric tumor is justified. A barium series with pictures taken with the patient in different positions might throw some light on the subject. At times they may cause obstruction by pressure or a twist in the mesentery. This, of course, is a surgical emergency and the obstructive symptoms overshadow the original symptoms.

Two methods of treatment are suggested for the solid tumors, enucleation or resection of the bowel with removal of the tumor. One of four methods may be tried with the cystic tumors, enucleation, resection of the bowel with removal of the tumor, incision and drainage and marsupialization. Aspiration certainly has no place in the surgery of today.

Vance states that the operative mortality is high. The twenty-seven cases which he collected had an operative mortality of 41%. Wilensky states that resection adds to the operative risk and should be avoided if possible. He goes on to say, however, that in

\*Read by title at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

those cases where the overlying intestine is centrally placed and a tumor bulging both leaves of the mesentery equally, or if the growth is adherent to the gut at its wall or involved in the process, resection should be resorted to at once.

With this rather brief survey I wish to add two more cases.

CASE I. John Horn, thirteen years old, school child.

C. C. Painful mass in lower right side of abdomen.

F. H. Father died with rheumatism. Mother died suddenly during pregnancy. One brother and two sisters living and in good health. No T. B.

P. H. Measles and pertussis. Influenza 1920. In 1918 he had an attack diagnosed as appendicitis. He was in a hospital for two months. He developed a mass in his right lower quadrant which was treated by electricity.

P. C. Ever since this attack four years ago, he has had some pains in his abdomen. He has not vomited but food gives him cramps. His pain is worse at night. He is obstinately constipated. He is very active when not having pain in his abdomen. He was taken to the King's Daughter's Clinic where he was seen by Dr. Lawrence Royster and referred to me for operation.

Physical Examination: Well nourished and well developed white boy, apparently not very sick. Head negative. Pupils react normally to light and accommodation. Tongue clean and moist. Teeth in good condition. Neck negative. No palpable glands. Chest negative. Heart and lungs normal. The abdomen is negative except for rigidity and tenderness on right side, most marked in lower right quadrant. There is a suggestion of a mass around his appendix which is tender on pressure. External organs of generation normal except for phimosis. Both testicles are in the scrotum. Limbs are negative. Wassermann negative. Urinalysis negative. White blood count 6500.

Diagnosis: Probably tuberculosis of the caecum.

At operation a firm hard mass was found occupying the mesentery of the lower ileum. It was firmly attached to the bowel and movable with it. The intestine was clamped on either side and the intestine and tumor were

removed with a cautery knife. Before an anastomosis was made, it was seen that one end of the gut did not have sufficient blood supply to take care of it and a further resection was necessary. Then an end-to-end anastomosis was done, a chronically inflamed appendix was removed, and the abdomen was closed in layers without drainage. The following day his condition was not satisfactory, he was vomiting bile, and his pulse was rather rapid. He was given a gastric lavage and a large amount of dark brown fluid returned. After that his convalescence was uneventful except for a superficial infection of his wound which added to his stay in the hospital. He was discharged on his twenty-fourth post-operative day, with the wound practically healed.

The following is a report of Dr. Roche of the tissue sent to the laboratory: "The tissue consists of mesentery with loops of small intestine forty-four cm. in length and another piece of intestine fourteen cm. in length. Occupying the mesentery is an indefinitely outlined mass involving the wall of the mesentery at one point. The mass has a grayish, roughened external surface with raised yellowish nodules scattered here and there over the external surface. On section through the center of the mass, the cut surface has a dark red spongy consistency, showing many dilated and cystic vessels from which milky fluid mixed with blood exudes. Appendix sixteen cm. long, external surface smooth, meso-appendix very fat, lumen filled near distal end with fecal masses. On section, mucosa for about two cm. from proximal end appears normal. From this point to the distal end there is a marked hypertrophy of the mucosa which is covered by a hemorrhagic exudate.

"Frozen sections of the mesenteric tumor show dilated lacteals and lymph spaces. The lymphatics surrounding the tumor show a simple hyperplasia. Diagnosis: Chyle or lymph angioma."

CASE II. B. S. Colored woman. Age 21 years. Married.

C. C. Pain in lower abdomen on both sides.

F. H. Negative.

P. H. Negative, except that in 1919 she had an abdominal operation by a colored physician for "ovary trouble," and has not menstruated since. She has been married five

years and has had one full term pregnancy, no miscarriages.

P. I. Began three months ago, gradual onset with pain in both sides of lower abdomen. There has been intermittent nausea and vomiting ever since the onset. She states that she has lost thirty-five pounds in weight in the last three months. She has been constipated ever since she has been sick. A physician was called to see her who told her that she had a "pus tube" and needed an operation.

Physical Examination: A well developed but rather poorly nourished colored female. Weight one hundred pounds. Head and neck negative throughout. Chest negative, heart and lungs normal. Abdomen—operative scar in mid-line. There is some abdominal distention, with tenderness and rigidity over the lower abdomen. A mass the size of a cocoon is felt above the symphysis. On vaginal examination the cervix is normal and the stump of the uterus can be made out supravaginally. Tubes and ovaries are not palpable. There is nothing in the cul-de-sac. The limbs are negative, reflexes, normal.

The most probable diagnosis, recurrent ovarian malignancy.

She was operated upon May 17, 1922. The omentum was found adherent to the stump of the cervix and broad ligament. The uterus, both ovaries and tubes had been removed at the previous operation. On freeing this adherent omentum, the tumor was found to lie between the layers of the mesentery of the lower segment of the ileum, with several centimeters of the ileum densely adherent to it. The gut was clamped on each side, burned through, and the tumor removed. It was found that in removing the growth it had been necessary to sacrifice about fifteen centimeters of the mesentery on each side. This free intestine without sufficient blood supply was amputated with a cautery and an end-to-end anastomosis completed the operation. The abdomen was closed without drainage. Very little blood was lost during the operation but the patient had a fair amount of shock and was given fluid subcutaneously several times during the next forty-eight hours; after that her convalescence was uneventful. She was discharged from the hospital on June 5th, twenty days after her operation. Shortly before leaving the hospital she complained of pain over McBurney's point and developed some tenderness and rigidity of

the right rectus. She had a slight acceleration of the pulse rate and a leucocyte of 14,000 but no rise of temperature.

Following is the pathological report of Dr. Roche: "The tissue sent to the laboratory consists of a large irregular mass in the mesentery, 18 by 18 by 16 cm. External surface rough and irregular. Center of mass is oval shaped, hard, and resembles a uterine fibroid. Extending entirely over the mass, passing over the top and down either side, crossing in front at the lower edge of the tumor is a loop of small intestine. The lumen of the intestine is free except on top of the mass where the attached surface has ulcerated through and formed a fistula ending in a cavity in the tumor mass. The cavity is filled with a foul smelling substance made up of undigested food, blood clots, etc. Whole partly decomposed strawberries can be made out. The cavity is about 12 cm. in depth and communicates on either side with the lumen of the small intestine. On section the wall of the hard central mass is composed of loose white fibrous tissue showing few blood vessels. Lining the cavity is a smooth glistening surface resembling mucous membrane but is more firm. Parts of the cavity show a rough granulated surface with a purulent exudate and much hemorrhage surrounding it. Microscopically the lining of the cavity showed no evidence of mucous membrane. Two small pieces of small intestine showed marked congestion, otherwise normal. Altogether 90 cm. (about three feet) of small intestine were resected. Frozen sections made from the lining of the central mass and parts of the wall showed fibromatous tissue similar to fibromata found in the uterus.

"Diagnosis: Fibroma of the mesentery, adhesions of small intestine to the mass, necrosis and ulceration of intestines.

"The question of a diverticulitis with resulting inflammatory change has to be considered. This seems hardly probable since the mass lay entirely within the leaves of the mesentery and the cavity was not mucous lined and the sections showed fibroid tissue with few blood vessels."

The first tumor has been classified as a cystic tumor but it was not a true cyst as solid tissue predominated and the mass resembled very much a sponge.

142 Main Street.

## OVARIAN CYST WITH REPORT OF AN UNUSUAL CASE.\*

By J. COLEMAN MOTLEY, M. D., F. A. C. S.,  
Abingdon, Virginia.  
Surgeon to Johnston Memorial Hospital.

A certain element of surgical romance will always be associated with ovarian cysts because of the pioneer work of Ephraim McDowell. Our whole experience in the realm of abdominal surgery had its beginning in the first ovariectomy by this fearless doctor. During recent years mammoth tumors of the ovary have been quite rare because of the very simple reason that they fall into the hands of a surgeon and are removed before they attain great size.

Histologically, the very large cysts are usually cystadenomas that arise from the remains of Pfluger's tubes or the Wolfian body. Cystic tumors that arise from the Graafian follicle usually do not grow to large size.

In 1922, J. W. Ward reported a cyst weighing 221 pounds. Unfortunately his patient died one hour after the removal of the tumor. Ward reported from a review of the literature five cases weighing more than 225 pounds, viz: Binkley 225 pounds; Tuffier 235 pounds; Bullitt 245 pounds; Barlower 298 pounds; and the very remarkable case of Spohn in which he estimated the weight of the tumor at 328 pounds. Four other cases of more than 200 pounds are recorded, twenty-nine weighed more than 150 pounds and seventy-eight more than one hundred pounds.

Dr. J. S. Horsley, in 1911, reported the successful removal of a cyst weighing 116½ pounds. In 1900, J. B. Bullitt (quoted by Horsley) collected from the literature up to that time twenty-two operated cases of ovarian cysts weighing more than one hundred pounds. Bullitt reports the case operated on by A. M. Cartlege and himself, weighing 245 pounds, to which reference has already been made. This case died from intestinal obstruction one week after operation. Of the twenty-two cases reported seven died, a mortality of 32%, so it can be readily seen that these patients are relatively poor surgical risks.

In the case I wish to report the tumor is rather small compared with some which have been recorded, but the condition was unusual

in my experience and I hope the brief history of the patient will not be without interest:

Mrs. D. H. D., case No. 7713, age 51, admitted to Johnston Memorial Hospital May 11th, 1923, complaining of an abdominal tumor of 25 years' duration. One paternal aunt had a similar tumor. The family history was otherwise negative. The patient has always enjoyed good health. She has suffered with considerable constipation in recent years on account of the pressure of the tumor. Had a severe illness 32 years ago, which was probably typhoid. A mild attack of influenza during the first epidemic. She had a prolonged cough during the past winter and has had nasal catarrh for many years. Appetite and digestion always good. No urinary symptoms. Married 31 years; five children, 3 living and well; two still-births. Passed her menopause three years ago.

*Present Illness*—About 25 years ago the patient first noticed that her abdomen was beginning to enlarge. Seventeen years ago she was examined by a physician who told her that she had a "sac of water" in her abdomen. The tumor has been gradually increasing in size until the past winter when she became practically helpless because of the weight and pressure. Six or seven years ago there was a sudden decrease in the size of the tumor until she was almost normal in the waist-line, but the tumor soon began to enlarge again. She

suffered considerably with shortness of breath when the tumor suddenly disappeared. She feels well now except for the burdensome weight of the tumor and the obstinate constipation. She states that at times she "belches up gall."

*Examination*—Patient is a woman of small

\*Read at the meeting of the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

frame, good color and healthy appearance. Eyes, head and mastoids negative. There is an atrophic rhinitis. There are no teeth except a few snags and roots. Temperature and pulse normal; blood vessel walls soft. Blood pressure, systolic 165; diastolic 95 mm. The heart is pushed upward by the abdominal tumor so that the apex beat is in the fourth interspace 9 c.m. to the left of the midsternal line; the heart is regular, has a good muscle tone and there are no murmurs. The chest is negative, except for the bulging out of the rib margins by the abdominal tumor. There is a moderate anterior curvature of the lumbar spine, probably due to the weight of the tumor. Abdomen: occupying the whole abdomen is a huge, symmetrical tumor. The distance from the superior to the inferior pole is 43 inches; from side to side 46 inches. The tumor is smooth and tense but cystic in character, and there is a distinct fluid impulse on one side when tapped on the opposite side. Pelvis: the uterus can be felt pressed down behind the abdominal tumor. Blood count: W. B. C. 8,200; polys. 87%. Urine: albumen slightest visible trace, with two to four r.b.c. to the high power field, a few bacteria, otherwise negative. Impression: mammoth ovarian cyst.

On May 12th operation was done. A low right para-median incision was made. The cyst was found to be adherent to the entire anterior parietal peritoneum. A small nick was made in the cyst wall, a large rubber tube was thrust into the cyst cavity and the fluid

contents syphoned off into a barrel. The opening in the wall was then closed, the cyst dissected free from its dense adhesions to the abdominal wall, its pedicle ligated, and the sac removed. The abdomen was closed with a gallon of hot salt solution left in the cavity. A considerable quantity of the cystic fluid was spilled while the tube was being placed in the sac for syphonage. What was collected, with the cyst wall, weight 107½ pounds.

The day before operation the patient weighed 240 pounds. Two weeks following the operation her weight on the same scales was 105½ pounds.

Her post-operative course was fairly uneventful except that for about a week she had a relative paresis of the intestines and her bladder was retentive. The bowel paresis was followed by a few days' incontinence, and following this there were several days more of alternating constipation and diarrhoea.

In a personal letter, dated August 21st, the patient writes: "I can say I am thankful to tell you all that I am getting along just fine. Feeling better than I have for several years. I will soon be strong enough to do all my house work. I now weigh 125½ pounds."

#### BIBLIOGRAPHY.

### HOW DOES RADIUM PRODUCE ITS RESULTS?\*

By A. P. JONES, M. D., Roanoke, Va.

The underlying principle that abnormal tissues are more readily affected by the rays of radium than are normal tissues is now universally recognized, and forms the starting point for all radium therapy.

This simple statement, however, is entirely too vague, too much of a "glittering generality," to satisfy the inquiring mind, or to furnish a measure of the effects of a given dosage. Many investigators have, therefore, made studies of the histological picture presented by tissues which have been exposed to the rays of radium.

A recent case of my own demonstrated very nicely the sequence of events after treatment with radium, and suggested the title of this paper.

The patient, Mrs. J. W. P., aged 55, was

\*Read at the meeting of the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

first seen on February 22nd, of this year. At that time she had on the outer surface of the right thigh an elevated nodule about the circumference of a dime, not pigmented, but with a history of recent rapid growth. A gross diagnosis of epithelioma was made and radium applied. At the end of a month, though decreased in size, the growth was still evident and treatment was repeated. Two further treatments were given and finally, on August 1st, not satisfied with the progress made, I excised the growth with the cautery.

Study of frozen and paraffine sections showed the following interesting features:

At first glance the feeling was that a mistake in diagnosis had been made, as the whole field seemed to be filled with fibrous tissue. Closer study showed, however, occasional, widely separated clumps of definite epithelial cells, completely cut off by the encircling strands of connective tissue. These epithelial cells were of the type seen in an ordinary squamous celled epithelioma, four to twelve in a group, and very evidently degenerating. The cell outline was irregular, the cytoplasm small in amount, and the nuclei irregular in staining and vacuolated. In a word, what we have is an epithelioma undergoing fibrosis and this shows a late stage of the process.

In looking up the literature, especially as quoted in Simpson's "Radium Therapy" (C. V. Mosby, 1922), one finds that the sequence of events following the application of radium may be divided into two distinct stages. The first we may call the Stage of Destruction, and the second the Stage of Repair.

In the Stage of Destruction, the curious and interesting feature is that the effect is delayed for a period of two or three to ten days, in marked contrast to the immediate result of cauterization. Microscopic study shows that the elements of this tissue most affected are the nuclei of the epithelial cells which rapidly begin to go to pieces, and a little later on the injury to the capillaries and the invasion of the polymorphonuclear and mononuclear leucocytes is observed.

Soon the fibroblasts make their appearance and with them is instituted the Stage of Repair, which goes on, as we have seen, to a replacement of the original growth by fibrous tissue.

The similarity of the process to the familiar phenomena of inflammation and repair by

granulation tissue has been recognized by all of you.

It becomes evident, then, that the penetration of the radium rays, and the correspondingly wider zone of affected tissue, constitute the only real difference between the reaction to radium and the familiar picture of inflammation and repair.

*Jefferson Hospital.*

## SUBACUTE BACTERIAL ENDOCARDITIS IN CHILDREN.\*

By W. C. CAUDILL, M. D., Pearisburg, Va.

That subacute bacterial endocarditis is more common than was formerly thought is evidenced by the many recent reports of various observers. The fact that it is commonly met with and difficult of recognition is my object in presenting this paper.

I prefer to speak of this condition in children, not because the etiology, pathology or clinical course of the disease is so different from the same condition found in adults, for it is very much the same, but because I feel that due emphasis has not been given this grave malady in childhood. However, it is not as frequent in children as adults, which is probably due to the fact that it arises for the most part in individuals who have had previous inflammation of the heart valves with permanently damaged leaflets, or is engrafted upon a congenital heart lesion. Clark, in a recent article in the *Journal of the A. M. A.*, has dwelt entirely upon this latter phase of the disease and states that in children, in whom both congenital and acquired cardiac affections are frequent, it is surprising, as Cautley has pointed out, that bacterial endocarditis is not more common than it is. In my opinion, the congenital heart lesion is one of the most important predisposing factors of subacute bacterial endocarditis in children.

The exciting organism is usually the streptococcus viridans which Aschoff suspects is a modified pneumococcus. The Bacillus diphtheriae, however, as well as the staphylococcus, meningococcus, the pneumococcus, the Bacillus coli, the Bacillus anthracis, the gonococcus, and other organisms, have been found in some cases in the absence of the streptococcus.

Subacute bacterial endocarditis should be considered to be of secondary origin in all cases. The avenues of entrance of the infecting agent

\*Read at the meeting of the Southwestern Virginia Medical Society at Abingdon, September 6 and 7, 1923.

are numerous. The blood is furnished with the specific organism from any source to which infection may be carried and from which the blood current is infected. The essential point to remember is that the condition is the result of a bacteremia and the source of infection be determined if possible. An effort should be made to determine the specific organism by repeated blood cultures, but it is unfortunate from the bacteremic point of view that blood cultures are so often sterile in malignant endocarditis. Smith says, "Certainly they seem to be more uniformly negative in the early period of the disease, at the very time when they could be of the most value in diagnosis and in treatment, than they are later in the condition when the patient is desperately ill."

I have already mentioned that this condition is difficult to recognize, and this is especially true in the early stages of the disease because in many cases the purely cardiac symptoms are in the background and the first thing that calls our attention to the heart is embolic manifestations.

Billings in 1909 reported a series of fourteen cases and stated that in one patient the symptoms began two years before the real condition was recognized. One case began fourteen months before a definite diagnosis was made. Another patient probably suffered from the disease for more than two years, and in the early part of the illness, the diagnosis of typhoid was made for a condition which was, in all probability, infectious endocarditis, the diagnosis having been based on the fact that there was fever and splenic enlargement.

Yet of the various forms of endocarditis in children, the subacute bacterial type presents the most definite clinical picture. The disease may be insidious or precipitate in its onset. It is usually insidious and for weeks or months the child may not appear to be very ill. The chief complaint may be slight headaches, gastro-intestinal symptoms, painful joints or pains in the left upper quadrant of the abdomen. The fever is continued over a long period of time and is usually of comparatively low grade, though it may reach 104° to 105° and is irregular and remittent in type. Leucocytosis is practically always constant and is an important aid in diagnosis. There is progressive weakness and emaciation with marked pallor and anemia. The spleen is usually enlarged, palpable and tender. Painful cutaneous nodules may be found upon the hands and feet.

Clubbing of the fingers may or may not be present. Erythematous and petechial rashes are common and chills and sweating are usually present during some stages of the disease. Embolism may cause the most diverse manifestations, among which are embolic pneumonia, delirium, coma, hemiplegia, monoplegia, and central derangements of vision and hearing in consequence of implication of arterial branches in the brain or meninges. There may be pain in the lumbar region and bloody urine from infarction of one or both kidneys, resulting in a glomerulo-nephritis.

Now add to this clinical picture the knowledge of the pre-existence of a heart lesion, either congenital or acquired, and if these symptoms are kept constantly in mind, it seems to me that a diagnosis of subacute bacterial endocarditis should be made certainly within the first few weeks of the disease, even though the blood cultures and cardiac findings are negative. I wish to report the following case:

History: H. S., a girl, aged seven. Congenital heart lesion was discovered a few days after birth. Father suffers from angina pectoris. Mother has had more or less rheumatism all of her life. Five sisters, all living and in good health; no brothers.

Patient had a severe attack of diarrhea at nine months of age. Had measles and another attack of diarrhea at age of three. Had an attack of pharyngeal diphtheria in November, 1921; 15,000 units of antitoxin was given and patient made an uneventful recovery. The heart showed no signs of distress at any time during or following the attack, and the blowing systolic murmur, which had been present since birth, remained practically unchanged. The tonsils remained hypertrophied and injected until tonsillectomy was done in November, 1922. Another attack of diarrhea occurred in February, 1923, and from this time on the patient did not feel very well.

The active symptoms of the present attack began in March, 1923. The patient had a slight epistaxis, also diarrhea, and complained of headache and soreness over abdomen, which was intensified over the splenic area. The temperature ranged from 100° to 102°, and was always higher in the afternoon. A provisional diagnosis of typhoid was made in spite of the fact that the blood count at this time was 12,000, but was later ruled out by a still higher leucocyte count and two negative

Widals. The temperature continued an irregular, remittent course, being almost normal for a few days only to recur again. The patient was bright and did not seem very ill. Leucocytosis remained constant and reached as high as 36,000. Gas and slight soreness of the abdomen was still present and an increasing degree of pallor could be noted. Kidney intoxication in some form was next considered most probable. The urine showed slight albumen, a few red cells, and a few hyaline and granular casts. There was no clubbing of the fingers, no petechiae, and no painful nodules in the hands or feet. Endocarditis was suspected but a positive diagnosis was not made until the latter part of June, when a typical attack of embolic pneumonia occurred. The pneumonic process cleared up after about ten days and the lung remained clear until August, when there was a second attack similar to the first. Since June an increase in the transverse diameter of the heart has been noted as well as frequent changes in the character and intensity of the murmur. The course has been steadily downward with increasing weakness, pallor, and anemia. For the past few weeks hematuria has been more or less constant. The temperature curve remains the same. There is still no clubbing of the fingers and no petechiae. At present the patient is in a state of extreme emaciation, complete anorexia, rapid pulse, mild delirium, and the end is not far off.

No blood cultures were obtained in this case on account of the profound nervous irritability of the patient; but I do not doubt for one moment that she is dying from subacute bacterial endocarditis.

NOTE:—The patient died September 8, 1923.

### INFLUENCES AT WORK ABOUT THE INFANT.\*

By DANIEL M. MOORE, M. D., Stonega, Va.

Man is the superior being of the animal kingdom. He heads the list as the most intelligent, has the highest state of mental development and towers over all others and uses them to serve his purposes in his various pursuits. But this is man in his adult life. Where does he stand at birth? The frog distributes her eggs in some quiet waters and

goes about her business, the ostrich lays her eggs in the sand to be hatched out by the sun, the young calf can walk at birth and has intelligence to know the source of its food supply, while the house cat comes into this world with its eyes closed and is cared for by its faithful mother until it can better care for itself. But of all helpless and dependent creatures the human infant heads the list. Ascend the scale of animal life and notice how nature, as she increases the intellect, also increases the responsibility of the parent to care for the offspring! This responsibility rests heavily on the human race. Nature has endowed the lower animals with an instinct for self preservation in many respects that man has to learn by experience and transmit to his offspring by precept and example. The young squirrel or monkey knows what foods are suitable and what are poisonous. Consequently, they do not have to contend with a string of diseases that come as a direct result of indiscretions of early life. If mortality statistics were available among lower animals for the first year of life, they no doubt would show a sad reflection on the intellect of man, however high his state of enlightenment may have attained. We, no doubt, have gone far astray from nature's way in caring for the young and it is up to us to get back to nature's way if we are to measure up to the responsibilities that she has placed upon us. What influences are we as physicians bringing to bear toward the betterment of the offspring of the present day generation? Are we not responsible to a degree for this wandering away from nature's way? Let us consider for a while some of the influences that are at work about this little tender piece of humanity, the infant; and surely there is nothing in this world more susceptible to influences.

Some one has said that "The life history of the individual depends upon three great factors, viz; heredity, environment, and the will." Since we are dealing with the infant primarily, of course the last named, the will, has not come into play yet as far as the infant itself is concerned, but we may bring influences to bear on that life that will enable the will of that infant later on in life to help the next generation in a variety of ways.

Every human being has a multitude of ancestors representing as many lines of life which in the end go to make up a heritage that

\*Read before the Wise County (Va.) Medical Society.

is indeed complex. The influences along these lines are as numerous as the sands on the sea shore and too appalling for finite mind of man to comprehend, but we shall consider them only as to how they may be applied to the present generation and thereby improve the heritage of this and succeeding generations. Every human organism has a threefold existence, namely; the ante-conception, the antenatal, and the post-natal. In the ante-conception period there are of course two separate and distinct germ cells upon which these hereditary influences play their important role. Have we stopped to think of the influences we are wielding on preconceived life in our every day battle with diseases? Isn't our mission, while primarily aimed at the relief of human suffering, most vitally concerned with improving the heritage of those yet unborn? Are we not missing the opportunity of our lives for leaving the world better by having lived in it when we lightly pass the buck on the present day venereal question? A heavy toll has been exacted by this grim monster not only in the death rate but in stunting and dwarfing the bodies and minds of those that are cursed by its influence. The tubercular question also gets in its work not so much by direct inheritance but through its tendencies. Alcoholism has done its share toward breaking down the heritage of multitudes. These great national movements along these lines have as their ultimate object and aim the improvement of the present generation and the heritage of succeeding generations. Venereal prophylaxis has a great future ahead of it and it will succeed in so far as the medical man is willing to lend his aid in educating the youth of the land to the terrible effects that follow in the wake of his experimental youth. They put a light regard on these matters and who but the medical man has the opportunity to impress the seriousness of these affections not only upon the youth himself but his posterity after him? Eugenics will come to its own in the no great distant future and will no doubt exert a very beneficial influence along these lines. Therefore the great bulk of hereditary influences must be applied to the present generation in order to be beneficial to the next. The influences that may be brought to bear on antenatal life are not so numerous, but none the less important. The obstetrician here comes in for a large responsibility as respecting the

child, for his care should begin with conception and extend up to and include the delivery of the child. It is up to him to keep that mother in as sound mental and physical health as possible in order for the child to be healthy. Maternal impressions, however much these may be ridiculed, we are bound to admit exert a tremendous influence on the child *in utero*, and the mother's mental state should be under constant supervision.

Granted now that we have a normal healthy newborn babe and a normal healthy mother. Heredity has, as far as this child is concerned individually, done its work, and from now on it is to be a struggle with environments. We are all more or less familiar with these environments and what a struggle the little fellow has if he is to survive. We shall not recount these struggles and their effects but suggest some influences that may be brought to bear on this little life that will tend to increase the child's chances in this struggle. The average present day mother has very little knowledge of the duties and responsibilities of motherhood and it is precious little that the schools and colleges are doing toward instructing the future mothers. She realizes her handicap and is as apt and eager a pupil as you will find in any school. Are we going to leave her to pick up a smattering knowledge from some old experienced though misguided mother that has raised a dozen scrawny children? Take a little time and give this mother some fundamental principles on which she can build. Tell her the importance of a well regulated life and diet for herself, make her promise you that she will nurse her child every three hours and no more, tell her how to bathe the baby and what clothes are suitable for the time of the year, the importance of fresh air, etc., and if you have gained her confidence your time will have been well spent for she will take in more than you might give her credit for. Make yourself available to her as an information bureau and do not permit her to repeat the follies of some older mother and learn in the bitter school of experience what she might have learned from you had you only taken a short time for that purpose. Some day this mother will be the old mother in that community and she in turn will be instructing other mothers and we perhaps have started a stream of influences whose scope and end we do not know.

Great things have been accomplished in the last few years in the way of artificial feeding of infants. Many infants owe their lives to these accomplishments but, however great they may be, they are being abused, and we should take care that they are not turned into a curse. The breast fed infant has a chance on life that is worth two or possibly three of that of the artificially fed infant. Cases are few and far between in which a mother is totally unable to breast feed her infant. Jacobi, who has just recently passed to the great beyond, once said that "There is no such thing as a non-lactating mother." The supply may be inadequate and it may be necessary to supplement the supply with some artificial food but do not allow a complete substitution because of this fact alone. The most despicable failure of all failures is the mother that fails to nurse her child when there is no valid reason why she should not, unless possibly it be the doctor that permits such practices to accommodate some fashionable or lazy mother. We must take care that these benefits that have been derived from the advances along these lines are not offset by the series of disadvantages that will naturally follow if these practices are carried beyond the field for which they were primarily intended.

The chief business of the infant is to grow and develop and it is our business to see that every influence is brought to bear upon both parent and child that will produce the strongest tendencies toward bringing this about. We need to emphasize the fact that an infant is not a play thing to be disturbed and fussed over by every one that comes near it, but that it must be kept quiet and surrounded by clean fresh air. Cold dry air is not such a curse as the average mother thinks and short exposures to it each day do a great deal toward raising the child's resistance to disease. It is during these sudden changes in the temperature about a child with a low resistance that various diseases gain their entrance and bring about their deadly work. Study the mortality curve during the twelve months of the year and you will find that it reaches its peak during the hot months. There are two main reasons for this; the depressing effect of excessive heat (the same results can be brought about by too much clothing), and the favorable conditions present for the growth and proliferation of pathogenic bacteria in and about the child. Much

can be accomplished toward this end if we can educate the mothers to the importance of regulating the heat and cold about the infant. They are extremists in these matters and if we can instill a little rational procedure into their minds we may save the lives of a great many babies, and at the same time pass the effect on to the next generation.

The acute infectious diseases reap a great harvest each year from the infants in the first year of life. Many infants have given up their lives as a result of some mother's indifference in exposing them to these diseases with the thought uppermost in mind of "letting them get it and get through with it." Let us impress the importance of protecting these little tender lives from these affections, at least until they are more able to withstand the onslaughts that accompany these acute diseases, and our reward will be the saving of many lives as well as the health of many individuals. We should make an attempt to teach the parents the seriousness of these affections and show them how much better chance the child will have if it is kept away from these until later on in childhood.

As you have probably already noticed, I have attempted to bring out the importance of the doctor as an educator as well as a healer in his dealings with the infant. It is up to us to take these matters seriously in hand if we are to keep up with the times along the line of prophylactic medicine which is just now beginning to come into prominence in medicine, but will be the field to receive the greatest amount of attention in the future.

#### THE CARE OF TUBERCULOUS PATIENTS WITH REFERENCE TO THE PRE- VENTION OF GIVING THE DIS- EASE TO OTHERS.\*

By J. B. NICHOLLS, M. D., Catawba Sanatorium, Va.

The purpose of this paper is to present to you briefly some measures whereby the tuberculous patient may be rendered safe to other people with whom he may come in contact.

All of us realize that tuberculosis is spread from one person to another either through ignorance or carelessness. With the number of people who are dying from tuberculosis in Virginia from year to year, we can readily

\*Read at the meeting of the Southwestern Virginia Medical Society in Abingdon, September 6 and 7, 1923.

see that we have many cases of tuberculosis with us all the time which are a menace to other people, and especially to those with whom they are daily living. Past experience has shown that a tuberculosis sanatorium is a safe place in which to live; and the object of sanatorium treatment is not only to teach the patient how to recover as far as possible, but to teach him also the necessary precautions to carry out in order to prevent giving the disease to others. I would not consider a tuberculosis sanatorium a safe place in which to live, if some measures were not practiced in order to render the patient safe, so far as protecting those around him is concerned.

The adult is less susceptible to the repeated infections of the tuberculosis germ than is the child. The measures I am going to present to you offer protection to people of *all* ages, but I wish to lay special stress upon the protection of children. The heavily infected children of today will make the tuberculous patients of tomorrow. The individual, who may be spoken of as the "careless" consumptive, may give the disease to anybody of any age; and he is a source of great danger to those who have not reached adult life.

In order to prevent tuberculosis, we must certainly consider—along with the other well known principles of proper regulation of life and habits—the *destruction* of the germs which are being thrown off from the tuberculous in the expectoration and cough.

The following directions carried out carefully, in disposing of the discharges and the things that come in contact with the discharges from the patient, will prevent others from getting heavily infected and from the probability of developing the disease.

The "open" case of tuberculosis, which is expectorating bacilli from time to time or all the time, should be separated to a certain extent from the other members of the family; he should be made to see that it is necessary that he sleep alone and in a room alone; that it is dangerous to have any one else in the room with him; that it is very necessary that children be kept out of his sleeping room day and night; and that he should have as little furnishings in the room as possible to make it comfortable, but that he should have all the light and ventilation that is available. It is better still for him to have some arrangement

for sleeping out of doors on a porch, in order that he may be removed from the confinement of a room, thereby lessening the chance of the room's becoming heavily infected. He should have separate dishes to eat and drink from, and they should be boiled for ten minutes each time after using them. All articles of food which are left after meals should be burned.

Teach the patient that it is dangerous for him to expectorate promiscuously and that he should have sputum cups in which to expectorate, and that they should be burned after using them. Sputum cups may be obtained at very little cost.

The spray emitted by the cough ejects fine particles of mucus from the mouth and respiratory tracts, and the germs of tuberculosis are found in the fine droplets. Cover the mouth and nose with a handkerchief or paper napkin when coughing and sneezing. Especially should this matter be emphasized as a precautionary measure when the patient is in a house and in close contact with other people.

Let the tuberculous mother know that she is spreading a heavy infection and that she will eventually cause the child to have tuberculosis, if she does not carry out carefully these precautions. The child should be taken away from the "open" case of tuberculosis, if possible; but I realize this will hardly be possible in a number of cases.

Stop the promiscuous kissing of children by grown people. The child should *never* be kissed in the mouth and not at all by the tuberculous.

Everything that comes in contact with the tuberculous patient should be sterilized by boiling—or should be burned if not of any further use. The soiled bed clothes should be kept separate and boiled. The person who waits upon the patient should wash his hands after handling the patient or after handling anything that comes in contact with the patient. Keep the fingers and other objects out of the mouth. This is a thing we all should do whether attending the sick or well.

Any sputum which has been spilled on the floor should be wiped up with a rag which has been soaked in a 5% compound cresol solution. Then pour on more solution and let it stand for an hour on the place where the sputum was spilled.

The bed-ridden case should be isolated as far as possible, and only adults should be allowed

to visit the room. In many cases of this type there is an involvement of the intestines and urinary tracts. The "stools" and urine of such cases should be handled just as carefully as those of typhoid cases. Disinfection may be carried out in these cases by adding to the excreta an equal quantity of 5% cresol solution, or a 3% chlorinated lime solution and letting it stand for four hours.

The disinfection of a room after the removal of a patient should always be carried out carefully. Rubbish should be burned. Linen and all washable things should be wrapped in a clean sheet and boiled. Woodwork and furniture should be scrubbed with either a 5% phenol preparation or a 3% chlorinated lime. The walls should be refinished where possible, and wooden walls should be scrubbed as the other woodwork is treated. There should be no carpets or rugs in the room which can not be properly disinfected afterwards or burned. Follow this by opening the room to ventilation and to the sunlight for a period of at least a week.

Patients who do not cough or expectorate at any time are not of any real danger, provided they have been instructed to use the simple precautions of keeping their fingers and other objects out of their mouths, and of keeping the hands clean, and of not using the same drinking cup or eating utensils.

If we physicians will make a real effort to teach people how tuberculosis is spread from one person to another, it will not be a hard task to get them to use these simple measures of prevention. They should be made to realize that the responsibility rests upon them, after they have had the proper knowledge of the spread of the disease. Let us all remember that the so-called "careless" consumptive *is* dangerous; but that the person who has tuberculosis and who has been instructed properly *is not* dangerous, so long as he carries out these precautions.

#### DIAGNOSTIC CONSIDERATION OF THE GONOCOCCUS AND OTHER DIPLOCOCCI IN CHRONIC URETHRAL INFECTIONS.\*

By THOMAS V. WILLIAMSON, M. D., Norfolk, Va.

The common staphylococcus, growing on the urethral mucous membrane, may take on a

diploid form and be Gram-negative. It may be identical in size and shape with the gonococcus and, when it is associated with a history of Neisserian infection, it may be, and frequently is, mistaken for the gonococcus. Indeed, a positive history is not imperative for this mistake to occur. The laboratory detects this degeneration form of the staphylococcus in disturbances of the genito-urinary mechanism, both in children and adults in whose record no history of gonorrhoea whatever may be traced. It is a frequent occurrence to find organisms in chronic urethral, prostatic and seminal vesicular discharges which, when treated with the basic aniline stains alone, cannot possibly be distinguished from the gonococcus. The micrococcus *catarrhalis*, an infrequent and mildly active inhabitant of the urethra, is also Gram-negative. Thus, it is clearly evident that, in the class of cases under consideration, a positive diagnosis of gonorrhoea cannot be made with uniform accuracy when either the basic aniline stains or the Gram method are the sole criteria. The case history, the complement fixation test, and culture, plus the microscopic findings, are the essential elements upon which the diagnosis should rest.

*The Case History.*—The first few minutes of association with a patient enables the examiner to arrive at a fairly comprehensive opinion of what findings may be expected in the case. Subsequent examination often reveals the fact that the inference drawn from a detailed history is conclusive and correct.

A history of an acute infection, following recent exposure, clearly indicates a pure gonorrhoeal invasion. But the physician is riding to a fall, if he relies on the history and physical findings alone for his diagnosis. He must find diplococci in the discharge in characteristic numbers, grouping and staining reactions before he can safely say that a given acute urethritis is gonorrhoeal. Instances of typically acute urethritis occur in which gonococci can never be found. However, this contingency does not frequently obtrude itself into the diagnosis.

This is one extreme. The other extreme presents itself in those cases wherein an infection has persisted for a long time. The longer an infection has lasted the less possibility there is that gonococci will be found. It is rare, indeed, to demonstrate their presence after a

\*Read at meeting of Seaboard Medical Association of Virginia and North Carolina in Newport News, Va., December 6-7, 1923.

lapse of three years. They usually disappear in much less time than that under careful, adequate treatment. The time limit of three years may be relied upon with a fair amount of certainty. Both laboratory and clinical experience vouch for this conclusion. A recent series of fifty cases of chronic urethritis giving a reliable existence history of over three years, were subjected to culture, complement fixation test, and microscopic examination in this office. In none of them were gonococci found. Therefore, a true history of infection time is of paramount importance.

In those infections occupying an intermediate position between the two extremes, the history also plays a decided role. The unwary may slip up here; while the alert examiner, if his investigations follow the direction pointed out by the history, will clear up many puzzling cases. For example: A patient presents himself with a story of recurring attacks of acute urethritis without fresh exposure. Between the attacks, he is apparently rid of gonococci since none can be found by ordinary examination. Granting that the history is reliable—and in spite of an ingrained propensity in these patients to lie, it is always an excellent practise to do this—an intensive diagnostic study is in order. Repeated provocative therapy to the urethra, prostate and seminal vesicles may set up a reaction on the part of the culpable micro-organisms which permits easy recognition by the laboratory. Negative microscopic findings from a single examination should not be conclusive. Especially is this true if the complement fixation test is positive. Repeated examinations will often succeed where a single one fails. In any case, the history should be given equal rank with the other elements entering into the complex.

From this brief dissertation on the case history, it will be seen that the following conclusions may be made:

(a) A history of acute infection following exposure points with fair certainty to a gonorrheal invasion.

(b) A history of an infection dating back three years or more indicates, almost conclusively, that gonococci no longer exist.

*Complement Fixation Test.*—The complement fixation test is a modification of the Wassermann technique in which a gonorrheal antigen is substituted in place of the syphilitic preparation. It was first employed in 1906 by

Meüller and Oppenheim for the diagnosis of arthritis. They found that it gave a positive reaction in the gonorrheal type of the disease. Swartz and McNeil<sup>1</sup> later applied the test to all forms of the disease.

Briefly, the findings with the test are as follows:

(a) That the results are negative in the first few weeks of a Neisserian infection, due to the fact that sufficient antibodies have not been developed within the blood to induce a positive phase.

(b) That the blood gives a positive reaction after the first few weeks when the gonococcus is undoubtedly present.

(c) That a positive reaction is sometimes obtained in cases apparently clinically cured when all other tests fail to detect the presence of gonococci.

(d) That the test is sometimes positive for weeks or months after clinical cure, by reason of the fact that the system is slow to eliminate the antibodies which gave rise to the positive phase.

(e) That, when a short time has elapsed after clinical cure, it is uniformly negative.

The conclusions arrived at by the pioneers with the test have been abundantly substantiated since that time. They are quite striking and it is rather remarkable that this laboratory procedure has not been more universally employed by the profession. The conclusions are:

(1) A positive reaction, except within the narrow limits described above, is indicative of a focus of infection remaining in the body and is sufficient ground to refrain from pronouncing a cure, to interdict intercourse, and to prohibit marriage.<sup>2</sup>

(2) The gonococcus fixation test is of undoubted value in chronic gonorrheal infections.<sup>3</sup>

(3) A non-gonorrheic does not give a positive complement fixation test.<sup>4</sup>

(4) Positive culture is more certain evidence that an infectious lesion persists than a positive fixation test. Nevertheless, the practitioner will be wise to rely more upon the complement fixation test than upon any thing else for the diagnosis of gonorrhea.<sup>5</sup>

The chief value of the test to the clinician is: (a) The ease and certainty with which unpolluted specimens are obtained. This is not true of culture.

(b) To establish or rule out the presence of gonococci when other means are doubtful.

(c) To determine if an infection is a recurrence or not. Should a specimen, taken within three weeks from the time symptoms appear, be negative, the disease is of recent origin. Should the reverse be true, a recurrence may be suspected.

*Culture.*—Ever since Bumm (soon after its discovery by Neisser in 1879) succeeded in growing the gonococcus on artificial culture media, the technique has been difficult to carry out and variable in result. A positive culture is, of course, absolute proof of gonorrhoeal identity. However, the organism is so frequently mixed with other bacteria which tend to obscure it, or kill it in the test tube, and it dies so quickly at a temperature but a few degrees above or below that of body heat, that uniformly accurate results are not achieved by culture. Therefore, a negative return is not conclusive evidence that the urethra or adnexa do not harbor the pathogerm.

The value of culturing the urethral discharges is not confined to the gonococcus alone. There are the Gram-negative micrococcus catarrhalis and the involution or pleomorphic forms of the staphylococcus to contend with. In contradistinction to the gonococcus, which grows only upon specially prepared food, these bacteria thrive luxuriantly on most ordinary culture media. The staphylococcus, in the presence of albumen,<sup>6</sup> may be either Gram-negative or Gram-positive. Its variation in size and shape sets the practitioner an impossible task to distinguish it from the gonococcus under the microscope with diagnostic certainty. Martin, of Norfolk,<sup>7</sup> has shown that these confusing diploid forms of the organism will, on repeated culture and subculture, revert to the true coccus shape and be consistently Gram-positive.

It must be remembered that the micrococcus catarrhalis, rather infrequently inhabits the urethra and its appendages. It is troublesome when it does appear but, fortunately, this is not often the case. It is entirely different with the degeneration types of the staphylococcus. They abound there much more freely and are a major source of uncertainty and perplexity when a positive opinion as to definite etiology is desired. It is a great relief to have culture methods clear up this maze.

It would seem that by causing the staphylo-

coccus to revert to type, culture renders its most valuable service.

The writer is inclined to believe that, in many instances, bacteria resembling the gonococcus under the microscope, but which fail to grow as such on culture media, are merely the diploid forms of the staphylococcus to begin with. Instead of diplococci they show as cocci on the culture plate. There is then a reversion to type from pleomorphism in a single culture, no reculture being necessary to identify the staphylococcus. It is quite probable that culture of the gonococcus is much more reliable than it is credited with being, and that the masquerading staphylococcus, through its inconsistent impersonation, is often responsible for the apparent failure of culture for the former organism.

*Microscopic Findings.*—In the early frankly acute stages of gonorrhoeal urethritis, a positive diagnosis can be arrived at with a reasonable degree of certainty from microscopic findings alone. The organisms are quite numerous, characteristic in intracellular grouping, true to diplococcic form, unassociated with other bacteria, and respond without variation to fresh staining reagents. The discharge is composed principally of polymorphonuclear leucocytes which evidence an active phagocytosis.

As the severer symptoms fade and wane into the declining stages of inflammation, the microscopic picture rapidly changes. Leucocytes diminish in number, phagocytosis is less active, desquamated epithelial cells and mucous filaments appear, and other bacteria become identified with the morphology.

Normally, the urethra harbors an infinite variety of bacterial flora, which is not pyogenic until an avenue of entrance is created for it. The gonococcus opens the gate by passing between the epithelial cells, thus causing a loosening and desquamation thereof. Then the parasites, awaiting without, pass in and become pyogenic. They seem to be more virulent and aggressive, and more resistant to germicides than the gonococcus; eventually, they appear to be the sole survivors in the urethral feeding ground. The morbidity then consists of a secondary infection supplanting or following a primary gonorrhoeal implantation.

For the most part, these secondary organisms do not take on the microscopic characteristics of the gonococcus. This observation does not

hold good with the micrococcus catarrhalis or the pleomorphic types of the staphylococcus.

The catarrhalis is a true Gram-negative diplococcus but, as a rule, it is not near so numerous as the gonococcus and is much larger. It is a bold outstanding bacterium. It is clean cut and sharply defined. Careful focusing will reveal a faint halo around the gonococcus which tends to make its outline less sharp than its prototype. The gonococcus is usually clumped in small groups while the catarrhalis is more generally disseminated throughout the field. The catarrhalis is not intracellular. From the verbal picture, the distinguishing points are clear. Nevertheless in chronic discharges, where leucocytes are few, where phagocytosis is feeble, and where the gonococcus is swollen in degeneration stages, the inexperienced microscopist may become confused.

The staphylococcus may be both Gram-negative and Gram-positive in the same specimen. In shape, it may range from the round coccus to the coffee bean diploid form; while in size, it may vary widely in the same seemingly irresponsible manner. This helter-skelter behavior is what makes the staphylococcus so confusing since somewhere in the great range of variation, it may be about the size and shape of the gonococcus and be Gram-negative. Under such conditions the finger of suspicion naturally points to the staphylococcus, but culture and the fixation test are needed to prove its definite identity.

To the writer, the most striking point in the visual detection of the staphylococcus is its apparent affinity to epithelial cells. It is strongly attracted to them. It appears in greater numbers around or superimposed upon these flat cells than elsewhere in the specimen. When thus situated, it seems to be more uniformly diploid than when it is free or entangled in mucous shreds. In many chronic urethral discharges the only organisms observed will be seen resting on epithelial cells.

Therefore, in such discharges, where there is a considerable percentage of epithelial cells; where there is an absence of true phagocytosis; and where the majority of diploid organisms rest upon epithelial cells, the evidence is strongly presumptive that the staphylococcus is the offender. Indeed, this is a practical certainty.

Thus we see that, in the finer points of diagnosis, the subject of chronic infections in the

urethra is rather complex. In dealing with them, the physician would be terribly handicapped if the facilities of the modern laboratory were denied him. Can we wonder then that, in the years gone by, there should have been a generous measure of misconception regarding their etiology? Professional observation of the disease inevitably leads to the conclusion that the vast majority of those who have suffered a gonorrhoea have happily married and that from the union no evil consequences have resulted. We know that when there is a transmission of the disease there is also, if the truth be known, almost invariably, a history of recent infection in the partner transmitting it. No prudent man is willing to say how long the gonococcus does or may survive in the male urethra, but experience, plus the aid of the laboratory, gives us the courage to say that when clinical signs of the disease are gone, the danger of transmission is past. An intelligent and unremitting co-operation between the clinician and laboratory expert certainly relieves the gonococcus of much of the odium once attached to it and places the blame at the door of the rightful perpetrator of the trouble—a trouble, which, although it cannot be transmitted to others, may do an immense amount of injury to the genito-urinary mechanism of its possessor.

The necessity for correct knowledge of the etiology of urethral inflammations cannot be overstressed. These morbid processes affect a function which has a vitally important bearing on the happiness of the human race. Dr. Paul B. Barringer says that "the reproduction of species is the goal of individual existence." Since this is so, it follows naturally that a disease which hinders the performance of this function is a distressing calamity. It may prove to be a calamity in two ways. Should a superficial examination fail—as well it might—to reveal the presence of gonococci, the ensuing consequences would be a sad commentary on the carelessness of the practitioner, when the sum of their far-reaching effect is totaled. On the other hand, should an organism masquerading as the gonococcus be mistaken for it, the effect on the patient himself is not pleasant to contemplate. Nothing is more demoralizing and devitalizing to manhood than for an individual to believe that he is a gonorrhoeal carrier and may remain so for years.

I recall four referred cases in my own work which may serve to illustrate this point quite forcibly to medical men. Two were doctors; two were dentists. All four had had a gonorrhoea at some time in life. Slight urethral catarrh yet existed. They desired to marry but dared not do so because diplococci, which has been confused with the gonococcus, had been occasionally found in the urethral smears. An intensive laboratory study succeeded in ruling out the gonococcus. Marriage followed with no consequent regret.

In conclusion, it is safe to say, that nowhere in the broad field of medicine is exact knowledge of the etiology of disease more imperatively essential than in the manifestations dealt with in this article.

### FOCAL INFECTIONS.\*

By FLETCHER D. WOODWARD, M. D., Newport News, Va.

The title Focal Infection should really grace a comprehensive monograph, but I will make no such attempt. If I should be able to give you a brief resume, and serve to freshen your memories and stimulate the search for them as a cause of disease, I will be content.

In attempting a definition, I will say Focal Infection is a broad term—meaning a circumscribed point of infection, causing remote tissue involvement, not by continuity or contiguity, but by the lymph or blood stream due either to absorbed bacteria or bacterial toxins.

The most frequent sites are the teeth and tonsils, in which locality pus, under pressure by mechanical means of chewing and swallowing, creates diffusion into the blood stream. Other less frequent sites are nasal accessory

sinuses, ear, intestine, gall-bladder, appendix, kidney pelvis, seminal vesicles, prostate, uterus, cervix and lymph nodes; others have been reported and still others are yet to be added.

The type of infection most frequently found in some member of the hemolytic streptococcus group or streptococcus viridans, probably because these bacteria are such poor antigens that immunity, if produced, is transient, according to Rosenow. The symptoms caused by these infections are legion and when one goes through the literature of reported cases he is tempted to add to the old adage about syphilis—know focal infection in all its manifestations and you will know medicine. Its study is rapidly changing our ideas as to many forms of chronic diseases, and at the same time making the phrase “etiology unknown” appear less frequently in our text books.

Recently, C. P. Jones<sup>1</sup> reported a clear cut case of “Interstitial Keratitis Due to Apical Abscesses” and, while we all know that syphilis is the cause in the vast majority of such cases yet there have always been cases in which it could not be proven, but focal infection is not mentioned as a possible cause even in our most recent texts.

It might be added here that in all of these types of diseases in which focal infection might play a role we should not stop our search even when syphilis or some apparent cause is found—even in acute appendicitis, gastric ulcer, acute pancreatitis, etc. Our duty has not been fulfilled until a thorough search for them has been made and eradicated, if found.

Realizing that preventive medicine is our ultimate goal, we must constantly search for, and correct these infections from infancy through old age, as our one greatest weapon in attaining this goal. Clinical studies have furnished proof that they are present in a high percentage of the sick, and removal was followed by improvement in general health or cure of the disease present, at which time we have frequently noted an immediate exacerbation of the systemic condition, which is significant of causal relationship, followed by improvement or cure. There are also many cases in which removal has had no effect. These are apparently due to the fact that the secondary processes are themselves acting as foci.

Autogenous vaccines made from bacteria in the original focus will help in this type of

\*Read before the Walter Reed Medical Society, Yorktown, Virginia, October 10, 1923.

case, but here again we also find them of little value at times—perhaps due to the fact that fibrosis has gone on to such an extent that antibodies are unable to reach the focus.

E. C. Rosenow has perhaps done more than any other man to bring our attention to this subject and, while his experiments are often harshly criticized and his results questioned, one need only to review his work to become convinced of his sincerity and the correctness of his conclusions.

He<sup>2</sup> has produced elective localization experimentally in endocarditis, appendicitis, gastric ulcer, cholecystitis, rheumatic fever, erythema nodosum, herpes zoster, myositis, etc., and in these experiments localization has occurred more often in the specific organ than other tissues in the body. These results have all been verified.

He has also produced gall stones and renal calculi in 87% cases in dogs following devitalization and infection of teeth with strains isolated from cases of nephrolithiasis. These conditions he<sup>3</sup> considers hematogenous because the lesions in cholecystitis, ulcer of stomach, pancreatitis and appendicitis, in early stages, are often sharply circumscribed, hemorrhagic, and situated in mucosa, submucosa, or peritoneal coat, with no evidence of diffuse involvement of mucous membrane, while experiments to produce gastric ulcer by feeding bacteria are unsuccessful, and also failure to produce cholecystitis when injected directly into the lumen of the gall-bladder.

Since streptococci in teeth and tonsils may have elective localizing power, he places them in the front rank of importance as sources of hematogenous infection.

It has been observed repeatedly that acute attacks of the above diseases often follow exacerbations of infection in sinuses, teeth, or tonsils, hence these sources should always be looked for as a routine procedure and, when found, infection about teeth eliminated first. Ulrich has reported that 68% of all artificially devitalized teeth have apical abscesses.

The view of many obstetricians is that foci of infection predispose to eclampsia, abortion and ill health of the foetus. It is borne out by Rosenow's experiments and A. H. Curtis,<sup>4</sup> who reports, that streptococci associated with spontaneous abortion in women tend to lodge in uteri of pregnant rabbits and produce abortion. This view was also advanced by Samuel

Downing<sup>5</sup> who says that focal infection is a probable cause of breast abscesses, pyelitis, abortion, nephritis and eclampsia in pregnant women. All pregnant women at the Mayo Clinic who present signs of dental or oral sepsis are subjected to full mouth roentgenograms.

The kidneys are frequently diseased as a result of focal infection. W. J. Mayo<sup>6</sup> says acute nephritis is often due to toxin, not bacteria, from foci in teeth, tonsils, gall-bladder, duodenal ulcer, etc., and especially is this true in those cases of acute nephritis going on to chronicity. He does not believe though that true Bright's is due to this cause.

The hematogenous kidney infections, must be differentiated from the above. Here we have the result of a bacteriemia, not toxins with the possible sequelae of infarcts, perinephritic abscesses, pyonephrosis, calculi, pyelitis, etc. The source of infection here is from distant foci.

C. H. Mayo,<sup>7</sup> speaking of causation of kidney stones, says the infection theory seems the only tenable one to him, but he contends the development of stones requires two factors of infection, i. e., two types of bacteria, one producing a hematogenous infection, and one only coming from some local focus, perhaps only momentarily inhabiting the blood stream; these factors in the presence of mucoid material produce stones, which is analogous to the production of stone in infected gall-bladder, tonsils, etc.

Bumpus and Meisser<sup>8</sup> say that pyelonephritis may often be due to focal infections, harboring streptococci which have a selective affinity for the urinary tract.

We must also bear in mind that pyelitis once developed may itself act as a focus, because India ink injected into the pelvis of a dog's kidney can be recovered in remote tissue, so why not the absorption of bacteria and bacterial toxin?

Eradication of foci should play a big role in the prevention of cardiac diseases. It has been estimated that 180,000 people died of heart disease in the United States last year, and that 200,000 school children have heart lesions today. It is my impression that about 2% of the children admitted to the Manhattan Eye, Ear and Throat Hospital in New York for tonsillectomy, and examined by me, had heart lesions.

Robert Halsey, of New York, says that organic heart disease in children aged five to nine years causes more deaths than any of the so-called children's diseases except diphtheria; it also has a higher death rate among children than pulmonary tuberculosis.

Maurice Lewison<sup>9</sup> says that, in heart block and paroxysmal tachycardia, foci of infection should be carefully looked for, and that the importance of infection as a factor in cardiac failure is too frequently overlooked, and the generally accepted theory of back pressure and cardiac strain should be abandoned in most cases.

As for the thyroid in its relation to focal infection, Stuart McGuire<sup>10</sup> said recently: "While we do not know much about the etiology of exophthalmic goiter, it is a fact that the condition follows frequently some acute disease, and is maintained by a focus of infection. Before beginning treatment of any case the teeth and tonsils, and other possible sources of poison should be determined, and eradicated, if found." He cites one case of severe thyroid toxemia which was completely cured by the extraction of four abscessed teeth, along with supportive treatment.

Crile says that in general 50% of goiters are apparently arrested after removal of any infection, whether it be tonsils, teeth, sinuses, etc., and, in those cases where symptoms persist after operation, it is due to leaving too much thyroid or failure to remove the focus.

Frequently goiter patients date their onset to attacks of tonsillitis and remark that their condition is aggravated during such attacks. I have seen two cases in which acute thyroiditis followed acute tonsillitis.

There is less evidence in the literature of the intestine acting as a focus than teeth, tonsils and sinuses, but we all know it is a frequent source and, when we consider that it contains approximately six hundred times as much lymphoid tissue as the pharynx, one reason is apparent, and also since definite strains of streptococci may be recovered from sinuses or tonsils and also from the stool, it shows us that these masses can become infected.

There are also many cases in which the less frequent sites mentioned at the beginning of this paper have been a cause, but we will not consider them at this time.

I have chosen for this paper the most frequent sites for focal infection, and some of

the least considered, but most serious of diseases produced by them, because we are all more or less familiar with the well worked out relation to arthritis, acute rheumatic fever, iritis, etc.

It is interesting to note that I was able to pick out in the literature some fifty odd diseases whose etiology was focal infection. Among them were endocarditis, myocarditis, bursitis, erythema nodosum, purpura hemorrhagica, glaucoma and other various forms of ocular disease, neuritis, herpes zoster, chorea, arthritis deformans, osteomyelitis, cyclic vomiting of childhood, and neuritis of the highly specialized nerves as optic, auditory and olfactory.

We now see that there are many sites in the body where focal infections are possible, and many and varied diseases as the result and, if one bears this subject in mind continually when examining patients, he will be frequently rewarded in curing or improving the condition of his patient, and in preventing serious diseases, which otherwise might occur.

#### SOME QUESTIONS AS TO LIFE.

By CHARLES MINOR BLACKFORD, M. D., Staunton, Virginia.

There is nothing of more profound interest to living beings than is the study of life itself, and nothing can be of greater importance than a complete understanding of it, should such an understanding be attained. When the most philosophic of the English poets wrote that

"The proper study of mankind is man," and thereby repeated the dictum of the Latin poet who said: "I am a man, and I consider nothing human alien to me,"\* their sayings merely confined to humanity the statement to which we of later days have given wider scope by saying that we are living beings and we consider nothing pertaining to life as unworthy of study. Of recent years much research has been given to life itself—not to what was formerly called natural history; the forms and habits of animals and plants,—but to the nature of life, the characteristics of that force which divides living from non-living bodies; which enables living bodies to perform functions which non-living bodies cannot perform, and which, so long as it persists, gives to the tissues of living organisms the power of maintaining and renewing the chemical combinations of which they consist and which fall apart when life ceases. Like Sidney Smith's celebrated definition of an archdeacon as "A person who performs archidiaconal functions." we can only define life by stating what living beings do. Life has no antithesis: there is no word of opposite meaning. Probably the majority of people would think of "Death" as the antithesis of "Life," but death is only the cessation of life: its last step, so to speak. Non-living things are often spoken of as dead, as in the familiar expression—"As dead as a doornail," but this use is merely a poetic license and the word "dead" cannot in strictness be applied to anything which has never lived. In fact, our ideas as to what constitutes the state which we call "living" are so vague that they cannot be clearly expressed.

There are certain phenomena usually connected with life, which, to the ordinary untrained observer, seem to differentiate living beings from lifeless ones beyond the possibility of mistake. Before looking into these, it will be well to remember that the microscope has greatly extended our knowledge of living beings and has shown us organisms which are unquestionably alive, but of whose existence the scientists of seventy-five years ago were totally ignorant. The functions and life histories of these tiny bits of matter form as important a part of the great drama of life as do those of the most highly organized animals and plants, and from the study of them we have learned most of the modern science of biology.

On the other hand, the application of new methods of research has shown phenomena which have greatly complicated the distinction between living and non-living matter which once seemed so clear and sharp.

One of the most obvious manifestations of life is the ability of a living being to move spontaneously. In a sea, lake or stream there are certain things such as logs, fallen leaves and the like, which are only moved by winds, currents or other external agencies. These bodies make up what is called the "plankton," whereas there are other things such as fishes and aquatic animals, which move by their own forces and are not included in the plankton. In general, it may be said that the plankton is non-living, but this is not scientifically true, for fisheggs and the larvae of many aquatic animals form part of the plankton because they are incapable of spontaneous movement, but they are none the less living. Although all living bodies may not be able to move themselves as a whole, it was long thought that any body which can spontaneously move must be living. If we put a drop of pond water under the microscope, we see numberless particles moving with considerable speed in the water and we say that it swarms with life. We may see a small mass of slime throwing out projections in various directions and slowly drawing itself across the microscopic field. We recognize this organism as a living being and we give it the name of *Amoeba limax*, the slug amoeba, and we say that it is alive because it moves. Physicists\* have shown, however, that movements of precisely the same character are carried on by substances which cannot, by any stretch of imagination, be regarded as living; movements in oil drops, in organic and inorganic mixtures and even in globules of mercury, which no means at our command can distinguish from amoeboid movements made by protozoa or white blood cells. These movements result from purely physical and chemical reactions which cause changes in the surface tension of the liquids under examination. Leo Loeb† demonstrated that in the blood cells of the horse-shoe crab (*Limulus*), amoeboid movement depends on stimulation caused by

\*G. Quincke. *Annal. d. Physik. und Chem.* 1870 and 1888. Quoted by E. A. Schaeffer, British Association for the Advancement of Science, Dundee Meeting, 1912.

†Loeb, Leo, M. D., Amoeboid Movement, Tissue Formation and Consistency of Protoplasm. *Science*; March 18, 1921, page 261.

\*Homo sum; humani nihil a me alienum puto.

changes in the consistency of the protoplasm; a phase of liquefaction being followed by one of hardening. On these phases also depend the agglutinability of the blood cells and the formation of tissues from isolated cells, and they play a part in thrombosis and inflammation. By later experiments he showed that the character of the amoeboid movements may be varied greatly by changes in the consistency of the protoplasm produced by taking up fluid from the surrounding medium, and that the phenomena of wound healing may be imitated by graded differences in the osmotic pressure in the medium surrounding the cells. In brief, these functions which have been regarded as characteristic of life or "vital force," are merely manifestations of physical reactions. As Dastre puts it: "Vital spontaneity, so readily accepted by persons ignorant of biology, is disproved by the whole history of science. Every vital manifestation is a response to a stimulus, a provoked phenomenon. It is unnecessary to say this is also the case with brute bodies, since that is precisely the foundation of the great principle of the inertia of matter. It is plain that it is also applicable to living as to inanimate matter."†

All of us have seen the swarms of gnats or other small bodies which gather around a light and keep up a ceaseless dance in the illuminated space. This movement is regarded as a proof that these tiny beings are alive, but, if we observe the microscopic grains of dust suspended in almost any liquid or fine globules of oil suspended in water, we see what is a much similar movement. This spectacle has struck all observers since the invention of the simple microscope, but in 1827 the English physicist Brown gave this movement much study, and since that time it has been known as the Brownian movement. It is an oscillation, a swinging back and forth of the particles and is not attended by any great change in locality. The larger particles move quite slowly while the smaller ones are very active, and those near the limit of microscopic visibility move so swiftly across the field that they can rarely be caught in flight. The character of the liquid medium seems to have no effect on the movement except that it is more lively in alcohol or ether, which are mobile liquids, than in glycerine or sulphuric acid, which are more viscid.

It is seen in the tiny bubbles of gas enclosed in the drops of water sometimes found in quartz crystals which were formed in the Plutonian age of the world; it occurs in strongly acid or alkaline liquids which have been heated under pressure to temperatures at which life would be impossible. In other words, it is not a vital phenomenon, and at our present stage of knowledge, its cause is unknown. It is, therefore, evident that motion may go on in lifeless bodies, and that movement cannot be accepted as characteristic of life.

The next great group of phenomena which was long associated exclusively with life, is that connected with growth and reproduction. For a body to begin its existence as a tiny bit of matter; to take in nourishment from a suitable pabulum; to grow to an approximately fixed size and into a fixed form and then to produce other bodies like it, has been held to be a characteristic function of a living organism. That living beings and living beings only are capable of reproducing their kind has been held as a fundamental truth, especially in view of the researches into bacteriology during the past fifty years, and the classic experiments of Koch, Pasteur, Ehrlich and the other founders of modern bacteriology and pathology, seemed to have settled the question beyond a peradventure. "Omne vivum ex vivo" became a commonplace expression in biology, but as we have learned more and more of the properties of matter, the absolute truth of this saying has become open to question. Were we to put it "Every cell springs from a previous cell," we would approach a truth, but it must be borne in mind that a cell is quite a highly organized being. It consists of a nucleus which our staining methods show to be extremely complex in structure, and of a mass of protoplasm which is far more complex than was formerly believed. In other words, although we may accept the statement that cells are not spontaneously generated, we must accept it just as we accept the fact that cats are not spontaneously generated, and remember that between the lowest living matter and an amoeba or a bacterium there lies almost as long a line of evolution as there is between an amoeba and a cat.

With living beings it is found that they begin as very small bodies which are often radically different in form and appearance from the parent. As development proceeds,

†Dastre, *La Vie et la Mort*. English translation by W. J. Greenstreet, 1911, page 280.

the embryo becomes larger and resembles the parent more closely, and this growth continues until approximately a certain size is reached. The individual then ceases to grow in any marked degree, but gives rise to another organism which, in turn, repeats the same process of development. In general, the germ cell requires a stimulus of some sort to urge it into action, and this stimulus is commonly supplied by union with a germ cell from another individual. This is not essential however. The experiments of Jacques Loeb on the chemical fertilization of the eggs of the sea urchin and the observations of Leo Loeb\* on the parthenogenic development of eggs in the ovary of the guinea pig, where in some instances the ova developed in the Graafian follicle up to the formation of the placenta, indicate that some stimulus, other than that supplied by the spermatozoon, may suffice to start development. As the French say: "Ce n'est que le premier pas qui coute" and, if a purely chemical or physical stimulus can originate the process of development, there is no reason why it should not carry it on to its conclusion without the aid of any special vital force.

Those who held or still hold that there is a mysterious "Vital Force" which produces these activities in living bodies find it difficult to explain similar activities in bodies which are unmistakable non-living. An inorganic crystal begins from a tiny nucleus, grows in size and into a shape so definite that it may be taken as a test of the composition of the crystal and, having reached a more or less definite size, will cease to enlarge but will originate new similar crystals. Furthermore, if during the formation of the crystal a facet be scratched or an angle broken, growth will cease and the damage be repaired; a process which is suggestive of the healing of a wound. If a mixed pabulum be prepared; if, for instance, a mixed solution of alum and copper sulphate be allowed to crystallize, the two salts will separate out in the process, and chemists use repeated crystallizations as a means of freeing colloids from impurities. In brief, a non-living, inorganic salt appears to develop a body which is true to type, which is able to repair injuries inflicted on it, which will increase to an approximately typical size and will then produce offspring as perfectly as does an animal

or plant. It therefore appears that growth and reproduction are not absolutely characteristic of life nor are they dependent on other than the same laws which control inorganic matter.

I cannot go into the work which Ledue and others since his day have done with inorganic colloids which, placed in an appropriate medium, show striking similarities to the growth and fission of living organisms. Even the very complex process of karyokinesis which is preparatory to fission in a cell, can be imitated with a solution of a simple inorganic salt, such as sodium chloride in which particles of lampblack have been suspended, for the carbon particles arrange themselves under the influence of the electrolytes in a manner which a skilled biologist cannot distinguish from those adopted by the particles of chromatin in a dividing nucleus. I would like to mention the problems of latent life in which animals and plants lie until the conditions favorable to their resuscitation come about. I would like to say something in regard to the organic products which were long thought to be elaborated only through the agency of "vital energy"; an idea which fell when Graebe and Liebermann, in 1868, made alizarin, the coloring matter of madder, from its elements and laid the foundation for the wonderful chemical industries of today. It is true that there are many organic compounds which have not yet been made synthetically, but this does not mean that they may not be produced as our knowledge advances. As Huxley put it: "There are many things which are unknown; whether there be anything which is unknowable can be settled only by the future," and one of these is the full answer to the question "What is Life?"

### THE INCIDENCE OF HEART DISEASE IN THE NEGRO RACE.

By W. S. WOODY, B. S., M. D., Hopewell, Va.

In approaching the subject of heart disease one does so with fear and trembling. So much has been and is being written on the subject that one hesitates to further tax an already overburdened literature. However, it is not my intention to discuss either the diagnosis or treatment of its various forms, nor to mention the newer instruments of precision which have lately added so much to our armamentarium in attacking this malady. I prefer rather to approach it from the standpoint of the im-

\*Leo Loeb, M. D. The Parthenogenic Development of Eggs in the Ovary of the Guinea Pig. *Science*, July 13, 1923. Page 35.

portance of its incidence, especially as to its occurrence in the negro race.

The problem of heart disease is certainly one of the most important which the medical man of today must face. A few years ago Osborne wrote, "Of late years the disturbances of the heart are beginning to assume a more prominent place in the list of causes of death, so that perhaps only tuberculosis and kidney disturbances are more prominent." I think that, if he were allowed to modify this statement in the light of more recent years of experience, he would admit that even these diseases are falling into the background in their order of occurrence.

Life insurance companies are reporting and stressing the fact that there is a constantly increasing death rate from cardiac conditions. It has become a problem which hovers over humanity with a constantly increasing dread; and is of great importance to us—not only from a standpoint of mortality rate, but as a serious economic problem—in the vast army of those who each year are incapacitated for work from this cause.

With typhoid fever, diphtheria, tuberculosis and smallpox, we have learned to cope in a way of which we are justly proud. With other infectious conditions we hope to accomplish that which will in time relegate them to the limbo of the past. "Safety first" campaigns and the instruction of workers in nearly all industrial enterprises are accomplishing wonders in the reduction of morbidity and mortality rate from accidental causes. Much has been and is being accomplished in the prevention and treatment of nutritional and metabolic disturbances. Surgery is forging ahead at a marvelous rate, while the mortality rate from heart disease is on the increase.

In my own practice the alarming occurrence of cardiac diseases has struck me as of very significant relative frequency in the negro race. In fact, the frequency with which I find it, especially in the negro man of forty or over, makes it very hard for me at times to prevent myself from jumping to conclusions. Very often in obtaining a history, HEART flashes across my mind so large that it is with a distinct effort put out of my consciousness while a further history and examination are obtained in an effort to find other possible causes of their symptoms.

A consideration of statistics concerning the

mortality rate from cardiac conditions in various states is not amiss, and will be found to be rather impressive. In all states within the registration district from the years 1913 to 1921 there was an increase of from 167.8 to 173.2 per 100,000 population, in the mortality rate of heart disease. Topographically, there is a remarkable incidence of occurrence in the northeastern states as compared with the southeastern. For instance, in the states of Maine, Massachusetts, New Hampshire, New York, Vermont, Rhode Island and New Jersey for the year of 1921, there was an average death rate from cardiac conditions of 209.5 per 100,000 population, as compared with a rate of 108.9 in the seven southern and southeastern states of Virginia, North Carolina, South Carolina, Tennessee, Mississippi, Kentucky and Louisiana—a proportion of nearly two to one. An individual comparison of these states for the year 1921 gives the following figures: Maine, 222.3; Massachusetts, 206.7; New Hampshire, 211.9; New York, 211.3; Vermont, 255.9; Rhode Island, 179.5; New Jersey, 179.; while the southern states for the same year showed, Virginia, 137.3; North Carolina, 109.2; South Carolina, 105.; Tennessee, 94.6; Louisiana, 122.1; Kentucky, 97.4, and Mississippi, 97.

In the southern states a comparison of the death rate between the white and negro race shows a marked preponderance toward the colored; a total average for the seven named southern states being for the year 1921, whites 96.7, while the colored rate was 144.9—or about three negroes to every two whites.

An individual comparison in these states between these races follows: Virginia, white 122.5; colored 172.6; North Carolina, white 99.7; colored 131.2; South Carolina, white 100.1; colored 109.8; Tennessee, white 81.2; colored 151.6; Louisiana, white 105.7; colored 148.5; Kentucky, white 87.9; colored 187.9; Mississippi, white 80.; colored 112.5.

Of all states, Vermont leads with a death rate from cardiac conditions for the year 1921, of 255.9, and an average rate for the years of 1912 to 1921 of 243.6. Next highest comes, for the same ten years, New Hampshire, with an average of 226.8, and the neighboring state of Massachusetts, with an average of 213.8. Montana, off in a district by itself, has the lowest rate for the year 1921, being 90.9, and an average for the last ten years of 98.7, while Kentucky is next lowest with a rate for 1921 of

97.4 and an average rate for last ten years of 103.9.

A comparison of cities with rural districts shows a higher death rate in the cities. For 1921 the average death rate in cities from heart disease was 174.3, while in rural districts it was 141.1. For the last ten years the rate in cities was 178.2, while for a similar period in rural districts it was 145.3. In cities there was an increase from the years 1913 to 1921, of from 171.2 to 174.3, while there was in rural districts a decrease of from 145.8 to 141.1.

Among the states showing the largest increase in death rate from heart disease was Florida, which, from 1919 to 1921, increased from 95.5 to 119.1, for whites and from 102.7 to 119. for colored—a total for both races of from 98. to 119.1, or an increase of 21.1 for 100,000 population in three years. In Maryland, for the years 1913 to 1921, there was an increase from 141.6 to 172.1 for whites, and from 224.7 to 247.2 for colored—a total for both races from 156.2 to 184.7, or an increase of 28.5 in nine years. In Mississippi, for the years 1919 to 1921, there was an increase from 63.3 to 80. for whites, and from 86.9 to 112.5 for colored—a total for both races from 75.7 to 97, or an increase of 21.3 in three years. South Carolina, for the years 1916 to 1921, showed an increase for whites from 84.7 to 100.1, and for colored from 101.2 to 109.8—a total for both from 93.4 to 105, or an increase of 11.6 in six years. In Virginia, for the years 1913 to 1921, the increase for whites was from 104.4 to 122.5, and for colored, from 160.3 to 172.6—a total from 122.1 to 137.3, or an increase of 15.2 in nine years. In Vermont the increase for the years 1913 to 1921, was 231.2 to 255.9, or 24.7 in nine years, while New York, for a similar period, showed an increase from 177.6 to 211.3, or 33.7 in nine years. Some of these figures are rather startling and especially as it applies to the negro race; some states, as for instance Kentucky, showed a preponderance of over two to one as compared to whites.

Not only is this true in the negro adult, but applies to negro children as well. Recently, in a routine examination of negro school children, including both sexes and ranging in age from nine to fourteen years, I found as high as twenty per cent of them subject to unsuspected compensated heart lesions, a majority of them being aortic lesions. The etiological

factors in this series were, so far as could be determined, syphilis, diseased tonsils and in a few instances a history of rheumatic fever. The findings in this series of cases is probably out of proportion to what would be found as an average in a larger group. However, the number was sufficient to bring the relative incidence of cardiac conditions in the negro forcibly to mind.

Next in importance to its frequency of occurrence, to my mind, is that the proportion of aortic lesions in the negro far surpasses that in the white. In the negro man of forty or over aortic regurgitation is probably as often met with as all other valvular lesions combined. Aortic stenosis and mitral valve lesions occur about in the same proportion to each other as in whites but, as stated, much more frequently as a whole. Myocardial weakness is, of course, frequently seen in connection with valve lesions and arteriosclerosis. Pulmonary and tricuspid lesions are relatively rare, while purely functional cardiac disturbances are, as a rule, much more rare in the phlegmatic negro than in the more high-strung white.

With these facts before us, the question of why the negro is so much more often the victim of heart disease naturally presents itself. This is probably a question of some individual speculation and variable opinion. A brief survey of some of the more common factors concerned in the production of cardiac conditions and especially those which commonly produce aortic lesions, will probably go a long way in explaining its incidence.

*Acute Infectious Conditions*—Very often the negro pays little attention to the common infectious diseases in children unless they become severe enough to threaten life. Even should the services of a physician be secured, the parents are prone to disregard advice as to the importance of a prolonged convalescence. As a rule, they consider that as soon as the child himself feels able to leave the bed all danger is over, either disregarding or knowing nothing of the disastrous effect that such a procedure may have on a tired toxic heart. It is very characteristic for them to live today and let tomorrow take care of itself.

*Focal Infections*, especially diseased tonsils, come in for little consideration as a whole by the negro. Very often the sore throat is treated by external applications or even left to take

care of itself; disregarding the after-effects that may arise, the focus is allowed to remain as a constant source of danger to the development of cardiac lesions.

As for *Veneral Disease*, indiscriminate sexual indulgence and lack of regard for personal cleanliness and prophylaxis, together with a lack of knowledge of the seriousness of both the condition itself and its possible consequences, leads to a relatively much higher rate of occurrence of both syphilis and gonorrhea in the negro. Subsequent to its development, their disregard for proper treatment often leaves either a focal infection or a systemic condition—in either case a serious menace to the development of cardiac lesions.

As a rule, the negro is subjected to much harder manual labor than the average white. The constantly increased arterial pressure which results from adrenal stimulation by the increased carbon dioxide in the blood stream tends toward the development of arteriosclerosis and its train of cardiac complications, and often results in the aortic lesions which are so commonly encountered in the middle aged or older negro man.

Thayer found two-thirds of all cases of arteriosclerosis due to over-work, while Reisman believes syphilis to be the more important cause where there is no renal disease. There can be little doubt that the great causes of this high rate in the negro are syphilis and heavy manual labor, and this would explain the relatively higher rate of aortic disease, both being important factors in the production of aortic lesions.

What shall we do to influence this important condition? Shall we fold our hands and be satisfied to do the best we can with our feeble drugs when the victim of decompensated heart lesions at last presents himself for treatment? With how hopeless an outlook must we view our efforts in this line as to their ultimate outcome? No one knows better our inability to replace a diseased valve or to restore to normal functional capacity a diseased heart muscle.

What then can we do? We must realize that, in order to influence the mortality rate from this condition, our efforts must above all things be along the lines of prevention and to this end we must bend our energies: Campaigns against venereal diseases; a more careful search for and more emphatic instructions

concerning the importance of the eradication of focal infections; the insistence of a prolonged convalescence in infectious diseases, especially a prolonged rest where on first sitting up the heart shows some form of arrhythmia. The modification of cough and support of the heart in all severe respiratory conditions, where the added strain of severe coughing, together with the toxin of the disease strain the heart muscle to the breaking point, are very important considerations in the treatment of these conditions. The warning against the abuse of alcohol is to be mentioned, although this is not so important a factor in the production of heart disease as formerly.

In short, we must realize and bring the public to realize with us that this great subject must be approached from the standpoint of prevention.

*New Stewart Building.*

#### PRESENTATION OF THE BRONZE BUST OF DR. RAWLEY WHITE MARTIN TO CONFEDERATE BATTLE ABBEY.

By STUART McGUIRE, M. D., Richmond, Va.

I am keenly appreciative of the privilege that has been accorded me in allowing me, as a representative of the Rawley W. Martin Memorial Association, to make the presentation of his bust to the Battle Abbey.

Dr. Martin was born the year my father was born. They both served in the Confederate Army. They were close personal friends and were frequently associated in professional practice and in matters of public welfare. Dr. Martin was a constant visitor at our home, and from my earliest boyhood I was taught to respect and admire him and to hold him as a model to be lived up to. In later years I had the good fortune to see him often at the bed-side of patients, at the sessions of medical societies and at the meetings of the State Board of Health. I learned to know him and to love him, and I was as intimate with him as it was possible for two men of our respective ages to be; hence the selection of me for this most pleasant task may not be altogether without justification.

In the time allowed me it is impossible to tell the story of his life, which was filled with activities in many and varied fields of work, or to describe the qualities of mind and heart which so endeared him to all who knew him.

I must therefore content myself with a bare sketch of the essential facts of his history in order to have opportunity to emphasize the military side of his career.

Dr. Martin was born in 1835. He received his academic education at the University of Virginia and graduated in medicine from the University of New York in 1858. He located in Chatham, Va., and began the practice of his profession in 1860. At the outbreak of the War Between the States he was offered a commission as a medical officer, but declined it and entered the army as a private. His courage and efficiency soon became recognized and he received rapid advancement. He commanded a company at Malvern Hill, a regiment at Gettysburg, and at the time of the surrender at Appomattox papers were in transit promoting him to the rank of Brigadier General.

At the close of the war, Dr. Martin returned to Chatham and resumed the practice of medicine. In 1867 he married Miss Ellen Johnson of Pittsylvania County. In 1895 he moved from Chatham to Lynchburg where he lived until his death in 1912.

Dr. Martin always spoke of himself as a country doctor but, while he embodied all the virtues of that character so dear to literature, there was nothing provincial in his point of view or scope of work. To his patients he was not only a beloved physician, but a trusted counselor as well. To his community he was an alert, broad-minded citizen whose views had weight in matters of Church and State. To his profession he was an example of industry, ability, learning and high ethical standards. To his family and friends he was a modest, lovable, patient Christian gentleman whose heart knew no evil and whose soul feared no danger.

Dr. Martin's activities won him many public positions of honor. He was a member of the Board of Visitors of the Virginia Military Institute and of the University of Virginia. He was one of the founders and for many years the President of the Medical Examining Board of Virginia. He was at the time of his death President of the State Board of Health, and he was largely responsible for the establishment of the State Tuberculosis Sanatoria which have done such useful work. He was active in many medical organizations and was unanimously elected President of the Medical So-

ciety of Virginia, the highest honor in the power of the medical profession of the State to bestow.

It is Dr. Martin's war record that must be stressed on this occasion. It is a crowded narrative of splendid service. He was at Big Bethel, Seven Pines, the Seven Days' Campaign, Second Manassas, Sharpsburg, Harpers Ferry, Fredericksburg, the Suffolk Campaign and Gettysburg. Tributes to his gallantry in the performance of duty are unstinted, and in a number of cases are embodied in official reports.

General Clement A. Evans in his Confederate Military History relates this incident: "Fletcher Harwood, color-bearer of Company K, was cut down by a shell at Malvern Hill, and as recorded in the War Records, instantly Captain Martin seized the flag and with words of encouragement called on all to follow. The noble, manly conduct of Captain Martin was such as to challenge the admiration of all." Colonel Tomlin's report of the final charge that evening contains the following: "The different members in our regiment were formed into one company under command of Captain Martin whose gallantry was not exceeded by anyone in that memorable battle." The regiment lost 30 killed and wounded out of 128 in action.

The charge of Pickett's Division at Gettysburg and the part played by Dr. Martin is described as follows in an article written after the war by the Rev. James E. Poindexter of Maryland who was Captain of one of the Companies of the 53rd Regiment and personally participated in the assault:

"During the cannonade which preceded the charge, Colonel William R. Aylett, commanding the 53rd was wounded and retired from the field. The command of the Regiment then devolved on Colonel Martin, and as the 53rd was the 'batallion of direction' of Armistead's Brigade, he was thus thrown during the whole subsequent advance in the very closest contact with that heroic chief. As we neared the enemy, General Armistead, at the request of General Kemper, gave the order 'double quick' and the 53rd, led by Lt. Col. Martin, rushed forward with other regiments of the Brigade, through the storm of shot, and gained the stone fence behind which the Federals had lain. Here the men halted, and then it was that Colonel Martin displayed, in full view of

friends and foes, that brilliant courage which marked him out as 'the bravest of the brave.' He mounted the fence and calling aloud 'forward with the colors' leaped down on the side nearest the enemy and strove by voice and gesture to urge on his men. He was the first man in Pickett's Division to scale that fence. And now the intrepid Armistead, his hat on the point of his sword, followed Colonel Martin over the fence, and called on the gallant band that rushed over after him to make one supreme effort to carry the heights. 'Give them,' he cried, 'the cold steel.' But alas their splendid valor was displayed in vain. The Federals poured in a withering volley and Colonel Martin, his thigh bone dreadfully shattered, fell unconscious, not four feet from the lamented Armistead.

"It may give some idea of the terrible loss sustained by Armistead's Brigade when I mention that after the few who survived the charge returned to the point from which they started, Lieutenant Bilharz took command of the 53rd, and Major Joe Cabell of the 38th Regiment, took charge of the Brigade.

"In view of these facts, and they are facts for which many now living in Pittsylvania County, Virginia, are ready to vouch—I respectfully submit that if Pickett's Division deserves the praise which its behavior at Gettysburg has won alike from friend and foe, then the name of Rawley W. Martin is worthy of imperishable honor. I would not detract from the fame of Armistead and Pickett. Their noble deeds have passed into history. Their names can never be forgotten. But the man who outstripped Armistead himself in the path of glory, the man who in the face of fearful odds dared to advance beyond all others, the man who climbed with unfaltering step that rocky barrier and led the dauntless band that followed into the very jaws of death need never blush to see his name coupled with theirs. The county which gave him birth, the state for which he shed his blood, might well glory in his valor. But his modesty is equal to his courage, and so it is that his matchless valor has not received that public recognition which it richly merits."

I am happy that this complaint is no longer true. I am glad that a permanent memorial will now be placed in such a beautiful and historic building. I am proud as the spokesman of the Rawley W. Martin Memorial As-

sociation to present to the Battle Abbey a bronze bust which bears the following inscription:

RAWLEY WHITE MARTIN, M. D.  
 LIEUTENANT COLONEL 53RD VIRGINIA INFANTRY  
 C. S. A.

Born 1835; Died 1912

"He commanded his Regiment forming Armistead Battalion of Direction in Pickett's Charge at Gettysburg on Cemetery Ridge. A tribute from his friends in commemoration of his devotion as a soldier, physician and citizen to the highest ideals of duty and service."

**PRESENTATION OF THE PORTRAIT  
 BUST OF DR. HUNTER HOLMES  
 McGUIRE TO CONFEDERATE  
 BATTLE ABBEY.**

By DON P. HALSEY, LL. D., Lynchburg, Va.

MR. CHAIRMAN, DR. HODGES, LADIES AND GENTLEMEN: In the sixty years that have rolled around since the great War between the States, the fact has become clearer and more distinct to every thoughtful student of history that the most valiant, the most heroic, the most efficient, the most brilliantly led, and the most wonderful army in all respects that ever marched and fought upon this planet was the Army of the Northern Virginia. Its infantry, its cavalry, its artillery were alike matchless and incomparable, and in the vitally important department of its staff it was also thoroughly well equipped and served. In its medical and surgical staff, especially, was it fortunate in the character of the men who composed it. Handicapped as they were by lack of supplies, they nevertheless fulfilled through their ability and fidelity the requirements of their arduous duties in a manner beyond all praise. At the head of the Medical Department of Stonewall Jackson's army, and after Jackson's death as the medical director of the Second Army Corps until the end of the war, was Dr. Hunter Holmes McGuire, a man whose great figure now looms up in history in even nobler and more commanding outlines than during the days of his masterly achievements. To all Virginians, and to all men of his profession throughout the world, his name is familiar as that of a brilliant physician, a surgeon of surpassing genius and a teacher of preeminent power. It is not, however, as a great exemplar of the highest

achievements of a noble profession that we wish to honor him here today. That would anyhow be a work of supererogation, for already have his praises in his chosen life work been sounded by eloquent tongues, and recorded by brilliant pens, and his niche is secure and high in the temple of fame. It is to Hunter McGuire the patriot that we now desire to give homage. The great surgeon, the eminent teacher, the president of all the highest associations of medical and surgical scientists, the founder of a great medical college and of a great hospital, has already received the highest honors that can be bestowed upon one to whom such honors are possible. Today we place him as a soldier of the Southern Confederacy among his comrades of the days of yore, and wreath upon his brow the immortelles that belong to those who for four long years on glory flooded fields struggled to maintain the empire of principle in the earth, and who with honor untarnished and consciences inviolate fought desperately for the cause they knew to be right. If those bronze lips could speak I doubt not that they would say that Hunter McGuire would not exchange the honor of having fought under the starry and stainless flag of the Confederacy for all the other honors that were heaped upon him, for all the gold piled up in treasury vaults, or for the costliest diadem that ever sparkled in a monarch's crown.

To you then, Dr. Hodges, as the representative of R. E. Lee Camp No. 1, on this occasion, I have the honor to commit, on behalf of his worthy and distinguished son, this portrait bust in bronze of Hunter Holmes McGuire, Doctor of Medicine, Doctor of Laws, a soldier of the Confederacy who followed and fought with Stonewall Jackson, and whose name will forever be associated with his among the tenderest, the most precious and the most glorious memories of the "Storm cradled nation that fell."

## Analyses, Selections, Etc.

### The Relationship of the Ion Content of the Cell to Symptoms of Disease with Special Reference to Calcium and Its Therapeutic Application.

F. M. Pottenger, Monrovia, Calif., discusses the physio-chemical changes of the cell nor-

mally and pathologically. He believes the "action of the cell may be carried on independently of the correlating and integrating forces of the two great systems of body regulators, the nerves and the incretions; but full and purposeful activity requires a co-ordination of all regulatory forces," but the nerve or incretion action is also dependent on the chemical and physical state of the cell. If the physio-chemical equilibrium of the cell is disturbed beyond certain normal limits then symptoms of disease appear. He believes intake of the fundamental inorganic salts as important in cell metabolism as the intake of proteins, carbohydrates and fats.

Tables are given showing the cellular, liquid and chemical content of the blood, and he mentions that certain salts are antagonistic to each other when present in certain organs.

The author believes that besides nervous symptoms and glands of internal secretion other forces yet unknown to science control the metabolic process of the cell.

The calcium salts seem to be bound up with the sympathetic nervous system and act very much in the manner of suprarenin. He bases this on experimental work done on the heart, intestines and other organs under sympathetic control. It is suggested that the thyroid, pituitary and parathyroids have to do with calcium retention in the body, while the gonad system has the opposite effect.

Clinically, calcium strengthens the systole of the heart, relaxes the musculature and reduces the secretions of the respiratory system through its effect on the sympathetic and opposes the parasympathetic action.

With calcium or suprarenin the sympathetic nervous system can be stimulated to such a degree as to overbalance the parasympathetic nerves. On the other hand atropine inhibits parasympathetic action while pilocarpin stimulates it.

The author further believes that a great many more visceral diseases are attributable to the vegetative nervous system than have been heretofore generally accepted.

Therapeutically, he suggests the use of calcium or adrenalin, or both, for sympathetic stimulation, or atropine for parasympathetic inhibition in the following: (1) anaphylaxis; (2) serum reactions; (3) urticaria; (4) asthma; (5) hay fever; (6) bronchitis; (7)

affections of the gastro-intestinal tract. The sphincters have the opposite innervation.

He does not suggest this therapeutics as a cure-all but believes it to be of great value in these types of cases. Five c. c. of a five per cent solution of calcium chloride in ampules is used intravenously at intervals of two days to a week. Injections should be made slowly, requiring five to ten minutes. The reaction, if any, consists of warmth, constriction of the throat, or burning in rectum. These pass off in a few minutes. (*Annals of Clinical Medicine*, Nov., 1923, Vol. 2, No. 3).

H. R. MASTERS.

## The Truth About Medicine

In addition to the articles enumerated in our letter of December 1st, the following have been accepted:

Cutter Laboratory

Anti-Anthrax Serum for Human Use—Cutter.

Diphtheria Toxin-Antitoxin Mixture—Cutter.

Diphtheria Toxin for the Schick Test—Cutter.

Rabies Vaccine-Pasteur—Cutter.

Tetanus Antitoxin for Human Use (Concentrated)—Cutter.

E. R. Squibb and Sons.

Diphtheria Toxin-Antitoxin, 0.1L+.

Winthrop Chemical Company,

Elixir of Veronal.

### NEW AND NON-OFFICIAL REMEDIES.

National Radium Emanator.—A portable appliance for activating water with emanation; the emanation is emitted from a solution of radium chloride, barium chloride and sodium chloride. The appliance is claimed to produce 40 microcuries (150,000 Mache units) of radium emanation to 1,000 c.c. of water daily. The actions, uses and dosage of radium are discussed in *New and Non-official Remedies*, 1923, p. 255. National Radium Products Co., New York. (*Jour. A. M. A.*, December 8, 1923, p. 1953).

Iodostarine-Roche.—Diiodotariric Acid.—An iodine addition product of tariric acid, derived from the fruit of a species of *Picramnia*. Iodostarine-Roche contains 47.5 per cent. of iodine. It acts in the tissues similarly to inorganic iodides. It is not broken up in the stomach, but a portion of the iodine is split off when it enters the intestine. The undecomposed portion is readily absorbed and, as in the case of other fats, is largely deposited in the tissues where it is slowly split up. The action of iodostarine-Roche is exerted more slowly than that of the inorganic iodides. Iodostarine-Roche is supplied in the form of tablets iodostarine-Roche 0.25 Gm., and as chocolate tablets iodostarine-Roche, containing iodostarine-Roche equivalent to iodine 0.01 Gm. Hoffmann-LaRoche Chemical Works, New York. (*Jour. A. M. A.*, December 15, 1923, p. 2032).

Tetanus antitoxin for human use—Cutter.—Tetanus antitoxin, concentrated (see *New and Non-official Remedies*, 1923, p. 284), marketed in syringes containing 1,500 and 5,000 units each. Cutter Laboratory, Berkeley, Calif.

Diphtheria toxin-antitoxin mixture—Cutter.—Diphtheria toxin antitoxin mixture (see *New and Non-official Remedies*, 1923, p. 284), each c.c. representing 3 L+ doses of diphtheria toxin neutralized with sufficient antitoxin to conform to the toxicity requirements of the U. S. Public Health Service. It is marketed in vials containing, respectively, 1 c.c. and 50 c.c., and in syringes containing one immunizing treatment. Cutter Laboratory, Berkeley, Calif.

Anti-anthrax serum for human use—Cutter.—An anti-anthrax serum (see *New and Non-official Remedies*, 1923, p. 287), marketed in double-ended vials containing 50 c.c. for intravenous injection. Cutter Laboratory, Berkeley, Calif.

Rabies Vaccine-Pasteur—Cutter.—An anti-rabic vaccine (see *New and Non-official Remedies*, 1923, p. 294), prepared according to the method of the Hygienic Laboratory of the U. S. Public Health Service. The emulsion from the cord is shipped daily and is diluted at the time of injection. The treatment consists of twenty-one daily injections. Cutter Laboratory, Berkeley, Calif.

Diphtheria toxin for the Schick test—Cutter.—A diphtheria immunity test (see *New and Non-official Remedies*, 1923, p. 323), marketed in packages of two vials, one containing diphtheria toxin and the other physiologic solution of sodium chloride for dilution. Cutter Laboratory, Berkeley, Calif.

Capsules Carbon Tetrachloride (human use)—P. D. and Co.—A brand of carbontetrachloride—N. N. R. It is marketed in capsules containing 20 minims. Parke, Davis and Co., Detroit.

Elixir of Veronal.—Each fluid drachm contains veronal (see *New and Non-official Remedies*, 1923, p. 63), 2 grains in a menstruum containing alcohol 33.5 per cent. Winthrop Chemical Co., New York.

Diphtheria Toxin-antitoxin Mixture (new formula)—Squibb. Diphtheria toxin-antitoxin mixture (see *New and Non-official Remedies*, 1923, p. 284), containing in each cubic centimeter 0.1 L+ dose of diphtheria toxin neutralized with the required amount of diphtheria antitoxin. Marketed in packages of three vials, each containing 1 c.c., and in vials containing, respectively, 10 c.c. and 20 c.c. of the mixture. E. R. Squibb and Sons, New York. (*Jour. A. M. A.*, December 23, 1923, p. 2115).

### PROPAGANDA FOR REFORM.

Liquid Petrolatum as a Laxative.—Liquid petrolatum is indigestible. It is not absorbed, and, therefore, cannot produce poisoning. In ordinary quantities the administration of liquid petrolatum does not seriously impair the alimentary efficiency. Like all laxatives used in very large quantities, liquid petrolatum may diminish the degree of utilization of food by promoting evacuation before the functions of digestion and absorption can be entirely completed. Liquid petrolatum may produce gastric distress and, therefore, should be taken in a way to interfere least with gastric digestion by administration before bedtime or an hour before meals. In reporting on a proprietary brand of liquid petrolatum widely exploited to the public, the Council on Pharmacy and Chemistry warned that constipation should be treated by dietary and hygienic means, as evacuants are but temporary measures. It further cautioned that liquid petrolatum is medicinal: it modifies greatly the intestinal flora; it acts as a lubricant and emollient; it modifies the absorptive powers of the intestinal mucous membrane; it is capable of influencing the digestion of fats; and, in short, liquid petrolatum is a drug, the indiscriminate and excessive use of which should not be en-

couraged. (Jour. A. M. A., December 1, 1923, p. 1896).

**Spahlinger Treatment for Tuberculosis.**—Spahlinger is a resident of Geneva, who received medical training but took his degree in law. Later he abandoned law for research work. The Spahlinger treatment makes use of vaccine and serum therapy. The theory from which the treatment is evolved is that the tubercle bacillus emits different toxins under varying conditions of temperature, environment, etc. Many of these are claimed to be isolated as either exotoxins or endotoxins. The vaccines—of which there are said to be about twenty—are used for prophylaxis for treatment of the milder cases of tuberculosis and for the production of the various serums used in the treatment of the more severe cases. It has been reported that the British ministry of health is prepared to encourage the experimental trial of the Spahlinger preparations under scientific supervision. The British Red Cross has appropriated money to enable Spahlinger to work on a larger scale in the production of his preparations. The reports in regard to the efficacy of the preparations which have appeared in British medical journals are conflicting, and the Red Cross organization has made it clear that the products are in the experimental stage. (Jour. A. M. A., December 1, 1923, p. 1896).

**Does Heat Injure Vaccines?**—It is generally believed that vaccines lose in potency on standing at room temperature. But so far as known, the sterilization of vaccines by heat does not injure the antigenic potency any more than other methods of sterilization, e. g., chemicals. The astounding deduction of a manufacturer of vaccines that heat sterilization, at a definite temperature for a given time must be highly injurious, because vaccines lose in potency on standing for weeks and months at variable room temperature, is simply a pseudoscientific statement intended presumably to bolster up the merits of the advertised wares in the eyes of the more or less thoughtless purchasers. (Jour. A. M. A., December 22, 1923, p. 2135).

## Book Announcements

**The American Illustrated Medical Dictionary (Dorland).** A New and Complete Dictionary of Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Veterinary Science, Nursing, Biology, and kindred Branches; with the Pronunciation, Derivation and Definition. By WM. A. NEWMAN DORLAND, M. D., F. A. C. S., Member of Committee on Nomenclature and Classification of Diseases, of the A. M. A. Twelfth Edition, Revised and Enlarged. Philadelphia and London. W. B. Saunders Company. 1923. Large 8vo of 1,296 pages with 338 illustrations, 141 in colors. Flexible leather, \$7.00 net; thumb index, \$8.00 net.

The present edition measures up well with claims made for this dictionary in the past. This edition has been increased by sixty-nine pages, with a total of over 3,000 new words. Included in these are many new dental words with definitions. This fact adds greatly to the value of the book, owing to the close relation now existing between medicine and dentistry. The elaborate tables given are a most valuable

aid. These too have been revised to the last minute.

It is with interest we note that the publishers secured for special work in this edition the services of Dr. E. C. L. Miller, professor of bacteriology and biochemistry at the Medical College of Virginia. It is stated that he "has checked every chemical word in the book, including all drugs and proprietary medicines, giving special attention to the accuracy of definitions and chemical formulae and to the completeness and inclusiveness of the vocabulary. He has also revised and added to the terminology of Bacteriology, Parasitology, Immunology, Public Health, and Genetics." To our many readers who are familiar with Dr. Miller's painstaking work, this feature alone would commend the dictionary in question.

### Medical Record Visiting List or Physicians' Diary.

Revised. New York. William Wood & Company. Medical Publishers. Sixty patients per week record. Price, \$2.00 net.

This is the usual weekly visiting list with space opposite each name for special memoranda. The forepart contains twenty-seven pages of helpful hints in emergencies of various kinds, and will at times be found very useful. The book is bound in flexible leather, and contains a pocket for memoranda slips.

**Operative Surgery.** Covering The Operative Technique Involved in the Operations of General and Special Surgery. By WARREN STONE BICKHAM, M. D., F. A. C. S., New York. Former Surgeon in Charge of General Surgery, Manhattan State Hospital, New York; Former Visiting Surgeon to Charity and to Touro Hospitals, New Orleans. In six octavo volumes totaling approximately 5,400 pages with 6,378 illustrations mostly original, and separate Desk Index volume. Now ready—VOLUME I containing 850 pages with 921 illustrations, and VOLUME II containing 877 pages with 1,088 illustrations. Philadelphia and London. W. B. Saunders Company. 1924. Cloth, \$10.00 per volume. Sold by subscription only. Index Volume free.

**Neurologic Diagnosis.** By LOYAL EDWARD DAVIS, M. S., M. D., Ph. D. in Surgery. Assistant Professor of Surgery, Northwestern University Medical School; Fellow of National Research Council 12mo. 173 pages with 49 illustrations. Philadelphia and London. W. B. Saunders Company. 1923. Cloth, \$2.00 net.

**Hernia.** Its Anatomy, Etiology, Symptoms, Diagnosis, Differential Diagnosis, Prognosis, and Operative Treatment. By LEIGH F. WATSON, M. D., Associate in Surgery, Rush Medical College, Chicago. 232 original illustrations by W. C. SHEPARD. St. Louis. C. V. Mosby Company. 1924. 8vo. 660 pages. Cloth, \$11.00.

# Virginia Medical Monthly

FOUNDED BY LANDON B. EDWARDS, M. D., APRIL, 1874.  
OWNED BY THE MEDICAL SOCIETY OF VIRGINIA.

## Editorial

### Cholelithiasis.

Last month, editorially, we considered the acute forms of the diseases of the gall-tract. Stress was laid upon the importance of interpreting symptoms, often very meager and indefinite. A brief comment was made upon the nature and cause of these forms. The etiologic relation of primary foci of infection to gall-tract infection was pointed out, illustrating the connection by Rosenow's well-known work which showed the relation of tonsil and teeth infections to gall-tract infection, by the well established relation of typhoid infection to gall-bladder diseases, by the clinical connection or association of pneumococcus infection and gall-tract disease. The probable antecedent existence of these primary infections of the gall-tract, probably in the more subacute and less virulent types, to gall-stone formation, was also suggested as very probable, although the state of the bile elements (especially cholesterin) were in mind as forming a small percentage, without previous inflammation of the gall-tract mucous membrane.

Paramount importance was laid upon the need of recognition of these pathological states in the gall-tract through a keen and interpretative attitude of mind on the part of physicians as they view the passing throng of patients complaining of digestive disturbance—the "dyspeptics."

Now we desire to direct our reader's thought to the following comments on cholelithiasis, or the gall-stone-stage of gall-tract disease. One must be impressed with the probable uselessness of our comments when one reflects upon the vast amount of "literature" in current publications during the last six months. To show how fully the subject has been covered, we might call the reader's attention to a good index of the articles appearing in the world's medical current publications in the latter half of 1923. The Index Number of *The Journal of the American Medical Association* (December 29, 1923, Vol. 81, number 26, page 2,233), under "Gall-bladder," shows the following titled contributions on the subject: Gall-bladder calculus and pregnancy; g. calculus and transduodenal choledochotomy; g. calculus, differential diagnosis; g. calculus, digestive hemoclastic with; g. calculus, digestive juices with; g. calculus, ileus from; g. calculus in common duct, diagnosis and management of; g. calculus is cause, not result of infection; g. calculus, mutual influence of gastro-intestinal tract and; g. calculus, nocturnal colic with; g. calculus, orthology and pathology of extra-hepatic bile ducts in their relation to; g. calculus, pathogenesis of; g. calculus, production of; g. calculus, "recurrences" after operations for; g. calculus, roentgenography of; g. calculus, surgical treatment for; g. calculus, time element in formation of; g. diseases, achlorhydria in; gall-bladder disease in childhood; g. disease, reaction in colon to; g. drainage, nonsurgical; g. evacuation reflex; g. infection: g. infection, pancreatitis as related to; g. inflammation, gastric secretion in; g. inflammation, indications for surgery in; g. inflammation, masked; g. bladder inflammation without gall-stones; and others.

The foregoing list of titles, gathered by a careful agency, covering papers published during the preceding half-year on the subject of gall-bladder, points to the widespread interest in the subject. The large number of papers indicate, besides, the frequency and incidence of the condition. A thoughtful perusal of this list of publications rather indicates, as before stated, that the predominance of interest in this subject by the profession is in the late type of gall-bladder disease as illustrated by the formation of gall-stones. As one sees, the antecedent phases of gall-tract disease,

Roentgenogram showing gall stones removed by operation.

namely, cholecystitis and cholangitis, have not claimed the study and publication to any considerable extent during the past six months. Should this be taken as an indication that the primary conditions just mentioned are overlooked by the physicians? Is it true cholecystitis and cholangitis do not "register" until the gall-stones assert mechanical and inflammatory changes? It is to be hoped that more work will be done and more publications given hereafter in dealing with the primary diseases of the gall-tract with special reference to the etiology, symptomatology and prevention. When the profession becomes alive to the inaugural stages of cholelithiasis and applies preventive measures, there will occur less of the pathology which we now are compelled to consider at such length in current literature. These observations, however, in no wise alter the fact that there is a high degree of incidence of gall-tract infection with gall-stones.

#### CAUSES OF GALL-STONE FORMATION

An excessive concentration of cholesterin may be a non-infective cause of calculus. The normal amount of cholesterin in bile is from 20

to 80 mgm. per 100 cc. of bile; in blood from 130 to 180 mgm. per 100 cc. of blood. It is conceivable that a prolonged excess of cholesterin in bile may be precipitated in the stagnation of the balance of the gall-bladder and the formation of gall-stone to take place. A pure cholesterin calculus results.

But infection is the chief cause of gall-stone formation. The typhoid, paratyphoid and colon bacilli from the intestinal tract, streptococci from the mouth, and pneumococcus from the respiratory organs should be mentioned as the chief microorganisms of cholecystitis and gall-stone formation. Conditions which may cause concentration of cholesterin or may produce stagnation of bile are frequently the associated causes with microorganisms, above mentioned, of gall-stone formation. So it is met with in obesity, tight lacing, and visceroptosis. Associated with cholecystitis and gall-stones, we not infrequently have an acute appendicitis.

#### THE TIME ELEMENT AND NUMBER

Gall-stones may form in fifty days; recently in the *Journal of the A. M. A.* (Nov. 17, 1923, page 1,671) a case is cited in which gall-stones

formed in eighty-six days; but far more frequently months are required to form gall-stones. Gall-stones may exist and be quiescent for years. There may be one or many. They vary in form and density. In more than half of the cases the gall-bladder is the site of calculi. There may be pure cholesterin calculi. There may be pure cholesterin calculi coated with bilirubin calcium, this constitutes about twenty per cent of all gall-stones and may be taken as an evidence of an inflammation occurring in the gall-tract subsequent to the formation of the cholesterin part of the calculus. There may be mixed cholesterin and

Cholecystitis chronica with a stone in the cystic duct. (After W. C. MacCarty. "Collected Papers by the Staff of St. Mary's Hospital, Mayo Clinic," published by W. B. Saunders Co., Phila.) Taken from Barker's "The Clinical Diagnosis of Internal Diseases," Vol. II).

bilirubin calcium calculi. These are the most common and may be taken as an evidence of infection. There may, however, be pure bilirubin calcium calculi. These result from a precipitation of bilirubinate of calcium produced by an inflammatory exudate in the ducts. There are also certain rare chemical formations: as incompletely formed cholesterin gravel, calcium carbonate stones, calculi with foreign bodies in the center.

#### DYSPEPSIA'S ROLE IN CLINICAL PICTURE

The beginning symptoms of gall-stone, as the initial symptoms of cholecystitis and

cholangitis, may masquerade as stomach symptoms. In this way attention is drawn to the stomach, to food taking and indigestion—or to "dyspepsia." The patient complains after eating food—not of the gall-tract but of the stomach. There is a heaviness, a fullness, a distention after eating. He belches after awhile and is relieved of oppression, he probably has heartburn, a distinct discomfort or pain under the right costal border on deep breathing. He suffers from flatulence, dull pain in right hypochondrium, and a pain located under the right shoulder blade.

#### MECHANICAL EFFECTS OF GALL-STONES

There are certain mechanical effects of gall-stones when they exist in sufficient number or size. A collection in the gall-bladder may produce a pyloric stenosis, obstruction of the common duct, or compression of the portal vein. Impaction of a stone in the cystic duct may set up biliary colic, and, if persistent, produce distention of the gall-bladder, with bile and mucus. This condition may bring about enormous distention of the gall-bladder, a thinning of its wall and a cystic degeneration of its contents. The process may result in a chronic inflammation and atrophy of the gall-bladder. The presence in the common duct of gall-stones may set up attacks of biliary colic. There may be one stone, but the whole duct may be filled with stones. The impaction of the common duct may be the cause of jaundice.

The duct may dilate, however, and relieve the impaction, permitting the bile to flow. In impaction there may be hepatic fever and other symptoms of systemic involvement. It is possible to have a spontaneous cure by the discharge of the calculus into the duodenum. But long before this, surgical treatment should be sought. In the ampulla of Vater, a gall-stone may be lodged and, if of sufficient size, may produce an obstruction. This may cause the bile to flow into the duct of Wirsung, bringing about an acute hemorrhagic pancreatitis. The obstruction of the intestines by a gall-stone occurs, but is rare. Only recently a case has been noted in the literature. Such patients were frequently over fifty years.

#### INFLAMMATORY AND INFECTIVE CHANGES DUE TO GALL-STONES

With gall-stones in the gall-bladder, inflammatory changes are prone to persistently

reoccur and chronic cholecystitis to supervene. Ulceration, diverticula, scars, hour glass contractions, are some of the changes that follow. In addition a recurrent or chronic pericholecystitis may exhibit adhesions between the gall-bladder and adjacent pylorus, duodenum, transverse colon, and omentum. In such a mass of pathology we may obtain symptoms largely simulating dyspepsia.

In Memoriam

### WOODROW WILSON

Twenty-eighth President of the United States of America.  
Born at Staunton, Virginia, December 28, 1856,  
Died at Washington, D. C., February 3, 1924.

---

#### To the Physicians of the State:

I wish to inform you regarding the activities of the present legislature with respect to matters concerning doctors and the practice of medicine.

At the beginning of the session a bill was introduced in the House and Senate, re-imposing a license tax on doctors. I at once called together the Legislative Committee, and Dr. Williams, Chairman of the Executive Committee, called together the Council of the Medical Society of Virginia. The Council instructed the Legislative Committee to do everything in its power to defeat the bill, whereupon the Committee busied itself, and with the backing of the component societies and the doctors all over the State, we defeated the bill, as the House Committee passed it by indefinitely and the Senate Committee on Finance reported it out, with the recommendation that it not pass, only three voting for it, and twelve against it.

Dr. W. G. Painter, President of the Wise County Medical Society, in a letter to his Senator, said, in part:

"The physicians of the State will regret very much to see the time come when they shall be looked upon as a purely commercial or revenue producing body, either by themselves or the State. We have higher ideals than this. We aspire to a service far beyond that which can be in or hedged about by mere dollars and cents."

Up to this time, we have been successful also in keeping off any legislation offered by the chiropractors. I doubt very much if they will introduce any further bills during this session.

The Legislative Committee, after consideration, thought it wise to let the Medical Act remain as it is for the present.

Respectfully,

H. U. STEPHENSON, M. D.,

*Chairman, Legislative Committee, Medical Society of Virginia.*

#### Legislative Activities of Medical Society of Virginia.

In view of the interest being manifested by doctors throughout the State in medical matters before the present legislature, we asked Dr. H. U. Stephenson, chairman of the Legislative Committee of the Medical Society of Virginia, to prepare us an announcement of what is being done. In the above notice he has told concisely what has been accomplished. We feel we should add that Dr. Stephenson has been untiring in his efforts in behalf of this work and has been most ably assisted by doctors and societies from all over the State. It is simply an evidence of what organization properly directed can do.

Early in the session of the Legislature, it seemed that medical educational standards would be attacked. For this reason, a meeting of the Legislative Committee was called to which were invited local members of the Executive Council and prominent educators. This conference resulted in securing the endorsement of at least the present standards for medical education in Virginia, not only from those assembled but also by letters from presidents of all of the schools of liberal arts in the Commonwealth.

However, the first bill introduced affecting the medical profession was the one for the re-imposition of a license tax on doctors. Dr. Stephenson has explained in detail how this resulted. Upon his request, the Executive Council of the State Society held a meeting which was well attended by men representing every section of the State. Their enthusiasm and work against the imposition of this tax, augurs well for the success of any project the doctors of Virginia wish "to put over." Since Dr. Stephenson prepared his report, this bill

has been defeated in the Senate by a vote of 27 to 4.

It is not known, as we go to press, what, if any, bill will now be presented with regard to doctors. Should the need arise, call will be made on the local societies and individual doctors of the State, and we feel sure they will not fail their committee or society in any emergency.

### **The Tri-State Medical Association of the Carolinas and Virginia**

Is to meet in Greenville, S. C., February 20-21, 1924. The officers of the association have requested the local committee not to provide for any entertainments that will interfere with the scientific work and the main objects for which the members are to be assembled. They are endeavoring to act within the scope of their instructions and at the same time afford the members the opportunity for the best meeting in the history of the Tri-State Medical Association.

Make your reservations in the Imperial or Ottaray Hotels. As the accommodations of these two hostelries will probably be taxed to their fullest extent, it is requested that arrangements be made for at least two in a room, if possible.

The local committee on arrangements from the Greenville County Medical Society is composed of:

Dr. L. O. Mauldin, Chairman, Dr. Hugh Smith, Secretary, and Dr. J. L. Anderson, Dr. R. C. Bruce, Dr. W. C. Black, Dr. E. W. Carpenter, Dr. C. B. Earle, Dr. C. W. Gentry, Dr. S. G. Glover, Dr. I. H. Grimbald, Dr. A. S. Pack, Dr. W. H. Powe, Dr. H. D. Wolfe.

For information as to hotels write the proprietor of the Imperial Hotel or the proprietor of the Ottaray Hotel, Greenville, S. C.; for other information to members of the committee.

### **Admission of Whisky and Brandy to the U. S. Pharmacopoeia, Tenth Revision.**

Announcement has just been made by E. Fullerton Cook, Chairman of the Revision Committee of the United States Pharmacopoeia, that standards for whisky and brandy as medicines will be included in the new Pharmacopoeia now being revised. This is in response to a demand by the physicians of the country.

Under the national prohibition laws, whisky and brandy are classed as medicines and as such are legally prescribed in many cases of serious illness, but at the present time no legal standards exist for their purity.

All physicians of the General Revision Committee, acting as a sub-committee, were appointed to study the situation and take the necessary action. This sub-committee has issued the following statement:

"In view of the fact that a large number of physicians in the United States believe alcohol to be a valuable therapeutic agent, and in view of the widespread adulteration of the alcoholic liquors at present available, the members of this Referee Committee feel that for the protection of the public, there should be an official standard for medicinal spirits."

By including standards for whisky and brandy as medicines, in the Pharmacopoeia, which is the legal standard for drugs and medicines under the Food and Drugs Act, the machinery of the U. S. Department of Agriculture and of the Boards of Health and Boards of Pharmacy throughout the country is enlisted in protecting the sick against adulterated and poisonous products.

### **Richmond Has Campaign Against Cancer.**

In accordance with the plan of the American Society for the Control of Cancer, during January Richmond doctors conducted a campaign against cancer which culminated in a mass meeting held on the 28th. Dr. Paul Howle was selected as general chairman of the movement in this city. The object of the campaign was purely educational. A number of doctors were appointed to appear before the various clubs and civic organizations to give a plain and simple statement of facts about cancer together with advice as to detecting the initial symptoms that patients may seek advice when the disease is in a curable stage.

A great deal of interest was manifested in the campaign, 1,200 attending the mass meeting on the last day, at which Dr. George A. Soper, managing director of the American Society for the Control of Cancer, was the chief speaker. Dr. Robert C. Bryan, state chairman of the Society, opened this meeting and talks were made by several Richmond doctors as well as by Dr. Soper.

Figures given by Dr. W. A. Plecker, director of the Bureau of Vital Statistics, showed that there were last year 1,365 deaths from cancer in Virginia; that the disease is fatal to

one woman in eight and one man in fourteen, over the age of forty years. As cancer at the outset is local in character and frequently curable, these figures should make more people "Stop—Look—Listen."

#### Married.

Dr. Harry Lee Claud, Newport News, Va., and Miss Julia Marvin Sarvey, in Norfolk, Va., January 5.

Dr. Lawrence O. Snead, Richmond, and Miss Empsie Shapard, Halifax, Va., February 9.

Dr. Horace Orlando Bell, Richmond, and Mrs. Alice Arlina Streit, New York City, recently.

Dr. William Harvey Dixon, Rocky Mount, N. C., and Miss Margaret Freeborn Betts, Richmond, January 19.

Dr. Walter Edward Futrell, Morganton, N. C., and Miss Phoebe Palmer, Sanford, N. C., in Richmond, January 18.

#### Dr. V. B. Hirst,

Of New York City, a graduate of the University of Virginia Medical School in 1918, recently visited his mother in Purcellville, Va.

#### Congress on Medical Education, Medical Licensure, Public Health and Hospitals.

All interested are cordially invited to attend this annual congress which is to be held in Chicago, March 3, 4 and 5, at Congress Hotel. The program promises many excellent addresses on various subjects. Dr. Arthur Dean Bevan, Chicago, is chairman of the Council on Medical Education and Hospitals of the A. M. A.; Dr. John Milton Dodson, director of the Bureau of Health and Public Instruction; Dr. Irving S. Cutter, Omaha, president of the Association of American Medical Colleges; Dr. David A. Strickler, Denver, president, of the Federation of State Medical Boards of the United States; and Dr. Frank Billings, Chicago, president of the American Conference on Hospital Services.

#### The Albemarle County (Va.) Medical Society

Has elected the following officers for the year 1924; President, Dr. Percy Harris, Scottsville; vice-president, Dr. W. E. Bray, University; secretary-treasurer, Dr. F. C. McCue (re-elected) Charlottesville. Meetings are held the first Tuesday of each month. Several new members were elected at the January meeting.

#### Dr. J. G. Bentley,

Whose address was until recently at Dunbar, Va., is now at Blackwood, Va.

#### Dr. Newton G. Wilson,

Formerly of Fieldale, this State, after being in North Carolina for some months, has located at Summerfield, N. C.

#### Dr. Charles A. Easley,

Who after practicing for several years in Bluefield, W. V., went to Pittsylvania County, Va., on account of his health, is now well and is taking up general practice in Chatham, Va.

#### Dr. G. G. Hankins,

Of Hampton, Va., has received an appointment to the staff of the Philadelphia General Hospital, in which institution he is now taking special work.

#### Dr. James N. Greear, Jr.,

Of the class of '20, University of Virginia Medical School, who has been at Manhattan Eye, Ear and Throat Hospital, New York City, for over a year, has located at 1740 M Street, Northwest, Washington, D. C., where he will limit his practice to eye, ear, nose and throat.

#### Child Health Magazine.

With the January issue, *Mother and Child*, for the last four years the official publication of the American Child Health Association and the American Child Hygiene Association, became *The Child Health Magazine*. The pages are doubled in size, and rather fully illustrated. We wish the magazine continued success.

#### Dr. W. C. Caudill,

Pearisburg, Va., has been elected a member of the board of directors of the First National Bank of that place.

#### Dr. R. Finley Gayle,

Richmond, associate in nervous and mental diseases at the Medical College of Virginia and extension lecturer of the College of William and Mary, is this month giving a course of lectures in mental hygiene in its relation to education, before the Richmond School of Social Work and Public Health.

### Officers with Loudoun Confederate Veterans.

At a meeting held in Leesburg, Va., the last of January, Dr. C. F. Russell, of Herndon, was elected commander, and Dr. J. E. Copeland, of Round Hill, surgeon of the camp.

### Members of Hopewell Board of Health.

Dr. J. N. Elder and Dr. W. S. Woody have just been appointed members of the City Board of Health of Hopewell, Va. Other members of the board are Mayor D. Lane Elder and Dr. J. C. Bodow.

### The Southwestern Virginia Medical Society

Will hold its regular Spring meeting in Radford, March 20 and 21, under the presidency of Dr. S. S. Gale, of Roanoke. Other officers are Dr. D. L. Kinsolving, Abingdon, vice-president, and Dr. E. G. Gill, Roanoke, secretary-treasurer. A banquet will be tendered the visitors by the physicians of Radford on the evening of the 20th. An attractive program has been arranged, including a symposium on Diabetes by Drs. K. D. Graves, Roanoke, F. H. Smith, Abingdon, Gibson Davis, Christiansburg, and H. H. Trout, Roanoke. Dr. A. M. Showalter, Cambria, will open the discussion on this subject.

The local committee on arrangements is composed of Drs. John J. Giesen, E. G. Hall and J. A. Noblin, all of Radford.

### Dr. John D. Stewart,

Of New York City, by invitation, read a paper before the Richmond Academy of Medicine in January. While in Richmond, he was entertained at dinner by Dr. M. C. Sycle.

### Dr. and Mrs. Benjamin F. Iden,

Manassas, Va., entertained at a reception on January 27, in honor of their fiftieth wedding anniversary. They have spent their entire married life in Manassas, where Dr. Iden has been engaged in the practice of medicine for more than fifty years. Their two sons, Dr. John Hooe Iden, of the U. S. Navy, and Dr. B. F. Iden, Jr., are also members of the medical profession.

### U. S. Civil Service Examinations.

The U. S. Civil Service Commission announces open competitive examinations, receipt of applications to close February 26, for

specialist in maternal and infant hygiene, assistant in maternal and infant hygiene, and expert in maternal and infant care. Full information and application blanks may be obtained from the above named Commission, Washington, D. C., or the secretary of the board of U. S. Civil Service Examiners at the post-office or customhouse in any city.

Open competitive examinations are also announced for medical officer, junior grade; medical officer, grade A; and medical officer, grade B. Applications will be rated as received until June 30, 1924.

Applications will also be received for positions as reconstruction aide (occupational therapy) and reconstruction pupil aide (occupational therapy) until March 11; and for graduate nurse, applications to be rated as received until June 30.

### Dr. Greer Baughman,

Richmond, professor of obstetrics in Medical College of Virginia, by invitation read a paper on "The Toxemias of Pregnancy" before the Norfolk County Medical Society on January 28.

### Mrs. R. Lloyd Williams,

Norfolk, Va., president of the Woman's Auxiliary to the Medical Society of Virginia, while on a visit to her old home in Houston, Texas, was given a Christmas entertainment by the Woman's Auxiliary of the Harris County Medical Association, at the home of Dr. and Mrs. S. C. Red, in Houston. Mrs. Red is president of the Woman's Auxiliary of the American Medical Association. Dr. Williams, who accompanied his wife on her visit to Texas, was included as one of the honor guests and the local doctors were invited.

Dr. Williams returned to Virginia for the opening of legislature to take his seat in the House of Delegates as one of the representatives from Norfolk.

### Citation in the Award of the Sofie A. Nordhoff-Jung Cancer Research Prize.

Dr. Johannes Fibiger, professor ordinarius in pathological anatomy at the University of Copenhagen, has demonstrated, following repeated experimentation, that parasites play an important role in the formation of certain types of tumors in the proventriculi of rats.

Furthermore he has succeeded in effecting papillomata and undoubted carcinoma through the parasite nematode. Where others have failed after years of persistent researches, he first met with success in artificially inducing malignant tumors through external irritations and so thrown wide new avenues to future findings. Though the earlier results of Fibiger's work date back a number of years, he unremittingly labored towards an interpretation of the significance of parasitic irritants in malignant tumor formation, likewise of mechanical and chemical irritants. Fibiger and his associates have contributed generously to the literature of cancer production through the feeding to rats of oats and the application of tar to their tissues. In this way they have confirmed the successful work of Stahr and Yamagiva.

In a word, Fibiger's advances towards the solution of the problem of the causative irritants productive of cancer are at the same time most comprehensive and most remarkable.

His name will ever appear inscribed on the first page of the History of Cancer Research.

The Commission on the award consisted of Professors Borst, Doederlein v. Romberg and Sauerbruch, all of the University of Munich.

#### **Newport News Doctors Visit Richmond Hospitals.**

Dr. Joseph T. Buxton, of the Elizabeth Buxton Hospital, Newport News, Va., accompanied by about twenty doctors from that place, recently visited Richmond and inspected the new Johnston-Willis Sanatorium and the McGuire Clinic. They were highly enthusiastic in their praises of both institutions.

#### **Dr. E. E. Walker,**

Recently of Phenix, Va., is now associated with Dr. Samuel W. Price, of Scarbro, W. Va., in the practice of medicine.

#### **Bank Directors.**

Dr. W. C. Powell and Dr. F. J. Wright, Petersburg, have been elected members of the board of directors of the Banking Trust and Mortgage Company of that city. Among the other directors are Dr. W. W. Seward, of Surry, and Dr. W. P. Hoy, of Petersburg.

#### **Dr. Lawrence T. Price,**

Richmond, has been elected commander of Stonewall Jackson Camp, No. 981, Sons of Confederate Veterans.

Dr. P. D. Lipscomb, also of this city, was re-elected surgeon.

#### **Fire at Memorial Hospital, Winchester.**

Fire of undetermined origin destroyed the central portion of the main building of Memorial Hospital, Winchester, Va., early on the night of the 18th of January. The loss of approximately \$100,000 was only partially covered by insurance. All patients were removed in safety to homes and local hotels.

We have not been advised as to future plans for the hospital, but, as it had practically outgrown its present building, it is probable that a new hospital may be built on another site.

#### **Directors of a Richmond Bank.**

Dr. M. L. Anderson and Dr. J. R. Blair, both of Richmond, have been elected among the directors of the Systematic Savings Corporation, of this city.

#### **Dr. Virgil Hammer,**

One of the best known physicians of the Valley of Virginia, has been critically ill at his home in Luray, Va.

#### **Superintendent of St. Luke's Hospital Resigns.**

Miss Martha Baylor, for the past five years superintendent at St. Luke's Hospital, Richmond, resigned February 1. Miss Baylor is president of the Virginia State League of Nursing Education and has been actively interested in advancing the standard of nursing education in Virginia. She plans a special course of study at Columbia University, New York City, after which she expects to devote her time to teaching.

Miss Elizabeth Hendricks, formerly in charge of the operating room at St. Luke's, has succeeded Miss Baylor as superintendent.

#### **U. S. Veterans' Bureau in Danville Closed.**

The United States Veterans' Bureau, established in Danville, Va., for more than a year, with Dr. Claude N. Rucker in charge, has been closed and Dr. Rucker has been transferred to Huntington, W. Va. Dr. Rucker

had three hundred cases under his supervision while in Danville. That district will hereafter be looked after from the Roanoke office.

#### **Dr. W. Armistead Gills,**

Formerly of Richmond, but with the United States Navy since June, 1917, has been placed on the list of retired officers of the U. S. Navy. Dr. Gills' last service was on the Asiatic squadron.

#### **New Business Manager at Hygeia Hospital.**

Mr. W. L. Lucas, for nearly ten years credit manager of O. H. Berry & Company, of this city, has accepted the position as business manager of Hygeia Hospital, Richmond, the change becoming effective in January. The office Mr. Lucas holds is a new one at Hygeia Hospital and has been created on account of the large increase in number of patients cared for there. The hospital is owned and operated by Dr. J. R. Blair. At present it is undergoing a number of improvements.

#### **On Hospital Board.**

At a recent meeting of the board of directors of the Petersburg, Va., Hospital, Dr. William F. Drewry was re-named vice-president, and Drs. R. A. Martin and H. G. Turner were among those named as members of the board.

#### **Dr. W. Brownley Foster**

And family, of Roanoke, Va., were recent guests of Dr. Foster's parents in Richmond.

#### **In the Confederate "Hall of Fame."**

On February 2nd, there were presented to Battle Abbey (the Confederate Memorial Institute), Richmond, bronze busts of two of Virginia's most renowned and beloved members of the medical profession—Hunter Holmes McGuire, M. D., and Rawley White Martin, M. D. Not because of their achievements in the medical world were they thus honored, but because of their patriotism and of the fact that they were leaders of men in peace as well as in war.

The bust of Dr. McGuire was presented by Senator Don P. Halsey, of Lynchburg, Va., and accepted by Dr. J. Allison Hodges, of Richmond; that of Dr. Martin was presented by Dr. Stuart McGuire, of Richmond, and accepted by Mr. Randolph Harrison, of Lynchburg. Most fitting was this double presentation as Dr. McGuire and Dr. Martin were closely

associated in the medical history of Virginia and were life long friends. In this issue of the journal\* we give the speeches of presentation. We regret space forbade our making claim for the speeches of acceptance also, as they too bore fitting tribute to the lives of these two noble men.

\*See pages 787-790.

#### **Dr. P. L. Hill,**

A medical missionary to Choon Chun, Korea, who has been on a furlough in this country on account of his health, was a recent visitor in Richmond, where he delivered several addresses. He graduated from the Medical College of Virginia in 1917 and has many friends in this State. Dr. Hill expects to return shortly to his post of duty.

#### **Income Tax.**

Every one is now so familiar with the payment of Federal income tax that it is only necessary to state that returns, with first payments should be made to the collector of internal revenue for the district in which you live by March 15th.

#### **The Alleghany County Medical Society,**

At its meeting in Clifton Forge, January 15, elected the following officers for the ensuing year: President, Dr. W. H. F. Miller, Clifton Forge; vice-president, Dr. J. V. Jordan, Covington; secretary, Dr. R. P. Hawkins, Jr., Clifton Forge; and treasurer, Dr. W. M. Revercomb, Clifton Forge.

#### **The Mercer County (W. Va.) Medical Society,**

At its annual meeting held recently, elected Dr. Joseph B. Kirk, Bluefield, president, and Dr. Walter W. Harloe, Matoaka, secretary-treasurer.

#### **Erratum.**

In the list of officers of the Warwick County (Va.) Medical Society, in the January issue (advertising page 32), we gave the name of Dr. O. T. Amory as secretary. This should have been Dr. A. D. Ownbey, secretary, Dr. Amory being vice-president.

#### **Cancer,**

A practical quarterly journal devoted to the best interests of cancer, which made its first appearance in October, is published by J. B. Lippincott Company, East Washington

Square, Philadelphia, and not by F. A. Davis, as stated at that time. The price is \$5 a volume in North America. Dr. L. Duncan Bulkley has associated with him in the editorial work some of the country's best informed men on the subject of cancer.

### **The Rockefeller Foundation,**

Located at 61 Broadway, New York City, has issued its annual report for 1922. In addition to giving the annual reports of the president, secretary and treasurer, it tells in detail of much of the work done by the Foundation, especially in foreign countries. The illustrations are good and add much to the interest of the report.

### **Revoke Charter.**

It is announced that the circuit court at Richmond, the latter part of December, revoked the charter of the Oriental University, operated in Washington, D. C., with charter obtained from Virginia. It had for some time been known to be a fraudulent institution and was considered one of the "diploma mills."

### **Dr. Lewis B. McBrayer**

Has resigned as superintendent of the N. C. Tuberculosis Sanatorium, at Sanatorium, and will be succeeded by Dr. Paul P. McCain, who has been assistant superintendent.

### **Motion Picture for Health Associations.**

The Metropolitan Life Insurance Company, 1 Madison Avenue, New York City, with the advice of the National Health Council, has produced a motion picture of two reels, entitled "Working for Dear Life," with an idea of giving the audience at least a working idea of what a thorough health examination should be. The scenario is said to be well planned and the argument convincing.

With the idea of promoting health conditions throughout the country, the above named company will send the film free, except for transportation charges, to Health Associations and other organizations desiring it.

### **Graduate Nurses' Association of Virginia Undertakes Big Project.**

This Association has pledged itself to raise \$50,000, through its own efforts for the endowment of a chair of nursing at the University of Virginia. Such a course would give nurses in this section an opportunity to secure near home the graduate work for which they now have to go to Northern schools. It is

stated that the proposed chair of nursing will be the first of its kind in the South. As a means to raising part of this endowment money, groups of nurses in several Virginia cities plan to put on a pageant simultaneously throughout Virginia on May 12, the birthday of Florence Nightingale. This pageant is to show the development of nursing since the days of Florence Nightingale, with special reference to the growth of the profession in this state.

### **Increase in Number of Deaths From Automobiles in Virginia.**

Dr. W. A. Plecker, State Registrar, states that although deaths from violence in many forms are on the increase, none can compare with the great increase in automobile deaths, as shown by comparison for the first nine months of 1922 and for a similar period in 1923. For 1922, there were 94 deaths recorded in Virginia from automobile accidents, for the first nine months; in a similar period in 1923, there were 137. There were only 142 deaths for the whole of 1922. Should this rate of increase continue for the next ten years, the automobile will soon be a major cause of deaths in this State.

### **A New A. C. S. Monograph**

The publication of a new American Chemical Society Monograph is announced by The Chemical Catalog Company of New York. This recent book by Dr. George W. Raiziss, Ph.D., and Joseph L. Gavron, B. S., is entitled "Organic Arsenical Compounds," and is a most comprehensive work on this subject.

Doctor Raiziss, Professor of Chemotherapy, Graduate School of Medicine, University of Pennsylvania, was the first laboratory worker in the United States to successfully develop American-made arsphenamines for use in the treatment of syphilis. Mr. Joseph L. Gavron has been associated with Doctor Raiziss in literary and laboratory work done in The Dermatological Research Laboratories of Philadelphia.

### **The Eastern Division of the American Roentgen Ray Society**

Held its annual meeting in Atlantic City in January, Dr. Thomas A. Groover, of Washington, D. C., presiding. It was an excellent meeting and well attended. Virginia doctors in attendance were Drs. A. L. Gray, Fred M. Hodges, C. M. Hazen and D. D. Talley, of Richmond, James W. Hunter, of Norfolk, J. T.

McKinney, of Roanoke, Hunter B. Spencer, of Lynchburg. Dr. Charles Eastmond, of Brooklyn, was elected chairman; Dr. Ralph D. Leonard, of Boston, vice-chairman, and Dr. Fred M. Hodges, of Richmond, Va., and Dr. The meetings are held in January of each year at Atlantic City.

#### **Dr. Bell Succeeds Dr. Maloney With Richmond Health Bureau.**

Dr. G. R. Maloney, for nineteen months with the Bureau of Health of the Department of Public Welfare of Richmond, resigned his position as chief of the division of communicable diseases, the first of February, with the intention of entering general practice. He has been succeeded by Dr. H. O. Bell who recently joined the Bureau in the capacity of medical inspector.

#### **Dr. Oldham Escapes From Perilous Position.**

Dr. M. C. Oldham and a friend, of Lancaster, Va., had a narrow escape from death, the middle of January while out duck hunting. A terrific wind storm broke and, despite strenuous efforts, they were unable to make shore. After dark they began firing guns with the hope of attracting help. Owing to the high wind, the report of the guns could not be heard but they were finally sighted by the blaze from the muzzles of their guns and help was sent them. They were much exhausted from their experience and suffered greatly from the intense cold.

#### **In Charge of Health Units.**

Dr. E. L. Sutherland, formerly of Roanoke, Va., took charge of the Nansemond-Suffolk joint county and city health unit, beginning January 15, succeeding Dr. I. C. Riggan who resigned to take up a course of study at the Johns Hopkins School of Public Health Administration.

Dr. E. D. Woodard, of Bayboro, N. C., has entered upon his duties in charge of a health unit in Isle of Wight County, Va.

#### **A Word of Appreciation.**

We wish to express our thanks to members of the Medical Society of Virginia for their splendid co-operation in sending checks to cover 1924 assessments in response to the "blue slips" placed in the January journal. It is gratifying to learn from this response also that the VIRGINIA MEDICAL MONTHLY "is not without honor" in its own state.

Don't forget, however, that our advertisers

are entitled to a portion of the time you can spend in looking over our pages.

#### **The Virginia Tuberculosis Association,**

At its annual meeting in Richmond, January 18, elected Dr. Charles R. Grandy, of Norfolk, president. He succeeds Captain W. W. Baker who had been president since the organization of the association. Captain Baker was elected honorary president. Dr. William M. Smith, of Alexandria, was elected executive secretary, and Dr. E. C. Levy, of Richmond, was elected first vice-president.

#### **The Norfolk County Medical Society**

Has adopted the report of the special Committee on Narcotics, urging members to refer all cases of drug addiction to the City Health Department for appropriate hospital treatment. It also advised total discontinuance of the dispensing of narcotics, issuing prescriptions instead, thereby lessening liability to reproach.

#### **Dates Set for State Society Meeting.**

At a meeting of the Executive Council on January 22, the dates were set for the Staunton meeting of the Medical Society of Virginia, as October 14, 15, 16 and 17, 1924. It is announced that the new hotel will be completed in the Spring. This with the Virginia Hotel with which it is connected, the Beverley, the Y. M. C. A., and other places which may be secured in case of necessity, should provide ample accomodation, though it is always well to make reservation as far in advance as possible, so as to be at the hotel of choice. The doctors of Augusta County are manifesting much interest in the approaching meeting and will shortly announce committees in charge of the various features of the meeting.

#### **Dr. Garnett Nelson**

Has been re-elected president of the Richmond Tuberculosis Association for the ensuing year.

#### **Dr. R. W. Garnett,**

Health Officer of Danville, Va., has declined an offer to become health officer of Greensboro, N. C., that he may continue with the work he has been doing in Danville.

#### **New St. Luke's Hospital in Bluefield, W. Va.**

Early in January, the new St. Luke's Hospital was opened in Bluefield, W. Va. Located in the residential section of the city, the hospital is a model of completeness in every

respect and thoroughly fireproof. Dr. C. M. Scott, assisted by Dr. T. E. Vass, is in charge of the surgical department, and Dr. R. H. Hoge is in charge of the medical department. The hospital can care for approximately one hundred patients. The nurses's home in a separate building has sixteen large rooms, likewise equipped with all modern conveniences. So far as known, this hospital is the first institution of its kind in the world to be thoroughly equipped with radio. Each bed in the hospital is provided with a head piece and the system is so devised that when a patient has callers, all who care to may "listen in."

#### **The National Committee for Mental Hygiene,**

At its annual meeting recently held in New York City, re-elected Dr. Frankwood E. Williams, of that city, medical director for the ensuing year.

#### **Health News.**

The first weekly issue of this bulletin, published by the New York State Department of Health, made its appearance in January. It "inaugurates a policy of furnishing information on current events in public health, to the health officers, public health nurses, physicians, organizations and individuals interested in public health work." Dr. Nicoll is to be congratulated on this evidence of progress in his department.

#### **Dr. C. C. Coleman,**

Richmond, has returned from a trip to Florida, where he enjoyed a winter vacation.

#### **Have You Told Your Patients About "Hygeia"?**

This journal of "individual and community health" is published monthly by the American Medical Association at the price of \$3 a year. It is intended primarily for the layman but furnishes interesting reading for any one. Highly educated people are frequently ignorant of the fundamental principles of health, but they are always interested in learning something of what the doctor knows. This magazine if generally read by laymen should do much in helping the doctor in his fight against quackery.

#### **Fire in Clinic Building at Johns Hopkins.**

A fire believed to have been caused by a short circuit broke out in a machinery room directly beneath one of the operating rooms in the women's clinic building at John Hopkins Hos-

pital on January 30. Three women prepared for operation were removed and the flames were confined to the one building.

## Obituary

#### **Dr. Claybrook Fautleroy,**

Of Dragonville, Va., died at the home of a sister in Richmond, on January 10. He had been in bad health for sometime. He was born in King and Queen County, Va., sixty-four years ago and received his medical education at the University of Pennsylvania, Philadelphia, from which he graduated in 1882. Dr. Fautleroy had been a member of the Medical Society of Virginia since 1888. He is survived by his wife and a large family connection.

#### **Dr. Paulus Fitz James Miller,**

Of Virginia Beach, Va., after having been in bad health for sometime, died at a Norfolk hospital, January 19. Interment took place in Richmond. Dr. Miller was sixty-nine years of age and was a member of the Medical Society of Virginia. He was a physician of the "old school" and was much beloved in his section.

#### **Dr. Henry Dorrance Beyea,**

A retired surgeon of Philadelphia, who had recently made his home at Ware Neck, Va., died early on the morning of January 20th. He was apparently in good health, having been out in the neighborhood the previous afternoon. Dr. Beyea was fifty-six years of age and a graduate in medicine from the University of Pennsylvania in 1891. He had joined the Medical Society of Virginia a few months ago. He is survived by his wife and four children.

#### **Dr. Luther Emmett Holt,**

One of the best known pediatricians of this country and professor of diseases of children in Columbia University, College of Physicians and Surgeons, New York City, died in Peking, China, the middle of January, from heart disease. Last Fall, he was assigned by the Rockefeller Foundation as visiting professor of pediatrics to the Peking University Medical College and had just about completed the course of lectures which he was to give in that city. He was sixty-eight years of age and had graduated in medicine from Columbia University, New York, in 1889.

## CALCREOSE

TABLETS  
POWDER  
SOLUTION

### Creosote in Tuberculosis

"It is again coming into favor. There seems to be no doubt but that it has a very definite effect in reducing expectoration and in lessening purulency. As a certain amount of the drug is excreted by the bronchial mucous membrane, this may explain, in part, its beneficial effects."  
—John Guy: Pulmonary Tuberculosis; Its Diagnosis and Treatment, 1923, p. 252.

**C**ALCREOSE (calcium creosotate) is a mixture of approximately equal parts of beechwood creosote and calcium. It possesses the pharmacologic activity of creosote, but, apparently, does not cause the gastro-intestinal disturbances to which patients object. Therefore CALCREOSE can be administered for comparatively long periods of time in large doses.

### HEMORRHOIDS UNDER REGIONAL ANESTHESIA.\*

By STANLEY H. GRAVES, M. D., F. A. C. S., Norfolk, Va.

Since it has been proven that the only satisfactory method for curing hemorrhoids is by operation, every effort should be put forward to successfully combat the suffering and discomfort incident to hemorrhoidectomy, and an operative technic worked out, and adopted, that can be speedily performed, without pain or great inconvenience to the patient. The writer believes that, with the use of regional anesthesia, such a method is at our disposal and, in the hands of a skilled operator and properly utilized, should not cause any pain, at the same time being safe, simple and satisfactory.

After the patient has been examined, hospitalized, and prepared, one of four methods of operative procedure are at one's disposal. Named in their order of popularity, they are the ligature, clamp and cautery, excision of veins, and the Whitehead operation. My preference is the ligature. It appears to be the method of choice, has been utilized in the removal of hemorrhoids for many years, and is still universally employed by surgeons throughout the world. Few instruments are required, the operation can be performed in a few minutes, and is very rarely accompanied by profuse bleeding or post-operative complications.

The next is the clamp and cautery, especially useful in the removal of internal hemorrhoids. In fact, this method is applicable to so many cases, that it is often a personal preference with the operator as to whether he utilize the ligature or clamp and cautery. The few disadvantages of the method are hemorrhage, and the failure of the cautery to work at the appointed time. I have greatly overcome this difficulty by using the electro-cautery. Some

little practice and experience will be required with this type of cautery to properly regulate the heat. If the point is too hot, it predisposes the case to hemorrhage and, in touching tabs, the transmitted heat may cause the skin edges to slough, which is invariably followed by much discomfort and pain.

The excision method is occasionally used on very large external piles. Here the tumor masses are removed in successive stages, first an incision, dissecting out the large veins, suturing or ligating them, and then suturing of the wound. The operation is comparatively safe, and discomfort or post-operative complications are as infrequent as with the simple ligatures. I rarely employ the Whitehead operation; it has too many disadvantages to commend its frequent use. It should be utilized in only a few selected cases, then by a skilled operator.

When considering regional anesthesia for the removal of hemorrhoids, we have two routes for selection. The sacral block and the ano-rectal field block. Caudal or sacral anesthesia is accomplished by passing the needle through the sacral hiatus, and depositing the anesthetic in the sacral canal. This opening is the result of defective closure, or non-closure of the laminae of the last sacral vertebra, and is covered by the sacro-coccygeal membrane. The hiatus lies at about the junction of the sacrum and the coccyx, and is bounded by the sacral cornua on each side, and the spinous process of the fourth sacral vertebra above. It has the shape of an inverted "V." The sacral canal is a prismatic space occupying the whole length of the sacrum, and is connected with spinal canal by its upper extremity, its lower extremity being the sacral hiatus.

With the patient lying flat on his stomach, and a cushion under his hips to raise the sacral region, and render the landmarks more accessible, the sacral hiatus is located by passing the index finger on the middle of the back from the tip of the coccyx toward the sacral region. A depression will be felt about the junction of

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

the coccyx with the sacrum, and outlined by the sacral cornua on either side and the spinous process of the fourth sacral vertebra in the midline above. The outlining of these three points, that are palpable in the majority of cases, will define a triangular space, at the middle point of which the needle is introduced with ease and success. A spinal puncture needle, with its stylet in and the bevel turned upwards, is introduced through a wheal of novocain raised at this point, at an angle of about twenty degrees, with the normal to the skin surface at the site of the puncture. After piercing the sacrococcygeal membrane, the needle strikes the anterior wall of the canal. It is now withdrawn slightly, and the body of the needle depressed, and advanced gently and gradually into the canal, keeping in the middle line until about 6 c.m.— $2\frac{1}{4}$  inches—has been introduced. If there is obstruction a short distance from the point of entrance, a little manipulation of the sacrococcygeal membrane and gentle movement of the needle will usually release it. If this is not successful, the needle must be withdrawn and introduced a little higher up. When in correct position, the stylet is withdrawn, and a little time is allowed to make sure that no blood or cerebrospinal fluid comes out. If this should occur, the needle is withdrawn slightly until the flow ceases. It is best, before making the injection, to attach the empty syringe and make the aspiration test before the solution is introduced, so as to be quite certain that no intraspinal or intravenous injection is made.

The syringe is now filled with the solution, which consists of 30 c.c. of a 2 per cent solution of novocain and is slowly injected. A very good point to remember is that when the needle is correctly in the sacral canal the fluid passes in very easily, and free from pain but, when not in the canal, considerable pressure is required, and the patient will complain of some pain. In my work I have preferred the novocain put up in the following combination:

	Sodium Bicarb	0.15 gm. (pure)
	Sodium Chlo	0.10 gm.
For a 2% solution:	Novocain Hydroc	0.60 gm.
	Distilled water	30.00 c.c.

Five drops of adrenalin is added at the time of use.

The injection having been made, the patient is directed to turn on his back. Anesthesia will not set in satisfactorily for fifteen minutes,

and can be tested with a needle or clamp on the skin around the anus.

The ano-rectal field block is performed by introducing the novocain around the lower segment of the rectum, catching the nerves outside, and away from the bowel. The patient is placed in the lithotomy position, and from two to four small wheals of novocain are made around the anus and about 2 c.m. from the hemorrhoids. If this is done with a very small needle and the skin pinched up when the needle is introduced, patients will very rarely complain of the puncture. A 5 c.m. needle with some flexibility is now introduced in the various wheals and a circular injection made under the integument. This injection greatly relieves the sensitive condition of the piles, and admits the passage of the finger into the rectum without discomfort. At this point, a 10 c.m. flexible needle is affixed to the syringe, and introduced at the injected points successively and passed along the inner aspect of the sphincter muscle, injecting the fluid as the needle is introduced, the finger in the rectum guiding the needle and eliciting the quantity of solution injected by the submucous bulging. In about ten minutes the anesthesia should be complete. Very rarely will the sphincter require any dilatation, for under regional anesthesia the tissues relax themselves. A  $\frac{1}{2}$  to  $\frac{7}{10}$  per cent solution is used and 50 to 80 c.c. will be the usual amount required. Two to 3 drops of adrenalin chloride is added to each 10 c.c. of fluid.

In a series of one hundred hemorrhoidectomies in my service at the Sarah Leigh Hospital, the following anesthetics were used:

Sacral Block	61
Gas Oxygen	22
Ether	8
Sacral & G. O.	3
Lower Field Block	5
Gas Ether	1

Five of the gas oxygen cases had sacral block which failed to work satisfactorily; two of the ano-rectal block had sacral injections that proved to be inadequate. The after effects or complications may be enumerated as follows:

Three complained of considerable pain in and around the field of operation, all three clamp and cautery; one hemorrhage, a clamp and cautery; one sloughing of the outside skin, caused by use of cautery on tags after the employment of ligature; four cases complained

of some pain in the sacral region radiating toward the hips for a few days, which then entirely disappeared. It must not be overlooked that all of this series were hospital cases and none of the variety treated in the office, such as thrombotic piles and skin tags.

After the operation, a suitable wedge-shaped dressing is placed over the anus and a well fitting T-binder is applied. Sometimes a tube or wick of gauze, well coated with vaseline, is used in the rectum, but they predispose to pain, difficult micturition and hemorrhage when removed, *therefore*, should be discouraged in all uncomplicated cases. The changing of the outside dressing as may be required and the use of morphia and a hot water bag over the dressing as needed for pain, and liquid diet, constitute the after treatment. A gentle cathartic is given on the second or third night, the bowels acting as a rule during the forenoon of the following day. After the bowel evacuation, the patient is placed in a tub of hot water for ten or fifteen minutes, then dressed. Deod. Tr. Opium may now be resorted to for pain and any tendency to straining; soft diet is ordered for two days; when general diet is permitted. The stay in the hospital is from one week to ten days for clamp and cautery and ten days to two weeks for ligature and excision. If the injections are made correctly, and the solution represents its full strength, the entire field of operation should be so anesthetized that all manipulations are perfectly painless, unless rough handling, and undue pulling against the adjacent unanesthetized tissues cause excitement and distress.

In my experience there have been no ill effects from this method, and it certainly reaches the ideal more nearly than any method known today. It is applicable to almost all cases, especially in the very old and infirm, and where other anesthetics are contra-indicated. The tissues are nicely relaxed, *thereby* overcoming much trauma incident to the manual stretching of the sphincter, and the block—lasting from one to one and one-half hours, prevents a great deal of after suffering. Patients are freed from painful shock, post-operative shock, and vomiting which often follow the general anesthetic. Failures are generally due to technical errors, congenital defects, occlusion of the sacral foramen, traumatized pelvis and malignancy of the sacral canal.

## DISCUSSION.

DR. S. S. GALE, Roanoke: I think the Doctor has covered the ground on regional anesthesia in hemorrhoidectomy very thoroughly. Personally I have had some experience in the use of caudal block in operating on internal hemorrhoids.

I had the misfortune to do a caudal block not long ago, not on an internal hemorrhoid case but for stricture of the urethra, and I lost my patient. This patient was a very sick and very much run down man and had retention of urine, cystitis and poor kidney function. For that reason I thought the caudal block would be the safest anesthesia. In this case I overlooked the point which the Doctor has made in doing these blocks, that is not passing the needle further than 6 cm. into the caudal canal. While I had studied the technic of several different clinics I had failed to grasp the point the Doctor mentioned of not passing the needle into the canal beyond 6 cm. After passing the needle into the canal, attach the syringe and see if blood or spinal fluid can be aspirated into the syringe. If so, change the position of the needle until no fluid nor blood runs into the needle. Labat states that often if no fluid can be aspirated this is not positive proof that the needle may not be in the spinal canal and that the only certain method of keeping the needle out of the canal is not to pass it beyond 6 cm. After this unfortunate occurrence I carried on quite a lengthy correspondence with Dr. Labat. I described this case to him and asked him if he could tell me why the patient died. Of course the correspondence was unsatisfactory as he did not see the patient and did not know me nor my technic, but after summing up the matter I feel certain that I put the needle in too far.

I have used caudal anesthesia in a number of cases and have never had any accidents nor any bad results except in this case which I wanted to bring to your attention.

I make it a rule never to put anything in the rectum. Of course, Dr. Graves made the point that nothing should be put into the rectum except when it is necessary to control hemorrhage. If you do put anything into the rectal canal you will have pain. In my cases I have never had a post-operative hemorrhage.

In regard to the after treatment and the movement of the bowels, I have adopted the plan of starting these patients on mineral oil as soon after the operation as possible and in two or three days the bowels will move.

DR. WILLIAM E. ANDERSON, Farmville: I would like to take about two minutes to say hemorrhoids can be operated on with local anesthesia fairly well. Local anesthesia will in many cases prove entirely satisfactory, but, when there is to be a considerable number of hemorrhoids removed, especially when high up, general anesthesia is preferable and the clamp and cautery is the procedure for removable.

DR. WALTER COX, Winchester: I came over especially to hear this important paper, and I was very much interested when he said he had performed the operation practically without pain. This is the first question patients always ask me.

We have a very peculiar situation at Winchester. Three of my patients have refused to go to the sur-

geons for fear of the pain. These people are going to some quacks at Grand Rapids, Mich. These people, Burlleson Bros., have a painless operation for hemorrhoids. I know this because I have talked personally with patients—and they get results—some form of electric treatment. I have examined three people who came back most enthusiastic.

I have been trying to find out their methods, have written for equipment, etc. These people put the patient on the table twice in severe cases, but in other cases only once. They do it by putting some kind of electric needle in the rectum.

One man was cured of prolapse of the rectum, hemorrhoids and fistula. I would like to know more about these people and in some way learn the secret.

Dr. ———: I do considerable rectal work. I took some work under Dr. ———\*, of New York, and I would like to say he never dilates the sphincter, never uses deep traumatism, as it increases discomfort. During my stay with him he had good results with evidences of very little pain.

He never uses opiates, whether done under local or general anesthesia. He has written several books on diseases of the colon and rectum.

Dr. GRAVES, closing discussion: I want to thank all of the gentlemen for their discussion. It is very nice to have them bring out these important points.

I think Dr. Cox must have gotten the wrong idea about the opiates. I said I sometimes used a hypodermic of morphia. I operated on a young man a few days ago who had right much pain, but he is the first one I have had to give more than one dose of morphia in the last several cases. The report that Dr. Cox gave of an unusual treatment for hemorrhoids reminds me of some other treatments that used to be considered cure-alls. One especially was the cancer cure. These quacks guaranteed to cure cancer with a paste. One application of the paste was enough. One dose of salvarsan used to be considered a cure. I feel sure that all of you will recall some of these cases returning for further treatment if they only lived long enough.

\*Stenographer failed to obtain names.

### URETERAL CALCULI.\*

By JOHN H. NEFF, M. D., University, Va.

This paper is based in the main upon an analysis of the clinical records of fifty-eight cases of ureteral calculi. While the group is not a large one, a review of the contained data may at least emphasize points of symptomatology and diagnosis which can hardly be restated too often. Certainly this is true if judged by the statistical revelation of diagnostic error.

The most striking, yet not surprising, fact disclosed by this study was the inability in any instance to ascribe a definite cause for the stone. It was uniformly assumed that the calculus had formed in the kidney, from whence it had entered the ureter and there lodged. Hunner believes that a goodly proportion of ureteral calculi develop primarily

in the ureter, that a pre-existing ureteral stricture is responsible for the inauguration of the stone forming process. While it was evident from the size of some of the stones that considerable increment must have occurred after entrance into the duct, our analysis yields no information of either a positive or negative character about Hunner's theory. The researches at the Mayo Clinic in recent years place greatest stress on abnormal bio-chemical processes and specific infection as the important etiological factors in lithiasis rather than on mechanical obstruction. A discussion of the many theories of stone formation, however, would lead one far afield and is beyond the proper limits of an avowedly clinical summary. The solution of the problem will aid materially in the prevention of recurrences but it is rather probable that calculi will continue to be the most frequent cause of serious ureteral obstruction.

It is will-nigh axiomatic that obstructive lesions in the upper urinary tract are commonly deceptive in their symptomatology. No exception to this rule is found in the series under discussion. Characteristic renal colic, with its severity and typical radiation from the kidney to the bladder or bladder to the kidney and the further frequent extension to the external genitalia and down the thigh, is too clear cut and too familiar to warrant mistake in diagnosis. But our records show that in one-third of the patients the pain departed from what might be called this text book type.

In fifteen per cent of the series all the pain is stated to have been in the lower quadrant of the abdomen. The most usual site was at a level just within the midpoint of Poupart's ligament and from here radiating downward. The predominant pain in a few has been further out toward the umbilicus and with practically no extension elsewhere. Eleven patients—eighteen per cent—have had all their pain in the upper half of the abdomen, most pronounced usually in the kidney region, but only too often infringing on the so-called gall-bladder territory or, as complained of in one case, even most marked in the epigastrium. The ready possibility of diagnostic error in either the upper or lower right abdomen is quite obvious where such pain is associated with active nausea, a little temperature and some tenderness. One unique case had no pain whatsoever. This patient was admitted with a quite typical history of left side pyone-

\*Read at the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

phrosis. Routine X-ray examination of the urinary tract revealed a characteristic shadow in the line of the left ureter but also a very suggestive shadow on the right side. Cystoscopic study demonstrated conclusively that the shadow on the right side was a stone and the stone was removed by operation. We have seen many cases of silent renal calculi but this is our first experience with a symptomatic quiescence on the part of a ureteral calculus.

Error in diagnosis is naturally more liable to occur with stones on the right than on the left. Thirty-eight of the fifty-eight cases had their stones in the right ureter. In this group, four—ten per cent—had had abdominal operations for the same symptoms prior to recognition and removal of a ureteral calculus. Four appendectomies and one exploration of the gall-bladder composed the list, one of these operations being accredited to us and three to other surgeons. In another ten per cent of these patients with right sided stones, our pre-operative diagnoses were wrong, somewhat retrieved possibly by the fact that the true condition was discovered at operation and corrected. The diagnoses in these four latter cases were,—appendicitis twice, gall-bladder disease once, appendix abscess once. The diagnosis of an appendix abscess was made in a patient admitted as an emergency with signs of an acute inflammatory process in the abdomen, exquisite tenderness and an ill-defined mass just medial to the anterior superior spine of the right ilium. The condition proved to be a ruptured ureter with extensive extravasation of urine secondary to a calculus. Two of these patients for whom our pre-operative diagnosis was incorrect had been X-rayed with negative findings and also cystoscoped, one with ready catheterization of the suspected ureter, in the other the ureter could not be entered because of spasm. A wax tipped catheter was not used in the first patient; the examination was not repeated in the second. Either by ourselves or other surgeons, therefore, the appendix or gall-bladder have been unjustly inculpated in twenty per cent of the patients with right sided stones, and in ten per cent unnecessary operations were performed. These figures lend support to the argument for an incision sufficiently large for thorough exploration where the pre-operative diagnosis in the right abdomen is in any degree uncertain, and suggest further that exploration must be

carried out no matter how many concretions in, bands about, or kinks of a non-inflamed appendix are found.

In a bare majority of the patients tenderness was elicited either in the kidney region or along the course of the ureter. Tenderness has, of course, been greatest in the presence of an accompanying pyelitis or pyonephrosis, though anything approximating heavy infection has been relatively infrequent for the whole group.

The urine was negative for pus or blood in four instances, that is, seven per cent of the series. The urine of thirty-one patients contained blood and pus in various proportions, sixteen cases only pus, seven only blood. There was a wide variation in the cellular content of the urine from the same patient upon repeated urinalyses.

The X-ray examination was negative in six of the fifty-five exposures, a percentage of eleven. In each of these six cases the calculus was later demonstrated by other means—by its passage, by operation, or by the cystoscope. The fallibility of the X-ray in demonstrating ureteral stones is, of course, well recognized by surgeons and urologists. It is possibly doubtful if general practitioners realize that some excellent roentgenologists make the statement that the failure of demonstration is as high as twenty or twenty-five per cent. Certainly the average patient seems to hold the conviction that the X-ray is all revealing and can tell no lies.

It has also to be borne in mind that characteristic pain, a positive urine, and seemingly typical shadows on an X-ray plate do not fully justify a diagnosis of ureteral calculus. The suspected shadow must be proven to be a stone by cystoscopic methods, alone or in conjunction with the X-ray. Thus we have had occasion to identify a calculus by use of a wax tipped catheter in nine instances, by a ureterogram in another nine cases, and by demonstrating apposition of the shadow and an opaque catheter in fifteen cases. Failure to prove the nature of suggestive shadows may lead to unnecessary operations upon the ureter. For example, we have found pyonephrosis the true condition in a man previously operated upon for ureteral calculi but none found. The first diagnosis had rested on a basis of typical colic, a bloody urine, two shadows low in the pelvis and a bloody efflux from the right ureter.

A plate with a leaded catheter in the ureter showed the shadows were extra-ureteral.

The cases here reported have been seen during the past fifteen years. During this period there has been what might be termed a revolutionary change in the treatment of ureteral calculi. Some years ago the choice lay between a policy of waiting for spontaneous passage or operative removal. The development of cystoscopic technique, however, and the various additions to the cystoscopist's armamentarium by such men as Lewis, Buerger, and others have completely altered the situation. Patients now seen in their early attacks where calculi are small are advised to play a waiting game, provided of course there are no unusual complications, and many of them pass their stones without much difficulty. For the others, where the stone has evidently become caught in the ureter and bids fair to hang at any point, cystoscopic manipulations to aid passage are begun and, if patiently carried out, are rewarded with a high degree of success. Operations are relegated to the last position, to be undertaken only where cystoscopic methods fail or where the condition is an emergent one.

Twenty-three patients of our series have remained under cystoscopic treatment until either the stone was passed or else we decided that our manipulations were futile. Cystoscopic efforts were successful in twenty-one of the twenty-three cases. Of the two failures, no progress had been made in one after some seven treatments and the stone was therefore removed by operation. In the second case, presenting a very low stone and a heavy infection above it, there was retrograde migration to the kidney probably during a quite severe reaction following the third dilatation. The calculus was later removed from one of the middle calices.

In these cystoscopic treatments we have employed the usual bougies, catheters, scissors and dilators of different types. The preliminary instillation of a little four per cent cocaine solution at the site of the stone has seemed to help materially in lessening pain and, by decreasing spasm, has rendered much easier the passage of an instrument by the obstruction. Olive oil has been injected freely for lubrication, primarily for the entering instruments and secondarily for the stone coming out. We prefer, if possible, to get two or more bougies or catheters by the stone and so

far this procedure has seemed more valuable than any other. As a rule, bougies have been left in position for twenty-four hours and have then usually come away with a marked drag, probably bringing the stone down into the grasp of the duct below the old point of lodgement and thus into a position where the expulsive efforts of the ureter could be more effective. The Lewis dilator has been used at least once in practically all cases. In one patient, a stone caught first at the orifice was readily freed by incision of the meatal lip with scissors.

The average interval between treatments has been about ten days. More than three treatments have been required in only three patients, viz., four, six and eight. The calculi have been situated in the lower portion of the ureter in twenty of the twenty-one successful cases. It is quite probable that a fair number of the stones would have been expelled without any instrumentation. Eleven of the twenty-one patients, however, had had attacks of colic for eight months or more, fifteen for more than two months. Only six were seen within ten days of the first attack of renal colic.

Sixteen patients of the whole series have come to operation. Immediate surgical attention was demanded only in the case with a ruptured ureter and extravasation of urine. Operative procedure here was limited to extensive extraperitoneal drainage. An entirely extraperitoneal ureterotomy was done in seven cases. In eight patients the peritoneum was first opened, the stone located, milked upward if possible, the ureter exposed with the aid of a hand within the abdomen, the peritoneum closed and the operation from this point carried out as in a primary extraperitoneal exposure. Opening the peritoneal cavity has been time saving, certainly where the calculus was deep in the pelvis. In all operations the ureteral incision has been sutured and we have found it distinctly helpful to place the sutures just after the duct has been incised upon the stone, but before the stone was lifted out. Routinely the ureter was dilated at and below the point of stone lodgement.

The average duration of hospital convalescence in these operative cases was twenty-four days. There was no leakage of urine in eight cases, some leakage in four, data as to this feature was lacking in the remaining histories.

The one post-operative complication was a femoral thrombosis followed by secondary pulmonary infarcts.

There was one operative death. This occurred in a woman with marked argyria, fifty-eight years of age, who presented an infected hydronephrosis due to a stone in the mid ureter. Because of her poor condition, a rubber tube was first placed to the kidney through the flank but did not drain well. Her temperature continued high and the stone was removed in the hope of securing better drainage. No improvement resulted and the patient died some six days later.

We have received reports from eleven of the twenty-one successful cystoscopic cases and none of those reporting have had further trouble. Thirteen of the fifteen cases surviving operation have reported. Nine have had no trouble since leaving the hospital, four have later passed stones.

In conclusion, the analysis of this case series justifies emphasis of the following points:

1. The urine, X-ray findings, and type of pain may be quite misleading in ureteral stone cases. Where there is even a remote possibility of a stone being present, complete urological study is demanded.

2. Cystoscopic manipulations should receive a thorough trial in uncomplicated cases of ureteral calculi before recourse is had to operative removal.

## PAPILLARY ADENOCYSTOMA OF THE PANCREAS.\*

By GEORGE TULLY VAUGHAN, M. D., LL. D., F. A. C. S.,  
Washington, D. C.

It seems that infections of the pancreas occur more frequently than cysts or neoplasms. Carcinoma is the most common of the new growths. In 11,472 necropsies, Segre found 127 cases of carcinoma and two of sarcoma. Hale White found one case of sarcoma in 6,708 necropsies. According to Deaver and Pfeiffer, carcinoma is the most common tumor of the pancreas, forming one per cent of all cases of carcinoma. The secondary are more frequent than the primary, coming from the stomach or biliary passages—ten per cent of gastric carcinomas extending to the pancreas—while the most common benign tumor is the cystadenoma.

Various forms of cyst may occur, as reten-

tion cysts, cysts from inflammation or hemorrhage, hydatid cysts, malignant cysts, and congenital cystic disease.

A cystoma is a neoplasm in which cysts make up some part of its structure. Such tumors are found frequently in the ovary and breast but rarely in the pancreas.

According to Ziegler the papillary adenocystoma constitutes a common variety of cystadenoma. "It is characterized by the fact that *papillary* excrescences develop in glands which have undergone cystic dilatation. In the ovary or breast such excrescences are usually slender and delicate, forming villous-like or cauliflower elevations which fill a larger or smaller part of the cysts. Larger papillae are always more or less branched and consist of a cellular stroma whose surface is covered with tall cells of the character of goblet-cells. The contents of the cysts consist of ropy mucus mingled with desquamated cells which have undergone mucous degeneration. Papillary adenocystomata show a certain degree of malignancy."

Haubold (*Princ. and Practice of Surg.*) says "Proliferation cysts of the pancreas are usually multilocular . . . and pathologically two types are recognized, the benign cyst-adenoma and the cystic epithelioma which is malignant. In many instances the clinical course is the determining factor as to the malignancy of the growth, it being often difficult histologically to differentiate between them.

Kemp (*Dis. Stom. Intest. and Pancreas*, 1917) says that among the true cysts of the pancreas we have retention cysts and proliferation cysts or cystic neoplasms. The latter are cystic tumors due to spontaneous proliferation of the epithelial elements of the gland with accumulation of fluid in the cavities so formed, and may be simple or malignant. Proliferation cysts or cystic neoplasms are characterized by irregular gland-like growths below the epithelial lining of the cyst and by the presence of papillary projections from the cyst lining. Sotti, under the name of adeno-cystoma papilliform, describes a tumor of the pancreas with metastases in the lymphatic glands and lungs.

About 173 cases of operations on cysts of the pancreas have been recorded (1917).

Partial extirpation of the pancreas has been carried out, according to Glaessner, twenty-eight times with fourteen operative recoveries and fourteen deaths.

\*Read by title before the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

My case is as follows:

Mrs. W. C. C., white, 64 years old, had an ovarian cyst removed twenty years ago—the nature of the cyst is not known. For several years has been troubled with “indigestion.” About ten days ago she was taken with severe pain in the right hypochondriac region, chills, fever, and leucocytosis of 14,000. No jaundice but cholecystitis was suspected at the time. When seen by me with Dr. Crosson, her pulse was running from 80 to 120 and temperature from 99 to 102, leucocytes 14,000. There was no diarrhea or glycosuria. There was slight fullness and tension in the epigastrium and tenderness which extended clear across the abdomen. The diagnosis was tentative; ulcer of the stomach or duodenum, cholecystitis, pancreatitis, or appendicitis.

At the operation slight adhesions were found about the liver, gall-bladder, and stomach, and a mass in the head of the pancreas behind the duodenum. On account of its intimate adhesion to the descending duodenum and the numerous blood vessels, the mass was opened through the duodenum by an incision through its anterior wall, and a small incision through the posterior wall directly into a cavity in the mass from which about a teaspoonful of tissue looking like granulation tissue was scooped out. On passing the finger into this cavity, a second cyst was broken into from which the same kind of material was scooped out.

The incision in the anterior wall of the duodenum was then closed, but the one in the posterior wall communicating with the cyst cavities was left open. The gall-bladder and ducts seemed normal to palpation. The abdomen was closed without drainage.

The patient became delirious in a few days, with irregular heart action, then coma set in and death five days after operation, perhaps from acidosis.

The fragments of tissue removed were examined by Dr. Neuman and pronounced papillary adenoma.

### THE GATEWAY OF DIGESTION.\*

By M. O. BURKE, M. D., Richmond, Va.

Embriologically the mouth is not a part of the gastro-intestinal canal, and in the early development of the foetus the mouth is separated from the canal by three membranes.

\*Read before the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

The gastro-intestinal canal is derived from the primitive gut (the fore-gut, mid-gut and hind-gut) which is formed by the infolding of the hypo-blast.

“The buccal cavity is formed from the external (the epi-blast) layer of the blastodermic membrane, which passes inward and meets the pharynx or upper part of the fore-gut. The two cavities are, however, at first completely separated from each other by all the layers of the blastoderm, but at an early period of development a vertical slit appears between them: this gradually widens and becomes the opening by which the common cavity of the nose and mouth communicate with the pharynx.”

The mouth is a complex and a compound organ: complex in that it is made up of various parts linked together; compound in its ultimate object of aiding digestion. The lips hermetically seal the opening of the mouth when necessary; prevent air from entering and saliva from escaping; is especially useful in retaining food during mastication, and in protecting the teeth and preventing the mouth from becoming dry.

The teeth are of three kinds—the incisors for cutting, the canine for holding and tearing, and the molars for grinding. The tongue is for tasting, testing the consistency, mixing the food with saliva, changing the mass from side to side, and finally for carrying the mass back into the pharynx and assisting in deglutition. The sense of touch is more highly refined in the tongue than any other part of the body. The salivary and mucous glands are for keeping the mouth moist, moistening the food so it can be swallowed, digesting a part of the starch, and secreting an antiseptic. The mouth is a *mill* for grinding food, a *mixer* and a *stoker*. In many of the lower animals it is also a *harvester*.

The saliva must possess some healing properties as manifested by lower animals in always licking their wounds and sores. Yet we know that the saliva of man and beast is often a powerful poison. It is said that the bite of a blue gum negro is as poisonous as the fangs of a rattlesnake.

A mouth may be clean and pleasant to inspect, but some are veritable cess pools. When we stop to think that the pleasure of eating is in the mouth and that all of our food passes through the mouth, we are forced to realize the importance of keeping the mouth clean.

The mouth does not absorb food or water but some drugs and poisons can be taken up by the membranes of the mouth.

The digestive functions of the mouth are preparatory rather than complete. We sometimes feed patients through a stomach tube. If we had no mouth or only an exposed pharynx, all food would have to be especially prepared and we would be deprived of the pleasure of eating.

The three preliminary acts are mastication, insalivation and deglutition. Insalivation and deglutition depend largely upon mastication. All vegetable and animal food is composed of cells. The cells are surrounded by capsules or cell membranes. The capsule must be broken or removed before the digestive juices can produce the chemical change necessary for absorption. Heat and moisture are important elements in the rupture of the capsules; saliva furnishes moisture and a chemical that aids in the dissolution of vegetable capsules; mastication increases the flow of saliva and the grinding process should aid in breaking some of the capsules. An enormous amount of work is done each day by the mouth. It has been estimated that the daily pressure exerted by mastication amounts to about 1,700 pounds.

When food is properly cooked, we find the cells swollen and nearly every capsule broken. When improperly cooked the cells are shrunken and the capsule unbroken and often surrounded by a coat of grease. Such food is necessarily hard to digest and must depend upon the chemical dissolution of the capsule before the cell can be reached. Food that is slightly masticated is difficult to swallow and requires extra time and effort for the digestive secretions to penetrate the masses. Mastication is very essential to good digestion. Sound teeth and a healthy mouth are necessary for mastication.

Good digestion and a healthy mouth are important to good health. The mouth is frequently the starting point of grave diseases. Rosenow has shown that streptococci from various organs have an affinity for the same organ when injected into the circulation of another animal. Can we not expect to find a similar embryological condition in the human body? A focal infection in the blastodermic derivatives is more likely to produce trouble in organs or tissues derived from the same membrane.

"It has been proven that the mouths of all

adults and most children contain bacteria," but it does not follow that every individual is infected by these bacteria.

The skin and mucous membrane are immune to bacteria so long as there is no break in the continuity or the presence of material to act as a culture media. The membrane may be healthy and its continuity intact and still support a deposit on which bacteria may propagate. Some bacteria generate a toxin which may destroy the membrane and thus gain an entrance. Even then the bacteria may be destroyed by the white cells and plasma of the blood.

The importance of dental prophylaxis is emphasized by Keyes' observations in an Orphan Asylum, where the percentage of infectious diseases was reduced fifty per cent at the end of six months and to approximately two per cent during the following year.

During the last decade, infant mortality, typhoid fever, deaths from tuberculosis and diphtheria have been greatly reduced. The average life span has been increased about twenty years, but the death rate from forty-five to sixty-five is greater than ever before. Nephritis, heart disease and arteriosclerosis have claimed most of the victims. Focal infection of the mouth has been found to be a frequent cause of these troubles. The way we eat and the way we live may account for many more.

204 East Franklin Street.

### THE CHRONIC PATIENT.\*

By R. L. RAIFORD, M. D., Sedley, Va.

The biggest question which faces the medical profession today is the "Chronic Patient." The wonderful strides made in surgery in recent years have been the marvel of the ages for attainment, and have placed this branch of medicine in a position of distinction of which we may well be proud. Such men as Pasteur, General Gorgas, Dr. Reed, and Stiles have gained undying fame in the realm of communicable diseases. The abdomen and other forbidden parts of the body are now explored and treated with impunity. The once dreaded swamp and morass have long since become virtual garden spots and so safe for health that their fertile soils are inviting settlers from the far corners of the earth. Thanks to vaccine and the passing of the stegomyia, no longer is

\*Read before the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

mankind harassed by the scourges of smallpox and yellow fever, and diphtheria has been robbed of much of its terror by the early and scientific use of antitoxin. The teaching of sanitation and cleanliness has been instrumental in hurrying such diseases as typhoid and the serious diarrheas of infancy down the long road of the dodo and the mastodon. School inspections and free clinics are fast placing in the reach of everybody the chance to prevent or have treated most acute diseases of childhood or adult life, and the triumph of skill has lessened the terrors of serious wounds and injuries. The wild cry of "Mad Dog" from a scared populace is well-nigh forgotten to the youth of today, and the horrors of the Great White Plague are rapidly being dispelled by its early recognition and treatment on the part of the physician and the healthful co-operation to this end on the part of the patient.

The modern physician can conscientiously and with the satisfaction of the knowledge of hard fought battles of science and well earned laurels of achievement swell out his chest and point to these and many other singular and most worthy advances in the early and accurate diagnosis and most commendable treatment of a very large per cent of the acute diseases to which human flesh is heir, but when we turn to the "Chronic Patient" we have only to observe the pompous display of ill-gotten gain and wealth of the quack and the charlatan to read in these facts the sad story of our own inefficiency and failure to properly diagnose and treat this group of unfortunate patients.

We will assume as an undisputed fact that the average sick person first seeks the aid of a regular practitioner of medicine and it is only after failure to get the relief sought for here that he is finally induced by the flattering promises of the irregular to seek aid from this source.

We will, therefore, assume further, as a foregone conclusion that, cuss the quack as we may, legislate against him in the most severe manner possible, the indisputable fact still remains that so long as we, as a profession, fail to recognize and cure the ailments of the chronic ambulatory patient, just so long will there be material on which these impostors will fatten and grow rich.

One by one the so-called idiopathic diseases are being stricken from the list. Such terms

as idiopathic peritonitis, idiopathic heart diseases and idiopathic pleuritis no longer have a place in the vocabulary of the modern physician. And yet how we cling with deathlike tenacity to customs old and revered! Only a few weeks ago quite a learned doctor discussed lengthily with me, holding out against any argument I could muster, that both insanity and epilepsy were in the main purely functional and had no real physical cause. He might as well argue that your faithful Ford, without cause, gets cranky at times and will not run properly.

Medicine and surgery were founded largely in an atmosphere of empiricism. The pioneers in this branch of science knew nothing of the modern laboratory methods of checking their physical findings, and yet we must still take off our hats to the splendid accuracy of their deductions. Therefore, rheumatism instead of being of an infectious origin was a diathesis, and malaria instead of being due to a parasite was of a miasmatic nature; and such fallacies were common all along down the line of diseases. This guesswork in diagnosis was more than eclipsed by a guesswork treatment and nothing was ever exact. The consequence is that men who still practice empirical medicine get on fairly well with acute diseases which are quickly over. Here, nature, with a little expert assistance, will make a cure in a large per cent of cases and the attending physician often gets the credit for doing more than he has really done. No matter if he has made a slip and called typhoid, malaria, or a mild scarlet, roseola, so long as the patient recovers promptly, little harm in the individual case is done.

Not so, however, with the "Chronic Patient." Here, nature has for a long time been making a supreme effort to restore the disabled organism to normal, but some hidden chronic infection of an obscure nature is continually pulling down as fast or faster than she can rebuild. Neither does the over lauded medication which gets so much undue credit in the self-limited diseases help us much more with our chronic patients. The consequence is that we flounder around, first using one much vaunted remedy and then another until we lose confidence in ourselves and our patients lose confidence in us; so that the desire to change to another doctor or even a quack is welcome news to us. The outcome of it all is that we get disgusted with such inexact haphazard

methods of diagnosis and treatment and this, perhaps, accounts for so many good men laying down their profession for the business world.

But the light of a new day is dawning and, when it opens up in the full radiance of its noonday sun, we shall no longer guess our diagnoses and apply a fantastic empirical remedy which so frequently does such little even imaginary good. We shall recognize the fact that having eliminated abuse of our systems and an inherited tendency towards certain diseases we have left, trauma and infection to account for the remaining ailments of mankind, and that the most of the high sounding names of diseases to be found in the usual treatises on medicine are in fact merely names for the varying symptoms of some obscure underlying infection which must be rooted out if we will really cure our patient.

The fact is that one of the greatest drawbacks to the advancement of medical science has been this giving of so many names to the same pathological entity. In trying to classify disease according to these names, one often becomes lost in the confusion, making the reading of medicine tiresome and often disgusting, thus, in part at least, accounting for so many men not keeping abreast of the latest advances of the profession.

We must not lose sight of the fact that the primary focus of infection so often gives no local symptoms of pain or discomfort and yet may be the cause of havoc being wrought in some other even distant part of the system. High blood pressure, nephritis, appendicitis, gall-tract infections, heart diseases, indigestions, rheumatic conditions, the various skin diseases, the psychoses and many other so-called diseases so often are due to some obscure infection and are preventable if taken in time or often curable if treated from this standpoint. Who of us are not continually having patients come to us stating that Dr. A pronounced her case nervous indigestion, Dr. B called it a nervous heart condition, Dr. C thought it was simple neurasthenia, but Dr. X was sure it must be gaseous dyspepsia, and so on down the line *ad infinitum*, according to the predominating symptoms when the patient was seen, when a painlessly infected incisor or an impacted molar may have been the true cause of all the category of symptoms?

Preventable medicine is not finished by the

controlling of communicable diseases, however much we may laud this particular branch of work. The restoration of a chronic dyspeptic by the removal of a gall-bladder or an appendectomy, however commendable, does not exclude the fact that these are often or perhaps always only secondary to the real primary cause which should have been corrected in early life.

Proper institutional provision for those unfortunate citizens suffering from the various forms of psychoses is most laudable but, if as being demonstrated by some of the best men of our land, these are just tail-end results of a long-standing hidden infection, we must learn to recognize the earlier symptoms of these infections and by proper treatment prevent the inroads on the mentality of this class of patients. Or, having failed in this, we must still hunt for and root out, where possible, such infections and give these unfortunates the best possible chance to be restored to normal, mental and physical health again.

The surgeon of today realizes that his post-operative infections are not altogether dependent on a rigid aseptic technic. More and more stress is being laid on the preliminary cleaning up of the infections of the teeth, tonsils and sinuses, to the end that it may possibly prevent the need of many major operations altogether and make those that are necessary less hazardous and more beneficial to the patient.

Obstetrical records could also be robbed of many a tragedy had some chronic ailment been recognized and the hidden infection causing it been cleaned up before or even during the pregnancy.

If we, therefore, assume that the average chronic patient who comes to us is ailing from some infection, often obscure and elusive, then the natural deduction would be that to render any permanent benefit we must work towards the end of removing this infection. In order to carry out effectively such a line of treatment, we must necessarily know where to look for such an infection. Fortunately for the diagnostician, the mouth and nose may be considered the primary ports of entrance in a vast majority of cases. Fortunately, too, we may still find the causative infections located in the nose, throat or mouth in a large percentage of our cases, making them comparatively easy to locate and remove. But not finding the offending infection in these sites should not discour-

age us in our hunt for it when symptoms indicate that such an infection really exists. No chronic patient should be considered properly examined until we have at least checked up on the teeth, tonsils, nasal cavities and accessory sinuses, uterus, prostate and rectum, as well as all organs located in the chest and abdomen. Furthermore, having found and cleaned up one or more points of infection without relieving symptoms should not discourage us to look still further for and eradicate other foci, and we should never consider ourselves beaten until we have located and cleaned up every accessible point where hidden germs may be lurking.

In conclusion, let me say that if we pay less attention to empirical medicine and look in every case for a definite cause for the symptoms of which our chronic patients complain, we will speedily find that we will not only get better results but our work will at once become vastly more interesting and give us a feeling of satisfaction we have not experienced before.

A closer study of disease from this angle will convince us:

*First:* That a very large proportion of all sickness and mortality is chargeable to infections;

*Second:* That many of the chronic and so-called incurable diseases of middle or late life can be prevented by the early removal of the primary infection, or may even yet be much benefited or often cured by treating them from this standpoint;

*Third:* That in obstetrical and surgical cases, complicating infections and mortality may be greatly reduced by a closer study and removal of all focal infections, where possible, before operation, and

*Fourth:* That, by considering the symptoms of all our chronic patients as of an infectious origin, where a given effect is always preceded by a definite cause, we will have made a long stride towards finally and completely rescuing the practice of medicine from an antiquated and long outlawed empiricism and placing it in the forefront among the other exact sciences.

#### A GOOD GUESS.

The doctor's small son was entertaining a friend in his father's office, and they were looking with awed admiration at the articulated skeleton in the closet. "Where did he get it?" asked the small guest in a whisper. "Oh, he's had it a long time. I guess maybe that's his first patient!"—*Life*.

## MAN, THE PHYSICOCHEMICAL COMPLEX. ELECTRICITY AND THE ELECTRON. REASONING AS A CHEMICAL RE- ACTION, RESULTING IN AN ATOM COMPLEX THOUGHT.\*

By CHARLES ELMORE BOWLES, M. D., Pulaski, Va.

In presenting a paper of this character it is necessary that I mention numerous accepted theories and recognized facts, derived from the various fields of scientific endeavor, and select those laws under which the particular phase of this most intricate and complex system exist. For no definite conclusions can be reached until definite laws can be applied with equal force to the chemical, biological, physiological, psychological and cosmic processes. I shall follow three definite laws and attempt to show that man and his thoughts are chemical in nature, controlled and developed by the operation of these laws.

1. The law of chemical valences.
2. The law of complexity.
3. The law of attraction and repulsion.

According to the law of chemical valence, certain chemical elements and compounds attract certain other elements, the reaction taking place under the stimulus of a definite form of energy. Through this law we come to understand the behavior of a chemical reaction, and why certain elements enter into the compound, while others in the surrounding are left out. Applying this law to conditions existing in the late cosmic or archeozoic era, when the waters of the cooling globe held various chemical elements in solution, we find conditions ripe for marked chemical reactions to take place and for the chemicals to combine into higher and more complex formulae, each combination attracting or appropriating special types of elements until the compound became so complex and delicate, that further stimulation produced a blending of the elements, one into the other, so that the compound now acts as a single unit or chemical cell. The cell having retained the energy generated by the reaction, thus became endowed with internal motion and the transition from inorganic to organic was accomplished.

Various theories concerning the special elements involved and the particular form of energy appropriated have been advanced but

\*Read before the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

all agree that organic sprang from inorganic. That life arises from earth and water, we find to be the opinion of Aristotle and since then the same views have been held by philosophers, poets, theologians and laymen. Lucretius said that all things are produced out of the earth, forming in the rain water and the warm vapors raised by the sun. Ross, in the seventeenth century, said that to question this is to question reason, sense and experience. In the scientific theories of today, we find according to Pflüger, that the cyanogen radical is an integral part of the molecule complex of living protoplasm and that this radical contains a large amount of internal energy, and in this way energetic internal motion is injected into living matter. According to Pflüger's hypothesis, there arose a simple homogeneous material, from which has evolved the highly differentiated protoplasmic mass or cells of organic life today.

Allen says that solar energy, acting on the damp earth containing the raw materials, caused dissociation and rearrangement of the atoms. Then further reaction, catabolic and anabolic, occurred by virtue of the nitrogen compound. This constructive process continued until organic life became manifest.

Osborn asserts that water, nitrates and carbon dioxide, which are known to be essential to the perchlorophylic and chlorophylic stages of the life process, were brought together so as to capture and transform the electric energy of the chemical elements, characteristic of protoplasm.

In Moore's theory, we see albumin and silica in colloidal form appearing in solution or suspension in the waters of the cooling globe. These combining with other chemical elements, as the temperature permits, form solution aggregates or complexes, in which the unit of chemical structure passes from atom to molecule. Moore applies the law of complexity to this, that matter, so far as energy environments will permit, tends to assume more and more complex form in labile equilibrium, atoms, molecules, colloids and living organisms, arising as a result of this law. The sensus of opinion seems to be that there was a gradual blending of the elements, until they could no longer be distinguished in the protoplasmic cell.

It is impossible to analyze protoplasm for, in disturbing the fundamental organization, that is, in breaking up the compound, we cause a cessation of those phenomena characteristic

of life, leaving matter in the non-living state before us. Living protoplasm is a colloidal complex, comprising chiefly the elements carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, sodium, calcium, potassium, chlorine, iron and magnesium. Certain combinations of these, in the form of carbohydrates, proteins and fats, are distinctly characteristic of protoplasm and are not found elsewhere in nature. The manifestation is clearly a physico-chemical complex and its fundamental phenomena is energy. It consists in appropriating energy from its environments and using it to develop higher complexes. One of its peculiarities is its proneness to change its composition under the stimulus of slight changes in the energy equilibrium between itself and its surroundings. By applying the three fundamental laws, chemical valence, complexity attraction and repulsion, we see the chemical or protoplasmic cell appropriating energy and selecting certain chemical elements from its surroundings and gradually developing another compound or nucleus within itself, which is later expelled as a new cell. Finally, through changed conditions and the incorporation of new elements, a new type of cell is developed, which likewise selects elements in accordance to its new valency.

In this way the cells gradually became differentiated into the various tissues and organs of the body, each related but being composed of one or more different elements, therefore having a different function or action, as the chemical reactions or metabolic changes occurred in the body. These facts are very pertinent when we recall that the chemical composition of the body is as follows: Water 66%, nitrogen 3.1%, hydrogen 2.1%, carbon 15.8%, calcium 2.5%, phosphorus 1.2%, oxygen 6.7%, iron, sodium, chlorine, iodine, potassium, fluorine, sulphur and magnesium in varying quantities. The action or function of the various tissues or organs depends upon the particular elements and the proportion of the elements composing them. The muscle contains phosphate of magnesium, potassium, sodium, iron and potassium chloride; connective tissue has silica as its specific substance, while elastic tissue contains calcium fluoride. The bony structure contains calcium fluoride and magnesium phosphate, with a large amount of calcium phosphate. Cartilage and the mucus cells have for their specific inorganic material sodium chloride. This also occurs in

all solid and fluid parts of the body. The hair and crystalline lens have iron and other inorganic substances, while the nerve tissue, which has now become an isolated system, contains phosphate of magnesia, chlorine, sodium, potassium and iron. From this we see that while all the tissues are closely related, yet each contains some specific inorganic substance which causes its function and appearance to differ from that of the other tissues with which it has a common origin.

The brain, the highest type of tissue, not only differs from the other tissues of the body, but the various groups of cells differ from each other, just as the different portions of the internal organs differ, this difference being brought about by the particular chemical combinations forming the cells in each part of the organ, as a result of gradual chemical differentiation.

The brain substance also shows itself to be chemical on analysis, but we must remember that this organ has probably been developing for some 500,000 years or more or since the early Paleozoic era and that Paleolithic man had reached the verge of intelligence. That since that time there has been an ever increasing rapidity in the differentiation of the brain cells. After ages of development, we still find it to contain such substances as lipoids or phosphorus bearing compounds, composed chiefly of lecithin and kephalin. These phospholipins are chemically phosphoric acid in combination with neutral fats and a nitrogenous base, cholin. From lecithin the glycerophosphates are derived, while cholestrol, an alcohol, is also found in the brain. From what has been said, it will readily be seen that any disturbance in the chemical composition or deficiency of inorganic supply, immediately affects the protoplasmic cell, so that its accustomed energy will no longer cause a reaction, and a pathological condition results. The end products of proteolysis, as amino-acids, may be catabolized by bacterial action, with the result of toxic amines. These intering into combinations with the chemicals in the tissues produce a disturbance, so that the cell is no longer sensitive to its accustomed energy. This occurring in the brain tissue produces sluggish or confused reactions. Doubtless man, the physiochemical complex is in reality a delicate and highly developed series or complex of inorganic chemical compounds, which is constantly appropriating energy and elements

and blending them in protoplasmic form, and in which there is ever occurring a vast congeries of chemical reactions.

#### ELECTRICITY AND THE ELECTRONS.

Dr. J. S. Hughes, of Kansas State College and chairman of the biochemical division of the American Chemical Society, recently read a paper before that society, in which he stated that thought is a chemical process and that nerve impulses are purely electrical energy; that whenever the lipins surround the water in the nerves, they become ready conductors, but if the water surrounds the lipins they are poor conductors. He is now carrying out experiments along this line. To me it seems that the nerve impulses, which are doubtless electrical energy, are conducted by the rapid vibrations and interchanges of the electrons, composing the nerve cells and fiber, and that the electric energy is generated by the chemical change taking place in the protoplasmic cell, just as in the original cell as it passed through the transitional stage from inorganic to organic. The brain cell, being a highly developed chemical complex, and containing certain inorganic elements, undergoes a definite chemical reaction, when stimulated by the electric energy derived from its surroundings. The source of this energy may be a chemical reaction in some distant organ or tissue of the body or other brain cells but, for our purpose, I shall consider only those derived from the organs of special sense as a result of some external impression or psychic phenomena. In investigating energy, we find that certain waves are absorbed and others reflected and the effect on the sense organ is modified by the type, length, duration and intensity of the energy or electronic wave, as demonstrated in Young-Helmholtz and Herings theories of color sensations and the skin reaction in sunburn. The absorbed rays produce a chemical reaction and, when affecting the skin, result in the familiar blister and a change in the valency of the tissue, so that the rays are now reflected and produce no further effect.

The flower placed by the window leans toward the light for the reason that here the direct rays produce a reaction on the side of the plant exposed to the energy and the elements are drawn from the other parts of the plant to supply the needs of the reaction. Therefore, the plant becomes more developed on this side and is drawn over. Some plants

and chemicals develop or react better in low temperature and in these cases the condition would be reversed. The sense organ of sight acts similar to plants, when exposed to direct rays of light, the reaction taking place in the rods, cones and pigment of the retina. The rods become colorless and the pigment increases in color, the light first producing a visual yellow and then a visual white, and, if the length, duration and intensity is sufficient, inflammatory changes occur.

This also applies to the other sense organs, and the organ of hearing probably undergoes a chemical change or interchange of electrons between the endolymph and crystals of calcium carbonate in the capsula. Since we see that there is an actual absorption of energy or electronic waves by the chemical tissues, which results in a reaction, it is necessary that we know the composition of these electronic waves before we can determine the particular reaction and know what result to expect. In order to do this it is necessary that we keep before us the fact that all matter is composed of molecules, molecules of atoms, and atoms of electrons, and that all nature is in constant motion and undergoing chemical changes or reactions. In the reactions, certain atoms and electrons are combined while others are displaced or repelled, just as certain elements are combined and others expelled in forming compounds. This is more clearly explained in the phenomena of osmosis. Here we find that water is a fluid the molecules of which are in constant motion. Pure water has the formula  $H_2O$  and these molecules undergo practically no dissociation into their constituent atoms and for this reason it is not a conductor of electricity.

Sugar solutions for the same reason are not conductors.

Solutions of most of the salts, bases and acids, are conductors of electricity, since these substances undergo dissociation and the simpler materials into which they are broken up are called ions. These ions are simply groups of freed electrons. If sodium chloride is dissolved in water, it becomes a conductor, for it is broken up into two electrically charged parts or ions, the sodium ion being charged with positive electricity and the chlorine ion with negative. Solutions of hydrochloric acid contain free positive hydrogen and negative chlorine ions. The term ion is not equivalent to atom, for it may contain enough electrons to form a group of atoms. The negative

charge is equal to the positive charge, but, in the case of sulphuric acid, there are two positive hydrogen ions and only one negative  $SO_4$  ion. Substances which have this property are termed electrolytes.

In a simple electric battery, containing a zinc and copper plate immersed in dilute hydrochloric acid, potential electricity is produced when the acid attacks the zinc and pulls zinc or positive ions into the solution. This gives a positive charge to the solution about the zinc plate, increasing the potential difference and repelling the positive hydrogen ions toward the copper plate, where some of them enter the copper atoms, forcing copper electrons to the next portion of the wire, etc., through the wire. The reduction of the zinc atoms causes the chlorine to be attracted to this pole, where the same interchange takes place between the chlorine and zinc plate. The excess of hydrogen and chlorine is deposited on the respective plates, as is seen in electro plating. When a contact between the wires takes place, the two circuits flow in opposite direction through the wire. Should the wire be applied to tissue, the electrons composing the electrodes would pass into the atoms of the chemicals composing the tissues and, by increasing the atomic weight, convert the molecules into a new element and cause a chemical reaction to occur. That the electrons actually pass from the wire is clearly demonstrated by the experiments of J. J. Thomson, of Cambridge, England, and Perrin, of Paris, in studying the cathode rays. According to Thomson, these cathode particles are the primordial particles out of which the seventy odd atoms known to chemistry are built up. The chief difference between the various atoms of chemistry consists in the number of these particles or electrons which enter into them, the hydrogen atom containing about 2,000 electrons, the oxygen atom 32,000, the mercury atom 400,000, etc.

The number of electrons entering the wire depends upon its composition and the solution used. Copper and zinc in solution of hydrochloric acid produce an electromotive force of one volt. Carbon and zinc produce one and one-half volts, but copper and carbon produce much less than one volt. By changing the solution, we can still further modify the voltage, the electromotive force depending upon the materials of which the cells and conductors are composed. The resistance of materials

varies greatly and is increased directly in proportion to its length and inversely, in proportion to its size. Applying these facts to the nerve tissues, which consist of phosphorus, magnesium, sodium, chlorine, potassium and iron, we find it well provided with electrolites which readily undergo dissociation, with the result that the ions or electrons, by rapid vibration and a series of interchanges, convey the impulse through the nerve fiber and cell to the brain and, entering the atoms of the chemicals forming the brain cells, produce the reaction or reasoning which results in a chemical compound, thought. These facts would lead us to believe that electricity is nothing more than the electrons or ions thrown off or repelled by the chemical reaction or interchange and traveling at the stupendous speed of from 100,000 to 300,000,000 meters per second. When these rapid traveling electrons or ions come in contact with the sense organs and are absorbed by the atoms of the chemicals composing the tissue, the atoms become more complex and an actual increase in weight occurs. This increased atomic weight, changing the valency of the molecule or element, causes the chemical reaction to occur in which other electrons are liberated or repelled. These interchanging through the nerve fiber cause a reaction in the nerve cell, and thus repel ions to which one or more dendrites of the next cell are sensitive, and in this way direct the impulse over a definite root.

In the nerve, as in the wire, whenever the passage of the electrons or current is partly obstructed or resistance increased, there is a piling up of the electrons, and many become liberated or thrown off as heat. Where this occurs in the tissues, the temperature is raised and some of the liberated ions enter into combinations with the chemicals composing the cells, resulting in an atomic compound, thought, in the case of the human brain cell, or muscular action in the case of muscle. These reactions would also liberate certain electrons or positive or negative charges. That this actually occurs is seen by the experiments of Reymand and later perfected by Herman. These investigators, by attaching a galvanometer to two portions of a detached muscle, found that the amount of electric current produced in the muscle could be measured. The energy was the result of the chemical reaction in the muscle, produced indirectly through the nerve or directly by muscular contact. The

stimuli may be chemical, mechanical, electrical or thermal, but in each of these there must be an interchange of electrons, between the stimulus and the tissue for, in the case of a chemical stimulus, the appropriated electrons or ions is the electricity or energy that causes the reaction. The nature of the chemicals in the tissue becomes changed as a result of the increased atomic weight. To illustrate, the hydrogen atom contains 2,000 electrons; then suppose that 30,000 electrons are repelled by the stimulus and absorbed by the hydrogen atom, we would have an atom composed of 32,000 electrons, or oxygen. The compound containing this new element would immediately react and unite with other elements to form a new compound, with the liberation of definite ions. This occurring in the nerve ending would cause a reaction to continue throughout the nerve and at the end of the nerve; the repelled ions would cause a reaction in the brain cell, resulting in a definite atom, sensation or thought. The ions entering the brain cell are the sensations received from the outside world, the atom compound resulting being the implanted memory impression or thought. These ions or sensations, being appropriated by another cell, are grouped together, so as to form a more complex atom, or perception. Likewise the perceptions are grouped or blended to form conceptions, or a still more complex atom. The sensation, perception, conception, etc., probably each affect only one atom of the millions of atoms composing the cell. Later, whenever an exactly equal and like stimulus is applied to the same nerve terminal, another atom becomes changed. This continues, until finally all the atoms in the molecules of the cell become so complex that the molecules become changed into new elements. The positive or negative sign of the molecule is thus changed, so that the sensations or ions from the stimulus are now repelled. There is virtually a damming back of the ions or current in the nerve, until the sign of the sense organ becomes changed, or the poles of the magnet reverse. At this point we fail to receive or are not conscious of further sensations or ions of the same kind, since electrons of like kind repel each other. Electrons of the opposite sign would now be necessary, in order to produce a further sensation or reaction. This doubtless explains why we become insensible to our surroundings or

definite forms of stimuli and yet react to others.

In the above illustration, we changed the composition of the tissue from positive to negative elements by the addition of psychic energy or negative electrons. Applying this theory to any of the special senses, it can readily be demonstrated that fatigue, sleep, or a change to the opposite sign is produced in direct proportion to the type, duration and intensity of the stimulus or electronic application. Fatigue is a partial saturation of the elements with ions of the opposite sign and sleep a greater saturation, the waking phase occurring when some of the molecules become changed and attract ions of the opposite sign. Death probably results from an intensification of the same process or the disintegration of the complex.

As a physiochemical complex, conforming to the same laws that govern the universe, man must react and develop whenever the electrons, sensations or impressions from the outside world are absorbed by the atoms composing the molecules of the tissue cells. To summarize:

Man is a chemical complex, reacting under the influence of definite forms of energy or ions.

Energy or electricity consists of definite groups of electrons or ions.

Chemical elements are converted into higher elements and caused to react by appropriation of energy or ions.

The ions appropriated by the brain cells in the association centers are what we term sensations and the grouping of these sensations or ions into perceptions, conceptions, etc., form more complex atoms and finally new chemical elements.

Our surroundings, whether appropriated through sight, hearing, taste, smell or feeling, become a part of us and, increasing the atom complex, result in a chemical reaction.

Psychic energy actually produces chemical elements and reactions in the brain and body on man.

#### DISCUSSION.

Dr. L. G. PEDIGO, Roanoke: Because we do not discuss it, we do not wish Dr. Bowles to think the paper was not appreciated.

One idea set forth by Spencer is that all progress evolves differentiating homogeneous bodies of complex, and all papers are based upon the current idea in this line of investigation that nerve force and electricity are identical. Personally, I do not believe

this. They are indestructible, but if we investigate the dynamic relation of nerve forces to various insulating, conducting areas, we find a great difference.

Dr. BOWLES, closing: Dr. Williams asked if it was a known fact that the electrons produced a chemical change in the brain? It is not a known fact. The paper is based upon the experiments of J. J. Thompson, of Cambridge, and Perrin, of Paris, with cathode rays. Thompson found that the cathode rays are deflected by a magnet or electro static charge, as was to be expected if they were negative charged, and Perrin proved that they actually imparted negative charges to the body on which they fell. The X-rays are not deflected by a magnet or by electro-static charges and do not carry electric charges. On this ground, Thompson formulated the theory that these cathode particles are the primordial particles out of which the seventy-odd atoms known to chemistry are built up, the difference between the various atoms consisting in the number of these particles.

Applying this to the chemical body and brain, it seems only logical to conclude, that when a sensation, ion or electric charge, reaches the brain cell it is deposited in the atom, as one of the sensations producing perceptions, conceptions or a more complex atom or thought. I am now carrying on a few experiments along this line, following the principle that the electrons or ions actually pass through the wire and by using various cathodes of different materials, hope to inject these substances into the body.

#### CHORIOANGIOMA: REPORT OF A CASE.\*

By R. M. PAGE, M. D., University, Va.

Mrs. J. M., a primipara, 28 years of age, was admitted to the University of Virginia Hospital, March 4, 1922, and was delivered the same day of a male child. It was a normal baby and there were no birthmarks. It weighed 2850 gm. Labor was spontaneous and at term. There was a normal amount of bleeding. The placenta was expressed 20 minutes later without difficulty.

Fig. 1—Chorioangioma. From above.

On examination, this appeared normal except for a dark red tumor about 8 cm. in diam-

\*Read before the fifty-fourth annual meeting of the Medical Society of Virginia in Roanoke, October 16-19, 1923.

eter presenting on the foetal side. The measurements of the placenta were 19x12x2 cm. The whole was hardened in 10% formalin. On section after hardening, the tumor was found almost spherical and approximately 6 cm. in diameter. It was darker in color and more spongy in consistency than the normal placental tissue. It was separated from it by a well defined capsule. The membranes which covered it on the foetal surface were smooth and glistening.

Fig. 2—Chorioangioma. Side view.

The following is the microscopic report by Dr. W. E. Bray of the University of Virginia Clinical Laboratory:

"Sections show a placental tumor undergoing marked regressive change, situated in the membranous portion of the chorion. The tumor consists of numerous blood capillaries, varying in size and shape and containing blood of fetal type, with many nucleated red cells, a few of which are in mitosis. The capillaries are lined by flattened endothelium, but owing to the hyalinization about the capillaries, many of the lining cells are not seen. No mitoses are seen in these cells. There is only a moderate amount of stroma, which is

Fig. 3—Chorioangioma. Section through.

of the embryonic connective tissue type. At the margin of the tumor there is a band of loose connective tissue which is relatively free from blood vessels, forming a thin capsule and separating the tumor from the trophoblast.

"There is marked hyalinization of the

stroma, especially about the capillaries, and this is so marked toward the center that the stroma takes a diffuse acid stain.

"*Diagnosis*: Chorioangioma (capillary hemangioma), with hyalinization of stroma."

There are approximately 100 cases of tumor of the placenta on record. The majority of these belong to the group of hemangiomata, of which this case is an example. As noted by Williams,† there is very little to be found on this subject in American medical literature. Williams' article has a pathological description by Mallory and is illustrated.

Fig. 4—Chorioangioma. Microphotograph x 75.

This case is reported on account of its rarity. From the reports in literature, about half of the cases were associated with some complication of pregnancy or parturition but, on account of their infrequent occurrence, they are insignificant as causes of these complications.

†Williams—Angioma of the Placenta Surgery, Gynecology and Obstetrics, February, 1921, Vol. XXXII, pp. 523-526.

## ETHYLENE-OXYGEN ANESTHESIA:

### A Report of 116 Anesthesias.\*

By J. S. HORSLEY, Jr., M. D., Richmond, Va.

Ethylene is an unsaturated hydrocarbon ( $C_2H_4$ ) and is found in nature as a constituent of coal gas. At ordinary temperatures and pressures it is a colorless gas having a peculiar ethereal odor and a somewhat sweetish taste. It can be prepared by heating a mixture of sulphuric acid and ethyl alcohol. It has been used commercially in a more or less pure form for several years for heating, lighting and welding.

The anesthetic properties were first observed and studied by Crocker and Knight of the Hull Botanical Laboratory of the University

\*Read before the Richmond Academy of Medicine, February 12, 1924.

of Chicago in 1908. Their investigation was brought about by an attempt to discover the cause of large losses sustained by carnation growers shipping their products into Chicago, who found when these flowers were placed in greenhouses they would "go to sleep," and buds already showing petals failed to open. Their study of the effect of illuminating gas, of which ethylene forms approximately four per cent, on flowering carnations, showed that ethylene was the chief constituent which determined the toxicity of the gas for plants. ". . . One part of ethylene in 2,000,000 parts of air caused the already open flowers to close, on twelve hours' exposure, whereas one part in 1,000,000 prevented the opening of buds already showing petals." (Luckhardt & Carter). Because of these effects of ethylene on plants, Luckhardt started his investigation of the toxicity of ethylene for animals. We are indebted to Dr. Arno B. Luckhardt, Associate Professor of Physiology at the University of Chicago, not only for the discovery of ethylene as a gas anesthetic, but also for his scientifically thorough experimental and clinical work which is making its universal use safe and possible. The introduction of no other general anesthetic has ever been accompanied by such general satisfaction and such a low incidence of accidents and complications.

In August, 1922, Luckhardt and Carter, of the University of Chicago, completed their work on the physiologic properties of ethylene gas on laboratory animals, which work has since been confirmed by Brown, of Toronto. Nine months later they reported the first 106 cases in whom operations had been performed under ethylene-oxygen anesthesia at the Presbyterian Hospital, Chicago. Up to the present time there have been no other published reports of cases of ethylene-oxygen anesthesia except those of Luckhardt and Lewis, who reported 800 cases performed at the Presbyterian Hospital, Chicago; Brown, of Toronto, who briefly mentions a few cases; and Lundy, of Seattle, who reports its use in four infants. A good many other clinics, such as the Mayo Clinic, are using this anesthetic and verbally report its satisfaction.

October 9, 1923, Dr. Luckhardt first demonstrated ethylene-oxygen anesthesia in Richmond by having the anesthetist of St. Elizabeth's Hospital anesthetize him. Following this very personal demonstration, the first

ethylene anesthesia in Richmond for operative procedures was given under his supervision. That night before the Richmond Academy of Medicine he again had his personal demonstration of ethylene, as most of you recall. Since that time, with the exception of a short period during which our ethylene supply was out, we have been using ethylene-oxygen as our routine anesthetic instead of nitrous oxide-oxygen and ether which we had previously used.

This preliminary report of 116 consecutive anesthetics of ethylene-oxygen anesthesia at St. Elizabeth's Hospital, Richmond, Va., largely confirms the clinical observations of Luckhardt and Lewis. Of these 116 anesthetics, 6 were inductions for ether, 15 were ethylene-oxygen and ether combined, and 95 were straight ethylene-oxygen.

#### PRE- AND POST-OPERATIVE MEDICATION.

The usual pre-operative routine of "no breakfast, soap suds enema and  $\frac{1}{4}$  grain of morphin sulphate with  $\frac{1}{120}$  grain of atropin sulphate given  $\frac{1}{2}$  hour before operation" was followed in nearly all of these cases. This was done in order to obtain a fair comparison with the nitrous-oxide-oxygen and ether anesthetics which had gone before. With ethylene anesthesia, morphin seemed to be a distinct aid in the production of the anesthetic state, and atropin seemed to be unnecessary, as there was no excessive mucus or moisture of the respiratory tract which occurs with ether. Most of the cases, with the exception of those following operations upon the gastro-intestinal tract, carried out the customary post-operative orders of "flat in bed,  $\frac{1}{4}$  grain of morphin sulphate every four hours s. o. s. for 24 hours, hot or tap water ad lib." and had weak tea or fruit juices begun in small quantities after 24 hours.

#### INDUCTION.

The ease and rapidity with which anesthesia was induced was very striking. The absence of struggling and excitement was usually marked. Only three patients out of 116 anesthetics struggled during the induction period. These were robust men of questionable alcoholic history, and were extremely nervous just before the anesthetic was started. Unlike nitrous oxide-oxygen and ether, ethylene produced a sense of well-being and comfort, and a feeling of "fading away," and lacked the

whirling, pounding, frightening sensations which so commonly accompany ether, and to a less extent, nitrous oxide inductions. The average time for induction was 2.3 minutes; the shortest  $\frac{1}{2}$  minute and the longest 5 minutes.

#### RELAXATION.

Relaxation was not as complete as with ether, and more complete than with nitrous oxide. Relaxation was found to be satisfactory in *all* types of operations outside of the peritoneal cavity. This included amputation of extremities, radical amputation of the breast, rib resection, nephrectomies, vaginal and rectal operations, thyroidectomies, neck dissections, nerve and tendon suturing, prostatectomies (perineal and suprapubic), etc. Except in unusually muscular and robust young adults relaxation was satisfactory in all intra-peritoneal operations of the lower abdomen. In 34% of the upper abdominal operations relaxation was complete enough to permit operation; in the remaining 66% relaxation was unsatisfactory, and ether had to be used during a part of the operation. Even in the latter cases ethylene anesthesia was an advantage for much less ether had to be used and then only for about half the period of anesthesia. Two resections of the colon, 1 pylorotomy, 2 gastro-enterostomies, 2 cholecystectomies, were done with perfectly satisfactory relaxation.

#### COLOR

The color of the patients approached nearer the normal than with any of the other general anesthetics. Cyanosis was strikingly absent. The skin was usually pink and occasionally almost a cherry red. When cyanosis developed, the anesthetic was being improperly administered.

#### SLOWING OF PULSE RATE.

The average pulse rate before, during, and at the close of the anesthetics was carefully noted, and a slowing of the pulse was found to be a characteristic of ethylene-oxygen anesthesia.

A pulse of 120 per minute before operation would drop to 90 per minute as the patient became relaxed, and would remain there. Some drops were more and others less marked, the pulse usually approaching and maintaining its normal rate for the individual while at rest. In very severe and prolonged operations the

pulse rate rose toward the end, but no case was noted where the pulse rate increased when the nature of the operation itself did not account for the increase.

#### ABSENCE OF RESPIRATORY IRRITATION.

Excessive secretion of saliva or mucus did not occur with ethylene. In 116 anesthetics, there was not a single case of post-operative respiratory complication which could be attributed to the anesthetic. Patients with mild acute pharyngitis, coryza or bronchitis upon whom we used to refuse to operate, at least temporarily, were given ethylene-oxygen anesthesia and in no case was the condition made worse. The two cases of active pulmonary tuberculosis gave no evidence of extension or irritation of the process following major operations under ethylene-oxygen anesthesia.

#### ABSENCE OF SWEATING.

Two very important factors in the production of surgical shock are the loss of body fluids and chilling. Every one is familiar with the marked diaphoresis accompanying ether and, to a less extent, nitrous oxide anesthesia. This condition of the skin promotes chilling, a fact which is important not only as one of the causes of surgical shock, but also as a factor predisposing to complicating respiratory infections. A dry, warm skin was a striking characteristic of ethylene anesthesia. Sweating did not occur when the anesthesia was smooth and properly given.

#### OozING.

In some cases there seemed to be a slight increase in the oozing while ethylene was being given. This fact, however, has not led to any poor results or complications.

#### RAPIDITY OF RECOVERY.

The rapidity with which patients recovered from ethylene-oxygen anesthesia was quite striking. By recovery, I mean the length of time from the moment the anesthetic was stopped to the time the patient recognized persons and answered questions sensibly. One patient recovered in  $2\frac{1}{2}$  minutes after an anesthesia of 2 hours and 28 minutes. The average time for the patient to become rational after the anesthesia was stopped was 1.7 minutes; the shortest  $\frac{1}{2}$  minute, and the longest 7 minutes. The margin of anesthesia for ethylene was narrow and that occasionally

made it rather difficult to give smoothly. When the anesthesia was lightened too much, the patient would suddenly partially wake from a peaceful sleep and frequently swallowed or gulped, or made some spasmodic movement of the abdominal muscles. Manipulations about the diaphragm when the patient was not deeply anesthetized often brought on these movements which largely explained the poor relaxation in operations upon the upper abdomen.

#### POST-OPERATIVE NAUSEA AND VOMITING.

The causes of post-operative nausea and vomiting are numerous. The anticipation of the operation, the administration of morphin, the operation itself, and the effects of the anesthetic, all are important factors in the production of these very disagreeable symptoms. It was fairly common to have patients retch and spit up some clear fluid as they reacted. Thirty-seven per cent of our cases did this. Most of them did not remember this seemingly unpleasant occurrence. Nausea and vomiting were less following ethylene anesthesia than following any other general anesthetic in our hands, moderately less than nitrous-oxide-oxygen and decidedly less than ether. Vomiting of one or more times occurred in 39% of the patients following ethylene.

Two of the very nervous female patients complained of brief "fainting spells," sometimes accompanied by nausea.

#### POST-OPERATIVE "GAS."

The occurrence of post-operative intestinal "gas" was strikingly low, and no case developed the marked and obstinate distention, not so infrequently encountered following ether. "Gas" was a discomforting feature in 20% of the cases.

#### SAFETY.

Luekhardt and Carter have shown that when ethylene gas is pushed to the limit in dogs, the respiratory center fails first, and at a time when the force and frequency of the heart are quite normal. Artificial respiration quickly restores the animal. Death from nitrous-oxide-oxygen is sudden and caused by cardiac syncope, the patient rarely, if ever, being resuscitated. The longer nitrous-oxide-oxygen anesthesia is kept up, the more dangerous it becomes. For these reasons alone ethylene is much safer as an anesthetic than is nitrous-

oxide. No latent after-effects were noted. The study of post-operative urinalyses, kidney functions, blood counts, blood smears, hemoglobin determinations, etc., showed no evidence of any form of deleterious post-anesthetic change. The oldest patient was 79 years and the youngest 5 years old.

#### CONCENTRATION OF ETHYLENE.

Forty-seven of the 116 ethylene-oxygen anesthetics were given by the Ben Morgan machine. This is primarily an ether machine which uses a gas as an induction anesthetic. The gas part of the apparatus simply consists of connections for the smaller size gas cylinders with a rubber re-breathing bag which in turn connects with a mask with an adjustable valve outlet. No accurate determination of the percentage of the gases used can be had with this machine, as the gas bag is filled only by the hand screws of the cylinders. Roughly it was thought that about four parts of ethylene to one part of oxygen was used. Incidentally, ethylene was found to be an excellent gas for an induction anesthetic for ether. It was superior to nitrous oxide, as may be judged from its properties and actions which have already been touched upon. The remaining 69 cases were given ethylene and oxygen with the Model G McKesson gas machine. It automatically feeds the gases from the cylinders into rubber bags where the desired pressure is kept constant and the gases are administered to the patient in known percentages. By means of this more accurate check a smooth and safer anesthetic could be given. It was found that the average percentage of ethylene necessary to maintain surgical anesthesia was 82%, and varied from 75% to 90%, according to the age, type of individual, and the depth of anesthesia or degree of relaxation desired. After about five minutes the patient became more relaxed and towards the end of a prolonged anesthetic a lower percentage of ethylene was required to maintain a deep anesthesia than was required earlier after induction. We have not used ethylene as a re-breathing anesthetic. We hope to report more fully on this factor in a subsequent paper.

#### EXPLOSIBILITY.

In the presence of oxygen, ethylene forms an explosive mixture, when brought in contact with a free flame. Brown claims that the

mixture having the greatest explosibility is one containing fifteen times as much oxygen as ethylene, so that with an ordinary anesthetic mixture the explosive action is not great. Luckhardt states that it is not quite so explosive as ether vapor. The electric cautery has been used in 41 of the 116 anesthetics without any trouble, although care is always taken to increase the operating room ventilation temporarily while the cautery is being used and the cautery is never used near the mask nor in operations on the head or neck. Carelessness in this respect may lead to an accident. It would seem, however, to be no more dangerous than ether vapor as regards explosibility.

#### ODOR.

The odor of the gas is sweetish, somewhat like that of sorghum molasses. Only three patients distinctly objected to the odor. It was unpleasant to some visitors who were unaccustomed to it, but, when inhaled for anesthetic purposes, consciousness was so quickly lost that many of the patients did not remember any odor at all.

#### OPINIONS OF PATIENTS.

Practically without exception patients who had previously had other general anesthetics stated their preference for ethylene. Voluntary statements of the patients would go somewhat as follows: "Didn't mind it," "Liked it," "Greatly preferred it to ether," "Much better than gas (nitrous oxide)," and others were more or less indifferent toward it.

#### FAILURES.

We encountered one failure in a series of 116 operations. After five minutes of ethylene-oxygen administration this patient was still partially conscious and would move about. Ethylene was stopped and only after 25 minutes of ether by the open mask method did he become anesthetized. All other patients completely lost consciousness and remained quiet. Thirteen per cent, primarily the upper abdominal cases, failed to give proper relaxation and ether had to be added.

#### ILLUSTRATIVE CASES.

*Amputation of Thigh—Case 1.* W. R. L., an Indian man, aged 48, had received five months before entrance an extensive burn of the right leg while lying drunk in front of a fire. Attempts at skin grafting were made

elsewhere, resulting only in marked suppuration and further deformity. He had had a diarrhoea, probably toxic in origin, for several weeks. On admission to the hospital his right leg from the knee down was suppurating and gangrenous, he had the appearance of an extremely toxic person, with marked emaciation, a very definite chronic nephritis and myocarditis, and a partially decompensating heart. Two days after admission his right thigh was amputated at the lower third under ethylene-oxygen anesthesia. Pulse before operation was 118, during 106, and at the close 96; period of induction was 4 minutes; time of anesthetic 34 minutes; time to become rational 2½ minutes. The color was excellent and the skin dry and warm throughout the anesthesia. There was no post-operative nausea, vomiting, gas, or complications. The entire anesthesia in this case was ideally satisfactory.

*Cæsarean Section—Case 2.* Mrs. S. D. B., a primipara of 37 years, had previously had left tube and ovary removed. On account of the patient's age, marked obesity, and a contracted pelvis, with breech presentation, a Cæsarean section and resection of the right Fallopian tube were done under ethylene-oxygen anesthesia. A normal 6½ pound boy began to cry as he was delivered. During and at the close of the operation the pulse was 100; time of induction was 1 minute; time of anesthetic 50 minutes, and time to become rational was 4 minutes. The color was pink, skin was dry and warm throughout the anesthesia, and relaxation was very satisfactory. There was no post-operative nausea, vomiting, gas or complications.

*Excision of Colon and Enterostomy—Case 3.* Mrs. E. E. R., aged 46, had previously had twenty-three operations done elsewhere. These operations consisted of cholecystectomy, radical amputation of right breast, operation for acute intestinal obstruction, four rectal operations, three sinus operations, and others. In addition to these troubles, she had become a morphine addict. On account of partial obstruction from extensive adhesions and disease of the colon, excision of the colon and enterostomy was done under ethylene-oxygen anesthesia. The pulse before operation was 110, during and at the close 138. Blood pressure before was 108/70, and after the operation 110/78; time of induction was 3 minutes; time of anesthetic 2 hours and 28 minutes;

time to become rational  $2\frac{1}{2}$  minutes. Color was pale pink and the skin was dry and warm throughout the operation. There was no post-operative nausea or vomiting, and slight post-operative "gas." This patient had had the previous twenty-three operations done under ether, nitrous-oxide-oxygen, local anesthesia, and combinations of them, and stated concerning ethylene-oxygen anesthesia, "Best anesthetic I've had." She should be amply capable of judging the value of anesthetics from the patient's point of view.

*Appendectomy, Excision of Two Lipomata and Radical Mastoid Operation—Case 4.* Mrs. W. L. A., aged 40, had an appendectomy, excision of a large lipoma of chest and one of left hip, and a radical mastoid operation performed at one time by two teams of operators, using ethylene-oxygen anesthesia. The pulse before, during and at the close of the operation was 72, time of induction was 4 minutes, time of anesthesia was 1 hour and 49 minutes, and the time to become rational was 4 minutes. The skin was pink, dry and warm throughout the operation. Relaxation was satisfactory. She had slight post-operative nausea, and spit up a small amount of clear fluid several times during the first eight hours. No post-operative gas or complications were present. The patient stated that she did not mind the anesthetic.

*Repair of Vesico-Vaginal Fistula with Three Consecutive Ethylene-Oxygen Anesthetics—Case 5.* Mrs. N. S. H., aged 62, had three consecutive ethylene-oxygen anesthetics during a plastic repair of a large vesico-vaginal fistula which was caused by a burn following an over-enthusiastic radium treatment for cancer of the cervix. She had a chronic nephritis, pharyngitis and laryngitis, and was considered a very poor operative risk. The anesthetics lasted 52, 65 and 27 minutes, respectively. They were completely satisfactory followed by no extension of the existing diseases and no complications.

*Excision of Large Ovarian Cyst: Patient had Advanced Bilateral Pulmonary Tuberculosis—Case 6.* Miss C. S. F., aged 42, had had a long-standing advanced bilateral pulmonary tuberculosis. For several weeks previous to entering the hospital she had given symptoms of partial intestinal obstruction with nausea, vomiting, abdominal cramps and distention. Examination showed very extensive bilateral pulmonary tuberculosis, with a large cavity at

the right apex and a large abdominal tumor. Operation was begun with local anesthesia and on account of the many adhesions and incomplete relaxation ethylene-oxygen anesthesia was given. An adherent degenerating papillary-cyst-adenoma of the right ovary, 15 cm. in diameter, was removed, the adhesions were separated, and the partial obstruction was relieved. The pulse before the operation was 100, during 84, and at the close 130. The induction time was  $1\frac{1}{2}$  minutes, time of anesthetic 55 minutes, and time to become rational 2 minutes. The skin was pale pink, dry and warm throughout the operation. The patient showed a mild degree of surgical shock at the close of the operation from which she recovered readily. There was slight post-operative nausea, no post-operative vomiting, and only moderate post-operative "gas." No complications have set in, and there has been a definite improvement in the pulmonary condition.

*Thyroidectomy With Comparison of Nitrous-Oxide-Oxygen and Ethylene-Oxygen—Case 7.* Mrs. W. R. S., aged 45, had a typical exophthalmic goitre with a basal metabolism of plus 29. The left lobe of the thyroid was removed under local and nitrous-oxide-oxygen combined anesthesia. The pulse before operation was 126, during 130, and at the close 124; time of induction was 3 minutes; times of anesthesia 40 minutes, and time to become rational 2 minutes. The skin was good color, slightly moist and warm. The patient was very noisy, frightened, and incompletely relaxed. She vomited three times after operation, had a moderate amount of nausea, and no gas. Four days later the right lobe of the thyroid was removed under local and ethylene-oxygen combined anesthesia. The pulse before the operation was 150, during 124, and at the close 124. The time of induction was 2 minutes; time of anesthesia 37 minutes; and time to become rational 3 minutes. The skin was pink, dry and warm throughout the operation. There was no post-operative nausea, vomiting or gas. The patient was calm and quiet throughout and the relaxation was satisfactory. The patient stated that she liked the ethylene anesthesia much better than she did the nitrous oxide.

*Upper Abdominal Operation With Incomplete Relaxation—Case 8.* Mrs. B. M., aged 52, had a cholecystectomy, appendectomy, drainage of the common bile duct and separa-

tion of partially obstructing adhesions from the sigmoid and colon. After 12 minutes of ethylene-oxygen anesthesia the relaxation was still incomplete and ether was given along with the ethylene and oxygen for 44 minutes. The pulse before the operations was 120, during 100, and at the close 96; time of induction 3 minutes; time of anesthetic 1 hour, and time to become rational approximately 30 minutes. The skin was pink, dry and warm throughout the operation. Relaxation was satisfactory only after ether was added. There was a moderate amount of post-operative nausea, slight gas, and the patient vomited twice.

#### SUMMARY.

Ethylene was discovered and used as a gas anesthetic by Luckhardt. A report of 116 ethylene-oxygen anesthetics occurring at St. Elizabeth's Hospital, Richmond, Va., in large part confirms the clinical observations of Luckhardt and Lewis.

The following points concerning ethylene-oxygen anesthesia were striking:

1. Beneficial effect of pre-anesthetic use of morphin and seemingly unnecessary use of atropin.
2. Ease and rapidity of induction.
3. More complete relaxation than with nitrous-oxide and incomplete relaxation in 66% of upper abdominal operations.
4. Absence of cyanosis and presence of pink color.
5. Slowing of pulse rate.
6. Absence of respiratory irritation and post-operative complications.
7. Absence of sweating and presence of dry, warm skin.
8. Slight increase in oozing.
9. Rapidity of recovery.
10. Low incidence of post-operative nausea and vomiting.
11. Low incidence of post-operative "gas."
12. Absence of any latent after-effects, and increased safety over other general anesthetics.
13. Average of 82% and limits of 75% to 90% of ethylene concentration to secure and maintain surgical anesthesia.
14. Explosibility of ethylene slightly less than that of ether vapor; caution in use of open flame and cautery in its presence.
15. Sorghum-like odor objectionable to only 3 patients.

16. Patients show preference for it over the other general anesthetics.

17. One failure for an anesthetic state, and failure to produce satisfactory relaxation for 13% of the 116 operations.

18. Report of eight illustrative cases.

#### CONCLUSIONS.

Ethylene-oxygen anesthesia produces a state of sleep more nearly that of normal than does any other general anesthetic. We feel that it is the most ideal routine general anesthetic yet known. It has made it possible for us greatly to lower the incidence of post-operative complications; to decrease largely the customary post-anesthetic discomfort; and to operate on certain very poor operative risks which without ethylene operation would have either been refused or in all probability would have proved fatal.

#### THE INSPIRATION OF MEDICINE.\*

By JOSEPH T. BUXTON, M. D., Newport News, Va.

Every life is a gift from the Creator of all life, a gift not to be despised or lightly regarded, but to be used in the accomplishment of the purpose which prompted the gift. For back of every life is a purpose. And we may count ourselves a success only as we fulfill that purpose.

This accomplishment is not possible unless we set before us ideals just as high as the purpose which underlies our life. We may and probably will not measure up fully to these ideals but certain it is that we shall never attain to anything higher than the standards we set up. Every life should have its ideals.

To me the highest conception of life is to be

\*President's address before the Seaboard Medical Association of Virginia and North Carolina, Newport News, Va., December 4-6, 1923.

found in him who seeks to understand and interpret the needs of the lives of others and then to administer to those needs. The keynote of any life that may be termed successful is expressed in one word, "Service." We live, not to be ministered unto, but to minister. Service, unselfish and sacrificial, if necessary, is the key which unlocks the door of glory and opens up to us those honors which fame cannot give and which money cannot buy. We live in deeds not years, in thoughts, not in figures on a dial. He most lives who thinks the most, feels the noblest, acts the best."

Among the secular professions, there is none that offers a larger field or more abundant opportunity for genuine service than is to be found in the practice of medicine. It is a great and noble profession, worthy of the dedication of the best that is in us. It is impossible to estimate its value to the community and the opportunities it offers for service are well nigh unlimited. What greater inspiration can any man have than is to be found in the knowledge that in his work he may be a saver of life unto life and a contributor to the happiness of those whom he serves?

The first inspiration I would mention is that which is to be derived from the lives of those men who in the practice of their profession have immortalized their names by the contributions they have made to its advancement.

Time would fail me were I to attempt even to call the roll of all the illustrious men from whose lives we might gain some inspiration for a larger endeavor. I shall be forced to content myself with the mention of only a few, with the hope that from those suggested you may be inspired to make a study of others whose success was as a signal and who are equally, perhaps, entitled to our consideration.

It will not surprise you that in this connection I should make mention first of the name of Edward Jenner, of whom it has been said that, "the most consummate cynic must admit that, up to the present time, he has been the greatest benefactor of mankind the world has ever known." Of him it is said that the ignorant Indians declare "we shall teach our children to speak the name of Jenner and to thank the Great Spirit for bestowing upon him so much wisdom and benevolence."

His successful inoculation against smallpox

135 years ago robbed disease of one of the greatest scourges known to the medical world. In this day it is hard to appreciate the value of this great contribution. We have only to recall, however, some of the ravages of this dread malady to understand its significance. It is said that in the days of Empress Katherine more than two million souls perished in Russia alone. In the 16th century in Mexico three and one-half millions died, leaving scarcely enough alive to bury the dead. More than sixty million of people are said to have fallen victims to this disease alone in the century prior to the discovery of Jenner. Smallpox has been rightly called, "The most terrible of all the ministers of death." In Sweden, before vaccination, there were 2,045 deaths per million; since vaccination this number has been reduced to 155. In the Sheffield Epidemic, of the unvaccinated population, one in twenty died; of those who were vaccinated, one in thirteen hundred. Is any tribute too great to be paid to this great man?

October 16, 1846, was a real red letter day in the history of medicine, for on that day Dr. John C. Warren performed for the first time a major operation without inflicting pain. The discovery of anesthesia was the greatest boon ever given by the profession to mankind for the alleviation of pain. We have only to imagine a major operation without it to conceive of the horrors attendant upon surgery before its discovery. Not only so, but its discovery made possible the performance of many operations involving minute dissections, which prior thereto could not have been attempted. I have no doubt that in the final day of reckoning hundreds of thousands of men, women and children will rise to call John C. Warren "Blessed" for his great contribution to medical science. Ranking equally, probably, with the names of the two men to whom I have just alluded stands Joseph Lister, whose service to mankind can never be forgotten. Even after the discovery of anesthesia, surgery was still attended with much danger and many terrors. Before the discovery of antisepsis by Lister, blood poisoning, tetanus, and erysipelas were almost always attendant upon every operation. The result of the researches and investigations of Lister was to show to the surgeon how these terrors could be eliminated and life and health brought to many who otherwise would have

died as a result of the surgeon's knife. The name of Lister will live as long as man lives, for he lived to bless mankind.

Dr. William W. Keen, whose life itself has been and still is an inspiration to us younger men in the profession, in speaking of the place which such men have in the hearts and affections of those who today enjoy the benefits resultant upon their lives, makes the following beautiful comparison. He says, "In Mr. John Wanamaker's gallery is one of the most striking pictures I have ever seen. On a large canvas by Fritel, in the center of the picture, advancing directly toward the spectator, is a large cavalcade of warriors arrayed in corslet and casque. Their stately march at once arrests the eye. The leader is Julius Caesar. He is flanked by Napoleon and Alexander the Great and followed by Attila, Semiramis, and a lengthening host of those whom the world counts among its great 'Conquerors.' They advance between two long rows of rigid, ghastly corpses all stretched at right angles to their line of march. Spectral mountains in the distance hedge in a desolate plain given over to the vulture, the bat, and silence."

"I would that some artist might paint a companion picture of the 'conquerors in medicine,' instead of the 'conquerors in war.' Instead of spectral hills and a barren waste, the scene should be laid in a happy, smiling valley, bounded by the Delectable Mountains and kissed by a fertile sun. The stately procession should be led by Edward Jenner. He should be flanked by Joseph Lister and John C. Warren, and followed by Simpson, Billroth, Livingstone, Ambroise, Pare, Virchow, John Hunter, and many a modest, but unknown, hero who has yielded up his spirit in the performance of his duty. Instead of treading their way between lines of corpses, they should march between lines of grateful men and women and a host of God's little children who, on bended knee and with clasped hands, would reverently invoke Heaven's richest benediction upon their deliverers."

The second inspiration, to which I would refer, is to be found in the unexplored fields awaiting discovery. Medicine is a progressive science and there are many secrets yet hid from us and many discoveries yet to be made. We rejoice in the victories already won by which countless thousands have been liberated from the dominion of disease. But there remains

much still to be done. If we are true to our great profession, we will not sit idly by amid the ravages of the yet unconquered maladies but we will put to the best use the talents with which we have been endowed, in the hope that we may make some lasting contribution to the furtherance of medicine. Could there be a greater inspiration for the fullest dedication of our faculties than the possibility that by some service of ours we may be instrumental in alleviating human suffering and in bringing sunshine into those lives which heretofore have been dark? We have immense advantage over our predecessors for we have the heritage they have left us to build upon. Inspired by their successes and by what we may do we should suffer no limitations upon our endeavor.

Again I would invite your attention to the inspiration that comes from the faithful performance of the duties that come in the daily routine of life,—not the doing of the great things but the good we are able to do for the sick and suffering in the every day work of life. I refer to those ministrations about which no one ever knows but yourself and your patient. It may be the restoration of life to father or mother or child, it may be the lessening of suffering here and there, the bringing of comfort to one in distress or making easier the great transition of some soul who has been called upon to cease from its labors. This to my mind is the great inspiration of medicine. Dull and insensate indeed must be that man who is not moved thereby to the greatest effort of which he is capable. I can best tell you how great is this inspiration by adopting the language of another who in speaking of it has said:

"My best wish for you is that you may realize in your own lives these characteristics of the ideal physician. It will matter little then whether your life be long or short, for the proper measure of a life is not how long, but how it has been lived, and if you attain old age, when the hairs whiten and the crow's feet begin to show, when your natural forces are abated, you will then not be alone in the world, but will have honor, love, obedience, troops of friends, and one Friend above all others, the 'Great Physician.' And when you pass from this life into the next, then shall you be greeted not only by this one great Friend, but by many from whose pathway you have plucked the thorns and briars of this

earthly life; many whom, through the devious paths of convalescence, you have led back to perfect health, to home, husband, father, mother, children; and even if you have not been able to stay the hands of the Grim Reaper, those too will greet you whose last hours you have soothed amid the pangs of death and have helped through the new birth into the heavenly Jerusalem."

### THE SURGICAL MANAGEMENT OF GALL-BLADDER DISEASE.\*

By ARTHUR E. BILLINGS, M. D., Philadelphia, Pa.

There is still considerable difference of opinion as to the proper surgical treatment in disease of the gall-bladder. It is gratifying to see, as statistics in increasing numbers are being published from the large clinics in this country as well as from those abroad, that the same facts are being revealed which lead to uniformity of thought as regards the treatment of this very common lesion.

Two decades ago a patient who suffered from chronic dyspepsia with hematemesis was considered a fit candidate for gastroenterostomy. With a large number of operators at that time the actual demonstration of an ulcer was an unnecessary indication for the operation. We are all aware of the evil results that followed such a practice. Gall-bladder surgery, particularly cholecystectomy, has been abused much in the same way, but perhaps to a lesser degree. Much of this abuse can be attributed to failure in diagnosis or lack of judgment in the choice of the operation for the particular case, or both. The pathological intimacy that exists between the gall-bladder, appendix, duodenum and stomach which was not recognized until comparatively recently, served to complicate the diagnosis in gall-bladder disease. Such complications as chronic pancreatitis and hepatitis with hepatic insufficiency were not reckoned with in the treatment of this condition. In many instances a diseased appendix was removed or a gastroenterostomy was performed for duodenal ulcer while a pathological gall-bladder was left behind, with only partial or no relief to the patient. With our present knowledge of associated disease in these parts the discovery of

a lesion in one should mean careful investigation of the other for concomitant disease. Certain conditions, such as acute infection, poor general condition of the patient, etc., may occasionally prohibit the careful exploration that should be made a part of the routine procedure in these cases. Proper preoperative preparation of the patient will help to avert this complication. Too much emphasis cannot be laid upon the importance of the preoperative treatment, particularly in the jaundiced cases where duct infection is extensive and a high degree of cholemia is present, for as much may depend on this as upon the operation for the successful outcome.

Jaundice is a complication that demands special consideration from the standpoint of both preparation and operation. If it has existed for any length of time it becomes a tremendous hazard to immediate surgery even of the most conservative character. In these patients toxemia is marked, the calcium content of the blood is greatly reduced or exhausted, dehydration has taken place, the alkali acid balance is broken, and blood coagulation time may be lengthened to an alarming degree; the glycogenic function of the liver is disturbed and, briefly, hepatic incompetency is the condition that supervenes. To combat successfully this condition the prompt introduction of fluid is imperative. This may be accomplished through proctoclysis in the form of soda bicarbonate and glucose solution, normal saline solution by hypodermoclysis, or by intravenous infusion, or both. W. J. Mayo recommends the subcutaneous administration of a three to a five per cent solution of glucose, which we have used to great advantage. The intravenous administration of calcium chloride solution is indicated in all cases where blood coagulation is retarded, combined with free carbohydrate intake by mouth as recommended by Walters. Crile advises blood transfusion with heat applied over the liver as a preoperative and postoperative measure to stimulate activity in liver function. In severe cases blood transfusion is indicated before and after operation. Walters and Parham have clearly pointed out the close relationship of renal and hepatic insufficiency in obstructive jaundice. They state that operations on patients with obstructive jaundice offer three avenues of danger aside from the so-called accidents of surgery; these

\*Read by invitation before the Seaboard Medical Association of Virginia and North Carolina, at its meeting in Newport News, Va., December 4-6, 1923.

are hemorrhage, uremia and hepatic insufficiency. Walters and Bell of the Mayo Clinic have previously reported the necropsy findings in twenty-nine cases of obstructive jaundice in which serious postoperative hemorrhage had occurred in fifty-three per cent. A method of preoperative preparation was described and followed in thirty-four cases that have since come under their care, in only one of which did serious postoperative bleeding occur and in this case a ligature slipped on the cystic artery. Briefly, their treatment consisted in the administration of 5 c.c. of a ten per cent calcium chloride solution in redistilled water daily for three days. Large quantities of carbohydrates were given by mouth and glucose solution by proctoclysis in order to increase the supply of glycogen in the tissues of the jaundiced patient. Large quantities of water by mouth further increased the elimination of toxic bile products. In one of their cases a coagulation time of twelve minutes was uninfluenced by the administration of calcium chloride as directed above, after which blood transfusion was done and the coagulation time was promptly reduced to six minutes. They have not observed any toxic effects from the intravenous administration of calcium chloride either clinically or experimentally. The coagulation time should be reduced to normal limits to obviate the danger of serious bleeding after operation. A careful estimation of kidney function and blood urea should be made and ether anesthesia should be avoided. The tendency to uremia is marked in this condition and every precaution should be taken to safeguard the patient against it. It is one of the few conditions in which we do not use morphine routinely as an adjunct to the anesthetic. Gas-oxygen anesthesia is used routinely and with the very ill patients we combine it with local anesthesia, as advised by Crile. Biliary drainage through the duodenal tube, as advocated by Lyon, has proved of undoubted value in our cases as a part of the preparation before operation and of the after treatment.

The character of the operation in these cases is determined largely by the most urgent need which is biliary drainage; any operation of a more elaborate nature as a rule is contraindicated. If stones are found in the gall-bladder and common duct, a cholecystostomy with removal of stones should be done; if there is then doubt as to the establishment of suc-

cessful drainage, a choledochostomy should be done with the removal of any easily accessible stones. Any extensive exploration is ill advised at this time and any remaining stones and the gall-bladder can be removed at a secondary operation when there is less danger of a thorough operation resulting in a casualty.

A two stage operation in many cases is certainly safer for the patient. As to the management of acute inflammation of the gall-bladder uncomplicated by jaundice, operation is deferred as a rule for several days. If the cystic duct is obstructed completely, suppuration may have taken place but, with rest and heat locally and careful attention to the patient's general condition and elimination, the process will remain localized and subsidence in symptoms will usually occur in a few days. With the liver above, the transverse colon below and the omentum ever ready for mobilization, the anatomic position of the gall-bladder is such that infection of the general peritoneum rarely takes place even if the gall-bladder perforates. We, as a rule, under these conditions do a cholecystectomy after the acute symptoms have subsided. A small piece of rubber dam used for drainage is held in position near the cystic duct stump with a fine loosely applied catgut ligature. Where the gall-bladder is very adherent and edematous and identification of the common duct is difficult, the splitting of the gall-bladder on each side down to the cystic duct, turning the anterior free flap down and then doing a submucous enucleation of the posterior half, as advised by C. H. Mayo, simplifies the operation very much and helps to obviate injury to the common duct. Infrequently the acute symptoms may persist and it may become necessary to operate before subsidence in the attack has occurred. Our results in the cases on whom we have operated during an attack because of persistent acute symptoms have been entirely satisfactory.

A display of surgical judgment in the choice of operation for this type of lesion is essential. Drainage of, rather than removal of the gall-bladder will be indicated in a small percentage of cases, but cholecystectomy is preferable when the patient's condition warrants it. In the chronic type of gall-bladder with or without stones, uncomplicated by obstructive jaundice, we usually do a cholecystectomy. There are several reasons for this practice. First, when chronic pancreatitis is present, chole-

cystectomy with prolonged drainage, either by choledochostomy or through the cystic duct stump, gives better results than any other form of treatment. Secondly, the end results from cholecystectomy are more satisfactory than from cholecystostomy as shown in the statistics from the largest clinics in the country. Judd, in reviewing 2,027 cases in the Mayo Clinic, summarizes his impressions as follows:

1. "Removal of the gall-bladder reduces the risk of later trouble and ordinarily is to be preferred to cholecystostomy for drainage.

2. "It is not necessary to open and probe the common duct at every gall-bladder operation.

3. "Infection in the liver, gall-bladder or ducts is the most frequent cause of secondary trouble and may recur many years after the primary operation.

4. "The recurrence of stones is more frequent in the gall-bladder than in any other part of the biliary tract; the common duct is next in point of frequency,

5. "In a definite small percentage of cases stones will be overlooked in the common duct, in other cases the stones reform in the duct."

Of the 2,027 operations in this series, 219 or 10.8/10 per cent were secondary. In 109 of the 219 secondary operations calculi were found either in the gall-bladder, the ducts, or in both. Balfour and Ross report from the Mayo Clinic 5,997 cholecystectomies from January 1, 1910, to December 31, 1919, with one biliary fistula. For the same period they report 1,879 cholecystostomies with eleven postoperative fistulae. They state that comparative statistics of experienced surgeons show that cholecystectomy has a decided superiority over cholecystostomy in every respect, operative mortality, immediate and late results and biliary function.

Statistics such as these are illuminating and convincing. The gall-bladder after infection is once established in the form of cholecystitis probably never recovers completely even after drainage. There is much evidence to substantiate this postulation. Chronic hepatitis and pancreatitis are associated infections or complications which are favorably influenced or obviated by timely removal of the gall-bladder. There is still a group of the chronic cases which are puzzling from the standpoint of diagnosis, in which there are no stones present but a rather definite history of gall-

bladder disease with little or no gross evidence of cholecystitis on exploration except for a gall-bladder that does not empty easily on compression. Palpable enlargement of duct glands is usually absent, lipoid deposit in the wall of the gall-bladder may or may not be in evidence. I refer to the occasional case in which there is stenosis or angulation of the cystic duct which interferes sufficiently with drainage from the gall-bladder to cause the symptoms which are relieved by cholecystectomy. Seelig has directed attention to this in a discussion on bile duct anomalies. The stasis thus produced becomes a real factor in the development of advancing disease of the gall-bladder with the complicated infections so frequently associated with it, viz., pancreatitis and hepatitis.

In an exhaustive review by Peterman of the literature on the experimental work of the gall-bladder, it has been shown conclusively that stasis plays an important role in the etiology of cholecystitis. He found from this review that simple injection of virulent organisms, even in large amounts, into the lumen of a normal gall-bladder does not usually produce cholecystitis. Injection of virulent organism into the lumen of a gall-bladder in sufficient amounts after ligation of the cystic duct and vessels regularly produces cholecystitis. Intravenous injection of organisms, if in sufficient amount, is always followed by the appearance of these organisms in the bile. The organisms are probably carried to the liver through the blood stream, excreted in the bile, and carried through this medium into the gall-bladder; however, organisms are also carried at the same time among other places into the wall of the gall-bladder by the blood stream and lymphatics. Ehret and Stolz (whose work Peterman quotes) have observed that the organisms injected into the gall-bladder for the first few days increase in number and then decrease until the gall-bladder becomes sterile. This is explained on the assumption that increased concentration of bile destroys the organisms (Drennan). This may account for the large number of sterile cultures obtained from diseased gall-bladders at the operating table. Cholesterol is distinctly inhibitive to bacterial growth.

In cholecystitis streptococci are the organisms usually found. They are infrequently recovered from the bile but can nearly always

be found after maceration of the gall-bladder wall. Rosenow in experimental work on the etiology of cholecystitis and gall-stone formation has not only shown that the streptococcus is the most constant organism in its production but that it has definite powers of elective localization. The special affinity shown by different organisms for various tissues of the body has been seen over and over again clinically and this he has shown conclusively in his experimental work. He also maintains that infection of the gall-bladder is usually a result of blood stream infection. Mann has produced a specific cholecystitis by the intravenous injection of Dakin's solution; this Rosenow maintains supports elective localization from a chemical point of view. That it also occurs through the lymphatics less frequently is an accepted fact. In the course of gall-bladder disease there may be a cessation to the usual typical symptoms when the patient may be subjected to more remote disturbances such as neuritis, joint manifestations, and other constitutional symptoms, the gall-bladder thus acting as a focus of infection. In contrast to this, cholecystitis is undoubtedly often the result of focal infection elsewhere. Such foci should receive treatment in the routine management of gall-bladder infection.

## CANCER OF THE MOUTH.\*

By ROBERT LEE PAYNE, M. D., F. A. C. S., Norfolk, Virginia.

In the yearly report of the State Bureau of Vital Statistics, Dr. Plecker reports that there were forty-six deaths from cancer of the buccal cavity. This total of deaths from cancer of the mouth is not so large when compared with the deaths from cancer of other organs, but it goes to show that there are a larger number of individuals affected with incurable cancer of the mouth and that it behooves the surgeon to study these conditions and to do what he can to relieve the suffering individual. The mind of the surgical world at large is beset with the deepest pessimism when cases of cancer of the mouth and throat present themselves for treatment and, while the subject is a desperate one, it is not entirely hopeless. Various cancer hospitals throughout the world report practically no cure of cancer of the larynx and but few of the base of the tongue, but the state of affairs presented in cancer of the mouth lends a far more hopeful attitude, for the result in the treatment of this type of malignancy has been very gratifying and very encouraging during the last five years. The good results attained have been due to the recognition of the possibilities of radium in these cases, together with the realization of just how much can be added to the treatment through the aid of coagulation necrosis.

Cancer of the mouth cavity always originates in the mucous membrane covering the

\*Read before the Seaboard Medical Association of Virginia and North Carolina, in Newport News, Va., December 4-6, 1923.

tongue, the floor of the mouth, gum, palate and teeth, and no matter from what point it begins, the close proximity to the maxillary bone always results in the early involvement of this structure. The early involvement of the maxilla in tumors arising from the mucosa of the antrum and the nose makes the separation of these from the tumors originating in the mouth almost impossible at times. In addition, the close association of nasal mucous membrane with the mouth mucosa combines to make malignancy in the upper jaw more frequent than in the lower, and because of this association we also see a greater variety of clinical and morphological types of cancers. Cancer of the buccal mucosa, of the floor of the mouth and tongue are very much more common than sarcoma, the relative frequency being about three to one. Cancer also appears somewhat later in life than sarcoma, usually during the fourth, fifth and sixth decade and true carcinomata are five or six times as frequent in men as in women. It is broadly estimated by some pathologists that the fatality from cancer of the mouth has in the past run from seventy to ninety per cent of the cases.

The etiological factor in cancer of the oral cavity has not been stressed to the laity at large by the medical profession, and entirely too little attention has been paid to the subject of chronic irritation as a causative factor. Some authorities state that false teeth and old ragged loose teeth are the main exciting factors in producing cancer of the oral cavity. It is certain that all chronic ulcers and fissures act as a predisposing factor in the establishment of carcinomata in the mouth. Another condition so frequently seen by all of us and so common in the beginning of a malignant lesion of the mucous membrane of the mouth is that of leucoplakia. Most skin specialists consider leucoplakia as potentially malignant from the beginning, while some pathologists state that carcinoma develops in thirty per cent of leucoplakia cases improperly or not treated at all. The writer believes that all conditions of leucoplakia in the mouth should be considered potentially malignant and treated as a precancerous lesion. Chronic irritation from the use of tobacco, arising from a hot pipe stem, the edge of a broken tooth or the presence of an old active pyorrhea all seem to lead to a condition which is not only favorable to malignancy but often termi-

nates in malignancy. Whenever an ulcer or a new growth appears in the mouth of an individual over thirty-five years of age and remains stationary for a period of three or four weeks, in spite of the usual appropriate treatment, then this case should be considered suspicious of an early malignancy.

The question of metastases in these cases of cancer of the mouth has the most important bearing on the treatment of the condition and it is a recognized fact that malignancy of the tongue and the floor of the mouth metastasizes sooner than any of the other types found in the oral cavity. Usually the metastasis in this type of case is on the same side as that on which the lesion is situated but it occasionally happens that the opposite side is involved in the metastases while the affected one remains comparatively free. Malignancy of the mucosa involving the inferior maxilla always metastasizes to the sub-maxillary lymph-nodes and this occurs early in the affection while malignancy of the buccal mucous membrane, strictly speaking, rarely metastasizes or, if at all, at a late stage in the progress of the tumor growth. The most singular feature relative to cancer of the mouth is the fact that in cancers involving the superior maxilla there is little or no tendency to metastases and this, of course, makes the prognosis and the possibility of treatment very much better in malignant tumors of the mouth arising from the mucosa covering the superior maxilla.

The majority of malignant lesions of the oral cavity are the true epidermoid carcinomata, but we often have to distinguish between the malignant odontomata as well as the frequent occurrence of sarcoma in one form or another arising from the connective tissue in the mucous membrane. In addition to the characteristic giant cell sarcoma or epulis which is comparatively common, we also have sarcoma of the round, the spindle cell, the mixed cell and the melanotic type arising in the mouth and jaw. The round and spindle cell types of sarcoma are highly malignant, grow rapidly and, unless carefully treated, always end in early death. The tendency in these growths towards recurrence is very marked and, if at the time of operative treatment any vestige of the new growth is left behind, there is a rapid return of the growth and an increased tendency to metastasize to other portions of the body. It is true however that sar-

coma of the mouth and jaw have very little tendency to metastasize early in their course of development. The sarcomata are much more common in the superior jaw than inferior. The basal cell type of carcinoma is rarely ever found within the oral cavity.

It is rare that any of these malignant conditions of the oral cavity present themselves to the surgeon early in the disease and the picture of an advanced malignancy of the mouth with the victim weak and emaciated from inability to take food or liquid, coupled with the pain and suffering, presents to us a problem that is difficult of treatment.

The success met with in the treatment of these cases in the last few years has been attained through three methods or agents for handling this type of cancer. These consist of surgical removal with the knife or removal by some method of coagulation necrosis and the institution of proper radium treatment. The question of sequence or the precedence of one of these measures over the other has created a division among the men who are treating and seeing these cancers of the mouth. One school believes that the lesion should always be thoroughly treated with the radium first and then removed with the knife or some form of cautery. The other school believes that cautery or some form of coagulation necrosis should be instituted first and then the site of the growth thoroughly treated with radium. The writer belongs to the latter class and it has been our practice during the past five years to treat these cases by first complete removal of the growth by coagulation necrosis and this to be immediately followed by massive radium treatment.

Before we had radium, we always destroyed these growths with the dull cautery and I cannot recall a single case that got entirely well or remained well very long. Since we have had radium, those cases which formerly we considered hopeless have given us a fairly satisfactory percentage of apparently complete cure which in some instances have remained permanent for a period of three to five years. The suffering of these patients after this form of treatment is very intense and they present a very pathetic picture as they linger along during the first six to nine months after their primary operation, during which time the sloughs are separating and the sequestra loosening from the maxillary processes.

Usually all pain stops when the last bit of dead bone comes away and following this the mucous membrane soon rapidly covers over the healthy bone and complete healing rapidly takes place.

In conclusion I would like briefly to report one case of the type under consideration in this paper.

Mr. J. S. A. admitted to St. Vincent's Hospital, December 23, 1920, with the clinical diagnosis of cancer of the mouth. Portion of the oral cavity involved was the floor and to the left side. The lesion extended from one-half inch to the right of the frenum along the left side of the floor of the mouth and as far back as the last molar tooth, passing up onto the lateral aspect of the tongue from the frenum backward as far as the last molar tooth and running over on the alveolar process along the whole distance from the frenum to the last molar. A section of tissue removed proved in the pathological report to be a squamous cell epithelioma.

On December 26th, under a general anesthetic, all of the lower teeth on the left side were pulled, up to the lateral incisor of the right side, and dull heat with cautery irons instituted for forty-five minutes until a complete and deep coagulation necrosis of the entire growth had taken place. Twenty-four hours later the entire area of cauterization was covered with 600 milligram hours of radium, the tubes being placed about one and one-half centimeters apart. There were a large number of tender and enlarged glands under the left lower jaw and these were at the same time radiated through the skin with a dose of 1200 milligram hours. February 17, 1921, the condition of the mouth was very satisfactory except just at the point of the frenum where there appeared to be some little tendency for hyperplasia and many of the glands of the neck persisted, though small and not at all tender. At this time 400 milligram hours of radium was given to a small area just corresponding with the frenum of the tongue and 1,800 milligram hours were applied to the glands of the neck through the skin with proper screen.

On March 30, 1921, practically all of the floor of the mouth was healed except for an area of necrosis near the site of the last molar tooth where a piece of loose sequestrum could be felt. Up to this time, from the date of the original operation the patient had suffered

considerable pain and it had been necessary at times to give him an opiate. At this visit a piece of the lower jaw was removed in the form of a loose sequestrum and following this all of his pain was immediately relieved. He never took another dose of morphia and, in approximately two weeks, healing was about complete over the entire affected area.

On June 11, 1921, the mouth was entirely healed; the patient had gained thirty-five pounds in weight and up to this date his mouth has remained entirely healed and he seems to be in splendid health in every respect. The tongue is somewhat fixed to the left side of the floor of the mouth by scar tissue but he has a plate with teeth which he wears with comfort and the cure appears to be complete.

### THE VALUE OF VITAL RECORDS.

By LLEWELLIN ELIOT, M. D., Washington, D. C.

The importance of Vital Records—records of births, baptisms, marriages and deaths—is paramount, and their value may be assumed greater in the event of destruction by fire, flood or tornado of the church or other building, where such records are preserved. Leaving aside the factor of personal or genealogic vanity in these records, as concerns the individual, certified copies of records may be demanded in cases of litigation over the distribution of estates, divorce suits, cases of illegitimacy, the age of consent, admission to schools, the operation of the Child Labor Law, and admission to Military Institutions of the Government.

Every community, worthy a name, files vital records and, upon the application of a properly authorized party, certified copy will be furnished. In furnishing copy, the custodian must exercise judgment, in order not to promiscuously betray cases of illegitimate births.

Unfortunately the place of preservation of these records is not always fire-proofed, nor sufficiently guarded to prevent abstraction by interested parties; there should be no reason for such laxity on the part of the authorities and, while it would necessitate an outlay of public funds to provide file cases, lockers or safes, the outlay would be justifiable.

A first child may be born and live at the expiration of six and a half months' gestation, after marriage, and there may be created much

gossip and scandal and, should the parties have been of the free and easy social class, it will require expert medical testimony, based upon a full and careful study of the physical development of the child to quiet these scandal-mongering tongues and to establish the fact that there had been no undue intimacy of the contracting parties previous to marriage. Cases bearing upon this point have been reported; they are matters of record both civil and legal.

Previous to a contracted marriage, State laws protect; where one or both contracting parties should be under the legal age, the written consent of the parents or guardian is required; should objection be raised, that objection must be of a justifiable nature, and sustained otherwise it falls as an objection; forced marriages or those contracted under duress may be nullified by recourse to the court of the jurisdiction; proceeding further, one finds the law requires a license issued by a court's officer; this license furnishes, under oath names, ages, places of birth, and usually, the name of the minister selected to perform the ceremony; it further requires that this license be returned to the court when the ceremony has been performed; a justice of the peace has equal power, as a minister, to marry applicants. I believe the presence of witnesses is usual but not obligatory.

We will suppose every requirement has been complied with, a permanent record is made, and through no ingenuity can this record be denied or falsified. No question can be raised.

Now, let us suppose an eloping couple will reach a county seat after the day's work is done, say about midnight, with law officers and irate parents close on the trail; it is impossible to find the clerk of court, no license can be procured, perhaps the clerk is not willing to get from his bed to help out in the case, time flies, and something must be done and done quickly or the elopers must seek another town. A midnight prowler gives the name of a minister and he is approached, the case explained; on solemn promise to furnish the license at the earliest possible moment, he will waive the license and marry them. His impecuniosity or his over-zealousness has made him violate the law but, trusting to faith in human nature, he does not feel any concern. The time passes and there has been a lapse of memory, a dishonest intention in delay, and it will follow there is no license procured. We have here

an illustration of crooked legalness or legal crookedness; there is no license, no record, possibly no witnesses; our minister begins to fret or worry, still he cannot say a word, for the reason that he is a violator of the law and it is hardly possible to suppose he would do a thing that would incriminate himself. There is no way through which any one, not even the contracting parties can prove marriage unless their "*ipse dixit*" be accepted as a fact, and the case does not come before a Court's jury for settlement.

Let us go further in this case; in time a child is born to these parties, the question now comes up, what standing in law does this child possess, although there may have been parties present at the ceremony; and mother and father have all social rights and privileges of a married couple; they are not married in the eyes of the law; they come under the stigma of "common law husband" and "common law wife," although the name of the father is given the child. Presumptive evidence is all that can be offered in proof of paternity.

A Court of Appeals would not confirm the verdict of a jury of a lower court rendered from motives of sentiment and pity; the common law stigma must stand and litigation be begun anew.

In the early days of the Colonies, three hundred years ago, provisions were made for cases of like nature, and the published "Intention of Marriage" was accepted; if made a matter of public record, frequently, the matter ended there; in some instances a marriage ceremony was performed by a minister or some other one commissioned by the court, notwithstanding the fact that some years may have elapsed between the "Intention" and the ceremony; whatever children born to this union were legitimate.

In a Report of the Record Commission containing Boston Births, Baptisms, Marriages, and Deaths, 1630-1699, one finds:

Colony of Massachusetts, General Court in September, 1639, ordered,\* "That there bee records kept of all wills, administrations, inventories, as also of the dayes of every marriage, birth, & death of every person in this jurisdiction." In June, 1642, we read that "Whereas, at the Generall Cort the 4th 7th mo. 1639 there was provision made for the recording of severall particulers, amongst which it

is observed that birthes, deathes, & marriages are much neglected in many townes,—

"It is therefore ordered, that hereafter the clarks of the writts in severall townes shall take especially care to record all birthes & deathes of persons in their townes; & for every birth & death they so record they are to have allowed them the summe of 3d, & are to deliver in yearly to the recorder of the Cort belonging to the jurisdiction where they live a transcript hereof, together with so many pence as there are births and deathes recorded, & this under the penalty of 20s for every neglect; & for time past it is ordered, they shall do their utmost indeavor to find out in their severall townes who hath bene borne, & who hath died, since the first founding of their townes, & to record the same as aforesaid.

"Also the magistrates & other persons appointed to marry shall yearly deliver to the recorder of that Cort that is nearest to the place of their habitation the names of such persons as they have married, with the dayes, months, & years of the same; & the said recorders are faithfully & carefully to inrolle such birthes, deathes, & marriages as shall thus bee committed to their trust." In May, 1657, it was found necessary to go further, and, "This Court, taking into their consideration the great damage that would unavoidably accrue to the posteritie of this common wealth by the generall neglect of observing the law injoyning a record of all births, deaths & marriages within this collony, are therefore order that henceforth the clarks of the writts in each towne respectively take due care for effecting the same according to the intent of the aforesaid lawe; and in case any person or persons shall neglect their duty required by the said lawe more than one month after any birth, death, or marriage the clarke of the writts shall demand the same, with twelve pence a name for his care and paynes; and in case any shall refuse to satisfy him, he shall retourne the names of such person or persons to the next magistrate or commissioners of the towne where such person dwells, who shall send for the party so refusing, and in case he shall persist therein, shall give order to the counstable to levy the same. And if the clarke of the writts shall neglect his duty thereby injoynd him, he shall pay the following penalty; i. e. for neglect of a yearly retourne to the

\*The spelling is as the record.

County Court, five pounds, and for neglect of returning the name of any person retournable by this lawe, whether borne, married, or dead, more than thirty daies before his retourne to the County Court, five shillings, and that no future neglect may be heerein, the recorder of each County Court is hereby injoynd from time to time certify the County Courts repectively the names of all such clarks as shall neglect to make their yearly retourne according to this lawe, who, uppon notice, given, shall send for such clarke, and deale in the case according as lawe requirith."

These records are still in a fair state of preservation and may be consulted by those who may be interested.

The preservation and recording death records has become at this time an easy task; there are a number of persons required to supervise a burial,—an undertaker, a grave digger, a minister, and the family of the deceased. Records of deaths give places of interment; it is, therefore, not a very easy thing to illegally bury a body, at the same time they are necessary to the records of a State.

The difference between Vital Records and Vital Statistics, is, the one deals with the person, the other deals with morbidity and mortality.

1106 P Street, Northwest.

### A PROBLEM IN DIAGNOSIS.

By ALLEN H. MOORE, M. D., New Market, Va.

Despite the rapid advance of medical science, we still have with us diagnostic perplexities. Laboratory auxiliaries are commanded, but even with our perfected technique we are too often utterly in the dark as to the prevailing pathology. Do we not at times label a patient with a certain diagnosis haphazardly without thoroughly investigating via improved laboratory methods? We do. But does the laboratory always hand us a solution to our diagnostic problem? It does not.

It is deplorable that the public expects and demands of us a positive diagnosis upon our initial bedside visit. This certainly tends to create a "snap-shot" diagnosis and unintelligent explanations. I do not believe that we should depend too much on laboratory assistance, yet at times we cannot offer satisfactory or scientific reasons for existing symptoms without it.

On June 13, 1923, a patient, Mr. S. S., consulted me at my office for the first time. He complained of a constant nervousness, a feeling of weakness and a daily remitting headache. He wore an anxious expression and was somewhat melancholy. His family history was negative as was his personal history. He denied venereal infection. Physical examination revealed nothing. He was a well-built, tall, muscular individual. His temperature was normal. I specifically mention this for later comparison.

I informed the patient that my physical examination revealed nothing of a serious nature and that I thought a vacation was much needed. I prescribed complete rest, good, nourishing food, the usual hygienic measures and sodium bromide.

He returned to his work, stating that he was too busy just then to leave. On June 26th he came back to me, exhibiting the same symptoms. He stated that in the forenoon he felt perfectly well but in the afternoon his headache returned, as did his feeling of general weakness and nervousness. His appetite was poor. A second complete physical examination was also negative. His temperature was still normal.

He sought the advice of another physician who failed to locate any definite pathology. A third physician was consulted. At this time, July 29th, he was having a profuse sweat, chills and running a temperature of 103. He was referred back to me with a tentative diagnosis of malarial fever. In as much as he had recently moved from a malarial infested part of the state, this diagnosis seemed not improbable.

I made a third complete physical examination with a negative result. I prescribed quinine and put the patient to bed. The following laboratory work was done:

1. Blood smears for malarial plasmodium.
2. Blood culture for typhoid fever.
3. Widal reaction for typhoid, para-typhoid-A and para-typhoid-B, and colon bacillus.
4. Blood Wassermann.

5. Sputum examination for tubercle bacilli.

Repeated laboratory examinations were all negative. After being in bed for a few days, there was noted a slight improvement. The headache, chills and profuse sweating disappeared. The temperature curve was lower.

The temperature was normal until about noon and then there was a daily rise to 100 or 102. There was a decided improvement in his mental condition, but he stated that he still felt very weak. Up until August 6th, his condition remained about the same.

I asked for consultation. My consultant could find nothing definite. He suggested that the patient was having an atypical typhoid infection or a hidden tubercular infection. We decided to have him entered for hospital observation and treatment. A third consultant was called in to see the case. Repeated physical examinations were negative. Laboratory examinations were continued. X-ray examinations of the chest did not reveal tubercular pathology.

No diagnosis was made. His condition remained about the same. On August 24th, it was decided to remove him to the Johns Hopkins Hospital, Baltimore, Md., for further observation, where he remained until October 26th. His temperature continued remittent in character, varying from 100 to 103½. His headache returned and his feeling of weakness continued, more in the afternoon, when his fever was most pronounced. He had occasional sharp shooting pains in his chest and abdomen, and at one time had a bursitis of the left knee. The only definite thing that could be made out upon physical examination was a left side internal ear deafness and a slight general glandular enlargement. In spite of his fever, he gained fifteen pounds in weight and gained strength proportionately.

The following laboratory examinations were made:

*Urine*—No abnormalities found.

*Spinal Puncture*—Normal pressure; normal number of cells.

*Wassermann*—Negative.

Negative *colloidal mastie and colloidal gold curve*.

*Stool Examination*—Negative. No ova or parasites found upon numerous examinations.

*Blood Cultures*—Two every week, aerobically and anaerobically, all of which were negative with the exception of two, from which were obtained an anaerobic hemolytic streptococcus.

*Intradermal Tuberculin Test* was negative.

*X-Ray of Sinuses*—Sinuses clear.

*X-Ray of Chest*—Lungs clear; heart and aorta not enlarged.

*Gastro-intestinal Series*—Stomach normal. No lesion in stomach or duodenum. Caecum a little dilated. Transverse colon a little prolapsed.

*Impression*—Normal stomach with a few lower quadrant (right) adhesions.

*X-Ray of Teeth*—No periapical granulomata.

*Gastric Test Meal*—No evidence of retention; normal acidity. No blood.

*Bacteriological examinations and blood serum tests* for specific agglutinins against the following organisms: B. Typhosus; B. Para-typhosus-A; B. Para-typhosus-B.

*Nose and Throat Consultation*—Inner ear deafness with no involvement of the vestibular branch of the eighth nerve.

*Ophthalmoscopic-ophthalmological examination*—The eye grounds revealed nothing abnormal.

The temperature has subsided and the patient discharged from the hospital as improved. No definite diagnosis has been made. It was the opinion of those in charge of the above noted investigations that the continued fever had been due to a streptococcus viridans bacteremia. There was no evidence of an endocarditis. The portal of entry was not determined.

In recapitulation, it is interesting to note that a great deal of laboratory work was done and the work properly checked. Repeated complete physical examinations were made with negative results. The portal of entry of the existing infection was not determined. A bacteremia was the most plausible diagnosis

### THE CLOSED METHOD OF TREATING EMPYEMA vs. RIB RESECTION: SUMMARY OF CASES.\*

By G. CARLYLE COOKE, M. D., Winston-Salem, N. C.  
Department of Surgery, Lawrence Clinic.

Since there is great diversity of opinion as to the better method of treating empyema and as there are many who still adhere to the open treatment, it seems that there should be a more or less standardized procedure employed, and as this can only be brought about by the advantages of one method outweighing all others, it is the purpose of this paper not to present anything new, but to point out the merits of the closed method over the old very unsatisfactory rib resection.

\*Read before the North Carolina State Medical Society at Asheville, April, 1923.

## PATHOLOGY.

In considering the treatment of any disease process, the pathology, of course, must be understood in order that scientific counter actions of the different processes may be affected in rotation, otherwise the treatment is empirical. The aetiology and symptomatology will not be discussed as the diagnoses can always be made so easily by the use of a needle and the exact location so accurately mapped out by the use of stereoscopic roentgenogram.

The pathological lesion of empyema and pleurisy with effusion, both of which are considered in this discussion, occur in a cavity in which there is normally more or less a vacuum, with a negative pressure of about 8 m.m. Hg. on expiration to 12m.m. Hg. on inspiration.<sup>1</sup> This suction force serves in the place of an anatomical structure to pull the lung equally in all directions, to expansion with the expansion of the chest cavity during inspiration, and not interfere with the change in position of the lung surface with relation to the inner surface of the chest wall during respiration. Regardless of the causative organism, the mechanical derangement is the same. The fluid always gravitates to the lowest point available as the negative pressure does not alter the laws of gravitation. If there are no adhesions between the visceral and parietal layers of the pleura, the fluid will fill up from the bottom, and the negative pressure will not be neutralized until the lung is completely collapsed or has no more tendency to contract of its own normal resiliency. Therefore, it depends on the *modus operandi* of the causative agent as to whether the serous surfaces will become adherent so as to hold the lung in expansion before sufficient amount of exudate has collected to deplete the vacuum, or to cause a barrier against the fluid in lines of cleavage and cause the formation of thin sheets of fluid at different levels, and the surrounding line of adhesions serve to pull the lung in expansion with the expansion of the chest during inspiration. If the exudate begins as a fibrinous one before fluid collects, one can readily see how these adhesions occur, holding in their meshes pockets of pus of later formation. This is nature's way of tending to limit the disease in two ways: first, by limiting the space for fluid collection, and second, by maintaining respiration and circulation of the affected lung. This same process holds true in massive effusion with complete collapse of the lung.

Any fluid collecting in the pleural cavity contains in it fibrin-forming substances, and the resulting fibrin, which will form sooner or later, bridges the visceral and parietal pleura. Fibrin stimulates the growth of fibrous tissue,<sup>2</sup> or fibrous tissue is prone to grow luxuriantly into fibrin; it seems to use fibrin in its own formation so that in this way adhesive bands connecting the two pleural surfaces later contract, tending to pull the lung out. If this is not accomplished, the fibrous tissue will increase at the expense of the fluid and hasten its absorption, at the same time binding the lung surface to the chest wall. If this process be allowed to continue and the infection is not overwhelming, there may be walled off areas of fluid which are so often broken up at rib resection with the finger, frequently denuding areas of the lung surface, opening up new avenues for septic absorption, or causing the infection to spread back into the lung to the extent of lung abscess or secondary bronchiectasis.

The above process may take place in the presence of fluid but, if there is a pneumothorax, the pathology is entirely different. In the first place, the pleura is much less resistant to infection in the presence of pneumothorax than in any other state,<sup>3</sup> especially when it comes on suddenly. In my opinion this accounts for many cases which rapidly succumb to rib resection, together with the opening up of fresh tissue to the infection, both of the pleural surfaces and chest walls. Air does not float fibrin, so that, when a lung is collapsed by air, the fibrin-forming substances poured out on the pleural surfaces stimulate the thickened pleura to increased stiffness. This prevents the expansion of the lung completely with scar tissue which, when the cavity is obliterated, will affect it by filling the cavity with granulations or by pulling the chest wall in on the lung, thereby marking the victim with asymmetry of the chest for life, which is the general rule following rib resection. It is needless for me to say that the scar from thoracotomy may be as unsightly as any other operative label.

Another condition which is frequently overlooked when considering the pathology of empyema, especially where there is a large quantity of fluid, is that there is more or less displacement of the mediastinal structures; in massive effusions, the opposite lung may be encroached upon by the pressure and, as the

heart is held between the lungs, it also suffers from pressure. The great vessels, especially the veins, may have their lumina compressed, hindering the return flow of blood to the heart. In this way we may account for a great amount of cyanosis and dyspnoea seen so often, (for the respiratory stress cannot be accounted for by the lessened lung capacity in a great many cases but is due to toxæmia of the inflammation and the above mentioned conditions),<sup>4</sup> and the alteration of the mediastinal circulation and the effects of the change in position of the mediastinal structures on the cardiac and pulmonary nerve plexuses. When the condition comes on slowly, these structures may adapt themselves to the new position so that their functions may not become markedly altered, but any sudden change in these relations may bring about conditions of great importance which will be referred to under treatment.

As it is an admitted fact that thoracic suction plays an important role in maintaining a return flow of the venous blood to the heart, one can readily see how any condition lessening this function would materially alter the general circulation. Another point of much importance is the consideration of the proper method of treatment.

#### TREATMENT.

The most efficient method of treating empyema is the one which will most effectively rid the sufferer of the products of inflammation; in other words drain the abscess, and combat the causative agent, and at the same time maintain as nearly normal condition of the body as a whole as possible. In the first consideration, which I think can be well applied here, the treatment should not be left to the mechanical procedures alone, and I mention the importance of food, comfort and rest so that their importance may not be lost sight of. When any active boiler is leaking steam the only resort is to increase the fires until the leak is stopped. Bodily resistance is entirely dependent upon the nutrition of the individual, which is gained only by plenty of good food, warm body and rest. Preparation must be made to prevent all muscular exertion and mental anxiety as far as possible.

In discussing the operative methods, the one of preference will be described and the points of merit will be noted in turn. The patient is placed on the table in a position which is

most comfortable to him, not upon the unaffected side any more than is necessary to gain access to the most dependent point of the fluid collection and, as only a small opening is to be made in the skin under a local anæsthetic, this can usually be done with the patient on the back. A sharp trochar that will admit a soft rubber catheter of 18 or 20 f., which has been perforated on the opposite side from the regular eyelet, is inserted through the chest wall and, as soon as no resistance is felt, the obturator is withdrawn sufficiently to allow the catheter to be inserted through the opening at the Y without allowing the escape of any pus or the ingress of any air into the chest. The trochar which has been especially designed for this method is best (Fig. 1) but, if one is not available, an ordinary gall-bladder trochar, or straight one, will suffice, as the procedure can usually be accomplished so quickly that any leakage will be negligible, provided the catheter fits the trochar. The other end of the catheter is clamped and, when the entering end is in the pleural cavity not over 3 c.m.

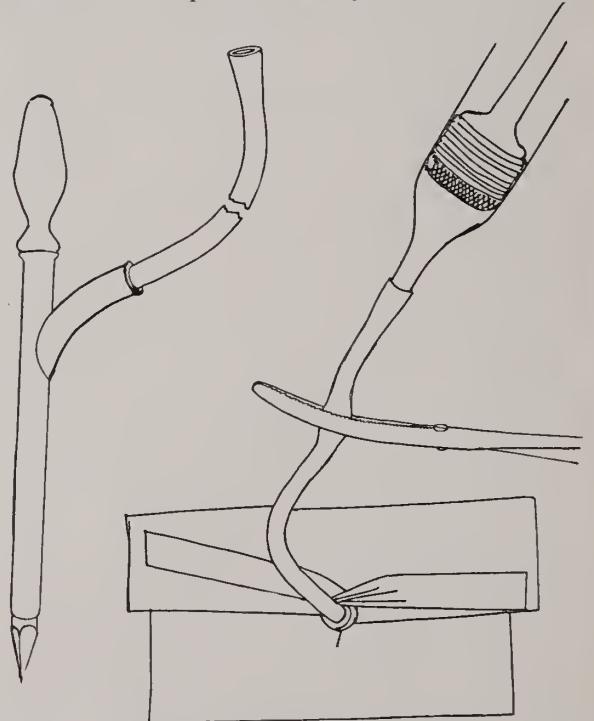

Figure 1.

approximately, the trochar is withdrawn leaving the catheter in place. Before any fluid is allowed to escape, the catheter is well anchored to the chest wall and, if the skin incision has not been made too large, this can be done with adhesive. The only dressing necessary or even a small

piece of gauze wrapped around the catheter and held by tightly applied adhesive strips as illustrated in Figure 1.

Now, in order to determine accurately whether or not the negative pressure has been depleted or whether there is positive pressure in the chest, I have improvised a water manometer about 20 in. (or 50 cm.) long, graduated in m.m. Hg. and a connection so that the fluid escaping, if any, will indicate the pressure on the manometer by displacing the air in the receptacle attached, as shown in Figure 2. If there is marked positive pressure, the catheter is clamped and no more pus allowed to escape until it can be attached to a permanent drainage receptacle (Figure 3.), with a stop cock interposed so that the flow can be regulated at will. As soon as this is

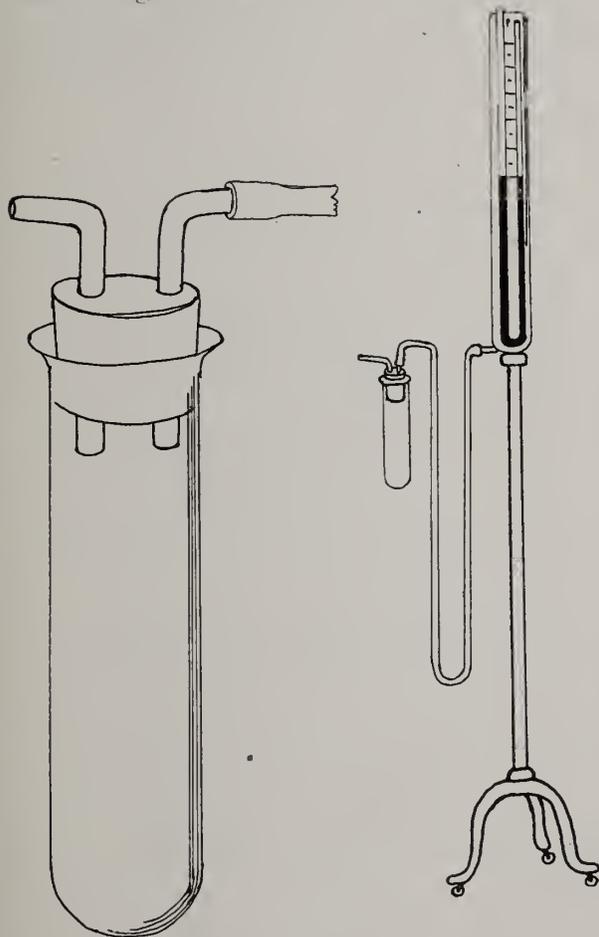

Figure 2.

done, the patient is returned to bed and the massive effusion with distention of the chest wall, displaced mediastinal organs and other conditions mentioned under pathology are slowly abated. Varying with the amount of

fluid present, the time utilized in completely evacuating the chest ranges from a few minutes to thirty-six hours. In this way the risk of shock can be entirely eliminated, the time that the patient has been kept from his room is so short that any mental anguish is *nil*, and there is no need for a general or extensive local anæsthetic, either of which has its disadvantages in doing a rib resection.

Figure 3 shows the type of vacuum which is easily obtained and the one which is used at the Lawrence Hospital. It is merely a 4 liter bottle fitted with a rubber stopper which has been pierced for 2 L-bent glass tubes. One tube is connected to the stop cock in the catheter and the other to a suction pump with a back flow check valve. As the fluid is slowly withdrawn by creating just enough vacuum in the bottle to maintain a constant desired flow, time is allowed for the complete re-adjustment of the thoracic organs and for restoration of the breathing capacity of the collapsed lung which is held in expansion equal to the evacuation of the fluid. This does not cause shock as it allows the lung to take up its increased circulation gradually. Frequently large clumps of fibrin will clog the catheter, but this has always been satisfactorily overcome by attaching the catheter to a large glass piston syringe (Fig. 1) and forcing salt solution through the catheter till the clot is dislodged. If it is then impossible to remove the

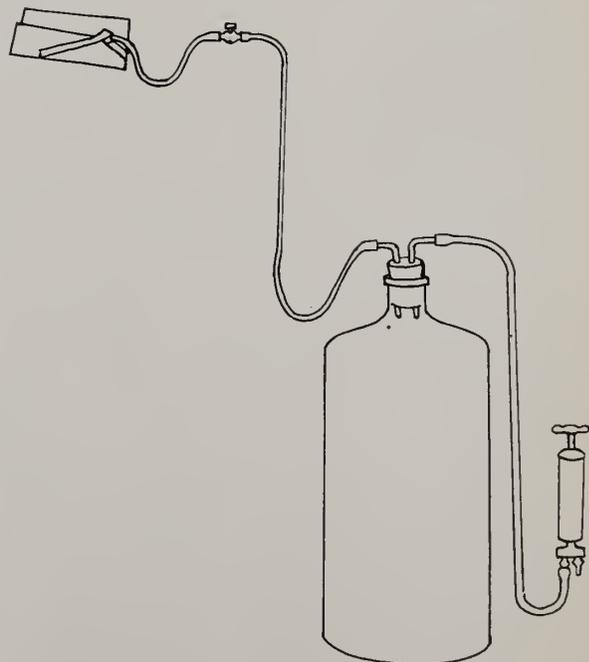

Figure 3.

fluid, one or two ounces of chlorazene solution, 1% is instilled and allowed to remain for an hour. The catheter should always be clamped before it is detached from stop cock or syringe for, if an air bubble enters the cavity, it will rise above the fluid and cannot be withdrawn until the fluid is completely evacuated.

If the fluid flows freely and no fibrin blocking occurs, the vacuum can be left in place so that every drop of fluid will be withdrawn as fast as it accumulates and the cavity only irrigated daily with a 1% chlorazene solution. When there is great amount of fibrin and clots, the vacuum may be left off for a few days and the cavity irrigated every two hours with about two ounces of the chlorazene solution and each time an ounce is left in to effect solution of the clots. Each day after the cavity has once been emptied, the fluid will decrease and finally the pleural surfaces will become adherent,

holding the lung in an expanded condition. Then the cavity may be irrigated and aspirated only once daily till the exudate becomes clear, when the catheter can be withdrawn and the wound dressed tightly, as the patient's resistance will by this time have increased so he will take care of any further accumulation and recover entirely. However, it is a good rule to watch the patient three days longer and note any temperature rise in case further accumulation occurs. If it is necessary to re-establish drainage, the catheter can be re-inserted through the old track without the use of a trochar and the treatment repeated till well.

There are certain essential factors that must be strictly observed for the treatment to be a complete success and some of these, I will admit, are difficult at times, but if one will keep up patient and persistent effort, the results

SUMMARY OF TEN CASES TREATED BY RIB RESECTION AT THE CITY MEMORIAL HOSPITAL.  
THESE CASES WERE PICKED AT RANDOM.

Case No.	No. of days in hospital	No. of dressings	Complications	Condition on discharge
S-1353	10	10	0	Discharged draining.
S-1189	210	230	0	Discharged draining.
S-1628	20	20	0	Discharged draining.
S-2343	42	43	0	Discharged draining.
S-1951	14	18	0	Discharged draining.
S-1990	11	11	Bronchial fistula	Died.
S-60	14	14	0	Discharged draining.
S-336	24	30	0	Discharged draining.
S-1214	17	20	0	Discharged draining.
S-1276	5	5	0	Discharged draining.
Average.	36.7	40.1	1	1 death.

All the patients in this group left the hospital draining, and most of them had no record showing that their tube drain had been removed so that the final result cannot be given in those discharged.

SUMMARY OF TEN CASES TREATED BY THE "CLOSED METHOD" AT THE LAWRENCE HOSPITAL. CASES TAKEN AS THEY CAME ON THE RECORD FILE.

Case No.	No. of days in hospital	No. of dressings	Complications	Condition on discharge
1190	29	4	0	Cured.
1089	30	6	} Inter-lobular abscess.	Cured by open drainage.
1098	30	5		0
1068	27	5	0	Cured.
633	30	4	0	Cured.
214	13	3	0	Cured.
1691	34	6	0	Cured.
326	18	3	0	Cured.
1617	34	6	0	Cured.
.....	12	3	0	Cured.
Average.	25.4	4.5	1	No deaths, all cured on discharge.

will be well worth it. *First*, the catheter must not be introduced too far into the pleural cavity, as it may double up against the walls and kink, thereby obstructing its lumen, or the end may project upward above the fluid level and not drain the most dependent portions, whereas if the eyelet simply remains clear of the chest wall, drainage will be complete. It is well to have the catheter marked in centimeters so one can tell just how far in the chest it is. *Second*, all air must be strictly excluded from the chest by carefully clamping the catheter before changing any connections. *Third*, there should be persistent irrigation with chlorazene solution as frequently as is necessary to dissolve and wash out any fibrin that may be present which may prevent complete drainage. *Fourth*, the catheter should be carefully watched and kept secure, and all precautions used to prevent the patient from pulling it out.

#### COMPLICATIONS.

Probably the most alarming accident which sometimes occurs is a sudden minute rupture of the lung surface into a bronchus and the development of a pneumothorax by allowing air to escape into the cavity from the lung, the latter collapsing just as if air had been admitted through the chest opening. I have seen this occur in three patients, but it caused no untoward results. When it occurs, suction and irrigation should be discontinued, except at most once daily, and the opening will heal over in a short while and the lung can be re-expanded. Care should be taken not to force fluid into the chest at this time as it may gain entrance to the lung and cause the patient distressing expectoration. Aspiration should not be discontinued more than forty-eight hours even in this condition, because sometimes a tag of fibrin will fall over the opening in the lung and act as a valve so that, on inspiration, air will be sucked into the cavity. As this cannot be expelled, the patient will "pump himself up," so to speak, even to the extent of causing death; however, if aspiration is kept up occasionally, this will be avoided.

#### CONCLUSIONS.

1. The treatment by the closed method is applicable to almost all cases of empyema.
2. By universal employment of this method, many cases of the acute streptococcal infection that would succumb to rib resection will be

saved, and the convalescence is much shortened in all cases, without the scarring that usually follows rib resection.

3. There is great saving in time and material by the few dressings that are required, besides avoiding the great discomfort to the patient that accompanies drainage by the open method.

4. There is most always a rapid return of appetite and vigor with no evidence of septic absorption which often follows several days after the opening up of a large suppurating cavity by rib resection because, once the pus is evacuated, the pleural cavity is obliterated by a functioning lung.

#### THE USE AND ABUSE OF TOBACCO.

By JAMES C. McGUIRE, A. M., M. D., Washington, D. C.

In praise of tobacco Charles Kingsley wrote in "Westward, Ho!" "When all things were made, none was made better than this, to be a lone man's companion, a bachelor's friend, a hungry man's food, a wakeful man's sleep, a chilly man's fire."

Now that John Barleycorn is supposed to have departed this life—though in some places, the announcement of his death seems premature—those who have been so zealous in prohibiting the things they personally abhor are turning their attention to prohibition of tobacco. A number of states have already passed laws prohibiting or restricting the sale of cigarettes, but in several there is already appearing a revulsion of feeling. The chief objection seems to be against cigarette smoking, bad-smelling pipes and cheap cigars are more or less permissible but "no cigarette fiends need apply."

For over three hundred years the pleasure derived from the use of tobacco has been eulogized in prose and verse. Indigenous to this country and used by the Indians from time immemorial, at first by inhaling the fumes through a pipe, other forms of its use were soon inaugurated by Europeans, to obtain its pleasurable, soothing effects. It is of interest

to note Humboldt, the great scientist, declared "The ancient Indian name tobacco referred to the pipe alone and not to the weed." At one time it was used as a basis of money, even clergymen gladly accepting it in payment for their services. First, I shall speak of how the great men of the world enjoyed the soothing effects of tobacco, praised and advised its use, then refer to those anti-tobacco zealots who have made ridiculous statements about it and the harm it may cause, endeavoring to prove most of their statements untrue. Most of the world's greatest authors, scientists, dramatists, musicians, poets, physicians, and even clergymen, have written of the great pleasure they have derived from the use of tobacco. The French dramatist and poet, Moliere, declared "Whatever Aristotle and all other philosophers may say, there is nothing like tobacco. The man who lives without it is not fit to live." Mark Twain confessedly smoked on an average of ten cigars a day and often praised their use. General Grant was still more addicted to its use, seldom being seen without a cigar in his mouth. It has been said that his excessive use of tobacco caused cancer of the throat, but, even if he had cancer, it could not have been caused by smoking, for no reputable physician would now declare that the fumes of tobacco could by any possibility cause a malignant growth.

The scientist Huxley did not start to smoke till he was over forty years of age, but later was said to have tried strenuously to make up for lost time. Darwin used snuff. Stevenson wrote: "Tobacco is a thing to be remembered, it is so dry and aromatic, so full and so fine." Thackeray agreed with the essayist Carlyle that "The pipe draws wisdom from the lips of philosophers and shuts the mouths of the foolish."

Would that some of those opposed to the use of tobacco would take this to heart. According to an old Spanish proverb, "A paper cigarette, a glass of fresh water and a kiss of a pretty girl will sustain a man a day without eating." Spencer in his "Faerie Queen," describes tobacco as "most divine." The novelists, Thackeray, Stevenson, Collins, Dickens, and many others were all great pipe smokers. Many of Dickens' characters used tobacco and praised its use. Surely you remember Tony Weller, the father of Samuel, who continually advised his son to "Bevare of the

vidows" and who was never so contented as when he had a pipe between his lips. The poet, Thomas Hood, said

"Some sigh for this or that,  
My wishes don't go far,  
The world may wag at will  
So I have my cigar."

According to the great novelist, Bulwer Lytton, "He who does not smoke has either known no great grief or refuses himself the softest consolation next to that which comes from heaven." Again he says, "Women in this scale, the weed in that, Jupiter hang out thy balance, and weigh them both, and if thou give the preference to women, all I can say is the next time Juno ruffles thee, oh Jupiter try the weed."

For the particular benefit of spiritualists, I will quote from a book recently written in all seriousness by a thorough believer in spiritualism, the great English scientist, Sir Oliver Lodge, that he had a communication through a medium with a departed soul now in heaven who declared "I was greatly encouraged at first to learn that smoking is permitted above, as well as below, but I was depressed to learn that the heavenly Habanas are apparently of poor quality, not made of solid matter but out of essences, ether and gases."

The great statesman and soldier, Bismarck, once declared the greatest pleasure he had ever derived from a cigar, was the one he did not smoke. "Reserving it, as his last cigar, looking forward to the pleasure he would later derive from smoking it, on a certain battle field he noticed a man shot through both arms and suffering intense pain. Bismarck wishing to help him, at first found only gold coins in his pocket—this could do the poor fellow no good; then remembering his precious possession, his last cigar, he lighted it and placed it between the soldier's lips; the smile of pleasure as the man took his first whiff could never be forgotten."

Lord Northcliffe, the English newspaper owner and editor, after lauding the "Yankees" fighting so bravely in the first trenches in France, advised their countrymen to send them cigarettes, chewing gum, magazines and newspapers; always you notice in such advice, cigarettes come first. According to the Department of Agriculture, thirty-nine billion cigarettes were produced in the United States

in the last year. There being such a demand for cigarettes, surely they must have much intrinsic merit or they would have been driven out of the market years ago by the fanatics who spend millions in trying to suppress their use.

In the last great European war, we all know how our soldiers desired them above all things, for the comfort they derived from them in the first line trenches or on forced marches, in the monotony of camp life, during convalescence from wounds and illness. A well known Army surgeon reported "I believe a wounded man waiting for his turn to appear on the table for a surgical operation is better fitted for the ordeal after smoking a few cigarettes than if he had been given a strong drug. We surgeons not only allow it but encourage their smoking. I have seen a whole ward, thirty to forty beds occupied by severely wounded men, complaining, restless, even crying with pain quieted with cigarettes and candy." A lady returned from abroad where she had helped the girls in distributing tobacco to wounded and convalescing soldiers as they arrived by train in London, Paris and other cities says "If you could see how thankfully they receive them one would think even the most violent opponents to tobacco could hardly have the heart to deprive them of this solace."

Recently, an officer in the Aviation Corps, lost in a desolate part of Mexico, was found in the last stages of exhaustion and starvation; his rescuer declared the first thing this man said was "Please roll me a cigarette."

During the War, General Denikin of the Russian Army received through the Red Cross a consignment of American tobacco for himself and his troops. He said "With a regular ration of American tobacco the Southern Russian forces could drive the Bolsheviks out of Moscow in short order." He places tobacco in the first position as a stimulant to morale among soldiers. Occasionally, letters appear in newspapers blaming the Government and individuals for furnishing cigarettes to the soldiers. A clergyman recently declared "It is a very wicked thing to do, for it is well known that smoking has a deleterious effect upon the nerves and makes the men unfit for their strenuous life." Later I will prove this to be untrue. Another wrote "Cigarettes are the invention of the devil and will lead to all forms of sin," then adding the absurd statement "I

believe cigarettes cause pneumonia so prevalent among our troops." He might as well have said their use caused smallpox. But evidently there is a difference of opinion among some clergymen at home and those who were in the fighting line. A soldier tells of "a preacher man" who one Sunday walked six miles with a baseball bat in one hand and a bundle of cigarettes in the other, to give the boys some pleasure. "He asked if he could help us with our stalled mules. We replied 'Sure you can, by passing on so we can talk to these damn stubborn beasts in the only language they understand.' After the clergyman had talked to us and distributed the cigarettes one of the boys said 'I never before believed there was such a lot in this Christianity business. Now I am converted all right.'" The clergyman smilingly replied "You are all right, boy, you are on the right track." Surely this "preacher man" understood human nature wherever he found it. Finally, General Leonard Wood declared "The idea of sending tobacco to the American soldiers in France is a capital one. Nothing gives a soldier in the field more pleasure and contentment than a cool refreshing smoke after a hard day's fighting or waiting call to the firing line. Life in the trenches is very hard and I know the American soldier will appreciate and enjoy remembrances in the form of tobacco, cigars, cigarettes and pipes." In this opinion General McCain and most of the officers in the army and navy concur.

During a period of years I have mentally recorded a number of questions asked me as a physician as to the harmfulness of the use of tobacco, particularly in the form of cigarettes. From the very beginning, those who use tobacco were vilified, condemned to everlasting perdition and doomed to physical degradation, yet those who so expressed themselves were the least qualified to judge, for they persistently ignored the results obtained by investigations of competent physicians and others who scientifically studied the question. With the greatest assurance they iterate and reiterate statements that time and again have been proven false, such as "Tobacco contains a deadly poison that all scientists declare to be a strong stimulating narcotic." This statement has even been made by some physicians who should know better, for nicotine is neither a narcotic nor a stimulant.

Narcotic is properly defined, as an agent

causing sleep and allaying pain. Tobacco has no such effect; therefore it is not a narcotic, nor is it a stimulant. On the contrary, it is a strong sedative, quieting restlessness and calming bodily disquietude.

There is another statement that "There is two to five per cent nicotine in a good cigar, one-half to one grain in a cigarette." If this were true, one cigarette would contain enough poison to kill a number of men. They further show their ignorance of the nature of nicotine by measuring it in *grains*, whereas in reality it is an almost colorless *liquid*. When cornered, these people resort to the expression "Every man has a right to his opinion," but as to the statement of facts and harmfulness in the use of tobacco, "Every man" assuredly has no such right, for only the findings of those who have made thorough laboratory investigations, physicians who have studied effects by close clinical observation are worth serious consideration. It is here of interest to learn that an instructor at John Hopkins Medical School stated, "I have yet to see in a clinic or a pathological laboratory any evidence to condemn tobacco in any form."

In fact, the opponents resorted to cruel statements, that could only originate in the minds of visionary fanatics, endeavoring to impress immature minds incapable of judging for themselves. Some of their statements, so overdrawn, and at times so absurd, when brought to the attention of the general public, should be of great benefit to the manufacturers of tobacco by showing how far these anti-cigarette fiends will go to try to prove their untrue statements. "Fiends" is here used advisedly, for what could be more cruel than some of these published statements? For instance, at a certain meeting of "The Epworth League" at Denver, Colorado, an individual was allowed to deliver himself of the following: "Tobacco farmers are scoundrels, tobacco merchants are villains, all tobacco dealers and users are rogues and scamps." Mr. Elbert Hubbard, a year or two before his tragic death by drowning, published an article in one of our best known magazines entitled, "The Cigarette Habit," illustrated with a picture of a youth with cigarette in hand, surrounded with grinning skeletons and emaciated horrors, better suited as a frontispiece of "Dante's Inferno." Under this picture appear the words: "Hands that already play the devil's tattoo and roll cigarettes; these are the hands

that forge your name and close over other peoples' money." Remember, these statements were made solely and alone because the youth smoked cigarettes. Here are a few more of Elbert Hubbard's statements as to the *moral* effect resulting from the use of tobacco, "A loss of moral and mental control." "The first indication of degradation is in the youth's secretiveness." "For the young man who has become so calloused that he smokes cigarettes in the presence of his mother, sister, or sweetheart, there is little hope." "The poison has already tainted his moral nature, and for him the work of dissolution, disintegration and degradation has begun. He is defective—a physical, mental and moral defective. Cigarettes stupefy the conscience, deaden the brain, place the affections in abeyance and bring the beast to the surface." According to a newspaper dated February 16, 1916, "The Reverend Dr. Sunday preached a sermon to fourteen thousand Trenton women advising girls not to marry cigarette smoking, cussing libertines." Why cussing libertines?

It would be unnecessary to regard such statements seriously except that so many "old women" of both sexes will believe anything they see in print and that agrees with their preconceived ideas. The following are a few of the objections that have been made as to the use of tobacco. In replying to these and answering questions, it has been suggested that I had no more right to an expression than others, as this is partially true. I have for the most part quoted those who were the best qualified to judge by observation, study and laboratory investigation. As to the moral effect, of course it is impossible to reply, for to those who regard cigarette smoking as an abominable sin as Elbert Hubbard has said, "a habit that leads to degradation, disintegration and dissolution" it is a matter of opinion and unanswerable, therefore I will have to confine my remarks as to use of tobacco to its physical effect alone.

Some years ago a pamphlet was given to the students in a grammar school in Baltimore, Md., stating "tobacco is a powerful narcotic containing a substance called nicotine, a single drop of which placed on a dog's tongue will soon kill him—an ordinary cigar contains enough nicotine to kill two men if taken pure." One of the best known chemists and teachers at Johns Hopkins University, Baltimore, Md., who stated he never smoked or tasted liquor in his life (notice this particularly, for surely

he is an unprejudiced judge) declared in the *Maryland Medical Journal*, March, 1906, "Here are three little sentences containing four big lies. Tobacco is not a narcotic. Nicotine will not kill a dog in the manner described and an ordinary cigar used in the ordinary way, containing its usual amount of nicotine, will not kill two flies." After this statement it is needless to say the pamphlet "Containing the four lies" was quickly suppressed.

We often hear the statement that cigarettes are adulterated with poisonous drugs yet Dr. H. W. Wiley, formerly Chief Chemist of the U. S. Agricultural Department, the man above all others opposed to adulteration in any form, has declared in print and to me personally "I have had tested ten samples of cigarettes purchased in the open market at different places and found them entirely free from arsenic, opium or any other drug." Professor Kennicott, of Chicago, and Dr. J. F. Babcock, professor of chemistry, Boston University, and other investigators have found the same results in their examinations of cigarettes. Then, too, it would surely be an absurd financial venture for a manufacturer to add sufficient drugs to the tobacco to have an appreciable effect upon the smoker for the cost of the adulteration would be many times that of the tobacco itself. "Is it not true that cigarette smokers always prefer certain brands; does this not prove there is something in the cigarettes besides tobacco?" There are many reasons for this preference. Manufacturers have certain blends known only to themselves, that is tobacco of certain age, grown in different parts of the world that have different flavors. These are mixed in different proportions, then at times such a substance as licorice (an entirely harmless ingredient) may be added to give the taste the smoker prefers. Here is an example, according to a magazine article. A certain manufacturer wished to give a rich "pound cake flavor" to his cigarettes; failing to obtain it himself, he consulted an expert chemist. Eventually he received a reply "I examined cigarettes that came fairly close to the ideal flavor wanted and found that licorice had been used after it had been made hot." This was the secret of the particular flavor desired.

Granting nicotine to be a violent poison, "Is it not dangerous to allow even the smallest quantity to enter the system?" This question

is of course absurd for there are many dangerous drugs prescribed by physicians for our health's sake. Even much of our daily food and drink contain deadly poisons. A very active poison can be extracted from potatoes and many other foods. Caffeine, the active principle of coffee, and theine, derived from tea when taken in large amounts, cause insomnia, palpitation, stomach troubles, and emaciation, yet there is no active crusade against the use of tea and coffee. Even the air we exhale contains an active poison, carbonic acid gas, but fortunately, when we take small quantities of drugs, use moderation in our eating, drinking and smoking, we do not absorb sufficient poison to harm us.

One of the most vicious and harmful statements about the use of tobacco is to compare it with the morphine habit. Elbert Hubbard declared: "The choice between cigarettes and daily doses of cocaine, morphine or bromide (sic) is very light."

Now let us suppose a youth easily stops the use of tobacco; he may have to consult a physician who gives him morphine to relieve severe pain, or use cocaine locally for some surgical operation. Finally, the boy may take either of these drugs himself. Believing implicitly in Hubbard's statement he is not afraid, for he has been told he could give up the drug as easily as he did cigarette smoking, but can he? Assuredly he can not. He could no more voluntarily abandon the use of morphine, after having become accustomed to it than he could stop breathing. Then the youth awakens declaring: "Those anti-cigarette fiends taught me I could give up one habit as easily as I could the other, now see my condition in believing such false statements." So Mr. Hubbard's statements are not only untrue but vicious, causing such a youth irreparable harm.

Here are several amusing statements, though made in all seriousness. A certain good man declared "I believe the advanced age of men mentioned in the Bible would not be so uncommon today but for the hot nicotine fumes with which so many now poison themselves." He means "hot air" of course, for heat destroys most of the nicotine tobacco contains.

It has also been said "Tobacco smoking causes great heat of the body, this gives rise to violent fever and causes the blood to rush to the roots of the hair and destroys them. This

is the reason we see so many bald heads among the men but notice women are not bald because they do not smoke." Don't they, indeed? Many ladies do smoke, and but for convention's sake there is no reason why they should not. Truth to say, there is absolutely no proof that smoking in moderation will harm one sex more than the other. The mere statement to the contrary is not proof. Suffragists particularly must agree if men may smoke without actual disgrace, surely women may do so for what is permissible for the gander should be allowable for the goose. Even elderly women smoke. According to an associated press report, "At a poor farm in Minnesota, provision is made for a smoking room for the old women who all their lives have been accustomed to their pipe." Let us hope these old ladies have continued to enjoy their pipe in peace without the interference of so-called reformers and mollycoddles of both sexes, or pestiferous legislation. According to another newspaper statement in Washington, Indiana, a Mrs. Denny celebrated her hundredth birthday in July, 1917. She states that she has walked without a cane, does not wear glasses, traveled over twelve states, usually behind a team of oxen, and has used tobacco since she was sixteen years of age, declaring "the use of tobacco has kept me alive."

A friend now over eighty years of age, with an erect figure, a complexion any young girl might envy, not the slightest manifestation of nervousness in any form, as active as a man of forty, who made a second marriage after he was seventy years of age, and is supremely happy and contented, has daily smoked strong cigars since early youth.

An acquaintance wishing to prove the enormous amount of nicotine contained in cigarette smoke had me slowly blow it through a handkerchief. A yellow stain was left on the linen; of course this was simply the coloring matter in the tobacco. If it had been nicotine, one breath of a cigarette would have caused death. Then, too, nicotine is not yellow, but is an almost colorless liquid. This person also declared clergymen and physicians seldom used the weed. It has been my privilege to be intimately acquainted with many clergymen; and in the privacy of their homes and in the clubs, those who smoke average about as many as men in other walks of life. Of course they do not indulge in this pleasure before their women parishioners or upon the streets. Con-

vention prevents this. Having practiced medicine for thirty years, knowing many hundreds of physicians in different cities, I state three-fourths of all practitioners of medicine use tobacco in some form, many of them smoking cigarettes exclusively. Such a large proportion use tobacco because the vast majority of the medical profession believe that smoking in moderation never causes any ill effects. The *London Lancet*, recognized as the most authoritative medical journal in the world, after thoroughly investigating the results of the use of tobacco, declared: "Cigarette smoking is the least injurious form of tobacco in use."

Professor Bain, in his interesting pamphlet on the use of tobacco, declares science is almost unanimous as stamping the cigarette as "a form of tobacco, in the use of which ill or undesirable effects upon the body or mind, are practically nil."

In my individual experience, about twenty-five years ago I believed I was suffering from a condition popularly known as "Tobacco heart" resulting from smoking cigarettes. I consulted the best known, best informed diagnosticians in the country, Dr. DaCosta of Philadelphia, and the elder Dr. Loomis of New York City, who informed me I had no serious trouble of the heart, that probably the symptoms of which I complained were brought on by the excessive drinking of coffee. Dr. Loomis advised me to continue my smoking, stop the coffee, and report to him in a month. In the meantime, all disagreeable symptoms had disappeared, though I had continued to smoke twelve to fifteen cigarettes a day, and so have continued for the last thirty years, with no return of the "heart trouble" but, if I drink a cup of black coffee, in a short time I have a disagreeable sensation about the heart. In other words, the majority of those who believe they have a condition known as "tobacco heart" are really suffering from the effects of coffee. Dr. Loomis also said: "I consider the cigarette the least harmful use of tobacco. One is poisoned by the use of tobacco, if ever, by the amount of nicotine his system absorbs; he will get more of this by chewing, than from a pipe, next a good cigar, finally from cigarettes, even plus inhaling."

Cigarettes are said to harm the throat and the voice. If this is true, is it conceivable that the greatest opera singers in the world habitually smoke? Caruso is said to have

smoked many cigarettes a day, even between the acts. Would this great tenor, receiving the enormous salary he did, have run the risk of harming his voice by indulging in cigarette smoking, unless he knew by years of experience that they did him no harm? This is not alone applicable to Caruso, for it is well known that the majority of those who are famed for their voices on the operatic stage smoke cigarettes, many women as well as men.

Another tobacco smoker states: "I have been told even by physicians that the use of tobacco leads to organic diseases of the heart and lungs, and causes cancer, and even death may result from its use." I doubt if any regular practitioner of medicine would make such a statement before a medical association as to death being directly caused by smoking. No board of health would accept such a statement. It has been found that even direct applications of nicotine to the heart itself do not affect its pulsation.

The false statement has been made and reiterated that the use of tobacco leads to mental troubles, even to insanity. Professor John Bain, Jr., in his excellent treatise entitled "Cigarettes in Fact and Fancy" declares that "The Medico-Legal Society of New York sent inquiries to the superintendents of insane asylums in this country and abroad, as to the possible relationship between cigarette smoking and insanity. Several hundred replies were received. Every one, without exception, declared that not a case of mental disturbance had ever been traced to the use of tobacco in any form."

Professor C. E. Nammalk, M. D., LL. D., physician to Bellevue and St. Vincent Hospitals, New York City, says: "I am convinced that moderation in the use of tobacco is not attended by any of the dangers which fanatics ascribe to its use."

Dr. Wm. B. Fletcher, in a scholarly paper on the use of tobacco, read at the Mississippi Valley Medical Association, held in Indianapolis, 1905, declares "In the last twenty-two years I have examined over twelve hundred cases brought to the General Hospital for the Insane, and in my private practice where the cause of the malady was given as 'the cigarette habit.' In not a single case have I reason to believe that tobacco had anything to do with the disease."

Finally, if those who condemn the use of

tobacco would only try a smoke, would fill and light their pipes and take their ease, we would hear less complaint from them, for then surely they would appreciate the words: "The pipe draws wisdom from the lips of philosophers and shuts the mouths of the foolish." Ye who condemn tobacco put this in your pipes and smoke it, remembering Carlyle's advice: "Tobacco should be an incentive to silence, not to speak a word more than one has got to say." I light my pipe, gaze upon the glowing logs, and dream, sincerely hoping that anti-tobacco zealots may soon learn the error of their ways and be more charitably disposed towards those they have so strenuously condemned.

1311 K Street, Northwest.

### PELVIC STONE, WITHOUT SYMPTOMS, WITH COMPLETE RENAL DESTRUCTION.\*

By W. T. GAY, M. D., Suffolk, Va.  
Junior Surgeon and Urologist to Lakeview Hospital.

We are more or less familiar with the majority of typical cases of pelvic stone, and while we are ever on the alert to find some improvement in the method of diagnosis and treatment of the typical case, we owe it to ourselves and to the patient to spend much time and thought with the atypical—the case which presents only a few or very indefinite symptoms. With this thought in view, I will give below a more or less detailed report of a case falling in this category, with the hope that it will be of some practical benefit when similar cases are encountered.

The subject of the paper is a little misleading, because there were symptoms, but symptoms which pointed away from the real pathology rather than to it. With the history and symptoms that the patient gave, and being in the class of the fair, fat, and forty, it was quite natural to try to make her have a diseased gall-bladder; but such was not the findings, as we will see below.

Case No. 3296. A white, married, female patient, age fifty-three, was admitted to Lakeview Hospital on March 15, 1922, complaining of discomfort in right abdomen, with marked weakness and fever.

*Family History.*—One sister died at the age of 55, from cancer of the breast. One sister now living has tuberculosis.

*Past History.*—She had the usual diseases of

\*Read before Southside Virginia Medical Society at South Hill, Virginia, December 12, 1922.

childhood, and attacks of rheumatism, bronchitis, some digestive disturbance characterized by gas, belching and bloating. Married thirty-one years—two children living and healthy. Miscarriages fourteen. Menopause three years ago.

*Genito-Urinary History.*—Had never at any time in life had any urinary disturbances, kidney colic or pain in kidney region.

*History of Present Illness.*—For the past four years she noticed at frequent intervals a slight discomfort in right abdomen anteriorly. Recently there has been some soreness in right lumbar region, extending across crest of ilium and deep down in right abdomen anteriorly. For the past several months has noticed a marked weakness and fatigue coming on after slight exertion. For the past month has been having fever daily, ranging from 99 to 101. Two days before admission, developed a severe cold, with temperature 102, cough and soreness in chest.

*Physical Examination.* — Showed a very corpulent woman weighing 220 pounds, which is her average normal weight. Skin very pale, dry and rough. Cheeks flushed. Heart sounds very distant with a soft systolic murmur at apex, not transmitted. Blood pressure—diastolic 85, systolic 150. Definitely diseased tonsils. Lungs showed a few scattered rales over the upper right chest. Slight tenderness in right abdomen just external to G. B. region. Slight tenderness on deep pressure in lower part of right lumbar region, otherwise the examination was negative.

On day of admission she gave a turbid urine, specific gravity 1016, acid reaction, much albumin and pus, R. B. C. 5,012,000, W. B. C. 14,400, Polys 70, Lymphs 30, HB. 65.

*X-ray Examination.*—Showed a stone about one-half inch in diameter opposite the third lumbar vertebra and two inches from mid-line.

*Cystoscopic Examination.*—Bladder mucosa normal. Urine in the bladder turbid and full of flakes and shreds. Left ureteral orifice normal in size, position, and appearance; catheter passed without obstruction. Urine excreted with normal rhythm and frequency, P. S. P. time six minutes, forty per cent eliminated in two hours. Considerable pus from left side. Right orifice contracted, catheter met obstruction in pelvic portion, which obstruction could not be passed by catheter. No urine coming from this side. One week later cystoscopic and X-ray examinations gave the same results.

Being a poor surgical risk and having considerable pus coming from the left kidney, operation was delayed with the hope of bettering her condition. However, in spite of all palliative treatment, she continued to run a septic temperature, ranging from normal to 102°, with a gradual rise in the leucocyte count. At the end of three weeks pain in the lumbar region became slightly more marked and you could now palpate a mass low down in this region. The leucocyte count went up to 18,800 and the patient showed marked signs of growing worse, so it was decided best to drain this mass under local anesthesia. A thick, creamy pus was liberated from a honeycombed abscess, the origin of which was not determined.

Improvement was immediate and rapid; at the end of three weeks her general condition was markedly improved. T. P. R. normal; P. S. P. elimination seventy per cent; urine practically free of pus, but the sinus leading to abscess cavity continued to discharge much pus.

On cystoscopic examination the ureteral catheter now easily passed the right ureter to the kidney pelvis. Still no urine came from this side. A pyelogram was made, 45 c.c. of fifteen per cent sodium bromide solution being run into the right pelvis without any discomfort to the patient. The X-ray plate showed the left ureter to be in a normal position, while the right passed markedly to the right with a wide curve outward then turning inward terminating about two inches lateral to the level of the third lumbar vertebra. The opaque solution showed a contracted and low pelvis with rounding of the calices and pocketing. The shadow then extended downward and outward where it took on a narrow linear appearance for about two inches when it again ballooned out as a large irregular cavity corresponding with the position of the previously drained abscess.

One week later a right nephrectomy was done. In the lumbar region on a level with the crest of the ilium was found a mass of fatty and connective tissue, oval in shape and one-half size of a normal kidney. The only structure remaining that could possibly be recognized as kidney substance, was an ill-defined poorly developed kidney pelvis which contained one stone 2.5x1.5 cm. Above and entirely separate from the first mass was a second which was about half the size of the first. This, the remains of the suprarenal, was

soft and slightly cystic. Microscopic sections showed an occasional cell resembling lining cells of kidney tubules, otherwise there was an entire absence of tissue resembling kidney. The second mass showed scattered areas of fairly normal adrenal structure. There was no evidence of tuberculosis or malignancy in either section.

The patient made a good post-operative recovery with a rapid and complete healing of the wound. Tonsillectomy was performed three days before discharge. When last seen, four months after discharge, she was entirely free of symptoms, urine negative, and had regained her normal weight.

#### CONCLUSIONS.

The failure of the catheter to pass right ureter on the first examination was due to the pressure of the lumbar abscess with distortion of the ureter.

The development of the abscess was what forced the patient to seek relief. This abscess, which was very slow of development, was secondary to the infected and functionless kidney which no doubt extended over a period of years and had been neglected because attention had not been directed to the urinary tract.

There was a large stone (2.5x1.5 cm.) in pelvis of kidney which had never given rise to any kidney colic. It is possible this may have developed after the kidney ceased to function.

There was an entire absence of any urinary disturbance at any time during the life of the patient. We get the first knowledge of her true condition when we examine the record of urinalysis and find the urine loaded with pus and albumin.

Anyone of us can make the simple urinary tests and, if made as a more routine part of our everyday practice, it would often lead to an early diagnosis or point out the direction in which we must investigate in order to make a diagnosis that will enable us to offer some hope of relief before the damage is beyond repair.

---

#### ALL LIT UP.

A little girl, brushing her hair, found that it "cracked," and asked her mother why it did.

"Why, dear, you have electricity in your hair," explained the mother.

"Isn't that funny?" commented the little one. "I have electricity in my hair, and grandmother has gas in her stomach."—*Exchange*.

## Analyses, Selections, Etc.

### SCIATIC HERNIA.

#### A Report of a Case of Hernia of Meckel's Diverticulum Through the Greater Sciatic Foramen.

By JOHN W. BRODNAX, M. D., Richmond, Va.

Associate Professor of Anatomy, Medical College of Virginia.

Of all forms of hernia the sciatic type is one of the rarest, or, at least, it would appear so, if the number of recorded cases can be taken as an index to the frequency of their occurrence. A careful search of the literature on this subject reveals the fact that less than thirty cases have been reported up to the present time, and of these only one has been contributed by an American surgeon. It is to Dr. John Edward Summers<sup>1</sup> of the University of Nebraska that credit is due as the first surgeon in this country to report a case of sciatic hernia. In a very excellent paper on this subject, read before the Western Surgical Association, December 9, 1921, Dr. Summers describes a case of sciatic hernia complicated with myxomatous tumor of the scrotum. This case, as far as available literature at my disposal is concerned, constitutes the only one recorded in this country. Possibly other cases have been reported. If so, I have been unable to find any mention of them.

In sciatic hernia the intestine, or whatever structure it might be, for it may contain any viscus or organ sufficiently movable to reach and pass out of the pelvic cavity, escapes through either the greater or lesser sciatic foramen. This part of the pelvic wall presents three weak spots and, anatomically, it is possible for hernia to take place through any of these places. The greater sciatic foramen is filled-in by the pyriformis muscle which has a small slit-like cellular interval, both at its upper and lower borders. Hernia may occur through either of these intervals, or it may pass through the lesser sciatic notch, which represents the third weak spot. After passing out of the pelvic cavity it presses beneath the gluteus maximus muscle and, if small, may remain under cover of that muscle and escape detection, or it may reach such proportions as to form in the gluteal fold a well marked tumor. "In all cases through whichever opening the hernia passes it must always have the sacrotuberous ligament below it." This is an

important point in differentiating sciatic hernia from a perineal hernia. In the latter, the sacrotuberous ligament, which is easily felt, lies above the hernial opening. Garre<sup>2</sup> likens the sacrotuberous ligament in this respect to the inguinal ligament in distinguishing between inguinal and femoral hernia.

Probably chiefly on account of the rarity of sciatic hernia, comparatively little is known of its etiology. One case reported in 1873 by Crossle<sup>3</sup> is of particular interest in as much as it gives a clear history of the cause. This case occurred in a woman who, while in the act of lifting a heavy iron plow into a cart, became suddenly conscious that something had given way in a situation deeply seated, where she later discovered a small tumor about the size of a pigeon's egg, situated on the margin of the gluteal fold on the same side. This tumor gradually increased in size until, when it was examined by Crossle, it had reached the size of a foetal head "at term."

Of the recorded cases two-thirds of them were in females. The greater frequency in

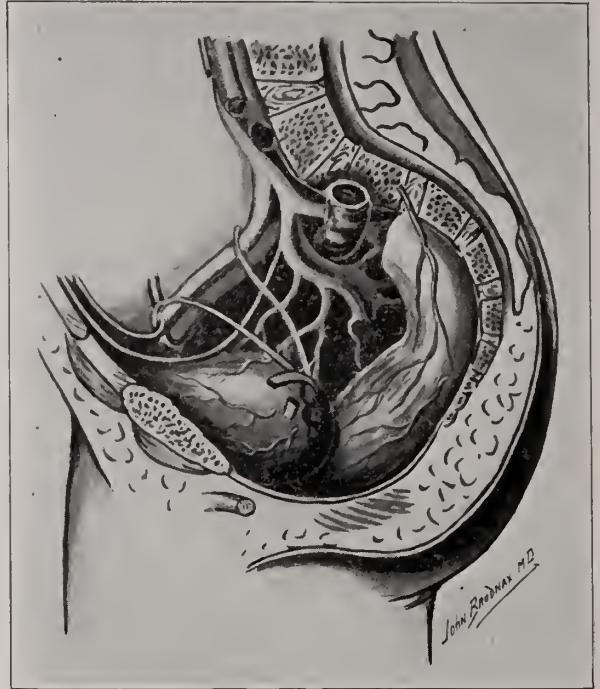

Fig. 2. Sciatic hernia as seen from the exterior of the pelvis.

that sex may be accounted for by the fact that the sciatic foramina are slightly larger and the sacrotuberous ligaments longer and more lax in females than in males. Doubtless, also, the ill effects of pressure and trauma attendant on labor predispose women to this form of hernia. "Sciatic hernia occurs more frequently on the right side than on the left, having been observed on that side ten times out of fourteen cases. M. Koppl has noted nine cases of strangulation out of the twenty-six cases published in the literature."

Although Sir Astley Cooper<sup>4</sup> is generally credited with having reported the first case of sciatic hernia in 1800, the literature shows that fifty years earlier, in 1750, a German physician of the name of Papien describes a case which came under his observation, in a letter addressed to the Swiss physiologist, Haller.

The case which I report tonight came under my observation in the dissecting hall of the Medical College of Virginia in 1922, and consequently nothing of the personal history of the individual is known. The subject was a negro convict, nineteen years of age, who came to his death by a gunshot wound of the chest, received while he was attempting to escape from the convict road force in one of the counties of the State.

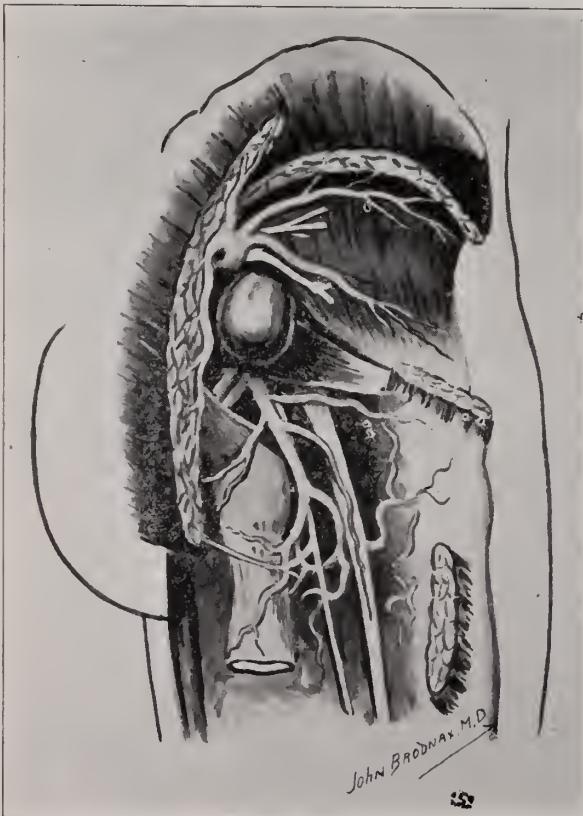

Fig. 1. Sciatic hernia as seen from the interior of the pelvis.

Not anticipating any abnormal condition in the pelvis, the contained viscera had been much disturbed before the hernia was discovered. I noticed, however, an unusual quantity of small intestine in the pelvic cavity, which at first appeared to be bound down by adhesions, but a more careful examination showed the anchorage to be due to a herniated Meckel's diverticulum through the greater sciatic foramen. The diverticulum, which was about 10 centimeters in length, was attached to the ileum about two feet from the ileo-caecal valve. At its point of origin the ileum was slight-narrowed and markedly kinked. The gut passed out through an opening about 15 millimeters in diameter above the pyriformis muscle and in front of the superior gluteal vessels and nerve, and ended in a globular tumor about the size of a hen's egg, which rested upon the dorsal surface of the pyriformis entirely under cover of the gluteus maximus muscle. There was no visible surface enlargement and, in all probability, the individual was never aware that such a condition existed. I show

two drawings of this case which give you a better idea of the character of the hernia than a written description. The other drawing is a copy of the illustration of the Crossle case, which was published in the reports of the Dublin Pathological Society in 1873, and which has been frequently used in text books since that time as an illustration of sciatic hernia.

As previously stated, Dr. Summers' case, as far as I have been able to ascertain, is the only case up to this time that has been reported in America, and the one I report tonight stands second, with the unique feature of being the first recorded case of sciatic hernia where Meckel's diverticulum formed the herniated mass.

## Correspondence.

### Effect of Freezing on Toxin-Antitoxin Mixture.

February, 1924.

TO THE EDITOR:

There appeared recently in some of the daily papers of Virginia a news item in regard to the occurrence of twenty cases of illness in Concord, Massachusetts, following treatment with toxin-antitoxin. Inquiries were at once instituted to ascertain from the Department of Public Health of Massachusetts the circumstances attending these cases of illness. The pertinent portions of the reply from the Massachusetts authorities were as follows:

"Our first report of reactions came from the Concord Board of Health. Upon receipt of this report which stated that severe reactions had been observed in a small group of school children following immunizations with toxin-antitoxin, an immediate investigation was made to determine if possible the source of the trouble. This investigation brought out the fact that the toxin-antitoxin which was used on Wednesday of last week had become frozen during the extreme cold of the preceding Saturday and Sunday. A similar experience

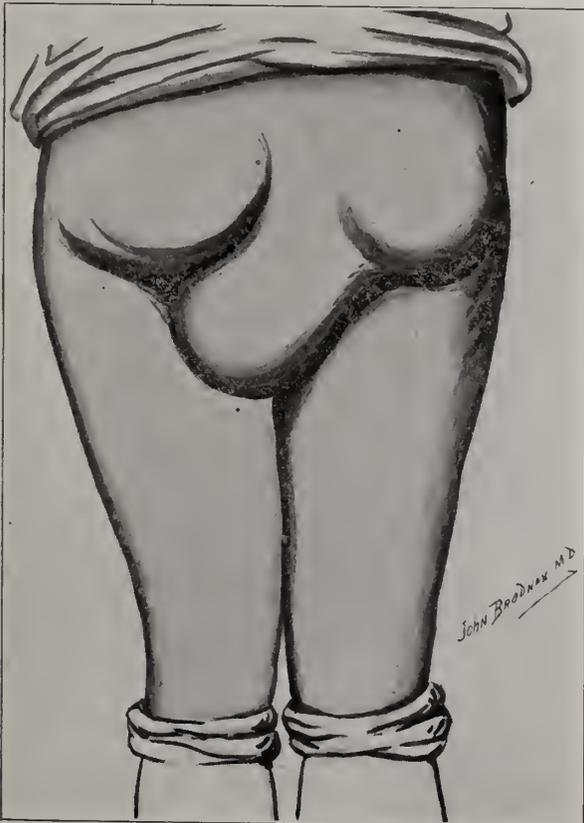

Fig. 3. Drawing of case of sciatic hernia reported by Crossle.

has been reported from Bridgewater where twenty severe reactions followed the injection of some frozen material, and one case each has also been reported from Holyoke and Boston.

"The lots of toxin-antitoxin mixture in question had satisfactorily passed all laboratory tests and had been tested and approved by the Federal Government, and with thousands of doses of these lots which had been given throughout the State the only reactions occurred with the material which was known to have been frozen after delivery.

"A member of the staff of the United States Hygienic Laboratory has been asked to make a complete investigation of the matter, and Dr. William Park, Dr. Bela Schick, Dr. M. J. Rosenau, Dr. Hans Zinsser and Dr. Edwin H. Place have been called in consultation in order that everything possible might be done for the patients.

"Experiments already carried out at the State Antitoxin and Vaccine Laboratory show that the reserve stocks of the particular lots used are still entirely satisfactory in every way, but that freezing alters this product, causing it to develop a toxicity which it did not originally possess.

"All toxin-antitoxin which had been distributed previous to or during the recent extreme cold spell has been recalled and all boards of health in the State have been requested to notify physicians of the possible danger attending the use of any product that might have been frozen, with the request that they also return to the laboratory any of this material now in their possession."

Toxin-antitoxin is now being administered to 2,000 or more children a month in the State of Virginia and it is very important that the experience of the Massachusetts Department of Public Health should be borne in mind. There is very little danger of the mixture freezing in transit through the mails in Virginia, but instances have already occurred where the material was allowed to freeze after the package had been opened and a portion of it had been used. In the interest of safety such material must be discarded.

The most satisfactory results will be obtained if toxin-antitoxin and similar biological products are kept in a refrigerator. This precaution will avoid deterioration by warmth or by extreme cold.

GEORGE C. PAYNE, M. D.,

*Epidemiologist, Va. State Board of Health.*

## The Truth About Medicine

In addition to the articles enumerated in our letter of December 29, 1923, the following have been accepted:

### Abbott Laboratories:

Potassium Bismuth Tartrate—D. R. L.

Ampules Potassium Bismuth Tartrate with Butyn—D. R. L., 0.1 Gm.

Ampules Potassium Bismuth Tartrate with Butyn—D. R. L., 0.2 Gm.

### Britt, Loeffler and Weil:

Loefflund's Malt Soup Stock (Dr. Keller's Formula).

### Hynson, Wescott and Dunning:

Flumerin—H. W. and D.

### Lederle Antitoxin Laboratories:

Corpus Luteum—Lederle.

Corpus Luteum Extract—Lederle.

Ovarian Residue—Lederle.

1 Per Cent. Silver Nitrate Solution—Lederle.

Whole Ovary—Lederle.

### Parke, Davis and Co.:

Ergot Aseptic

Ampules Ergot Aseptic 1 Cc.

### Scarlet Red Sulphonate—P. D. and Co.

Scarlet Red Emulsion, 4 per cent.—P. D. and Co.

Scarlet Red Ointment, 5 per cent.—P. D. and Co.

Scarlet Red Ointment, 10 per cent.—P. D. and Co.

### NEW AND NON-OFFICIAL REMEDIES.

Potassium Bismuth Tartrate—D. R. L.—A basic potassium bismuth tartrate containing from 64 to 69 per cent of bismuth. For a discussion of the actions and uses, see Bismuth Preparations in the Treatment of Syphilis (Journal A. M. A., August 25, 1923, p. 661). Potassium bismuth tartrate—D. R. L. is supplied only in the following forms: Ampules potassium bismuth tartrate with butyn—D. R. L., 0.1 Gm. (containing potassium bismuth tartrate—D. R. L., 0.1 Gm. suspended in 2 Cc. of a 0.6 per cent. solution of butyn in a fixed oil); Ampules potassium bismuth tartrate with butyn—D. R. L., 0.2 Gm. (containing potassium bismuth tartrate—D. R. L., 0.2 Gm. suspended in 2 Cc. of a 0.6 per cent. solution of butyn in a fixed oil). The product is administered intramuscularly. The Abbott Laboratories, Chicago.

Scarlet Red Sulphonate.—The sodium salt of azobenzene-disulphonic-acid-azobetanaphthol. The actions and uses of scarlet red sulphonate are essentially the same as those of scarlet R medicinal Biebrich (see New and Non-official Remedies, 1923, p. 275). It is marketed only in the following forms: Scarlet red emulsion, 4 per cent.—P. D. and Co., Scarlet red ointment, 5 per cent.—P. D. and Co., Scarlet red ointment, 16 per cent.—P. D. and Co. Parke, Davis and Co., Detroit. (Journal A. M. A., January 19, 1924, p. 269).

Ergot Aseptic.—A liquid extract of ergot containing the soluble constituents of the drug. It is standardized biologically so that 1 Cc. represents 2 Gm. of ergot. The actions and uses of ergot aseptic are the same as those of ergot. The dose is 1 to 2 Cc. injected intramuscularly. Ergot aseptic is marketed only in 1 Cc. ampules. Parke, Davis and Co., Detroit.

Loefflund's malt soup stock (Dr. Keller's formula).

—A preparation essentially similar to extract of malt U. S. P., but containing a small amount of potassium carbonate. Loefflund's malt soup stock is designed for use in preparing the malt soup of Dr. Keller. Britt, Loeffler and Weil, New York. (*Journal A. M. A.*, January 26, 1924, p. 303).

#### PROPAGANDA FOR REFORM.

**Intarvin.**—Because of numerous inquiries, the Council on Pharmacy and Chemistry publishes a preliminary report on Intarvin. The product is marketed by the Intarvin Company, Long Island City, N. Y. Dr. Max Kahn has applied for a patent on it. Many statements have been given the lay press by those interested in the promotion of Intarvin, but as yet no publication has appeared in the medical press, except preliminary reports by Kahn. Intarvin is proposed for use in diabetes or in conditions where acidosis occurs. It is a synthetic fat which, it is claimed, can be assimilated by the diabetic without the production of products that cause acidosis, as is the case with ordinary fats when these are consumed by diabetics. Intarvin is stated to be the glyceryl ester of margaric acid admixed with ten to twelve per cent of liquid petrolatum. While the usefulness of Intarvin is curtailed by the discovery of insulin, it should be valuable in planning a diabetic diet if the claims made for it are substantiated. Intarvin is still in the experimental stage and it is unfortunate that so much newspaper notoriety has been given it. Until acceptable evidence is available for its usefulness, palatability and practicability, judgment of its worth must be suspended. (*Journal A. M. A.*, January 5, 1924, p. 51).

**Chemical Foundation Wins.**—During the late war, our government seized many German patents on synthetic drugs. Later the Alien Property Custodian, on executive order of President Wilson, sold 4,700 German chemical patents to the Chemical Foundation, Inc. This corporation agreed in turn to license any American firm that could present evidence of reliability in chemical manufacture to manufacture under these patents. As a result of this action, physicians may today obtain different brands of arsphenamin instead of one proprietary "Salvarsan"—and at competitive prices. The same is true of other useful synthetics. About a year and a half ago, President Harding instructed the Alien Property Custodian to take steps to secure the return of all patents sold to the Chemical Foundation, Inc., on the ground that the price paid was inadequate and the transaction illegal. Suit was instituted by the government against the Chemical Foundation, Inc., for the recovery of the patents. The suit was won by the Chemical Foundation, Inc. In the decision of the court, it was held that the price was adequate, for the reason that many of the patents were nonworkable and that, therefore, because of the financial risk and hazard, the value of the patents "was too slight and problematical to warrant the payment by American citizens of a sum even remotely approximating what they might have been worth to the German owners for their monopolistic purposes." Hence, the bill of complaints filed by the government was set aside. (*Journal A. M. A.*, January 12, 1924, p. 130).

**The Action of Salicylates, Cinchophen, Neocinchophen and Related Products.**—The latest (1923) edition of *Useful Drugs* speaks of the salicylates, cinchophen, neocinchophen and related drugs as "highly efficacious" and "exceptionally efficient" in the management of certain phases of arthritis. The assumption that the drugs exert an etiotropic action

by destroying bacterial agencies responsible for the disease has repeatedly been disproved. They do not function as germicides, for example, in rheumatic fever assumed to be caused by micro-organisms. Recently, Hanzlik and Painter compared the anti-phlogistic effect of salicylates, cinchophen and neocinchophen in experimental edema of head and neck. They concluded that the so-called antiphlogistic action of these drugs as exemplified in the prompt amelioration of objective signs of inflammation, including the swelling and edema of the joints, is not due to a direct action on the inflammatory process. Experimental edema of the head and neck in animals was not beneficially influenced by previous and simultaneous treatment of the animals with sodium salicylate, cinchophen or neocinchophen. Negative results with respect to antiphlogistic effects have also been observed in the treatment of other kinds of edema. Consequently it is concluded that the beneficial effects of these drugs in rheumatic fever appear to be produced neither through etiotropic nor organotropic, but rather through symptomatic action, the benefits being mediated through antipyresis and analgesia. (*Journal A. M. A.*, January 19, 1924, p. 213).

**Diphtheria Antitoxin for the Infant.**—In the presence of diphtheria, no age is a contraindication to the administration of antitoxin. The dose for infants of from ten to thirty pounds and under two years of age, has been given as from 2,000 to 10,000 units. The immunity to diphtheria in young infants seems to depend on antitoxin received from the mother through the placental circulation. This immunity is possessed by more than 90 per cent of children in the early weeks of life, but at the end of a year this has been lost by about half of them. Serums are well borne by young children, as they have little sensitiveness to foreign proteins. A suitable immunizing dose of diphtheria antitoxin for an infant would be from 200 to 500 units, and the therapeutic dose from 2,000 to 10,000 units. (*Journal A. M. A.*, January 19, 1924, p. 228).

**Dermatosis From Fur.**—Reports have been published of persons who have suffered severe eruptions and irritations of the skin following the wearing of furs. Investigation has shown that these disturbances are caused by paraphenyldiamin, which is used to dye furs black and by quinone, an oxidation product of paraphenyldiamin, which gives a brown color. The untoward effects may be prevented largely by extreme care in the finishing and dyeing processes with special attention to remove all excess dye, and particularly traces of quinone from the fur. (*Journal A. M. A.*, January 26, 1924, p. 307).

**Effects of Bromids on Epilepsy.**—The harmful effects of the prolonged administration of bromids, aside from the skin and intestinal effects, are gradually increasing dullness, heaviness, torpor, stupidity, with greater self-centering of interests and unintelligence. The size of the dose that is necessary to control the fits is probably an important factor in determining the amount of damage that will be done. (*Journal A. M. A.*, January 26, 1924, p. 325).

## Book Announcements

**Pediatrics.** By Various Authors. Edited by ISAAC A. ABT, M. D., Professor of Diseases of Children, Northwestern University Medical School, Chicago. In eight octavo volumes, totaling 8,000 pages, with 1,500 illustrations, and separate Desk Index volume free. Now ready, VOLUME I, containing 1,240 pages with 284 illustrations, and VOLUME II, containing 1,025 pages with 180 illustrations. Philadelphia and London. W. B. Saunders Company. 1923. Cloth, \$10.00 per volume. Sold by subscription.

After the lapse of nearly ten years since preparations for Abt's pediatrics were begun, the first two volumes have come from the press. As stated in the preface, this system of pediatrics is a collection of monographic treatises on subjects of interest in the diseases of infancy and childhood. The authors are from every section of the United States, and are all men of eminence, who have made valuable contributions to the literature of the subjects on which they have written in this system.

Volume I begins with a concise history of the "Encyclopedias Which Refer to the Diseases of Children," by Dr. Abt. Following this is a "History of Pediatrics," by Fielding H. Garrison. In this very scholarly and interesting treatise Dr. Garrison traces the progress of pediatrics from the earliest times down to the present day. The subject is handled in a very fascinating manner.

"Congenital and Acquired Predisposition and Heredity," by Clarence C. Little, is based largely on experimental investigations and, though rather technical, should be of considerable interest even to the general reader.

"The Anatomy of the Infant and Child," by Richard E. Scammon, is well illustrated and a valuable article for reference purposes. The subject of "Growth and Development" by T. Brailsford Robertson is well handled.

"Physiology of Metabolism in Infancy and Childhood" is treated in a very thorough manner by John R. Murlin. A very brief discussion of the "Application of Physical Chemistry to the Physiology of Childhood" is given by Jesse F. McClendon. "Hygiene of the School Age," by Josephine E. Young, is a very complete and excellent treatise in which is discussed every phase of the child's activities as related to health. It contains much practical matter that will be of especial interest to the practicing physician.

"Hygiene of the Home" and "Hygiene of Infants in General," by Walter Reeve Ramsey, are brief but practical discussions.

"Climatotherapy," by F. L. Wakeham, contains a climatic description of a number of health resorts, and a too brief discussion of treatment by this agency.

"Hygiene of Crippled Children" is considered in a very short article by H. Winnett Orr.

For the practitioner, Volume II will probably be of more interest than Volume I. Space does not permit a complete list of the subjects discussed. Of particular interest is the illuminating article on "Mortalities of Infancy" by Richard A. Bolt. "Peculiarities of Disease in Childhood," by John Diven, and "Prophylaxis and Treatment" by E. R. Debuys deserve special mention for their excellence. There are valuable articles on "Diseases of the Newborn" by N. O. Pearce and on "Premature Infants" by Julius H. Hess.

The articles on infant feeding, deficiency diseases, metabolic disorders and related subjects are given considerable space and are of a very practical nature.

For a work of this character there is remarkably little repetition.

Though here and there are statements with which some pediatricians will take issue, these two volumes of Dr. Abt's system are of an unusually high calibre and should be in the library of every doctor particularly interested in child welfare. It is hoped that the volumes yet to be published will be up to the high standard set by these two.

J. B. STONE, M. D.

**Management of the Sick Infant.** By LANGLEY PORTER, M. D., M. R. C. S. (Eng.), L. R. C. P. (Lond.), Professor of Clinical Pediatrics, University of California Medical School, etc., and WILLIAM E. CARTER, M. D., Assistant in Pediatrics and Chief of Out Patient Department, University of California Medical School. Second Revised Edition. Illustrated. St. Louis, C. V. Mosby Company. 1924. 8vo. 659 pages. Illustrated. Cloth, \$8.50.

**Practical Chemical Analysis of Blood.** A Book Designed as a Brief Survey of this Subject for Physicians and Laboratory Workers. By VICTOR CARYL MYERS, M. A., Ph.D., Professor and Director of the Department of Biochemistry, New York Post-Graduate Medical School and Hospital. Second Revised Edition. Illustrated. St. Louis, C. V. Mosby Company. 1924. 8vo. 232 pages. Cloth, \$4.50.

**Geriatrics.** A Treatise on the Prevention and Treatment of Diseases of Old Age and the Care of the Aged. By MALFORD W. THEWLIS, M. D., Editor, Medical Review of Reviews; Associate Editor, The Therapeutic and Dietetic Age. With introductions by A. JACOBI, M. D., LL.D., and I. L. NASCHER, M. D., Second Edition, Revised and Enlarged. St. Louis. C. V. Mosby Company. 1924. 8vo. 401 pages. Cloth, \$4.50.

**Selected Essays on Orthopedic Surgery.** From the Writings of NEWTON MELMAN SHAFFER M. D., Emeritus Professor of Orthopedic Surgery, Cornell University Medical College; Consulting Orthopedic Surgeon, St. Luke's Hospital, New York, and to the N. Y. State Orthopedic Hospital for Children, West Haverstraw, etc. With forewords by DR. LOVETT and DR. FISHER, and comments by DR. COTTON, DR. NUTT, DR. BLADGEN, and MR. HARDON. Illustrated. G. P. Putnam's Sons. New York and London. The Knickerbocker Press. 1923. 8vo. 636 pages. Cloth, \$5.00.

**An Outline of Radium and its Emanations.** A Complete Handbook for the Medical Profession. Published by National Radium Products Company, under the direction of VYNNE BORLAND, M.B., Ch.B., B.Sc., Glasgow, Director, Medical Consulting Department. The object of the book is to tell something about Internal Radium Therapy. Paper. 33 pages. Price, \$1.00.

**Beginning Again at Ararat.** By MABEL EVELYN ELLIOTT, M. D., Medical Director of Near East Relief. With Introduction by JOHN H. FINLEY. Illustrated. New York, Chicago, London and Edinburgh. Fleming H. Revell Company. 1924. 340 pages. Cloth, \$2.00 net.

**International Clinics.** A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on the Treatment of Medicine, Surgery, Neurology, Pediatrics, Obstetrics, Gynecology, Orthopedics, Pathology, Dermatology, Ophthalmology, Otology, Rhinology, Laryngology, Hygiene, and other topics of interest to students and practitioners. By Leading Members of the Medical Profession throughout the World. Edited by HENRY W. CATTELL, M. D., Philadelphia, Pa., with the collaboration of fifteen eminent physicians and surgeons. Volume IV. Third-third Series, 1923. Philadelphia and London J. B. Lippincott Company. 1923. 308 pages, with a number of illustrations. Cloth.

**Genitourinary Diseases and Syphilis.** By HENRY H. MORTON, M. D., F. A. C. S., Professor of Genitourinary Diseases and Syphilis in the Long Island College Hospital; formerly members of the Committee on Venereal Diseases in the Office of the Surgeon General, etc. Fifth edition, revised and enlarged, with 328 illustrations and 38 full page colored plates. New York. Physicians and Surgeons Book Company. 353 West 59th Street. 1924. 712 pages. Cloth, price \$10.00.

**A Physician's Manual of Vaccine Therapy.** By G. H. SHERMAN, M. D. Press of the Bacteriological Laboratories, G. H. Sherman, M. D., Detroit. 160 pages. This manual gives in concise, comprehensive manner data pertinent to the application of bacteriological vaccine therapy in the prophylaxis and treatment of infectious disease.

## Awards from the Benjamin Franklin Fund.

Benjamin Franklin spent much time in England from 1757 to 1762 representing the American colonies. While there he placed one hundred pounds in the hands of members of the society of friends as a trust, to be invested with accumulations, for not less than one hundred and fifty years. Thereafter at the discretion of the trustees, awards were to be made from time to time for the most valuable contributions to science considered by them, either manuscript or published, on the subject of cures, but particularly in relation to surgery, the nervous system and part "mind treating" have in the recovery and preservation of health.

Announcement is now made by Roberts Lloyd-Gresham, for the trustees, of the first awards from this fund.

Minor Award, Fusakichi Omori or Tokio, unpublished treatise "The Rotary Knife in Surgery"; Award, Charles P. Steinmetz of Schenectady, privately published treatise, "The Nervous System as a Conductor of Electrical Energy"; Major Award, Pierson W. Banning of Los Angeles, on published work, "Mental and Spiritual Healing; All Schools and Methods; A Text Book for Physicians and Metaphysicians."

## The U. S. Civil Service Commission,

Washington, D. C., announces that applications will be rated as received until June 30, 1924, for the following positions:

Medical interne (psychiatric); Medical Officers, junior grade, grade A, and grade B; Graduate nurse; and Reconstruction aide and reconstruction pupil aide in occupational therapy.

Full information about these applications may be received from above named Commission.

## How to Plant The Home Grounds.

The Southern Nurserymen's Association, P. O. Box 169, Birmingham, Ala., has issued a number of short articles pertaining to beautifying the home grounds, with special reference to the growing of more fruit for home use. They tell of the kinds and varieties of fruits suitable for home orchards and tell when and where to plant trees and shrubbery to make the home grounds especially attractive.

## Editorial

### Pernicious Anemia.

Before commenting upon the changes in and characteristics of the blood in pernicious anemia, certain features of the disease may be pointed out. These clinical evidences result from the blood changes. Abnormal blood destruction in the patient brings about more or less characteristic symptoms in the color of the skin, in alterations of the liver and spleen, in febrile reactions and in increased amounts of blood-derived pigments in the plasma and excreta.

*The color of the skin* is typical lemon color. This hemolytic jaundice may or may not be the first evidence to attract the attention of the patient. In early period of the disease this pallor may not be characteristic; later it becomes so. The degree and intensity of the hemolytic jaundice depends, roughly speaking, upon the degree of blood destruction, but this does not always follow. An absence of pallor does not preclude advancing hemolysis. The saturation of the skin with pigments is an associated factor that enters into the intensity of the icterus.

In a report of a group of cases from Johns Hopkins Hospital in which there was an analysis of the clinical histories of 111 patients with pernicious anemia, 2.7 per cent showed "good" color, while the remaining 97.3 per cent showed discolored skin, described as "pale yellow with brown tint, lemon yellow, sallow, ashen, icteroid tint, pale and slightly yellow."

The spleen and liver present rather constant changes in pernicious anemia.

The spleen is particularly associated in the process of increased blood destruction. The spleen shows a high degree of vascularity and blood engorgement in the pulp areas in contact with the connective tissue spaces, while the sinuses are rather empty. Here the hemolysis occurs, it is believed; hemolysis occurs also in the liver and in other parts of the body as well. In the Johns Hopkins report, however, in 80 per cent of the patients the spleen was not palpable; in 5.4 per cent increased splenic dullness was recorded; and in 19 per cent the spleen was recorded as palpable. Another observer states that in about 40 per cent of the cases the spleen is enlarged to the degree that it is palpable.

The liver is enlarged in pernicious anemia, the degree probably varying with the stage. In the Hopkins cases (111 cases—histories studied) the liver was recorded as enlarged in thirty-seven cases. The dual enlargement of liver and spleen, doubtless, occurs.

*Fever.* The temperature of the body is usually above normal showing highest variations from normal during stages of hemolysis, or so-called relapses. This is not invariably the rule, however. It is an irregular fever of low grade, sometimes characterized by a high swing.

*Condition of Teeth.* In the Hopkins cases 14.4 per cent (of 111 cases) had had all teeth extracted; 25.2 per cent had good teeth; 67 per cent had bad teeth.

*The Tongue and Mouth.* In about 45 per cent of cases the tongue and mouth symptoms appear. This usually consists in soreness, rawness, sensation of burning, particularly on the anterior half of the tongue. The tongue is red and dry, superficially ulcerated. Glossitis is constant. The mucosa of the mouth presents the same process.

*The Stomach.* The occurrence of a diminished hydrochloric acid in gastric secretion is common. In fact, the patient frequently applies for treatment because of stomach trouble, complaining of loss of appetite, heartburn, nausea, vomiting, diarrhea, colicky pain in stomach and intestines. The blood picture may be wanting in all confirmatory signs of pernicious anemia, although the mouth and stomach symptoms are marked. Progressive blood

destruction brings forward characteristic blood picture.

*The Course.* The disease is characterized by remissions and relapses. They have recently been divided into following groups—

- (a) Acute: progressively downward;
- (b) Milder: marked by fair remission with hemolysis absent during remission;
- (c) Considerable degree of hemolysis with slow and mild remissions, with serious relapses;
- (d) Chronic: slow progress downward, with mild remissions;
- (e) Continuously chronic, progressing very slowly on downward course.

*The Causes.* Much has been written on the etiology, but we do not know the cause, or causes. (a) "A reversion of the hematopoietic functions to a somewhat embryonic type;" (b) "Dietary hemolytic toxins produced in the process of intestinal putrefaction;" (c) "Infective disease of unknown etiology;" (d) "Altered lipid metabolism or a condition of hypersplenism;" (e) "Unsaturated fatty acids" acting as hemolytic poisons; amino acids acting as hemolytic agents—are a few of the explanations offered for the chronic hemolytic anemia, known as pernicious anemia.

*The Blood.* The blood system is a primary and a fundamental consideration. In this system, apparently, are found the most emphatic and important changes. Probably, all symptoms arising from other systems of the body, named and not named in the foregoing sketch, depend upon blood changes which are found in nearly all cases, at least, in advanced stages of the disease.

*Red Blood Cells.* The count of red blood cells may go to five million. Two million or less is usual count, varying with stage of the disease. Patients with a count of between five million and two million may enjoy fair strength, although patients may die with count around three million. The change for the better in count may mean an increase in number of cells, due to cessation of hemolysis or from increased formation in spite of hemolysis.

*Hemoglobin.* In pernicious anemia, hemoglobin remains relatively high. The standards of estimation vary. But the general opinion is that the red cell count is lower relatively than hemoglobin and so color index is one or above one in pernicious anemia; the blood looks red, but watery.

*Red Cells.* Every red blood cell, physiologists tell us, sooner or later undergoes disintegration. The real and ultimate fate of red blood cells is not known, but it is supposed from suggestive evidence that the spleen and liver serve as sites of final disintegration whether the intermediate stage of destruction is by phagocytic action or fragmentation.

The formation of the red cells is in the red bone marrow and oxygen appears to be the needed stimulus to red cell formation. In pernicious anemia the red cells show any of the abnormalities. Macrocytosis (giant-cell formation) is the chief characteristic of the blood in pernicious anemia. Microcytes also are commonly observed. Abnormalities of the red cells embrace all forms. The evidence of many microcytes and fragmented cells points to a recent increase in cell destruction. Poikilocytosis (varied cell formations) is marked. In good remissions the cells may be difficult of interpretation; in relapses the blood picture is more easily recognized. Polychromatophilia (many + color + to love, or stainable with various stains) and stippling frequently occur. Nucleated red cells are usual in pernicious anemia. Megaloblasts (large + germ) are very usual and were formerly taken as pathognomonic. The blasts, disclosing an effort on the part of the bone marrow to regenerate, appear to come out in crises as though the marrow was making final efforts to regenerate the blood.

The white cells are diminished (leukopenia) denoting marrow deficiency. The blood platelets show the same state of exhaustion by a diminution in number. Coagulating time of the blood in pernicious anemia is not markedly abnormal.

Finally, the summary of Wilson and Evans in the study of the clinical histories of 111 cases of pernicious anemia in the Johns Hopkins Hospital from 1918 to 1922 may be of interest.

1. Pernicious anemia is about equally common in men and women, or possibly, slightly more common in men.

2. It is a disease of adult life. It is never seen in children, is uncommon in old age, and occurs most frequently between the ages of 40 and 60 years.

3. It is very uncommon in negroes.

4. The anemia, once established, practically never completely regenerates.

5. Anisocytosis and poikilocytosis are constant findings. Basophilia is rather uncommon, although it does occur.

6. Although a leucocytosis may occur in the presence of an infection, a leucopenia is the characteristic finding.

7. An eosinophilia as high as 17 per cent may be found, but an actual increase in eosinophile cells are the rare exception. The same applies to the large mononuclear and transition cells.

8. Myelocytes, as high as 10 per cent, may be found in an occasional case.

9. Free hydrochloric acid in the gastric contents of these patients is so rare that, when present, it should put the diagnosis under suspicion.

10. The spleen is palpable in only about 20 per cent of pernicious anemia patients. It may, however, extend 5 to 6 cm. below the costal margin.

11. The liver is palpable in about 33 per cent of pernicious anemia patients. The edge may be palpated 5 to 6 cm. below the costal margin.

12. All patients, whatever other discomforts they may have, suffer from one or more of the following symptoms: weakness, disturbances of digestion, and nervous disorders of the extremities.

## News Notes

### Virginia Society for Crippled Children.

By the formation recently of the Virginia Society for Crippled Children, a definite progressive step was taken consistent with the most advanced ideas in the care and education of ALL crippled children, not just the limited number who are fortunate enough to find their way into existing hospitals and schools. At the present time a project of international scope is being developed, involving eleven of the United States and two Provinces of Canada; this Society has for its fundamental principle "the assuming of the responsibility for

the care, cure, and education" of the 300,000 cripples in our land. All the above state units are working together toward the same end through their combined effort under the name of The International Society for Crippled Children.

The Virginia Society for Crippled Children is one of the component parts of the parent organization and will help to aid in and control this larger and broader activity, as well as develop the work in its own state. This Society is not in the interest of any one hospital, city, or individual, but is to work for the betterment and enlargement of present facilities and the development of newer units where necessary.

In the State of Virginia there are estimated to be about 7,500 crippled children, these figures being very conservatively based on the experience of other states, especially Kentucky and Tennessee. Kentucky was supposed to have had 5,000 crippled children, whereas more accurate figures recently, following surveys, show it has about 12,000. Hence, the estimate for Virginia will probably be well below the actual number present. The number of these children treated during the past five years, according to recent estimates, is not over 2,000, so that with the constant developing of crippling conditions, the immensity of the problem can be appreciated. There are at least four or five thousand children at present who need treatment badly, but who cannot receive same under present facilities.

The procedure best suited to the particular needs of this problem is summed up in the phrase "take the facilities to the child in so far as is possible." That is, develop the necessary facilities of care, cure, and education as near to the homes of these children as can be, particularly as regards the education. Only a few centers are necessary to carry out the acute hospital, or operative care, due to the fact that only twenty-five per cent need hospital treatment, but many so-called convalescent homes are needed in which are held special classes for physical as well as mental education, vocational and special training, etc.; in these classes the children can receive the individual attention so necessary if any progress is to be made.

Before any steps can be taken toward the development of this work, the accurate number and location of all the cripples should be known, and a determination made as to their physical and mental status; in other words, surveys of the various cities and counties must

be made and numbers of clinics held, and general interest must be aroused. The Virginia Society for Crippled Children will sponsor and stimulate proper surveys of any and all communities by enlisting the interest and help of any and all groups or clubs desirous of furthering this great work. It is the earnest desire of those interested in this Society and its work to get the active co-operation of all existing organizations, especially the medical societies upon whose members rests the fundamental foundation of all work of this character. The physician knows, or ought to know, intimately the parents of these children, as well as the children themselves, and he can therefore advise and instruct them as to the best course to pursue; he can see that the children are cared for in the early and developmental stages, so that the attention of this Society can be directed toward their relief or at least toward the finding of facilities for their care and education.

This Society wishes to bring together into one concerted effort all clubs and agencies desiring to help and work toward the goal of finding and alleviating the distresses of nature as expressed in these children. It should be a community affair, not limited to any one group or club, although a beginning must be made by some one group.

The next meeting of The Virginia Society for Crippled Children will be in March, when permanent officers will be elected and a constructive policy formulated. All clubs or organizations desiring to enlist in this work can get full information from the Secretary-Treasurer of the Society. The temporary officers are Dr. L. T. Royster, University, president; Mr. L. B. Hindman, Roanoke Y. M. C. A., vice-president; Professor Chas. G. Maphis, University of Virginia, secretary-treasurer.

### **"Strike" Malpractice Damage Suits**

Are among the latest frands to be perpetrated against physicians. Several of these have been attempted against New Jersey physicians. In an effort to suppress them, the Medical Society of New Jersey has appointed a Defense Council to look after the interests of its members. This Committee has petitioned the press of the State to co-operate with them by refusing to publish accounts of suits against physicians until they are terminated in court. In their request they state that "in no instance has the Medical Society protected, or will it

protect, any physician who has been guilty of negligence, dishonesty or incompetence, much less of violation of law."

During the past few years, suits have been brought against some New Jersey physicians by individuals, with the assistance of unscrupulous lawyers who place pecuniary advantage above ethical consideration. They seem to believe that, to avoid the publicity of such an action, even where there is not a remote chance of obtaining a verdict, a physician will settle out of court. It is simply a form of blackmail. The plan of the Defense Council is to hear the physician's side of the case and, if they regard him guiltless, to order the case defended. In the past two years not a dollar has been collected by law out of suits aggregating \$400,000. In every case defended by the State Society, the verdict has been in favor of the physician.

### **A "Delano Nurse" in Buchanan County, Va.**

Miss Mary Emily Thornhill is the first nurse to be assigned to Virginia under the terms of the will of the late Jane A. Delano, director of Red Cross Nursing Service during the World War. Miss Delano left a fund with which to pay special nurses who are assigned to territories where the need for educating the population in primary public health rules is great. Miss Thornhill has been detailed to Buchanan County which, with a population of 15,500, is said to have the highest birth as well as the highest death rate of any county in Virginia. There are only two physicians in Buchanan County in general practice and two physicians associated with lumber companies—four in all—and no public health nurses. This is an isolated mountainous section in which travel is done by horseback.

Miss Thornhill, a graduate of the Children's Hospital, in Washington, is exceptionally well fitted for her new work. She saw active service during the World War and later took a special course in Public Health Nursing in Richmond. Since then, she has been interested in working for crippled children in Alexandria and vicinity. She reports that the people in Buchanan County are already meeting her more than half way in their eagerness to learn how to improve their living conditions.

Miss Thornhill is the fourth "Delano Nurse" to be appointed by the Red Cross in the United States, the others being located in Alaska, on the coast of Maine, and at Highlands, N. C.

### **The Tri-State Medical Association of the Carolinas and Virginia**

Held its annual meeting in Greenville, S. C., February 20-21, under the presidency of Dr. Dr. Chas. O'H. Laughinghouse, of Greenville, N. C. The meeting was well attended, the papers interesting, and the Greenville doctors contributed in every way to the entertainment and pleasure of those in attendance.

Richmond, Va., was selected as the meeting place for the February, 1925, meeting and headquarters will be at Jefferson Hotel. Officers elected for the ensuing year are: President, Dr. F. H. McLeod, Florence, S. C.; vice-presidents, Drs. Garnett Nelson, Richmond, C. S. Lawrence, Winston-Salem, N. C., and E. W. Carpenter, Greenville, S. C.; secretary-treasurer, Dr. James K. Hall (re-elected), Richmond. New members of the Executive Council are Drs. W. B. Porter, Roanoke, Va., E. S. Boice, Rocky Mount, N. C., and Francis B. Johnson, Charleston, S. C. Those holding over are Drs. F. M. Hodges, Richmond, D. A. Stanton, High Point, N. C., W. R. Wallace, Chester, S. C., F. C. Rinker, Norfolk, J. W. Long, Greensboro, N. C., and George H. Bunch, Columbia, S. C.

### **The Convalescent Home for Crippled Children**

Was formally opened in Richmond on February 24. This home has fourteen large rooms and a new sun parlor and will comfortably accommodate twenty-five convalescent crippled children and a corps of nurses and attendants. The children are taken from Dooley Hospital in this city, and help to relieve the congestion there. No surgeon or physician receives remuneration for his services and expenses in the care of these little patients, and all the money is contributed personally or by local organizations. Dr. W. T. Graham is chief orthopedic surgeon to the home.

It is interesting to note that, since Dr. Graham and the visiting nurses began their work among Virginia's crippled children in July, 1918, 1,231 maimed children have been operated upon, and 1,149 of these have practically been cured. In connection with this work, orthopedic clinics are now held in several Virginia cities.

### **Conference of Maritime Quarantine Authorities of the West Coast of South America.**

Dr. Belasario Porras, the President of the Republic of Panama, called a conference to

meet in Panama, R. P., on February 25, 26, 27, 28 and 29 for the purpose of considering the international standardization of maritime quarantine on the west coast of South America and the prevention of international spread of communicable disease in that litoral.

The conference held formal discussions each morning at which were taken up questions bearing upon maritime quarantine regulations; the methods, periodicity and certification of ship fumigation; uniform quarantine declarations and uniform bills of health. Afternoons were devoted to practical demonstrations of public health and hospital methods. Clinics were held at various hospitals. Interesting demonstrations were given.

The Medical Association of the Isthmian Canal Zone held a special meeting at the Santo Tomas Hospital for the conference. A visit was made to the site of the Gorgas Memorial Institute and this constituted one of the outstanding features of this international meeting. There were many social functions for the delegates.

The secretary-general of the conference was Surgeon William Colby Rucker, U.S.P.H.S., Chief Quarantine Officer of the Panama Canal. Physicians, surgeons and public health workers visiting the Isthmus of Panama at the time of the conference attended.

### **The Medical Work of the Near East Relief.**

This pamphlet, edited by Geo. L. Richards, M. D., gives in brief outline something of the work performed by the Medical Division of the Near East Relief during its first year in Turkey. It is a record of obstacles overcome and results attained and, for the most part, is made up of reports furnished the editor by the physicians themselves. It gives much interesting reading.

Copies will be sent upon request to "Near East Relief," 151 Fifth Avenue, New York, N. Y.

### **Hygeia,**

The magazine of individual and community health, deals with subjects pertaining to personal health, mother craft, diet and foods, community health, medical news and discoveries, school health, and has a special children's department and one of questions and answers. Is any magazine better suited to be put into the hands of your patients desiring knowledge of health? Its gives impressionable people as well as those seeking knowledge the best views

of these subjects from the most competent authorities in the country. The price is only \$3 a year.

A "clip sheet," giving abstracts of articles from *Hygeia*, is published by the American Medical Association each month. Upon request, this "clip sheet" could be sent your local newspapers for the purpose of reprinting items.

#### **Married.**

Dr. Herbert Claiborne Jones and Miss Catherine Scott Smith, both of Petersburg, Va., February 23.

Dr. Arthur Hooks and Miss Edith Kelly, both of Bristol, Va., March 8. Dr. Hooks graduated from the Medical College of Virginia in 1912 and served in the medical corps during the World War. He has for three years been years been associated with Dr. T. F. Staley, of Bristol, in treatment of diseases of the eye, ear, nose and throat.

#### **Dr. S. A. Conduff,**

Of Laurel Fork, Va., is in New York City, taking a special course in diseases of the eye, ear, nose and throat.

#### **Dr. G. W. Parson,**

Of the class of '22, Medical College of Virginia, who has been located at Swords Creek, Va., is now associated with his brother, Dr. A. D. Parson, at Raven, Va.

#### **Dr. W. E. Dickerson,**

Who located in Danville, Va., upon completing his service at Retreat for the Sick, Richmond, last year, has moved to Bramwell, W. Va.

#### **Dr. T. C. Harris,**

Recently of Martinsville, Va., has moved to Radford, Va.

#### **Dr. L. M. Abbott,**

Who has been located for some years at Lignite, Va., has moved to Flinn, Alleghany County, Va.

#### **Dr. J. Edwin Wood, Jr.,**

Who graduated from the University of Virginia in 1921, after service at the Massachusetts General Hospital, and later studying in Boston, returned to Virginia this past fall and became connected with the medical staff of the University of Virginia.

#### **Dr. L. L. Williams, Jr.,**

Who has been connected with the malaria control work in Virginia for the past two years, under the auspices of the U. S. Public Health

Service, has been detailed by the service to a similar work in South Carolina. He is at present in Columbia, S. C., and will probably be absent from Virginia until May.

#### **Dr. Watson S. Rankin,**

State Health Officer of North Carolina, now on leave of absence from that State, that he might serve for a year as field director with the American Public Health Association, was in Richmond the latter part of February, studying the work of the local Bureau of Health.

#### **To Endow Phipps Psychiatric Clinic.**

It has just been announced that Mr. and Mrs. Henry Phipps were the anonymous donors, last year, of \$1,000,000 to Johns Hopkins University. The gift was conditional upon the raising of an additional \$1,000,000. This has now been pledged and the permanent endowment of the Phipps Psychiatric Clinic is a certainty.

#### **Pittsylvania Board of Public Welfare.**

Dr. R. W. Bennett, Toshes, and Dr. L. E. Fuller, Witt, are among those who have been appointed members of the Pittsylvania County (Va.) Board of Public Welfare.

#### **Dr. William Evans,**

Norfolk, Va., was elected a member of the board of managers of the recently organized chapter of Sons of the American Revolution, in Norfolk, Va.

#### **Dr. and Mrs. E. C. Fisher**

And son returned to their home in Richmond, about the middle of February, after spending some time in Tampa and St. Petersburg, Fla.

#### **Dr. J. C. Bodow**

Is one of the charter members of the Rotary Club being organized in Hopewell, Va.

#### **Dr. E. A. Terrell,**

Of Fredericks Hall, Va., is spending a two months' vacation in Florida.

#### **With Chamber of Commerce Committees.**

Drs. Charles A. Blanton, Charles R. Robins, J. Shelton Horsley, and W. H. Parker, all of Richmond, have been named members of standing committees of the local Chamber of Commerce.

#### **Medals Awarded for Radiological Work.**

The Radiological Society of North America, at its meeting recently held at Rochester, Minn., awarded gold medals to Dr. Emil G. Beck and Mr. Clyde Snook, for their achievements in the field of radiology.

#### **The Virginia State Dental Association**

Will hold its annual meeting in Norfolk, Va., April 28-30. At this meeting there will

be presented several papers which will treat of dentistry in its relation to general medicine. Dr. C. B. Gifford, Norfolk, is president, and Dr. Harry Bear, Richmond, secretary.

#### **Dr. Chichester goes to Arlington County.**

Dr. P. M. Chichester, formerly medical inspector for the Richmond Bureau of Health, and for the past year director of the Loudoun County Health Unit, has been appointed to a similar position in Arlington County, succeeding Dr. James W. Cox, resigned. Dr. Cox will continue in health work but has not yet announced his plans.

It is understood that Loudoun County has not made the necessary appropriation for the continuance of the health work in that county under auspices of the State Board of Health.

#### **Dr. A. L. Stratford, II.,**

Who graduated from Medical College of Virginia in 1921, has returned to his home in Richmond and has opened offices at 315 East Main Street. He will be engaged in the practice of obstetrics. Since graduation, Dr. Stratford has had service with Bellevue and Nursery and Child's Hospitals in New York City.

#### **Dr. J. R. Gorman,**

Lynchburg, Va., who was recently operated on for appendicitis, is at his work again.

#### **News of Medical College of Virginia.**

Plans are being made for reunions of the classes of 1868, 1899 and 1914 during commencement exercises of the Medical College of Virginia in June.

Dr. George R. Shapiro, Brooklyn, N. Y., of the class of '17, is working on a plan to organize a chapter of Medical College of Virginia alumni in Brooklyn.

#### **Dr. Teusler Honored.**

Dr. Rudolph Teusler, formerly of Richmond, was decorated with the Order of the Sacred Treasure, fifth class, at ceremonies held in Tokyo, last month, incident, to the celebration of Japanese Empire Day. Dr. Teusler is a director of St. Luke's International Hospital at Tokyo, a member of the American Embassy staff, and the American Episcopal Mission.

#### **Masonic Honors.**

At the meeting of the Grand Lodge of Virginia Masons in Richmond, last month, the following are among those appointed district deputy grand masters: Dr. R. R. Nevitte, Temperanceville; Dr. T. G. Bradshaw, Windsor; and Dr. J. L. Early, Saltville.

#### **Dr. Cumming as Surgeon General, U. S. P. H. S.**

President Coolidge has forwarded to the Senate a recommendation for the re-appointment of Dr. Hugh S. Cumming as surgeon general of the U. S. Public Health Service. Dr. Cumming is a native Virginian and studied medicine in this State. He was first appointed to this position during President Wilson's administration.

#### **Dr. J. Shelton Horsley,**

Richmond, by invitation, read a paper on February 20th, in Newark, before the Academy of Medicine of Northern New Jersey. His subject was "Surgery of Intestine, with Special Reference to the Underlying Physiologic Principles."

We were interested in learning from Dr. Horsley, that this association, though rather small of membership, owns its own home and has a collection of rare old medical books which it would be difficult to duplicate.

#### **Memorial Health Building.**

Watertown, N. Y., has erected a new health building as a memorial to the men of that city who served in the World War. In addition to the office of the superintendent and offices for the local Red Cross chapter, quarters are provided for tuberculosis, child welfare, dental and other clinics.

#### **Dr. Leathers Member of National Board of Medical Examiners.**

Dr. Waller S. Leathers, dean and professor of Histology at University of Mississippi, School of Medicine, has been appointed a member of the National Board of Medical Examiners. Dr. Leathers has many friends in Virginia, having graduated from the University of Virginia in 1894.

#### **Dr. Joseph W. Peabody**

Has been appointed assistant professor of clinical medicine at Georgetown University, Washington, D. C. He will continue in charge of the Tuberculosis Hospital of the District as also medical director of the tuberculosis dispensary of the Board of Health.

#### **Dr. H. R. Fairfax,**

Who has been located in Bristol, Va., for several years, is taking a post-graduate course in New Orleans, after which he expects to locate at Brookhaven, Miss.

#### **Dr. Bernhard S. Steinberg,**

Who served for a year as an interne at Me-

morial Hospital, Richmond, after graduation from Boston University School of Medicine, in 1922, has now located in Boston for the practice of medicine.

#### **The American Proctologic Society,**

At its last meeting, decided to hold the first part of its meeting in New York City, where its scientific and business sessions will be held and, upon invitation of proctologists in England, to hold an adjourned meeting in London. Dates for the New York meeting are June 23-25, and the members will probably sail about June 28. Physicians in good standing are invited to join the Society on this trip. Information may be obtained from Dr. Ralph W. Jackson, secretary, 245 Cherry Street, Fall River, Mass.

#### **Dr. and Mrs. R. L. Hudnall,**

Who have been in Chicago, since their marriage last November, have returned to their home at Beverlyville, Va.

#### **Noted Endocrinologist Addresses Richmond Doctors.**

Dr. Arthur Biedl, professor of endocrinology at the University of Prague, addressed the Richmond Academy of Medicine, at its meeting on February 26, his subject being "Cerebral Adiposity." Dr. Biedl is in this country upon invitation of the Medical School of the University of Chicago, to deliver the annual Dodson Memorial Lectures. While in this country, he will make addresses at several medical schools. While in Richmond, he also spoke to the students at the Medical College of Virginia.

#### **Dr. George Green,**

A graduate of the Medical College of Virginia and now a medical missionary in South Africa, gave an illustrated talk at one of the Richmond churches last month, at which he told of the work being done in his mission field. After graduating in Richmond in 1905, Dr. Green served as one of the internes at St. Vincent's Hospital, Norfolk.

#### **Dr. Jury B. Loving,**

Who located in Danville, Va., last summer, upon completion of his internship at St. Luke's Hospital, Richmond, has moved to Williamsville, Bath County, Va.

#### **Dr. E. L. Marshall,**

Big Island, Va., has been named a vice-chairman of the Bedford County (Va.) Board of

Agriculture. The object of this organization is to do for the county what boards of trade and chambers of commerce do for towns and cities.

#### **Dr. Beverley R. Tucker**

Has been elected president of Westmoreland Club, Richmond, for the year beginning March 1, 1924.

#### **Roanoke Hospital Association Receives Gift.**

It is announced that a large gift has been made the Roanoke Hospital Association of Roanoke, Va., by a citizen of that city. This will make possible the immediate remodeling of the old unit of the hospital. It is the purpose of the Association to enlarge the hospital to a capacity of about 116 beds.

#### **Dr. H. S. Belt**

Recently returned to his home in South Boston, Va., after a visit to his brother in New York.

#### **Dr. Robert L. Kern,**

Richmond, was elected venerable master of the Libertas Lodge of Perfection, No. 5, Ancient and Accepted Scottish Rite of Freemasonry, at its annual meeting held in this city, the latter part of February.

#### **Dr. S. W. Maphis,**

Warrenton, Va., after spending sometime in North Carolina recuperating after illness, has gone to Hot Springs, Va., for a visit.

#### **Dr. C. H. Saunders**

And several friends of Chase City, Va., have returned home after spending sometime in Florida.

#### **"Value of Gelatine in Infant Feeding."**

Physicians who have not received the first report of the research work of the above pamphlet, may have a complimentary copy by addressing Charles B. Knox Gelatine Co., Inc., Johnstown, N. Y. They also issue pamphlets with attractive and palatable ways of preparing gelatine dishes for the sick and well.

#### **Index Number.**

This issue is index number of the VIRGINIA MEDICAL MONTHLY. We expect to maintain our high standards in the next volume and count on the co-operation of our members in this work. The scientific and business parts are interdependent the one on the other and it is our aim to keep them both on a high plane.

#### **Dr. E. A. Hatton,**

Who is in charge of medical inspection in the Portsmouth, Va., schools, was taken sud-

denly ill on the first of this month and is in Parrish Memorial Hospital, that city.

#### **Dr. E. R. Miller**

Has returned to his home in Harrisonburg, Va., after a visit to his son at the University of Richmond.

#### **Dr. S. C. Draper,**

Who has been practicing in Pulaski, Va., has gone to Norfolk, Va., where he will be connected with the Pension and Relief Department of the Norfolk and Western Railway.

#### **Public Health Summer Schools.**

In response to a great demand for summer school work in public health, the U. S. Public Health Service has arranged short term summer courses to be given at Columbia University, New York City, University of Michigan, Ann Arbor, University of Iowa, Iowa City, and University of California, Berkeley. The courses will extend over six to eight weeks and cover a wide range of subjects. Tuition fees will be moderate.

If interested, further information may be obtained from Surgeon General of the U. S. Public Health Service, 16 Seventh Street, Southwest, Washington, D. C.

#### **Wise County Medical Society.**

The regular meeting of this Society held at Norton, Va., February 27, was well attended. Dr. Charles Stevens, of Baltimore, addressed the Society on "Antitoxins and Vaccines." Dr. F. C. Handy, of Toms Creek, was elected a member. Dr. F. S. Givens, of Wise, was elected president, and Dr. C. B. Bowyer, Stonega, was re-elected secretary-treasurer. Following the meeting, a banquet was served members, friends and invited guests at the Norton Hotel.

#### **Dr. B. I. Bell,**

Williamsburg, Va., has returned to his home in that place, after spending sometime in New York City, specializing in X-ray and nose and throat work.

#### **Dr. Charles R. Irving,**

Who has been located at Howardsville, Va., since returning from the World War, has moved to Martinsville, Va., where he will be a member of the staff of the Lucy Lester General Hospital.

#### **Chiropractors Try to Secure Legislation.**

During the meeting of our State Legislature, just adjourned, two bills were presented

by different sets of chiropractors. One called for the creation of a chiropractic board; the other requested that a chiropractic be placed on the Virginia State Board of Medical Examiners. Neither of these bills exacted the educational requirements made by our State Board. Both were killed in different committees and, as we go to press, there seems no likelihood that the chiropractors will get through any legislation this year.

#### **The Medical Society of The District of Columbia,**

At its annual meeting, held recently, elected Dr. John D. Thomas president, Dr. Coursen B. Conklin secretary, and Dr. William J. Mallory legislative chairman.

#### **National Health Series.**

In order to make available to the general public at moderate prices authoritative books on all phases of human life, the National Health Council has arranged with the Funk and Wagnalls Company for the publication of The National Health Series. It will contain twenty books of about 18,000 words each, written by leading health authorities of the country. These books, bound in flexible fabrikoid, sell for 30 cents each, or \$6.00 for the series of twenty. They will be issued in sets of five each.

#### **The Tennessee State Medical Association**

Will hold its annual meeting in Knoxville, April 11-13, 1924. The president is Dr. H. L. Fancher, Chattanooga, and secretary Dr. Joseph F. Gallagher, Nashville.

#### **The Medical Society of The State of North Carolina**

Will hold its annual meeting in Raleigh, April 15-17, 1924, under the presidency of Dr. J. V. McGougan, of Fayetteville. Dr. L. B. McBrayer, of Sanatorium, is secretary.

#### **The American College of Physicians,**

At its recent meeting in Chicago, conferred fellowships upon 178 candidates. Dr. Harlow Brooks, of New York, was elected president for the coming year, and Dr. Frank Smithies, of Chicago, was re-elected secretary general.

#### **The South Carolina Medical Association**

Is to hold its annual meeting in Orangeburg, April 15-17. Dr. Leland O. Mauldin, Greenville, is president, and Dr. E. A. Hines, Seneca, secretary.

#### **Dr. Crile Resigns.**

It is announced that Dr. George W. Crile has tendered his resignation, effective July 1,

as professor of surgery at Western Reserve University Medical School, Cleveland, Ohio, and also as house surgeon of Lakeside Hospital. He plans to devote his time to research work and private practice.

Dr. Elliott C. Cutler, of Peter Bent Brigham Hospital, Boston, will succeed Dr. Crile.

#### **"Bread for The New Family."**

This pamphlet, issued by the Bureau of Child Welfare, of the Virginia State Board of Health, co-operating with the Children's Bureau, Department of Labor, U. S. A., is the third in the New Family Series. As its name indicates, it treats of bread and the kind of flour for making it to be used by the "New Family." Teachers, health workers and others interested may secure copies upon application to the State Registrar of Vital Statistics, Richmond, Va.

#### **Dr. Thomas C. Johnson,**

Who has been charge of the Thompson Hospital, at Lumberton, N. C., since the death of Dr. Neill A. Thompson in 1922, has now leased the hospital and will continue to operate it. Dr. Johnson has many friends in Virginia, having graduated from the University College of Medicine, Richmond, in 1903.

#### **Income Tax Returns**

Should be filed with the Collector of Internal Revenue for your district on or before March 15, 1924. A fine is imposed for non-compliance with this law. If personal illness is liable to delay this return, an extension of time should be secured from the Collector of your district.

#### **Sterilization Bill Presented Legislature.**

A Senate bill providing for the sterilization of inmates of State institutions for the insane, feeble-minded and epileptic, was reported unanimously by the House Committee on Asylums and Prisons, the latter part of February. Dr. A. S. Priddy, of the State Epileptic Colony, Lynchburg, and Dr. J. S. DeJarnette, of the Western State Hospital, Staunton, appeared in support of the bill, as did also prominent laymen interested in this work.

#### **The Augusta County (Va.) Medical Association**

Held its regular quarterly meeting in Staunton, February 6, Dr. A. F. Robertson, Jr., Staunton, presiding. Several papers were read, including an interesting symposium on Cancer. Dr. H. G. Middlekauff, Weyers Cave, Va., is secretary of this Association.

#### **Dr. Thomas D. Jones,**

Of Petersburg, Va., who graduated from the University of Virginia, Department of Medicine, last June, is now at the Houston Clinic, Houston, Texas.

#### **Dr. Harry L. Claud,**

Recently of Newport News, Va., has moved to Washington, D. C., where he will be located at 1744 N Street, Northwest.

#### **The American Congress on Internal Medicine,**

At its annual meeting in St. Louis, last month, selected Washington, D. C., as its 1925 meeting place, and elected Dr. William Gerry Morgan, of Washington, president. Dr. Frank Smithies, of Chicago, was re-elected secretary general.

#### **"Reciprocity Between the Health Officials and the Medical Profession."**

Under this caption, Dr. E. C. Levy, director of Public Welfare of Richmond, gave his presidential address before the last meeting of the American Public Health Association. It outlines the advantages to both the American Public Health Association and the American Hospital Association in bringing about a closer relationship between the public health administrator and the hospital and dispensary. He brings out clearly in his paper how health authorities uphold the rights of physicians and how they can be of service, the one to the other, and not antagonistic. It is a paper which should enjoy a wide publicity. A limited number of copies may be obtained from the American Public Health Association, 370 Seventh Avenue, New York, N. Y.

#### **Important Decision Helps American Chemistry.**

The decision of the U. S. Court, District of Delaware, in favor of The Chemical Foundation, Inc., is of far-reaching importance to the medical profession, and to the manufacturers of medicinal chemicals. Prior to the World War, the medical profession was practically dependent upon foreign sources of supply for many important drugs. Patents were held in this country by foreign owners—not that the drugs might be manufactured here, but that American firms might not make them.

In order to establish and foster the chemical industry in this country, the patents were sold by the United States Government to The

Chemical Foundation, Inc., so that no exclusive licenses might be issued to American concerns. This plan of devoting these patents to the public use has stood the test of actual trial, and has proven a success. Many of the important medicinal chemicals previously unobtainable from American sources, are now manufactured in this county, and the medical profession now has the assurance that, unless there should be some later and unexpected reversal of this decision, they may never again be dependent upon foreign monopoly in drug supplies.

To further foster the use of American-made medicinals, the Federal Trade Commission, the National Research Council, the Council on Pharmacy and Chemistry of the American Medical Association, and other agencies have suggested and provided new and distinctive names for American synthetics which are rapidly replacing those formerly made only abroad, and it is suggested that physicians might be performing a patriotic duty to use, specify, and refer to these drugs by their American names. Among the products so designated are arsphenamine, neoarsphenamine, barbital sodium, cinchophen, neocinchophen and procaine. The Chemical Foundation Inc., also licensed certain manufacturers to make, in this county, acriflavine and neutral acriflavine.

#### **X-Ray For Sale.**

One portable bedside unit complete with Coolidge Tube, Wappler. Capacity 30 milliamperes with a gap up to 5 inches. Operates on a 110 volt alternating current. All kinds of radiographic work can be done with it. Good as new. Address, "X. Y. Z.," care this Journal. (Adv.)

#### **Wanted—**

Assistant physicians, mental and tuberculosis, \$1,320—\$2,000 a year and maintenance. Apply State Employment Commission, 22 Light Street, Baltimore, Maryland. (Adv.)

#### **Wanted—**

About the 1st or 15th of April a physician to take over a large country practice in the bright tobacco belt of Pittsylvania County. Roads very good; church, school and store convenient.

For further particulars, communicate with Dr. W. J. Wigington, Java, Va. (Adv.)

## Obituary

### **Dr. William Fewell Merchant,**

Manassas, Va., died at his home in that place, February 21, at the age of 56 years. He graduated from the former University College of Medicine, Richmond, in 1897, and was located in South Richmond for some years, at which time he was a local surgeon for the Southern Railway. Later he moved to Manassas and, at the time of his death, was a surgeon for both the Southern and Chesapeake and Ohio Railways. He was also a member of the Prince William County Board of Health and of the Medical Society of Virginia. During the World War, he was stationed at Camp Lee and retired with the rank of captain in the medical corps. His wife and a son survive him.

### **Dr. Julian Thomas Doles,**

A practicing physician of Ivor, Va., died in Portsmouth, February 28, at the age of 59 years. He had been in poor health and was under hospital treatment. Dr. Doles studied medicine at the College of Physicians and Surgeons, Baltimore, from which he graduated in 1887. Dr. H. M. Doles, of Norfolk, is a son of the deceased.

### **Dr. Walter S. Roy,**

Of Front Royal, Va., died at the home of his daughter in Newport News, Va., the middle of February, and was buried in Front Royal. He was 82 years old. After serving throughout the Civil War, he took up the study of medicine at the Medical College of Virginia and graduated in 1868. Soon thereafter, he located in Front Royal, where he became one of the best known and most beloved physicians of that section of the State. He was at one time a member of the Medical Society of Virginia.

### **Dr. Theodore Frederick Reusch**

Died in Bedford County, Va., after an illness of four years, which dated back to his service in the World War, through which he served as captain in the medical corps. He was 40 years of age and graduated from the Homeopathic Medical College of Missouri, St. Louis, in 1908. His wife survives him.

# Over 300%

**M**ORE than three times as much S.M.A. was prescribed in 1923 as in 1922. We believe that the physician who has used it will understand the reason, for he is already aware of the assistance which S. M. A. has given him in his own practice, and he will see in this increase convincing evidence that many other physicians are also obtaining exceptional nutritional results with S. M. A.

From 1915 to 1920 S. M. A. was used only in The Babies' Dispensary and Hospital of Cleveland. In January, 1920 it was made available to all Cleveland physicians. In November, 1921, its distribution was extended so that every physician in the country might obtain it for his little patients. From the time that S. M. A. was first offered to the medical profession, there has been a steady increase in the number of physicians using it, and in the volume prescribed by them.

S. M. A. is a food for infants deprived of breast milk, or who require nourishment in addition to what the mother can supply.

Requires only the addition of boiled water to prepare. Needs no modification or change for normal infants.

Prevents rickets and spasmophilia. Promotes normal growth and development.

Formula by permission of The Babies' Dispensary and Hospital of Cleveland. For sale by druggists on the order of physicians.

Literature and samples to physicians on request. The Laboratory Products Company, Cleveland, Ohio.

## The Value of "Gelatinized" Milk in Mal-nutrition

HERE is an exact chart showing the growth curves of four infants suffering from mal-nutrition, resulting from imperfect assimilation of the milk nutriment—the most valuable of all foods. Note the sharp angle of recovery after plain edible gelatine was added to the milk formulae.

The colloidal action of the gelatine prevented excessive stomach curdling of the milk and insured the proper absorption of all the milk nutriment, besides supplying the Amino-Acid, Lysine, essential to healthy growth.

Gelatinization of the milk does not interfere in any way with any formula prescribed by the physician, but does, on the other hand, greatly augment the efficacy of every milk diet whether for infant or adult.

That Gelatinized Milk is one of the most important advances in dietary practice has been fully demonstrated, not only for infants, but also in all child and adult cases where impaired digestion prevents perfect nutritive assimilation. The only precaution necessary is to use a pure unflavored, unsweetened, granulated gelatine, of which the highest known standard is

# KNOX

## SPARKLING GELATINE

"The Highest Quality for Health"

### For the Perfect Gelatinization of Milk

Put one tablespoonful of gelatine in one-half cup of cold milk and let it soak for ten minutes. Place the cup in boiling water, stirring until gelatine is fully dissolved; then add this dissolved gelatine to the quart of cold milk or regular formula, from which you have taken the original one-half cupful.

In addition to the family size package, Knox Sparkling Gelatine is put up in one and five pound cartons for special hospital use. A trial package at 80c the pound, will be sent on request.

# The Rôle of the Lilly Research Laboratories in the Introduction of Insulin

---

**F**OLLOWING the discovery of Insulin the Lilly Research Laboratories were selected by the Insulin Committee of the University of Toronto to co-operate with the original investigators in the development of a process for the manufacture on a large scale of a highly purified, stable, uniform preparation of Insulin. As a result of the whole-hearted co-operation of the Lilly Research Laboratories with the Toronto group an ample supply of a high grade preparation of Insulin was available for the use of the medical profession of the United States within a few months.

## ILETIN (INSULIN, LILLY)

Iletin is now used by over eight thousand physicians in the treatment of approximately thirty thousand cases.

Every lot of Iletin offered for sale has been tested and approved by the Insulin Committee of the University of Toronto.

Iletin (Insulin, Lilly) is available only in a clear, colorless, sterile, aqueous solution, supplied in 5 c. c. ampoules.

Iletin(Insulin,Lilly)is effective only when given hypodermically.

## VICTOR X-RAY RESEARCH—A GUARANTEE

**I**T is research that has brought about the remarkable progress in roentgenological apparatus.

The wonderful X-ray apparatus of today, which has done so much to aid both the diagnostician and therapist and which has made it possible to *control* X-rays even more accurately than the effects of a drug are controlled, is due in a large part to research systematically conducted in behalf of the Victor X-Ray Corporation. Moreover, results of this research are embodied not only in Victor apparatus made for the hospital and specialized laboratory, but in simple equipment for the general practitioner.

No other manufacturer has so large an investment in research as the Victor X-Ray Corporation. A considerable portion of its earnings is reverted annually to be applied in physical and engineering investigation, to the end that

the art of roentgenology may be advanced and results made more and more certain.

This large investment in research is a guarantee for the future. It is contributory in a large degree to the unquestioned supremacy of the American roentgenologist. It is a guarantee of the Victor X-Ray Corporation's permanency—a guarantee that X-ray users may confidently look to it for technical advances which will aid them in making the X-rays even more valuable than they now are.

When research so conducted is productive of apparatus with which the roentgenologist may realize a higher grade of work, thereby increasing his efficiency, then the prices of Victor apparatus are moderate indeed. Consider the importance—to both you and your patient—of that vital ten or fifteen per cent higher efficiency, from the standpoint of diagnostic and therapeutic results.

*Giving us an opportunity to advise with you concerning your individual X-ray problem, does not obligate you in any way*

PHILADELPHIA

*(Licensed by the Chemical Foundation, Inc.)*

As the result of consistent research and refinements in the methods of production, The Dermatological Research Laboratories have very greatly improved upon the original arsenicals.

NEOARSPHENAMINE, D.R.L., as now offered, is meeting the requirements of the most exacting members of the medical profession. The world has never before known a drug of greater excellence. Government specifications for such products are high but NEOARSPHENAMINE, D.R.L., runs from 75 to 100% above them, as toleration tests show.

While allowing a wide margin of safety for the patient, NEOARSPHENAMINE, D.R.L., is practically the equal of Arspenamine for therapeutic effectiveness.

A handy package of NEOARSPHENAMINE: 10 ampules, with an equal number of ampules of distilled water included without additional charge, in these sizes: 0.9, 0.75, 0.6 and 0.45 gram. Ask your dealer. Whether ARSPHENAMINE, NEOARSPHENAMINE or SULPHARSPHENAMINE, let it be the reliable D.R.L. brand. Booklet on "The Treatment of Syphilis" sent on request.

## *Modern Colloidal Silver Therapy*

# NEO-SILVOL

**Esthetic** (*No dark brown stain*)

**Effective**

NEO-SILVOL is colloidal silver iodide. Though silver iodide is insoluble in water, Neo-Silvol, which contains 20% silver iodide, is readily soluble in water and remains in solution for a long time; the colloidal form of the silver iodide accounts for this important physical property.

Neo-Silvol is white in color, and solutions have a milky opalescent hue. This naturally means that you can apply effective silver medication to mucous membranes without staining everything within reach with the characteristic dark brown color of most other silver compounds.

Neo-Silvol is indicated in solutions of 2% to 30% in the local treatment of inflammations of the accessible mucous membranes, such as those of the eye, ear, nose, throat, urethra, vagina, bladder, and rectum.

Put up in 6-grain capsules for convenience in making up solutions as required. Also obtainable in ounce vials.

Samples are available for physicians.

**PARKE, DAVIS & COMPANY**

DETROIT, MICHIGAN

*Neo-Silvol is included in N. N. R. by the Council of Pharmacy and Chemistry of the A. M. A.*

## Professor Anderson's

**Whole-grain foods  
Food cells exploded**

Quaker Puffed Grains are whole grains  
steam exploded.

Under Professor Anderson's process, over  
125 million steam explosions are caused in  
every kernel.

Thus the food cells are broken for easy  
digestion. The whole-grain elements are  
fitted to feed.

### Food Confections

Puffed Grains also make whole grains de-  
lightful. Each grain is a tidbit, flaky and  
flavory, puffed to 8 times normal size.

Quaker Puffed Wheat in a bowl of milk  
forms an ideal way to serve whole wheat  
and milk.

ENGRAVERS FOR THIS JOURNAL

# The Oat

**Holds supreme place**

Professor H. C. Sherman rates the oat at 2465 in his "Composite Valuation of Typical Foods."

This scoring is based on calories, protein, phosphorus, calcium and iron.

It is the highest rating given to any grain food quoted.

Quaker Oats are flaked from just the choicest grains. A bushel of fine oats yields but ten pounds of these extra-flavory flakes. It is that flavor which gives the oat dish its delights, and one should always get it.

# A physician designed this keyboard for you

*Look it over carefully. It is the most advanced  
type of medical typewriter keyboard*

WE believe this is the first keyboard of its kind ever offered to your profession. It is a complete medical keyboard plus a complete "everyday" keyboard.

The New XC Model Corona has 90 characters, 6 more than an ordinary office typewriter, and this enables us to give you a complete typewriter for ordinary correspondence with the necessary additional symbols for use when you need them.

Incidentally, we can vary the keyboard to suit your own ideas. If the

keyboard, as you see it above, does not exactly meet your requirements, we can build one to suit you.

The price of this new 90-character model with medical keyboard is only \$5 more than the regular Corona—\$55 in all, including carrying case.

If you will mail the coupon below, we shall be glad to send you an interesting folder entitled "Corona and the Doctor's Office," and will include some additional information about this newest medical keyboard.

## *Department of Medicine*

I. COURSE LEADING TO DEGREE OF DOCTOR OF MEDICINE. Entrance requirements: two years of college work (including college courses in English, chemistry, physics, and biology) after the completion of a four year high school course or its equivalent.

The medical course extends over four sessions of nine months each, the last two devoted to instruction in the wards and outpatient department of the University Hospital and in the Blue Ridge Sanatorium of the State Board of Health. Women admitted on the same terms as men.

II. COURSES OF INSTRUCTION IN PUBLIC HEALTH. The Joint Health Department of Albemarle County, the city of Charlottesville, and the University affords unique facilities for the study of problems of public health, especially those of small cities and of rural districts. Two courses are offered at present.

Course No. 1. TRAINING FOR RURAL HEALTH OFFICERS. A twelve weeks course open to graduates of medical schools.

Course No. 2. TRAINING FOR SANITARY INSPECTORS. A ten weeks course open to high school graduates, 21 years or over and to those having equivalent training.

# "Formulas for Infant Feeding"

New Edition

## Whole Milk Formulas

For Infants about Three Months Old

(Average weight 12¼ pounds)

Mellin's Food      6 level tablespoons  
Whole Milk          16 fluidounces  
Water                16 fluidounces

(This amount is sufficient for 24 hours.)

Give the baby 4½ ounces every 3 hours; 7 feedings in the 24 hours.

Increase the quantity of milk one ounce every sixth day until the amount of milk is 21 ounces, and decrease the quantity of water one ounce every fifteenth day until the amount of water is 14 ounces; then prepare the modification according to the formula for an infant four months old.

Details relative to the nutritive value of the above modification will be found on the opposite page.

12

## Analysis of the Foregoing Mixture

Fat.....		1.81
Proteins.....	{ milk 1.70 } { cereal .42 }	2.12
Carbohydrates.....	{ lactose 2.29 } { maltose 2.40 } { dextrins .85 }	5.54
Salts.....		.52
Water.....		90.01
		100.00

## Weight in Grams of Food Elements in the Foregoing Mixture

Fat.....	18.10 Grams
Proteins.....	21.28 "
Carbohydrates	55.39 "
Salts.....	5.17 "

A total of 99.94 grams of well-balanced nourishment.

## Calories Contributed by Food Elements in the Foregoing Mixture

Fat.....	168 Calories
Proteins.....	87 "
Carbohydrates	227 "

Total Calories in mixture =	482
Calories per fluidounce =	15.1
Energy-quotient, or Calories per pound of body-weight =	39.3

The amount of protein in the foregoing mixture equals the protein in 1.63 ounces of whole milk to each pound of body-weight.

13

A thoroughly revised edition of our book, bound in leather, is now ready, and a copy will be mailed to physicians upon request.

To give some idea of the magnitude of this new work and how well it keeps step with the progress in infant feeding, we display two pages of this 80-page book. It will be noted that the formula adjusted to age and weight, together with simple instructions for progressive changes, is given on the left-hand page, and on the right practically every detail relative to the balance of nutrition is stated. This plan is followed throughout the book, thus giving information of daily usefulness not accessible in any other work of this nature.

Special formulas calculated to meet conditions other than normal, with suggestions for their practical application, broaden the scope of the work, which in its entirety marks a distinct advance toward a better understanding of infants' nutrition.

# THE STANDARD LOESER'S INTRAVENOUS SOLUTIONS CERTIFIED

## LOESER PRESTIGE

The respect that Loeser's Intravenous Solutions enjoy among the medical profession is not based on any single phase of excellence. This alone could not sufficiently account for the universally high estimation in which these solutions are held.

This esteem goes beyond the technical excellence of the solutions themselves. It is deeper than any appreciation of excellence alone could make it.

It goes, in fact, down to the bedrock of unshaken confidence in the name; a firm conviction that the name Loeser is synonymous for the original research which overcame prejudice and made intravenous injection a safe and practical office procedure.

# The University of Virginia Hospital

CHARLOTTESVILLE, VIRGINIA

A General Hospital, owned by the State of Virginia and conducted under the supervision of the Medical Department of the State University.

Ward service affords treatment to citizens of Virginia at low cost. A limited number of indigent cases taken free of charge.

Well appointed private rooms.

Exceptional location on the University grounds. Well equipped laboratories and X-Ray Department.

Contagious diseases, mental cases and drug habitues not received.

For further information, address

D. B. YANCEY, Superintendent.

# Glenwood Park Sanitarium, Greensboro, North Carolina.

SUCCEEDING TELFAIR SANITARIUM

The Glenwood Park Sanitarium is ideally located in a quiet suburb of Greensboro, having all the advantages of the city, yet sufficiently isolated to enable our patients to enjoy restful quietude and entire freedom from the noise and distractions incident to city life.

**CLASS OF PATIENTS**—Those who need help to overcome the bondage of habit. Rest from overwork, study or care. Diversion for the depressed and disquiet mind—and such as are suffering from any disease of the nervous system. The treatment consists of the gradual breaking up of injurious habits, and the restoration to normal conditions, by the use of regular and wholesome diet, pure air, sunlight, and exercise, with such other remedies as are calculated to assist nature in the work of restoration.

Special attention is given to the use of electricity. Twenty years' experience has proven it invaluable in cases of nervous prostration, incipient paralysis, insomnia, the opium and whiskey habits, and those nervous affections due to uterine or ovarian disorders.

For further particulars and terms, address W. C. ASHWORTH, M. D., Superintendent

**ELIZABETH BUXTON HOSPITAL  
AND TRAINING SCHOOL FOR NURSES  
BOULEVARD, NEWPORT NEWS, VA.**

**For MEDICAL and SURGICAL Cases**

For additional information address. MISS ELIZABETH NAGLE, Supt., Newport News, Va.

**Westbrook Sanatorium - - - Richmond, Va.**

Rooms single,  
or en suite,  
with or with-  
out private  
baths.

Hot water  
heat, electric  
lights and ar-  
tesian water.

Bowling, ten-  
nis, croquet,  
billiards and a  
gymnasium af-  
ford recrea-  
tion.

Electrical and  
hydrotherapy  
equipment.

Nurses and at-  
tendants trained  
for this  
special work.

Two of the  
physicians re-  
side in the in-  
stitution and  
devote their  
entire time to  
the patients.

The magnificent home of the late Major Ginter, by alterations and extensive additions, has been transformed into a private institution for the treatment of nervous diseases, mild mental cases and select alcoholic and drug habitues.

The grounds are ample, quiet is assured, and a new building for men makes easy the separation of the sexes. A number of cottages make possible satisfactory and congenial grouping.

## LAUS DE'O

For the Refuge and Reformation of Unfortunate Girls.

LASCASSAS, TENN.

We place at the disposal of the Medical Profession a strictly private and up-to-date retreat out in the country for the care and protection of unfortunate girls and infants. We want girls who would retrace missteps, leave the burden of their mistakes, preserve individual character and family reputation. Girls must come through a physician. We make this restriction in order to have only girls from the best class, who are worthy of help. Laus De'o is only two hours' ride from Nashville. Drs. J. C. Kelton and J. T. Harris are physicians and may be reached by letter at Lascassas, or phone Murfreesboro 6105 for information. Private letters should be address to Miss Kitty Cook, Lascassas, Tenn.

1230 Second Avenue, South,  
Phone, Main 3791 Nashville, Tennessee

## Loyalty to our doctors

When we select a doctor to practice upon ourselves and our families we are governed by his professional ability and his general character as a gentleman. We then put our lives in his hands and look to him for results.

We put our faith in him and stick to him. Should our case be serious and he thinks we should have additional service we expect him to suggest it.

Now doctor when your patients need a wheel chair, commode, bedtable or a comfortable chair or a hospital bed, why not suggest it to them and be sure to say you can find it at

SYDNOR & HUNDLEY, Richmond, Va.

## AN INVITATION TO PHYSICIANS

Physicians in good standing are cordially invited to visit the Battle Creek Sanitarium and Hospital at any time for observation and study, or for rest and treatment.

Special clinics for visiting physicians are conducted in connection with the Hospital, Dispensary and various laboratories.

Physicians in good standing are always welcome as guests, and accommodations for those who desire to make a prolonged stay are furnished at a moderate rate. No charge made to physicians for regular medical examination or treatment. Special rates for treatment and medical attention are also granted dependent members of the physicians's family.

An illustrated booklet telling of the Origin, Purposes and Methods of the institution, a copy of the current "MEDICAL BULLETIN," and announcements of clinics, will be sent free upon request.

# The HEALTH-O-METER For Every Member of the Family

With a capacity of 250 pounds the Health-O-Meter serves every member of the family from infant to parent.

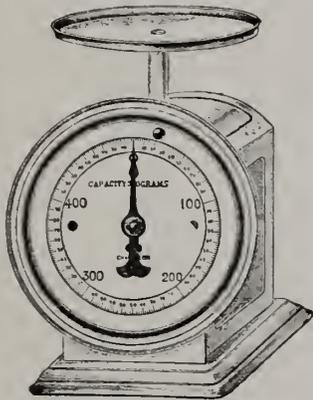

Homes and institutions everywhere are installing the Health-O-Meter because of its accurate weighing service—its practical size—its attractive appearance. The inlaid cork mat is kind to your bare feet. The legible dial is glass covered and mounted with a substantial nickel-plated sash. The finish is of heavy oven baked white enamel.

**POWERS & ANDERSON, Inc.**

**Surgical Instruments, Hospital Supplies, Etc.**

**603 East Main Street**

**RICHMOND, VA.**

These scales are finished in White Enamel with decorations. Dial is silvered finish on which the graduations and numerals appear in black. Capacity 500x2 gr. Price, \$10.00 net.

## DIETARY SCALE

No matter how careful the diagnosis or correct the prescription, and no matter how conscientious the acquiescence of the patient, the desired results from dieting can be obtained only when exactitude as to quantity, as well as to quality, is attained.

Therefore, it is absolutely essential that the food prescribed be weighed with exactitude; no more guess work method will answer the purpose—no inaccurate measuring or weighing apparatus will suffice. Such uncertain methods as taking the prescribed food in “portions” or estimated amounts is not only unsatisfactory but essentially detrimental and results in making “bad matters worse!”

So important has become the need of the accurate weighing of food prescriptions that a special scale, has been devised.

Balance type, \$15.00 for Hospital use.

“—a *Vitamin A* potency of more than 100 times that of the best quality butter.”

# SQUIBB'S COD-LIVER OIL

## From Lofoten Cod

— High in Vitamin Content.

Recent investigations have shown that Vitamin A, abundant in Squibb's Cod-Liver Oil, will prevent rickets, delayed and defective dentition, and impaired growth of bone; will promote growth; has a favorable influence on the calcium-phosphorus metabolism; and acts as a general metabolic stimulant.

Cod-Liver Oil Squibb, on account of its high Vitamin value, is particularly indicated during pregnancy and lactation, because

the infant is entirely dependent on the mother's diet for its supply of Vitamin; and the amount of the latter received by the infant during this period bears a vital relation to its health and development.

Cod-Liver Oil Squibb is collected by our own representative from Lofoten Cod, and tested for *VITAMIN A*; the label on each bottle states the vitamin value.

Squibb's Vitamin-Tested Cod-Liver Oil is more than a mere fat; it is an active therapeutic agent unmodified and undiluted by emulsifying substances.

When prescribing, Specify:

**COD-LIVER OIL SQUIBB**

# Prescribing a Milk Formula for the Underweight Baby

TEST after test, made by physicians of eminent authority, has proved that the underweight, mal-nourished infant who fails to respond properly to any feeding formula will show an immediate improvement if the milk is "gelatinized" as follows:

Soak one level tablespoonful of Knox Sparkling Gelatine in  $\frac{1}{2}$  cup cold milk, from the baby's formula, for ten minutes; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the quart of cold milk or regular formula.

Pure, granulated gelatine<sup>1</sup> (Knox) is a highly protective colloid;<sup>2</sup> as an adjunct to milk, it prevents excessive curding in the infant stomach, thus promoting its thorough digestion;<sup>3</sup> it facilitates complete absorption of all the milk nutriment;<sup>4</sup> and it prevents milk-colic, regurgitation, and diarrhea.

Plain, edible gelatine also furnishes, to the extent of 5.9%, the natural amino-acid, lysine, which is so essential to human growth. This makes it an invaluable element in the diet of growing children.

## KNOX SPARKLING GELATINE

*"The Highest Quality for Health"*

For the perfect gelatinizing of milk, as for all dietary purposes, Knox Sparkling Gelatine is recommended because it represents the highest standard of purity and is absolutely free from artificial flavoring or any other synthetic elements.

In addition to the family size package, Knox Sparkling Gelatine is put up in 1 and 5 pound cartons for special hospital use.

ORGANIZED 1871

HOME OFFICE: RICHMOND, VA.

**Oldest, Largest, Strongest Southern Life Insurance Company**

WE WISH TO CALL ATTENTION, ESPECIALLY TO THE YOUNG MEN OF  
THE MEDICAL PROFESSION, TO THE ADVANTAGES OF

## The ECONOMIC POLICY

This form of Insurance is especially adapted to men of moderate means with growing families, the insurance being arranged so as to give the greatest amount of protection at the time most needed and at the lowest possible premium. This policy contains a very attractive convertible clause which makes the contract elastic.

RATES FOR WHOLE LIFE—10-PAYMENT OR 15-PAYMENT ECONOMIC  
POLICY WILL BE QUOTED UPON APPLICATION

JOHN G. WALKER, President

## The Medical Examining Board of Virginia

WILL HOLD ITS NEXT MEETING IN RICHMOND, VA., June 17-20, 1924. All applications should be complete in the hands of the Secretary at least ten days in advance. For further information, write Dr. J. W. Preston, Secretary-Treasurer, Roanoke, Va., or Dr. Robert Glasgow, President, Lexington, Va.

## COLLEGE OF WILLIAM AND MARY THE STATE COLLEGE FOR MEN AND WOMEN

TWO PRE-MEDICAL COURSES—Two-Year and Three-Year—Three Year Course leads to Bachelor of Science degree after one or more sessions in medicine.

Other Special Courses—Teacher Training; Home Economics; Pre-Engineering; Pre-Law; Commerce; Business Administration; Finance; etc.

Regular academic courses leading to the Bachelor and Master degrees.

For particulars address **THE COLLEGE OF WILLIAM AND MARY**  
J. A. C. CHANDLER, President. **WILLIAMSBURG, VA**

## OPERATIVE SURGERY

Special course in general surgery, operative technique and gynecologic surgery given to physicians of both sexes. Enrolment limited to three.

DR. MAX THOREK  
THE AMERICAN HOSPITAL OF CHICAGO  
Irving Park Boulevard and Broadway  
CHICAGO, ILL.

Rolled Wheat—25% Bran

## LET US SEND a package to try

You'll find it a dish to advise.

Pettijohn's is a special wheat—the most flavorful wheat that grows. Each enticing flake hides 25% of bran.

So Pettijohn's rolled wheat is a tempting combination of whole wheat and bran—not an ordinary wheat.

We want to send physicians a full package to try. Write to The Quaker Oats Company, Railway Exchange, Chicago.

## Pettijohn's

Rolled Soft Wheat—25% Bran

The Quaker Oats Company, Chicago

# University of Virginia

## Department of Medicine

I. COURSE LEADING TO DEGREE OF DOCTOR OF MEDICINE. Entrance requirements: two years of college work (including college courses in English, chemistry, physics, and biology) after the completion of a four year high school course or its equivalent.

The medical course extends over four sessions of nine months each, the last two devoted to instruction in the wards and outpatient department of the University Hospital and in the Blue Ridge Sanatorium of the State Board of Health. Women admitted on the same terms as men.

II. COURSES OF INSTRUCTION IN PUBLIC HEALTH. The Joint Health Department of Albemarle County, the city of Charlottesville, and the University affords unique facilities for the study of problems of public health, especially those of small cities and of rural districts. Two courses are offered at present.

Course No. 1. TRAINING FOR RURAL HEALTH OFFICERS. A twelve weeks course open to graduates of medical schools.

Course No. 2. TRAINING FOR SANITARY INSPECTORS. A ten weeks course open to high school graduates, 21 years or over and to those having equivalent training.

### University, Va.

## *Modern Colloidal Silver Therapy*

# NEO-SILVOL

**Esthetic** (*No dark brown stain*)

**Effective**

NEO-SILVOL is colloidal silver iodide. Though silver iodide is insoluble in water, Neo-Silvol, which contains 20% silver iodide, is readily soluble in water and remains in solution for a long time; the colloidal form of the silver iodide accounts for this important physical property.

Neo-Silvol is white in color, and solutions have a milky opalescent hue. This naturally means that you can apply effective silver medication to mucous membranes without staining everything within reach with the characteristic dark brown color of most other silver compounds.

Neo-Silvol is indicated in solutions of 2% to 30% in the local treatment of inflammations of the accessible mucous membranes, such as those of the eye, ear, nose, throat, urethra, vagina, bladder, and rectum.

Put up in 6-grain capsules for convenience in making up solutions as required. Also obtainable in ounce vials.

Samples are available for physicians.

**PARKE, DAVIS & COMPANY**

DETROIT, MICHIGAN

*Neo-Silvol is included in N. N. R. by the Council of Pharmacy and Chemistry of the A. M. A.*

# ILETIN INSULIN, LILLY

## IN THE TREATMENT OF DIABETES

---

*Purity, Stability and Constant Unitage  
Essential to Satisfactory Results*

As a result of almost two years of research and experience in the production of Iletin (Insulin, Lilly) we are able to guarantee the purity, stability and constant unitage of the product.

**STABILITY AND PURITY**—The initial difficulties associated with its production, which were very great, have been almost entirely overcome. Manufacturing operations are conducted on a large scale by processes which have been found through wide experience to give a uniformly pure product which exerts the desired physiological effect. Iletin (Insulin, Lilly) is free from toxic substances and test lots show no deterioration over a period of more than a year.

**UNIFORMITY**—From a therapeutic standpoint it is of great importance that different lots of Insulin be constant in unitage. The maintenance of this constancy in successive lots is one of the most difficult problems of the manufacturer. Through the opportunities for studying this question afforded in the making of many large lots of Iletin (Insulin, Lilly) it has been possible to develop an elaborate system of standardization which enables us to guarantee the unitage within quite narrow limits. This affords the patient the protection against disturbances which may follow a change from one lot to another if the lots in question are not uniform.

On account of its uniformity in purity and unitage Iletin (Insulin, Lilly) has given good results in the past and may be relied upon to give uniformly satisfactory results in the future.

Supplied through the drug trade in ampoule vials containing 50 and 100 units respectively. Send for pamphlet.

### The Victor Stabilized Mobile X-Ray Unit

A practical, efficient, self-contained diagnostic unit. Used in both hospital and physicians' laboratories. Can be moved conveniently to any part of the building.

## “VICTOR”—The Standardized X-Ray Apparatus

The exact scientific procedure followed in conducting the research that enriches roentgenology with new Victor designs finds its counterpart in the manufacturing methods of the Victor organization. It is almost inconceivable that after months, even years, of expensive, arduous scientific investigation on the part of its research physicists and engineers, the Victor organization would incorporate discoveries and improvements in X-ray apparatus which is not of the finest construction.

Hence the principle that all Victor apparatus must be uniformly perfect, from the simplest and least expensive to the most elaborate hospital equipment, is never violated.

There is the “Victor Universal, Jr.” for general practitioners and small hospitals, the “New Universal” for more extensive service in roentgenography, fluoroscopy, and therapy; the famous Model “Snook,” which is a permanent monument in the annals of roentgenology; the Victor Stabilized Fluoroscopic and Radiographic

Unit, with its wide range of utility; the Victor Stabilized Mobile X-Ray Unit, which completely solves the problem of the semi-portable X-ray machine; the Coolidge X-Ray Outfit, which can be carried to the bedside; and the many invaluable Victor accessories, such as the Victor Potter-Bucky Diaphragm, the “Truvision” Stereoscope, and the well-known Victor-Kearsley Stabilizer. Each of these presents a separate problem in design and construction and in research and creative effort.

And yet in every piece of Victor X-ray apparatus, regardless of style, cost or size, regardless of technical limitations, will be found the most tangible evidence of the great care that has been taken in manufacture.

The selection of that particular equipment which best meets your individual requirements, is not a hard problem if you'll put it up to Victor Service. You will thus realize an appreciable help.

# OATS

**Rated Highest In  
Grain Foods**

Based on calories, protein, phosphorus, calcium and iron, oats have the highest rating of any grain food.

Professor H. C. Sherman, in his composite, "Valuation of Typical Foods," rates oats at 2465 — the highest of any grain food quoted.

For Quaker Oats, only the choice selected grains are used. Each bushel of these full plump grains yields only ten pounds of flakes. This richness gives that rare Quaker flavor which makes Quaker Oats so popular.

## Quaker Oats

*Just the cream of the oats*

# STRANGER *than* FICTION

Travel—adventure—danger—hair-breadth escapes! The stories Corona has told—the sights it has seen! The deadly African jungle, the Chinese bandits, the head-hunters of the South Seas, the huddled ice huts of the Arctic.

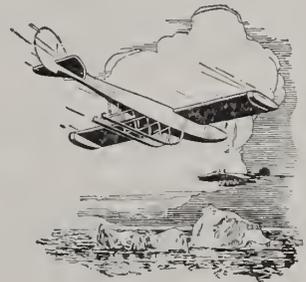

Mrs. Martin Johnson, wife of the famous wild-animal photographer, seems quite at ease as she demonstrates Corona to a group of head-hunting savages. Mr. Johnson has carried this Corona twice around the world and says it works as well today as the day he bought it.

**N**O ORDINARY typewriter can stand the hardship of the explorer's life. That is why nearly every explorer carries a Corona in preference to any other machine.

Corona went to Africa with Col. Roosevelt in 1909 and to Brazil in 1916 when he explored the "Mystery River." Corona was with Sir Ernest Shackleton on his last fatal dash for the pole—and spent 270 days under ice and snow with the MacMillan Arctic Expedition.

Corona is compact and portable, yet it turns out the same quality and quantity of work as a heavy office typewriter and it *stands up!*

You ought to own a Corona. It is the personal typewriter used by successful, ambitious people the world over. \$50 buys one complete in carrying case. Easy terms arranged if you desire. Mail the coupon *now!*

There are no typewriter repair shops in the Arctic, but that doesn't worry Captain Roald Amundsen who will carry Corona on his trans-polar flight. Mr. H. H. Hammer, his personal representative, says, "Corona has been chosen particularly on account of its thoroughly tested and proved durability."

## Whole Grains

### *Steam Exploded*

Quaker Puffed Grains are made by causing 125 million steam explosions in every kernel.

This breaks the food cells for easy digestion. The whole grain elements are supremely fitted to feed.

#### *A dainty dish*

Each flavory grain is an airy tid-bit puffed to 8 times its size. The terrific heat gives a rich nut-like taste that everybody likes.

Children revel in Puffed Grains. Serve it morning, noon and night.

Puffed Rice is the confection of breakfast foods. Puffed Wheat in milk or half and half is an ideal way to serve whole wheat—an inviting dish at night.

**DIETARY SCALE**

These scales are finished in White Enamel with decorations. Dial is silvered finish on which the graduations and numerals appear in black. Capacity 500x2 gr. Price, \$10.00 net.

No matter how careful the diagnosis or correct the prescription, and no matter how conscientious the acquiescence of the patient, the desired results from dieting can be obtained only when exactitude as to quantity, as well as to quality, is attained.

Therefore, it is absolutely essential that the food prescribed be weighed with exactitude; no more guess work method will answer the purpose—no inaccurate measuring or weighing apparatus will suffice. Such uncertain methods as taking the prescribed food in “portions” or estimated amounts is not only unsatisfactory but essentially detrimental and results in making “bad matters worse!”

So important has become the need of the accurate weighing of food prescriptions that a special scale, has been devised.

Balance type, \$15.00 for Hospital use.

SUCCEEDING TELFAIR SANITARIUM

The Glenwood Park Sanitarium is ideally located in a quiet suburb of Greensboro, having all the advantages of the city, yet sufficiently isolated to enable our patients to enjoy restful quietude and entire freedom from the noise and distractions incident to city life.

**CLASS OF PATIENTS**—Those who need help to overcome the bondage of habit. Rest from overwork, study or care. Diversion for the depressed and disquiet mind—and such as are suffering from any disease of the nervous system. The treatment consists of the gradual breaking up of injurious habits, and the restoration to normal conditions, by the use of regular and wholesome diet, pure air, sunlight, and exercise, with such other remedies as are calculated to assist nature in the work of restoration.

Special attention is given to the use of electricity. Twenty years' experience has proven it invaluable in cases of nervous prostration, incipient paralysis, insomnia, the opium and whiskey habits, and those nervous affections due to uterine or ovarian disorders.

For further particulars and terms, address **W. C. ASHWORTH, M. D., Superintendent.**

# Westbrook Sanatorium - - - Richmond, Va.

Rooms single, or en suite, with or without private baths.

Hot water heat, electric lights and artesian water.

Bowling, tennis, croquet, billiards and a gymnasium afford recreation.

Electrical and hydrotherapy equipment.

Nurses and attendants trained for this special work.

Two of the physicians reside in the institution and devote their entire time to the patients.

The magnificent home of the late Major Ginter, by alterations and extensive additions, has been transformed into a private institution for the treatment of nervous diseases, mild mental cases and select alcoholic and drug habitues.

The grounds are ample, quiet is assured, and a new building for men makes easy the separation of the sexes. A number of cottages make possible satisfactory and congenial grouping.

Jas. K. Hall, M. D.

Paul V. Anderson, M. D.

E. M. Gayle, M. D.

## AN INVITATION TO PHYSICIANS

Physicians in good standing are cordially invited to visit the Battle Creek Sanitarium and Hospital at any time for observation and study, or for rest and treatment.

Special clinics for visiting physicians are conducted in connection with the Hospital, Dispensary and various laboratories.

Physicians in good standing are always welcome as guests, and accommodations for those who desire to make a prolonged stay are furnished at a moderate rate. No charge made to physicians for regular medical examination or treatment. Special rates for treatment and medical attention are also granted dependent members of the physicians's family.

An illustrated booklet telling of the Origin, Purposes and Methods of the institution, a copy of the current "MEDICAL BULLETIN," and announcements of clinics, will be sent free upon request.

## THE BATTLE CREEK SANITARIUM

## THE ROOKWOOD SANITARIUM

A PRIVATE SANITARIUM WITH HOME INFLUENCE FOR THE CARE AND PROTECTION OF UNFORTUNATE YOUNG WOMEN

Patients accepted any time during Gestation. References cheerfully given to prospective patrons. Quiet and secluded. Adoption of babies when arranged. Rates to suit the individual. Graduate Registered Nurses in charge.  
Write for particulars.

PATRONAGE OF ALL ETHICAL PHYSICIANS SOLICITED

Address only:  
MRS. MARIAN SAGER, R. N.  
2010 Clifton Road      Nashville, Tenn.

## Nashville Private Maternity Hospital

For the care and protection  
of unfortunate young women.

Address: MRS. J. H. SWEENEY,  
1230 Second Avenue, South.

Phone, Main 3791      Nashville, Tennessee

## LAUS DE'O

For the Refuge and Reformation of Unfortunate Girls.  
LASCASSAS, TENN.

We place at the disposal of the medical profession a strictly private and up-to-date retreat out in the country for the care and protection of unfortunate girls and infants. We want girls who would retrace missteps, preserve individual character and family reputation. Girls must come through a physician. The restriction is made in order to get girls from the best class, who are worthy of help.

Laus De'O is a two hours' ride from Nashville; thirty minutes' ride from Murfreesboro. Drs. J. C. Kelton and J. T. Harris are attending physicians. Dr. Kelton will meet patients when desired, if called by phone on Murfreesboro Exchange 6105.

For private information, address Miss Kitty Cook or Dr. J. C. Kelton, Lascassas, Tenn.

THE THIEF THAT IS  
HARD TO CATCH.

Ordinary thievery is easily detected. But not the thief of nerve energy. Healthy eyes use only ten per cent of the body's nerve force while over-strained eyes sometimes steal fifty per cent. Exhaustion or breakdown results.

To prevent this subtle thievery—

HAVE YOUR EYES EXAMINED.

If glasses are necessary, our quarter century experience and scientific skill in building them accurately and satisfactorily is a factor to be seriously considered.

# THE STANDARD LOESER'S INTRAVENOUS SOLUTIONS CERTIFIED

## “Intravenous Solutions Need Not Be Isotonic”

(Loeser, Medical Review of Reviews, Jan. 24)

**EVERY PHYSICIAN** should read this article, in which the ultrascientific is converted into “plain told” facts of practical every-day value.

**EVERY PHYSICIAN** should know the truth about the evolution of intravenous, isotonic, hypertonic and hypotonic solutions and osmotic pressure.

**EVERY PHYSICIAN** should be acquainted with that chapter of scientific history in which occurred the monumental work and collaboration of Arrhenius, Van't Hoff and Ostwald on solutions.

**REPRINT MAILED ON REQUEST.**

*Clinical Reports, Reprints, Price List, and The “Journal of Intravenous Therapy” will be sent to any physician on request.*

**New York Intravenous Laboratory**

100 West 21st Street,

New York, N. Y.

### The Management of an Infant's Diet

## Constipation

Food not adapted to an infant's digestion, elements not in proper proportion to normal or individual needs, overfeeding, underfeeding, sluggish peristalsis, are the most common causes of constipation in the artificially-fed baby.

Every one of these determined factors being commonly associated with the daily intake of food, treatment other than dietetic is rarely necessary or advisable.

Suggestions that point out the procedure to be followed in adjusting the diet to overcome constipation due to the stated causes are embodied in a 16-page pamphlet, which will be sent to physicians upon request. The suggestions offered are based upon careful observation extending over a long period and should be of much service to every physician who is at all interested in infant feeding.

Mellin's Food Co., 177 State Street Boston, Mass.
